and Imaging, London, United Kingdom ; <sup>5</sup>Cambridge University, Department of Oncology, Cambridge, United Kingdom ; <sup>6</sup>University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom ; <sup>7</sup>Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Radiotherapy and Imaging, London, United Kingdom

### Purpose or Objective

Seroma describes collection of serous fluid within a cavity and can occur following breast surgery. A seroma prevalence of 37-57% has been reported. Seroma is associated with adverse effects (AE) following breast radiotherapy. These AE have been predominantly assessed by clinicians and photographs, and not by patients. This study investigates if seroma is associated with patient-reported AE in IMPORT HIGH (CRUK/06/003).

### Material and Methods

IMPORT HIGH (ISRCTN47437448) is a randomised, multi-centre phase III trial testing dose-escalated simultaneous integrated boost against sequential boost each delivered by intensity modulated radiotherapy (RT) in women with breast cancer. AE assessment included patient-reported outcome measures (PROMs) in a planned sub-set of patients. A case-control methodology was used to investigate the association of seroma with patient-reported AEs at 3 years. Cases were patients who reported moderate/marked breast appearance change and controls were those who reported none/mild changes. One control was selected at random for each case (unmatched). Seromas were identified on RT CT planning scans and graded as not visible/subtle or visible/highly visible. Logistic regression models were used to test associations between seroma and moderate/marked breast appearance change at 3 years, adjusting for patient and tumour/treatment factors. Tumour and treatment factors were reported by clinicians.

### Results

2621 patients were recruited to IMPORT HIGH. 1078/1149 patients at centres participating in the PROMs sub-study consented to PROMs. 836 patients responded to whether they had breast appearance change at 3 years, of whom 231 (28%) patients reported moderate/marked changes (cases); 231 controls were identified. RT CT planning data were available for 202 cases and 205 controls. 156/231 (68%) cases and 148/231 (64%) controls received chemotherapy respectively. Seroma prevalence was 41/202 (20%) in cases and 32/205 (16%) in controls. No significant association was found between visible seroma and moderate/marked breast appearance change [odds ratio 1.38 (95% confidence interval 0.83-2.29), p=0.22] regardless of chemotherapy use. Larger seroma volume was significantly associated with worse breast appearance change on univariate analysis only [1.21 (1.02-1.44), p=0.03]. Treatment group was not significant on univariate analysis. On multivariable analysis, independent risk factors for worse breast appearance change were larger tumour size [1.43 (1.13-1.82), p=0.003], haematoma [5.96 (2.20-16.11), p<0.001], current smoking [2.25 (1.06-4.74), p=0.03] and body image concerns at baseline [1.04 (1.00-1.09), p=0.04].

### Conclusion

Seroma prevalence in this study was lower than previously reported, perhaps reflecting the proportion of patients receiving chemotherapy in whom seroma resolves. Seroma was not associated with patient-reported breast appearance change but haematoma was a significant risk factor. Smoking cessation pre-radiotherapy should be encouraged to reduce AE.

### OC-0596 Importance of dose to the atherosclerotic plaque in the LAD for cardiac toxicity in breast cancer

V. Van den Bogaard<sup>1</sup>, D. Spoor<sup>1</sup>, A. Van der Schaaf<sup>1</sup>, L. Van Dijk<sup>1</sup>, J. Langendijk<sup>1</sup>, J. Maduro<sup>1</sup>, A. Crijns<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

Recent studies have demonstrated a dose-effect relationship between radiation dose to the heart and the risk of an acute coronary event (ACE). However, knowledge on the exact underlying mechanisms behind this radiation-induced cardiac toxicity is lacking. Such information is crucial for the development of new strategies to optimize radiotherapy (RT) treatment planning.

We hypothesized that radiation dose to atherosclerotic plaques leads to subsequent inflammatory reactions and increased risk of ACEs. Thus, dose to the plaques may be a stronger predictor of an ACE after RT than the dose to the left anterior descending coronary artery (LAD). Therefore, the aim of this study was to investigate the association between radiation dose to the LAD and the LAD-plaques and the risk of an ACE in breast cancer (BC) patients treated with 3D conformal radiation therapy.

### Material and Methods

The study cohort consisted of 952 BC patients treated with postoperative RT after breast conserving surgery. The LAD was delineated using an auto-segmentation tool. After calculation of the coronary artery calcium score, LAD-plaques with Hounsfield units  $\geq 130$  were manually delineated. The primary endpoint was the cumulative incidence of an ACE (defined according to Darby *et al.*) 9 years after treatment. For each individual patient, the mean heart dose (MHD), mean dose to the LAD and the mean dose to the LAD-plaques were collected from planning CT scans.

First, the relation between the dose to the LAD and the LAD-plaques and ACEs was analyzed with an univariable Cox-regression analysis. Then, an association analysis using a Cox-regression model was performed, only including patients who had a LAD-plaque. Furthermore, we used a multivariable Cox-regression analysis to calculate the excess risk of an ACE per patient including age, cardiac risk factors (0 or  $\geq 1$ ) and mean dose to the heart and LAD-plaques.

### Results

The median follow-up time was 7.5 years (range: 0.1-10.1 years). In total, 31 patients developed an ACE during follow-up. 167 patients (17.5%) had a LAD-plaque. Univariable Cox-regression analysis showed that the impact of the dose to the LAD-plaque was much stronger than the impact of the MHD and the mean dose to the LAD (Figure 1). A significant but modest association between radiation dose to the LAD and ACEs was found (regression coefficient 0.053 (95% CI 1.014-1.096),  $P=0.008$ ). However, a much stronger and significant association was found between the mean dose to the LAD-plaques and ACEs (regression coefficient 0.323 (95% CI 1.129-1.689),  $P=0.002$ ). In figure 2, the NTCP-curves are shown for a 50-year old patient in the presence of a cardiac risk factor for ACE.

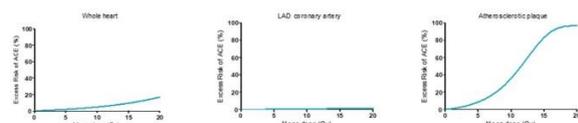

Fig. 1: Univariable Cox-regression analysis for the cumulative incidence of ACEs within the first 9 years after RT

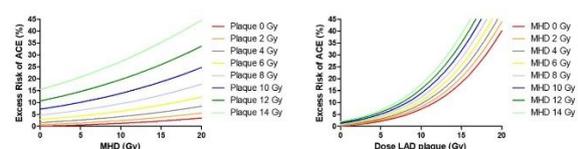

Fig. 2: NTCP-models for the cumulative incidence of ACEs within the first 9 years after RT in a 50-year old patient in the presence of a cardiac risk factor for ACE.

### Conclusion

The results of this study suggest that mean dose to the atherosclerotic plaque in the LAD is more important for the development of an ACE in BC patients than the MHD, possibly due to radiation-induced inflammatory reactions in pre-existent plaques. This will be further investigated.

#### OC-0597 Implementing a quality indicator project on a national basis: a feasibility study

A. Vaandering<sup>1</sup>, Y. Lievens<sup>2</sup>, N. Jansen<sup>3</sup>, C. Weltens<sup>4</sup>, L. Moretti<sup>5</sup>, K. Stellamans<sup>4</sup>, F. Vanhoutte<sup>2</sup>, P. Scalliet<sup>1</sup>, V. Remouchamps<sup>6</sup>

<sup>1</sup>UCL Cliniques Universitaires St Luc, Department of Radiation Oncology, Brussels, Belgium; <sup>2</sup>Ghent University Hospital, Department of Radiation Oncology, Ghent, Belgium; <sup>3</sup>University Hospital of Liège, Department of Radiation Oncology, Liège, Belgium; <sup>4</sup>AZ Groeninge, Department of Radiation Oncology, Kortrijk, Belgium; <sup>5</sup>Institut Jules Bordet, Department of radiation oncology, Brussels, Belgium; <sup>6</sup>CHU-UCL Namur - Site Saint Elisabeth, Department of radiation oncology, Namur, Belgium

#### Purpose or Objective

Quality indicators (QI) are measurement tools that can be used as guides to evaluate and improve overall quality of patient care. Monitoring QIs amongst departments allows for clinical practice benchmarking leading to exchange of best practice and the delivery of best-quality care. Mandated by the Belgian Federal Government, radiotherapy (RT) specific structural, process and outcome indicators were defined in a collaboration of the College for Physicians in Radiation Oncology (RO) in Belgium and the Belgian Quality Managers (QM) in radiotherapy Association (QMRT.be). Subsequently, a voluntary national QI data collection started, with the aim of generating benchmarking reports and supporting departmental and national quality improvement projects.

#### Material and Methods

The QI were defined through a simplified Delphi approach by a panel of RO, QM and medical physics experts following the national requirement to collect quantitative data annually (e.g. number of treatments) but also based on established guidelines or good practice. As such, 18 structural (e.g. number of equipment and treatment activities), 30 process (e.g. timely delivery) and 6 outcome QIs (recorded acute toxicity related to treatment for breast, head-and-neck and prostate cancer patients) have been defined. To evaluate the feasibility of data collection in all Belgian RT departments, a test phase was launched in 2015, collecting the full set of structural QIs, but limiting the number of patient-specific QIs (n=5 per pathology/department). Upon validation of this dummy run, as of 2016, a broader capture of process and outcome QIs was started (n=25 patients/pathology/department).

#### Results

A high department participation rate to this national QI project was obtained, with 100% of departments participating in 2015 and 2016 and 92% in 2017. This success rate is highly attributed to the presence of QM in each RT department. Over the 3 year-period, 33.993 data points were collected contributing to the establishment of the 54 QIs. The analysis of the collected QIs gave insight into national activity levels, resource availability, clinical practice and acute toxicity levels. This resulted in a yearly global report but also in the generation of individualized benchmarking documents in which each department is able to identify its performance as compared to other departments which are anonymously identified (see fig 1).

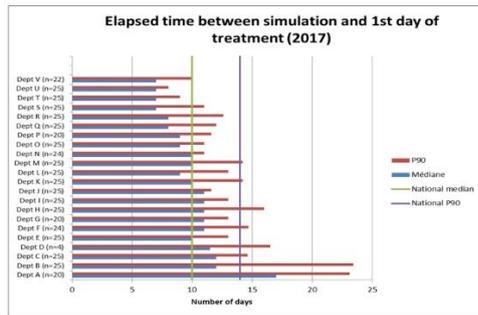

Fig. 1 - Process QI – Elapsed time between simulation and treatment for H&N cancer patients (n=509)

**Conclusion**

The development of a RT-QI project has been demanded by the Belgian national government as a potential tool to help RT departments to further optimise the quality of patient care. Although participation of each individual department is on voluntary basis, it has been shown feasible to collect defined QIs at national level with an almost complete participation rate. The analysis and generation of benchmarking documents guide centres in their quality improvement initiatives at departmental level and support national quality improvement initiatives.

**OC-0598 Estimating the need for palliative radiotherapy for breast cancer: A benchmarking approach**

C.J. Jin<sup>1</sup>, W. Kong<sup>1</sup>, W.J. Mackillop<sup>1</sup>  
<sup>1</sup>Queen’s Cancer Research Institute- Queen’s University, Cancer Care and Epidemiology, Kingston, Canada

**Purpose or Objective**

Palliative radiotherapy (PRT) benefits many patients with breast cancer, but optimal utilization rates remain undefined. The objective of this study was to estimate the appropriate PRT rate for the general breast cancer population.

**Material and Methods**

Ontario’s population-based cancer registry identified patients who died of breast cancer between 2009 and 2013. Multivariate analysis identified health systems factors affecting the use of PRT for breast cancer, enabling us to define a benchmark population with unimpeded access to PRT. Proportion of cases treated in the last 5 years of life (PRT<sub>5y</sub>) was standardized to overall population characteristics. Benchmarks were compared to province-wide PRT<sub>5y</sub> rates.

**Results**

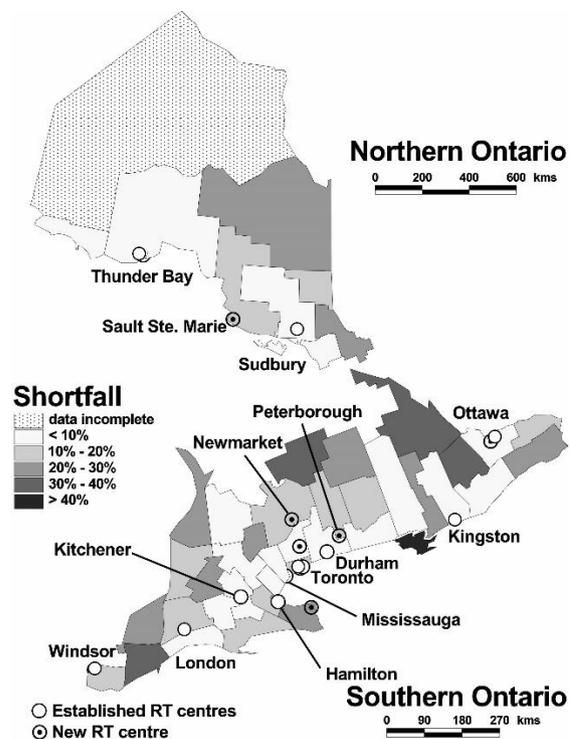

Overall, 36.2% of 11,075 patients who died of breast cancer between 2009 and 2013 received PRT at least once in the last 5 years of life. Availability of RT at the diagnosing hospital was the dominant determinant of increased PRT use; socioeconomic status and residential distance to nearest RT centre did not have a significant effect. Patients diagnosed at hospitals with on-site RT were therefore designated the benchmark population. The standardized benchmark for PRT<sub>5y</sub> was 40.7%, compared to the province-wide rate of 36.2%. Indication-specific benchmarks demonstrated that shortfalls in PRT use were highest for locoregional RT, followed by brain and bone metastases (Table). Age-specific benchmarks demonstrated that shortfalls in PRT use were >3 times greater in patients >70 vs ≤70 years. The extent of the shortfall varied widely amongst Ontario regions (Figure).

**Table: Benchmark Rates and Shortfalls in the Use of PRT<sub>5y</sub>**

	Standardized Benchmark Rate <sup>1</sup> (95% CI)	Actual Provincial Rate (95% CI)	Shortfall <sup>2</sup>
<b>Body</b>	8.8% (7.4%, 10.1%)	7.3% (6.8%, 7.8%)	16.8%
<b>Region</b>			
Bone	26.4% (24.0%, 28.8%)	23.7% (23.0%, 24.5%)	10.0%
Brain	14.4% (12.7%, 16.1%)	12.9% (12.3%, 13.6%)	10.2%
Other	7.5% (6.2%, 8.7%)	5.6% (5.2%, 6.1%)	24.4%
<b>Age</b>			
≤70	55.7% (50.5%, 60.8%)	52.3% (50.9%, 53.7%)	6.1%
>70	28.4% (25.0%, 31.7%)	22.9% (21.8%, 23.9%)	19.4%
<b>Total</b>	40.7% (37.8%, 43.6%)	36.2% (35.3%, 37.0%)	11.1%

*t*PRT<sub>5y</sub> rate among patients whose cancer was diagnosed at a hospital with RT on site, standardized to the distribution of life expectancy in the overall population;  
<sup>2</sup>Shortfall =  $(\text{Unmet Need} / \text{Total Need}) = (\text{Benchmark rate} - \text{Actual rate}) / \text{Benchmark rate} \times 100\%$

**Figure: Inter-county variations in shortfalls in the use of PRT for breast cancer in Ontario**

**Conclusion**

In a standardized benchmark Ontario population with unimpeded access to RT, 40.7% of patients who died of breast cancer received PRT, compared to 36.2% of the overall population. The gap between actual and optimal PRT rates was greatest in the elderly and varied widely across regions. An effort should be made to reduce the large age-related and regional differences in PRT use for patients with advanced breast cancer. This method provides a rational estimate of appropriate treatment rates required for monitoring and improving access to cancer care.

**OC-0599 Survival and local control deficits due to radiotherapy under-utilisation in NSW, Australia.**  
 G. Delaney<sup>1,2,3</sup>, G.S. Gabriel<sup>2,3</sup>, J. Shafiq<sup>2</sup>, R. Merie<sup>1</sup>, S. Vinod<sup>1,2,3</sup>, V. Batumalai<sup>1</sup>, M.B. Barton<sup>1,2</sup>  
<sup>1</sup>Liverpool Hospital, Area Cancer Services Radiation Oncology, Liverpool, Australia; <sup>2</sup>University of NSW,

*Medicine, Sydney, Australia ; <sup>3</sup>Ingham Institute of Medical Research, Liverpool Hospital, Sydney, Australia*

#### **Purpose or Objective**

Optimal radiotherapy utilisation rates suggest that approximately 48% of patients should receive radiotherapy based on evidence-based guideline recommendations and that 44% of cancer patients should receive radiotherapy within their first year of diagnosis (1). It has been widely reported that actual rates are often significantly lower than optimal. The aim in this study was to estimate the local control and overall survival shortfall that occurs as a result of radiotherapy under-use and to identify factors that predict under-use in NSW.

#### **Material and Methods**

All cases of registered cancer diagnosed in NSW, Australia, between 2009-2011 were identified from the NSW Cancer Registry and linked with data from all public and private radiation oncology departments. The actual Radiation Therapy utilisation (RTU) rate was calculated and compared with published evidence-based optimal rates (1). The deficit in radiotherapy use for each evidence-based radiotherapy indication was used to estimate the impact on 5-year local control (LC) and overall survival (OS). These were compared to the published estimates of radiotherapy benefits in the setting of optimal use (2). OS and LC shortfall in person number - defined as the number of people not achieving LC and OS benefit due to RT underutilisation - was then calculated. Univariate and multivariate analyses were performed to identify factors that contributed to reduced RTU.

#### **Results**

110 645 patients were diagnosed with cancer in NSW during the study period. The overall RTU rate was 25% within the first year of diagnosis compared to the reported optimal rate of 44% within the first year of diagnosis (2). The 5-year OS shortfall was 2.2% and 5-year LC shortfall was 10.9%. It is estimated that 1757 and 361 patients per year not receiving radiotherapy in NSW had local failure and poorer survival respectively during this study period. Male gender, older age, localised disease and longer travel distance were factors predicting radiotherapy under-utilisation on multivariate analysis. When compared with our analysis of NSW data from 2004, the current study shows an estimated overall survival improvement of 9% (3).

#### **Conclusion**

Under-use of recommended radiotherapy for cancer has been identified in this study, with a negative impact on patient outcomes. While improving, further work needs to be done to reduce this shortfall further. Older age, male gender and longer travel distance were predictors for sub-optimal RTU. These findings would assist in health service planning for radiotherapy and call for better adherence to treatment guidelines. Identification of the specific evidence-based indications with the greatest shortfall would assist with prioritising strategies to address the gap.

*Reus, Hospital Sant Joan de Reus, Catalonia, Spain ; <sup>5</sup>Hospital Universitari de la Vall d'Hebron, Hospital Universitari de la Vall d'Hebron, Catalonia, Spain ; <sup>6</sup>Institut Català d'Oncologia, Institut Català d'Oncologia, Catalonia, Spain; <sup>7</sup>Hospital Clínic de Barcelona, Hospital Clínic de Barcelona, Catalonia, Spain ; <sup>8</sup>Consorci Sanitari de Terrassa, Consorci Sanitari de Terrassa, Catalonia, Spain; <sup>9</sup>Hospital de la Santa Creu i Sant Pau, Hospital de la Santa Creu i Sant Pau, Catalonia, Spain ; <sup>10</sup>Hospital Clínic Plató, Hospital Clínic Plató, Catalonia, Spain ; <sup>11</sup>Hospital Arnau de Vilanova, Hospital Arnau de Vilanova, Catalonia, Spain*

#### **Purpose or Objective**

Non-adherence to external radiotherapy is an aspect of treatment which has not been fully explored. The objective of this study is to analyse the relevance of this problem and its impact on 1-year survival

#### **Material and Methods**

A Cohort study design was carried out with a prospective follow-up of cancer patients with indication of external radiotherapy. All patients with indication of treatment during year 2016 in the hospital of the public sector in Catalonia were included. Adherence was deemed acceptable if total dose received was over 90% of the dose prescribed. Statistical analysis was performed according to type of tumour, intention of treatment and age. Logistic regression was carried out to assess factors associated to adherence and Cox analysis was applied to assess their relationship with survival

#### **Results**

In total, 15.157 patients were included with an average age of 64.6 (± 14.0); 51.3% were males. Most frequent tumours were breast (27.4%), lung (16,1%) and prostate (12.4%). Radical intent was indicated in 69.2% of cases and 18.7% of patients received concomitant chemo. At least one day interruption of treatment, excluding public holidays, was observed in 41.8% of cases. The reasons (multiple choice) for these interruptions were, 75.8% due to problems with the equipment, 17.9% for medical reason, 7.9% due to the patient preference and 20.9% for others reasons. Patient adherence was of 95.5% of patients (receiving more than 90% of total dose). Radical intent was related (OR: 3.11; IC: 95%: 2.6-3.7) to better adherence. Older age was associated with lower probability of adherence. Head and neck, lung, digestive other than rectal and bone (including metastasis) cancers were associated with lower probability of adherence; while breast and prostate cancer patients were associated with significantly higher than average adherence. One-year survival was significantly higher among adherent patients, both in radical (HR: 4.5; IC95%:3.8-5.4) and palliative (HR: 2.1; IC95%:1.8-2.4) intent

#### **Conclusion**

Adherence of treatment is very high among this cohort of population based patients receiving treatment in the public sector in Catalonia. Lack of adherence is related to lower probability of survival and this factor should be considered in the follow-up of patients with radiotherapy treatment

#### **OC-0601 Stereotactic body radiotherapy for oligometastatic disease in belgium: costs and budgetary impact**

*D. Nevens<sup>1</sup>, I. Kindts<sup>2</sup>, N. Defourny<sup>3</sup>, M. Roskamp<sup>4</sup>, C. Mercier<sup>5</sup>, H. De Schutter<sup>4</sup>, C. Van de Voorde<sup>6</sup>, Y. Lievens<sup>7</sup>*  
<sup>1</sup>Department of Radiation Oncology, Iridium Kankernetwerk, University of Antwerp ; <sup>2</sup>KU Leuven-University Hospitals Leuven, Lab of Experimental Radiation Oncology, Leuven, Belgium ; <sup>3</sup>ESTRO, European Society for Radiotherapy and Oncology, Brussels, Belgium; <sup>4</sup>BCR, Belgian Cancer Registry, Brussels, Belgium; <sup>5</sup>University of Antwerp, Molecular Imaging-Pathology- Radiotherapy & Oncology MIPRO, Antwerp, Belgium; <sup>6</sup>KCE, Belgian Health Care Knowledge Centre,

Brussels, Belgium ; <sup>7</sup>Ghent University, Department of Radiation Oncology and Experimental Cancer Research, Ghent, Belgium

### Purpose or Objective

There is a steady rise in the use of Stereotactic Body RadioTherapy (SBRT) in oligometastatic disease (OMD). Besides a positive impact on patients' outcome, this may generate important financial consequences for radiotherapy budgets. Awaiting more clinical evidence, the Belgian compulsory health insurance system initiated a coverage with evidence development (CED) project for innovative radiotherapy, including SBRT, in 2011. Consequently, a provisional financing to treat OMD with SBRT was available in Belgium from 2013 onwards.

While analysis of the clinical and technical data captured between 9-2013 and 12-2017 is ongoing and inclusion in the formal reimbursement system pending, a cost-calculation and budget impact analysis (BIA) was carried out.

### Material and Methods

Using the CED data, the uptake of SBRT in patients with OMD in Belgium between 2013 and 2017 was reviewed. Based on these data, predictive growth scenarios for future uptake were developed. The cost of an SBRT treatment in the OMD setting in Belgium was calculated using the Health Economics in Radiation Oncology Time-Driven Activity-Based Costing (HERO TD-ABC) model developed by ESTRO, alimanted with national data on resources, treatments and operational parameters. Combining all this information, the future impact of this novel treatment indication on the radiotherapy budget in Belgium was evaluated.

### Results

The CED data showed a large increase in number of OMD treated with SBRT in Belgium: from 59 in 2013 to 459 in 2017. Based on this, three growth scenarios for uptake were developed: scenario 1, predicting a further linear increase; scenario 2, only accounting for demographic shift; and an 'intermediate' scenario 3 with linear increase for two more years, then plateauing to the demographic trends (Figure 1).

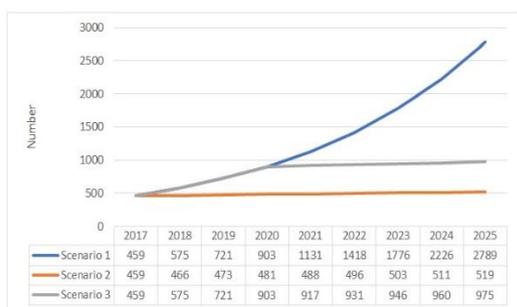

Figure 1

Using the HERO TD-ABC model, a real-life cost of 4,359 € per SBRT treatment was calculated, whereas the provisional financing within the CED program amounted to 3,802 €.

The 3 growth scenarios and the costs were combined to estimate the impact on the radiotherapy budget. For the TD-ABC costs, all OMD SBRT treatments were considered new indications, hence, additional SBRT courses and costs. For the CED financing data, 2 comparator scenarios were assumed. In the comparator 1 scenario, the SBRT courses for patients treated in the OMD setting are all considered additional SBRT courses. In the comparator 2 scenario, 50% of the SBRT courses are considered new cases and 50% are considered as previously treated with palliative intent, leading to a lower cost increment. Table 1 demonstrates the financial impact of the different scenarios.

		2017	Increase in 2020	Increase in 2025	
TD-ABC cost (€)	Scenario 1	2,000,781	1,935,396	8,155,689	
	Scenario 2	2,000,781	95,898	261,540	
	Scenario 3	2,000,781	1,935,396	2,249,244	
CED cost (€)	Scenario 1	Comparator 1	1,745,118	1,688,088	7,113,542
		Comparator 2	1,372,869	1,328,004	5,596,161
	Scenario 2	Comparator 1	1,745,118	83,644	228,120
		Comparator 2	1,372,869	65,802	179,460
	Scenario 3	Comparator 1	1,745,118	1,688,088	1,961,832
		Comparator 2	1,372,869	1,328,004	1,543,356

Table 1

### Conclusion

The possible impact on the radiotherapy budget of uptake of SBRT for OMD shows large variations. These data should be evaluated in the context of improved outcome and set against the background of the actual Belgian radiotherapy budget amounting to roughly 120 million €. Further real-life clinical and financial monitoring and prospective data gathering seems necessary.

### Purpose or Objective

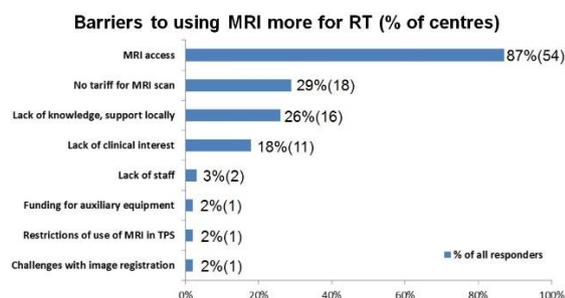

All centres using MRI in EBRT use rigid MRI to CT registration and two centres are currently using deformable image registration in addition. Commissioning and QA of image registration and MRI for EBRT showed large inter-centre heterogeneity caused by a lack of guidance.

Physics support for setting up a new MRI for EBRT service is varied across the UK with links with radiology being very important and 23% of centres reporting no support from physics staff with specialist MRI knowledge.

The largest reported barrier to utilising MRI further is a lack of MRI access (87% of centres) but a large proportion of all concerns are financially driven with a lack of tariff meaning centres do not get reimbursed for an MRI scan, see figure.

Looking forward, within the next five years, 37% of centres intend to use functional MRI, 38% of centres are planning for an MRI-simulator, 16% of centres are planning to utilise MRI-only radiotherapy and 10% are planning for an MRI-linac (on top of the 3% that currently have access).

### Conclusion

The current use of MRI for EBRT in the UK was audited. More than 2 in 3 of centres have some form of MRI access, but there are only 2 MRI-simulators at present. Collaboration with radiology departments is vital for both MRI access and staff support. The main barriers to fully integrate MRI are financially driven and a lack of tariff resulting in limited access. Knowledge gaps have been identified such as the lack of standardised QA guidance that will be addressed in the IPEM guidelines.

### OC-0604 The first UK survey of dose indices from radiotherapy treatment planning CT scans for adult patients

M. Williams<sup>1</sup>, T. Wood<sup>2</sup>, A. Davis<sup>3</sup>, J. Earley<sup>4</sup>, R. Plaistow<sup>5</sup>, R. Lindsay<sup>6</sup>, A. Palmer<sup>3</sup>, A. Nesbit<sup>4</sup>, S. Edyvean<sup>7</sup>, U. Findlay<sup>8</sup>

<sup>1</sup>Velindre University NHS Trust, Medical Physics, Cardiff, United Kingdom ; <sup>2</sup>Hull and East Yorkshire Hospitals NHS Trust, Radiation Physics, Hull, United Kingdom ; <sup>3</sup>Portsmouth Hospitals NHS Trust, Medical Physics, Portsmouth, United Kingdom ; <sup>4</sup>Royal Surrey County Hospital NHS Foundation Trust, Medical Physics, Guildford, United Kingdom ; <sup>5</sup>Cambridge University Hospitals NHS Foundation Trust, Medical Physics, Cambridge, United Kingdom ; <sup>6</sup>St James Institute of Oncology, Medical Physics, Leeds, United Kingdom ; <sup>7</sup>Public Health England, Radiation Dosimetry, Chilton,

United Kingdom ; <sup>8</sup>Public Health England, Medical Exposure, Chilton, United Kingdom

### Purpose or Objective

CT scans are an integral component of modern radiotherapy treatments, enabling the accurate localisation of the treatment target and organs-at-risk, and providing the tissue density information required for the calculation of dose in the treatment planning system. For these reasons, it is important to ensure exposures are optimised to give the required clinical image quality with doses that are as low as reasonably achievable. However, there is little guidance in the literature on dose levels in radiotherapy CT imaging either within the UK or internationally. The first UK wide dose survey for radiotherapy CT planning scans has been completed. The survey was initiated by a working party of the Institute of Physics and Engineering in Medicine (IPEM).

### Material and Methods

Patient dose metrics were collected for prostate, gynaecological, breast, 3D-lung, 4D-lung, brain and head & neck scans. Median values per scanner and examination type were calculated and national dose reference levels and 'achievable levels' of CT dose index (CTDI<sub>vol</sub>), dose-length-product (DLP) and scan length are proposed based on the third quartile and median values of these distributions, respectively.

### Results

A total of 68 radiotherapy CT scanners were included in this audit. The proposed national dose reference levels and achievable levels are shown in the table below. Significant variations in dose indices were noted, with head & neck and lung 4D yielding a factor of eighteen difference between the lowest and highest dose scanners. There was also evidence of some clustering in the data by scanner manufacturer, which may be indicative of a lack of local optimisation of individual systems to the clinical task.

Examination	Proposed reference level				Achievable level		
	PD (cm)	CTDI <sub>vol</sub> (mGy)	DLP (mGy·cm)	Scan length (mm)	CTDI <sub>vol</sub> (mGy)	DLP (mGy·cm)	Scan length (mm)
Breast	32	10	390	360	8	280	330
Gynaecological	32	16	610	400	12	510	380
Lung 3D	32	14	550	390	10	410	370
Lung 4D	32	63	1750	340	36	1170	330
Prostate	32	16	570	340	13	420	310
Brain	16	50	1500	290	42	1110	250
Head and neck	16	49	2150	420	26	1080	400

### Conclusion

The first UK wide audit of dose indices for adult patients undergoing CT scans for radiotherapy planning has been completed, and the results published (Tim J Wood et al 2018 Phys. Med. Biol. 63 185008). Reference values and achievable levels for CTDI<sub>vol</sub>, DLP and scan length have been proposed for seven common types of CT scan. It is anticipated that providing this data to the UK and wider radiotherapy community will aid the optimisation of treatment planning CT scan protocols.

### OC-0605 Is DIBH more robust than FB in VMAT left breast irradiation? Multicenter and multivendor analysis

Unit of Radiation Oncology Dept, Milan, Italy;  
<sup>8</sup>Humanitas Research Hospital, Radiotherapy and  
 Radiosurgery Dept., Milan, Italy

### Purpose or Objective

VMAT usually increases the dose conformity to the target but enhance the mean dose to organs at risk, mainly for the heart. Deep Inspiration Breath Hold (DIBH) was demonstrated to help in reducing the mean heart dose (MHD) and might be required in some cases. This study systematically investigates the possible advantages of DIBH in comparison to standard Free Breathing (FB) for left breast VMAT.

### Material and Methods

DIBH and FB VMAT plans for ten left side breast patients were optimized by two different TPSs (Monaco5.1 and Eclipse11) and Linac devices (Elekta Synergy and Varian TrueBeam). Dose prescriptions were 40.5Gy to the  $PTV_{breast}$  and 48Gy to the  $PTV_{boost}$  in 15 fractions.  $PTV_{breast} 98\% > 38.5Gy$ ,  $PTV_{boost} 98\% > 45.7Gy$ , and maximum dose to  $PTV_{boost} < 107\%$  were asked. OARs constraints were  $MHD < 4Gy$ ,  $V_{18Gy} < 5\%$  for heart;  $D_{mean} < 10Gy$ ,  $V_{20Gy} < 10\%$  for left lung;  $D_{mean} < 3Gy$  for right lung and breast. Several dynamic plan parameters and complexity indices were computed from the DICOM RTPlan files by using an homemade program. The overall modulation index  $Ml_{tot}$  was scored to take into account in a single parameter the leaf speed and acceleration and the gantry speed (GS). A global quality parameter accounting for both dosimetric scoring and plan complexity was defined as  $GP = (Ml_{tot} \times MHD / PTV_{breast} 98\%)$ . Pre-treatment QA verifications were carried out in both centers using the EPID-based Epiqa5.0 software (EPIDOSsro, Bratislava). Gamma index ( $\gamma$ ) analysis was performed with 3%G-3 mm, 2%G-2 mm and 3%L/3 mm criteria. Statistical significance was examined using a Wilcoxon signed rank-test for related samples and set at  $p \leq 0.05$ .

### Results

A significant better PTV coverage was found for DIBH plans in both centers compared to FB plans. DIBH plans were associated with a lower value in all the OARs dose parameters with significant reduction in MHD and  $V_{heart18Gy}$  ( $p < 0.005$ ). For FB plans  $MHD > 4Gy$  was observed in 30% of the cases. The plan complexity was generally slightly lower for DIBH plans than for FB ones, but differences were statistically significant only in few cases. The GP resulted significant lower in DIBH plans (Fig.1).

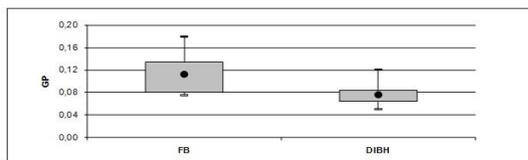

Fig.1 : Box plot for GP evaluated for DIBH and FB plans.

Regarding the plan delivery parameters, Eclipse used smaller and more complex MLC apertures, while Monaco further modulated the DoseRate and the GS than Eclipse, providing higher  $Ml_{tot}$  values. Both DIBH and FB optimizations yielded good results for QA verification with  $\gamma(3\%G-3mm) > 95\%$  in all cases (Fig.2); no significant difference was found. Higher  $\gamma(2\%G-2mm)$  values for DIBH plans than for FB were found for the Elekta institution with significant differences ( $p < 0.02$ ).

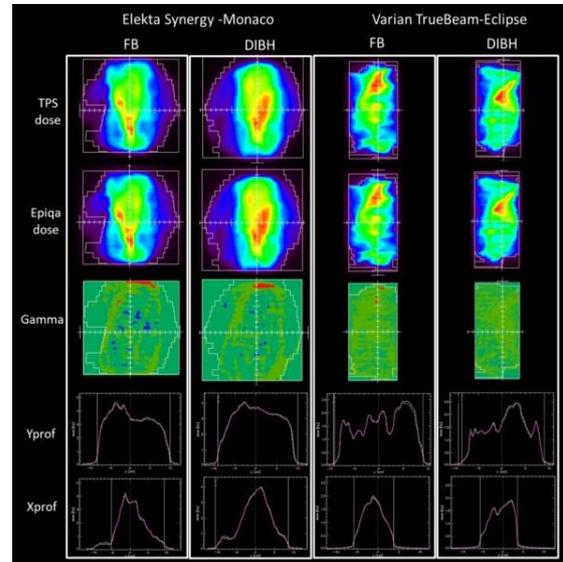

Fig.2: TPS and Epiqa dose distributions,  $\gamma(3\%G-3mm)$  results and isocenter dose profiles for FB and DIBH plans of same patient.

### Conclusion

VMAT DIBH technique is more robust than FB when the heart needs further sparing, because it allows an overall reduction of the OAR doses with a slightly lower level of plan complexity and without compromising plan deliverability.

### OC-0606 IMRT QA: comparing independent recalculation against measurement based methods

S. Kry<sup>1</sup>, M. Glenn<sup>1</sup>, C. Peterson<sup>1</sup>, D. Branco<sup>1</sup>, H. Mehrens<sup>1</sup>, A. Steinmann<sup>1</sup>, D. Followill<sup>1</sup>

<sup>1</sup>UT MD Anderson Cancer Center, Radiation Physics, Houston- TX, USA

### Purpose or Objective

To directly compare independent recalculation of the treatment plan against measurement-based IMRT QA to see which performed better at detecting unacceptable plans.

### Material and Methods

Acceptability of IMRT delivery was assessed with 337 IROC head and neck phantoms previously irradiated as part of clinical trial credentialing, 18 of which failed to meet IROC's 7%/4mm acceptability criteria. For each of the 337 cases, the institution's IMRT QA result, based on the method employed by the institution, was abstracted to determine how well their clinical QA (conducted on the phantom plan at the time of phantom irradiation) predicted the phantom irradiation result (i.e., did the phantom pass or fail). Each case was also independently recalculated by IROC using the institution's DICOM data and Mobius 3D (with linac class-specific beam models) to determine how well the recalculation predicted the phantom irradiation results (i.e., pass or fail). Comparisons between measurement-based IMRT QA and independent recalculation were made using truth tables to determine sensitivity and specificity of each, including subdivision by IMRT QA device (EPID, ArcCheck, ion chamber, or MapCheck). ROC analysis was also performed to evaluate the accuracy of measurement-based IMRT QA and independent recalculation as the strictness of the criteria for flagging failures varied.

### Results

For the 18 failing phantoms in the total cohort, measurement-based IMRT QA had a sensitivity of 6% (i.e., only 1 unacceptable plan was flagged based on clinical measurement-based IMRT QA methods). In contrast, the independent recalculation approach had a sensitivity of 72% (flagging 13 unacceptable plans). Overall, and when

the results were subdivided by IMRT QA device, the recalculation had a significantly higher sensitivity than any specific device examined (Table). Specificity was lower for the independent recalculation, but overall, incorporating both sensitivity and specificity, ROC analysis found superior performance (statistically significant) for the independent recalculation over clinical measurement-based IMRT QA. The area under the curve was 0.79 for the independent recalculation but only 0.60 for the measurement based approaches. Based on the ROC curves, the independent recalculation could detect 80% of unacceptable plans using a dose disagreement criteria (between the recalculation and the TPS value) of 3.8%. In order for measurement based IMRT QA methods to detect 80% of unacceptable plans, a clinically unrealistic criteria of 99.7% of pixels would need to pass a 3%/3mm criterion.

Device	# tests	#failing results	Measurement sensitivity (%)	Recalculation sensitivity (%)	Measurement specificity (%)	Recalculation specificity (%)
All	337	18	6	72	98	68
EPID	58	7	0	71	100	57
ArcCheck	93	4	0	100	100	70
Ion Chamber	44	1	0	100	91	67
MapCheck	121	5	20	40	100	67

### Conclusion

A simple independent recalculation using linac class-specific beam models had much better sensitivity at detecting unacceptable plans as compared to existing clinical measurement-based IMRT QA methods.

### OC-0607 IAEA supported national 'end-to-end' IMRT audit in Portugal

T. Santos<sup>1</sup>, M.D.C. Lopes<sup>2</sup>, E. Gershkevitch<sup>3</sup>, J. Izewska<sup>4</sup>  
<sup>1</sup>Faculty of Sciences and Technology, Physics Department, Coimbra, Portugal ; <sup>2</sup>Instituto Portugues de Oncologia de Coimbra Francisco Gentil E.P.E., Medical Physics Department, Coimbra, Portugal ; <sup>3</sup>North Estonia Medical Centre, Medical Physics Department, Tallinn, Estonia; <sup>4</sup>International Atomic Energy Agency, Dosimetry and Medical Radiation Physics Section, Vienna, Austria

### Purpose or Objective

IAEA has developed an IMRT audit programme to review physical aspects of IMRT H&N treatments through on-site visits. The audit was carried out in Portugal between April and September 2018. This abstract presents the results.

### Material and Methods

All radiotherapy centres performing IMRT treatments in Portugal, 20 out of 24 centres, have voluntarily participated. The centres equipment to perform IMRT is shown in Table 1.

Using a specially designed anthropomorphic H&N phantom - SHANE (CIRS Norfolk, VA) - and a set of contours, the audit methodology simulates all steps of a nasopharynx IMRT treatment, from CT scanning to treatment delivery, following the local protocol. To guide the planning optimization, a list of dose objectives and constraints was provided.

As part of the auditing process, pre-visit activities were performed concerning small field dosimetry and MLC performance which were also checked during the on-site visit. Beam output fluctuation on the audit day was taken into account.

The dosimetric verification of the H&N IMRT plan was performed with a dedicated dosimetry set including a small volume ionization chamber placed inside the phantom at four different locations (three PTVs and spinal cord) and an EBT3 film to assess the dose distribution in a coronal plane.

The agreement between the dose distributions in EBT3 film and calculated by the TPS was evaluated with FilmQA Pro software using triple channel dosimetry.

Table 1 – Audited radiotherapy equipment sets and techniques

Linac	TPS	Algorithm	Technique	Nr of Centres
Varian	Eclipse	AAA	Sliding Window	2
		AcurosXB	VMAT	10
		Monaco	VMAT	1
Elekta	Monaco	MC	Sliding Window	1
		MC	VMAT	4
Tomotherapy	VoLo	Fast Superposition	Step & Shoot	1
		CCC Superposition	Helical IMRT	1

### Results

Analysis of small field output factors calculated in the pre-visit phase showed that differences between participants' data and the Imaging and Radiation Oncology Core, IROC - Houston QA Centre reference dataset were generally within the tolerance of 3% for all field sizes. Good agreement was found between calculated and film measured profiles for the 2x2 cm<sup>2</sup> field in all centres. MLC QA test results were within 0.5 mm for the leaf positioning bias in all participating institutions.

All treatment plans have met the proposed plan constraints except three plans where at least one of the constraints was not accomplished.

The differences between ionization chamber measurements and calculated doses were on average -0.1 ± 2.0 % in PTVs and 0.2 ± 2.2% in the spinal cord, with the individual results of all centres within the established tolerances of ± 5% for PTVs and ± 7% for the spinal cord. One follow up visit was required to resolve a major deviation in the spinal cord.

Considering the results of film analysis, for global gamma criteria of 3%/3mm 20% TH, passing rates ranged from 90.3% to 99.1%, again all above the limit of acceptability of 90%.

### Conclusion

The IMRT audit supported by the IAEA carried out in Portugal showed an overall good agreement between planned and delivered doses although the IMRT treatment planning exercise was considered demanding.

### OC-0608 Credentialing of spine stereotactic ablative body radiotherapy in a multi-centre trial

N. Hardcastle<sup>1</sup>, O. Cook<sup>2</sup>, P. Mitchell<sup>3</sup>, S. Siva<sup>4</sup>  
<sup>1</sup>Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia ; <sup>2</sup>Trans-Tasman Radiation Oncology Group, Quality Assurance, Newcastle, Australia ; <sup>3</sup>Olivia Newton John Cancer and Wellness Centre, Medical Oncology, Melbourne, Australia ; <sup>4</sup>Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia

### Purpose or Objective

The NIVORAD trial (ALTG14/002, ACTRN12616000352404) involves administration of immunotherapy with or without Stereotactic Ablative Body Radiotherapy (SABR) to a single extracranial lesion in metastatic non-small cell lung cancer (NSCLC). Treated lesions receive a single fraction of 18-20 Gy and can include lung, soft tissue and bone including spine. Given the multi-disciplinary and complex nature of SABR delivery in particular with spine, a credentialing approach was created focusing on review of SABR treatment processes and measurement of a spine case.

### Material and Methods

Credentialing was split into two streams. Centres with a previous SABR site visit through TROG were required to perform an axial film measurement of a benchmarking spine plan in an appropriate local phantom and submit raw radiochromic film images for analysis. Remaining centres had an on-site review of SABR processes based on international guidelines, followed by an axial film measurement of the spine benchmarking plan. Films were

analysed for dosimetric and positional accuracy: up to 5% global scaling was allowed, followed by gamma analysis at 2%/2mm/10% threshold. Positional accuracy at target-cord interface and target-cord dose gradient (80%-20% width) was required to be within 1 mm of planned.

#### Results

A total of 18 centres have been credentialed; eight centres had previous site visits and submitted film and 10 centres had an on-site SABR process review and measurement. Delivery devices included linear accelerator, TomoTherapy and Cyberkife systems. Five centres were not able to achieve 90% gamma passing rate (Figure 1). Of these, three failed in low (< 5 Gy) dose regions and were > 80% passing rate thus were deemed acceptable. Two failed over the full dose range; one resubmitted a new plan, with the original fail attributed to inappropriate MLC constraints. The remaining centre elected not to have spine remeasured. One centre had positional discrepancy greater than 1 mm, and all centres were able to deliver the planned dose fall off from 80% of prescription dose to 20% of prescription dose within 1 mm at the target-cord interface. Figure 2 shows consistency in the dose gradient between planned and measured dose at the target-cord interface.

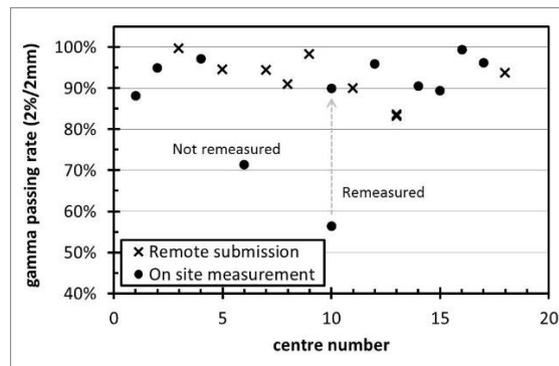

Figure 1: Gamma passing rate at 2%/2mm for all centres

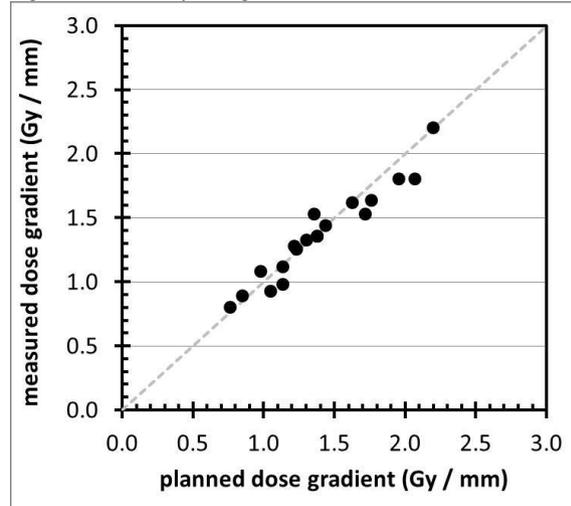

Figure 2: Dose gradient between the 80% and 20% of prescription dose at the target-cord interface

#### Conclusion

Credentialing measurements for spine SABR in a multi-centre trial have shown the majority of centres, independent of treatment modality can deliver spine SABR according to the treatment plan. The measurement process detected one centre with inappropriate MLC constraint setting that was rectified upon a repeat visit.

#### OC-0609 Urethra-sparing SBRT for prostate cancer: quality assurance of a randomized phase II trial

M. Jaccard<sup>1</sup>, T. Zilli<sup>1</sup>, A. Dubouloz<sup>1</sup>, L. Tsang<sup>2</sup>, S. Zvi<sup>2</sup>, N. Linthout<sup>3</sup>, S. Bral<sup>3</sup>, W. Verbakel<sup>4</sup>, A. Bruynzeel<sup>4</sup>, M. Björkqvist<sup>5</sup>, H. Minn<sup>5</sup>, L. Escude<sup>6</sup>, S. Jorcano<sup>6</sup>, J. Lencart<sup>7</sup>, A. Oliveira<sup>7</sup>, Z. Ozen<sup>8</sup>, U. Abacioglu<sup>8</sup>, J.M. Pérez-Moreno<sup>9</sup>, C. Rubio<sup>9</sup>, M. Rouzard<sup>1</sup>, R. Miralbell<sup>1</sup>  
<sup>1</sup>Geneva University Hospital, Radiation Oncology, Geneva, Switzerland; <sup>2</sup>Sheba Medical Center, Radiation Oncology, Ramat Gan, Israel; <sup>3</sup>Onze-Lieve-Vrouwenziekenhuis, Radiation Oncology, Aalst, Belgium; <sup>4</sup>VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands; <sup>5</sup>University Hospital Turku, Radiation Oncology, Turku, Finland; <sup>6</sup>Teknon Oncologic Institute, Radiation Oncology, Barcelona, Spain; <sup>7</sup>Portuguese Institut of Oncology, Radiation Oncology, Porto, Portugal; <sup>8</sup>Neolife Medical Center, Radiation Oncology, Istanbul, Turkey; <sup>9</sup>Hospital Universitario Sanchinarro, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

To present the radiotherapy quality assurance (RTQA) results from a prospective multicenter phase II randomized trial of short vs. protracted urethra-sparing stereotactic body radiotherapy (SBRT) for localized prostate cancer (PCa).

#### Material and Methods

From 08/2012 through 12/2015, 165 patients (pts) from nine institutions with localized PCa were randomized and treated according to two different overall treatment time schedules: either 9 days (arm A, 82 pts), or 28 days, once-a-week, the same week-day (arm B, 83 pts). The prescribed dose was 36.25 Gy in 5 fractions of 7.25 Gy to the prostate planning target volume (PTV) with ( $n=92$ ) or without ( $n=73$ ) inclusion of the seminal vesicles (SV) (5-mm isotropic expansion, with a 3-mm posterior margin). The urethra planning risk volume (uPRV=prostatic urethra+3-mm margin) was planned to receive 32.5 Gy. Patients were treated either with a volumetric modulated arc therapy (VMAT) ( $n=112$ , 72 with SV) or intensity modulated RT (IMRT) ( $n=53$ , 20 with SV) technique under stereotactic conditions using Novalis linacs and ExacTrac image-guided technology.

Dosimetric results, PTV homogeneity index (HI), Dice similarity coefficient (DSC), number of monitor units (MU), as well as deviations from protocol dose constraints were retrospectively analyzed and compared between pts treated with a VMAT vs. IMRT technique.

#### Results

Major protocol deviations occurred for 52 pts (32%), mostly for uPRV (12%) and PTV (5%) coverage, and for the rectal (RW) and bladder wall (BW)  $V_{90\%}$  (7%, each) (Table 1), while minor deviations occurred for 67 pts (41%). For PTV and uPRV coverage, deviations were more frequent in the IMRT group ( $p=0.001$  and  $p<0.0001$ , resp.). As compared to IMRT, treatment planning with VMAT resulted in a slightly better uPRV coverage ( $D_{98\%}=31.1$  vs. 30.6 Gy,  $p<0.0001$ ), less MU (2335 vs. 3454,  $p<0.0001$ ), and better HI (0.09 vs. 0.11,  $p<0.0001$ ) and DSC (0.85 vs. 0.75,  $p<0.0001$ ) values. Moreover, VMAT yielded better dosimetric parameters for the BW  $V_{50\%}$  (26.1% vs. 33.3%,  $p=0.0001$ ) and the penile bulb (PB)  $D_{mean}$  (30.7 vs. 31.1 Gy,  $p=0.008$ ), while other dosimetric parameters were similar. The inclusion of the SV in the PTV impacted negatively on the RW  $V_{90\%}$  (9.1% without vs. 10.4% with,  $p=0.0003$ ) and RW  $V_{80\%}$  (13.2% without vs. 15.7% with,  $p=0.0003$ ). The PTV volume was found to mildly linearly correlate with the BW  $V_{50\%}$  ( $r=0.523$ ,  $p<0.0001$ ) and the femoral heads (FH)  $D_{2\%}$  ( $r=0.572$ ,  $p<0.0001$ ).

Table 1: Means and standard deviations (SD) of dosimetric parameters, protocol dose constraints, and number of plans with protocol deviations.

	Mean $\pm$ SD	Protocol constraints (acceptable deviations)	Major (minor) protocol deviations
PTV D <sub>98%</sub> (Gy)	34.4 $\pm$ 0.4	$\geq$ 34.4 Gy (33.7 Gy)	9 (32)
PTV D <sub>2%</sub> (Gy)	38.1 $\pm$ 0.6	< 38.8 Gy (39.9 Gy)	0 (10)
RW V <sub>100%</sub> (%)	1.7 $\pm$ 1.5	< 5% (10%)	0 (4)
RW V <sub>90%</sub> (%)	10.2 $\pm$ 3.3	< 10% (15%)	11 (66)
RW V <sub>80%</sub> (%)	14.5 $\pm$ 4.2	< 20% (25%)	0 (16)
BW V <sub>100%</sub> (%)	6.6 $\pm$ 3.4	< 10% (15%)	1 (20)
BW V <sub>90%</sub> (%)	12.6 $\pm$ 4.9	< 20%	11
BW V <sub>50%</sub> (%)	28.4 $\pm$ 11.2	< 50% (60%)	1 (3)
PB D <sub>mean</sub> (Gy)	8.8 $\pm$ 7.5	< 27.2 Gy	3
uPRV D <sub>98%</sub> (Gy)	31.0 $\pm$ 0.9	$\geq$ 30.9 Gy (30.2 Gy)	19 (15)
uPRV D <sub>2%</sub> (Gy)	34.6 $\pm$ 0.5	< 35.8 Gy	2
FH <sub>right</sub> D <sub>2%</sub> (Gy)	13.1 $\pm$ 3.2	< 18.1 Gy	7
FH <sub>left</sub> D <sub>2%</sub> (Gy)	13.1 $\pm$ 3.0	< 18.1 Gy	4

### Conclusion

The retrospective QA analysis of this prospective SBRT trial showed up to a 32% rate of dosimetric variations with potential impact on tumor control and/or toxicity profile. Use of an IMRT technique and inclusion of SV in the PTV were the major causes of protocol deviations. Integration of prospective RTQA protocols is encouraged for future PCa SBRT clinical trials to prevent and correct protocol violations before start of treatment.

#### OC-0610 Modelling of xerostomia after radiotherapy for head and neck cancer: a registry study

E. Onjukka<sup>1</sup>, C. Mercke<sup>2</sup>, A. Discacciati<sup>3</sup>, G. Alexandersson von Döbeln<sup>2</sup>, E. Björgvinsson<sup>2</sup>, H. Carstens<sup>2</sup>, S. Friesland<sup>2</sup>, G. Gagliardi<sup>1</sup>, C. Lenneby Helleday<sup>2</sup>, H. Sjödin<sup>2</sup>, G. Wickart Johansson<sup>2</sup>, I. Lax<sup>1</sup>  
<sup>1</sup>Karolinska University Hospital, Medical Radiation Physics and Nuclear Medicine, Stockholm, Sweden ;  
<sup>2</sup>Karolinska University Hospital, Oncology, Stockholm, Sweden ;  
<sup>3</sup>Karolinska Institute, Institute of Environmental Medicine, Stockholm, Sweden

#### Purpose or Objective

The purpose of this study is to model the incidence of late xerostomia in patients treated with radiotherapy (RT) for head-and-neck (H&N) cancer, based on data from a local quality registry.

#### Material and Methods

Since 2013 patients followed up after RT for Head and Neck cancer at Karolinska University Hospital are entered into a quality registry and scored for toxicity of the skin, mucosa, larynx, and mandible, as well as xerostomia, dysphagia and trismus, according to a modified RTOG/LENT-SOMA scale. Also patient- and treatment-related factors are recorded, including RT dose/volume parameters for external-beam RT, concomitant drug therapy, performance status, gender, age, tumour location, tumour stage, HPV association and smoking status. The registry has a compliance of 70% and currently includes records of 1400 patients.

The treatment technique is predominantly IMRT/VMAT (87%) with 6 MV. Prescribed dose to primary target volume

is; >73 Gy in 12%, 68 Gy in 69%, 66 Gy in 8% and 50 Gy in 9%. The dose/fraction is 2.2 Gy for the highest dose group and 2.0 Gy for the other groups. The number of fractions/week is 6 in 51% and 5 in 45% of the patients. The dose per fraction to elective volumes is 2.0 Gy or 1.52 Gy for two sequential dose plans and simultaneous integrated boost plans, respectively.

A logistic regression model of grade  $\geq 2$  late xerostomia was fitted for patients who had at least one follow-up scoring late toxicity, and no missing values for the included variables. Re-irradiated patients were excluded from the analysis. Forward selection of model parameters was used and discrimination and calibration were assessed with AUC and calibration curves. An internal validation with bootstrap was performed to correct the performance measure for optimism.

### Results

Out of the 673 patients included in the study 43% had a maximum score of grade  $\geq 2$  late xerostomia. The cohort characteristics are listed in the table. The following variables were selected when fitting the model: mean dose to the total parotid volume (ipsilateral + contralateral), tumour type, gender and concomitant drug therapy. A greater odds ratio was associated with higher parotid dose, oropharynx tumours, female gender and concomitant cisplatin treatment, respectively. The optimism corrected AUC was 0.638 (95%CI: 0.597; 0.678) and the calibration slope was 0.798 (95%CI: 0.535; 1.061). The model performance did not improve when forcing the inclusion of the mean dose to each parotid separately, and the odds ratios for the two parotids were equivalent.

	Grade <2 xerostomia	Grade $\geq 2$ xerostomia	p-value
N	384	289	
Female gender	114 (30%)	112 (39%)	0.014
Age (year), median (IQR)	63.5 (54, 70)	62 (56, 70)	0.75
Tumour type			<0.001

### Conclusion

This large registry study showed that for the patients treated with RT for H&N cancer, the strongest risk factor for late xerostomia is the dose to the total parotid volume. There does not seem to be any benefit in *predominantly* sparing the contralateral parotid.

#### OC-0611 Planned and delivered DVHs of the skin predict acute cutaneous toxicity after IGRT for HN cancer

M. Mori<sup>1</sup>, S. Foti<sup>2</sup>, I. Dell' Oca<sup>2</sup>, M. Branchini<sup>1</sup>, S. Broggi<sup>1</sup>, G.M. Cattaneo<sup>1</sup>, N. Di Muzio<sup>2</sup>, C. Fiorino<sup>1</sup>  
<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

#### Purpose or Objective

To explore the ability of skin dose-volume histograms (DVH) to predict the risk of acute cutaneous toxicity (ACT) after Radio-chemotherapy for Head and Neck (HN) cancer patients (pts) and to test if DVHs recalculated during therapy may improve prediction.

#### Material and Methods

Seventy HN pts were treated with Helical Tomotherapy (HT) with radical intent (SIB technique: 54/66 Gy to PTV1/PTV2 in 30fr) and concurrent chemotherapy (excluding Cetuximab). The skin was defined as a superficial body layer 2mm thick (SL2). Prospectively evaluated CTCAE v4.0 ACT data were available. Average absolute DVH of SL2 for pts who developed severe (G3) and severe/moderate (G3/G2) ACT were assessed. The differences against DVHs of patients without ACT (G0/G1/G2 and G0/G1 respectively) were analyzed by two-tails t-test; univariable logistic analyses were performed selecting DVH values corresponding to the lowest p-values at t-tests. Multivariable logistic analyses were also performed considering CTV volume, age, sex, chemotherapy as potential predictive factors. In addition, the effect of dose changes during therapy was quantified in 32/70 pts, by recalculating DVHs at half and end therapy with a previously validated dose-of-the-day calculation method. The association between therapy DVHs and G3/G2 ACT was tested and compared against the one using planning DVH.

#### Results

Sixty-one % of pts experienced G2/G3 ACT (rate of G3=19%). As reported in Fig 1 (left), differences in skin DVHs (G2/G3 vs G0/G1) were significant in the range 53-68Gy. V56 was the most predictive parameter (OR= 1.12, 95%CI= 1.03-1.21, p= 0.001), with a best cut-off of 7.7cc. The logistic model for V56 was well calibrated (slope/R<sup>2</sup> of calibration plot: 0.97/0.99). When considering G3 ACT (Fig 1, right), V64 was the best predictor (OR= 1.13, 95%CI= 1.01-1.26, p= 0.027) with a best cut-off of 2.7cc. Average V64 were 2.2cc and 6cc for the two groups (G3 vs G0-G2); the logistic model for V64 also showed good calibration (slope/R<sup>2</sup>: 0.99/0.60). The association between DVHs and G2/G3 ACT was significant also in the subgroup of 32 pts with dose-of-the-day calculations available; t-tests on average DVHs at planning, half and end of treatment (Fig 2), showed none improvement of the association with ACT when considering therapy DVHs in place of planning DVHs.

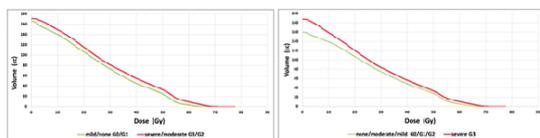

Figure 1: Average absolute DVH of SL2 for pts who developed severe/moderate (G3/G2) Vs mild/none (G0/G1) on the left. Only severe (G3) Vs moderate/mild/none (G2/G1/G0) on the right.

#### Conclusion

The relationship between SL2 DVH and ACT after HT of HN pts with a SIB approach was quantified. The results should help in identifying pts at risk and in implementing more effective skin-sparing planning strategies. In particular,

constraining V64 < 3cc (corresponding to 4x4cm<sup>2</sup> skin surface) should keep the risk of G3 ACT below 10%. Considering therapy DVHs in place of planning DVHs does not seem to improve prediction.

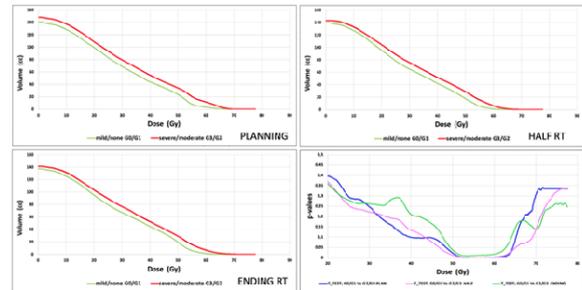

Figure 2: Average absolute DVH of SL2 for pts who developed severe/moderate (G3/G2) Vs mild/none (G0/G1) at planning on the left top, at half RT on the right top and at ending RT on the left bottom. On the right bottom the t-test average DVHs comparison of three RT phases shows none improvement of the association with ACT when considering therapy DVHs in place of planning DVHs.

#### OC-0612 A case-control study of brainstem substructures and morbidity following pediatric proton therapy

C. Stokkeväg<sup>1</sup>, D.J. Indelicato<sup>2</sup>, L.F. Fjæra<sup>3</sup>, Y. Lassen-Ramshad<sup>4</sup>, K.S. Ytre-Hauge<sup>3</sup>, Z. Li<sup>2</sup>, L. Toussaint<sup>5</sup>, O. Casares-Magaz<sup>3</sup>, S. Flampouri<sup>2</sup>, R. Mikkelsen<sup>6</sup>, C. Pedro<sup>7</sup>, O. Dahl<sup>1</sup>, L.P. Muren<sup>5</sup>  
<sup>1</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway ; <sup>2</sup>University of Florida, Department of Radiation Oncology, Jacksonville, USA ; <sup>3</sup>University of Bergen, Department of Physics and Technology, Bergen, Norway ; <sup>4</sup>Aarhus University Hospital, Danish Centre for Particle Therapy, Aarhus, Denmark ; <sup>5</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark ; <sup>6</sup>Aarhus University Hospital, Department of Neuroradiology, Aarhus, Denmark ; <sup>7</sup>Portuguese Institute of Oncology Francisco Gentil de Lisboa, Department of Radiotherapy, Lisbon, Portugal

#### Purpose or Objective

Brainstem toxicity is a rare but severe condition that can follow treatment of pediatric brain tumors. Dose received by the brainstem is one of the treatment-specific causes of brainstem morbidity. Current data on brainstem toxicity are limited and the brainstem is often regarded as a single organ with dose constraints determined without considering potential regional sensitivity within the brainstem. The brainstem core has in some studies been found more radiosensitive than the outer surface, and diffusion tensor imaging has recorded non-uniform changes across different substructures of the organ. In order to investigate if outcome could be explained by different radio-sensitivities across the brainstem, dose/volume parameters in different anatomical brainstem regions were evaluated for pediatric brain tumor patients with brainstem toxicity vs. patients with no toxicity.

#### Material and Methods

A matched case-control was performed within a cohort of 954 pediatric brain tumor patients treated with proton therapy from 2006 to 2017. Ten patients presenting with symptomatic grade 2+ brainstem toxicity were each matched to three controls based on diagnosis, age within  $\pm 1.5$  years and by whole brainstem dose metrics (D0.1cc within  $\pm 2$  Gy, and D10% within  $\pm 2$  Gy). The brainstem core (brainstem cropped by 3 mm) and the regions medulla oblongata, midbrain, pons were segmented on T1/T2 MRI sequences fused with the CT scan used for treatment planning. The pons was further divided into four transversal zones (posterior, middle posterior, middle anterior and anterior) to approximate fiber tracts (Figure 1). Dose/volume metrics (obtained using an RBE of 1.1) for

each segmented structure were compared between cases and controls using two-way ANOVA tests with significance level 0.05.

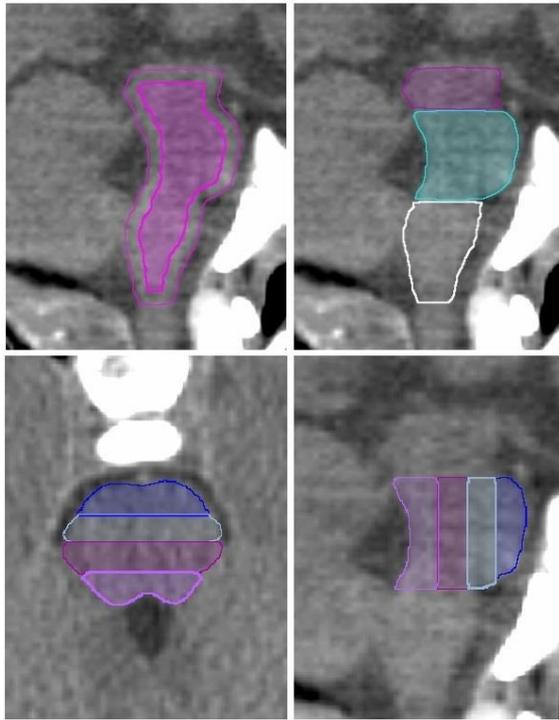

Figure 1. Brainstem structures: full brainstem and core (upper left), midbrain, pons and medulla oblongata (upper right), posterior, middle posterior, middle anterior and anterior pons (lower panels: left in transvers; right in sagittal).

## Results

Average D0.1cc, D10% and D50% of each brainstem substructure were not statistically significant different between cases and controls (Figure 2). Significant difference was also not found between the dose/volume parameters for the full brainstem. For both cases and controls, the medulla oblongata and anterior pons had the largest variance in all dose/volume parameters, whereas the variance of D50% was also high for the posterior pons.

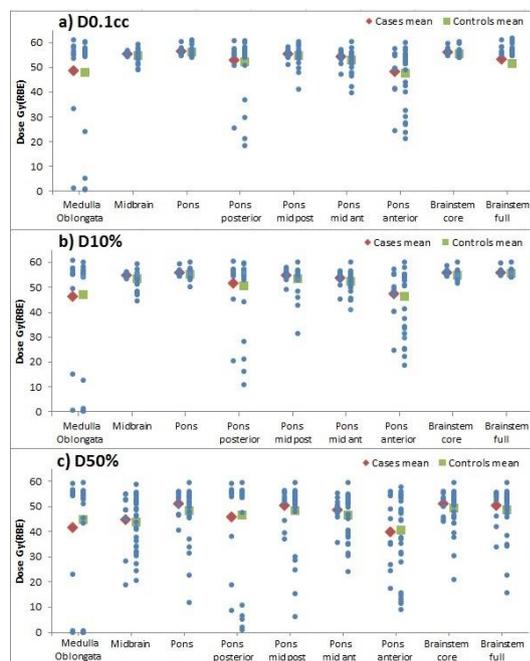

Figure 2: Dose/volume metrics for cases (shifted left) and controls (shifted right). Medulla oblongata, midbrain, pons, and the four transversal zones of the pons: posterior, middle posterior, middle anterior, anterior pons and brainstem core. The full brainstem dose metrics were used for matching.

## Conclusion

The brainstem morbidities manifested in the ten cases could not be explained by the investigated dose metrics, including the specific brainstem substructures. The variations in radio-sensitivity may therefore be due to other patient-specific factors not controlled for in this study, or may be better explained by other metrics including variable RBE doses.

### OC-0613 Spatial dose patterns of radiation pneumonitis in lung cancer patients treated by photons or protons

G. Palma<sup>1</sup>, S. Monti<sup>2</sup>, T. Xu<sup>3</sup>, E. Scifoni<sup>4</sup>, P. Yang<sup>3</sup>, S. Hahn<sup>3</sup>, M. Durante<sup>5</sup>, R. Mohan<sup>6</sup>, Z. Liao<sup>3</sup>, L. Cella<sup>1</sup>  
<sup>1</sup>National Research Council, Institute of Biostructures and Bioimaging, Napoli, Italy ; <sup>2</sup>Ircs SDN, Image Processing Department, Napoli, Italy ; <sup>3</sup>MD Anderson Cancer Center, Department of Radiation Oncology, Houston, USA ; <sup>4</sup>Istituto Nazionale di Fisica Nucleare, Trento Institute for Fundamental Physics and Applications, Trento, Italy ; <sup>5</sup>GSI Helmholtz Centre for Heavy Ion Research, Department of Biophysics, Darmstadt, Germany ; <sup>6</sup>MD Anderson Cancer Center, Department of Radiation Physics, Houston, USA

### Purpose or Objective

Radiation pneumonitis (RP) is a common side effect of thoracic Radiation Therapy (RT), and its incidence has been reported similarly in both Intensity-Modulated RT (IMRT) and Passive Scattering Proton Therapy (PSPT) [Liao *et al.*, JCO 2018]. Aim of this study is to investigate the spatial pattern of pulmonary and cardiac radiosensitivity (RS) to RP in patients enrolled in a prospective randomized trial of IMRT versus PSPT for locally advanced Non-Small-Cell Lung Cancer (NSCLC).

### Material and Methods

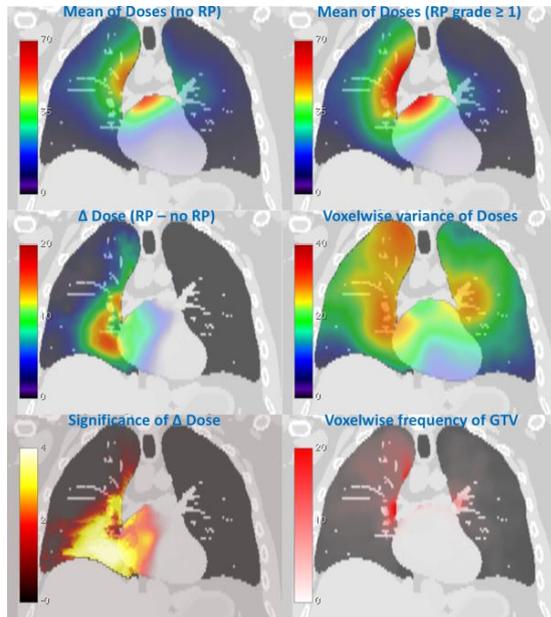

We analyzed data of 178 prospectively treated at a single institution with PSPT (64 patients) or IMRT (114 patients) for NSCLC. All patients were treated to a prescribed dose of 60 to 74 Gy in conventional daily fractionation with concurrent chemo-radiotherapy. Median patient age was 66 years (range: 33-85 years). Fifty-five patients (31%) in the trial developed RP of any grade scored according to CTCAE v. 3.0.

Each planning CT and dose map was spatially normalized to a common anatomical reference using a B-spline inter-patient registration algorithm after masking the gross tumor volume. A Voxel-Based Analysis (VBA) was performed according to a non-parametric permutation test accounting for multiple comparison, based on a cluster analysis method [Monti *et al.*, SciRep 2018]. The underlying general linear model of RP was designed to include dose maps and potential non-dosimetric variables significantly correlated with RP. A 3D significance map was derived and the clusters of voxels with dose differences that significantly correlated with RP at a  $p$ -level of 0.05 ( $S_{0.05}$ ) were generated accordingly.

The VBA was performed on the Entire Cohort (EC) and, separately, on the sub-cohorts of IMRT and PSPT. In order to quantify the match between the significance  $p$ -maps obtained on a sub-cohort ( $p_{IMRT}$  or  $p_{PSPT}$ ) and the  $p$ -map obtained on EC ( $p_{EC}$ ), the metrics DIV was computed as the Dice Index between the sublevel sets of  $p_{IMRT}$  or  $p_{PSPT}$  and  $p_{EC}$  with same relative volume  $V$  [Monti *et al.*, SciRep 2018].

### Results

The VBA on EC highlighted extended areas of significant dose differences between patients with and without RP in the lower part of the right lung and in the heart (Figure).

The mean dose in  $S_{0.05}$  for RP patients was 26 Gy, and for patients without RP was 11 Gy. The maps  $p_{IMRT}$  and  $p_{PSPT}$  showed a similar spatial pattern of  $p_{EC}$ , quantified by both the Areas Under the  $DIV[p_{EC}, p_{IMRT}]$  and  $DIV[p_{EC}, p_{PSPT}]$  Curves of 0.86.

#### Conclusion

Similar significance patterns highlighted by the 3 VBAs justify the choice to analyze the 2 sub-cohorts as a whole in search of valuable insights into the thoracic RS. The completely different dose patterns of PSPT provide an unprecedented chance to look at the results of a VBA, with a sensible reduction of a potential bias related to the spatial correlation of IMRT dose distributions. This lays more robust foundations to the previously reported hypotheses that the lower parts of the lungs and the heart play a prominent role in the development of RP [Monti *et al.*, SciRep 2018].

#### OC-0614 NTCP models of late rectal morbidity after proton therapy in 1036 prostate cancer patients

J. Pedersen<sup>1</sup>, S. Flampouri<sup>2</sup>, C. Bryant<sup>2</sup>, Z. Li<sup>2</sup>, N. Mendenhall<sup>2</sup>, L.P. Muren<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark ; <sup>2</sup>University of Florida Health Proton Therapy Institute, University of Florida Health Proton Therapy Institute, Jacksonville- Florida, USA

#### Purpose or Objective

Normal tissue complication probability (NTCP) models may be used to guide patient selection and treatment evaluation for proton therapy (PT), but current models are derived from outcomes following photon-based radiotherapy. Since photons and protons have fundamentally different properties (reduced dose bath with PT and a higher relative biological effectiveness, RBE), NTCP models for photons might not be applicable to PT. The aim of this study was therefore to derive parameters of an established NTCP model when using prospectively recorded late morbidity data from PT, focusing on rectal morbidity and prostate cancer.

#### Material and Methods

Dose volume histogram data for the rectum and rectal wall from 1036 prostate cancer patients (with no pre-treatment anti-coagulation medication) treated with PT between 2006 and 2010 were used. Patients were prescribed target doses of 78-82 Gy (RBE = 1.1) in 2 Gy fractions. Lyman-Kutcher-Burman model parameters were derived for two alternative late grade 2 rectal bleeding endpoints (CTCAE v3.0): Grade 2A (GR2A) was classified as

medical (e.g. prescribed suppositories) and Grade 2B (GR2B) was classified as procedural (included minor cauterization and topical formalin application). Model parameters were derived for both the rectum and the rectal wall by maximum likelihood estimation, and profile likelihood estimation was used to calculate confidence intervals for the parameters. Patients were also sorted by NTCP values (low to high), and divided into 12 groups of 86-87 patients to allow for a comparison between the calculated NTCP and the clinically observed frequency of morbidity.

#### Results

Late GR2A+2B rectal bleeding was observed in 155/1036 patients (15%) and GR2B in 45/1036 patients (4%). The volume parameter  $n$  was low (0.04-0.14) both for GR2A+2B and GR2B, and lowest for GR2B for the rectum. For uniform irradiation of one-third of the rectum ( $V = 1/3$ ) an NTCP of 5% was found at 59 Gy for GR2A+2B and at 75 Gy for GR2B (Fig. 1). There was a close to 1:1 relation between the calculated NTCPs and the observed morbidity across the 12 groups (Fig. 2). However, there were large variations between the groups, most pronounced for GR2B (Fig. 2). The area under the curve values ranged between 0.62-0.63 for GR2A+2B and 0.54-0.55 for the GR2B.

Figure 1:

NTCP models for grade 2B + 2A and grade 2B only morbidity, for both the rectum and the rectal wall, showing the dose response for uniform irradiation of the whole organ (blue), 2/3 of the organ (green) and 1/3 of the organ (red). Note that the volume effect is smallest for the GR2B endpoint, and also smaller for the volume than the rectal wall. The best fit LKB parameters including their confidence intervals are summarised in the legends, for both morbidity endpoints and both the rectum and rectal wall. Note that the y-axis is not same scale.

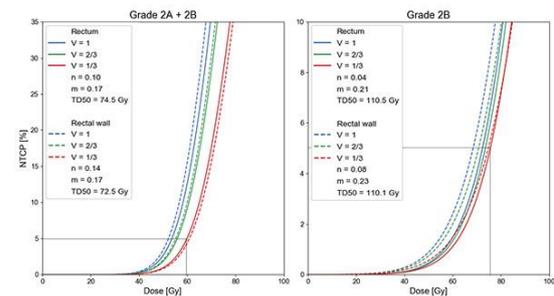

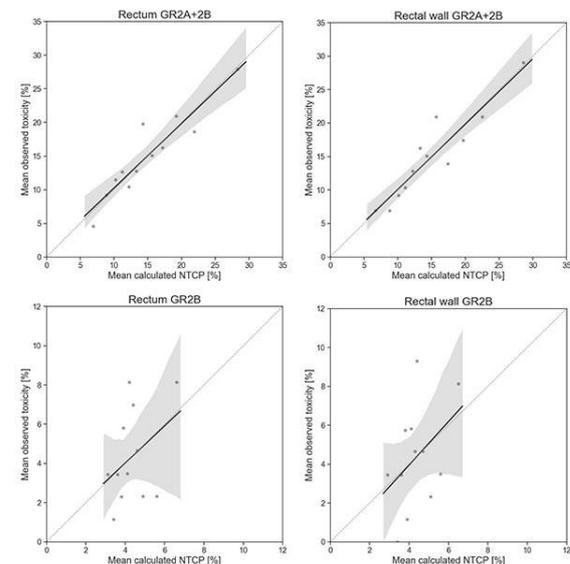

Figure 2:

Mean calculated NTCP values (based on best fit LKB parameters) vs. the actually observed frequency of morbidity for the twelve groups, both morbidity endpoints (GR2A+2B and GR2B), and both the rectum and rectal wall. Each data point shows the mean calculated NTCP (sorted from low to high) vs. observed frequency of morbidity for groups of 86-87 patients. Black solid lines are the best fit regression lines for the points, while the grey dotted lines are the identity line. As can be seen, the fitted lines and the identity line are almost identical indicating that the derived parameters fit the data.

## Conclusion

PT specific NTCP model parameters for prospectively recorded late rectal morbidity in more than 1000 patients were derived. The volume parameter was generally small indicating a weak volume effect, most pronounced for the GR2B endpoint. There was a difference of >15 Gy between the doses resulting in 5% morbidity for the two alternative endpoints. The models were internally validated, showing the appropriateness of our methodology. However, the predictive power on an individual level was moderate, in particular for GR2B due to fewer events. Further optimization of model performance will be explored, incorporating also spatial measures of the dose distributions.

## OC-0615 Predicting urinary toxicity via 2D and 3D dose map analyses in prostate cancer radiotherapy

E. Mylona<sup>1</sup>, A. Cicchetti<sup>2</sup>, T. Rancati<sup>2</sup>, F. Palorini<sup>2</sup>, S. Supiot<sup>3</sup>, N. Magné<sup>4</sup>, G. Crehange<sup>5</sup>, O. Acosta<sup>1</sup>, R. De Crevoisier<sup>1,6</sup>

<sup>1</sup>INSERM U1099 - University of Rennes, Laboratoire Traitement du Signal et de l'Image, Rennes, France ; <sup>2</sup>IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy ; <sup>3</sup>Institut de Cancérologie de l'Ouest - René Gauducheau, Radiotherapy Department, Nantes, France ; <sup>4</sup>Lucien Neuwirth Cancer Institute, Radiotherapy Department, St Priest en Jarez, France ; <sup>5</sup>Centre Georges François Leclerc, Radiotherapy Department, Dijon, France ; <sup>6</sup>Centre Eugène Marquis, Radiotherapy Department, Rennes, France

### Purpose or Objective

Risk estimation of urinary toxicity after prostate radiotherapy is generally based on bladder DVH, disregarding any spatial dose-distribution information. The objectives of the study were:

- To identify bladder subregions associated with urinary toxicity via pixel-wise and voxel-wise statistical analysis on 2D dose-surface maps (DSM) and 3D dose-volume maps (DVM), respectively.
- To evaluate their prediction capabilities with respect to the DVH of the whole bladder.

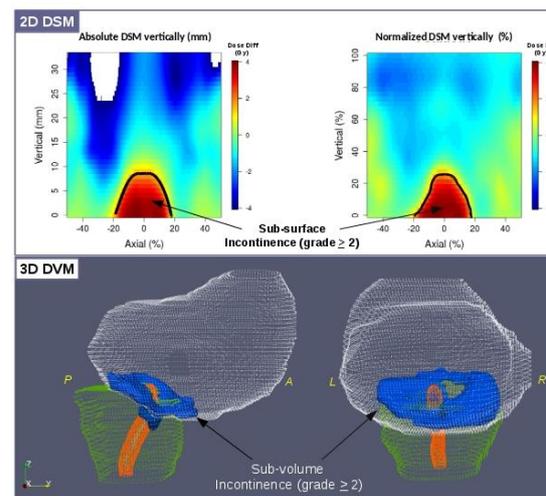

### Material and Methods

In total 272 prostate cancer patients treated with IMRT/IGRT from two multicentric phase III trials (STIC-IGRT and PROFIT), were prospectively analyzed. Local relationships between dose and specific urinary endpoints were investigated via 2D DSMs and 3D DVMs, by analyzing the planning dose distribution at pixel and voxel scales, respectively. DSMs were generated by anteriorly cutting and virtually unfolding the bladder surface. Maps were laterally normalized and aligned at the most inferior-posterior point. Normalized DSMs (nDSM) both laterally and vertically were also computed. DVMs were produced by first non-rigidly registering the population to a common coordinate system and then propagating the 3D dose distribution according to the transformation beforehand obtained. Pixel and voxel-wise non parametric analyses were performed, for DSMs and DVMs respectively, to identify regions of statistically significant dose differences between patients with/without toxicities. The spatial correlation between the regions found with the nDSMs and DVMs for each symptom was evaluated with the Jaccard score (intersection surface divided by union surface). Prediction capability was estimated by the area under the ROC curve (AUC) from logistic regression, performed at each dose bin of the DVH of the sub-volumes, the dose-surface histogram (DSH) of the sub-surfaces, and the DVH of the whole bladder.

### Results

A local dose-effect relationship was found for three late toxicity endpoints: incontinence (grade $\geq$ 2), retention (grade $\geq$ 1) and dysuria (grade $\geq$ 1). The 5-year toxicity rates were 4%, 23% and 13%, respectively. The subregions found with the two methods are mostly located in the inferior

and posterior bladder. The Jaccard scores were 0.3 (dysuria), 0.42 (retention) and 0.7 (incontinence). Figure 1 shows the identified sub-surface (top) and sub-volume (bottom) for urinary incontinence. Table 1 shows the prediction capabilities, for each endpoint, of the sub-volume's DVH, sub-surface's DSH and whole bladder's DVH. The dose bin with the highest significant AUC is reported.

Endpoint (late toxicity)	Method	Most predictive bin	AUC (p-value)	OR (95% CI)
Incontinence (grade $\geq$ 2)	Sub-surface DSH	S78	77.5 (0.01)	1.03 (1.01-1.06)
	Sub-volume DVH	V79	79.7 (0.01)	1.04 (1.01-1.07)
	Whole bladder DVH	V80	70.2 (0.01)	1.21 (1.05-1.41)
Retention (grade $\geq$ 1)	Sub-surface DSH	S62	62 (0.05)	1.01(1-1.02)
	Sub-volume DVH	V37, V62	68 (<0.01)	1.02 (1.01 - 1.04)
	Whole bladder DVH	-	NS	-
Dysuria (grade $\geq$ 1)	Sub-surface DSH	S77	70 (<0.01)	1.18 (1.07-1.3)
	Sub-volume DVH	V53	78.7 (<0.01)	1.06 (1.02-1.09)
	Whole bladder DVH	V63	70.1 (0.02)	1.04 (1.01-1.07)

Abbreviations: DVM= dose-volume map, DSM=dose-surface map, OR= odds ratio, AUC= area under the ROC curve, CI= confidence interval, NS = non significant

### Conclusion

Specific bladder subregions were identified by the two methods as more predictive of urinary toxicity than the whole bladder. Particularly, the DVM method highlights the importance of volumes near the bladder surface, but inside bladder volume, underlining the influence of variable bladder filling and, thus, entailing the need of optimizing dose even in "non-obvious" regions (i.e. what appears to be urine at planning CT).

## OC-0616 Introducing information on gut microbiota into toxicity modeling: preliminary results from a trial

**Purpose or Objective**

A mono-institutional trial was set up in 2017 to investigate the role of gut/saliva microbiota (MB) in driving radio-induced toxicity (tox) after RT for prostate (PCa) and head&neck cancers.

We here focus on introduction of information on gut MB into a normal tissue complication probability model (NTCP) for acute gastro-intestinal (GI) tox in the PCa cohort.

**Material and Methods**

130 consecutive PCa patients (pts) receiving conventional (78Gy @2Gy/fr) or moderately hypofractionated (65Gy @2.6Gy/fr) VMAT+IGRT in 5 fr/week were enrolled.

A detailed evaluation was done pre-RT, during RT and at RT end, including gut MB measurement. Stool samples were collected using gut-OMNIgene devices (Oragene). DNA extraction was carried out using the QIAamp-DNA-Stool-Mini-Kit (Qiagen). The bacterial 16S ribosomal-RNA reads were analyzed with the QIIME software and pooled in Operational Taxonomic Units (OTUs) with Uclust software.

Grade 2 (G2) CTCAE acute G ltox was the primary endpoint.

For this preliminary evaluation 20 pts were selected: 10 with G0 and 10 with G2 tox. Unsupervised clustering (fuzzy c-means algorithm) was used to separate the pts into 2 MB clusters, based on relative abundance of OTUs at bacterial class level in MB before RT start. Information on MB clustering was introduced as a dose-modifying factor (dmf) into a logit NTCP model (characterized by D50=dose associated to 50% tox probability and steepness parameter k). Mean dose to the rectum was chosen as dosimetric predictor (as already found in the literature).

**Results**

Unsupervised clustering identified 13 pts included in a first MB cluster (A) and 7 in a second cluster (B), average OTU composition for pts in clusters A and B are presented in figure 1.

4/13 (31%) and 6/7 (86%) pts with tox were found in clusters A and B, respectively (p=0.019). MB clustering resulted in AUC=0.75 (95%CI=0.51-0.91) for tox discrimination. NTCP model including only mean rectal dose had D50=49Gy, k=16 (AUC=0.85, 95%CI=0.62-0.97). When clustering was introduced, k=20.5, D50=42Gy for cluster A vs D50=32Gy for cluster B were found: MB clustering dmf (B vs A)=0.76 (AUC=0.87, 95%CI=0.65-0.98), with significant improvement in goodness of fit and calibration. Model curves are reported in figure 2.

Figure 1: average Operational Taxonomic Unit composition at Class level for patient in microbiota clusters A and B

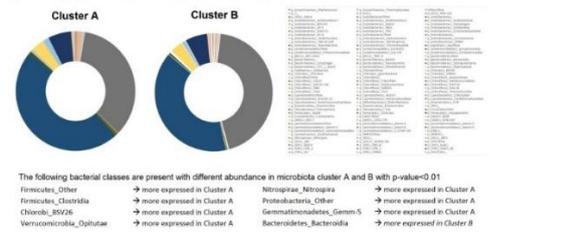

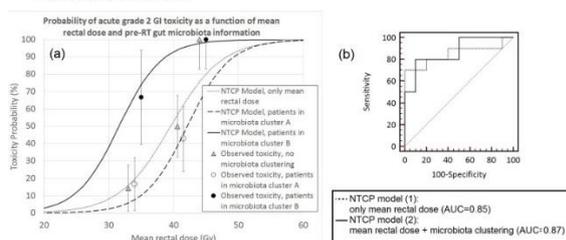

Figure 2. (a) Probability of acute grade 2 gastro-intestinal toxicity as a function of mean rectal dose and gut microbiota clustering. Observed complication rates are also reported (symbols with error bars representing the 68% confidence interval in observed frequencies as calculated from proportions in the study population and based on normal distribution of event). (b) ROC curves for NTCP models with and without inclusion of gut microbiota clustering as dose-modifying factor.

**Conclusion**

This preliminary study demonstrates the possibility of introducing patient-specific MB information into NTCP model, through use of unsupervised clustering to exploit the whole MB information (176 classes) without dramatically increasing the number of features to be included in the model.

Results obtained in a small sample of PCa pts seem promising in indicating that pts with/without radio-induced acute tox have different constitutional gut MB profiles.

Introduction of MB clustering into NTCP highly improves model performance. If confirmed in the whole accrued population, this could represent an important finding, not only for prediction of tox but also for design of possible interventional trials to reduce tox by modification of gut microbiota before RT start.

**Proffered Papers: RTT 6: Education and quality management for optimising patient care**

**OC-0617 Work interruptions in radiotherapy and their impact on patient safety.**

S. Cucchiaro<sup>1</sup>, M. Delgaudine<sup>2</sup>, N. Gourmet<sup>1</sup>, P. Coucke<sup>1</sup>  
<sup>1</sup>C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium ; <sup>2</sup>C.H.U. - Sart Tilman, STA Quality Department, Liège, Belgium

**Purpose or Objective**

Task Interruptions (TI) are common in hospitals and especially in Radiation Therapy (RT) Department. The main objective is to evaluate the number and characteristics of those interruptions in our RT department in order to propose solutions to reduce them to a minimum. There are many TI sources (phone calls, talk, noise,...), often of short duration and most often induced by team members. They affect attention, can generate stress, as well as treatment errors. The idea is to understand the TI, when they occur, where and who produces them and how the work is resumed. The goal is to implement prevention barriers to tasks identified as critical in the process and to allow a safe recovery of the task.

**Material and Methods**

Following an adverse event where an identified root cause was TI, we decided to carry out an exploratory study whose main objective is to be able to identify the sources of TI in the treatment unit as well as the timing of these interruptions. We used an observation grid (figure 1) with several items such as time, duration, nature, reason and consequence of the interruption. The TI were observed at the 5 service treatment units. The collected data has been analyzed in order to confirm that there are TI at the Radiation Therapists (RTTs) during a radiotherapy treatment, and that these TI can be a source of errors.

TI Hour	Step processing	Source of TI	Nature of TI	Reason for TI	Reaction to TI	Task recovery	Impact on activity	Duration of TI
1	Reception of the patient	1) Phone call	1) Professional of the sector	1) Contribution of information	1) Suspends action and treats the 2nd Action	1) Resume at the beginning of the task	1) No apparent consequence	1) Less than 1 min
2	Patient positioning	2) Patient	2) Professional of other sectors	2) Information search	2) Suspends action and delegates the 2nd	2) Resuming at TI	2) Loss of time in the task	2) Between 1 to 5 min
3	Imaging	3) Ambient noise	3) Professional non-service	3) Request for help	3) Continues the action in multitasking mode	3) Recovering from a period after the TI	3) Forgetting a task part	3) Between 5 and 10 min
4	Irradiation	4) Other	4) Patient	4) Request for help	4) Stop interrupting TI	4) Error in the activity	4) Error in the activity	4) Greater than 10 min
5	Check patient chart / administration		5) Ambulance / Volunteer	5) Other	5) Stop interrupting TI	5) No recovery		

Figure 1: Observation Items

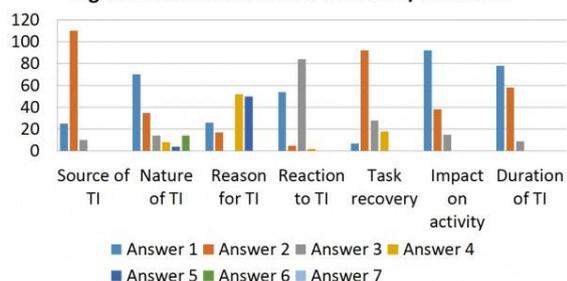

**Results**

A 5-hour observation at each treatment unit was performed for a total of 25 hours. 145 TI have been recorded. We were able to highlight an interruption every

10 minutes on average, that is, one interruption per treatment.

Moreover, these TI are characterized as a physical disturbance, on the part of a health professional, of a duration less than a minute and intervening mainly when the RTT is at the linac console, so during its activity of registration (image matching) and treatment delivery. In terms of impact on activity, we found that the TI lead to a break in the progress of the activity, and when they undergo one or more interruptions in their treatment activity, the RTTs react in different ways depending on the type of interruption. We observed 2 types of reactions: they can either stop their action and process the second, then return to the first task when the second is over or continue their 2 actions simultaneously, so in pure multitasking mode. Results in figures 1 and 2.

Figure 2: Observation results 145 TI / 25 Hours

## Conclusion

There are many TI in a RT department. This study allows us to highlight that TI can be a source of error and that there are a large number of elements on which it would be possible to act to limit risks.

RTT activity is impacted by many TI, attention is diverted, activities are performed in multitasking mode. It is important to limit TI, to optimize the work environment, to set up a formalized task recovery. Multiple solutions are discussed: awareness of RTT to refuse to be interrupted, identify people who should not be interrupted and recover the interrupted task in a safe way. The next step will be to extend the observation of TI to all those involved in the RT workflow.

## OC-0618 Clinical audits as a quality improvement tool in radiotherapy departments: the Belgian experience

A. Vaandering<sup>1</sup>, P. Scalliet<sup>1</sup>, F. Vanhoutte<sup>3</sup>

<sup>1</sup>UCL Cliniques Univ. St. Luc, Academic Department of Radiation Oncology, Brussels, Belgium ; <sup>2</sup>Belgian College for Physicians in Radiation Oncology, Brussels, Belgium ;

<sup>3</sup>Ghent University Hospital, Department of Radiation Oncology, Ghent, Belgium

## Purpose or Objective

The potential benefits of clinical audits are multiple and have the overall aim of encouraging continuous quality improvement through the implementation of corrective actions based on the recommendations emitted by the audits. A national project carried by the Belgian College of Radiotherapy brought about the instauration of systematic clinical audits of all radiotherapy (RT) departments using the IAEA QUATRO (Quality Assurance Team for Radiation Oncology) methodology from 2011 to 2015 included. The impact of these audits was then evaluated and the emitted recommendations were analysed to identify areas of weakness on a national basis.

## Material and Methods

The QUATRO methodology is a peer-review based audit covering all parts of the RT process that gives rise to a report containing a detailed account of the audit including a list of recommendations that the department is encouraged to implement (1). The recommendations extracted from all 25 audit reports were classified using

the coding key proposed by Izweska et al. (2). This taxonomy categorises these into four main divisions: issues pertaining to staffing, infrastructure, process or organisational factors. These are further subdivided into a 3-level categorisation code. Departments were also sent a questionnaire listing their recommendations and in which they were asked to evaluate the overall usefulness of the these as well as the usefulness and the actual impact of each individual recommendation based on an ordinal rating scale (see table 1).

Relevancy scale	Evaluation	The recommendation was not relevant at all to the department's situation/context	The recommendation was little relevant to the department's situation/context	The recommendation was moderately relevant to the department's situation/context	The recommendation was very relevant to the department's situation/context	The recommendation was primordial to the department's situation/context
		Score 0	1	2	3	4
Impact scale	Evaluation	The recommendation had no impact on the department's organisational/infrastructural situation	The recommendation had little impact on the department's organisational/infrastructural situation	The recommendation had a moderate impact on the department's organisational/infrastructural situation	The recommendation had a big impact on the department's organisational/infrastructural situation	The recommendation had a primordial impact on the department's organisational/infrastructural situation
		Score 0	1	2	3	4

Table 1 – Usefulness and impact score of the recommendations

## Results

Of the total of 381 emitted recommendations, 34% concerned process optimization. Twenty-seven percent of the recommendations concerned infrastructure (30% concerned the quality of the facility or the equipment). Finally, 19% and 20% of recommendations concerned organisational and staff issues respectively (e.g. RTT training and professional development). Twenty-three out of the 25 departments responded to the questionnaires. Fifty-four percent of the departments found the recommendations very useful. When scoring the usefulness of the individual recommendations, 42.7% were found to be very relevant with those pertaining to staff and organisation issues scored as being most relevant. When scoring the impact of the individual recommendations, 23.5% were deemed to have an important impact, the majority having a moderate impact (30.6%). Recommendations deemed to have the most impact were those pertaining to process optimisation.

## Conclusion

Revisions of the emitted recommendations have allowed the auditors to identify, on a national basis, common areas of improvement. Similarly, the questionnaires have been able to demonstrate that the recommendations were globally deemed very relevant. However, the global impact of these on the department's organisational/infrastructural situation was scored lower and this in majority due to factors outside of the department's control. Encouraged by this analysis, a second cycle of audits has started in Belgium with a modified QUATRO document (B-QUATRO).

1. International Atomic Energy Agency. *Comprehensive Audits of Radiotherapy Practices: A tool for Quality Improvement*. Vienna : IAEA, 2007.

2. Izweska J, Coffey M, Scalliet P, Zubizarreta E, Santos T, Vouldis I, Dunscombe P. Improving the quality of radiation oncology: 10 year's experience of QUATRO audits in the IAEA Europe region. *Radiation Oncology*. 2017, p. in press.

## OC-0619 Using continuous quality improvement to improve safety and reduce imaging errors in radiotherapy

D. Tan<sup>1</sup>, L. Davies<sup>1</sup>, M. Williams<sup>1</sup>, S. Jones<sup>1</sup>, N. Bales<sup>1</sup>, C. Beswick<sup>1</sup>, P. Wheeler<sup>1</sup>

<sup>1</sup>Velindre Cancer Centre, Radiotherapy, Cardiff, United Kingdom

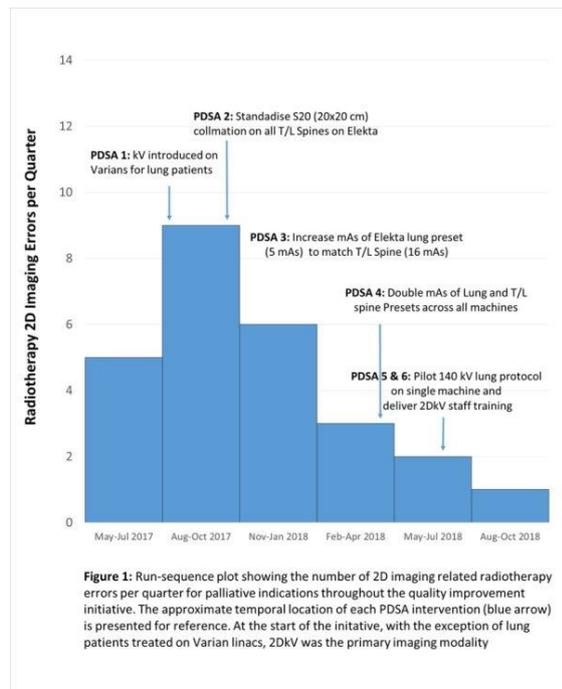

## Purpose or Objective

A quality improvement (QI) project was implemented to facilitate the transition from standard two-dimensional megavoltage (2DMV) electronic portal imaging (EPI) to 2D kilovoltage (kV) imaging for the geometric verification of palliative indications within a radiotherapy (RT) department. Utilising QI methodologies, the aim of this work was to develop an image optimisation programme to ensure suitable image quality (using 2DKV imaging) whilst keeping doses as low as reasonably practicable (ALARP). It

was expected that the embedment of QI processes within the practice would enable both the delivery of accurate and meaningful radiation dose as well as the reduction in the number of imaging related radiotherapy errors (RTE).

#### Material and Methods

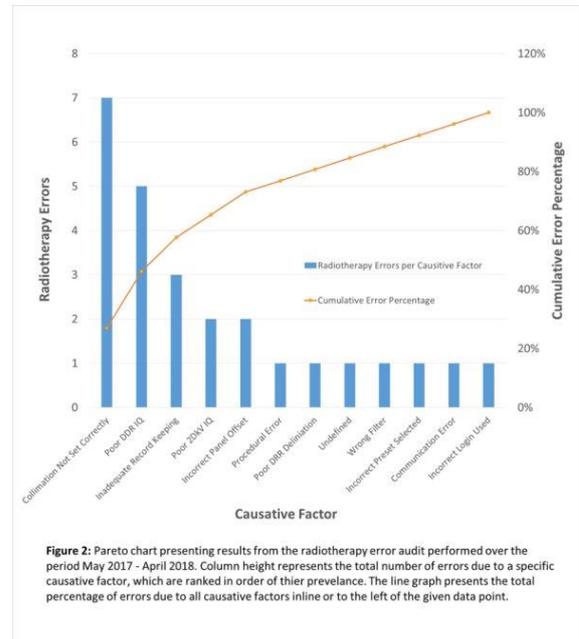

The Institute for Healthcare Improvement's Model for Improvement framework utilising plan, do, study, act (PDSA) cycles was employed to help structure and drive quality within this project. Four project measures were identified to monitor progress against the QI aim: subjective image quality, image dose, RTE and staff feedback. The QI programme was initiated in May 2017 and is still ongoing. During this period an RTE audit, frontline staff survey, subjective image quality audit, and a 'live' staff and RTE feedback was initiated to inform our intervention strategy, which consisted of 6 PDSA cycles (Figure 1). Following each intervention, relevant project measures were monitored to establish efficacy of the intervention.

**Figure 1:** Run-sequence plot showing the number of 2D imaging related radiotherapy errors per quarter for palliative indications throughout the quality improvement initiative. The approximate temporal location of each PDSA intervention (blue arrow) is presented for reference. At the start of the initiative, with the exception of lung patients treated on Varian linacs, 2DkV was the primary imaging modality

#### Results

During the QI period the 'live' feedback from staff and RTE identified collimation and image quality as key areas for improvement, which was consistent with the image quality audit. For the staff survey 31 out of 52 therapeutic radiographers responded, with 80% of respondents being involved in some aspect of 2DkV imaging  $\geq 5$  times per month. There was a good level of confidence in all aspects of 2DkV imaging, however poor digitally reconstructed radiograph (DRR) quality was identified by 35% of staff as a major issue in the image guidance process. Other factors affecting quality related to the imaging workflow, inadequate collimation, and lack of confidence with utilising higher dose protocols. These findings were congruent with the RTE audit results (Figure 2), which also identified inadequate record keeping as a significant contributory factor to RTE. Figure 1 presents a run-sequence plot of RTE per quarter, alongside the timeframe of each PDSA cycle. Across the course of the QI initiative a steady and sustained reduction in RTE was observed, with current quarterly error rates running at one fifth of their pre QI values.

**Figure 2:** Pareto chart presenting results from the radiotherapy error audit performed over the period May 2017 - April 2018. Column height represents the total number of errors due to a specific causative factor, which are ranked in order of their prevalence. The line graph presents the total percentage of errors due to all causative factors inline or to the left of the given data point.

#### Conclusion

The use of a QI model to drive continuous improvement within this setting has been highly successful and has resulted in a clear reduction in imaging related RTE. Utilising the PDSA cycles has highlighted that whilst improvements have been made, a key number of interventions remain and require continual development and monitoring.

#### OC-0620 Stop: No! Take Action: Yes! A new approach to act on anatomical changes seen on CBCT

M. Buijs<sup>1</sup>, F. Pos<sup>1</sup>, M. Frantzen-Steneker<sup>1</sup>, F. Koetsveld<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

#### Purpose or Objective

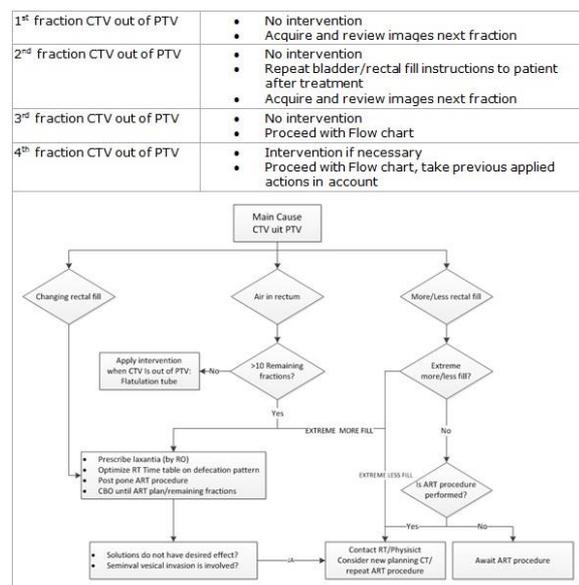

Currently for the most common treatment sites Traffic Light Protocols (TLP) have been developed to recognize and react to anatomical changes seen on CBCT scans. For the RO's as well as the RTT's this method proved to be quite labor-intensive, as it involves alerting the RO, handover of the findings, and finally decision making by the RO. Therefore a new approach was developed to act on anatomical changes: the Take Action Protocol (TAP). In this approach the RTT's do not only have a role in detecting anatomical changes, but are also deciding on the appropriate action and follow up in a standardized way, resulting in a significant shift in responsibility. The aim of this study was to evaluate the implementation of this "Take Action Protocol" and assess its impact on workload, burden of the RTT's responsibility, and the accuracy of the reviewing and decision making.

#### Material and Methods

During a pilot period from Sept 2017 to Febr 2018 the TAP, designed in collaboration with RO's and Medical Physicists, was applied for bladder and prostate patients. The protocol consists of a primary decision to act on the anatomical change seen on the online CBCT. When the anatomical change appears to be systematic, a flow chart guides the decision regarding the follow up of the treatment, see figure 1.

To evaluate the use of the TAP, CBCT images were retrospectively reviewed by an IGRT specialist to assess the accuracy of the reviewing and decision making. Also the impact on the workload was evaluated by scoring the amount of contact moments with an RO. Two surveys were

performed to assess the impact on workload for both RTT's and RO's, the burden of the responsibility for the RTT's and the involvement of the RO's by comparing one for the standard TLP and one for the TAP.

## Results

In 16 out of 22 bladder and 18 out of 56 prostate patients anatomical changes were seen on CBCT, that required a decision of the RTT's (see table 1). For the TAP, in only 2 bladder and 6 prostate patients further decision making of an RO was required (compared to all 34 for the TLP). 99% of the CBCT's were reviewed accurately by the RTT's. In 5 out of 34 patients additional instruction in the decision making by an IGRT specialist was required.

The results of the surveys showed that for both the RTT's and the RO's, the TAP provided a better balance between workload and efficiency in relation to the clinical relevance of acting on anatomical changes. The perceived involvement of the RO's and burden of the responsibility for the RTT's was comparable between the two protocols. Also acting appropriately on clinical relevant anatomical changes, was found to be improved by applying the TAP.

Table 1

	Anatomical changes on CBCT		Online interventions	Flow Chart actions	
	$N_{age}$	$N_e$	$N_e$	RTT	RT/PA
Bladder	16	38	15	6	2
Prostate	18	42	7	8	6

## Conclusion

The Take Action Protocol for anatomical changes provides an accurate method to act on anatomical changes, and gives RTT's more responsibility in the decision making, with an improved balance in efficiency and workload in relation to the clinical relevance of adapting on these anatomical changes.

### OC-0621 Changing responsibilities for RTTs on the MR-linac

A. Betgen<sup>1</sup>, J. Bilderbeek<sup>1</sup>, T. Janssen<sup>1</sup>, J. Kaas<sup>1</sup>, M. Nowee<sup>1</sup>, T. Vijlbrief<sup>1</sup>, L. Wiersema<sup>1</sup>, U. Van der Heide<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

The current set-up of patients for irradiation on a conventional linac consists of positioning the patient, acquiring verification images with cone-beam CT,

registration of the images to the planning CT and correcting the setup with an automatic couch shift. In our department this entire procedure is performed by RTTs. Traffic light protocols guide fast decision making in case of anatomical deviations and prevent the necessity of a physician or physicist. With the clinical introduction of the MR-linac (Unity, Elekta AB), a linear accelerator with an integrated MRI scanner, workflow has changed. At the Unity MR-linac, set-up errors are always corrected by a plan adaptation based on the pre-beam MRI. Therefore, a new radiation plan is computed for each fraction, which has to be evaluated and approved online, which necessitates the presence of a physician and physicist. Our aim is to implement similar traffic light protocols on the MR-linac for decision making by RTTs only, which will alleviate the need for a physician and physicist to be present for all fractions.

### Material and Methods

In the pre-clinical phase, MRI scans were acquired at the MR-linac of patients with different tumor sites after informed consent. Based on a maximum of 5 MRI scans per patient, an MR-linac workflow, which included plan adaptation, was simulated. For anatomical changes we used our existing anatomical traffic light protocol, in which it is indicated when a physicist or physician should be contacted offline. Furthermore, isocenter shifts in LR, AP and CC direction were simulated within Monaco (v5.19.03) to analyze the differences between the reference plan and the adapted plans and to define limits in which the differences would be clinically acceptable. This resulted in a dosimetric traffic light protocol to judge whether the adaptation is better (green), worse but acceptable (orange) or unacceptable (red). 'Orange' plans can be approved by the RTTs, where 'red' plans need to be judged by a physician and/or physicist (an example is presented in table 1). An independent check of the adapted plan was performed for Monitor Units (MU), MU-fluence, largest aperture and area weighted MUs.

### Results

Currently, four prostate cancer patients and one rectum cancer patient started their treatment on the MR-linac, with 60 fractions given. For one patient, the anatomical traffic light protocol resulted in an off-line replanning, which is part of our routine adaptive procedure. In two fractions the dosimetric criteria for the PTV coverage were not met, which resulted in a red traffic light. In these two cases the physician and physicist decided to continue treatment. Limits were only exceeded by 7 and 14 cGy. In one case the independent MU check was not within the boundaries, but also accepted by the physicist.

	anatomic	dosimetric PTV coverage	dosimetric organs at risk	physics	accepted by
fr. 1	green	yellow	green	green	RTT
fr. 2	green	red	green	green	physician/physicist
fr. 3	green	yellow	green	green	RTT
fr. 4	green	yellow	green	green	RTT

Table 1. Example of decision making with traffic light protocols. Fraction 1, 3 and 4 are accepted by RTTs only.

### Conclusion

After a learning period and multidisciplinary discussions, the expectation is that RTTs at the MR-linac can perform online plan adaptation without the presence of a physician or physicist.

### PV-0622 NCTP model for postoperative pulmonary complications after trimodality therapy in esophageal cancer

M. Thomas<sup>1,2</sup>, G. Defraene<sup>1,2</sup>, M. Lambrecht<sup>1,2</sup>, W. Deng<sup>3</sup>, J. Moons<sup>4</sup>, P. Nafteux<sup>4</sup>, S.H. Lin<sup>3</sup>, K. Haustermans<sup>1,2</sup>  
<sup>1</sup>KU Leuven - University of Leuven, Department of Oncology - Laboratory Experimental Radiotherapy, B-3000 Leuven, Belgium ; <sup>2</sup>UZ Leuven - University Hospitals Leuven, Department of Radiation Oncology, B-3000 Leuven, Belgium ; <sup>3</sup>The University of Texas MD Anderson Cancer Center, Department of Radiation Oncology, Houston - Texas, USA ; <sup>4</sup>UZ Leuven - University Hospitals Leuven, Department of Thoracic Surgery, B-3000 Leuven, Belgium

### Purpose or Objective

To develop a normal tissue complication probability (NTCP) model for postoperative pulmonary complications after neoadjuvant chemoradiotherapy (nCRT) followed by surgery in esophageal cancer (EC) patients. The added value of dosimetry to clinical information was verified.

### Material and Methods

We analyzed data from 697 patients with EC treated with nCRT followed by surgery at two major institutions between 2002-2017 (287 patients) and 2007-2017 (410 patients, including 134 patients treated with proton beam therapy (PBT)). A multivariable (forward stepwise built) logistic regression analysis studied the predictive value of clinical and treatment-related variables (gender, age, body mass index, smoking behavior, chronic obstructive pulmonary disease, histology and tumor and nodal stage) and additionally dosimetric variables (absolute and relative lung and heart volumes receiving 5Gy (V5) to 55Gy (V55), mean dose and radiation technique: 3D-CRT (reference category), IMRT, VMAT and PBT) for the presence of a postoperative pulmonary complication, which were extracted from prospectively obtained databases. Model performance was assessed by the Area Under the Curve (AUC) of the receiver operating characteristic curve. Model validation was performed using a nonrandom split-sample (TRIPOD type 2B study) of 90 patients selected based on treatment date (last 30 patients of each institution treated with photons and last 30 patients treated with PBT).

### Results

In total, 221 of 607 patients (36.4%) developed a pulmonary complication. Dosimetric information significantly improved the apparent AUC from 0.67 (95%CI 0.63-0.71) to 0.77 (95%CI 0.73-0.81) (likelihood ratio test  $p < 0.001$ ). In the optimal multivariable logistic regression model (Table 1 and Figure 1), the mean lung dose (OR 1.066), increasing age (OR 1.022), squamous cell carcinoma (OR 2.072) and radiotherapy technique (IMRT: OR 0.326; VMAT: OR 2.372; PBT: OR 0.276) were selected as predictors associated with the development of a pulmonary complication. In the validation set, the NTCP model had an AUC of 0.64, which increased to 0.71 after a refit of the model coefficients.

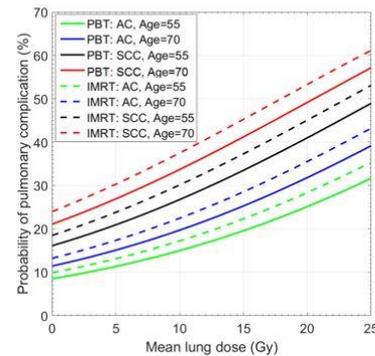

Table 1: Optimal multivariable logistic regression model for postoperative pulmonary complications (221 events).

95%CI = 95% confidence interval; AC = adenocarcinoma; SCC = squamous cell carcinoma; 3D-CRT = 3-dimensional conformal radiation therapy; IMRT = intensity modulated radiation therapy; VMAT = volumetric modulated arc therapy; PBT = proton beam therapy

Pulmonary complications		Odds ratio (95%CI)	p-value
Age (year)		1.022 (1.002-1.042)	0.029
Histology	AC	reference	
	SCC	2.072 (1.319-3.254)	0.002
Mean Lung Dose (Gy)		1.066 (0.999-1.139)	0.054
Radiotherapy technique	3D-CRT	reference	
	IMRT	0.326 (0.194-0.546)	<0.001
	VMAT	2.372 (1.054-5.337)	0.037
	PBT	0.276 (0.122-0.622)	0.002

Figure 1: Graphical representation of the optimal multivariable logistic regression model for patients treated with proton beam therapy and IMRT

PBT = proton beam therapy; IMRT = intensity modulated radiation therapy; AC = adenocarcinoma; SCC = squamous cell carcinoma

### Conclusion

Based on 697 patients with EC treated with nCRT followed by surgery at two major institutions, a useful NTCP model for the development of a postoperative pulmonary complication was obtained. Model validation suggests that updating the model is necessary when applied in a different patient cohort. The radiation technique variable was selected as a predictor independently from the mean lung dose, indicating the need to continuously update and adapt dose-volume models to new treatment conditions. By applying this NTCP model, we can select EC patients at high risk of treatment-induced complications in which we can further investigate the benefit of PBT.

### PV-0623 Tumor-stroma ratio for predicting pathologic response after chemoradiotherapy in esophageal cancer

I. Lips<sup>1</sup>, G.W. Van Pelt<sup>2</sup>, F.P. Peters<sup>1</sup>, J.A. Krol<sup>1</sup>, D. Van Klaveren<sup>3</sup>, J.J. Boonstra<sup>4</sup>, W.O. De Steur<sup>2</sup>, A. Farina Sarasqueta<sup>5</sup>, W.E. Mesker<sup>2</sup>, M. Slingerland<sup>6</sup>

<sup>1</sup>Leiden University Medical Center LUMC, Radiation Oncology Department, Leiden, The Netherlands ; <sup>2</sup>Leiden University Medical Center LUMC, Department of Surgery, Leiden, The Netherlands ; <sup>3</sup>Leiden University Medical Center LUMC, Medical Statistics, Leiden, The Netherlands ; <sup>4</sup>Leiden University Medical Center LUMC, Gastroenterology and Hepatology, Leiden, The Netherlands ; <sup>5</sup>Leiden University Medical Center LUMC, Pathology, Leiden, The Netherlands ; <sup>6</sup>Leiden University Medical Center LUMC, Medical Oncology, Leiden, The Netherlands

### Purpose or Objective

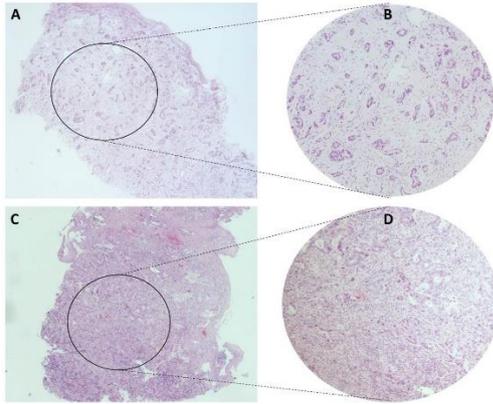

Standard treatment for patients with resectable esophageal cancer (EC) is neoadjuvant chemoradiotherapy (nCRT) followed by surgery. Treatment with nCRT leads to a pathologic complete response (pCR) in approximately 30% of patients. Surgery might be safely omitted in this selected group of patients, however with the current available options, predicting pCR after nCRT is insufficient.

The tumor micro-environment, including the supportive stromal component, plays a crucial role in the progression and spread of cancers. The amount of stroma in direct relation to the tumor has been proven to be a prognostic factor for survival in breast cancer, colon cancer and EC. For esophageal adenocarcinoma (EAC) scoring tumor-stroma ratio (TSR) in biopsy specimens was proven to be representative, reproducible and easy. In addition, in patients with EAC TSR was proven to correlate with response to neoadjuvant chemotherapy. The main focus of this study was to investigate the value of TSR in the prediction of pathologic response (PR) after nCRT in EC.

### Material and Methods

Patients with adenocarcinoma or squamous cell carcinoma of the esophagus who received nCRT followed by a resection between May 2010 and Sept 2015 were evaluated. Haematoxylin and eosin stained sections of pre-treatment biopsies were collected and TSR was independently assessed by two investigators. Patients were categorized in stroma-low ( $\leq 50\%$  stroma) and stroma-high ( $> 50\%$  stroma) groups for further analyses (Figure 1). The tumor regression grade (TRG) of the primary tumor was assessed to determine favorable (TRG 1-2) and non-favorable (TRG 3-5) PR. Univariate and multivariate logistic regression analyses were performed to investigate the relationship between TSR and PR.

Figure 1. Haematoxylin and eosin stained biopsy sections of EC. (A) Tumor with large spots of stromal tissue (stroma-high). Magnification (B) shows evident stromal proliferation between tumor cells. (C) Tumor with low stromal proliferation (stroma-low). As shown by the magnification (D) there is almost no stroma between the tumor cells.

## Results

A total of 94 patients were included in this study; 76 tumors were categorized as stroma-low and 18 as stroma-high. Median age was 64 years (range 25-82), 76% were men, 80% of the tumors were adenocarcinoma, most patients (77%) had cT3 stage and differentiation grade was well in 12%, moderate in 35% and poor in 53%.

A pCR (TRG 1) was found in 28 patients; 14 patients showed a near pCR (TRG 2). Non-favorable PR was seen in 31 (TRG 3), 19 (TRG 4) and 2 patients (TRG 5), respectively.

In univariate analysis patients with a stroma-low tumor had an approximately three-and-a-half times higher likelihood of a favorable response (TRG 1-2) on nCRT compared to patients with a stroma-high tumor (OR 3.50, 95%CI 1.06- 11.61,  $p = 0.04$ ). After adjustment for known predictive factors (gender, histology, cT-status and differentiation grade) a stroma-low tumor proved to be an independent predictive factor for a favorable PR (TRG 1-2) (OR 3.64, 95%CI 1.05-12.68,  $p = 0.04$ ).

**Conclusion**  
Tumor-stroma ratio was found to be a predictor of pathologic response in esophageal cancer patients receiving neoadjuvant chemoradiotherapy. Larger validation studies are needed to verify these results.

**PV-0624 pathologic response in pancreatic cancer treated with neoadjuvant MRI-guided radiation therapy**  
S. Rudra<sup>1</sup>, R. Brenneman<sup>1</sup>, S. Badiyan<sup>1</sup>, A. Wang-Gillam<sup>1</sup>, W. Hawkins<sup>1</sup>, R. Fields<sup>1</sup>, S. Strasberg<sup>1</sup>, M. Roach<sup>1</sup>, H. Kim<sup>1</sup>  
<sup>1</sup>Washington University in St. Louis, Radiation Oncology, Saint Louis, USA

## Purpose or Objective

The objective was to report the outcomes of patients diagnosed with initially unresectable pancreatic cancer who receive MR-guided adaptive radiation therapy (MRgRT) and chemotherapy then subsequently received surgical resection.

## Material and Methods

We retrospectively reviewed our institutional pancreatic cancer treatments to identify patients who received MRgRT and then subsequently underwent surgery. Patients were treated with dose-escalated RT regimens of either 50 Gy in 5 fractions (BED=100) or 67.5 Gy in 15 fractions (BED=97.9). Pathology reports from patients who received surgery were reviewed to identify response to neoadjuvant therapy. Grade 3 or higher abdominal toxicities were recorded. Overall survival (OS) was calculated using Kaplan-Meier analysis from date of starting RT.

## Results

A total of 88 patients (48 locally advanced pancreatic cancer patients, 21 borderline resectable pancreatic cancer patients, and 19 medically inoperable patients) received MRI-guided RT for unresectable pancreatic cancer from 2015 to 2018. Of this cohort, 17 patients (19%) received surgical resection after neoadjuvant therapy [8 (17%) patients with locally advanced pancreatic cancer and 9 (43%) patients with borderline resectable pancreatic cancer]. Median follow up after RT for this subgroup was 12 months. Median time from RT to surgery was 3 months. Pathologic response was found to be complete response in 3 patients (18%), partial response in 13 patients (76%) and progressive disease in 1 patient (6%). No acute toxicities were noted. Late grade 3+ abdominal toxicities were noted as follows: 2 patients with gastrointestinal bleeding due to ulcers at anastomotic sites, 1 patient developed cholangitis after surgery requiring hospitalization, and 1 patient developed a pseudoaneurysm of the celiac artery. The patient with progressive disease on the surgical specimen survived for 11 months after RT. The 2-year OS rate for the entire resected cohort was 60%.

## Conclusion

Neoadjuvant chemoradiation using adaptive MRgRT and dose-escalation generally resulted in at least partial response and in a few cases, complete pathologic response of the original unresectable pancreatic tumor. Prospective clinical trials evaluating adaptive MRgRT with dose escalation in borderline resectable and locally advanced pancreas cancer are in progress.

## PV-0625 Biological factors influencing outcomes in SBRT for colorectal cancer oligometastases (OM)

S. O' Cathail<sup>1</sup>, T. Smith<sup>2</sup>, R. Owens<sup>3</sup>, Y. Tsang<sup>4</sup>, M. Harrison<sup>2</sup>, M. Hawkins<sup>1</sup>

<sup>1</sup>CRUK/MRC Institute for Radiation Oncology University of Oxford, Oncology, Oxford, United Kingdom ; <sup>2</sup>Mount Vernon Cancer Centre, Oncology, London, United Kingdom; <sup>3</sup>Oxford University NHS Foundation Trust, Oncology, Oxford, United Kingdom ; <sup>4</sup>Mount Vernon Cancer Centre, Radiotherapy, London, United Kingdom

## Purpose or Objective

Stereotactic ablative body radiotherapy (SBRT) is offered to patients who have oligometastatic (OM) disease and are not suitable for surgical or other ablative treatments. OM Colorectal (CRC) cancer has been identified as potentially having worse outcomes compared to other histology types. We hypothesise that tumour biology impacts outcome in OM CRC.

## Material and Methods

A multi institution of prospective OM CRC patients treated with SBRT. Patients had  $< 3$  metastases, in  $< 2$  organs on multimodality imaging and exhausted local treatments options. PS 0-1. SBRT was delivered in 3-8 fractions depending on location.  $\alpha/\beta = 10$  was used to estimate biological effective dose. Location of primary and KRAS status was recorded. Progression was defined by imaging criteria as local (within field), locoregional (same organ but outside RT field) or distant. Univariate analysis was performed with log rank tests of Kaplan Meier curves and cox proportional hazard models. Significant variables on univariate testing were entered into a multivariate cox proportional hazard model.

## Results

Between 05/13 -05/18 132 CRC OM cases were treated and 95 patients had complete data for analysis. 70 (74%) metachronous OM. The median age was 67 years (range 36-89). 51 (54%) patients were male. Primary site of disease was rectum in 53 (56%), left colon in 22 (23%) and right colon in 15 (16%). OM sites treated: 27 liver, 56 lymph nodes (LN), 9 lung and 3 other. Median BED<sub>10</sub> was 79.2 Gy (range 37.5 - 151.2). Median FU was 13.7 mo (IQR 4.6 - 25.3). In-field local control at 1 year was 85.5% (95% C.I 76% - 96.2%). Median PFS for the cohort was 10.7 mo (95% C.I 8.1 - 15.2). The median PFS for the liver, lung and LN metastases were 6, 13 and 19 mo respectively. There was a significant difference in PFS based on metastasis location, with lymph node disease being associated with improved PFS (HR 0.34, 95% C.I 0.19 - 0.626, p = 0.0004; overall log rank, p = 0.0019). Lung was borderline. KRAS status was available for 47 patients (50%), 34 wild type and 13 mutant. WT KRAS status was associated with improved PFS (HR 0.44, 95% C.I 0.19 - 0.97, p = 0.04). No significant difference in PFS was seen when comparing groups by primary site, colon side, age, gender or whether presentation was with synchronous or metastatic disease. On MVA, metastasis location of lung and lymph node and KRAS WT or unknown status, remain statistically significant predictors of improved PFS.

## Conclusion

In this cohort lymph node metastases appear to be associated with improved PFS compared to lung, bone or liver sites independent of KRAS status. KRAS WT is a good prognostic factor for PFS in treatment with SABR. These findings could be used to further refine the selection of CRC OM for treatment with SABR and incorporating systemic treatment. The excellent local control, regardless of KRAS subtype, suggests that OM PFS is driven by locoregional or widespread failure highlighting need for exploring biological differences.

## PV-0626 Mismatch Repair System Deficiency increases response to neoadjuvant chemoradiation in rectal cancer

N. Meillon<sup>1</sup>, D. Vernerey<sup>2</sup>, J.H. Lefèvre<sup>3</sup>, G. Manceau<sup>4</sup>, M. Svrcek<sup>5</sup>, J. Augustin<sup>6</sup>, J. Fléjou<sup>3</sup>, O. Lascols<sup>7</sup>, J. ## Purpose or Objective

Defective mismatch repair system (MMR) has been shown to have a favorable impact on outcome in colorectal cancer patients treated with surgery or immunotherapy, adjuvant chemotherapy being discouraged unless there is nodal involvement. Its impact on radiosensitivity is unknown in rectal cancer patients.

## Material and Methods

Patients treated for locally advanced rectal cancer between 2000 and 2016 were studied. MMR status was studied on the histological sample through PCR and immunohistochemistry. Reported points included age, sex, clinical and radiological tumor stages at diagnosis, modalities of neoadjuvant treatment, post-treatment

pathological staging, tumor regression score, and local, distant relapse-free, and overall survivals. An inverse probability of treatment weighting (IPTW) analysis was performed to evaluate the association of MMR proficiency on surgical and clinical outcomes. The primary endpoint was downstaging defined as a lower T and/or N after than before neoadjuvant treatment.

## Results

Among the 307 patients included, 21 (6.8%) had defective MMR (dMMR). Median follow-up was 36.7 months (95%CI: 34,7-39,7). dMMR patients were significantly younger than proficient MMR patients (pMMR) (60.4 y.o. (52.8-69.8) vs 45.4 y.o. (41.8-56.2), p<.0001) and trended towards a higher N stage (N1 patients: 14 (87.5%) for dMMR vs. 178 (64.0%) for pMMR, p=0.055).

In an unmatched analysis, dMMR patients had a higher pathological downstaging rate (17 (85.0%) vs. 137 (52.7%), p=0.005) and had a lower rate of recurrence (10.0% vs. 30.5%, p=0.12).

After IPTW matching, dMMR patients had a higher pathological downstaging rate (OR=5.77, 3.24-10.26, p<0.0001) and a longer recurrence-free survival (OR=0.29 (0.16-0.54), p<0.0001), although local recurrence free survival and overall survival did not differ significantly (HR=1.038 (0.475-2.27), p=0.925 and HR=0.65 (0.34-1.22), p=0.176 respectively).

Table. Survival endpoints IPTW analysis

	Hazard Ratio	95%CI	p-value
Overall survival	0.65	0.34-1.22	0.176
Recurrence free survival	0.34	0.19-0.60	0.0002
Disease free survival	0.30	0.17-0.53	<.0001

	Odds Ratio	95%CI	p-value
Downstaging	5.77	3.24-10.26	<.0001
Resection status	1.45	0.70-3.00	0.318
Recurrence	0.29	0.16-0.54	<.0001
Local recurrence	1.03	0.48-2.27	0.925
Metastatic recurrence	0.30	0.16-0.58	0.0003
Death	0.68	0.35-1.33	0.261

Abbreviation: CI, confidence interval.

## Conclusion

MMR deficiency was associated with tumor downstaging after neoadjuvant chemoradiation as well with increase recurrence-free survival. dMMR patients could be good candidates for rectal preservation strategy.

## PV-0627 IL17F-rs641701 polymorphism as prognostic factor in rectal cancer after preoperative chemoradiation

### Purpose or Objective

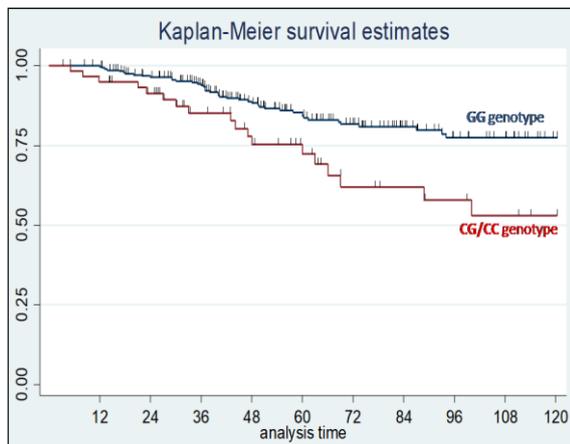

Patients (pts) with locally advanced rectal cancer (LARC) exhibit heterogeneous responses to Preoperative Chemoradiotherapy (preopCRT) and prognosis. Risk stratification based on clinical and biologic factors is an area of active investigation in order to personalize treatment. Immunogenetics, the study of polymorphisms (SNPs) in genes involved in immune system activity, could detect biomarkers virtually involved in tumor response to treatment and in prognosis. The aim of this study was to identify immunogenetic biomarkers of early recurrence and long term survival in LARC pts treated with preopCRT and radical surgery.

### Material and Methods

From December '93 to November '15, LARC pts undergoing preopCRT and surgery were consecutively enrolled at the National Cancer Institute-IRCCS Aviano and IOV-IRCCS Clinica Chirurgica I of Padova University. According to study purposes, pts were split in a training set and in a replication set. Firstly, 147 SNPs in 34 immune-related genes were analyzed in germline DNA samples of the training set. The potential association between these SNPs and the 2yrDFS was analyzed with logistic regression model. Significant SNPs arisen in the training set ( $p < 0.05$  after bootstrap analysis) were analyzed in the replication set with logistic regression. Secondly, replicated variants ( $p < 0.10$ ) were tested in the entire population in terms of 5yrMFS, 5yrDFS, and 10yrOS by multivariate Cox regression.

### Results

Clinical and pathological parameters of the 371 LARC pts were well balanced between the discovery ( $n=234$ ) and the replication set ( $n=137$ ). Three prognostic biomarkers were significantly associated with the 2yrDFS in the training set (*IL17F*-rs641701, *IL17F*-rs9463772, and *STAT3*-rs8069645:  $p=0.010$ ,  $p=0.020$ , and  $p=0.048$ , respectively), but only *IL17F*-rs641701 was significant in the replication set ( $p=0.099$ ). In the merged population of pts, this SNP was still significantly associated to both 5yrDFS (HR (95%CI)=1.84 (1.01-3.25),  $p=0.035$ ), and 5yrMFS (HR (95%CI)=2.11 (1.11-4.01),  $p=0.023$ ). *IL17F*-rs641701 was also significantly associated with 10yrOS (HR (95%CI)=2.66 (1.51-4.70),  $p=0.001$ ) (Fig.1), highlighting its pivotal prognostic role. To note *IL17F*-rs641701 effect on prognosis is independent from Tumor Regression Grade (TRG), as a matter of fact, when stratifying pts according to different TRG, *IL17F*-rs641701 marker identified subgroups of pts with significantly different prognosis within the same TRG group.

### Conclusion

The role of host immune system in the tumor control and its interaction with commonly used chemo-radio treatment is challenging. In this scenario, the assessment of *IL17F*-rs641701 as new potential prognostic biomarker in LARC pts could represent a link between immunity and disease control after preopCRT. Its independency from the already acknowledged prognostic factors as TRG, should encourage its use in the clinical practice to improve pts stratification according to the risk of disease progression to better tailor therapeutic approaches in LARC.

### PV-0628 Association of androgen deprivation duration and cardiovascular mortality in prostate cancer men

A. Yorozu<sup>1</sup>, S. Sutani<sup>1</sup>, K. Toya<sup>1</sup>, Y. Shiraishi<sup>1</sup>, S. Saito<sup>2</sup>

<sup>1</sup>Tokyo Medical Centre- NHO, Department of Radiation Oncology, Tokyo, Japan; <sup>2</sup>Tokyo Medical Centre- NHO, Department of Urology, Tokyo, Japan

### Purpose or Objective

To investigate whether duration of androgen deprivation therapy (ADT) is associated with an increased risk of cardiovascular mortality (CVM) in men treated with brachytherapy and/or external beam radiotherapy (EBRT) for intermediate and high-risk prostate cancer.

### Material and Methods

This is a retrospective analysis of prospectively collected data from men treated between 2003 and 2012 at one institution. Data on 1,628 patients treated for intermediate ( $n=1,234$ ) or high-risk ( $n=394$ ) prostate cancer with iodine-125 brachytherapy ( $n=486$ ), EBRT ( $n=196$ ), and a combination of brachytherapy and EBRT ( $n=946$ ) were included. In total, 1,005 patients (61.7%) received neoadjuvant ADT, concurrent with or in the absence of adjuvant ADT. Patients were divided into two groups according to the total duration of ADT: a short course group ( $n=803$ ) received  $\leq 12$  months (median duration: 6 months), and a long course group ( $n=202$ ) received  $>12$  months (median duration: 24 months) of ADT. The primary endpoint of this study was a CVM, which was defined as a death from myocardial infarction, sudden cardiac arrest, coronary artery disease, cardiac ischemia, malignant arrhythmia, or cerebrovascular stroke. Statistical analysis was conducted using a Kaplan-Meier estimator, a Cox regression model, and a competing risk model.

### Results

After a median follow-up time of 7.6 years (interquartile range: 5.6-10.2 years), overall survival was 92.1% at 7 years. In total, 194 men died; there were 53 cardiovascular deaths, 41 prostate cancer deaths, 67 other malignancy deaths, 31 other benign disease deaths, and two deaths due to unknown causes. The 7-year CVM rate was 1.2% in the non-ADT group, 2.1% in the short course ADT group, and 5.3% in the long course ADT group ( $p < 0.001$ ). In terms of baseline patient characteristics, long course ADT was significantly associated with elderly patients, EBRT treatment, high-risk group, and total androgen blockade. Univariate analysis revealed that older age, baseline cardiovascular disease, baseline diabetes, and long course ADT were significantly associated with increased CVM. Competing risk analysis revealed that duration of ADT was significantly associated with CVM, as well as age, baseline cardiovascular disease, and baseline diabetes. The 7-year overall survival rate was 94.3% in the non-ADT group, 92.1% in the short course ADT group, and 84.9% in the long course ADT group ( $p=0.008$ ). The Cox regression model revealed age and risk group as significant factors associated with overall survival; the duration of ADT was not significantly associated with overall survival.

### Conclusion

Long course ADT is associated with an increased risk of CVM in patients undergoing brachytherapy and/or EBRT for intermediate and high-risk prostate cancer. Age, baseline comorbidities, and duration of combined ADT

should all be considered to minimize the risk of CVM, when treatment options of brachytherapy and/or EBRT are discussed according to risk groups.

#### PV-0629 Late toxicity and PROMs in pelvic or prostate RT in high risk prostate cancer: A randomized trial.

#### Purpose or Objective

The benefit of whole pelvis radiotherapy in node negative, high-risk prostate cancer is uncertain. While oncological outcomes of whole pelvis (WPRT) and prostate only (PORT) radiotherapy are awaited from ongoing trials, we present the toxicities and patient reported outcomes measures (PROMs) from a randomized controlled trial.

#### Material and Methods

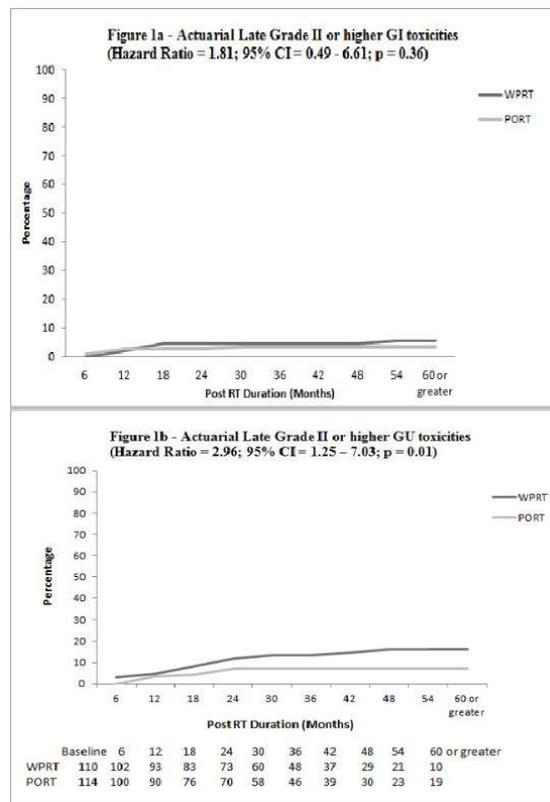

This single institution randomized controlled trial was conducted in node negative, high-risk adenocarcinoma prostate with an estimated nodal risk (Roach) of over 20%. Patients were randomized using stratified block randomization based on history of TURP (yes vs no), Gleason score (6-7 vs 8-10) and PSA levels (<50 vs >50). All patients received at least 2 years of androgen deprivation therapy and hypofractionated, daily image guided, intensity modulated radiotherapy to a dose of 68Gy in 25 fractions to prostate (2.72Gy/#) with 50Gy in 25 fractions to the pelvic nodes including the common iliac region in WPRT arm using simultaneous integrated boost. Late gastrointestinal (GI) and genitourinary (GU) toxicities (RTOG scale), PROMs (EORTC QLQ C-30 and PR 25) were documented at pre-treatment and every 3-6 months post treatment.

#### Results

A total of 224 patients were randomized to WPRT (n=110) and PORT (n=114) arms. Both the arms were well balanced for patient and disease characteristics. Median follow up was 37 months. Both the treatment arms were well tolerated with less than 3% actuarial grade III GI and GU toxicities and no grade IV toxicities (Table 1). Actuarial grade II or higher late GI toxicities were similar in both arms (Hazard Ratio = 1.81; 95% CI = 0.49 -6.61; p = 0.36), whereas late GU toxicities (grade II or higher) were significantly worse in WPRT arm (Hazard Ratio = 2.96; 95% CI = 1.25 - 7.03; p = 0.01) (Table 1; Figure 1a and 1b). A total of 217 patients (WPRT = 112; PORT = 105) completed 1068 questionnaires, with a median assessment time of 11 months (Range = 2 - 73 months). Each patient completed a mean of 5 assessments. Mean scores for global, bowel, urinary symptoms or any other domain were clinically or statistically no different between the two arms.

Table 1 - Actuarial Late Toxicities

	GI	- GI	- GI	- p	GU	- GU	- GU	- p
Overall - n	WPRT - n	PORT - n	WPRT - n	PORT - n	WPRT - n	PORT - n	WPRT - n	PORT - n
	224 (%)	110 (%)	114 (%)	value	224 (%)	110 (%)	114 (%)	value
I	52 (23.3)	28 (26.7)	24 (23.1)	0.92	86 (38.6)	39 (37.1)	47 (45.2)	0.02
II	9 (4)	5 (4.8)	4 (3.8)		22 (9.9)	16 (15.2)	6 (5.8)	
III	1 (0.4)	1 (1)	0 (0)		5 (2.2)	3 (2.9)	2 (1.9)	

#### Conclusion

This is the first randomized trial addressing the question of pelvic RT in patients with high risk, node negative prostate cancer using modern image guided radiotherapy and moderate hypofractionation. At a median follow up of 3 years, there were low grade III toxicities in both arms. Grade II GU toxicity was higher with WPRT while the GI toxicities and the PROMs were similar in the two arms.

#### OC-0631 Stem cell sparing IMRT for head and neck cancer patients: a double-blind randomized controlled trial

R. Steenbakkers<sup>1</sup>, M. Stokman<sup>1</sup>, R. Kierkels<sup>1</sup>, M. Schuurman<sup>1</sup>, A. Van den Hoek<sup>1</sup>, H. Bijl<sup>1</sup>, M. Dieters<sup>1</sup>, R. Coppes<sup>2</sup>, J. Langendijk<sup>1</sup>, P. Van Luijk<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>UMCG University Medical Center Groningen, Radiation Oncology - Cell Biology, Groningen, The Netherlands

#### Purpose or Objective

Head and neck cancer patients treated with radiotherapy often suffer from xerostomia. Critical for the radiation response of the parotid glands are the parotid gland stem cells, mainly located in the main salivary gland ducts (van Luijk, 2015). Reducing dose to these High Stem Cell Density (HSCD) regions may prevent xerostomia. This double-blind randomized controlled trial (RCT) aimed to determine the impact of dose reduction to the HSCD regions on parotid gland stimulated salivary flow

(FLOW12M) and patient-rated xerostomia 12 months (XER12M) after treatment.

#### Material and Methods

Patients with HNC treated with definitive bilateral radiotherapy (70 Gy in 35 fractions) with or without systemic treatment were eligible for the study. Target volumes and organs at risk (OARs) were delineated according to international guidelines. The parotid gland HSCD regions were contoured using in-house made software. Next, for every patient a standard parotid gland sparing IMRT plan (ST-IMRT) was generated. Second, a HSCD region sparing IMRT (HSCD-IMRT) plan was generated by reducing dose at the HSCD region as much as possible while keeping the whole mean parotid gland dose the same (Figure 1). Finally, patients were randomized between ST-IMRT (arm 1) and HSCD-IMRT (arm 2). Primary and secondary end-points were FLOW12M and XER12M, respectively.

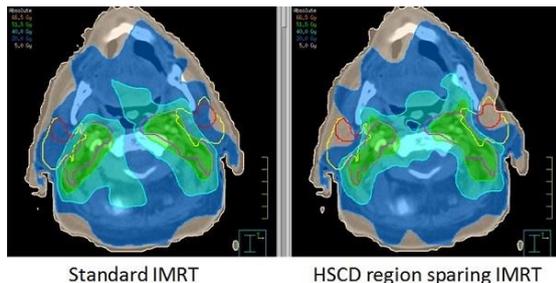

Figure 1. Dose distributions depicted on a CT of a patient with cT3N0 laryngeal cancer using standard IMRT and HSCD region sparing IMRT. The yellow lines are the parotid glands and the red lines are the HSCD regions. With standard IMRT the mean HSCD region dose is 15.8 Gy (right) and 20.6 Gy (left) and with HSCD region sparing IMRT this is 7.4 Gy (right) and 10.8 Gy (left).

#### Results

The study population was composed of 102 patients. 54 were assigned to receive ST-IMRT (arm 1) and 48 HSCD-IMRT (arm 2). The mean parotid gland dose was similar in both arms (contralateral: 24.2 and 23.8 Gy ( $p = 0.801$ ) for arm 1 and 2, and ipsilateral: 31.7 and 30.8 Gy ( $p = 0.659$ ), respectively). HSCD region sparing significantly reduced the dose to the HSCD region (contralateral: 16.4 to 12.6 Gy ( $p = 0.007$ ) for arm 1 and arm 2, respectively, and ipsilateral: 25.0 to 17.4 Gy ( $p = 0.005$ ), respectively). Baseline xerostomia and other OARs (oral cavity and submandibular glands) dose were similar in both arms. Compared to baseline, FLOW12M was reduced with 16.8% and 8.5% ( $p = 0.621$ ) for arm 1 and arm 2, respectively and XER12M was 50.0% and 45.9% ( $p = 0.720$ ), respectively. Multivariate analysis showed that the mean ipsilateral HSCD region dose and baseline xerostomia (none vs. any) were the most important predictors for XER12M. Subset analysis on patients without baseline xerostomia ( $n = 57$ ) showed that the rate of XER12M was markedly lower, i.e. 40.0% v. 23.8% ( $p = 0.253$ ) in arm 1 and arm 2, respectively. Furthermore, in this subgroup the only significant different dose parameter between patients with or without XER12M was ipsilateral HSCD region dose (28.9 v. 19.1 Gy,  $p = 0.007$ ).

#### Conclusion

In this double-blind RCT, stem cell sparing IMRT did not significantly improve salivary flow or reduce xerostomia 12 months after radiotherapy. However, the ipsilateral HSCD region dose was the most important dosimetric predictor for xerostomia, suggesting that dose to the HSCD region is more important for the development of xerostomia than dose to the entire parotid gland.

#### OC-0632 Radiotherapy-related lymphopenia affects overall survival in patients with lung cancer

A. Abravan<sup>1</sup>, C. Faivre-Finn<sup>1</sup>, J. Kennedy<sup>2</sup>, A. McWilliam<sup>1</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>The University of Manchester\ The Christie NHS Foundation Trust, Division of Cancer Sciences\ Radiotherapy Related Research, Manchester, United Kingdom; <sup>2</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom

#### Purpose or Objective

Lymphopenia during radiotherapy (RT) has an adverse effect on patient's quality of life and can be life threatening. However, the relationship between RT dose and lymphopenia is still unknown. This work utilized data mining to identify anatomical regions where the received dose is correlated with lymphopenia. A predictive model of lymphopenia is also proposed.

#### Material and Methods

562 lung cancer patients treated with curative intent RT were used as a development set. All patients had baseline lymphocytes  $\geq 0.5 \times 10^9/L$ . A Cox model was used to assess prognostic factors of overall survival. Next, two matched groups were defined - patients with and without lymphopenia  $\geq G3$  (lymphocytes at nadir  $< 0.5 \times 10^9/L$  according to CTCAE v4.0) - based on planning target volume (PTV), baseline lymphocytes, prescribed dose, and histology. The purpose of matching was to eliminate tumor effects and improve data mining sensitivity. Following matching, 386 patients remained and image-based data mining was used to identify regions where dose correlates significantly with lymphopenia  $\geq G3$ . For that purpose, dose matrices (equivalent dose at 2 Gy/fraction,  $\alpha/\beta=10$ ) were aligned using registration of the planning CT images to one reference patient. Then, mean dose distributions were obtained for the two groups and organs of significance were detected. For these organs, various dose parameters were collected and those having the highest correlation with lymphocytes at nadir were selected for analysis. Multivariate analyses were conducted for the full development set by employing the identified dose parameters, along with non-dosimetric parameters significant in univariate analysis ( $p < 0.05$ ). Finally, the model was validated on 301 esophageal cancer patients.

#### Results

Cox regression showed that lymphopenia  $\geq G3$  in addition to age, PTV, performance status, and RT duration was an independent factor predicting overall survival in lung cancer (Figure 1). The heart, lung, and thoracic vertebrae showed regions where the difference in dose between the matched groups, with and without lymphopenia  $\geq G3$ , was significant. Mean dose to the heart and lung, and  $V_{20}$  of the thoracic vertebrae (volume receiving  $>20$  Gy) correlated most with lymphocyte counts at nadir in the matched set. A model including RT duration, baseline lymphocytes, vertebrae  $V_{20}$ , and mean heart dose was then chosen following backward elimination (Table 1). The Hosmer-Lemeshow test, based on deciles of risk, indicated that the model was a good fit. Accuracy and C-statistics of the model in the development set was 75% and 0.82 and in the validation set was 75% and 0.76, respectively.

Figure 1. Gross (left) to right Kaplan-Meier curves show overall survival, stratified by lymphopenia G3 in the matched and development lung cancer set.

### Conclusion

Lymphopenia  $\geq$  G3 during RT is a significant risk factor for survival in lung cancer patients and careful management is thus required e.g. by minimizing vertebrae  $V_{20}$  and mean heart dose in order to limit irradiation of stem cells and blood pool. If dose constraints cannot be met, more frequent monitoring of lymphocyte counts during therapy and use of prophylactic antibiotics are recommended.

### OC-0633 Single dose high dose-rate (HDR) brachytherapy as monotherapy for localised prostate cancer

<sup>1</sup>National Radiotherapy Trials Quality Assurance RTTQA, Mount Vernon Cancer Centre, London, United Kingdom; <sup>2</sup>The Institute of Cancer Research, 15 Cotswold Road, Sutton- SM2 5NG, United Kingdom; <sup>3</sup>Laboratory of Radiation Physics, Odense University Hospital, Odense,

Denmark ; <sup>4</sup>The Royal Marsden, The Royal Marsden, Downs Road- Sutton, United Kingdom

### Purpose or Objective

RAIDER (CRUK/14/016) is the first international multicentre trial of tumour focused radical bladder radiotherapy delivered with plan of the day (PoD). A quality assurance (QA) programme, led in the UK by the National Radiotherapy Trials Quality Assurance (RTTQA) Group, was implemented to support participating centres. The pre-trial questionnaire identified only a third (11/33) UK centres had prior PoD experience. Therefore the QA programme initially included pre-trial education and assessment for Therapeutic Radiographers (RTTs) and on-trial retrospective feedback. Here we report initial findings on guideline compliance with respect to agreement of RTT led online plan selection with the offline plan selection of RTTQA reviewers. The strategy adopted to sustain compliance is outlined.

### Material and Methods

RAIDER is a two-stage phase II clinical trial randomising bladder cancer patients undergoing 20 fraction (f) or 32f radiotherapy to standard planning versus tumour focused PoD. Plan selections (small, medium, large) for 36 patients treated with PoD in Stage 1 (technical feasibility) were reviewed remotely offline by a single blinded observer from RTTQA. Plan selections were categorised, as per guidelines, using a traffic light approach:

Green = Acceptable

Amber = Acceptable variation

Red = Unacceptable variation

Green and amber cases were defined as guideline compliant.

The proportion of compliant plans was compared between groups by chi-squared tests.

Deviations from guidelines were assessed and plan selection guidance reviewed. Following updated guidance, online plan selections have so far been assessed for 17 Stage 2 patients.

### Results

439 CBCTs were reviewed from 19 centres. 318/439 (72%) plan selections by RTTs were guideline compliant. In the non-guideline compliant cases, the plan selections by RTTQA were smaller (87%), and larger (3%) and in 10% of cases the action taken would have been different e.g. remove the patient from treatment couch. 13% (n=16) of the non-compliant cases were deemed to require real-time active intervention by RTTQA. Compliance was greater in the 32f cohort, in centres with no previous PoD experience, in centres which previously employed weekly CBCTs for bladder patients, and for plan selections made in 2017, Table 1.

Table 1: Chi-square test comparing compliance in fractionation, PoD experience, bladder CBCT frequency and year of randomisation

Variable	Description	Frequency (n=439)	Guideline compliant cases		p value
			N	%	
Fractionation	32 fraction	206	135	77.5	0.03
	20 fraction	239	183	88.2	
PoD experience	Previous PoD experience	180	122	67.8	0.044
	No previous PoD experience	259	196	75.7	
Bladder CBCT frequency	Daily CBCT	58	33	56.9	0.004
	Weekly CBCT	381	285	74.8	
Year of randomisation	2015 + 2016	15 (2015) + 182 (2016)	133	66.5	0.012
	2017	242	187	77.3	

Expected count are projected frequencies if the null hypothesis is true, e.g. there is no association between fractionation and compliance

Based on these Stage 1 results the QA programme was revised to include:

1. Updated trial documentation detailing plan selection steps
2. Formal PoD reports for all centres
3. An interactive workshop with RTTs
4. A plan selection presentation
5. One-to-one training sessions

Since the implementation of these revisions for Stage 2, 102 CBCTs have been reviewed, from 16 centres. 98/102 (96%) plan selections were guideline compliant.

### Conclusion

In the Stage 1 feasibility study 72% plan selections were guideline compliant. To develop this compliance the trial's QA programme was revised. Initial results indicate that guideline compliance has improved as a result; thus, to support RTTs to deliver PoD, pro-active continuous QA is recommended.

### OC-0635 Targeting TEMPRSS2:ERG fusion to achieve a tumor-specific radiosensitization in prostate cancer

S. Köcher<sup>1</sup>, B. Beyer<sup>2</sup>, T. Lange<sup>3</sup>, L. Nordquist<sup>1</sup>, S. Burdak-Rothkamm<sup>1</sup>, T. Schlomm<sup>2</sup>, C. Petersen<sup>4</sup>, K. Rothkamm<sup>1</sup>, W. Mansour<sup>1</sup>

<sup>1</sup>University Medical Center Hamburg - Eppendorf UKE, Lab of Radiobiology and Experimental Radiation Oncology, Hamburg, Germany ; <sup>2</sup>Prostate Cancer Center-University Medical Hamburg Eppendorf, Martini-Klinik, Hamburg, Germany; <sup>3</sup>University Medical Center Hamburg-Eppendorf, Institute of Anatomy, Hamburg, Germany ; <sup>4</sup>University Medical Center Hamburg - Eppendorf UKE, Department of Radiotherapy and Radiooncology, Hamburg, Germany

### Purpose or Objective

Radiotherapy (RT) is one of the mainstay treatments for prostate cancer (PCa). Despite all technological advances in RT delivery over the recent years, improvements in molecular characterization of PCa have not changed clinical practice. Decision-making in RT for PCa is still guided by conventional clinical-pathological factors such as PSA-levels and Gleason scores. Local recurrence after RT is thought to occur predominantly in regions bearing higher histological tumor burden. Consequently, PCa is still the third-leading cause of cancer-related death in males. Therefore, there is a great need for development of strategies that improve both local control at the tumor site and eradicate occult metastasis in PCa patients.

### Material and Methods

ERG negative (DU145 and PC3) and positive (VCaP, DU145-ERG) cell lines were used to conduct the in vitro experiments. Plasmid assay was used to monitor a repair switch to PARP1-EJ. Immunofluorescence technique was employed to monitor  $\gamma$ H2AX, 53BP1 and RAD51. Ex vivo assay was established to monitor DSB repair in (i) xenografts established from DU145 or PC3 cells and (ii) 100 tumor biopsies freshly collected from 50 PCa patients. FISH was used to analyze ERG status in TMA from PCa patients.

### Results

Cells overexpressing ERG (VCaP or DU145-ERG) show a deregulation in DSB repair with a repair switch to PARP1-EJ. Consequently, PARP inhibition significantly increased the number of residual  $\gamma$ H2AX/53BP1 foci after IR exclusively in ERG overexpressing cells. HR defect was excluded by (i) plasmid assay, Rad51 foci formation and sensitivity to PARPi alone. We employed a functional ex-vivo assay, which allows the analysis of DSB repair in fresh tumor tissues. We confirmed the repair switch to PARP1-EJ in xenografts of ERG overexpressing cells as evidenced by elevated residual  $\gamma$ H2AX/53BP1 foci after PARP inhibition. We analyzed ERG fusion in (i) 14,000 PCa patients, who underwent radical prostatectomy and (ii) 1,426 PCa patients, who underwent salvage radiotherapy. Multivariable Cox proportional hazards model did not show any statistically significant differences between ERG status and PSA-recurrence free survival in both cohorts (p=0.35 and p=0.24, respectively). Next, tumor tissues from 50 PCa patients were collected, sliced in 100-300 $\mu$ m to prevent hypoxia, treated with or without the PARPi olaparib 2h-pre 2Gy and  $\gamma$ H2AX and 53BP1 foci were monitored. Our data showed no difference in the induction of DSBs but significantly higher number of residual  $\gamma$ H2AX/53BP1 foci in ERG-overexpressing patients compared to ERG low expressers.

### Conclusion

Collectively, these data indicate that ERG-overexpression is not a predictive marker for the response after RT in PCa but drives a switch to PARP1-EJ which in turn render cells radiosensitized by PARP inhibition. Clinically, this would rationalize the combination of PARP inhibitor olaparib with radiotherapy in ERG-positive PCa patients.

**SP-0636 The DNA damage response to radiotherapy: mechanisms and therapeutic opportunities**

M. Morgan<sup>1</sup>

<sup>1</sup>University of Michigan, Department of Radiation Oncology, Ann Arbor, USA

**Abstract text**

Cellular responses to radiation-induced DNA damage include cell cycle arrest, a transient delay in DNA synthesis, and activation of DNA repair pathways. In addition, emerging data suggest that DNA damage response (DDR) pathways may also modulate innate immunity. Research characterizing the vital role these pathways play in determining tumor cell survival has led to tremendous enthusiasm for the development of small molecule inhibitors which target critical proteins within DDR pathways, many of which are in clinical development in combination with radiation. This talk will provide an overview of current strategies designed to maximize the therapeutic efficacy of DDR inhibitors in combination with radiation, including incorporation with standard-of-care chemoradiation, novel combinations of DDR inhibitors targeting multiple steps in the DDR pathway, and integration of DDR inhibitors with immune checkpoint therapy.

K. Rothkamm<sup>1</sup>

<sup>1</sup>University Medical Center Hamburg - Eppendorf UKE, Department of Radiotherapy / Laboratory of Radiobiology and Experimental Radiation Oncology, Hamburg, Germany

**Abstract text**

The delivery of large radiation doses in a reduced number of fractions is becoming more and more popular in the treatment of primary tumours such as breast and prostate cancer as well as in stereotactic body radiotherapy (SBRT) of oligometastases. While clinical trials data provide increasingly robust evidence supporting hypofractionation in certain therapeutic settings, the underlying biology is still poorly understood. Vascular damage, immunogenic and dose volume effects as well as the "Rs" of classical radiobiology may shape the overall response of tumours and normal tissues to altered fractionation. Cell cycle checkpoint control and DNA damage repair have recently been proposed as important biological modulators of cellular fraction size sensitivity. These recent mechanistic insights may help us establish predictive biomarkers of tumour fractionation sensitivity.

**Teaching Lecture: Recent insights into radiotherapy tolerance from the REQUITE Consortium**

---

**SP-0639 Recent insights into radiotherapy tolerance from the REQUITE Consortium**

C. West<sup>1</sup>

<sup>1</sup>The University of Manchester, Translational Radiobiology, Manchester, United Kingdom

**Abstract text**

Logic dictates that the needs of the many outweigh the needs of the few. Radiotherapy is given to maximise the probability of local control while accepting that a small proportion of patients might suffer with long-term side-effects that impact negatively on their health-related quality-of-life. Although toxicity is reduced with modern radiotherapy techniques, it is increased with multi-modality treatment. Worldwide, the total number of people who are alive within 5 years of a cancer diagnosis was estimated to be 43.8 million in 2018. If 40% of survivors received radiotherapy as part of their treatment, many people could be suffering with late effects even if the overall percentage is small. The importance of survivorship issues is increasingly recognised and includes the need for research to identify patients at risk of long-term side-effects. Many models and biomarkers have been reported and few validated. Some are starting to be implemented clinically. The ability to develop and validate models requires insights into radiotherapy tolerance. Accurate insight is only possible with high-quality data.

The EU funded REQUITE consortium established a high-quality resource for multi-national validation of models and biomarkers that predict risk of late toxicity following radiotherapy. An international, prospective cohort study recruited patients in 26 hospitals in eight countries. Eligible patients had breast, prostate or lung cancer and planned potentially-curable radiotherapy. To reflect real-world patients versus patients selected for inclusion in randomised trials, radiotherapy was prescribed according to local regimens, but centres used standardised data collection forms.

Between April 2014 and March 2017 REQUITE recruited 2,069 breast, 1,808 prostate and 561 lung cancer patients. Patients were followed for up to 2 years. The data highlight heterogeneity in patients and treatments across centres/countries that might pose a challenge when attempting to validate predictive models and biomarkers. For example, cancer patients tended to have a higher body mass index in Spain and the UK than in the other countries; the percentage of breast cancer patients who received intensity modulated radiotherapy ranged from <20% (France, Italy, Spain, US) to >80% (Belgium, UK); and the percentage of prostate patients having hormones ranged from 13% (Germany) to ~80% (Belgium, UK). The pre-radiotherapy baseline adverse effect data highlight that across all cancers and toxicities healthcare professional graded scores were lower than patients' grades. Baseline patient-reported grade  $\geq 2$  adverse effects varied between 12% (USA) and 41% (UK) for breast pain (breast patients); between 1% (Netherlands) and 13% (Belgium) for urinary incontinence (prostate patients); and 9% (Italy) to 38% (France) for dyspnoea (lung patients). Example prevalences of 2-year (1-year for lung) grade  $\geq 2$  CTCAE toxicities are 13% atrophy (breast), 3% rectal bleeding (prostate) and 27% dyspnoea (lung). Data from the REQUITE consortium highlight differences in patient characteristics and treatments that will affect radiotherapy tolerance.

##### Abstract text

Stereotactic Radiation Therapy (SRT) is a widely used radiation therapy technique relying on accurate delivery of highly conformal, sharply delineated high doses in few fractions to small target volumes and an accurate avoidance of critical risk organs. SRT is used intracranially (a.k.a. SRS) or extracranially (SBRT or SABR). SRT places major demands on clinicians with respect to peculiarities about the physics and dosimetry of small photon beams and the planning algorithm's limitations. Image guidance and quality assurance procedures are also more stringent. Finally, the radiation biology of hypofractionated radiation treatment for tumors and normal tissues must ideally be considered.

ICRU Report 91 (2017) arose from the lack of guidelines consistent with previous ICRU Reports about prescription, recording and reporting including Report 50 (ICRU, 1993), 62, (ICRU, 1999), and 83, (ICRU, 2010) for these types of clinical treatments. The Report provides a historical background and definitions of SRS and SBRT, emphasizing the characteristics stereotactic localization, hypofractionation, small beams and small targets, inverse optimization, image guidance; and the need for precise volume definition. Clinical prescriptions and dose tolerances for hypofractionation are still the subject of investigation and clinical debate and, aside from stating the limitations of LQ models and alternative models in this context, the Report is not prescriptive on this matter. Three main features that dominate the dosimetry of small beams from accelerators are a lack of charged-particle equilibrium, partial source occlusion and the importance of size and construction details of the detector used. In the Report, IAEA-AAPM TRS-483 (2017) recommendations are retained for reference dosimetry in a machine-specific reference field (*msr*) and for small fields, more than a single detector is recommended to determine relative output factors where the measured data should be corrected with the detector type-specific field output correction factor data. For reasons of dose accuracy required in extracranial situations, ICRU Report 91 mandates the use of advanced type-b model-based dose calculation algorithms. As SRT is characterized by high gradients in the dose distribution and hypofractionation it comes with the need to perform daily correction and verification of target location at a sub-mm precision using IGRT and appropriate QA procedures. ICRU 91 maintains the definition of prescription and risk volumes consistent with previous ICRU documents and the report discusses imaging modalities for GTV definition.

The Report maintains prescription of absorbed dose to the isodose surface  $D_v$  that covers an optimal percentage volume of the PTV while optimally restricting dose to the planning risk volume (PRV). With regards to recording and

reporting, the quantities SRT near maximum and SRT near minimum dose are introduced that take into account that for small volumes a minimum absolute volume is required in the assessment of the quantities.

This educational lecture will present a review of ICRU Report 91 (2017) including its rationale, small field dosimetry, volume definition, dose calculation, IGRT and QA as well as the prescription guidelines. The discussion will integrate this with the IAEA TRS-483 recommendations on small field calibration as well as with ongoing work by the AAPM Work Group on SBRT on the extraction of clinical and radiobiological information from the published SBRT outcomes literature.

Educational objectives:

1. to understand the implication of small photon radiation beams in calibration, relative dose measurement and treatment planning dose calculations in the context of Report 91 and TRS-483;
2. to learn about the ICRU Report 91 recommendations on volumes definition and dose-volume prescription, recording and reporting.

##### Abstract text

Epidemiology of eligible cases for protontherapy, as well as selection criteria, are very controversial. Actually, the size of the eligible population is more a question of care offer than a true scientific question, since protons allow almost constantly a better dose distribution than photons for rather the same biological efficiency, thus assuming fewer side effects.

On the other hand, western European states as typical "providence states" are committed to provide to every patient the best possible cares. To be sustainable, this extremely costly policy needs a careful selection of the medical procedures that are the most "cost efficient". Protontherapy is at best ten times more expensive than X-rays, this is the point.

Thus, for a given patient and a given tumour, what is the most cost-effective procedure between X-rays and protontherapy? Raw physical dosimetric data cannot fully address this question. A difference of dose may not always translate in better outcomes and cost-effectiveness and, thus, may not be meaningful clinically. Nevertheless, radiation oncologists are aware of a benefit of proton therapy in given situations because of the better dose distribution of protons.

These situations are : when dose differences can lead to reduction of toxicities or side effects in a significant health cost sparing way and can improve QOL; when proton therapy results in dramatic reduction of integral dose, which is a critical advantage regarding second cancers for young patients or even of vital importance for genetically radiosensitive patients; when protons allow significant dose escalation for radioresistant tumours; when dose sparing with protons preserves options to irradiate future tumours in case they occur in the same anatomical region (rectal cancer years after cervix

cancer, prostate cancer years after rectal cancer, lung cancer after another lung cancer...); finally when re-irradiation might be curative but over toxic with X-rays. With such different endpoints, the benefit of protons requires different investigational methods. Their common principle is to translate a physical dose difference into a difference of risk that must be translated in differences of either medical outcome, QOL or health costs. All these situations are raising the concern to define what is a “significant” difference, in terms of human utility and economical sustainability.

Moreover, one must also take account of the potential medical drawbacks of protontherapy, namely a series of uncertainties that are not fully mastered yet: the range uncertainties, the lack of possibilities to check the anatomical accuracy of dose delivery, and certainly the underestimated question of the high RBE at the deep end of the beams... necessarily out of the GTV and possibly in sensitive tissues we aim at sparing. Some specific toxicities have been described that might be related to this question of RBE uncertainties. The scientific methods to address these endpoints deserve discussion. Only the classical phase III prospective controlled randomized clinical trials, for comparisons, can provide accurate contemporary comparative real measures of effects. However, they are rather expensive, unsuitable for rare situations or very late endpoints and results are delayed and short lasting. On the other hand, modelling appears as an attractive solution for immediate application and medical choice of protons vs photons. However it is not so easy either. As the assessment process is built on physical dose, several successive rounds of modelling are required to calculate the different endpoints. In particular, this needs many parameters related to the patient / tumour / treatment / outcomes that are as many sources of uncertainties. Thus a careful association of these two approaches is advisable.

First, clinical trials, with randomization, either of phases II or III, should produce a strong basis of high level of proof to allow the vital funding of protontherapy by health insurances. Randomized studies have also the valuable advantage to allow meta-analysis of studies of individual insufficient power. Meanwhile, they can provide initial values of model parameters.

Second, protontherapy can be continually modelled to estimate the expected gain and its cost effectiveness for each individual patient in the “real life” beyond the restrictive frame of clinical trials. All medical cases can feed cumulative databases to back statistically analysis to constrain and refine the models as a continuous improving process, relying in particular on machine learning, which is a kind of artificial intelligence. Finally, large interconnected databases will allow data mining and in-silico clinical trials, using modelling, to explore new applications and medical strategies. But, of course a critical and necessary input is the careful and shared follow-up of patients to identify early and late toxicities by the referent physician of the patient as well as by the protontherapy specialist.

#### Teaching Lecture: MR-guided radiotherapy in the pelvic region

---

##### SP-0643 MR-guided radiotherapy in the pelvic region

A. Tree<sup>1</sup>

<sup>1</sup>Royal Marsden Hospital Trust & Institute of Cancer Research, Uro-Oncology, London, United Kingdom

##### Abstract text

MR-guided radiotherapy is now a reality with two platforms, MRIdian and Unity, in clinical use in multiple centres. Daily adaptive replanning to online MR images is

now implemented routinely in these centres. Many dosimetric and machine-related hurdles have been surmounted to deliver MR-guided radiotherapy to date, but our clinical experience is still in its infancy. There are potential pitfalls and specific complexities of MR-guided radiotherapy from a dosimetric and clinical perspective. The changes in anatomy presented daily are unpredictable and their clinical relevance is uncertain. This lecture will outline clinical experience to date and explain some of the lessons learned so far with MR-guided radiotherapy.

The potential future advantages of MR-guided adaptive radiotherapy will be explored, sharing a vision of where this technology may take us in the next 5-10 years.

#### Symposium: Radiotherapy biomarkers: a confluence of imaging, genetics and pathology

---

##### SP-0644 Advances in imaging to predict and monitor radiation response

U. Van der Heide<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

##### Abstract text

A vast body of literature exists on a range of imaging biomarkers predicting response after radiotherapy. Functional techniques such as PET with FDG or hypoxia tracers and various forms of functional MRI have been shown to have prognostic value. Increasingly, combinations of texture features from anatomical and functional images are proposed that predict outcome. These methods can potentially be applied in radiotherapy to stratify patients between different treatment options before the onset treatment or at a later time point. A drawback in the adoption of functional imaging techniques in clinical practice is the substantial variability in methodology, both with respect to acquisition and analysis. Quantitative imaging techniques may be a way to resolve this issue. It will facilitate comparison of imaging data from longitudinal studies as well as multicenter trials.

To strengthen the evidence on biomarkers, single center as well as multi-center studies using functional imaging techniques, need to show that within their trial protocol consistent quantification of imaging is ensured. Quality assurance programs need to be part of trial protocols and can help broad implementation of quantitative techniques in the community.

Repeated imaging during the course of fractionated radiotherapy informs on anatomical and functional changes of the disease and creates the prospect of adaptation of treatment plans. Trials that modify the treatment several weeks into the treatment based on functional imaging, are ongoing. Also, the value of functional imaging for stratification of patients after neoadjuvant radiotherapy is being investigated. The analysis of longitudinal data can however be challenging. Deformations of tissue or shrinking of the tumor over time, make a voxel-by-voxel comparison of quantitative images acquired at different time points impossible. Descriptive statistics over the entire tumor volume may reflect response to the treatment, but in this approach the changes in spatial heterogeneity are lost. Frequent, preferably daily imaging may be beneficial in this context as from day to day the effect of tumor regression will be limited. Up to now, daily quantitative imaging was not feasible in clinical practice. However, with the introduction of MR-guided radiotherapy, patients receive an MRI exam during each treatment fraction. We recently showed that functional imaging is also feasible in this setting, creating the prospect of monitoring functional response to the treatment in unprecedented detail.

Abstract not received

**SP-0646 Translation of biomarker signatures in daily clinical use?**M. Krause<sup>1</sup><sup>1</sup>TU Dresden- Med. Faculty Carl Gustav Carus, Department of Radiotherapy and Radiation Oncology, Dresden, Germany**Abstract text**

During the past decades, cancer treatment has been improved in a technically and medically manner. Nonetheless, the 5-year overall survival rate for head and neck squamous cell carcinoma (HNSCC) is still at about 50%. Currently, most patients with functionally inoperable HNSCC are treated with primary radiochemotherapy (RCTx). In contrast to radiotherapy alone, clinical trials showed that patients who received RCTx benefit in terms of increased overall survival and loco-regional control as well as freedom of distant metastases. However, concomitant chemotherapy is leading to increased toxicity. Another obstacle is the heterogeneity of tumor response to this treatment. Therefore, biomarkers are urgently needed to identify patient groups who require de-escalated or intensified treatment schedules based on their tumor biology in addition to established clinical parameters. Currently, a panel of promising biomarkers is tested in numerous clinical studies, such as human papilloma virus (HPV) status. A positive HPV infection status may be a suitable biomarker for patient stratification towards de-escalation treatment regimens. However, additional biomarkers are needed for further stratification of patients with HPV-negative tumors. This talk will give an overview about the results of biomarker studies and ongoing clinical trials.

**SP-0648 Criteria for choosing dose and irradiation techniques for palliative treatment**Y. Van Der Linden<sup>1</sup><sup>1</sup>Leiden University Medical Center Lumc, Department Of Radiotherapy, Leiden, The Netherlands**Abstract text**

Radiotherapy is an important treatment modality for advanced cancer patients who experience clinical symptoms caused by metastatic disease or the primary tumour itself. And times are changing, with the possibility to treat oligometastatic disease using stereotactic techniques and ablative doses with the goal of prolonged symptom control, and maybe, even prolonged survival. When considering the use of palliative radiotherapy it is therefore recommendable to think about some important issues

1- How do we select our patients for palliative

radiotherapy? Where in the disease trajectory is the individual patient?

2- What are the goals of palliative radiotherapy from the perspective of the patient? And how do we match these goals with the expected toxicity and clinical outcome?  
3- How do we choose between different radiation techniques and dose schedules? What is the evidence to support these choices?

During the talk these issues will be discussed

#### SP-0649 Uncertainties in single fraction treatment

J. Dhont<sup>1</sup>

<sup>1</sup>Vrije Universiteit Brussel, IMEC-SMIT-VUB ETRO, Brussels, Belgium

##### Abstract text

Uncertainties, possible differences between the planned and delivered therapy, enter the radiotherapy treatment workflow at every step of the process. Proper identification and understanding of the extent of each uncertainty, on both a patient and treatment system level, are crucial to enable precise and accurate radiotherapy delivery. Not only to ensure sufficient target dose and minimal dose to organs at risk, but also to be certain of the dose delivered; a prerequisite for further optimization to advance radiation oncology. In case of standard fractionation, most uncertainties such as organ motion become random, blurring the planned dose around the target. Only few uncertainties are systematic after multiple fractions, often caused by wrong calibration of set-up equipment, inducing a shift of the planned dose relative to the target. To be certain of sufficient dose to the CTV despite uncertainties, PTV margins are applied. Proposed margin recipes rightly make a distinction between random and systematic errors, with higher contribution coming from the latter. However, in case of single fraction treatment, an uncertainty shift occurs. Errors such as inaccurate patient set-up no longer become random but induce a single shift in the dose with respect to the target, as systematic errors do. Only few random uncertainties remain when the total dose is delivered at once, significantly altering the PTV margin when the treatment confidence level is to remain the same.

#### SP-0650 The Role of the RTT in the Palliative Patients Journey

K. Moore<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, radiotherapy, Glasgow, United Kingdom

##### Abstract text

As radiographers become more autonomous within radiotherapy we are taking on roles that have traditionally been undertaken by the medical staff or by clinical nurse specialists.

While nurses have had many years experience in consulting with the palliative patient, and many publications that describe how well this is done by our nursing colleagues there is very little in the way of evidence where a non medic/non nurse health care professional leads this type of consultation. This presentation will explore the RTT role within the palliative radiotherapy aspect of patient care and communicating the purpose of treatment.

Breaking bad news to a patient or discussing where they are with regard to end of life care takes experience, confidence and most of all knowledge of treatment options and outcomes. There are models for us to refer to such as the SPIKES model, however these 3 cases will demonstrate that providing the answers to the patient questions is often fraught with more questions than answers.

#### SP-0651 Healthy tissue response to a single fraction treatment : Impact of the individual radiosensitivity

N. Foray<sup>1</sup>

<sup>1</sup>U1052 Inserm - Radiobiology group- Lyon- France, Radiobiology, Lyon, France

##### Abstract text

The ATM protein is a major stress response factor involved in the DNA double-strand breaks (DSB) repair and signaling. We have recently provided evidence that the rate of the nucleo-shuttling of ATM protein was a good predictor of tissue radiosensitivity: irradiation triggers the monomerization of the abundant cytoplasmic ATM dimers, which allows the ATM monomers to diffuse in the nucleus. Once in nucleus, the ATM monomers phosphorylate the variant H2AX histone protein, which triggers the recognition of DSB and their repair via non-homologous end-joining (NHEJ) pathway. From hundreds fibroblasts derived from patients suffering from genetic disease or post-radiotherapy radiosensitivity, we have shown that delay in the nucleo-shuttling of ATM may cause lack of DSB recognition, incomplete DSB repair and radiosensitivity (1-4). A classification of radiosensitivity in three groups was proposed (5, 6): group I: radioresistance and low cancer risk, fast ATM nucleo-shuttling; complete DSB repair; group II: moderate radiosensitivity and high cancer risk, delayed ATM nucleo-shuttling; incomplete DSB repair; group III: gross DSB repair defect whatever the rate of the ATM nucleo-shuttling, hyper-radiosensitivity and high cancer risk with two sub-groups : sub-group IIIa (delayed ATM nucleo-shuttling, e.g. ataxia telangiectasia (ATM mutations)); sub-group IIIb (normal ATM nucleo-shuttling, e.g. the LIG4 syndrome (LIG4 mutations)) (1, 6). This model permits a relevant biological interpretation of the linear-quadratic model that links cell survival and radiation dose (7). We will ask from which threshold of DNA repair defect and ATM nucleo-shuttling, a palliation in RT can be deleterious.

#### SP-0652 The role of DNA replication stress in glioma stem cell radiation resistance

R. Carruthers<sup>1</sup>, S. Ahmed<sup>2</sup>, K. Strathdee<sup>3</sup>, A. Chalmers<sup>4</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom; <sup>2</sup>University Of Sunderland, Faculty of Health Sciences and Wellbeing, Sunderland, United Kingdom; <sup>3</sup>University Of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom ; <sup>4</sup>University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom

##### Abstract text

Radiation resistance and tumour recurrence are hallmarks of glioblastoma, which is one of the most aggressive human malignancies. Despite advances in the treatment of many other solid tumours, survival in glioblastoma has remained unchanged for many years, and many promising novel agents have failed to alter outcome in large phase 3

clinical trials. One contributing factor is thought to be the failure of many therapeutics to target glioblastoma stem-like cells (GSC) which exhibit DNA damage response (DDR) activation and enhanced DNA double strand break (DSB) repair. Although DDR activation and radiation resistance in GSC were documented many years ago the underlying reasons for this have remained enigmatic. Elucidation and understanding of this phenomenon would have significant implications for efforts to increase the efficacy of radiotherapy in the clinic. In this presentation we will provide an overview of DDR activation observed in GSC and explore its implications for radiation resistance. We will describe a unique DNA replication phenotype in GSC that predisposes them to high levels of DNA replication stress as an underlying mechanism for DDR activation and discuss possible sources of elevated replication stress in this cell population. Finally, we will examine targeting of DNA replication stress response as a promising therapeutic and radiation sensitisation strategy for clinical translation.

#### SP-0653 Tumor cell connections causing radiation resistance

F. Winkler<sup>1</sup>

<sup>1</sup>University of Heidelberg, Neurology, Heidelberg, Germany

##### Abstract text

The recent discovery of ultra-long and thin membrane protrusions of glioma cells, called tumor microtubules (TMs), has added to our understanding of these incurable tumors (Osswald et al., Nature 2015). Astrocytoma (including glioblastoma) cells extend these highly functional structures to colonize the brain, and to interconnect to one large communicating multicellular network. Glioma cells integrated into this TM network resist the cytotoxic effects of radiotherapy and chemotherapy. This talk will cover how our understanding of the disease "glioma" has changed, and how novel therapies are developed to tackle this basic cellular mechanism of resistance against radiotherapy, chemotherapy, and surgery.

#### SP-0654 Transcriptional response to temozolomide in Glioblastoma reveals critical role of long non-coding RNAs

##### Abstract text

Resistance to the alkylating agent temozolomide (TMZ) is a major cause of Glioblastoma (GBM) recurrence and dismal prognosis. To date, the epigenetic regulation of the O6-methylguanine methyltransferase (MGMT) promoter is the only TMZ-predictive marker with clinical relevance, but there is little knowledge of regulatory transcriptional pathways involved in therapy resistance. Here, we provide a comprehensive overview of the transcriptional response to TMZ in patient-derived cellular GBM models, with a special focus on the contribution of non-coding RNAs as novel markers of chemoresistance. Using RNA-Seq and small RNA-seq, we have uncovered a complex transcriptional response to TMZ and identified a subset of long non-coding RNAs (lncRNAs) mediating regulatory circuits. Interestingly, lncRNAs were mapped to processes linked to drug sensitivity, cell cycle regulation and/or developmental pathways. Among these lncRNAs, we characterized a novel lncRNA termed RADAR (RNA associated with DNA Damage and Replication) and show that RADAR is a chromatin-associated lncRNA involved in cell cycle control, apoptosis and sister chromatid cohesion. Altogether, this integrative analysis of RNA-seq

data provides new RNA-based predictors of chemoresistance, as well as potential targets to counteract this resistance in GBM.

##### Abstract text

Commonly defective core signaling pathways in glioma contributing to radioresistance include the tumor protein p53 (TP53) pathway, the retinoblastoma (RB) pathway and receptor tyrosine kinase (RTK) pathway. Combined treatment of irradiation, the key component of the current standard treatment of glioblastoma (GBM) patients, with drugs that selectively target these pathways, might improve the outcome of therapy.

Studies were performed on GBM cell lines and patient derived primary cultures grown as monolayer and multicellular spheroids with endpoints cell proliferation, clonogenic cell survival, spheroid growth rate, - volume reduction and - time to regrow. We investigated the single agent efficacy and radiosensitizing potential of a panel of novel targeted small molecule drugs including MK2206, RAD001, BEZ235, MLN0128 and MEK162. Effects on cell cycle distribution and expression of key target proteins were evaluated.

Out of the panel of drugs, both the allosteric AKT inhibitor MK2206 and MEK162 (binimetinib), which is an allosteric inhibitor of MEK1/2, were found to act as radiosensitizer. MK2206 delayed the growth of spheroids and sensitized to both irradiation and temozolomide via reduced phosphorylation of Thr308 and Ser473 residues of AKT. MEK162 was found to down-regulate and dephosphorylate the cell cycle checkpoint proteins CDK1/CDK2/WEE1 and DNA damage response proteins p-ATM/p-CHK2. When combined with radiation this led to a prolonged DNA damage signal. Next, the combination of MEK162 (50 mg/kg) and irradiation (3 x 2 Gy) was studied on orthotopic GBM8 brain tumor xenografts. The data showed a significantly reduced growth rate, increased growth delay and prolonged survival time of the animals. In addition, RNA expression of responsive cell cultures correlated to mesenchymal stratification of patient expression data. However, the delivery of MEK162 to the tumor site, like most chemical compounds, is abrogated by the blood-brain barrier (BBB). First in vitro data on BBB crossing demonstrated effective passaging of the drug when loaded in polymeric nanocarriers.

In conclusion, both the AKT inhibitor MK2206 and the MAPK inhibitor MEK162 demonstrated radiosensitizing potential in GBM spheroids in vitro and in orthotopic GBM xenografts in vivo. We identified a patient subgroup that might benefit from MEK inhibition combined with radiotherapy. This combinatorial treatment approach opens a novel therapeutic avenue for GBM patients.

**SP-0656 For the motion: resectable pancreatic cancer**  
T. Brunner<sup>1</sup>

<sup>1</sup>*Otto-von-Guericke-Universität Dept. Radiation Oncology, Magdeburg, Germany*

Abstract not received

**SP-0657 Against the motion: resectable pancreatic cancer**

M. Falconi<sup>1</sup>

<sup>1</sup>*San Raffaele Hospital, Pancreas Surgery, Milano, Italy*

**Abstract text**

The management of resectable pancreatic cancer is challenging and different strategies can be applied including upfront surgery followed by adjuvant therapy or neoadjuvant treatment followed by surgical resection. This decision is based on the presence of an anatomical and/or biological borderline resectable tumor. In the setting of neoadjuvant treatment, there is a lack of evidence that support the routine use of preoperative radiation therapy with chemotherapy, especially when considering multi-agents chemotherapy regimens (i.e. FOLFIRINOX; gemcitabine plus nab-paclitaxel). The rationale for preoperative chemoradiation is related to a lower rate of R1 resection rate following radiation therapy, but actually no RCT showed a real advantage of this approach over chemotherapy alone. In the setting of adjuvant treatment, there is an unclear role for adjuvant radiotherapy, that is most likely recommended for patients with a R1 resection. Most studies did not find any advantage in the survival rate following chemoradiation compared to adjuvant chemotherapy alone. However, several studies administered suboptimal and obsolete schedule of radiotherapy and/or included small cohorts of patients, and as a consequence this represents a major limitation of any comparison of chemoradiation versus chemotherapy alone, both in the adjuvant and neoadjuvant setting. Novel radiotherapeutic approaches including stereotaxic body radiation therapy should be evaluated in powered randomized clinical trial considering specific aims (local recurrence, overall survival, toxicity).

**SP-0658 For the motion: locally advanced pancreatic cancer**

F. Huguet<sup>1</sup>

<sup>1</sup>*Hôpital Tenon, Department of Radiotherapy, Paris Cedex 20, France*

**Abstract text**

At diagnosis, about 25% of patients with pancreatic adenocarcinoma presents with a locally advanced (non-metastatic but unresectable due to vascular invasion) or borderline resectable tumor. Despite the technical progress made in the field of radiation therapy and the improvement of the efficacy of chemotherapy, the prognosis of these patients remains poor. Recently, the role of radiation therapy in this setting has been much debated. However, some arguments support the use of radiation therapy for these patients. First, as shown in LAP07 trial, radiation therapy delivered after a phase of induction chemotherapy increases local control. Second, it allows a time without treatment for patients longer than chemotherapy alone. Third, patients who receive neoadjuvant radiation therapy have a higher chance to achieve a R0 resection and a major pathological response

(ypT0-1 ypN0). Moreover, new radiation techniques such as SBRT allow dose escalation to the target volume while improving sparing of nearby normal structures. Combined with more effective chemotherapy regimens, it should improve the outcome of these patients.

<sup>2</sup>*Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada*

**Abstract text**

The incidence of Human papillomavirus (HPV) associated oropharyngeal carcinoma (OPC) is increasing in developed countries, and HPV positive OPC is a distinct disease entity from HPV negative OPC characterized by a unique epidemiology, molecular biology and oncogenesis. In addition, patients with HPV positive disease tend to be younger and healthier than their HPV negative counterpart due to differences in risk profiles, especially less heavy smoking and alcohol consumption, which again results in less significant comorbidity.

HPV positive squamous cell carcinoma is more sensitive to radiotherapy than HPV negative disease, and the highly significant prognostic impact of tumor HPV-status on treatment outcome and survival has led to the inclusion of HPV-associated p16 expression in the eighth edition of the AJCC/UICC TNM classification system. The overall general favorable prognosis in HPV positive OPC is however heterogeneous, and it is well known, that advanced disease-stage (T3-4N2) and smoking (>10packyears) negatively impacts prognosis, which have resulted in the definition of a group of intermediate risk patients with HPV positive disease.

Traditional treatment of advanced stage OPC consists of concurrent chemo-radiation, which is associated with substantial acute toxicity and long term morbidity, ultimately impacting quality of life for long-term survivors. As patients with HPV positive disease are typically younger, they will have to live longer with potential long term effects from treatment. This, combined with the general good prognosis, has led to the initiation of clinical trials investigating de-intensified therapies in HPV positive disease, in order to reduce toxicity without compromising outcome. Various strategies are presently being investigated within clinical trials including de-intensification of treatment by substituting Cisplatin with the EGFR-inhibitor Cetuximab, radiotherapy alone, reduction in adjuvant radiotherapy following primary surgery with minimally invasive surgical techniques based on pathology features and reduction in radiotherapy dose following induction chemotherapy in good responders.

Given the somewhat dismal prognosis of the intermediate risk HPV positive patients, trials have been initiated focusing on optimizing outcome for this group of patients also, for instance by incorporation of concurrent immunotherapy into primary radiotherapy. The first groundbreaking results have been published regarding the substitution of Cisplatin with Cetuximab

from two large-scale randomized trials (De-ESCALate and NRG Oncology RTOG1016), both showing significantly worse tumor control and survival outcomes for patients treated with Cetuximab, with comparable frequency and severity of acute toxicity and late morbidity. In this light, Cisplatin continues to be the standard of care for radiosensitization in all eligible patients with advanced HPV positive OPC, and treatment de-intensification strategies should only be evaluated within the frames of well-designed clinical trials.

The focus of this talk will be to summarize the current understanding of how to optimally treat HPV positive OPC integrating an overview of the design and rationale of ongoing clinical trials and a presentation of lessons learned from completed clinical trials.

#### SP-0661 Predictive models in treatment of head and neck cancer

H. Langendijk<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

##### Abstract text

The relationship between 3-dimensional dose distributions and risks on radiation-induced side effects can be described by Normal Tissue Complication Probability (NTCP) models. NTCP-models may contain only one dose-volume predictor (dose metrics), but generally the performance of these model significantly improve when adding multiple other predictors (multivariable NTCP-models). According to the so-called model-based approach, next to outcome prediction, NTCP-models can be applied for dose optimization, selecting the best radiation technology, plan adaptation and even technology validation. For many side-effects, the risk may depend on more than one dose metrics to different organs at risk (OARs). To produce treatment plans that eventually result in adequate target dose coverage with the lowest probability on side effects, dose distributions to OARs should be translated into NTCP-profiles using NTCP-models (model-based dose optimization). For the selection of the best treatment plan, or even for the selection of patients for more advanced radiation technologies, like protons, information on NTCP-profiles next to dose profiles are essential to ultimately obtain the best clinical result, i.e. local control with the lowest rates of radiation-induced side effects. Currently, adaptive radiotherapy is mainly guided by dose deviations compared to the nominal plan. However, depending on the shape of the NTCP-curve, apparently large dose deviations do not necessarily translate into clinically relevant changes in the risks of side effects. Vice versa, relatively small dose deviations may result in major changes in the risk of side effects when they appear in the dose range with the steepest dose-effect relationship. Also here, NTCP-guided adaptations, also referred to as biologically-driven adaptive radiotherapy (BIOART) is more likely to result in the best clinical result. Many radiation technologies aiming at reduction of side effects are introduced in routine clinical practice, based on the ALARA-principle without any proper clinical validation. An alternative for RCT's is the so-called model-based validation, testing the null-hypothesis that observed toxicity rates obtained with the new RT technology is similar to that expected (based on NTCP-models) from the old technology. In summary, the model-based approach allows for a continuous improvement and validation of newly introduced radiation techniques and ultimately the most optimal outcome for patients treated with radiotherapy.

#### SP-0664 Update on commercial scintillators

S. Beddar<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston- TX, USA

##### Abstract text

Within the last two decades, there has been a substantial research directed towards the use of scintillators to measure absorbed dose in radiation dosimetry in general and particularly in radiation therapy. The evolution of the many studies that focused on these new type of detectors followed 3 phases: 1) identifying suitable clinical applications where scintillation detectors would offer additional advantages over the commonly used detectors or dosimeters, 2) optimization of detector designs and component's system depending on the application of interest and 3) transfer and translation to the industry to commercialize these new detectors. A brief introduction to scintillation dosimetry, including a summary of their advantages and disadvantages will be presented.

The lecture will focus on commercial scintillators and an update on their present status including new scintillation detector developments that are ongoing. At the present time there are two commercial systems available on the market. One designed for absorbed dose and dose characterization for external beam radiation therapy (EBRT) commercialized by Standard Imaging. The second one designed for in vivo dosimetry and dose monitoring commercialized by Radiadyne. A third commercial system is in the development and clinical trial testing phase for HDR brachytherapy to be commercialized soon by Dosilab. Their first system is targeted at the QA of HDR brachytherapy equipment.

Finally, current and on-going research to respond to future needs such as brachytherapy in the domain of in vivo dosimetry and dose-tracking, including electromagnetic (EM) tracking will be presented.

#### SP-0665 Multichannel film dosimetry

I. Mendez Carot<sup>1</sup>

<sup>1</sup>Institute of Oncology Ljubljana, Department of Radiation Physics, Ljubljana, Slovenia

##### Abstract text

The dosimetry system composed of radiochromic films and a flatbed scanner is a dosimeter of choice in many radiotherapy and radiology applications. Upon irradiation, films polymerize, becoming increasingly dark with the absorbed dose. Variations in the visible absorption spectrum can be measured with a scanner, which yields three different signals (R, G and B), one for each color channel. Multichannel film dosimetry consists of the combination of the information provided by several color channels in order to obtain more accurate dose distributions. Various multichannel film dosimetry methods have been proposed in the literature. Each of them based on different assumptions regarding the

behavior of the dosimetry system. This lecture will describe some of the most employed multichannel methods: its assumptions, formulas, uncertainties, and weaknesses. Multichannel film dosimetry can deliver more accurate doses, mainly by mitigating spatial heterogeneities in the film-scanner response, in particular, variations in the active layer thickness. This lecture will also explain which sources of uncertainty are reduced by using multichannel methods and what other corrections can we apply to improve radiochromic film dosimetry.

#### SP-0666 Developments in time-resolved detectors

A. Rozenfeld<sup>1</sup>

<sup>1</sup>Centre for Medical Radiation Physics, University of Wollongong, University of Wollongong, Australia

##### Abstract text

A range of silicon-based dosimeters has been made available to address the challenges of ensuring an ever safer and more accurate treatment delivery in radiotherapy. These dosimeters, extensively used in the clinic, possess a set of convenient features: a response which is stable and linear with deposited dose, and the possibility of manufacturing sensitive volumes sufficiently small while retaining relatively high sensitivity. The present lecture reviews, in terms of design, applications and limitations, innovative silicon dosimeters able of high-spatial and temporal resolution which are being developed at the Centre for Medical Radiation Physics (CMRP).

Monolithic diode arrays with spatial resolution better than 2mm and temporal resolution better than 0,1ms are discussed for dose QA in a heterogeneous fully customized phantom for IMRT and VMAT treatments with small photon fields that dynamically track the tumor motion using dynamic multi-leaf collimator (DMLC). Diode arrays with spatial resolution as high as 0.05 mm for in body application for *in vivo* real time source dwelling position and time verification in high dose rate (HDR) and immediate source position as dropped in low dose rate (LDR) brachytherapy with submillimetre spatial resolution are discussed. Finally, the use of a MOSkin, a metal-oxide-semiconductor field-effect transistor (MOSFET) and innovative epi-diode detectors for time resolved rectal wall dosimetry and source tracking in gynaecological multi catheter applicator respectively in HDR brachytherapy are presented

##### Purpose or Objective

The standard approach for CT-number to stopping-power-ratio (SPR) conversion in particle therapy is the use of a heuristic stepwise translation, a so-called Hounsfield look-up table (HLUT). It is defined by each treatment facility individually and depends on both the calibration method and CT scan protocol. A recent survey has shown broad variability in these parameters [1], making a simple comparison on HLUT level unfeasible. Hence, we present a comprehensive experimental evaluation of inter-centre variation and absolute accuracy in SPR prediction within the European Particle Therapy Network (EPTN).

##### Material and Methods

A head and a body phantom with 17 tissue surrogate inserts were scanned consecutively at the participating centres using their individual clinical scan protocol. The inserts were tissue-equivalent concerning particles; their composition and SPR were blinded for the participants. The SPR calculation was performed using each centre's CT scan and HLUT (Fig.1). The inter-centre variation and absolute accuracy in SPR prediction were quantified for each tissue surrogate individually and then summarised into the relevant tissue groups: lung, soft tissues and bones. Finally, to evaluate the integral effect on range prediction for typical clinical beams traversing different tissues, for three simplified beam paths the determined SPR deviations were accumulated according to their respective tissue distribution. So far, data from 9 out of 17 participating centres was available.

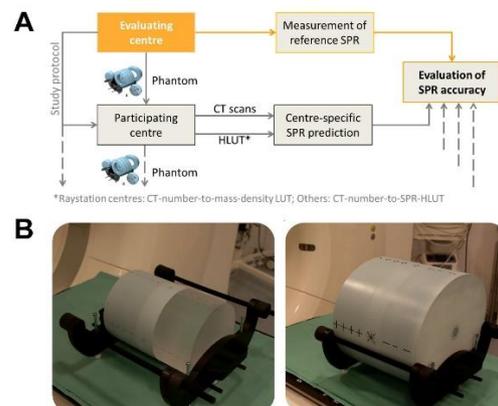

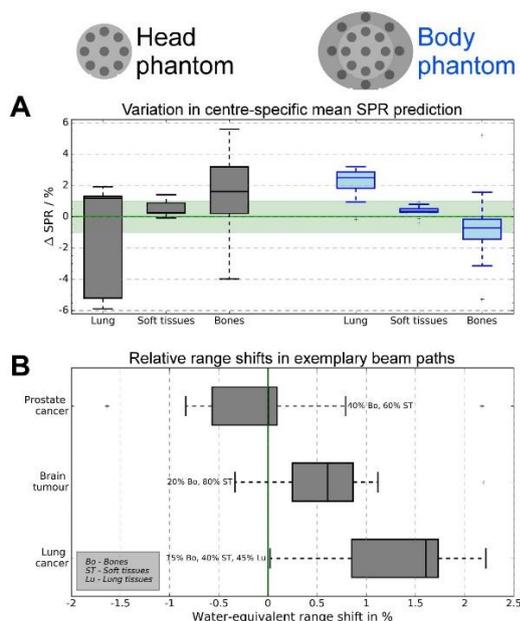

Figure 1: (A) Scheme of the study design. SPR: Stopping power ratio; HLUT: Hounsfield look-up table. (B) Experimental setup of the head (left) and body phantom (right) with the tissue surrogate inserts placed in the centre part of each phantom.

## Results

A  $2\sigma$  inter-centre variation in SPR prediction of 5.7% and 5.5% relative to water was determined for the bone inserts in the head and body setup, respectively. Comparable results were achieved for the lung tissue surrogates (6.4% and 2.2%). In the soft tissue region an overall higher accuracy was achieved with a variation below 0.9% in both setups and a mean SPR prediction accuracy below 0.5%. In the head setup, both lung tissues and bones were overestimated in most centres, while in the body setup the bones were underestimated (Fig. 2A). For the three exemplary beam paths, inter-centre variations in relative range were 1.5% on average. In specific centres, range deviations from reference exceeded 1.5% (Fig 2B).

**Figure 2:** (A) Variations in stopping-power-ratio (SPR) prediction between 9 centres. The 17 tissue surrogates were classified into the relevant tissue groups lung (2), soft tissues (11) and bones (4) and then averaged centrewise. (B) Resulting range shifts relative to water along three simplified beam path scenarios, resulting from an accumulation of the SPR deviations in the three tissue groups weighted with their relative contribution in the beam path. Whiskers in boxplot are defined by last values within 1.5x interquartile range.

## Conclusion

Large inter-centre variations in SPR prediction were observed in low- and high density tissue surrogates. The differences in deviation for bone between the two setups indicate a strong influence of scanning parameters such as the level of beam hardening correction, potentially resulting in range shifts of clinical relevance. As the study allows for a direct attribution of the measured deviations to the calibration methods and scan protocols used by the individual centres, it stresses the need for inter-centre standardisation. While this work addresses the accuracy in SPR prediction under idealised study conditions, a direct conclusion on overall range accuracy in patients is not possible. The study is currently still ongoing.

Southwestern Medical Center, Radiation Oncology, Dallas, USA

## Purpose or Objective

To evaluate the dosimetric accuracy of proton therapy treatment planning using synthetic CT images generated from magnetic resonance images (MRI) with a generative adversarial network (GAN).

## Material and Methods

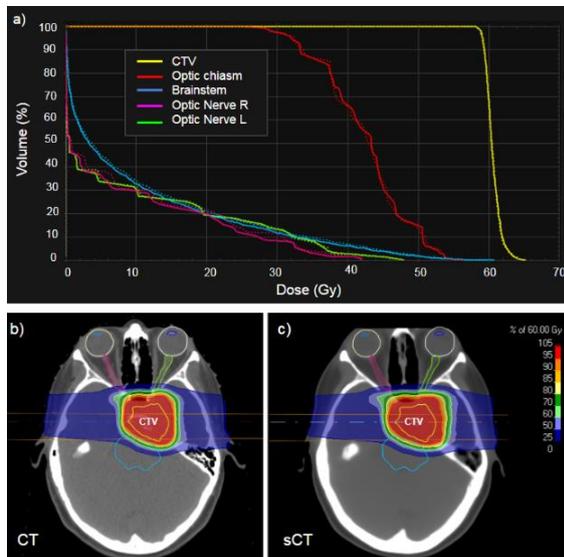

The GAN is a type of unsupervised deep learning algorithm that uses two neural networks that compete against each other: one network generates synthetic CT (sCT) candidates (generator), while the other evaluates them by comparison with real CT images (discriminator). This process is repeated until the discriminator cannot distinguish anymore between the real and synthetic CT, which entails that the generator learnt to accurately transform MR to CT images. The model was trained with (T1-weighted) MRI and CT slices from 63 brain cancer patients, and tested separately in 12 different patients. Synthetic CT images of the same patients were rigidly registered to the CT images using mutual information. Proton pencil beam scanning plans were created on the real CT of the 12 test patients, using RayStation v5.99 (RaySearch Laboratories AB), and recomputed on the sCT for dosimetric comparison. Robust optimization on the CTV with 3% range uncertainty and 3mm accounting for setup error was used to create the plans.

## Results

The average absolute error between the dose computed on the CT and sCT for the 12 test patients, and its standard deviation (SD), on the mean (Dmean) and maximum dose (Dmax) for relevant organs in the nominal case is presented in Table 1. For the CTV, the error on the dose delivered at 95% (D95) and 5% (D5) of the volume is also reported. Overall, the error remained below 2.5% of the dose prescription (60 Gy in all patients), for all considered metrics. Figure 1.a shows the DVH for one of the test patients, with overlapping lines for the dose on the CT (solid line) and sCT (dotted line). Figure 1.b and 1.c show the dose distribution on the same patient for CT and sCT, respectively, for a slice on the center of the target volume. The generation of a full 3D sCT for a given set of MRI slices took only 9 s.

		Average (%)	SD
CTV	D95	0,43	0,41
	D5	0,52	0,40
	D <sub>mean</sub>	0,28	0,21
Brainstem	D <sub>max</sub>	1,29	1,69
	D <sub>mean</sub>	0,40	0,43
Optic chiasm	D <sub>max</sub>	0,86	0,63
	D <sub>mean</sub>	1,36	1,10
Optic Nerve L	D <sub>max</sub>	2,43	2,34
	D <sub>mean</sub>	1,38	1,29
Optic Nerve R	D <sub>max</sub>	1,81	2,38
	D <sub>mean</sub>	0,46	0,66

**Table 1.** Average absolute error between the dose on CT and sCT for the test patients, and its standard deviation (SD), expressed as % of the dose prescription.

### Conclusion

The GAN model was able to generate high-quality synthetic CTs from MR images, which can directly be used for MRI-only treatment planning. Given the sensibility of scanned proton beam dose distributions on small differences along the beam path, our model shows a superior dosimetric accuracy that competes very closely to more conventional methods, such as atlas-based approaches, but requires no hand-crafted features and beats them in terms of computational speed. Our next task involves a complete evaluation of the plans robustness against multiple source of errors.

### OC-669 Development of a novel MRI-only treatment planning approach for ocular proton therapy

E. Fleury<sup>1,2</sup>, P. Trnková<sup>1,2</sup>, E. Erdal<sup>1</sup>, K. Hassan<sup>3</sup>, J. Beenakker<sup>4</sup>, J. Herault<sup>5</sup>, J. Pignol<sup>6</sup>, M. Hoogeman<sup>1,2</sup>

<sup>1</sup>Erasmus Medical Center, Radiation Oncology, Rotterdam, The Netherlands; <sup>2</sup>Holland Proton Therapy Center, Radiation Oncology, Delft, The Netherlands; <sup>3</sup>Leiden University Medical Center, Division of Image Processing, Leiden, The Netherlands; <sup>4</sup>Leiden University Medical Center, Department of Ophthalmology, Leiden, The Netherlands; <sup>5</sup>Centre Antoine Lacassagne, Radiation Oncology, Nice, France; <sup>6</sup>Dalhousie University, Radiation Oncology, Halifax, Canada

### Purpose or Objective

Proton therapy (PT) for Uveal Melanomas (UM) is often employed to lower the risk of irreversible side-effects such as vision impairment, loss or even enucleation. However, a main shortcoming is that high-resolution 3D image data for target volume definition and treatment planning is not used in clinical practice. Instead, the target volume is defined by 2D fundus photography or ultrasound and demarcated by tantalum clips stitched to the sclera. Moreover, the sole commercial treatment planning system (TPS) uses a simplistic eye model, and fails to account for detailed 3D information to accurately characterize the tumor and organs-at-risk (OARs). Besides, the optimal gazing angle for each patient needs to be manually defined and is not objectively optimized. To overcome these limitations, we aim to develop an MRI-only workflow for PT of UM in a multidisciplinary and multicenter approach. This project is to develop an MRI-based planning method with dose-based gaze-angle optimization.

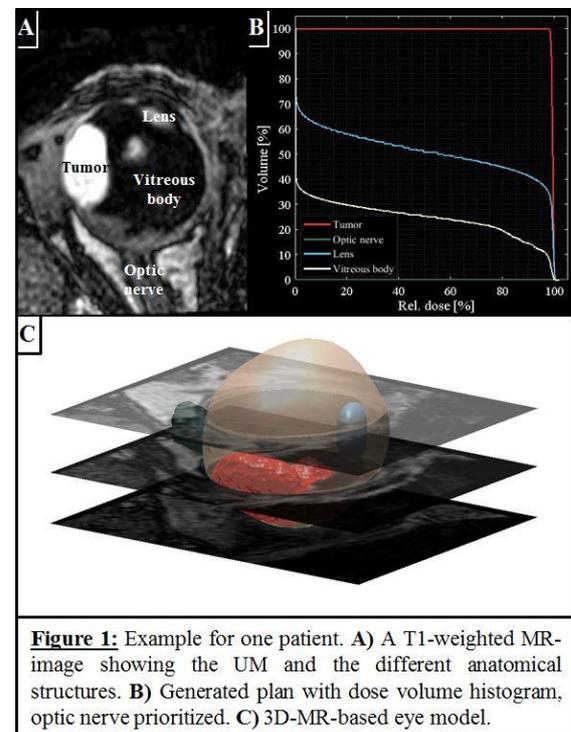

### Material and Methods

5 patients referred to a single academic center for UM treatment were prospectively included into the study after signing an informed consent. High-resolution ocular images were acquired on a 7T Philips Achieva MRI (Best,

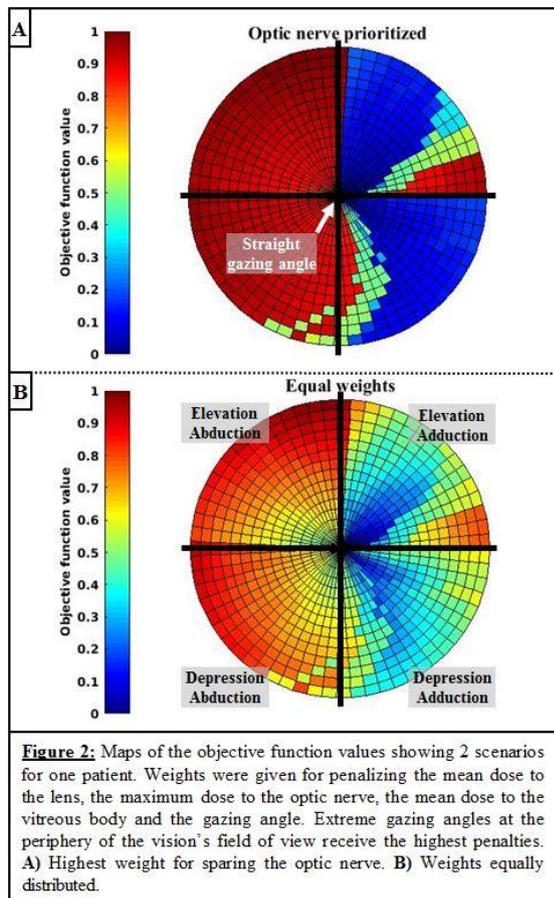

Netherlands) using a dedicated eye coil and sequences to reduce eye-motion artefacts. UM and OARs were automatically segmented, and subsequently, a 3D model of the eye was created (Figure 1). A TPS was developed in-house using a semi-analytical broad beam algorithm for passive scattering, in which the 3D eye-model was integrated. Human eye motion was mimicked through an Euler-sequence of rotations around the optical axis (abduction/adduction, elevation/depression and possible torsion). These rotations were used to simulate various clinically feasible gazing angles. For tumor coverage a safety margin was set by adjusting the range and modulation width of the Spread-Out-Bragg Peak proximal and distal edges. Lateral conformation was achieved by a collimator adjusted to the tumor contour. To optimize dose to OARs, a weighted-sum objective function was computed for each gazing angle, which also included an objective to penalize extreme gazing angles. Weights could be adjusted to prioritize sparing of specific OARs.

### Results

The novel treatment planning approach has been tested on 5 patients. Tumor coverage was reached for all cases ( $D_{95\%} > 95\%$ ). Figure 2 shows an example of the weighted-sum objective function for one patient for the clinical feasible gazing angles. Fig 2.A shows the map if optic nerve is prioritized. It shows that the half right's patient side should be avoided, while for the left half most angles are optimal. Fig 2.B shows the objective values for equally weighted sparing of OARs. This tool has great prospects for improving decision-making.

**Figure 1:** Example for one patient. A) A T1-weighted MR-image showing the UM and the different anatomical structures. B) Generated plan with dose volume histogram, optic nerve prioritized. C) 3D-MR-based eye model.

### Conclusion

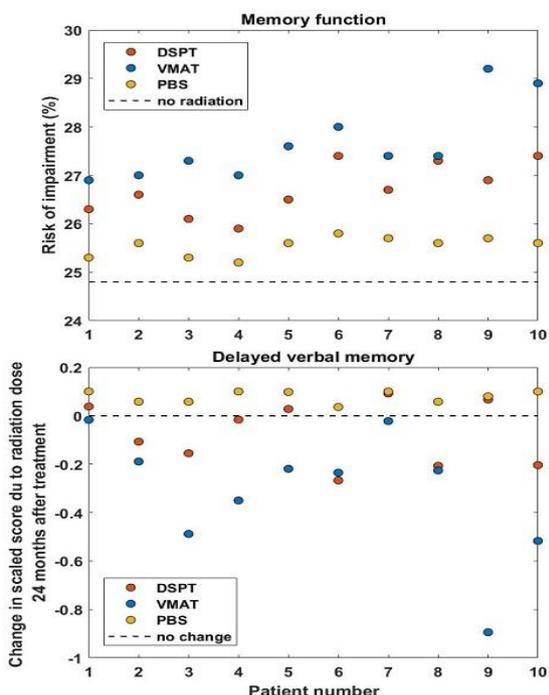

A MRI-based TPS for ocular proton therapy was developed. For the first time in eye proton therapy treatment planning, a trade-off for OARs sparing was implemented, while maintaining the tumor coverage.

### OC-0670 Temporal lobe sparing radiotherapy for cognitive preservation in pediatric brain tumor patients

*This abstract is part of the media programme and will be released on the day of its presentation*

**Figure 2:** Memory impairment estimates based on temporal lobe doses (top) or left hippocampus V20Gy (bottom). For the bottom panel, a positive score (higher than the 'no change' line) represents improved delayed verbal memory. Patients are sorted by increasing CTV volume, and results are presented for the three treatment modalities.

**Conclusion**

The irradiated volumes of temporal lobe BSCs were consistently the lowest with PBS, predicting better post-treatment memory in children with centrally located brain tumors.

**OC-0671 Which planning strategy is better for Head and Neck Cancer: PTV based or CTV based robust IMPT ?**

W.G. Wang<sup>1</sup>, A. Qin<sup>1</sup>, P. Kabolizadeh<sup>1</sup>, X. Li<sup>1</sup>, D. Yan<sup>1</sup>, G. Liu<sup>1</sup>, R. Deraniyagala<sup>1</sup>, I. Grills<sup>1</sup>, C. Stevens<sup>1</sup>, D. Krauss<sup>1</sup>, X. Ding<sup>1</sup>  
<sup>1</sup>Beaumont Health, Proton Therapy Center, Royal Oak, USA

**Purpose or Objective**

A comprehensive plan evaluation platform was established based on the daily Cone-Beam Computed Tomography(CBCT) to assess the treatment robustness quality between PTV based IMPT(PTV-IMPT) and CTV based robust optimized IMPT(ro-IMPT) planning strategies in bilateral Head and Neck Cancer (HNC) treatment.

**Material and Methods**

9 bilateral HNC patients' CT structure sets were used in this study. Daily CBCT were converted into synthetic-CT (sCT) for dose reconstruction. The accuracy of the proton dose calculation in sCT is cross-validated via the same day's verification-CT sim (vCT) with 3D gamma index comparison. PTV-IMPT and ro-IMPT were generated on the initial planning CT. CTV high-risk volume(CTV\_high) received 70Gy and CTV low/intermediate-risk(CTV\_low) received 60Gy. For PTV-IMPT, the PTVs were expanded 3mm from the CTV; For ro-IMPT, robust optimization used 3mm setup and 3.5% range uncertainties. Dose accumulations were then calculated on the 35 sets of daily sCT and the target coverages were compared to the initial plans.

**Results**

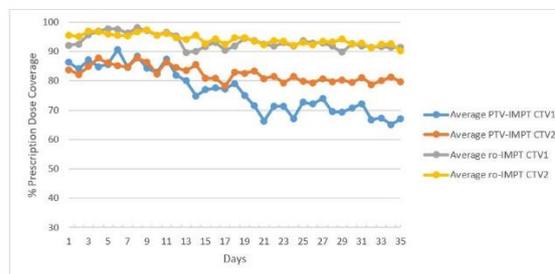

The 3D gamma index dose comparison (3mm/3%) showed an average pass rate of 98.2%+/-1.5% comparing the same day's pair of sCT and vCT with both plans (total 38 pairs). Through the dose accumulation of 35 treatment fractions, the PTV-IMPT plan group's mean V100 of CTV\_high/CTV\_low coverage degraded to 80.70%/85.73%

compared to 96.72%/96.13 of the ro-IMPT group (p<0.002). There was no significant difference in the OAR dose between the two planning strategies. One patient did have suboptimal coverage (CTV\_low <90%) even with ro-IMPT. Significant weight loss was noted for this patient during the treatment course (>5 lbs).

Table 1. Dose comparison between initial plan and dose accumulation from 35 fraction.

OAR	Planning Method	Initial Plan Mean (Range)	Accumulated Plan Mean (Range)
Brainstem max (cGy)	PTV-IMPT	1939 (703-2840)	2093 (1052-2714)
	ro-IMPT	1809 (933-2406)	1999 (1286-2682)
Spinal Cord max (cGy)	PTV-IMPT	2004 (1236-3258)	2516 (1283-3761)
	ro-IMPT	2204 (1489-3349)	2586 (1433-3655)
Ipsilateral Parotid mean (cGy)	PTV-IMPT	2943 (2104-3761)	3272 (2101-4276)
	ro-IMPT	2829 (2213-3465)	3178 (1903-3994)
Contralateral Parotid mean (cGy)	PTV-IMPT	1397 (862-1990)	1814 (1167-2697)
	ro-IMPT	1362 (983-2075)	1802 (1242-2979)
Mandible D0.1cc (cGy)	PTV-IMPT	6964 (6867-7007)	6986 (6708-7227)
	ro-IMPT	6993 (6865-7151)	7014 (6704-7132)
Larinx mean (cGy)	PTV-IMPT	4662 (3037-6152)	5030 (3327-6565)
	ro-IMPT	4674 (3100-6245)	4997 (3331-6288)
Oral Cavity mean (cGy)	PTV-IMPT	3391 (2102-4335)	3694 (2720-4703)
	ro-IMPT	3501 (2630-4917)	3749 (2736-5407)
Constrictor mean (cGy)	PTV-IMPT	5854 (5289-6266)	6003 (5377-6451)
	ro-IMPT	5699 (5152-6129)	5869 (5234-6385)
Constrictor V70Gy (%)	PTV-IMPT	23.3% (0-43.2%)	23.9%(10.9%-36.5%)
	ro-IMPT	19.7% (0-39.2%)	21.86%(0-40.6%)

Table 2. Average Dose Coverage to the target on the daily basis.

**Conclusion**

A comprehensive plan robustness evaluation platform based on the CBCT is established in our clinical workflow and enables dose accumulation and plan robustness evaluation on a daily basis. ro-IMPT demonstrated an optimal planning strategy over PTV-IMPT for bilateral HNC treatment. However, special cautions are needed for patients with significant weight or geometry changes.

**OC-0672 Proton radiotherapy for left-sided breast cancer in patients with pectus excavatum anatomy**  
 S. Korreman<sup>1</sup>, S. Andreassen<sup>2</sup>, J.B.B. Petersen<sup>1</sup>, B. Offeren<sup>3</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology and Danish Center for Particle Therapy, Aarhus C, Denmark ;  
<sup>2</sup>Aarhus University, Department of Physics and Astronomy, Aarhus C, Denmark; <sup>3</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

**Purpose or Objective**

For breast cancer patients with challenging anatomy, such as pectus excavatum, it can be impossible to cover the entire breast and IMN without exceeding dose limits to the organs at risk using standard techniques. Proton therapy

may present a solution to this, and warrant referral of this subgroup of breast cancer patients for protons.

#### Material and Methods

Five patients with left-sided breast cancer, and visually confirmed pectus excavatum, were included in the study. Three treatment techniques were compared: Standard two-field tangential plans (forward planned using dynamic wedges and field-in-field techniques, plus occasional use of low-weight patch fields from other angles), VMAT with two arcs with separate isocenters, and IMPT using two or three fields (see figure 1). All treatment planning was done in the Eclipse TPS vs 13.7 (Varian Medical Systems). For all plans, the objective was to cover the PTV (whole breast plus IMN) within 95-107% of prescription dose 50Gy, with dose limits to whole heart ( $V_{40Gy}<5\%$ ,  $V_{20Gy}<10\%$ ), left anterior descending coronary artery (LAD,  $V_{20Gy}=0\%$ ,  $V_{10Gy}<5\%$ ) and lung ( $V_{20Gy}<25\%$ , mean dose  $<18Gy$ ).

#### Results

Target coverage was generally better in proton plans than in photon plans - see figure 2a - and was more consistent between patients for protons than for photons. For none of the patients could the minimum target dose of 95% be achieved for the entire PTV, however for proton plans  $V_{90\%}>99\%$  could be achieved for all patients, and  $V_{95\%}$  was always above 93%.

For organs at risk, proton plans could achieve doses below the dose limit levels for all patients and for all considered OAR. In figure 2b dose to LAD is shown for all plans. For whole heart, the mean[range]  $V_{40Gy}$  for the five patients was 1.2[0;5.6] for protons, 1.2[0.2;3.1] for VMAT and 9.2[0.8;16.7] tangential photon plans. The mean[range]  $V_{20Gy}$  was 1.7[0.7;2.3], 13.6[8.4;27.4] and 16.4[4.2;28.2] for protons, VMAT and tangential plans. Mean heart dose was 1.6[0.9;3.1]Gy, 11.4[7.5;15.1]Gy and 9.2[3.6;14.4]. For LAD,  $V_{20Gy}$  was 0 for all proton plans and  $V_{10Gy}$  was 1.4[0;3.7]. For VMAT photon plans LAD  $V_{20Gy}$  was 6.2[0;19.3], and  $V_{10Gy}$  was 46.5[16.9;80.8]. For tangential photon plans  $V_{20Gy}$  was 50.2[23.4;67.2] and  $V_{10Gy}$  was 56.3[28.8;75.5].

For lung, the mean[range]  $V_{20Gy}$  for the five patients was 15.6[14.3;17.7] for protons, 30.9[25.8;39.4] for VMAT and 34.7[24.3;51] for tangential photon plans. The mean[range] mean lung dose was 7.6[7;9.6]Gy, 17.2[15.6;21]Gy and 17.3[12.3;24.4]Gy.

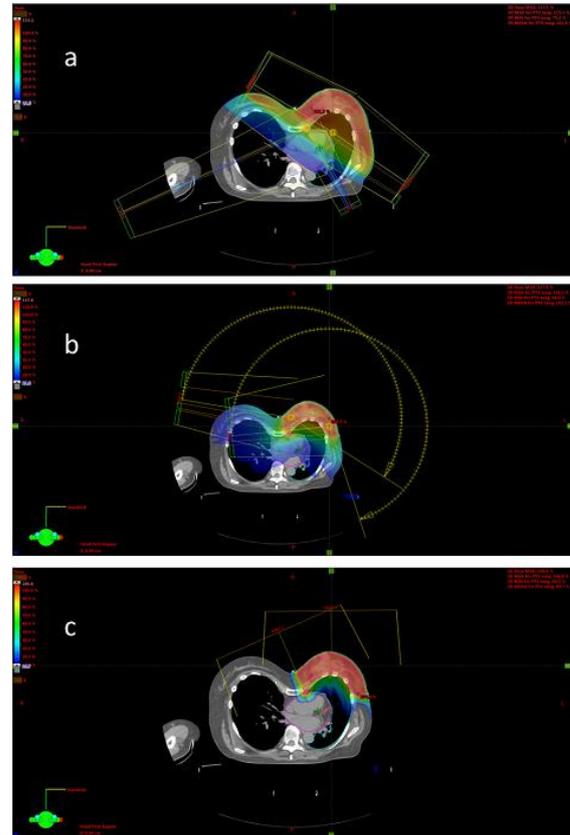

Figure 1:

The three planning techniques tested. (a) Tangential forward planned photon treatment using dynamic wedges and field-in-field, (b) Two-arc VMAT with separate isocenters, and (c) two-field proton IMPT.

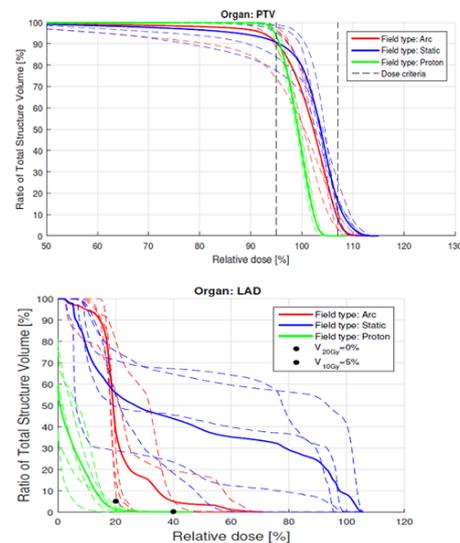

Figure 2:

DVHs for (a) target coverage and (b) LAD doses for the three planning techniques used. The dotted lines are for the separate patients, the solid lines are average DVHs over all patients.

#### Conclusion

For patients with left sided breast cancer, and the challenging anatomy pectus excavatum, proton therapy could advantageously be used to achieve adequate target coverage without compromising doses to organs at risk, for all patients included in this study. This could not be achieved for any of the patients using photon therapy with

any technique tested. For this subgroup of breast cancer patients the benefit from proton therapy is so large that it should be considered as an immediate indication for referral.

### OC-0673 LET variation as a function of different optimization approaches in proton beam therapy

G. Martino<sup>1</sup>, N. Van Lobenstein<sup>1,2</sup>, A. Carlino<sup>1</sup>, A. Resch<sup>3,4</sup>, M. Stock<sup>1</sup>, G. Kragl<sup>1</sup>

<sup>1</sup>MedAustron Ion Therapy Center, Medical Department, Wiener Neustadt, Austria; <sup>2</sup>Delft University of Technology, Faculty of Mechanical- Maritime- and Materials Engineering, Delft, The Netherlands; <sup>3</sup>Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Medical Radiation Research, Vienna, Austria; <sup>4</sup>Medical University of Vienna Austria, Department of Radiotherapy, Vienna, Austria

#### Purpose or Objective

Compared to photons, protons allow for decreased integral dose and an enhanced biological effectiveness, typically set to a constant value of 1.1. Amongst other factors, RBE depends on the LET of the projectile, which is increasing with decreasing proton energy. This creates concerns that a constant RBE might not sufficiently describe clinical situations where it is unavoidable to use beams stopping in front of critical OARs. In mixed particle fields, a dose-averaged LET ( $LET_d$ ) over the entire particle spectrum is a meaningful quantity to correlate to biological effect. In this work the computation of  $LET_d$  was performed with an MC algorithm available in a research version of the TPS RayStation. The  $LET_d$  computed in RS was benchmarked against Gate/Geant4. The aim of this work is to set up a validated tool to evaluate  $LET_d$  distributions resulting from different optimization strategies for cases with critical beam incidences.

#### Material and Methods

For LET benchmarking two regular shaped fields (box of  $5 \times 5 \times 5 \text{ cm}^3$ ) centered at a depth of 6 and 30 cm in water were optimized in RS and forward calculated in Gate/Geant4. All the plans were computed in a  $1 \times 1 \times 1 \text{ mm}^3$  dose grid. We compared depth  $LET_d$  profiles at the central axis of the two SOBPs and transverse  $LET_d$  profiles at three different depths corresponding to the distal part, central and proximal part of each SOBP. Plans were generated for a pediatric skull base case in RS using different optimization strategies (Single Field Optimization (SFO) and Multiple Field Optimization (MFO)), different number of beams (1 and 2), different maximum spot weights and number of distal energy layers (1 to 3).

#### Results

The benchmarking of RS against Gate/Geant4 showed an agreement within  $\pm 5\%$  for all depth  $LET_d$  profiles and transverse  $LET_d$  profiles analyzed (Fig. 1). The evaluation of Dose-Volume and LET-Volume Histograms within and around the PTV in our pediatric case showed that different optimization strategies lead to different dose and  $LET_d$  distributions in concentric rings around the PTV. Fig. 2 shows that the DVHs for a ring of 0.5 cm diameter around the PTV is similar for all optimization strategies. Here, the 2-fields SFO plan showed slightly higher integral doses. In all cases, the maximum value is the prescribed dose of 54 Gy(RBE). The corresponding  $LET_d$  showed lower values in the single-field plan in 60% and higher values in 40% of the ring volume. Very similar  $LET_d$  values were obtained in the SFO and MFO plans. The maximum  $LET_d$  value of the single-field plan is almost double if compared to the SFO and MFO plans.

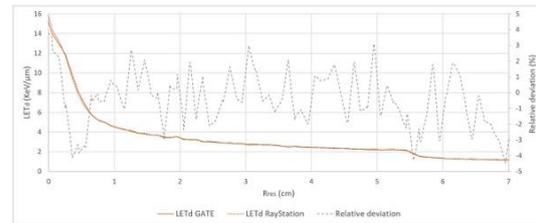

Figure 1: Depth  $LET_d$  profile computed with Gate/Geant4 (solid line) and with RS (dotted line) as function of residual range ( $R_{res}$ ) for the box placed at shallow depth (6 cm in water). The relative deviation in percent of the  $LET_d$  computed with RS from the  $LET_d$  computed with Gate/Geant4 is also shown.

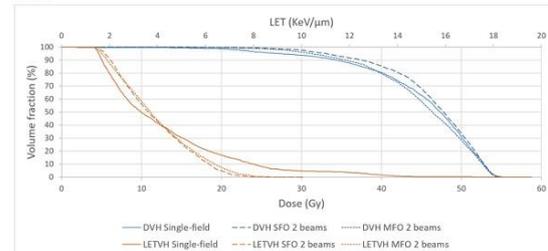

Figure 2: Dose-Volume histograms and LET-Volume histograms in a ring of 0.5 cm lateral distance from the PTV. The plans corresponding to three different optimization strategies are displayed: Single-field (solid line), two-fields SFO (dashed line) and two-fields MFO (dotted line).

#### Conclusion

$LET_d$  calculated by RS is in good agreement with Gate/Geant4 and offers a reliable tool for LET distribution display. Preliminary results suggest that 2-fields plans offer a better balance between  $LET_d$  and integral dose outside the target if compared to single-field plans. Altering the number of distal energy layers and the spot weight has an inferior impact (maximum 3% in the  $LET_d$ ) compared to increasing the number of beams.

#### Symposium: Focus on the Pelvic Region

### SP-0674 Status on adaptive strategies in the pelvic region - how far are we?

Y. Seppenwoolde<sup>1</sup>

<sup>1</sup>Medizinische Universität Wien, Department of Radiotherapy, Vienna, Austria

#### Abstract text

Despite the increased accuracy of irradiation techniques like IMRT and VMAT, sparing all organs at risk (OAR) in the pelvic area is still challenging because large changes in shape and position can be present due to variations in filling. With the introduction of cone-beam CT scanners and other on-board imaging systems, it became possible to observe these changes of internal organ configurations during each treatment fraction. Theoretically, this enables re-adaptation of plans according to tumour shrinkage and changes in OAR morphology, resulting in reduction of toxicity and better target coverage. Full online plan adaptation requires that re-delineation, re-optimizing of dose distributions and repetition of all legally required quality assurance steps should be performed in less than a few minutes. These workload intensive procedures would require a high degree of automation and workflow-integration that is still largely absent in off-the-shelf products.

Nonetheless, by finding a well-balanced compromise between full automation and degree of plan adaptation, it is possible to apply simplified schemes of adaptation that provides improved treatment. In clinical practice, different on- and offline methods are used. For cervix, bladder and rectum, volumetric imaging based library of plans, library of margins, 'ITV' with different steps of integration, (daily) reoptimisation or 'CBCT-guided evolutive library' are most appropriate,

often combined with an off-line way to detect tumor shrinkage. For cervix and bladder, inter/extrapolated motion prediction models can be generated based on pre-treatment imaging, though generation of these extra structures is still not straightforward and often based on in-house developed software.

For prostate, different ways of motion measuring are possible (i.e. implanted markers, RFID or ultrasound) because the prostate volume and shape remains primarily constant, just its global position varies, depending on surrounding organ filling/muscle motion. Tracking and gating can be used for the faster (intra-fraction) prostate motion.

For the library-based methods, plan selection is found to be robust: most studies show good correlation between online plan selection and offline clinician/expert panel plan selection; even with reduced image quality it is still possible to determine whether a target is within the pre-defined contours of the library. Reporting trustworthy dose-volume parameters to correlate with outcome is more of a challenge, as for the large and uncorrelated motion patterns in the pelvic region, DIR and dose warping algorithms are not well validated and re-delineation is too laborious (and not robust) on CBCT images to be used in clinical routine. Recent developments on CBCT based dose calculation are promising to improve this topic. An important aspect is patient safety: clinical (non-research) versions of commercial R&V software are not optimal for handling multiple plans of which only one is selected and the others disregarded, meaning that check and double check remains necessary to avoid mistakes. Robust and back-up procedures are necessary in case no decision can be made or if imaging fails.

#### SP-0675 Bladder filling - does it matter?

D. Bodusz<sup>1</sup>

<sup>1</sup>*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland*

##### Abstract text

Contemporary radiotherapy techniques of pelvic tumors may reduce normal tissue dose by conforming closely to target volumes. This allows reducing the toxicity of the treatment. To achieve this goal, it is necessary to reproduce the patient's position, the position of internal organs and their volume in accordance with the treatment plan performed in TPS (Treatment Planning System). The image guided radiation therapy techniques enable checking the position of internal organs as well as their volume. The protocol of preparation for radiotherapy includes obtaining the reproducibility of the bladder or rectum filling through the application of guidelines for patients. Many publications have shown the importance of bladder filling on CT images performed for treatment planning and bladder volume variations compared to the treatment plan during the whole course of radiotherapy. The main aim of this lecture is to summarize the available data in this topic, present our own experiences and give recommendations. This presentation will also focus on the discussion about various bladder preparation protocols, image guided radiotherapy techniques and on the impact of bladder volume on acute genitourinary toxicity.

#### SP-0676 MR-based treatment planning for prostate cancer

E. Persson<sup>1</sup>

<sup>1</sup>*Skåne University Hospital, Hematologi- Oncology and Radiation physics, Lund, Sweden*

##### Abstract text

MRI has today a given place in the radiotherapy workflow for several diagnoses. The superior soft tissue contrast of MRI makes it optimal for definition of the target area for radiotherapy. CT are traditionally used in the remaining

parts of the radiotherapy workflow, including delineation of organs at risk (OAR), treatment planning and reference images for patient positioning at treatment. For prostate cancer patients, MRI is optimal to differentiate between the prostate and surrounding soft tissues and OAR. To use the MRI for target definition requires a registration between the MRI and CT, often performed based on patient anatomy or fiducial markers in the prostate. This registration between two different image modalities are however associated with registration uncertainty. To avoid these registration uncertainties, which may occur when combining modalities, a radiotherapy workflow with MRI as the single modality has been proposed - called MRI-only. The reduction of uncertainty is especially important when radiotherapy is moving towards more precise techniques for treatment delivery and shrinking margins. An MRI-only radiotherapy workflow has great value for the patient, reducing the number of imaging sessions. To the clinic an efficient and possibly cost-reduced workflow are offered with simplified logistics.

To use MR as the single imaging modality in the radiotherapy workflow introduces technical obstacles. The systems used today in radiotherapy are traditionally based on CT-information and tasks such as treatment planning and patient positioning are not a straightforward procedure using MRI. Building an MRI-only workflow includes several changes of the current practice, where new tasks and new methods for quality assurance are needed. This includes quality assurance of the MRI for the purpose of treatment planning, generation of electron density information from the MRI referred to a synthetic CT or a pseudo CT to be used for treatment planning, identification of fiducial markers in the MRI and patient positioning strategies based on the MRI or synthetic CT information etc. Training and education plays also an important role of the implementation of new techniques and the introduction of new methods need to be performed in a safe way. The clinical implementation of MRI-only has been limited to a few centers, but recently the interest has increased and new clinics have started to adapt their own radiotherapy workflows to MRI-only. The clinical implementations covers both commercial solutions as well as in-house developed methods.

##### Abstract text

Oligometastatic prostate cancer is a variably defined target, and an area of growing interest. One key question is how best to define this state, as prognosis will be dependent on the imaging modality used (conventional v functional), the tissues involved (nodal v bone v visceral), tempo of disease and the number of lesions detected (1 v 3 v 5 v more). Timing is also critical, given that the oligometastatic state can be detected either at diagnosis or following local treatment. There are options to

consider regarding the integration with systemic therapy. When detected at diagnosis, we also have an evolving understanding on the management of the primary tumour. The technical issues of delivering ablative or potentially immuno-stimulatory radiotherapy to such lesions raise their own challenges. Here we will explore the biology, technology and ongoing clinical trial activity in the oligometastatic state of prostate cancer.

#### SP-0678 SBRT for oligometastatic NSCLC

S. Senan<sup>1</sup>

<sup>1</sup>VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands

##### Abstract text

The oligometastatic paradigm suggests that patients with a limited number of metastases should be amenable to a curative treatment approach. The existence of an oligometastatic disease state in NSCLC is gaining acceptance. In the eighth edition of the American Joint Committee on Cancer staging system for lung cancer, a single extrathoracic metastasis (M1b) is staged as a separate disease entity than are patients with more widespread metastases (M1c). New insights in tumour biology also support the concept of aggressive treatment for oligometastases in order to improve outcomes [Turajlic S, Science 2016]. Metastatic spread can take place through multiple routes and in different directions, with metastases continuing to evolve after they have disseminated from the primary tumour. Potentially, metastases can re-infiltrate the primary tumour or surgical bed, a process called self-seeding. In addition, cross-metastatic seeding can occur, resulting in complex subclonal mixtures in the metastases themselves. Metastases present at the time a primary tumour is diagnosed are termed synchronous, whereas lesions presenting later (generally >3 months) are referred to as metachronous metastases.

In contrast to the considerable body of evidence in support of ablative stereotactic radiosurgery in patients with brain metastases, evidence in support for SBRT to oligometastases at any extracranial site was poor until recently. In metastatic NSCLC with so-called druggable mutations, the advent of effective systemic treatments has led to changes in ESMO and NCCN guidelines, both of which now recommend the ablative treatment of isolated lesions that grow after an initial response (oligorecurrence), or which fail to respond completely (oligopersistence). An individual patient data meta-analysis in 757 patients with 1-5 synchronous or metachronous metastases identified 3 prognostic risk groups by recursive partitioning analysis [Ashworth A, Clin Lung Cancer 2014]. A good prognostic group identified were patients presenting with metachronous metastases (5-year Overall Survival 48%), an intermediate risk group presenting with synchronous metastases and no nodal metastases (5-year Overall Survival 36%), and a poor prognostic group with synchronous metastases and regional nodal disease (5-year Overall Survival 14%). Direct evidence for SBRT in metachronous disease has come from the SABR-COMET trial, which randomly assigned 99 patients who had a controlled primary malignancy and 1-5 metastatic lesions to receive either palliative standard of care (SOC) treatments alone [control arm] or with SABR to all metastatic lesions [SABR arm] [Palma DA, ASTRO 2018]. Of these, 19 patients had a diagnosis of lung cancer. Median overall survival was 28 months in the control arm (95% CI 19-33 months) versus 41 months in the SABR arm (95% CI: 26 months to 'not reached'; p=0.09). Median progression-free survivals were 6.0 months (95% CI: 3.4-7.1 months) versus 12 months, respectively (95% CI: 6.9-30 months; p=0.001). Although grade 3 and higher toxicities were commoner with SBRT, no decreases in quality of life were observed. These findings represent the strongest clinical evidence

available in support of SBRT in the metachronous oligometastatic state across many tumor types. In synchronous oligometastases, the findings from 3 small studies, including 2 randomized trials, suggested that adding local ablative therapy (including SBRT) in such patients could improve progression-free survivals (ranging from 9.7-11.9 months) versus only standard of care (range 3.5-3.9 months) [Gomez DR, Lancet Oncol 2016; Iyengar P, JAMA Oncol 2017; Petty WJ, IJROBP 2018]. An update from one such study suggested that the overall survival was also improved by the addition of local ablative therapy [Gomez DR, ASTRO 2018]. However, there is a clear need to perform adequately powered, prospective randomized clinical trials to address this issue, especially given recent improvements in systemic therapy of NSCLC patients without any driver mutation. Recently, a multi-disciplinary group recommended guidelines for conducting trials of synchronous oligometastases, which could serve to have ensure more uniform trial eligibility criteria [Dingemans A, WCLC 2018]. The key elements of this document were as follows: (i) The definition, based on a systematic review, is to have a maximum number of 5 metastases, and limited to 3 organs. (ii) Eligible patients should have disease where a radical treatment is technically feasible with acceptable toxicity, taking into account all sites, that may modify the course of disease leading to a long-term disease control. (iii) All disease sites must be technically and safely treatable aiming for long-term control. (iv) Mediastinal lymph node involvement must be considered as locoregional disease in this definition. Other issues relating to trial design, as well as technical challenges in SBRT delivery, will be addressed during the talk.

#### SP-0679 Challenges in SBRT physics

T. Kron<sup>1</sup>

<sup>1</sup>Peter MacCallum Cancer Center, Physical Sciences, Melbourne, Australia

##### Abstract text

Background: Stereotactic Body Radiation Therapy (SBRT) has become in very short time an accepted treatment approach within radiation oncology. SBRT utilizes many features of modern radiotherapy technology, such as image guidance, motion management and small often intensity modulated fields, to deliver high biologically effective doses of radiation in very few fractions. It is the purpose of this presentation to highlight technological challenges in this context.

##### Argument

From a physics perspective challenges in SBRT can broadly be divided into three groups related to: i) equipment and software, ii) patient selection and set-up, and iii) target definition and re-identification during image guidance. Commissioning of equipment, such as 4DCT and small field dosimetry, has traditionally the first hurdle for the implementation of SBRT. For most of these tasks there are now standard solutions, protocols and recommendations that provide guidance for this work. While there are always emerging issues such as the combination of contrast injection and motion management, technical progress with equipment and the emergence of audits specifically designed for SBRT delivery contribute to generally safe implementation pathways. Patient positioning and immobilization may be more challenging as each patient is different. Long treatment times and various motion management options add to the complexity. Reproducibility of set-up feeds directly into decisions as to what image guidance method is appropriate and how frequently it would need to be applied. A particular challenge is the fast and reliable interpretation of the acquired images, which in many institutions leads to the requirement of radiation oncologists being present during image guidance.

Automation, and computer aided image interpretation are emerging to address these issues.

#### Conclusion

SBRT has enriched the practice of radiation oncology. This has not been without challenges and technical and workflow issues highlight the need to engage the whole multidisciplinary team for successful SBRT implementation.

#### SP-0680 Hints on optimal dose and fraction number from lung SBRT

R. Ruggieri<sup>1</sup>

<sup>1</sup>Sacro Cuore Don Calabria Hospital, Radiation Oncology, Negrar, Italy

#### Abstract text

Initial lung SBRT treatments [1] suggested that the LQ-model for cell survival (CS) might be inadequate at as high doses per fraction ( $d$ ) as 20 Gy. However, when compared with more complex LQL-models, the LQ-model produced equivalent goodness-of-fit for in vitro CS data even at high  $d$ -values, if a dose-range dependence from  $\alpha$  and  $\beta$  parameters was recognised [2]. When different CS-models were next used for BED, and hence TCP, computations, equivalence in goodness-of-fit resulted also for local-control data of early-stage NSCLC [3]; thus supporting the LQ-model, given its least number of free parameters, as the most appropriate CS-model for fitting TCP from SBRT of early-stage NSCLC. Further, when intra-tumour  $\alpha$ -heterogeneity was also included in TCP modeling of local-control data from lung SBRT, to deal with the hypothesis that tumor response is determined from the most radioresistant tumour clonogen sub-population, the goodness-of-fit from the LQ-model was even superior to the alternative LQL-models [4].

Once meta-analyses supported the existence of a dose-response relationship for SBRT of early-stage NSCLC [5], and then for oligometastatic lung lesions [6], with saturation of the effects over some threshold dose, the prescription of a minimum total BED of 100Gy<sub>10</sub> became the golden rule. Such threshold, however, might be modulated according to the tumour volume [7]: by reducing the dose to the smaller tumours (<3cm), so as by increasing the dose to the larger ones (>5 cm). Further, already from the Metha's analysis [5] it was deducible a wide increase in the necessary dose to get from the 3-fractions schedule the same level of local-control of the schedules with 4-5 fractions.

The above two observations, that a radioresistant clonogen sub-population might play a key role in severe hypofractionation, and that schedules with 4-5 fractions may be isoeffective although the use of a reduced dose (BED) with respect to 3-fractions schedules, strongly suggest that tumor hypoxia and its reoxygenation may be pivotal to lung SBRT. In support of this hypothesis, *in vivo* evidence was reported since 1975 of an 'inverse' dose behaviour between 3 and 5 fractions: i.e.,  $D_{50}(n=5)$  lower than  $D_{50}(n=3)$  [8]. Models including tumour hypoxia were able to reproduce such 'inverse' dose behaviour [9-10], by the re-sensitizing effect of reoxygenation, thus supporting the use for lung SBRT of schedules with  $\geq 5$  fractions, instead of 3 fractions [11]. By modeling reoxygenation in terms of a mono-exponential time factor [11], it is also possible to explain the wide (30%) observed difference in 3-year local control after lung SBRT, if alternate instead of consecutive days for treatment were used [12]. In conclusion, without the need to invoke any different cell-killing effect of radiation as a function of the  $d$ -value, tumour hypoxia seems to be the likely determinant of the optimal dose, number of fractions, and inter-fractions time-interval for lung SBRT.

#### Symposium: Plan of the day - present status and future aims

---

#### SP-0681 Online adaptive planning in pancreatic cancer

O. Bohoudi<sup>1</sup>

<sup>1</sup>VUMC, Radiotherapy, Amsterdam, The Netherlands

#### Abstract text

In recent years there has been growing interest in using stereotactic body radiotherapy for treatment of pancreatic cancer. Upper abdominal tumours such as pancreatic cancer are particularly suitable for performing adaptive treatment planning, because of the dynamic nature and proximity of several critical normal organs such as the duodenum, stomach and bowel. Recently, MR-guided RT systems have been clinically implemented, offering exceptional options for stereotactic and adaptive radiotherapy which necessitates fast and robust online planning. The aim of this talk is to describe and discuss an adaptive online strategy which can be performed within minutes, and only requires limited (re-)contouring by the physician.

#### SP-0682 Future developments in adaptive strategies

U. Oelfke<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research, Joint Department of Physics, Belmont, United Kingdom

Abstract not received

#### SP-0683 Clinical results of PotD strategies

S. Hafeez<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom

#### Abstract text

Radiation technologies permitting high quality on-line imaging have demonstrated that the target for radiotherapy is dynamic. Many dosimetric studies have illustrated that accommodating for the individual's actual anatomical change offers opportunity for margin reduction with subsequent improved target coverage and normal tissue sparing. Clinical feasibility of this approach has also now been shown.

There are many examples in medicine where pressures and demands for high-tech treatment have led to widespread implementation of innovation before, or even without, robust evidence has been generated. Arguably, well-designed clinical trials remain the optimal method to demonstrate outcome benefit for patients. At present, how best to utilise this adaptive strategy in order to maximise the clinical gains for our patients remains to be determined. Head to head comparative studies of adaptive techniques may not be ambitious enough to demonstrate true potential. Instead it may be necessary to leverage the improved therapeutic ratio to deliver radiotherapy in circumstances that would have been otherwise challenging.

The aim of this talk is to present an overview of the current clinical evidence base, to discuss the trials in development that will provide future evidence base, and the challenges associated with clinical evaluation of technological innovation.

**SP-0684 MRI online ART: opportunities and pitfalls**  
**V. Valentini<sup>1</sup>**

<sup>1</sup>*Policlinico Universitario Agostino Gemelli-, Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Roma, Italy*

**Abstract text**

The recent introduction of the magnetic resonance guided radiotherapy (MRgRT) delivery units leads to the possibility to reduce most of the sources of uncertainty that currently influence radiation therapy treatments delivery. The more reliable visualization of the therapy volumes, achieved through the higher soft-tissue contrast provided by the MR imaging and the possibility to monitor the tumour and organs at risk (OARs) position during the treatment fraction using a high-temporal resolution MR cine imaging, address indeed the main pitfalls of standard delivery approaches.

Besides these technological advances, the main advantage offered by the MRgRT is the possibility to online adapt the RT treatment plan, changing the dose distribution while the patient is still in treatment position and successfully taking into account the anatomy of the day. Aim of this talk is to describe and discuss the opportunities and pitfalls of this innovative approach, highlighting its role in managing the inter and intrafraction motion variability, the segmentation strategies to date available and the dosimetric aspects of this technique.

**Debate: This house believes that immunotherapy is really changing radiation oncology**

---

**SP-0685 For the motion: This house believes that immunotherapy is really changing radiation oncology**  
**E. Deutsch<sup>1</sup>**

<sup>1</sup>*Institut Gustave Roussy, Radiation Oncology, Villejuif, France*

**Abstract text**

RT has been used for more than a century for the clinical management of virtually all cancers with extraordinary results, both in terms of side effects and efficacy. Immunotherapy is revolutionizing the clinical management of patients affected by an increasingly wide array of tumors. However, a limited percentage of patients achieve long-term clinical benefits from immunotherapy employed as a standalone treatment, calling for the development of combinatorial regimens. Radiation therapy (RT) stands out as a particularly promising candidate in this setting, reflecting not only its established safety profile, but also the potential ability of RT to mediate robust immunostimulatory effects that may synergize with immunotherapy in systemic tumor control. Combining RT with immunotherapy is a logical approach to enhance local and systemic anti-tumour immunity in locally advanced and metastatic cancers to improve outcomes in previously incurable cancer. However, optimal radioimmunotherapy regimens may call for the redefinition of conventional RT doses and fractionation schedules. We will have to redesign RT regimens for radioimmunotherapy to mediate superior efficacy in the presence of limited side effects. Revisiting doses and fractionation schedules, reducing delivery volumes, sparing both draining lymph nodes, limiting the use of cytotoxic chemotherapeutics, employing radiomics to longitudinally monitor responses.

<sup>1</sup>*German Cancer Research Center Dkfz, Radiobiology/ Radiooncology, Heidelberg, Germany*

<sup>2</sup>*German Cancer Research Center Dkfz,*

*Radiobiology/ Radiooncology, Heidelberg, Germany*

**Abstract text**

In this debate arguments will be given against the motion that immunotherapy is really changing radiation oncology. In particular, it will be pointed out that clinical evidence for a breakthrough by combining radiotherapy with immunotherapy is shaky. Worse, no good biomarkers are available to predict response of immunotherapy alone, not to speak about biomarkers in the context of radioimmunotherapy. Ideas on rationales and mechanisms are plentiful, however supportive data for these ideas are rare and weak. Further details will be revealed during the debate.

**Abstract text**

The advent of immunotherapy is currently revolutionizing the field of oncology, where different drugs are used to stimulate different steps in a failing cancer immune response chain. Radiotherapy modifies the tumor microenvironment, causes the release of tumor (neo)antigens and immunostimulatory signals, which can enhance the effect of immunotherapy. This talk will explore the possibility of bimodal treatment combining radiotherapy with immunotherapy, in particular immunocytokines (“push the accelerator approach”) rather than checkpoint inhibitors (“release the break approach”). L19 targets the extra domain B (ED-B) of fibronectin, a marker of tumor neoangiogenesis, and can be used as immunocytokine when coupled to Interleukin 2 (IL2). We hypothesized that radiotherapy in combination with L19-IL2 provides an enhanced antitumor effect, which is in particular dependent on ED-B expression. In summary, we have shown in several preclinical models that radiotherapy (RT) combined with L19-IL2 can induce a long-lasting antitumor effect (including a “memory effect”), dependent on ED-B expression and infiltration of cytotoxic T cells. We have shown that this effect is comparable if not superior to anti-tumor effect of checkpoint inhibitors (e.g. anti PD(L)-1) combined with single dose radiotherapy. Having recently completed a phase I safety clinical trial (NCT02086721), these promising preclinical studies will be translated to a multicentric, H2020 funded, randomized Phase II clinical study in NSCLC patients with less than 10 metastases ([www.immunosabr.info](http://www.immunosabr.info), see this link for the Youtube animation: <https://youtu.be/6wDE6RkriKA>).

**Abstract text**

Longterm locoregional recurrences (LR) after definitive CRT in SCC still occurs in about 35% and is significantly worse compared LR rates after pCRT + S (13%). Even in patients with a good initial clinical response LR is in favour of surgery although overall survival is comparable. Treatment morbidity, quality of life and treatment costs are generally considered in favour of dCRT. Thus there is a need for application of more organ sparing treatment. Studies will be discussed that on one hand are trying to improve the outcome of dCRT (dose escalation, endoscopic resection, new drugs) and on the other hand will improve

the selection of good responding patients by histological or radiological response assessment.

**SP-0692 Against the motion This House believes that patients with Squamous Cell Carcinoma (SCC) of Oesophagus no longer need surgery**

W. Allum<sup>1</sup>

<sup>1</sup>*Royal Marsden Hospital Trust and Institute of Cancer Research, Surgery, London, United Kingdom*

**Abstract text**

The management of oesophageal SCC is a fully multidisciplinary process. There are options for treatment and the selection for an individual patient requires careful discussion in the context of each individual's health, stage of disease and personal wishes. The availability of options stimulates significant differences in opinion amongst all oncology disciplines, not only reflecting available evidence but also the pattern of disease epidemiologically. Across Europe there are significant variations with surgery, usually with neoadjuvant treatments, in some centres and definitive chemoradiotherapy in others. In the UK there is an apparent 50:50 split between surgery and chemoradiotherapy. National audit data show similar results stage for stage. Furthermore many UK patients have significant co-morbidity precluding radical surgery. Despite the sensitivity of oesophageal SCC to combination chemoradiotherapy, the rates of recurrence vary. This can occur as residual disease at the end of treatment or recurrent disease some time after treatment. Past series have indicated that salvage surgery was hazardous with limited survival. However more recent series have shown that although complication rates are greater than primary surgery, in experienced centres these rates are manageable. Furthermore 5 year survival rates show similar outcomes for planned surgery after neoadjuvant treatment and for salvage surgery. As a result the option of more selective surgery needs further investigation with not only the evaluation of surveillance programmes but also to address patient preferences based on careful discussion of all evidence. There is therefore still a definite place of surgery in the treatment of oesophageal SCC.

**Symposium: Controversies in the management of brain metastases**

---

**SP-0693 Whole brain irradiation with hippocampal avoidance**

A. Grosu<sup>1</sup>

<sup>1</sup>*Universitätsklinik Freiburg, Dept. of Radiation Oncology, Freiburg, Germany*

**Abstract text**

In patients with multiple brain metastases of solid tumors a whole brain radiotherapy (WBRT) is the most widely used treatment option. WBRT is associated with considerable neurotoxicity and may reduce the patients' quality of life. It is known that neural stem cells are located in the hippocampal region, supporting lifelong neurogenesis. The reduction of hippocampal functions like learning and memory as a consequence of WBRT is explained by damage to neural stem cells and by a lower ability for regeneration of neuron populations. Avoidance of neural stem cells in hippocampus may help to reduce the neurotoxicity of WBRT. Several studies have shown that a dose escalation to the brain metastases contribute to better local tumor control and putatively longer overall survival. By the use of new irradiation techniques a WBRT with hippocampal sparing and concomitant boost to the metastases (HA-WBRT) is feasible. The HIPPORAD - NOA 14 project aims to investigate the benefits of HA-WBRT compared to WBRT

without hippocampal avoidance on memory performance of patients treated for brain metastases. On a second level, structural and functional changes of the brain will be investigated which underly the neurocognitive side-effects of both treatments applying state-of-the-art neuroimaging techniques. It is hypothesized that the novel, recently established technique of WBRT with dose escalation to brain metastases and hippocampal avoidance minimizes the side-effect of cognitive deterioration while at the same time providing an optimal treatment for brain metastases.

**SP-0694 Radiosurgery alone in multiple brain metastases**

J. Zindler<sup>1</sup>

<sup>1</sup>*Erasmus MC, Radiotherapy, Rotterdam, The Netherlands*

**Abstract text**

Stereotactic radiosurgery (SRS) alone is a promising treatment strategy in the multimodality treatment of brain metastases (BM). Especially in low volume BM high local control rates can be achieved. Compared to whole brain radiotherapy (WBRT) it is assumed that the risk of side effects such as alopecia, fatigue, and neurocognitive damage is less and thereby quality of life is better preserved. Disadvantages of radiosurgery alone is the relatively high risk of development of new brain metastases during follow-up and a risk of symptomatic radionecrosis, especially in high volume BM. These disadvantage may impair quality of life of the patient. In the setting of more than 3 BM there is no level I evidence for the use of SRS in both low as high volume BM. Also for the use of WBRT, there is a general lack of level I evidence, especially since the publication of the QUARTZ trial in the primary setting (Mulvenna 2016), but also after the EORTC-trial (Kocher 2011/Solfiotti 2013) in the elective setting. Nowadays SRS is generally accepted as a treatment option for patients with a maximum of 3 BM. The main question is if SRS preserves better quality of life than WBRT in the setting of more than 3 BM, taking into account both the advantages as the disadvantages of SRS. This question is addressed in the Dutch NCT02353000 trial (Zindler 2017). Another potential value of SRS in the setting of a multimodality treatment with immunotherapy (Schoenfeld 2015) is the induction of a so called abscopal effect. Also upfront SRS in the setting of targeted agents is a promising treatment strategy to enhance penetration of the blood-brain barrier (Magnuson 2017). In conclusion, SRS is a promising treatment strategy for patients with more than 3 BM, but also in a multimodality approach with immunotherapy and targeted agents. In a rapidly changing field with more and more systemic treatment options, both the use of SRS as WBRT needs to be redefined in the setting of BM.

**SP-0695 Systemic treatment as alternative or addition to radiotherapy**

Nicolaus Andratschke<sup>1</sup>

<sup>1</sup>*University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland*

**Abstract text**

Brain metastases are common events in the natural course of many metastasized solid cancers like breast, lung and renal cancer or melanoma with a cumulative risk of 10-30% in adults. Radiotherapy has been the mainstay of treatment and cytotoxic systemic therapy was not considered a viable option as sole treatment strategy.

Still in recent years, complex treatment strategies have been developed and this has impacted on the general management of brain metastases, although formal comparative level I evidence is still missing.

As a prime example, management of NSCLC patients with brain metastases has changed significantly since the

introduction of potent TKI drugs targeting specific driver mutations with significant CNS efficacy. The role of immunotherapy in treating BM is less clear, but initial reports tend to challenge upfront local brain directed treatment as well. Regardless of the recent advances CNS failure remains a significant challenge in these patients and there is a clear need to precisely define the role and optimal timing of local therapies. This will be critically reviewed in the context of BM from NSCLC as we.

Finally, a quick look to BM from melanoma and breast cancer will reveal similarities and differences in the management of BM compared to NSCLC.

**SP-0696 Integration of surgery and radiosurgery**

S. Blamek<sup>1</sup>

<sup>1</sup>*Maria Skłodowska-Curie Institute and Cancer Center-Gliwice Branch, Department of Radiotherapy, Gliwice, Poland*

**Abstract text**

The results of recently published randomized clinical trials indicate that radiosurgery should be preferred over whole brain radiotherapy (WBRT) in patients with resected brain metastases. Along with the results of the studies showing the advantages of SRS as opposed to WBRT in patients with intact metastases, they put radiosurgery in the position of the first choice treatment in patients metastatic disease in the brain. Nevertheless, there is still a number of patients who will benefit from neurosurgical resection of the metastatic tumor. Patients with large lesions, tumors with cystic component, presenting symptoms of mass effect and compression of neural structures are pointed out as potential candidates for surgery. On the other hand, there is emerging evidence that good outcome in patients with large metastases treated with hypofractionated radiosurgery can be achieved even in patients harboring tumours exceeding 4 cm in diameter. It is now commonly accepted that the limiting factor for the use of radiosurgery is not the number of metastases but rather the total volume of the tumours in the brain. It is true for single fraction treatment but in case of fractionated treatment the total volume of the neoplasm may play less important role. Consequently, the indications for surgical treatment in case of single and multiple metastases both in the setting of primary management and salvage after treatment failure are evolving. There is also much controversy about target definition for radiosurgery in case of postoperative treatment. Cavity shape and volume change over time which makes timing of postoperative radiosurgery one of the factors influencing outcome. Alternatively, preoperative radiosurgery emerges as a solution, potentially allowing for combination of benefits of surgery and radiosurgery without jeopardizing outcome, especially in the context of postulated association between surgical procedure and the risk of leptomeningeal disease. Finally, the issue of differentiation between radiation necrosis and tumour progression is gaining importance. The patients are followed up with MRI after the initial treatment which allows for detection of tumor volume increase far before clinical symptoms become apparent. It results with more effective salvage treatment but at the same time the risk of unnecessary intervention is increased and the first choice salvage treatment less obvious.

**SP-0697 How to handle clinical inter-observer variation in contouring assessment**

M. Gooding<sup>1</sup>

*<sup>1</sup>Mirada Medical Limited, Science and Medical Technology, Oxford, United Kingdom*

#### Abstract text

“You don't learn to walk by following rules. You learn by doing, and by falling over” - Richard Branson.

To learn from our mistakes, we need to understand that we have made them first, and then find ways to address them. In this talk, we will look at the ways through which we can assess contouring accuracy, including quantitative, qualitative and dosimetric approaches, giving examples from published literature. However, such assessment is often confounded by clinical inter-observer variation, so we will also consider how we can address this in our assessments and consider its potential clinical implications. We will summarise by discussing what approaches can be taken to help us improve contouring quality.

#### SP-0698 CT-based delineation: What can we gain from state-of-the-art CT image acquisition and reconstruction techniques

C. Richter<sup>1,2,3,4</sup>, F. Negwer<sup>1</sup>, E.C. Troost<sup>1,2,3,4,5</sup>, P. Wohlfahrt<sup>1,2</sup>

<sup>1</sup>Oncoray - National Center For Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden-Helmholtz-Zentrum Dresden - Rossendorf- Dresden-Germany, Dresden, Germany; <sup>2</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute Of Radiooncology, Dresden, Germany; <sup>3</sup>Department of Radiotherapy and Radiation Oncology, Faculty Of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany; <sup>4</sup>German Cancer Consortium Dktk, Partner Site Dresden, Dresden, Germany; <sup>5</sup>National Center for Tumor Diseases NCT, Partner Site Dresden, Dresden, Germany

#### Abstract text

X-ray computed tomography (CT) has been the standard imaging modality in radiation oncology for both, treatment planning and delineation of targets and organs at risk for decades. For further improvement, especially for delineation, magnetic resonance imaging (MRI) and positron emission tomography (PET) are being extensively investigated and more often included into clinical routines. They can provide better soft tissue contrast and functional information. Still, also in the field of CT imaging relevant improvements have been made, that are not so much in the spotlight. Hence, this talk will focus on novel CT image acquisition and reconstruction techniques and their potential benefit for radiation oncology applications.

First, the potential value of dual-energy CT (DECT) for delineation will be discussed. DECT has already been proven to allow for a more accurate treatment planning, especially in particle therapy. It provides additional tissue information compared to conventional CT imaging. Furthermore, DECT enables the reconstruction of different CT datasets with varying image contrasts. Currently, it is unproven whether this additional information translates into improvement of the segmentation and delineation quality. The exploration of this benefit in combination with machine learning approaches is envisioned. First studies will be presented. Second, the potential of iterative CT reconstruction methods will be highlighted. They allow for a substantial reduction of imaging dose to reach a similar noise level as conventional filtered back projection. Hence, iterative reconstruction is of high relevance for adaptive protocols as it reduces the dose burden from more frequent CT imaging during treatment.

Third, the value and challenges of metal artefact reduction algorithms will be covered. It has been shown that the visual image impression can be substantially

improved for regions suffering from metal artefacts in conventional CT reconstruction, suggesting a direct benefit for delineation purposes. However, as these algorithms can also quantitatively alter the image in regions not influenced by metal artefacts, great care should be taken - especially in particle therapy planning. In summary, state-of-the-art CT imaging can provide additional value for radiation oncology purposes. This talk aims to increase awareness of this potential. By revisiting the institutional imaging protocol, one can potentially improve the image quality for delineation and/or safe dose to patients.

#### SP-0699 Development of MR techniques focused on improved delineation

M. Philippens<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology- Q.00.3.11, Utrecht, The Netherlands

#### Abstract text

Tumor delineation and delineation of organs at risk is an important but still difficult step in steering the dose in the treatment planning. Contouring of the tumor is mostly guided by changes in anatomy, asymmetry, and contrasts in the images. Also for the delineation of OAR contrast is needed to distinguish the organ from the background. As CT contrast of soft tissues is limited even after contrast administration, MRI is a logical choice to improve contrasts. The MR signal originates from the protons in water or fat. By manipulating the signal in a MR sequence the contrast can be adjusted. The delineation of gross tumor tissue (GTV) is in conventional radiotherapy mostly restricted to the pretreatment phase or when large changes have been recognized during therapy. However, with the introduction of MR linacs in the radiotherapy, MR delineation of both the GTV and OAR will become daily practice during treatment.

Conventional MR contrasts are T1 and T2 weighted (T1w and T2w, respectively), which can be combined with fat suppression as fat has a high signal intensity on both T1 weighted as T2 weighted MRI. Generally, observers do agree better on delineation of OAR on MRI than on CT. Also for prostate and nasopharynx tumors, MRI has shown to decrease the target volume. For other tumor sites, increase of tumor volume is very common. This might be due to tumor induced changes in the vicinity of the tumor, which are included by the observers. This shows that although the soft contrast is much better on MRI, the interpretation might be more difficult. Therefore, clear guidelines are needed to improve tumor delineation or MR contrasts which are easier to interpret. Both dynamic contrast MRI and diffusion weighted MRI are widely used. These techniques, also referred to as functional imaging, reflect the status of the microvasculature and the microanatomy. The drawback of DCE-MRI is that rigorous post-processing is needed to effectively use it for contouring. Diffusion weighted MRI gives high contrast, but is frequently inadequate due to deformations which are inherent to the acquisition method used, echo planar imaging (EPI). Recently, several advances have been made to mitigate these distortions. One approach is to decrease the distortions in the EPI using acquisition acceleration methods. Another approach is to replace the EPI acquisition with a fast spin echo or steady state free precession method, which are both used for standard clinical MR acquisition. The disadvantage is that the acquisition is slower and motion artefacts have to be tackled.

The role of DCE-MRI in delineating the gross tumor volume (GTV) has been studied in prostate, head and neck, cervical cancer and brain.

Diffusion weighted MRI has been more frequently studied as a tool to improve the delineation. The high contrast between tumor and background might even allow automatic delineation. Also diffusion tensor imaging (DTI)

has been applied in the brain, where it might help contouring glioma invading the white matter. Although different MR imaging contrasts might give different GTVs, we know that in imaging we will never see all tumor tissue. Therefore, CTV margins are used in daily clinical practice. The better the imaging resembles the histology of a tumor, the smaller the CTV margin that has to be applied. The extent of the tumor outside the delineated volume can be determined using pathological validation of the tumor using histology. As MR imaging develops, the historical CTV margins might be too large as was illustrated for laryngeal cancer [20]. For brain tumors also blood oxygen level dependent MRI also referred to as functional MRI (BOLD fMRI) can be used to avoid functional regions in the brain. This technique shows the vascular response to neuronal activity. Besides contrast also high resolution can help to better define small structures, such as cranial nerves in case of perineural growth or small lymph nodes. Besides MR imaging, also MR spectroscopy has played a role, but never became a widely spread method, probably due to the demanding level of expertise. Particularly for brain and prostate, 1H MR spectroscopic imaging has shown its value.

Due to the emerging MR guided radiotherapy, highly accelerated techniques for motion characterization, tracking and gating in combination with sufficient contrast to distinguish the tumor and OAR are being developed. As response monitoring during treatment is important for adaptation of radiotherapy, especially DWI is being further developed.

In summary, the use of MRI in radiotherapy will increase in the near future as delineation will not only be part of the pre-treatment imaging but also of the treatment guidance. Therefore, the choice of MR imaging techniques which give a high contrast and allow fast acquisition are desired to make improve delineation accuracy and variation.

#### SP-0700 The future of margins in the era of new (multi-modality) imaging technology

J. Stroom<sup>1</sup>, S. Vieira<sup>1</sup>, C. Greco<sup>1</sup>

<sup>1</sup>Fundação Champalimaud, Radiation Oncology, Lisboa, Portugal

##### Abstract text

A large part of technical development in radiotherapy this century has concentrated on improving treatment accuracy through use of new imaging technology. During planning, MRI and PET imaging techniques have been applied to add precision to target delineation. During treatment, off-line correction strategies based on MV portal images have been gradually replaced by online corrections and plan adaptations using cone-beam CT. On-line MRI capabilities are now being introduced to refine treatment setup even further, and several systems for intra-fraction monitoring of moving patient anatomy are available.

However, in this presentation we will try to make the point that even with all the new imaging techniques, it might be worthwhile to hold on to safety margins for standard fractionated treatments for a while. Whereas systematic and random uncertainties, often denoted by standard deviations  $\Sigma$  and  $\sigma$ , should diminish when applying the above-mentioned imaging techniques, they will not reduce to zero. So, for fractionated radiotherapy, margin recipes of e.g. the form  $A\Sigma + B\sigma$  might still be applied, albeit with smaller values for  $\Sigma$  and  $\sigma$  as before. On the other hand, even though they are widely used, there still are several unresolved issues regarding margin recipes. To start, no randomized clinical studies have proven one margin recipe over another. Then, the added value of using ITV for breathing motion is highly debatable and delineation uncertainties are frequently ignored, just like uncertainties in microscopic disease. Moreover, it is

assumed that margins for microscopic disease (CTV) and geometrical uncertainties (PTV) should be kept separated. These issues will all be discussed.

Finally, the main effect of the new imaging modalities on radiotherapy safety margins might be indirect. The improved accuracy and smaller margins allow for ever higher treatment and fraction doses. There is now evidence that a different radio-biology applies to single-dose radiotherapy (SDRT). Apart from the standard radiation mechanism that targets misrepair of double strand breaks, higher fraction doses (> 12Gy) are believed to also induce tumor cell kill by injuries to the tumor microvasculature. We will discuss the possible consequences of SDRT on safety margins; margin factors A and B might change and even negative margins are not unthinkable.

#### Symposium: A new era for radiotherapy (anthropomorphic) phantoms

---

#### SP-0701 Personalized phantoms through 3D printing

S. Crowe<sup>1</sup>

<sup>1</sup>Royal Brisbane and Women's Hospital, Cancer Care Services, Herston, Australia

##### Abstract text

The application of 3D printing (or additive manufacturing) technologies and techniques in medical physics has exploded in the past five years. 3D printing has been widely used for treatment equipment, including bolus, compensators, shielding, immobilisation devices and brachytherapy applicators. These bespoke patient-specific solutions can be precisely fabricated, in a cost-effective way, with limited expertise.

For the medical physicist, 3D printing allows the fabrication of a wide variety of tools for quality assurance, of varying complexity. The simplest applications include ancillary dosimetry equipment such as jigs or build-up caps; followed by simple phantoms for mechanical, dosimetric and imaging QA; and custom inserts for existing QA phantoms.

Perhaps the most exciting application is the fabrication of anthropomorphic phantoms, suitable for evaluating new treatment and imaging technologies and techniques, end-to-end audits, trial accreditations, and answering research questions. 3D printed phantoms can include (and have included) variable density media, radionuclides, programmable motion, deformable components and embedded 3D gel dosimeters.

This presentation summarizes the scientific literature surrounding 3D printing as applied to medical physics phantoms; provides advice for design, fabrication and QA; and describes the local experience of a radiotherapy department attached to a 3D printing and biofabrication research institute.

#### SP-0702 Do we need to touch? Latest developments in physical and digital phantoms for 4D radiotherapy

C. McGarry<sup>1,2</sup>

<sup>1</sup>Belfast Health and Social Care Trust, Northern Ireland Cancer Centre, Belfast, United Kingdom; <sup>2</sup>Queen's University Belfast, Centre for Cancer Research AqD Cell Biology, Belfast, United Kingdom

##### Abstract text

Physical and digital anthropomorphic phantoms have been developed to represent the human body's anatomy and attenuation characteristics for imaging and dosimetric studies in radiotherapy over many years. With the advancement of multimodality imaging used to capture intra-fractional motion at the pre-treatment and delivery stages of the radiotherapy process, dynamic phantoms have emerged with varying levels of complexity for

imaging and dosimetry purposes. Dynamic phantoms require the addition of organ motion correlated with breathing traces to ensure that they are patient mimicking.

Digital or 'computational' anthropomorphic phantoms are typically created from acquired tomographic images, segmentation of organs, and specification of organ densities / chemical composition before a final registration of the segmented images into a 3D volume. Computer simulations are extremely adaptable; allowing control of anatomical features using physics based algorithms. Organ trajectory, shape and density do not always truly represent the patient in computational simulations as intended. Moreover, instead of representing patient specific characteristics, most available anthropomorphic phantoms are created using population-averaged characteristics. However, due to the versatility of computational phantoms, multiple phantoms have emerged which represent a wider population without the cost of manufacturing.

Physical phantoms have the added steps of manufacturing the organs and placing them inside a body securely. A plethora of in-house and commercial dynamic radiotherapy phantoms have been developed for imaging and dose verification. These range from simple homogeneous phantoms, placed on unidirectional moving platforms, to phantoms with 6 degrees of freedom motion with lung and cardiac deformations. Physical phantoms can be used in Institution-specific protocols and can include pre-treatment imaging, dose delivery and pre-treatment verification including local set-up procedures. Trade-offs between reproducibility and the magnitude of organ deformations are inherent in the manufacture of physical dynamic phantoms. Emerging phantoms will need to account for the increasingly diverse methods of external tracking which must be accurately correlated with internal tumour motion.

With the advent of 3D printing technology and advanced material development, it is clear that improvements in physical dynamic anthropomorphic 4D phantoms will follow for radiotherapy validation. Similarly, computational phantoms will advance significantly with improved resolution, texture and deformation models. This presentation will summarize the advantages and limitations of each dynamic phantom type and will discuss if future 4D radiotherapy research should be in the digital or physical domain, or both.

#### SP-0703 MR Linac anthropomorphic end-to-end QA phantoms: IROC-Houston's experience

A. Steinmann<sup>1</sup>, D. Followill<sup>2</sup>

<sup>1</sup>Ohio State University Wexner Medical Center, Radiation Oncology, Columbus- Oh, Usa ; <sup>2</sup>University Of Texas Md Anderson Cancer Center, Outreach Physics, Houston- Tx, Usa

##### Abstract text

The National Cancer Institute (NCI) requires participating institutions intending to use IMRT in NCI-sponsored clinical trial to first become credentialed by demonstrating their ability to accurately deliver radiation. The Imaging and Radiation Oncology Core at Houston (IROC-Houston) has developed various site-specific anthropomorphic phantoms that are used in the credentialing process. These conventional phantoms were originally designed as end-to-end QA tests for traditional CT-only radiotherapy workflow.

Unlike conventional linear accelerators, magnetic resonance imaging guided radiotherapy MRIGRT systems use CT images to capture electron density information for treatment planning and MR images to verify treatment setup, treatment guidance and online adapted radiotherapy. Using a single phantom to perform an end-to-end QA test means the phantom must be used and visualized in both CT and MR imagers. IROC-Houston's

conventional phantoms are constructed of rigid materials that lack MR signal. This lack of signal causes the tumor and surrounding tissue to be indistinguishable in MR imagers. Therefore, IROC-Houston's conventional phantoms are not adequate for MR/CT workflows and new end-to-end QA head and neck (H&N) and thorax phantoms must be constructed for MRIGRT systems. The main purpose of this study was to design and manufacture a stationary H&N and dynamic thorax anthropomorphic QA phantom that could be used as an end-to-end tool to credential institutions for MRIGRT systems. These phantoms were designed for MRIGRT systems that have a magnetic field ranging from 0.35T to 1.50T and were constructed with MR/CT visible and dosimetrically tissue equivalent materials. An MR conditional pneumatic system was also designed for the MRIGRT thorax phantom to enable lung motion during CT simulation and treatment.

With the purpose of these phantoms being used as a remote end-to-end auditing tool for credentialing institutions in NCI-sponsored clinical trials, these phantoms were also evaluated through a reproducibility and miniature feasibility study. The reproducibility study was conducted by irradiating each phantom three times on a Unity MR Linac system (7MV/1.5T). The miniature feasibility study was performed by sending both MRIGRT H&N and thorax phantom to three institutions and were irradiated on either an MRIdian (Co-60/0.35T) or an MRIdian Linac (6MV/0.35T) MRIGRT system. The phantoms were evaluated using EBT3 radiochromic film and TLDs and used the same dose constraints and passing criteria as IROC-Houston's conventional H&N and thorax phantoms. This lecture will discuss the designs, constructions and treatment evaluations for both IROC-Houston's MRIGRT H&N and dynamic thorax phantom.

#### SP-0704 Phantoms in particle therapy to verify Monte Carlo dose calculation

P. Wohlfahrt<sup>1,2,3</sup>

<sup>1</sup>Massachusetts General Hospital and Harvard Medical School, Department Of Radiation Oncology, Boston, Usa ;

<sup>2</sup>Oncoray - National Center for Radiation Research In Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus - Technische Universität Dresden - Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany; <sup>3</sup>Helmholtz-Zentrum Dresden - Rossendorf, Institute Of Radiooncology - Oncoray, Dresden, Germany

##### Abstract text

High-conformal treatment techniques, such as intensity-modulated radiotherapy or volumetric arc therapy in photon therapy as well as pencil-beam scanning in particle therapy, have been developed in the last decades to achieve a high tumor coverage while sparing healthy tissue more effectively. These technological achievements already led to an improved clinical outcome. Further sophisticated developments in imaging for tumor detection and treatment planning (e.g., dual-energy computed tomography, quantitative and functional magnetic resonance imaging as well as targeted positron emission tomography), and dose calculation (e.g., robust optimization and Monte Carlo algorithm) recently enter the routine clinical workflow. These continuous improvements in treatment precision and accuracy are associated with challenges for medical physicists in the verification of its proper functionality and assessment of its remaining uncertainty. Simplified phantoms, which not adequately simulate the geometrical complexity and tissue heterogeneity of patients, are often not sufficient to represent realistic clinical scenarios and to demonstrate the benefits of new advanced technologies. The use of anthropomorphic phantoms of known composition are suitable for such an experimental validation but require measurement setups close to the physical limits. Here, the generation and experimental

verification of a ground-truth anthropomorphic head phantom as well as its application for treatment planning, Monte Carlo dose calculation and range verification in particle therapy will be presented.

**Debate: Workload/clinic logistics, and not technical uncertainties, are the main barrier to widespread implementation of adaptive RT practice**

---

**SP-0705 Practicalities and Not Technical Uncertainties Limit the Clinical Implementation of Adaptive Radiotherapy**

M. Velec<sup>1</sup>, E. Forde<sup>2</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Medicine Program, Toronto, Canada ; <sup>2</sup>Trinity College Dublin, Discipline Of Radiation Therapy, Dublin, Ireland

**Abstract text**

Image-guided radiotherapy has revealed the dynamic nature of patients who can unexpectedly exhibit positioning variations, substantial organ motion and deformation, weight loss and tumour responses. This motion degrades the planned dose, decreases treatment quality and may impact clinical outcomes. Systematically adjusting for these patient-specific variations through adaptive plan modification can improve the therapeutic ratio in individual patients and enable planning target volume reduction thereby reducing dose to nearby radiosensitive structures. However, widespread clinical implementation of adaptive radiotherapy including evaluation in clinical trials has been slow. This is in part due to ongoing technical issues, including the accuracy of tools vital to adaptive radiotherapy; such as auto-segmentation, auto-planning, deformable registration, and uncertainty in defining responding clinical target volumes. Appropriate commissioning and QA of these processes combined with conservative adaptation for targets can potentially overcome these safely. Another more palpable barrier to implementation is that clinical workflows are not yet streamlined enough for patients and staff to be practicable. Routine radiotherapy processes that are required for adaptation, including repeat imaging, planning and QA, can increase workload and create bottlenecks in the clinic. These logistics may potentially be overcome with adequate clinical experience, which may include RTTs assuming greater responsibility and independence in decision making and developing expertise in adaptive tools. Debate on whether practicalities or technical uncertainties limit the clinical implementation of adaptive radiotherapy will provide the community with direction on where future efforts should be focused. Widespread use of adaptive strategies will ultimately improve the effectiveness of radiotherapy by accounting for dynamic patient changes, and ensuring tumour control while minimizing toxicities.

**PO-0709 External beam radiotherapy for metastatic lesions of differentiated thyroid cancer**

M. Kenji<sup>1</sup>, Y. Hamamoto<sup>2</sup>, Y. Urashima<sup>1</sup>, N. Takata<sup>2</sup>, K. Kikuchi<sup>1</sup>, M. Miyagawa<sup>2</sup>, T. Mochizuki<sup>2</sup>  
<sup>1</sup>Matsuyama Red Cross Hospital, Radiology, Matsuyama city, Japan ; <sup>2</sup>Ehime University Graduate School of Medicine, Radiology, Toon City, Japan

#### Purpose or Objective

To evaluate the outcomes of external beam radiotherapy (EBRT) for metastatic lesions (MLs) of differentiated thyroid cancer (DTC).

#### Material and Methods

Between August 1997 to March 2018, 73 lesions in 36 patients (male/female = 15/21; age 35-87 years, median 62 years) received EBRT and were followed up by CT, MR images, and/or FDG-PET/CT in our institution. Median follow-up time was 14 months (range, 1-110 months). Among assessed 73 lesions, 56 lesions were distant metastases (bone/lung/other sites = 45/5/6) and 17 lesions were neck/mediastinal lymph-node metastases. Doses of EBRT were 8-70 Gy (median 40 Gy). Seventeen patients received radioactive iodine therapy (RAIT) after EBRT.

#### Results

One- and 3-year overall survival rates were 87% and 63%, respectively. One- and 3-year control rates of lesions received EBRT were 79% and 45%, respectively. Three-year control rates were 0% for lesions received <30 Gy (n=7), 35% for lesions received 30-49 Gy (n=38), and 82% for lesions received 50 Gy (n=28). There were statistically significant differences of control rates between <30 Gy and 30-49 Gy (p=0.0002), and <50 Gy and >50 Gy (P=0.00374). Three-year control rates according to sites of lesions were as following; 55% for neck/mediastinal lymph-nodes, 33% for the bone metastasis, and 65% for the lesions in other organs (P = 0.2201). Three-year control rates were 67% for lesions received RAIT after EBRT (27 lesions), and 30% for lesions received no RAIT after EBRT (46 lesions) (p=0.0093). There were no significant differences in control rates by age, sex, and pathological subtype (papillary carcinoma vs. follicular carcinoma). EBRT doses of >50 Gy and addition of RAIT after EBRT were statistically significant independent factors for the good control of lesions received EBRT on multivariate analysis.

#### Conclusion

Because a significant proportion of patients with MLs of DTC requiring EBRT survived for a long time, long-term control of irradiated lesions is required even in palliative intent radiotherapy. EBRT doses of >50 Gy and addition of RAIT after EBRT seemed to be useful for long-term control of lesions received EBRT.

#### PO-0710 IMRT+Carbon Ion Boost for Adenoid Cystic Carcinoma of the Minor Salivary Glands of the Oral Cavity

K. Lang<sup>1</sup>

<sup>1</sup>University Hospital Heidelberg- Radiooncology, Radiooncology Heidelberg, Heidelberg, Germany

#### Purpose or Objective

Adenoid cystic carcinomas (ACCs) are more frequently located in the minor salivary glands (MiSGs) of the oral cavity than in the major salivary glands and they are characterized by slow tumor progression and frequently local recurrence. Main treatment option is surgery followed by combined radiotherapy. This study summarizes our institution's experience with bimodal postoperative RT in ACCs of the minor salivary glands of the oral cavity to evaluate survival and toxicity.

#### Material and Methods

The retrospective analysis contained 67 patients with ACC of MiSGs of the oral cavity who underwent surgery followed by radiotherapy. The median cumulative IMRT

dose was 50 Gy followed by 24 Gy for C12 boost. Median follow-up was 40 months.

#### Results

Median 5-years overall survival (OS), progression free survival (PFS) and local disease free survival (LDFS) rates were 85.5%, 57.4% and 74.9%. Median time until progression was detected was 32 months (range: 2 - 205 months). Early grade > 3 mucositis, dermatitis and dysphagia were detected in 52.2%, 7.5% and 11.9%. Besides common toxicities two patients (3.0%) developed grade 3 toxicities with osteoradionecrosis of the jaw after 18 and 66 months. Higher-grade late toxicity (CTCAE grade 4) was not detected. There was no treatment related death.

#### Conclusion

Our results demonstrate that postoperative bimodal radiotherapy with IMRT plus C12 boost seem to be feasible and effective treatment method in ACC of MiSGs of oral cavity with good control and survival rates and tolerable toxicity.

#### PO-0711 Second Primary Cancer in Salivary gland cancer in South Korea: A Nationwide Population-based Study

J. Heo<sup>1</sup>, Y. Oh<sup>1</sup>, O.K. Noh<sup>1</sup>, M. Chun<sup>1</sup>, O. Cho<sup>1</sup>

<sup>1</sup>Ajou University School of Medicine, Radiation Oncology, Suwon, Korea Republic of

#### Purpose or Objective

The aim of this study was to evaluate the prevalence of second primary cancer (SPC) among salivary gland cancer (SGC) patients by using nationwide claims data in South Korea.

#### Material and Methods

The nationwide cohort assessed in this study patients who were diagnosed with SGC from January 1, 2010, to December 31, 2014. We analyzed cancer incidence according to the time sequence. Additionally, we evaluated standardized incidence ratios (SIRs) to estimate the risk of SPC in SGC patients.

#### Results

A total of 1,614 patients (868 male and 746 female subjects) who were diagnosed with SGC and received surgery were confirmed, and 829 patients received radiotherapy. Of these patients, one-hundred and fifty-five patients (9.6%) developed an SPC, and the most common cancer site was the thyroid (13.5%). Patients with SGC had a high risk of SPC (SIR 4.39, 95% CI: 3.73 - 5.14), particularly nasopharynx cancer (SIR 79.43), Non-Hodgkin lymphoma (SIR 14.95) and tonsillar cancer (SIR 66.67). Female had a higher risk of malignancy than male (SIR 5.14 for women and SIR 3.73 for men). Age was a significant predictive factor for SPC (P = 0.024) among clinical factors, and patients over 54 years were at a higher risk for mental disorders (hazard ratio: 1.43, P = 0.031).

#### Conclusion

SGC patients with surgery had a longer life expectancy and a higher risk of SPC than the general population did. Therefore, close surveillance for SPC is important in elderly patients with SGC.

#### PO-0712 A new prediction model for patient reported xerostomia; external validation in postoperative setting

H.P. Van der Laan<sup>1</sup>, L. Van den Bosch<sup>1</sup>, A. Van der Schaaf<sup>1</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, H.P. Bijl<sup>1</sup>, M. Dieters<sup>1</sup>, J.G.M. Van den Hoek<sup>1</sup>, S. Both<sup>1</sup>, E. Schuit<sup>2</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>Utrecht University- University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands

#### Purpose or Objective

A new model for patient-reported moderate-to-severe xerostomia at 6 months ( $XER_{M6}$ ) after treatment was previously developed in a unique, high quality dataset of 750 patients who received definitive radiotherapy for head and neck cancer (HNC) and externally validated in datasets from two other institutions. The aim of the current research was to validate this NTCP-model in a cohort of HNC patients who received postoperative radiotherapy (PORT) with or without chemotherapy (CT).

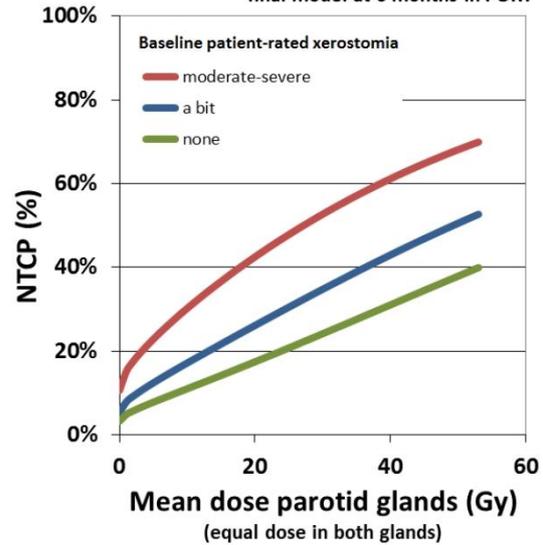

#### Material and Methods

The population of this prospective cohort study was composed of 218 HNC patients treated with PORT  $\pm$  CT. Baseline patient- and treatment characteristics, as well as acute and late toxicity and patient-rated outcome measures (i.e. EORTC QLQ-C30 and EORTC QLQ-HN35) were prospectively scored and linked to dose-volume parameters from both parotid and submandibular glands. The salivary glands were delineated according to the international guidelines (Brouwer et al. Radiother Oncol 2015) similar to those used in the development set. Multiple imputation was used to deal with missing data to avoid the bias of a complete case analysis. The original xerostomia model comprises baseline patient-reported xerostomia complaints, the summed square root transformation of the mean dose in both parotid glands ( $SSQ-D_{mean}$ ) and  $D_{mean}$  of both submandibular glands. A closed testing procedure was used to validate and, if necessary, update the xerostomia model for use in the postoperative setting.

#### Results

The prevalence of  $XER_{M6}$  was 27%, as compared to 41% (95%CI: 34.4% - 47.5%) as predicted by the model. A closed testing procedure to validate this model revealed that a model revision was necessary for use in the postoperative setting (Figure 1). Particularly, the association with the submandibular glands was weaker than described by the original model. In the current dataset, in contrast to the development dataset, patients often underwent neck dissections and had zero, one or two remaining submandibular glands post-surgery in 26%, 53% and 21% of the cases, respectively. Therefore, we tested whether a revised model including a variable for the number of post-surgery remaining submandibular glands or interaction terms including this factor, would better fit to the current dataset. However, this was not the case. Subsequently, we reduced our initial model, by excluding the mean dose in the combined submandibular glands, which did not change significantly the goodness of fit. The closed testing procedure then revealed that an update of the model intercept, to compensate for the lower response rate, was sufficient for this reduced model (ROC-AUC = 0.66, Nagelkerke  $R^2$  = 0.11) to be used in the postoperative setting (Figure 2).

#### Patient-rated moderate-severe xerostomia final model at 6 months in PORT

#### Conclusion

A new model for  $XER_{M6}$  was externally validated in the postoperative setting and established after excluding the variable describing the  $D_{mean}$  of both submandibular glands and an update of the model intercept.

#### PO-0713 PDRN-based cream in the prevention and treatment of radiodermatitis in Head and neck cancer: our experience.

F. Pastore<sup>1</sup>, A. Rese<sup>1</sup>, G. Panelli<sup>1</sup>, A. Pepe<sup>1</sup>, D. Toledo<sup>1</sup>, V. Iorio<sup>1</sup>

<sup>1</sup>Emicenter, Radiation Oncology, Mondragone, Italy

#### Purpose or Objective

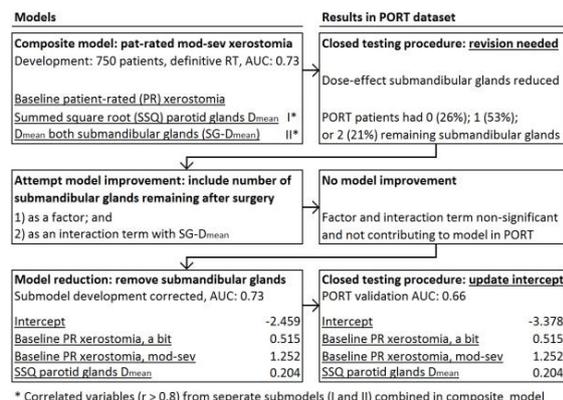

This study was designed to assess the efficacy and tolerability of a PDRN (Polideoxyribonucleotides)- based cream formulation in the prevention and treatment of radiodermatitis in patient with head and neck cancer treated with CRT (concomitant chemo-radiotherapy). PDRN is a well-known registered drug with tissue repairing, anti-ischemic and anti-inflammatory properties and we already tested it in a previous study on breast cancer patients.

#### Material and Methods

Patients with head and neck cancer has been randomized to use a cream, standard of care in our institution or a PDRN-based cream, throughout the duration of radiotherapy and for two weeks afterwards. Patients were monitored before therapy, weekly during therapy, and for 2 weeks after radiotherapy was completed, using RTOG skin toxicity grading scale. Patients were treated with Helicoidal Tomotherapy, choosing appropriate RT dose and fractionation according to disease presentation and with concomitant chemotherapy, using both conventional than hypofractionation schedules. We assessed on these patients several clinical variables as tumor histology, skin phototype, concomitant chemotherapy and medical conditions.

#### Results

Between december 2016 and march 2018, 102 consecutive patients, were enrolled in this study. Median age of the patients was 62.5 (range 46-84). 50/60 (83%) patients in the PDRN group vs. 57/62 (91%) patients in the control group had some grade of skin toxicity at the end of the treatment. At 4th week, 19/60 patients (31%) in the PDRN group vs. 37/62 (60%) patients in the control group had G2 grade of skin toxicity (p=0.0095). After 15 days from the end of the treatment, 5/60 patients (8%) in the PDRN group vs. 11/62 patients (18%) in the control group had some grade of skin toxicity (p=0.049). After 60 days from

the end of the treatment, 1/60 patients in the PDRN group vs. 4/60 patients in the control group had G1 grade of skin toxicity ( $p=0.047$ ). No differences were seen regarding other variables examined.

#### Conclusion

PDRN based cream improves the acute skin toxicity profile of head and neck cancer patients undergoing CRT. In these patients, the maximum skin toxicity grade is lower and the complete skin healing is faster. We need more patients and a longer follow up to assess late toxicity as fibrosis.

#### PO-0714 Toxicity profile of a SBRT boost as first-line treatment in oropharyngeal cancer patients

W. Heemsbergen<sup>1</sup>, S. Baker<sup>1</sup>, S. Petit<sup>1</sup>, J. Nuytens<sup>1</sup>, G. Verduijn<sup>1</sup>

<sup>1</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

To date, stereotactic body radiotherapy (SBRT) for head and neck cancer has been used primarily for re-irradiation of recurrent malignancies, despite the potential advantages in the setting of newly diagnosed disease and a growing interest internationally. There is sparse literature on long-term toxicity patterns in large patient series in the setting of a first-line treatment. In the current study we determined the late Grade  $\geq 3$  toxicity rates of a SBRT boost as primary treatment in the largest patient series to date.

#### Material and Methods

We performed a retrospective cohort study in 195 consecutive oropharyngeal squamous cell carcinoma patients collected from a prospective planning database. Eligible patients had T1-small T3 disease for which they were treated between 2009-2016 with a SBRT boost (3 x 5.5 Gy) to the primary tumor after accelerated 46 Gy IMRT to the primary tumor and neck, plus additional neck dissection in case of N positive disease (Table). The boost was delivered with a frameless robotic radiosurgery system. The GTV-CTV margin was 1 cm and the CTV-PTV margin was 5 mm for the IMRT phase and 3 mm for the boost. Main OAR dose constraints for the total plan (EQD2) were: spinal cord  $D_{max} < 50$  Gy and brain stem  $D_{max} < 60$  Gy (both hard planning constraints), parotid glands  $D_{mean} < 26$  Gy, submandibular glands  $D_{mean} < 39$  Gy, oral cavity  $D_{mean} < 50$  Gy, swallowing structures  $D_{mean} < 55$  Gy (where achievable). We determined Grade  $\geq 3$  toxicity rates ( $G_{\geq 3}$ ) as well as locoregional control (LRC), disease-specific survival (DSS), and overall survival (OS). Prognostic factors were assessed in Cox regression models. Sufficient follow-up (disease-free survival  $> 3$  months post-RT) for late toxicity assessment was available for 182 patients.

#### Results

Median follow-up was 4.3 years. Treatment compliance (100%) was high. Rates of cumulative 5-year (5Y) late  $G_{\geq 3}$ , LCR, DSS, and OS were 26%, 84%, 85%, and 67%, respectively. The most frequently observed  $G_{\geq 3}$  toxicities were mucosal ulceration or soft tissue necrosis ( $n=29$ , 5Y 17%), dysphagia or weight loss ( $n=15$ , 5Y 10%) and osteoradionecrosis (ORN) ( $n=11$ , 5Y 9%). At multivariable analysis, current smoker status was associated with increased  $G_{\geq 3}$  risks ( $HR=3.3$ ,  $p<0.01$ ), and pre-RT tooth extraction was associated with increased ORN risk ( $HR=6.5$ ,  $p<0.01$ ) Figure. Median interval extraction-start RT was 18 days and was not associated with ORN ( $n=63$ ,  $HR=1.9$ ,  $p=0.4$ ). Charlson Comorbidity Index  $\geq 2$  was associated with increased risks of dysphagia/weight loss ( $HR=6.6$ ,  $p=0.01$ ). These risk factors appeared to be more pronounced than reported in literature for conventional treatment.

#### Conclusion

Grade  $\geq 3$  toxicity profiles showed relatively high rates of soft tissue necrosis and osteonecrosis. LCR rates were

comparable with literature on conventional schedules for small tumors and survival was good in this population with 60% of advanced stage III-IVa disease. Strategies to mitigate severe toxicity risks are under investigation to improve the tolerability of the SBRT boost.

Baseline variables	N	%
Age (mean, range)	61(34-86)	
Male/female	122,73	63%,37%
ECOG 0/1	151,44	77%,23%
BMI $\leq 22$	43	22%
Pre-RT teeth extraction	63	32%
Packyears $\geq 10$	147	75%
Charlson Comorb Index $\geq 2$	97	50%
History or current alcohol abuse	59	30%
Smoker at diagnosis	103	53%
Stage grouping I-II / III-IVa	79,116	41%,59%

#### PO-0715 Nutritional intervention in head and neck cancer patients undergoing radiotherapy

L. Gutierrez Bayard<sup>1</sup>, M.D.C. Salas Buzón<sup>1</sup>, S. Garduño Sánchez<sup>1</sup>, M.J. Macías Lozano<sup>1</sup>, R. Rodríguez Sánchez<sup>1</sup>, S. Sayago Gil<sup>1</sup>, V. Díaz Díaz<sup>1</sup>, E. González Calvo<sup>1</sup>, I. Villanego Beltrán<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M. Lorente Sánchez<sup>1</sup>, J. Jaén Olasolo<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta del Mar, Radiation Oncology, Cadiz, Spain

#### Purpose or Objective

To evaluate the benefit of motivational interviewing in addition to nutritional counseling in head and neck cancer (HNC) patients undergoing radiotherapy (RT)(+/- systemic treatment), to improve patients' nutritional behaviours.

#### Material and Methods

Sixty-one intervention patients received motivational interviewing and cognitive behavioural therapy compared

to 67 historical controls who received treatment as usual. The intervention is based on behaviour change counselling methods, including motivational interviewing to improve motivation to eat despite a range of barriers ( pain, mucositis, nausea, salivary toxicity , taste changes and appetite loss), and to provide patients with practical behaviour change strategies.

Assessments will be conducted at 5 time points (first, third and final week of radiotherapy, 4 and 12 weeks post-radiotherapy).

The primary outcome was nutritional status at the end of RT as measured by the Patient Generated Subjective Global Assessment (PG-SGA). Secondary endpoints: quality of life (EORTC QLQ-C30) and anticancer treatment tolerance.

#### Results

Intervention patients resulted in smaller loss of body weight than control group (mean difference, 1.8 kg [95%CI, 0.65-2.5];  $P = 0.005$ ), and a clinically important reduction on the PG-SGA (34% of controls vs. 17% intervention;  $P = 0.04$ ) in favor of the intervention condition. Secondary endpoints: reduced the need for changes in planned anti-cancer treatments (i.e. RT and/or systemic treatment dose reduction, interruptions or complete suspension)  $HR=0.38$  [95%CI, 0.2-0.89],  $P = 0.03$ ), and global QoL ( $P < 0.002$ )

#### Conclusion

HNC patients undergoing RT (+/- systemic treatment), receiving motivational and nutritional intervention resulted in better weight maintenance, and was associated with better anti-cancer treatment tolerance and improved quality of life .

#### PO-0716 Skull-base chordoma treated with proton and carbon ion radiotherapy : CNAO clinical experience

A. Iannalfi<sup>1</sup>, E. D'Ippolito<sup>1</sup>, V. Vitolo<sup>1</sup>, B. Vischioni<sup>1</sup>, M.R. Fiore<sup>1</sup>, M. Bonora<sup>1</sup>, S. Ronchi<sup>1</sup>, A. Barcellini<sup>1</sup>, R. Petrucci<sup>1</sup>, S. Molinelli<sup>1</sup>, A. Mirandola<sup>1</sup>, S. Russo<sup>1</sup>, A. Facchetti<sup>1</sup>, A. Vai<sup>1</sup>, E. Mastella<sup>1</sup>, G. Viselner<sup>2</sup>, G. Magro<sup>1</sup>, M. Ciocca<sup>1</sup>, L. Preda<sup>2</sup>, F. Valvo<sup>1</sup>, R. Orecchia<sup>1,3</sup>

<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ; <sup>2</sup>National Center of Oncological Hadrontherapy, Diagnostic Image Unit, Pavia, Italy ; <sup>3</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

#### Purpose or Objective

Skull-base chordomas are rare and malignant tumors that originate from remnants of the chorda dorsalis (notochord). Particle radiotherapy provides dosimetric advantages and higher biological effective dose especially for radioresistant tumors . The aim of the study was to evaluate local control (LC) and toxicity profile of patients (pts) with skull-base chordoma treated with exclusive or adjuvant particle therapy (proton therapy -PT- and carbon ion therapy -CIRT-)

#### Material and Methods

Between September 2011 and July 2017, a total of 134 pts (79 men and 55 women) with a median age of 57 years (range 14-86) with histologically proven skull-base chordoma were treated with particle therapy at National Center of Oncological Hadrontherapy -CNAO. One-hundred and two (76%) pts had previous surgery and complete macroscopic resection was achieved only in 15 pts (20%). Sixty-one pts were treated with PT and 73 with CIRT. The particle choice (proton or carbon ion) was made on personalized basis. Median prescribed total dose was 70,4 Gy RBE (range 35,2-70,4 Gy RBE) in 8-22 fractions (median 16 fractions) of 3-4,4 Gy RBE (median 4,4 Gy RBE) for CIRT, and 74 Gy RBE (range 70-74 Gy RBE) in 27-37 fractions (median 37 fractions) of 2 Gy RBE for PT. Clinical outcome (LC, 3 year local relapse free- LRF5 and overall -survival - OS-) and toxicity profile in according with CTCAE criteria was evaluated

#### Results

The median follow-up was 32 months (range, 2-64 months). LC was 83%. In pts that underwent complete macroscopic surgery followed by PT, LC was 100%, in pts with incomplete resection/only biopsy and PT/CIRT, LC was 79%. The 3-year LRF5 and OS were 80% and 90% respectively. In field recurrence occurred in 13% (18 pts). In 16 out of 18 cases of recurrences the tumor was in close contiguity to the brainstem. Out of field recurrence was found in 5 pts: 2 cases occurred within surgical way, attributable to surgical seeding, One case of histologically confirmed cervical lymph-node relapse, 2 cases of newly appeared nodules of recurrence. Six pts (4%) developed distant metastasis after a mean interval of 12 months. The toxicity profile was favorable. Only 2 pts developed acute radiation induced high grade toxicity: with oral mucositis (grade 3). High grade (G3-G4) late toxicity occurred in 4% of pts: 1 case of complete visual loss (G4) expected because of optic nerve in field, 1 case of soft tissue necrosis, 2 cases of cranial nerve neuropathy and 2 cases of pituitary dysfunction

#### Conclusion

Particle therapy is the most innovative and conformal RT for treatment of skull base chordomas. It allows to deliver higher (biologically effective) dose levels and to obtain higher tumor control rates, minimizing radiation-related side effects

#### PO-0717 Addition of chemotherapy to hyperfractionated radiotherapy in advanced head and neck cancer

H. Jan<sup>1</sup>, T. Balint<sup>1</sup>, E. Boelke<sup>1</sup>, D. Freddy Noel<sup>1</sup>, B. Wilfried<sup>1</sup>, K. Kai<sup>2</sup>, M. Christiane<sup>1</sup>

<sup>1</sup>University Hospital Düsseldorf, Radiation Oncology, Düsseldorf, Germany ; <sup>2</sup>Johns Hopkins University School of Medicine- Baltimore- USA, Division of Biostatistics and Bioinformatics- Department of Oncology, Düsseldorf, Germany

#### Purpose or Objective

Adding chemotherapy (CTx) simultaneously to primary radiation therapy (RT) results in improved overall survival in patients with locally advanced tumors of the head and neck region (HN). A comparable effect has likewise been reported for hyperfractionated radiotherapy (HFX-RT) without concurrent CTx. Yet, the addition of CTx to HFX-RT has also been investigated in multiple trials. However a clear effect on oncological outcomes and toxicity profile has not been established and reported.

#### Material and Methods

We performed a literature search for randomized controlled trials comparing HFX-RT alone to HFX-RT + concurrent CTx in patients with locally advanced cancer of the head and neck region undergoing definitive radiotherapy. A meta-analysis was performed using the event rates and effect-sizes for overall survival (OS), cancer-specific survival (CSS) and disease-free survival (DFS) as well locoregional (LRC) and distant recurrence (DMR) as investigated endpoints. Additionally we compared selected acute and late toxicities in the included studies. Statistical analysis was performed using the Microsoft Excel add-in MetaXL 5.3 utilizing the inverse variance heterogeneity model.

#### Results

We identified six studies (n=1280 patients) randomizing between HFX-RT alone and the concurrent addition of CTx. OS was significantly improved in HFX-RT + CTx group ( $HR=0.77$  CI95%=0.66-0.89;  $p<0.001$ ). We found similar results in CSS ( $HR=0.72$  CI95%=0.60-0.88;  $p=0.001$ ) and DFS ( $HR=0.74$  CI95%=0.63-0.87;  $p<0.001$ ). The analysis also revealed improvements in the rate of locoregional and distant recurrences with CTx. Acute toxicities ( $\geq 3^\circ$  mucositis,  $\geq 3^\circ$  skin,  $\geq 3^\circ$  dysphagia) were not statistically different between both groups. Analysis of late adverse events included  $\geq 3^\circ$  xerostomia,  $\geq 3^\circ$  subcutaneous,  $\geq 3^\circ$  bone,  $\geq 3^\circ$  skin,  $\geq 3^\circ$  mucosal atrophy and

≥3<sup>rd</sup> dysphagia which were also not significantly different between the treatments.

#### Conclusion

The addition of chemotherapy to hyperfractionated RT schedules in definitive treatment of advanced HN-cancers improves all studied endpoints without a significant increase in the investigated high-grade acute and late toxicities.

#### PO-0718 Patterns of care for local recurrence of NPC after definite IMRT - a study by the HKNPCSG

W.T. Ng<sup>1</sup>, E.C. Wong<sup>1</sup>, L.L. Chan<sup>1</sup>, A.K. Cheung<sup>2</sup>, J.C. Chow<sup>3</sup>, D.M. Poon<sup>4</sup>, J.W. Lai<sup>5</sup>, C.L. Chiang<sup>6</sup>, K.H. Au<sup>3</sup>, A.W. Lee<sup>7</sup>

<sup>1</sup>Pamela Youde Nethersole Eastern Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>2</sup>Tuen Mun Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>3</sup>Queen Elizabeth Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>4</sup>Prince of Wales Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>5</sup>Princess Margaret Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>6</sup>Queen Mary Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>7</sup>The University of Hong Kong and The University of Hong Kong-Shenzhen Hospital, Departments of Clinical Oncology, Hong Kong, Hong Kong SAR China

#### Purpose or Objective

This retrospective study evaluated the patterns of care for patients with local recurrence of nasopharyngeal carcinoma (NPC) after intensity modulated radiotherapy (IMRT) treated in all public hospitals in Hong Kong from 2001 to 2010.

#### Material and Methods

Eligible patients were identified through the Hong Kong Cancer Registry data base. Patients with biopsy proven/radiologically documented local recurrence without concomitant distant metastasis were included. All patients received IMRT as the primary course of treatment. Patient demographics, tumour characteristics and treatment details were retrieved and verified. Survival outcomes after local recurrence were analysed.

#### Results

272 patients were identified. The median follow-up time was 31.5 months. Median time from primary diagnosis to local relapse was 29.6 months. The rT stage distribution was rT1: 30.5%, rT2: 9.6%, rT3: 25.4% and rT4: 34.6%. 74.3% had rN0 disease. Thirty one percent of patients received surgery, 35.7% received re-irradiation (RT), 23.2% received palliative chemotherapy alone and 10.3% had no active treatment. Early local recurrence was mostly treated with surgery (82.3% of Stage I, 38.1% of Stage II), while late recurrence was commonly treated non-surgically (52.1% of Stage III managed with re-RT; 42.3% of Stage IVA managed with chemotherapy alone). Adjuvant RT was commonly given in case of involved resection margin after radical resection (65.4%). Surgery was associated with 2.4% perioperative mortality, while re-RT was associated with 16.7% grade 5 late complications.

The 5-year overall survival (OS) for the whole group was 30.2%. Older age and advanced rT stage were adverse prognostic factors, while the use of surgery as primary treatment (mainly in early local recurrence) was associated with favourable outcome. The 5-year OS rates for patients who received surgery, re-RT, chemotherapy and no active treatment were 56.3%, 21.8%, 15.0% and 11.1% respectively. For the surgery group, resection margin status was the most important prognostic factor. Adjuvant RT did not improve local control and OS when compared with surgery alone and was associated with 28.5% of grade 4 toxicities or above. For the re-RT group, OS were adversely affected by older age and larger gross tumour volume. **Conclusion**

This study reflects the current patterns of care for local recurrent NPC in Hong Kong. Early detection of local recurrence is of paramount importance as surgery for resectable tumours is associated with the most favourable outcomes. Re-RT could be considered in selected patients with unresectable disease but favourable prognostic features.

#### PO-0719 head and neck contour peer review improves quality of radiotherapy targets

L. MCGEE<sup>1</sup>, J. Rwigema<sup>1</sup>, M. Halyard<sup>1</sup>, T. DeWees<sup>1</sup>, J. Gagneur<sup>1</sup>, S. Patel<sup>1</sup>

<sup>1</sup>Mayo Clinic Arizona, Radiation Oncology, Phoenix, USA

#### Purpose or Objective

Head and neck (HN) radiotherapy contour quality can directly impact local control and survival. However, few departments peer review (PR) contours prior to radiotherapy planning (RP). In an effort to further improve radiotherapy quality at our institution, we implemented a formal HN contour PR process. This series reports results of the first 7 months after initiation of this workflow.

#### Material and Methods

A formal HN contour PR process was implemented within our department. Contours were reviewed by radiation oncologists (RO) who specialize in HN cancer and revised prior to initiation of RP. A PR task item was built into the care path of the electronic medical record (EMR) to track the PR process. Dosimetry was not allowed to initiate RP until the PR task in the care path had been completed by the RO HN team.

RO participated in a weekly meeting to review contours. Together, the RO evaluated factors pertinent to individual patient contours including pretreatment imaging, physical examination photographs, recorded flexible scope examination, operative notes and surgical pathology. Contours were assessed by the RO HN team, and feedback was provided to the treating physician if contour revision was recommended. Contour revisions were graded by the RO present as follows: R0 (no change), R1 (minor revision, not deemed high risk) or R2 (major revision, deemed to have potential to negatively impact patient outcomes). The PR task was completed and grading of contours recorded in the EMR. The Cochran-armitage trend test was performed to determine if contour grade trend was significant over time.

#### Results

From February to August 2018, 110 HN cancer patients had the contour PR task completed in the EMR; 88 (80%) had grade recorded for contour revision. Four RO participated in the first 3 months; 3 RO participated all 7 months. Contours were graded as follows: R0 (N=50), R1 (N=20) and R2 (N=18). Over time the number of major revisions (R2) decreased (p=0.0001); month 1 (N=7) month 2 (N=3), month 3 (N=5) month 4 (N=2) and months 5-7 (N=0). Each individual RO who participated the entire time demonstrated reduction in R2 revisions; Oncologist A: month 1 (N=2), month 2 (N=1), month 3 (N=2), month 4 (N=1) and month 5-7 (N=0). Oncologist B: month 1 (N=2), months 2-4 (N=1) and months 5-7 (N=0). Oncologist C: month 1 and 3 (N=1) and months 2, 4-7 (N=0). The total number of RO revisions improved over time (p=0.0203); month 1 (N=5), months 2-3 (N=9), month 4 (N=5) month 5 (N=8), month 6 (N=12) and month 7 (N=3).

#### Conclusion

HN contour PR can be implemented into routine clinical workflow. The collective experience of multiple high volume RO led to improved contour quality over time for each RO. This improvement in contour quality may result in improved plan quality which in turn could lead to improved disease control and toxicity in patients treated after implementation of this process.

**PO-0720 Tumor volume/metabolism improve prognostication of anatomy-based stage for nasopharyngeal cancer?**

Y. Jeong<sup>1</sup>, K.K. Lee<sup>1</sup>, S.R. Moon<sup>1</sup>, S.Y. Noh<sup>2</sup>, J. Kwak<sup>2</sup>, S. Lee<sup>2</sup>

<sup>1</sup>Wonkwang University Hospital- Wonkwang University School of Medicine, Radiation Oncology, Iksan, Korea Republic of ; <sup>2</sup>Asan Medical Center- University of Ulsan College of Medicine, Radiation Oncology, Seoul, Korea Republic of

**Purpose or Objective**

We evaluated the prognostic value of the 8<sup>th</sup> edition of the AJCC/UICC staging system and investigated whether tumor volume/metabolic information refined the prognostication of current anatomy based staging system in nasopharyngeal cancer.

**Material and Methods**

The 133 patients with nasopharyngeal cancer who were staged with MRI and treated with IMRT between 2004 and 2013 were retrospectively reviewed, and all patients were re-staged according to the 8<sup>th</sup> edition of the AJCC/UICC staging system. The survival rates were estimated from the date of the start of radiotherapy, and univariate and multivariate analyses were performed to evaluate prognostic value of the 8<sup>th</sup> edition of the AJCC/UICC staging system and other factors including gross tumor volume and maximum standardized uptake value of primary tumor (GTV-T and SUV-T).

**Results**

The follow-up period was median 63 months (range, 7.2-155.8 months), and the 5-year OS was 80.8%. The stage group as well as age, pathology, GTV-T, and SUV-T were significant prognostic factors for OS in univariate analysis. In multivariate analysis, stage group (stage I-II vs. III-IVA) was the only significant prognostic factor (HR, 11.062, p=0.017), but, OS rates were not significantly different between stage I and II (5-year OS, 100% vs. 96.2%, p=0.347), and between stage III and IVA (5-year OS, 80.1% vs. 71.7%, p=0.673). Although SUV-T and GTV-T were not significant prognostic factors for OS in multivariate analysis, the incorporation of SUV-T and GTV-T into stage group improved prognostication of stage group. The OS rates were significantly different between stage I-II, III-IV (SUV-T ≤ 16), and III-IV (SUV-T > 16) (5-year OS, 97.2% vs. 78% vs. 53.8%, p < 0.001), and between stage I, II-IV (GTV-T ≤ 33ml), II-IV (GTV-T > 33ml) (5-year OS, 100% vs. 87.3% vs. 66.7%, p=0.021).

**Conclusion**

The current anatomy based staging system have limitations on prognostication for nasopharyngeal cancer even though that was based on the most accurate assessment of tumor extent by MRI. The tumor volume/metabolic information seems to improve the prognostication of current anatomy based staging system, and further studies are needed to confirm its clinical significance.

**PO-0721 Prognostic Value of Inflammatory Markers in Patients with Head and Neck Cancer.**

J. Mrochem-Kwarciak<sup>1</sup>, T. Rutkowski<sup>2</sup>, A. Wygoda<sup>2</sup>, A. Chmura<sup>1</sup>, K. Skłodowski<sup>2</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Analytics and Clinical Biochemistry Department, Gliwice, Poland ; <sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, I Radiation and Clinical Oncology Department, Gliwice, Poland

**Purpose or Objective**

Inflammation is generally accompanied cancer disease. Evaluation of the inflammatory biomarkers in the treatment of head and neck cancer (HNC) patients is of potential prognostic value. The aim of present study was

to assess the prognostic value of indicators calculated on the basis of initial hematology parameters: neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR), platelet-to-lymphocyte ratio (PLR), leukocyte count (WBC) and modified Glasgow Prognostic Score (mGPS) in patients with HNC after Radiotherapy alone or combined with chemotherapy.

**Material and Methods**

Between 01/2009 and 08/2013 191 patients with squamous cell carcinoma of nasopharynx (4%), oropharynx (39%), hypopharynx (13%), larynx (36%) or oral cavity (8%) were treated with curative intent with RT alone or combined with platinum-based chemotherapy. There were 47% patients with T1/2 and 53% with T3/4 of primary tumor stage and 31% and 69% of patients with N0 and N+ nodal stage disease, respectively. Complete blood counts (CBC), C-reactive protein (CRP) and albumin were estimated in blood or serum before the treatment. Patient mGPS was scored: as 0 when there were normal levels of albumin (≥35 g/l) and CRP (≤10 mg/l), as 1 when CRP was elevated (>10 mg/l) but albumin was normal and as 2 when CRP was elevated (>10 mg/l) and albumin was decreased (<35 g/l). Treatment outcome was defined as complete remission (CR - no evidence of disease) or treatment failure (TF - residual disease or recurrence).

**Results**

Median follow-up was 40 months. There was CR, and TF respectively in 69% and 31%. Second primary tumor or distant metastasis were observed in 12% of patients. Patients had significantly longer disease free-survival (DFS) when counts of WBC (< 6,77 G/l) and NLR (<2,01) were low (p=.002 and p=.03), respectively. Significantly longer overall survival (OS) was found for patients with low counts of WBC (<6,77 G/l) (p=.001), NLR (<2,01) (p=.01), or mGPS score (=0) (p=.04). No correlation was observed between LMR or PLR and DFS and OS.

**Conclusion**

In patients with head and neck cancer after radiotherapy alone or combined with chemotherapy high initial levels of NLR and WBC seems to predict worse treatment results. Low levels of inflammatory indicators like WBC, neutrophils count, mGPS, and high lymphocytes count may be associated with longer OS in this group in patients.

**PO-0722 Carbon ion radiotherapy for adenoid cystic carcinoma in the head-and-neck**

A. Hasegawa<sup>1,2,3,4</sup>, B. Vischioni<sup>3</sup>, M. Bonora<sup>3</sup>, S. Ronchi<sup>3</sup>, S. Molinelli<sup>3</sup>, M. Ciocca<sup>3</sup>, A. Facchetti<sup>3</sup>, F. Valvo<sup>3</sup>, P. Fossati<sup>5</sup>, B. Alicja Jereczek<sup>4</sup>, M. Koto<sup>2</sup>, T. Kamada<sup>2</sup>, J. Mizoe<sup>1</sup>, R. Orecchia<sup>3,4</sup>

<sup>1</sup>Osaka Heavy Ion Therapy Center, Radiation oncology, Osaka, Japan ; <sup>2</sup>National Institutes of Radiological Sciences Hospital, Radiotherapy, Chiba, Japan ; <sup>3</sup>National Center for Oncological Hadrontherapy CNAO, Radiation Oncology, Pavia, Italy ; <sup>4</sup>European Institute of Oncology IEO, Radiotherapy, Milan, Italy ; <sup>5</sup>MedAustron, Radiotherapy, Wiener Neustad, Austria

**Purpose or Objective**

The National Institutes of Radiological Sciences (NIRS)\* reported the clinical results of carbon ion radiotherapy (CIRT) for various types of head and neck malignancies, including acute and late morbidities, local control, and survival rates. In clinical protocols of the National Center for Oncological Hadrontherapy (CNAO), Fossati P et al \*\* demonstrated a practical method to translate NIRS RBE-weighted doses and the prescription doses of CIRT were applied based on this method. This study aims to evaluate the optimum dose of CIRT for adenoid cystic carcinoma (ACC) in the head-and-neck at CNAO compared to NIRS.

**Material and Methods**

Between December 2013 and June 2018, a total of 146 patients with adenoid cystic carcinoma of the head-and-neck were treated with carbon ion radiotherapy at CNAO. The prescribed tumor doses were 65.6 or 68.8 Gy (RBE) in

16 fractions over four weeks. Of 146 patients, 12 patients were irradiated with 65.6 Gy (RBE) and 134 patients were irradiated with 68.8 Gy (RBE). Each dose level is the dose equivalent to 57.6 and 60.8 Gy (RBE) of NIRS.

### Results

The patients consisted of 68 males and 78 females aged from 19 to 86 years with an average age of 54 years. The most frequent primary site was the nasal and paranasal sinus. Median follow-up time was 24.4 months (range, 4.2-60.9 months). Fourteen patients died because of local recurrence and/or distant metastasis, and 97 patients were alive without local recurrence at the time of this analysis. Median local control time was 21.4 months (range, 4.2-60.7 months). The 2-year local control and overall survival rates were 82% and 88%, respectively. The most frequent acute toxicity of 146 patients, grade 2 (G2) and grade 3 (G3) mucosal reactions were observed in 53 (36%) patients and 34 (23%) patients, respectively. No G3 mucosal reaction was observed in the 65.6 Gy (RBE) group. G2 acute skin reaction of all patients was observed in 30 (21%) patients. In the analysis of late toxicities, 8 (5%) patients showed G3 osteonecrosis and 5 (3%) patient showed G2 brain reaction. Only one patient needed the surgical intervention due to G3 encephalitis. All of these late toxicities were observed in the 68.8 Gy (RBE) group.

### Conclusion

The review article by Mizoe et al.\* reported the 2-year local control rate as about 95% and G2 and G3 mucosal reactions as 36% and 6%. Although our results were slightly inferior to this article, they showed acceptable toxicities and therapeutic effectiveness for adenoid cystic carcinomas. It is necessary to evaluate a large number of patients and a long follow up period.

### PO-0723 Benefits of deep learning for delineation of organs at risk in head and neck cancer

J. Van der Veen<sup>1,2</sup>, S. Willems<sup>3</sup>, D. Robben<sup>3</sup>, W. Crijs<sup>2</sup>, F. Maes<sup>3</sup>, S. Nuyts<sup>1,2</sup>

<sup>1</sup>KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium; <sup>2</sup>UZ Leuven - University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium; <sup>3</sup>KU Leuven - University of Leuven, Medical Image Computing ESAT/PSI, Leuven, Belgium

#### Purpose or Objective

Delineation of organs at risk (OARs) is necessary for correct treatment planning and for comparison of dose-volume histograms between doctors, centres and studies. Although guidelines exist, manual delineation shows significant inter-observer variability. The aim was to develop a 3D convolutional neural network (CNN) that allows automated delineation of OARs resulting in more efficient and consistent contouring of head and neck cancer (HNC) patients.

#### Material and Methods

OARs from 70 HNC patients were manually delineated using the international consensus guidelines by Brouwer et al. (2015). The planning CT scans together with the delineations were used to train a single 3D CNN to delineate 16 different OARs. The 3D CNN is based on the work of Kamnitsas et al. (2017) and has four pathways. Each pathway operates on a different resolution and region of interest (ROI), allowing both a broader ROI and fine details to be processed simultaneously. These pathways are concatenated, followed by extra convolutional layers to predict the final delineation. Next, the automated delineation (Auto) of OARs was performed on planning CT images of 15 new patients. Then, the automated delineations were subsequently corrected by a senior resident and supervised by the treating physician

prior to treatment planning (Auto+Corr). Two weeks later the same OARs were manually delineated by the same two radiation oncologists (Manual). To quantify efficiency of automated delineation, the time taken for correction of the automated delineation was compared to manual delineation time. Dice similarity coefficients (DSCs) were calculated to quantify overlap between different contours (Auto, Auto+Corr, Manual) where a value of "1" represents perfect and "0" no overlap (Figure 1).

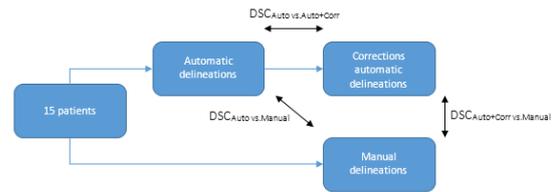

Figure 1: Overview of delineation process and DSCs relationships

$DSC_{Auto+Corr vs Manual}$  represents the overlap between manual delineation and corrected automated delineation

$DSC_{Auto vs Manual}$  represents the overlap between automated delineation and manual delineation

$DSC_{Auto vs Auto+Corr}$  represents the overlap between automated delineation and corrected automated delineation

### Results

Average correction time was significantly shorter than the average time needed for complete manual delineation (21 versus 34 minutes respectively,  $p < 6.5E-4$ ). The CNN performed best for spinal cord, oral cavity, mandible, brainstem and parotid glands with median  $DSC_{Auto vs Manual}$  of 0.92, 0.91, 0.91, 0.87 and 0.86 respectively. Median  $DSC_{Auto vs Auto+Corr}$  for these same OARs was 0.99, 0.96, 0.99, 0.94 and 0.97 respectively and this was in general significantly higher compared to  $DSC_{Auto vs Manual}$  ( $p < 1.1E-6$ ). For all OARs except supraglottic larynx, median  $DSC_{Auto vs Auto+Corr}$  was higher than  $DSC_{Auto+Corr vs Manual}$ , indicating that the corrections applied were smaller than the intra-observer variability (figure 2).

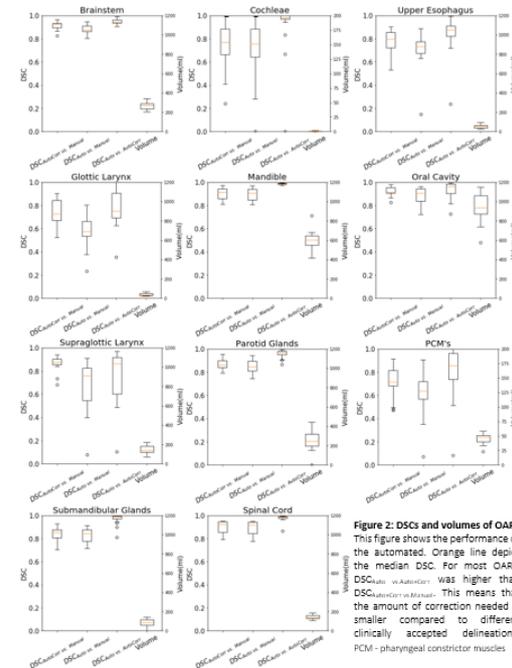

Figure 2: DSCs and volumes of OARs. This figure shows the performance of the automated. Orange line depict the median DSC. For most OARs,  $DSC_{Auto vs Auto+Corr}$  was higher than  $DSC_{Auto+Corr vs Manual}$ . This means that the amount of correction needed is smaller compared to different clinically accepted delineations. PCM - pharyngeal constrictor muscles

### Conclusion

We developed a CNN that allows more time efficient delineation of OARs in HNC patients. The CNN is able to produce automated delineations that only need small alterations in most OARs and it has therefore been implemented in clinical practice in our hospital.

### PO-0724 Texture analysis for predicting laryngeal preservation in advanced laryngo-pharyngeal cancers

Abstract withdrawn

**PO-0725 Multimodality imaging employing FDG-PET/CT paves the way for de-escalation of the elective dose**  
**S. Van den Bosch<sup>1</sup>, P.A.H. Doornaert<sup>2</sup>, C.H.J. Terhaard<sup>2</sup>, J.H.A.M. Kaanders<sup>1</sup>**

<sup>1</sup>Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands ; <sup>2</sup>University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands

**Purpose or Objective**

Modern multimodality imaging has improved the detection threshold of small nodal metastases in head and neck squamous cell carcinoma (HNSCC). This influences the tumorload in elective nodal target volumes and may have consequences for the radiotherapy dose required to control disease in this volume. This study investigates the effects of the introduction of FDG-PET/CT for radiotherapy planning on neck recurrence in HNSCC.

**Material and Methods**

A patient cohort that was treated for HNSCC with definitive (chemo)radiotherapy using IMRT/VMAT techniques in two tertiary head and neck clinics in The Netherlands from 2008-2016 was retrospectively analyzed. The focus of this analysis was on regional recurrence in the elective nodal target volume. For this purpose, co-registration was performed of the scans acquired during follow-up demonstrating the neck recurrence and the initial radiotherapy planning (FDG-PET)CT-scan. Actuarial rates of recurrence were calculated using the Kaplan-Meier method and multivariate analyses were performed using the Cox proportional-hazards model.

**Results**

A total of 633 patients with all stages HNSCC were included. A pre-treatment FDG-PET/CT-scan was acquired in 46% (290/633) and concomitant chemotherapy was administered in 38% (238/633) of the patients. Median follow-up was 32 months (IQR: 20-41). Two years after treatment, recurrence in the elective nodal target volume was observed in 3.9% (95% CI: 2.3-5.5) (24/633) of all patients. This was only 2.0% (95%CI: 0.2-3.8) in patients that had a FDG-PET/CT-scan for treatment planning ( $n=290$ ) versus 5.6% (95% CI: 3.1-8.2) in patients without ( $n=343$ ) ( $p=0.01$ ). The majority of these recurrences occurred synchronously with local recurrence: 17.4% (95% CI: 9.6-25.2) and were isolated in only 1.1% (95% CI: 1.0-1.2) ( $p<0.001$ ). For patients free of local recurrence, no recurrences in the elective nodal target volume occurred when a FDG-PET/CT-scan was acquired prior to treatment ( $p=0.01$ ). No differences in the rate of recurrence in the elective nodal target volume occurred in patients treated with concomitant chemotherapy 3.9% (95% CI: 1.2-6.6) versus 3.9% (95% CI: 1.9-5.9) ( $p=0.65$ ). In multivariate analyses, both local recurrence ( $p<0.001$ ) and acquisition of FDG-PET/CT-scan prior to treatment ( $p=0.03$ ) were significant predictors for recurrence in the elective nodal target volume, concomitant chemotherapy was not ( $p=0.59$ ).

**Conclusion**

The vast majority of nodal recurrences in the elective nodal target volume occur synchronously with local recurrence. Further, concomitant chemotherapy does not reduce this recurrence rate. Both observations indicate that most of these nodal manifestations are new seedings from the local recurrent tumor. Isolated recurrences in the elective nodal target volume are extremely rare (1.1%) and none occurred when FDG-PET/CT-scan was used for radiotherapy planning. This strongly supports the notion that elective neck dose can be safely de-escalated resulting in reduced toxicity of HNSCC radiotherapy.

**PO-0726 Lower toxicity incidence after SPECT/CT-guided elective nodal irradiation for head and neck cancer**

**P. De veij mestdagh<sup>1</sup>, W.V. Vogel<sup>2</sup>, M.L. Donswijk<sup>2</sup>, E. Lamers<sup>1</sup>, C. Carbaat<sup>1</sup>, W.H. Schreuder<sup>3</sup>, M.W.M. Van den Brekel<sup>3</sup>, A. Al-Mamgani<sup>1</sup>**

<sup>1</sup>Netherlands Cancer Institute / Antoni van Leeuwenhoek, Radiotherapy, Amsterdam, The Netherlands ; <sup>2</sup>Netherlands Cancer Institute / Antoni van Leeuwenhoek, Nuclear Medicine, Amsterdam, The Netherlands ; <sup>3</sup>Netherlands Cancer Institute / Antoni van Leeuwenhoek, Head and Neck surgery, Amsterdam, The Netherlands

**Purpose or Objective**

The great majority of patients with lateralized head and neck squamous cell carcinoma (HNSCC) treated with radiotherapy routinely undergo bilateral elective nodal irradiation (ENI), even though the incidence of contralateral regional failure after unilateral ENI is low. Excluding the contralateral neck from elective irradiation could reduce radiation-related toxicity and improve quality of life. The SUSPECT study (NCT02572661), a prospective fase 2 trial, investigates the feasibility, safety and clinical benefits of a novel, image-guided approach, in which lymph drainage mapping guides the elective irradiation of the neck in HNSCC patients. While we await data maturation for evaluation of oncologic safety, we report on the incidence, severity and duration of acute and late toxicity.

**Material and Methods**

Patients with lateralized cT1-3N0-2bM0 HNSCC were eligible for treatment with selective SPECT/CT-guided ENI (SSG-ENI). In case no contralateral drainage was visualized on SPECT/CT, patients received ipsilateral ENI only. If contralateral drainage to one "hot spot" was visible, the elective irradiation to the contralateral neck would be limited to the level containing the hot spot. In case of  $\geq 2$  contralateral hot spots on SPECT/CT, the patient was treated with conventional bilateral ENI, and not evaluable for the study endpoints. A matched historical cohort was formed that received conventional bilateral ENI (B-ENI) according to international guidelines. Matching was done based on tumor subsite, T- and N-classification, whether the patient received chemotherapy, and (for oropharyngeal tumors) HPV-status. Planning and treatment technique were identical to the study cohort.

**Results**

Fifty patients were treated with SSG-ENI, and were matched to 50 patients treated with B-ENI. Aside from follow-up time and CTV-PTV margin, baseline characteristics between the cohorts did not significantly differ. Mean irradiation doses to organs at risk were lower in the SSG-ENI cohort vs. the B-ENI cohort (contralateral parotid: 5 vs. 19 Gy; contralateral submandibular: 20 vs. 46 Gy; larynx: 39 vs. 52 Gy; constrictor muscles: 39 vs. 53 Gy; all tests  $p<0.001$  [Mann-Whitney-U]). The SSG-ENI cohort had a lower incidence of acute dysphagia, including tube feeding incidence (SSG-ENI: 10%, B-ENI: 50%,  $p<0.001$  [ $\chi^2$ ]), and a shorter median duration of acute mucositis and dysphagia. In the first year after treatment, incidences of grade $\geq 2$  late xerostomia and grade $\geq 2$  late dysphagia were significantly lower in the SSG-ENI cohort, including tube feeding incidence (3% vs. 26%,  $p=0.002$  [ $\chi^2$ ]). On multivariate logistic regression, bilateral ENI (OR 7.89, 95% CI 2.17-28.61,  $p=0.002$ ) and concurrent chemotherapy (OR 4.58, 95% CI 1.33-15.76,  $p=0.016$ ) were predictive for feeding tube placement.

Table 1: Comparison of acute and late toxicity between groups

	Incidence: n (%)			Duration: median (range) in days		
	SSG-ENI	B-ENI	p-value	SSG-ENI	B-ENI	p-value
Acute toxicity						
n=50/50						
Dermatitis grade ≥2	28 (56)	33 (66)	n.s.	21 (12-51)	25 (10-154)	n.s.
Dermatitis grade 3	11 (22)	7 (14)	n.s.	14 (10-21)	21 (5-29)	n.s.
Mucositis grade ≥2	40 (80)	44 (88)	n.s.	40 (14-120)	50 (14-206)	0.010
Mucositis grade 3	22 (44)	22 (44)	n.s.	26 (14-89)	51 (14-133)	0.023
Dysphagia grade ≥2	27 (54)	41 (82)	0.003	37 (13-150)	110 (12-155)	<0.001
Dysphagia grade 3 (tube feeding)	5 (10)	25 (50)	<0.001	45 (34-118)	102 (15-155)	n.s.
Late toxicity (90 days - 1 year)						
n=40/42						
Soft tissue fibrosis grade 2*	1 (2.5)	1 (2.4)	n.s.			
Xerostomia grade 2*	3 (7.5)	22 (52.4)	<0.001			
Dysphagia grade ≥2	1 (2.5)	17 (40.5)	<0.001			
Dysphagia grade 3 (tube feeding)	1 (2.5)	11 (26.2)	0.002			

Toxicity incidences: chi-squared test; toxicity duration: Mann-Whitney U test. All tests two-sided. \* no patients with grade 3 toxicity.

## Conclusion

Selective SPECT/CT-guided ENI decreased acute dysphagia, feeding tube placement, and late xerostomia, compared to conventional bilateral ENI. Additionally, it resulted in shorter duration of acute toxicity in general.

## PO-0727 Voice outcome following radiotherapy or laser microsurgery in patients with early glottic cancer

A. Allajbej<sup>1</sup>, F. Patani<sup>2</sup>, S. Di Biase<sup>2</sup>, D. Fasciolo<sup>2</sup>, C. Di Carlo<sup>2</sup>, C. Rosa<sup>2</sup>, L. Gasparini<sup>2</sup>, M. Di Francesco<sup>3</sup>, G. Falcone<sup>4</sup>, G. Quaternato<sup>5</sup>, A. Croce<sup>5</sup>, A. Di Pilla<sup>2</sup>, M. Trignani<sup>2</sup>, L. Caravatta<sup>2</sup>, D. Genovesi<sup>2</sup>

<sup>1</sup>SS. Annunziata, Radiotherapy, Chieti, Italy; <sup>2</sup>SS Annunziata, Radiotherapy, Chieti, Italy; <sup>3</sup>Papa Paolo VI Foundation, Speech rehabilitation, Chieti, Italy; <sup>4</sup>Papa Paolo VI Foundation, Phoniatrics, Chieti, Italy; <sup>5</sup>SS Annunziata, Otorhinolaryngology, Chieti, Italy

## Purpose or Objective

Oncological outcome of patients affected by early glottic cancer (EGC) treated with radiotherapy (RT) either Laser Microsurgery (LM) is similar, but it is not clear if and how these treatment modalities could differ in terms of voice quality (VQ) outcome and voice handicap. Prospective randomized studies comparing vocal outcomes following RT vs LM are lacking and voice evaluation methodology during follow-up is often not well structured. The aim of our study is to report clinical outcomes, focalizing on voice quality of patients who received either RT or LM.

## Material and Methods

We evaluated 45 EGC patients (Tis, T1 and T2 stages) submitted to primary RT or LM between 2008-2017. Overall survival (OS), progression free survival (PFS) and radiation induced toxicities according to CTCAE v. 4.0 scale were evaluated. For a subsample of this EGC population a multi-modality VQ analysis was performed. Voice evaluation includes: Voice Handicap Index (VHI-30), objective analysis using PRAAT software and perceptual rating performed by speech therapist (GRBAS scale). A clinical examination was performed jointly with radiation oncologist, otolaryngologist and speech pathologist, involving laryngeal evaluation with videostroboscope (VS) and laryngoscope

## Results

A total of 30 patients, average age of 74 years (range 54-86), received RT with a total dose of 66-70 Gy, 2 Gy/day, using 3-dimensional conformal technique. 15 patients received LM. Overall tumor stage distribution was: Tis (8.9%), T1 (86.7%), and T2 (4.4%). The median follow-up was 40.5 months (range 6-115 months). OS and PFS were 96.6% and 96.6% for RT group and 93.3% and 86.7% for LM group; from the original sample of 45 patients, in the context of ongoing VQ analyses 16 patients were evaluated to date. VHI-30 scores showed a mild (25.5) and severe (73.6) voice disability for RT and LM groups, respectively. Regarding GRBAS scale voice dysfunction in the LM group tends to be more moderate (67%) than severe (33%) whereas in the RT group tends to be more mild (40%) than moderate (20%).

VS evaluation showed reduced vocal cord motion in 50% of LM group and 10% of RT group and incomplete glottic closure in 100% of LM group and 40% of RT group. In the table we reported the vocal acoustic analysis and VS evaluation in both groups.

Table . Summary of videostroboscopy evaluation and vocal acoustic analysis of RT and LM groups

Laryngeal videostroboscopy evaluation		
Variable	RT (%)	LM (%)
Vocal cord motion		
Normal	80	50
Reduced	10	50
Amplitude vibration		
Normal	50	33,3
Increased	40	66,7
Mucosal wave		
Normal	80	33,3
Edema	10	66,7
Glottic closure		
Complete	50	0
Incomplete	40	100
Vocal acoustic analysis		
Variable	RT (mean ± SD)	LM (mean ± SD)
F <sub>0</sub> (Hz)	131,6 ± 23,8	206,8 ± 85,02
MPT (sec)	10,9 ± 3,21	7,44 ± 3,92
Jitter (%)	1,1 ± 1,52	1,86 ± 2,5
Shimmer (%)	10,35 ± 5,49	11,51 ± 5,58
HNR (dB)	13,48 ± 5,65	13,87 ± 5,60

\* For 1 patient in the RT group cordal examination was not possible due to important vagovagal reflex

MPT: Maximum phonation time, F<sub>0</sub> (Hz): Fundamental frequency, Jitter (%): Frequency variation, Shimmer (%): amplitude variation, HNR (dB): Harmonic s-to-Noise ratio. Threshold for pathologic voice: Jitter ≥ 1.04%, Shimmer ≥ 3.81%

## Conclusion

EGC patients can benefit from LM or RT both aimed to obtain organ and function preservation; as patients submitted to RT or LM can achieve similar OS and PFS rates, it is all about vocal "performance". Preliminary results from the recorded data (VHI-30, GRBAS scale and PRAAT analysis) seem to show a more favorable voice outcome in RT patients vs LM. The study is still ongoing; we attempt to recruit more patients, so then statistical analysis will be performed in order to compare clinical and voice outcome in two treatment modalities (RT and LM) and to confirm these results.

## PO-0728 Irradiation of salivary gland tumors with carbon ion radiotherapy (CIRT) at CNAO

B. Vischioni<sup>1</sup>, B. Dhanireddy<sup>2</sup>, M. Bonora<sup>1</sup>, S. Ronchi<sup>1</sup>, V. Vitolo<sup>1</sup>, M.R. Fiore<sup>1</sup>, E. D'Ippolito<sup>1</sup>, R. <sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy; <sup>2</sup>Post Graduate Institute of Medical Education and Research PGIMER, Department of Radiation Oncologist, Chandigarh, India; <sup>3</sup>University of Messina, Radiation therapy Unit, Messina, Italy; <sup>4</sup>Ospedale Vito Fazzi, Radiation therapy Unit, Lecce, Italy; <sup>5</sup>Osaka Heavy Ion Therapy Center, Radiation therapy Unit, Osaka, Japan; <sup>6</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

## Purpose or Objective

to report oncologic and functional outcomes of carbon ion radiotherapy (CIRT) in re-radiation setting for recurrent salivary gland tumors at CNAO.

## Material and Methods

From november 2013 to december 2016 patients (pts) with recurrent salivary gland tumors were enrolled in a phase-II protocol (CNAO-S14) to evaluate outcome of CIRT in the setting of carbon ions head and neck re-radiation in terms of toxicity and tumor control.

## Results

A total of 51 pts enrolled on the protocol were recurrent salivary gland tumors. Pts median age was 60 years (± 14.34), 53% males and 47% females. Majority of pts (74.5%) had adenoid cystic carcinoma, rT4a (51%) and rT4b (37%) stage, 90% without clinically diagnosed nodal

disease. Median dose of prior photon based radiation was 60Gy ( $\pm$  SD: 10.4, range: 24-78Gy). Median time interval between prior radiation and recurrence was 6.33 years (SD: 3.67, range: 1.08 to 20 years). Median dose of CIRT at the time of re-radiation was 60GyE at 3 GyE per fraction. During re-radiation, 11 pts (21.6%) had G0 toxicity (no toxicity), 19 pts (37.3%) had G1, 19 pts (37.3%) had G2 and 2 pts (3.9%) had G3 toxicity. Median follow-up was 19 months (SD: 14.42, range: 2-57). Twenty one (41.2%) pts had stable disease and 30 pts (58.8%) tumor progression at the time of last follow up. Furthermore, 14 pts (27.5%) had no late toxicity, 9 (18%) pts had G1, 19 pts (37%) had G2 and 9 pts (17.5%) had G3 late toxicities. Using Kaplan Meier method, estimated PFS (actuarial) at one, two and three years were 80%, 65.1% and 43.5% respectively. Estimated OS (actuarial) at one, two and three years were 90.2%, 69.1% and 54.5% respectively. The estimated mean and median PFS was 28.89 (SD: 3.06) and 25.00 (5.95) months respectively. In receiver operating curve (ROC) analyses, there was significant difference of median survival time after CIRT between the cut-off value of 34 cc of GTV in treated pts. The estimated median PFS in pts with GTV less than 34 cc and more than 34 cc were 34.00 ( $\pm$ 3.37) and 13 months ( $\pm$ 7.13) respectively (log rank test,  $p=0.038$ ).

### Conclusion

In re-radiation setting, CIRT is effective in controlling local progression of recurrent salivary gland tumors along with acceptable rates of acute and late toxicity.

### PO-0729 Prognostic factors analysis in a cohort of Nasopharyngeal cancer patients with 5-year follow-up

N.A. Iacovelli<sup>1</sup>, A. Cavallo<sup>2</sup>, A. Cicchetti<sup>3</sup>, L. Ferella<sup>1</sup>, N. Facchinetti<sup>1</sup>, T. Giandini<sup>2</sup>, S. Meroni<sup>2</sup>, D.A. Romanello<sup>1</sup>, P. Bossi<sup>4</sup>, L. Licitra<sup>4</sup>, E. Pignoli<sup>2</sup>, C. Fallai<sup>1</sup>, E. Orlandi<sup>1</sup>  
<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Radiotherapy Unit 2, Milan, Italy; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Medical Physics Unit, Milan, Italy; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Prostate Cancer Program, Milan, Italy; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Head and Neck Medical Oncology Unit, Milan, Italy

### Purpose or Objective

To evaluate clinical outcome and prognostic factors in a consecutive series of non-metastatic nasopharyngeal carcinoma (NPC) patients (pts) treated curatively with intensity modulated radiotherapy (RT) techniques (IMRT, Intensity Modulated Radiation Therapy or VMAT, Volumetric Modulated Arc Therapy) and chemotherapy (CT) with a minimum follow-up of 5 years.

### Material and Methods

A retrospective analysis of consecutive non-metastatic NPC pts treated between 2005 and 2013 was conducted. According to WHO, 123 patients (89.8%) were suffering from undifferentiated NPC, 5 patients (3.6%), 2 patients (1.5%) and 7 patients (5.1%) were respectively affected by squamous cell carcinoma G1, G2 or G3. Two pts were in stage I (1.5%), 23 pts (16.8%) were in stage II, 38 pts (27.7%) in stage III, 29 pts (21.2%) in stage IVA and 45 pts (32.8%) in stage IVB. Five pts (3.6%) received RT alone: 1 pt in stage I and 4 pts in stage II. Of the remaining 132 pts (96.4%) (9 pts with stage II and 123 pts with stage III and IV) 30 patients (21.9%) received CT concomitant to RT and 102 patients (74.4%) were treated with induction CT followed by RT-CT. IMRT was given with standard fractionation at a total dose of 70 Gy. A dedicated software (VODCA, www.vodca.ch) was used to collect and analyze dosimetric parameters. Clinical outcomes investigated in the study were local control (LC), disease-free survival (DFS) and overall survival (OS). Kaplan-Meier analysis was performed for the outcomes considering dose and coverage parameters, staging, CT and RT technique.

### Results

Overall, 137 pts were eligible for this retrospective analysis. With a median follow up of 70 months (range 12 - 143) actuarial rates at 2 and 5 years were respectively: LC 92.2% and 90.4%, DFS 83.1% and 77.2% and OS 92.4% and 82.8%. The median follow-up period was 70 months (range 12-143 months). T stage was dichotomized as T1-T2-T3 vs T4. At 5 years the group T1-T2-T3 reported a LC of 93%, a DFS of 79% and a OS of 88%, whereas T4 pts reported a LC, DFS and OS respectively of 56%, 50% and 78%. All outcomes (LC, DFS and OS) were significantly better with VMAT compared to conventional IMRT (Table 1). In particular T4-stage pts treated with VMAT fared similarly compared to pts with T1-T2-T3 stages treated with conventional IMRT (Figure 1). Regardless of RT technique, pts with a V95% > 95.5% had better LC ( $p=0.006$ ). Pts with a D99% > 63.8 Gy had better LC ( $p=0.034$ ) and OS ( $p=0.005$ ). The threshold value of 43.2 cc of GTV T was prognostic for LC ( $p = 0.016$ ). At multivariate analysis GTV T, RT technique (VMAT) and D99% resulted prognostic for LC ( $p=0.04$ ).

Parameter	Patients	LC	LC stat.	DFS	DFS stat.	OS	OS stat.
T1-T2-T3	98	93%	HR=5.67	79%	HR=2.36	88%	HR=2.15
T4	39	56%	$p<0.001$	50%	$p=0.014$	78%	$p=0.09$
VMAT	64	95%	HR=3.75	89%	HR=3.01	97%	HR=6.81
IMRT	73	78%	$p=0.027$	63%	$p=0.007$	77%	$p=0.03$

Tab1. Statistical values of Kaplan-Meier analysis for the three outcomes: survival rate, hazard ratios (HR) and p-value.

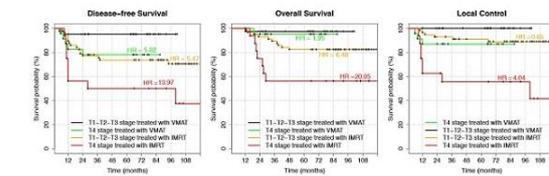

Fig. 1. Kaplan-Meier curves for the analyzed outcomes. Patients were stratified according to T stage and radiotherapy modality. (In black) Control (no late toxicity) and (in red) late toxicity (G1, G2, G3). HR= Hazard Ratio. OS= Overall Survival. DFS= Disease-free Survival. LC= Local Control.

### Conclusion

Although in a retrospective series, we demonstrated the prognostic value of some dose-volume parameters, potentially useful to improve planning procedure. In addition, for the first time in a non-endemic area, a threshold value of GTV T, prognostic for LC, has been confirmed.

### PO-0730 NTCP model for penetration/aspiration after (chemo)radiation including DVH parameters.

<sup>1</sup>University Medical Center Groningen- Groningen, Department of Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

Late aspiration, especially silent, is one of the most hazardous complications after (chemo)radiation ((CH)RT) for head and neck cancer, resulting in 3-year morbidity rates of approximately 20% and increased mortality. However, limited data exists on dose-effect relationship for late aspiration. Radiation doses to some of the swallowing organs at risk (SWOARs), such as pharyngeal constrictor muscles, are associated mainly with the subjective dysphagia measurements. The purposes of this analysis was to identify the best predictors of penetration/aspiration (as assessed on videofluoroscopy (VF)), after (CH)RT, using clinical data as well as DVH parameters.

### Material and Methods

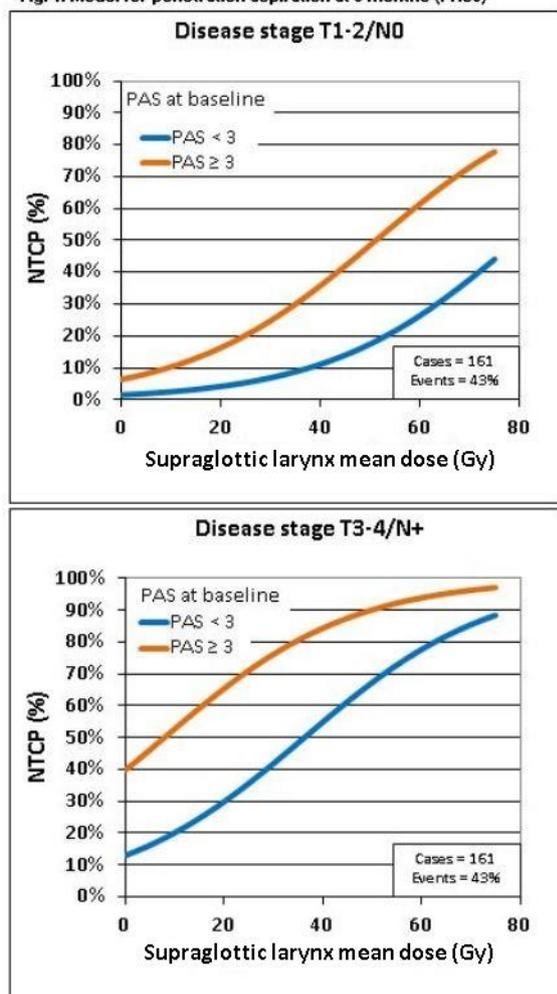

This prospective cohort study included 186 head and neck cancer patients receiving definitive (CH)RT. Patients underwent a comprehensive dysphagia assessment (including VF) at baseline and 6 months after treatment. 161 patients underwent VF at both time points and were included in this analysis. The primary endpoint was a Penetration Aspiration Scale (PAS) score  $\geq 3$

(penetration/aspiration) at 6 months after treatment, scored with VF (PAS6). From all baseline features, a set of candidate variables was selected based on plausible relevance in relation to PAS6. Average doses ( $D_{\text{mean}}$ ) to SWOARs were collected. Additionally, univariable analysis with correction for cross correlation of candidate variables was performed. Multivariable logistic regression with stepwise forward elimination and internal validation, using bootstrapping, was performed to correct for optimism of the model for PAS6.

### Results

The prevalence of PAS6 was 43% (73 patients). The best performing model included 4 independent prognostic factors for PAS6: PAS at baseline, T-stage, N-stage and  $D_{\text{mean}}$  to the supraglottic larynx. Figure 1. After internal validation using bootstrapping the model performance (Nagelkerke  $R^2$ : 0,398; ROC-AUC: 0.818) and calibration were good.

Fig. 1. Model for penetration aspiration at 6 months (PAS6)

### Conclusion

Patients with more advanced disease are at the highest risk of penetration/aspiration after (CH)RT. This risk increases substantially in case of penetration/aspiration observed at baseline VF. Moreover, increasing dose to supraglottic larynx contributes to further escalation of the risk of penetration/aspiration 6 months after (CH)RT.

### PO-0731 Transition from anatomical to geometric expansion modality for high-risk CTV in oropharyngeal cancer

P. Bonomo<sup>1</sup>, I. Desideri<sup>1</sup>, C. Becherini<sup>1</sup>, L. Visani<sup>1</sup>, V. Salvestrini<sup>1</sup>, M. Mariotti<sup>1</sup>, P. Garlatti<sup>1</sup>, L. Dominici<sup>1</sup>, L.

Livi<sup>1</sup>

<sup>1</sup>Azienda Ospedaliero-Universitaria Careggi, Radiation Oncology, Florence, Italy

### Purpose or Objective

The definition of primary tumor clinical target volume (CTV) for HNSCC has been recently reviewed in international guidelines. The aim of our work was to assess the impact of two different delineation approaches (anatomical vs geometric expansion) on the clinical outcome of patients with oropharyngeal cancer (OPC).

### Material and Methods

We performed a retrospective analysis of consecutive patients treated at our institution for OPC between January 2010 and April 2018. In 2014, our local policy to delineate high risk (HR) CTV for both primary (CTV-p) and nodal (CTV-n) GTVs shifted from an anatomical expansion (AE) to a geometric expansion (GE) modality, described as follows:

- AE: CTV-p consisted of the primary GTV plus the whole oropharyngeal anatomical compartment, edited for air cavities and anatomical barriers; CTV-n consisted of the nodal GTVs plus the corresponding lymph node level (delineated according to Gregoire's classification), including also the level immediately adjacent to it

- GE: CTV-p consisted of the primary GTV plus an isotropic 5 mm margin, manually edited for air cavities and anatomical barriers; CTV-n consisted of the nodal GTVs plus an isotropic 7 mm margin, manually edited to take into account anatomical barriers (i.e. sternocleidomastoid muscle, if not infiltrated). Of note, an additional 5 mm margin to the CTV-p was not added.

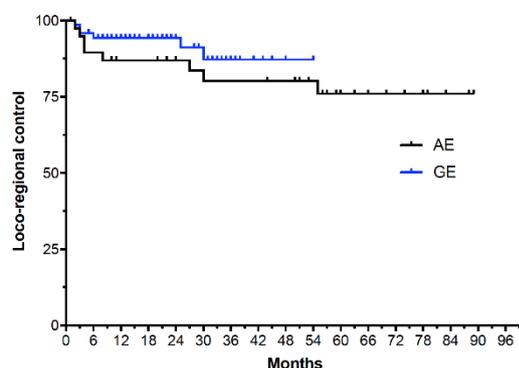

All patients received IMRT with 3 dose levels: the high, intermediate and low risk CTVs received 70, 60 and 50 Gy or 69.9, 59.4 and 52.8 Gy in 35 or 33 fractions, respectively, depending on whether a sequential or SIB technique was employed. A 3-5 PTV margin was added to CTV's (3 mm in case of daily image guidance). HPV status was not routinely available until 2015.

Locoregional control (LRC) was defined as the time from the last treatment day to local or nodal failure or both. Progression-free survival (PFS) was defined as the time from the last treatment day to disease progression or death from any cause. Overall survival (OS) was defined as the time from OPC diagnosis to death from any cause. Median LRC, PFS and OS were calculated. The relative estimates of LRC and PFS at 24 months were estimated by the Kaplan-Meier method.

### Results

A total of 116 patients were included (table 1). In terms of HR CTV expansion modality, 43 (37.1%) were treated with AE and 63 (62.9%) with GE, respectively. One patient in the AE cohort was lost to follow-up after first evaluation, therefore 115 patients are evaluable for outcome analysis. At a median follow-up of 26 months (range: 1-86), 87 patients were alive (75.6%). The median LRC, PFS and OS for the whole group were 24 (95% CI: 25.3-33.8), 24 (95% CI: 24.6-33.2) and 31 (95% CI: 30.7-38.6) months, respectively. There was no difference between the AE and GE cohorts in terms of 2-year LRC (86.9% vs 94.3%;  $p=0.28$ ) (figure 1) and PFS (68.8% vs 80.9%,  $p=0.56$ ).

Characteristic	No. of patients (%), n = 116	AE (%), n = 43	GE (%), n = 73
Median age, years (range)	62.5 (43-88)	60 (43-81)	63 (43-88)
Sex			
Male	84 (72.4%)	28 (65.1%)	56 (76.7%)
Female	32 (17.6%)	15 (34.9%)	17 (23.3%)

0	97 (83.6%)	37 (86%)	60 (82.1%)
1	19 (16.4%)	6 (14%)	13 (17.9%)
Charlson Comorbidity index (age-adjusted)			
<4	49 (42.2%)	22 (51.2%)	27 (36.9%)
4-7	63 (54.3%)	19 (44.1%)	44 (60.3%)
≥8	4 (3.5%)	2 (4.7%)	2 (2.8%)
Smoking history (packyears)			
0	23 (19.8%)	6 (13.9%)	17 (23.3%)
<10	19 (16.3%)	12 (27.9%)	7 (9.5%)
10-20	27 (23.3%)	5 (11.6%)	22 (30.2%)
>20	47 (40.6%)	20 (46.6%)	27 (37%)
HPV status			
Positive	52 (44.9%)	7 (16.3%)	45 (61.6%)
Negative	20 (17.2%)	7 (16.3%)	13 (17.8%)
Unknown	44 (37.9%)	29 (67.4%)	19 (26%)
AJCC stage (Vilth ed)			
II	11 (9.5%)	4 (9.3%)	7 (9.5%)
III	23 (19.8%)	7 (16.3%)	16 (22%)
IVA	72 (62.1%)	30 (69.7%)	42 (57.6%)
IVB	10 (8.6%)	2 (4.7%)	8 (10.9%)
Treatment modality			
RT alone	23 (19.8%)	16 (37.2%)	7 (9.2%)
conc. cisplatin-RT	88 (75.9%)	25 (58.2%)	63 (86.4%)
TPF followed by CRT	5 (4.3%)	2 (4.6%)	3 (4.14%)
IMRT schedule			
sequential	22 (18.9%)	6 (14%)	16 (22%)
SIB	94 (81.1%)	37 (86%)	57 (78%)

### Conclusion

The adoption of a GE expansion modality with resulting smaller HR CTVs was not associated with a detrimental impact on outcome in OPC.

### PO-0732 NTCP model for osteoradionecrosis after definitive radiotherapy in head and neck cancer patients.

N. Den Haan<sup>1</sup>, L. Van den Bosch<sup>1</sup>, A. Van den Hoek<sup>1</sup>, H. Bijl<sup>1</sup>, R. Steenbakkers<sup>1</sup>, M. Dieters<sup>1</sup>, H.P. Van der Laan<sup>1</sup>, H. Langendijk<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

The purpose of this prospective cohort study was to develop a normal tissue complication probability (NTCP) model for predicting the risk of mandibular osteoradionecrosis (ORN) in patients with head and neck cancer (HNC) treated with definitive (chemo)radiotherapy.

### Material and Methods

The population of this study was composed of 740 patients with HNC treated with definitive (chemo)radiotherapy in the period from January 2007 to June 2016. Mandibular ORN was scored prospectively as part of a standard follow-up program according to CTCAEv4.0. Mandibular dose-volume histograms (DVH) were extracted from the treatment planning system. Dosimetric parameters were compared using the Wilcoxon rank-sum test. The model

was developed using a multivariate logistic regression analysis with backward selection.

### Results

The median follow-up time for all patients was 36 months. In total 18 out of 740 cases (2.4%) developed ORN grade ≥ 2 and the median time to ORN was 12 months. The cumulative incidence of ORN over 6, 12, 18 and 24 months was 1.2, 2.1, 2.6 and 3.1%, respectively.

To identify the most important DVH-parameter, the mean values of the DVH-parameters between cases and non-cases were compared first. The mean and maximum dose to the mandible were higher among patients with ORN vs. non-cases (31.7 vs 45.3 Gy,  $p = 0.003$  and 53.1 vs 71.8 Gy,  $p < 0.001$ , respectively). DVH bins from V25 to V70 were all significantly higher in the ORN cohort compared with controls (figure 1). The best predictor for mandibular ORN was the V60 (volume receiving 60 Gy). No other significant prognostic factors or confounders for ORN were identified. The p-value for this model was 0.002, with an OR of 16.21 (95% CI 2.79-94.28) and an AUC of 0.78 (95% CI 0.71-0.85). See figure 2 for the NTCP model.

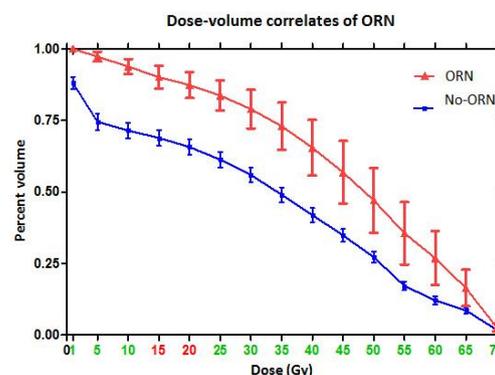

Figure 1. Comparison of the DVHs between the plans for ORN cases vs non-cases; each error bar is constructed using a 95% confidence interval of the mean. The numbers in green at the X-axis represent p-values <0.05, the numbers in red represent p-values >0.05.

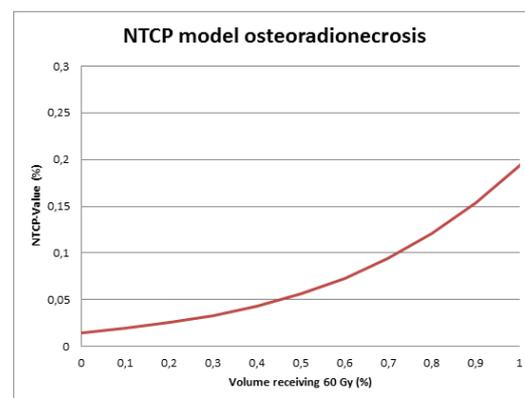

Figure 2. NTCP model osteoradionecrosis

### Conclusion

This is the largest prospective cohort study ever done on the development of mandibular ORN in patients treated with definitive radiotherapy or chemoradiation. In comparison to the incidence of ORN in the postoperative setting, the incidence of ORN is relatively low. The main risk factor is the dose to the mandible and in particular the high dose volume. The V60 turned out to be the most important prognostic factor.

### PO-0733 Non-invasive imaging for tumor hypoxia: a novel validated CT and FDG-PET-based Radiomic signature.

<sup>13</sup>Maastricht Clinic, 2.Department of Radiation Oncology, Maastricht, The Netherlands ;  
<sup>14</sup>Maastricht Clinic, Department of Radiation Oncology, Maastricht, The Netherlands

#### Purpose or Objective

Tumor hypoxia increases resistance to radiotherapy and systemic therapy as well as promoting tumor metastasis. Our primary aim was to develop and validate a CT- and FDG-PET-based hypoxia classification signature based on radiomic features.

#### Material and Methods

A total of 131 patients (78 head and neck squamous cell carcinoma, 61 non-small cell lung cancer, 13 pancreatic carcinoma and 13 esophageal carcinoma) with low dose [<sup>18</sup>F]-HX4-PET/CT and 61 patients with [<sup>18</sup>F]-FDG-PET from 5 imaging centers were included. One dataset with [<sup>18</sup>F]-FAZA PET/CT (36 NSCLC) and another dataset (40 HNSCC) with pimonidazole stained tumor biopsies were used as additional external validation datasets. The primary gross tumor volumes (GTV) were manually delineated on CT. In order to create three dichotomized groups between hypoxic and well-oxygenated tumors, [<sup>18</sup>F]-HX4-derived hypoxic fractions (HF) were thresholded at 10%, 20% and 30%. The HX4-derived HF was defined as the ratio of the hypoxic region (tumor-to-background ratio > 1.4) to the total GTV. A random forest (RF)-based classifier was trained to stratify patients into hypoxia-positive/ negative cohorts based on radiomic features.

#### Results

In the 20% HF threshold group, the area under the receiver operating characteristic curve (AUC) for an RF model combining 5 CT-derived radiomic features achieved 0.79±0.16 in the Boston/ NKI and 0.76±0.18 in the UCL validation sets respectively. In the same threshold group, an RF model combining 10 radiomic features derived from FDG-PET reached an AUC of 0.74±0.23 to classify hypoxia in an external validation dataset (Boston/ Maastricht).

#### Conclusion

Our hypoxia signatures derived from CT and FDG-PET have the potential to inform interventional trials studying hypoxia-targeting agents by identifying patients with tumors likely to be hypoxic.

PO-0734 Patterns of Care in the Management of WHO Grade II and III Spinal Ependymomas

D. Yebo<sup>1</sup>, K. Liao<sup>2</sup>, B.A. Guadagnolo<sup>1</sup>, G. Rao<sup>3</sup>, A. Bishop<sup>4</sup>, C. Chung<sup>4</sup>, J. Li<sup>4</sup>, C.E. Tatsui<sup>3</sup>, L. Rhines<sup>3</sup>, S. Ferguson<sup>3</sup>, A. Paulino<sup>4</sup>, A. Ghia<sup>4</sup>  
<sup>1</sup>MD Anderson Cancer Center, Radiation Oncology- Joint appointment Health Services Department, Houston, USA ;  
<sup>2</sup>MD Anderson Cancer Center, Health Services Department, Houston, USA ;  
<sup>3</sup>MD Anderson Cancer Center, Neurosurgery, Houston, USA ;  
<sup>4</sup>MD Anderson Cancer Center, Radiation Oncology, Houston, USA

#### Purpose or Objective

Spinal ependymomas are rare with an incidence of 1 per 100,000. The management and patterns of care for spinal cord ependymomas require further investigation given the paucity of data for high grade disease.

#### Material and Methods

A National Cancer Database (NCDB) was searched for eligible patients >18 years old with a diagnosis of spinal ependymoma at a Commission on Cancer facility from 2004 through 2014. Chi-square test, simple logistic regression, and multivariable logistic regressions were used to assess the potential significance of associations between patient characteristics and treatment received. Facility volume characteristics were assessed in relation to survival by evaluating the number of patients diagnosed and the facility volume was organized by relative quartiles. We assessed the average number of patients seen at each facility within a 1-year timeframe and over an equivalent 10-year timeframe.

#### Results

Our study of 1,345 patients with high-grade spinal ependymoma and almost one decade of follow-up data uniquely describes practice patterns and long-term overall survival (OS) independent of treatment received for grade II and grade III ependymoma. The majority of grade II patients received surgery alone (81.1%). In contrast, 36.8% of grade III patients received surgery alone. Only 56.3% of grade III spinal ependymomas received adjuvant therapy with either radiation therapy (RT) or combination RT and chemotherapy after surgery. Over 60% percent of patients with grade III disease received initial adjuvant RT, in contrast to only 15.3% of patients with grade II ependymoma (P< 0.001). Patients living ≤20 miles from a RT facility were more likely to receive RT (P<0.001) than those living further away. On multivariable logistic regression, grade (grade III: OR 8.6, P<0.001) and facility distance were significantly associated with receipt of RT (P<0.0001). Among all patients, the 5 and 10-year OS rates were 94.7%/ 85.1% for patients with grade II disease and 58.2%/46.4% for those with grade III disease (P<0.0001). The OS rates were higher at facilities treating at least 1.5 patients per year (i.e., an average of 15 patients over 10 years), which corresponds to the top 81st percentile in facility volume. The 5-year OS rates were 96.7% for patients treated at high-volume facilities, followed by 93.4% at facilities treating 6-14 patients, 92.5% for 2-5 patients, and 86.8% for <2 patients over 10 years (P<0.0019).

#### Conclusion

In conclusion, our study is the largest series to date reporting observational patterns of care for grade II and III spinal ependymomas. Despite guideline recommendations for adjuvant therapy in all grade III ependymomas regardless of extent of resection, approximately 2 in 5 do not receive immediate adjuvant therapy and our data suggests this may be related to distance lived from a CoC facility. Facilities at which larger numbers of patients with spinal ependymomas are treated may experience better long-term outcomes.

---

PO-0735 Cognitive function after radiation therapy for brain tumours

L. Haldbo-Classes<sup>1</sup>, A. Amidi<sup>2</sup>, L. Wu<sup>3</sup>, S. Lukacova<sup>1</sup>, G. Von Oettingen<sup>4</sup>, R. Zachariae<sup>2</sup>, J. Kallehauge<sup>3</sup>, M. Hoyer<sup>5</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Oncology,

Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital and Aarhus University, Department of Oncology and Department of Psychology and Behavioral Sciences, Aarhus, Denmark ; <sup>3</sup>Northwestern University Feinberg School of Medicine, Department of Medical Social Sciences, Chicago, USA ; <sup>4</sup>Aarhus University Hospital, Department of Neurosurgery, Aarhus, Denmark ; <sup>5</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus, Denmark

### Purpose or Objective

To assess cognitive function in patients with a primary brain tumour treated with radiotherapy (RT). The extent of RT-induced changes in cognitive function is unknown. RT with protons instead of photons spares more healthy brain tissue and may reduce the risk of cognitive dysfunction; however, existing knowledge regarding the parts of the brain that need to be spared to prevent cognitive dysfunction, is limited. To determine the cognitive domains most affected by RT, we compared cognitive functioning in brain tumour patients treated with neurosurgery and RT with brain tumour patients treated with neurosurgery only. Furthermore, we investigated the correlations between cognitive scores and RT dose-volume parameters in specific areas of the brain.

### Material and Methods

A cross-sectional study assessing cognitive function in 110 patients with a primary brain tumour grade I-III or medulloblastoma (grade IV) treated at Aarhus University Hospital (AUH), Denmark, between 2006 and 2016. Two cohorts were established: A cohort of 81 brain tumour patients who had received neurosurgery followed by RT (RT+) and a cohort of 29 brain tumour patients who had only received neurosurgery (RT-). The patients completed questionnaires and underwent neuropsychological assessment with standardized tests. RT dose-volume histogram (DVH) of specific areas in the brain were extracted from the treatment plans to explore correlations between dose-volume parameters and cognitive scores.

### Results

Mean age was 53.5 years with an average time since diagnosis of 7.3 years. Compared with normative data, lower average scores were observed for the entire group in the following domains: verbal learning and memory ( $p < 0.001$ ), attention and working memory ( $p < 0.001$ ), processing speed ( $p < 0.001$ ), and executive functioning ( $p < 0.001$ ). Compared to RT- patients, RT+ patients scored lower on domains concerning processing speed ( $p = 0.04$ ) and executive function ( $p = 0.05$ ) and had higher impairment frequency on verbal fluency ( $p = 0.02$ ) with 16% of patients exceeding 1.5 SD below the normative mean. At time of analysis, 52 RT+ patients' DVH of the left hippocampus was extracted. When examining scores on Hopkins Verbal Learning Test (HVLT), a test assessing verbal learning and memory, higher RT dose to the hippocampus was correlated with the number of people with impaired scores on HVLT.

### Conclusion

Our results indicate that treatment, including RT, for a primary brain tumour may have negative long-term impact on cognitive function, especially on processing speed and executive function. Preliminary data suggest that higher RT dose to the left hippocampus is associated with greater verbal learning and memory impairment.

### PO-0736 Radiation necrosis after a combination of EBRT and iodine-125 brachytherapy in gliomas

I. Hadi<sup>1</sup>, D. Reitz<sup>1</sup>, R. Bodensohn<sup>1</sup>, O. Roengvoraphoj<sup>1</sup>, M. Niyazi<sup>1,2</sup>, C. Belka<sup>1,2</sup>, F. Kreth<sup>3</sup>, S.B. Nachbichler<sup>1</sup>

<sup>1</sup>University Hospital- LMU Munich, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>German Cancer Consortium DKTK, Department of Radiation Oncology,

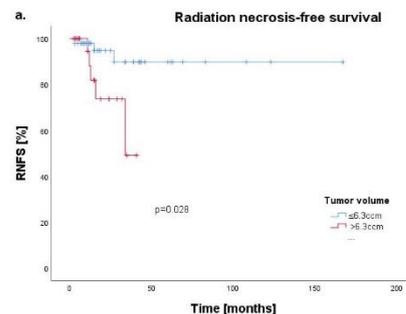

Munich, Germany ; <sup>3</sup>University Hospital- LMU Munich, Department of Neurosurgery, Munich, Germany

### Purpose or Objective

The frequency and the risk profile of radiation necrosis in patients with glioma undergoing either upfront stereotactic brachytherapy (SBT) and additional salvage external beam radiotherapy (EBRT) after tumor recurrence or vice versa remains unknown.

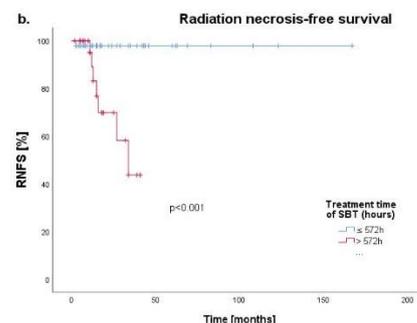

### Material and Methods

Patients with glioma treated with low-activity temporary iodine-125 SBT between 1999 and 2016 who had either additional upfront or salvage EBRT were included. Biologically effective doses were calculated. Radiation necrosis was diagnosed using stereotactic biopsy and/or metabolic imaging. The rate of radiation necrosis was estimated with the Kaplan Meier method. Risk factors were obtained from logistic regression models. ROC and AUC analyses were used to determine optimal cut-off values for identified risk factors.

### Results

Eighty-six patients (49 male, 37 female), with a median age of 47 years were included. Median follow-up was 15.0 months after second irradiation treatment. Fifty-eight patients received upfront EBRT (median total dose: 60 Gy), and 28 patients upfront SBT (median reference dose: 54 Gy, median dose rate: 10.0 cGy/h). The median time interval between both treatments was 19 months. In 8/75 (10.7%) patients a radiation necrosis was diagnosed. The one- and two- year risk of radiation necrosis was 5.1% and 11.7%, respectively. The logistic regression models indicated tumor volume of SBT (Fig.a), irradiation time of SBT (Fig.b), number of implanted seeds, and salvage EBRT as significant risk factors for radiation necrosis. Neither of the BED values nor the time interval between both treatments gained prognostic influence.

### Conclusion

The combination of upfront EBRT and salvage SBT or vice versa is feasible for glioma patients. The risk of radiation necrosis is mainly determined by the treatment volume but not by the interval between the therapies.

### PO-0737 Retrospective analysis of hypofractionated stereotactic radiotherapy for tumors larger than 2 cm

Y. Koide<sup>1</sup>, T. Kodaira<sup>1</sup>, H. Tachibana<sup>1</sup>, H. Tanaka<sup>1</sup>, N. Tomita<sup>2</sup>

<sup>1</sup>Aichi Cancer Center, Radiation oncology, Nagoya, Japan ; <sup>2</sup>Nagoya City University Graduate School of Medical Sciences, Department of Radiology, Nagoya, Japan

#### Purpose or Objective

Large brain metastases (BM) are associated with limited local control and neurotoxicity. Some recent studies reported that hypofractionated stereotactic radiotherapy (HFSRT) is a reasonable option for such tumors, relative to single-fraction therapy. We evaluated the efficacy and the safety of HFSRT for BM larger than 2 cm.

#### Material and Methods

From 2006 to 2016, 61 patients with BM larger than 2 cm were treated with HFSRT in our institution. The exclusion criteria were: (1) no available magnetic resonance imaging or computed tomography, (2) prior brain radiotherapy or surgery, and (3) combination with whole brain radiotherapy. All patients were treated using helical tomotherapy. The planning target volume (PTV) was set as the gross tumor volume plus a 2-mm margin in all dimensions. The prescription dose was 35 Gy in 5 fractions, and assigned to the 90% isodose surface used PTV coverage of 95%, normalized to 100% dose at the isocenter. Eligible patients were divided according to maximum BM diameter (group A [23 patients]:  $\geq 3$  cm, group B [22 patients]:  $< 3$  cm) to assess the relationship between tumor size and prognosis or safety. The primary endpoint was local control rate (LCR), and secondary endpoints were response rate (RR), brain progression-free survival (BPFS), median survival time (MST), and radionecrosis (RN). Univariate and multivariate analyses for LCR were conducted using Cox's proportional hazards model.

#### Results

A total of 45 patients with 58 lesions were eligible in this study. All patients completed planned HFSRT schedule without delay or discontinuation. At the last follow-up, 7 patients (15.6%) were alive, 34 patients (75.6%) had died, and 4 patients (8.9%) were lost to follow-up. The median follow-up period for all patients were 11.3 months (range: 1.7-93.9 months) and 15.2 months (range: 6.9-93.9 months) among patients who had not died. The median tumor volume for all lesions was 19.3 mL (range: 6.21-115.4 mL). The RR was 86.4% with an overall LCR of 64.7% at 12 months (67.1% for group A and 61.5% for group B [ $p = 0.45$ ]). The median BPFS and MST were 11.6 and 14.2 months, respectively. Univariate analyses revealed that female patients and gynecological cancer patients had poorer LCR, but they were not significantly independent prognostic factors in multivariate analyses ( $p = 0.06, 0.09$ , respectively). Two patients with breast cancer experienced RN (4.4%). One patient (group A) underwent resection 5 years after the HFSRT, and the other patient (group B) underwent resection 6 years after HFSRT.

#### Conclusion

HFSRT is safe for large BM but further studies are needed to determine optimal doses and fractions.

#### PO-0738 Extent of resection is potent prognostic factor next to molecular subtype in low-grade glioma

J. Choi<sup>1</sup>, S.H. Kim<sup>2</sup>, J.H. Chang<sup>3</sup>, S.H. Park<sup>1</sup>, C. Suh<sup>4</sup>

<sup>1</sup>Jeju National University Hospital, Radiation Oncology, Jeju, Korea Republic of ; <sup>2</sup>Yonsei University College of Medicine, Pathology, Seoul, Korea Republic of ; <sup>3</sup>Yonsei University College of Medicine, Neurosurgery, Seoul, Korea Republic of ; <sup>4</sup>Yonsei University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

We aimed to evaluate treatment outcomes and identify prognostic factors of low-grade glioma (LGG) patients according to the new 2016 WHO classification.

#### Material and Methods

The record of 153 patients diagnosed as WHO grade II LGG between March 2003 and November 2015 were retrospectively reviewed. Based on the 2016 WHO classification, 80 patients (52.3%) had diffuse astrocytoma (DA), IDH mutant; 45 patients (29.4%) had oligodendroglioma (ODG), IDH mutant and 1p/19q codeleted; and 28 patients (18.3%) had DA, IDH wild-type.

#### Results

The median age at diagnosis was 41 years (range, 22-74). Gross total resection (GTR) was performed in 71 patients (46.4%), subtotal resection in 31 (20.3%), partial resection in 43 patients (28.1%), and biopsy in 8 patients (5.2%). One hundred two patients (66.7%) received postoperative radiotherapy (RT). The median follow-up time was 69.9 months (range, 5.3-171.3). The 5-year and 10-year progression free survival (PFS) were 72.7% and 51.5%, and 5-year and 10-year overall survival (OS) were 82.5% and 63.5%, respectively. GTR and molecular subtype of IDH mutant and/or 1p/19q codeletion were favorable prognostic factors for both PFS and OS. Patients with tumoral IDH wild-type had significantly decreased OS than those with IDH mutation and 1p/19q codeletion. Among patients with ODG underwent GTR, no failure was observed after RT. Patients with IDH mutant and wild-type performed non-GTR had high recurrent rates after RT (47.6% and 57.9%). Regarding OS, age ( $< 40$  years), tumor location (frontal lobe), chemotherapy, and RT were not significant prognostic factors on multivariate analysis.

#### Conclusion

Molecular classification in LGG was of prognostic relevance, with the tumors that do not have IDH mutations and/or 1p/19 codeletion having a particularly poor outcome regardless of treatment. The favorable results were observed in patients who undergone GTR. Prospective study is needed to demonstrate the role of adjuvant treatment in LGG.

#### PO-0739 Sense and radiosensitivity - CyberKnife® stereotactic radiotherapy in patients with meningiomas.

H. Grzbiela<sup>1</sup>, R. Tarnawski<sup>1</sup>, E. Nowicka<sup>1</sup>, M. Gawkowska<sup>1</sup>, S. Owczarek<sup>1</sup>, M. Stapor-Fudzinska<sup>2</sup>

<sup>1</sup>Centrum Onkologii-Instytut im. M. Skłodowskiej-Curie Warsaw, III Radiotherapy and Chemotherapy Clinic, Gliwice, Poland ; <sup>2</sup>Centrum Onkologii-Instytut im. M. Skłodowskiej-Curie Warsaw, Radiotherapy Planning Department, Gliwice, Poland

#### Purpose or Objective

The objective of the study was to assess the effects of CyberKnife® stereotactic radiotherapy in patients diagnosed with meningiomas, and to evaluate, whether this technique, due to high conformality and steep dose fall-off, leads to a lesser degree of CNS toxicity, in particular concerning visual pathway toxicity.

#### Material and Methods

157 patients diagnosed with meningiomas, aged 20 - 79 (median 54), were treated in our Clinic between 2011 and 2014. 43 patients (27.4%) underwent neurosurgery at the time of diagnosis (pathology was meningothelial or psammomatous meningioma WHO grade 1), but during follow-up recurrence or progression of the tumor was observed. For 114 patients (72.6%), in whom surgery was not possible (due to tumor location or poor performance status), radiation therapy was primary treatment. All patients underwent CyberKnife® stereotactic radiation therapy. Tumor volume ranged from 1.5 to 37.5 cm<sup>3</sup>. Total dose received was 18 Gy (in 3 fractions), 21 Gy (in 3 fractions) or 16 Gy (in 2 fractions) - depending on tumor volume and location (especially in regard to the distance between tumor and visual pathway).

#### Results

All patients completed the treatment. 16 patients (10.2%) suffered from mild or moderate nausea (CTCAE grade 1 or 2), 37 patients (23.6%) reported headache CTCAE grade 1

or 2. No grade 3 or 4 acute toxicity was observed. Follow-up time was 38 - 75 months (median 58 months). To assess the results, MRI was performed every 6 months in the first two years of follow-up, then every 12 months. Partial tumor regression was observed in 28 patients (17.8%). In majority of patients (77.1%) the presence of a stable mass was confirmed. In 8 patients (5.1%) MRI scans revealed tumor progression (all of them underwent re-irradiation). None of the patients showed any severe neurological toxicity during follow-up. Most importantly, in patients with tumors located close to visual pathway, no visual impairment or loss of visual field was observed.

#### Conclusion

With the use of relatively low total dose we managed to achieve and maintain local control in 94.9% of patients and reduce the risk of CNS toxicity. Furthermore, it also allowed us to use re-irradiation in patients with tumor progression.

#### PO-0740 Can HSRS on tumor bed replace WBRT in resected brain metastases? Results of a phase II study

P. Navarria<sup>1</sup>, E. Clerici<sup>1</sup>, C. Franzese<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, T. Comito<sup>1</sup>, F. De Rose<sup>1</sup>, D. Franceschini<sup>1</sup>, C. Iftode<sup>1</sup>, A. Tozzi<sup>1</sup>, F. Pessina<sup>2</sup>, L. Bello<sup>2</sup>, S. Cozzi<sup>1</sup>, I. Renna<sup>1</sup>, L. Di Brina<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Clinical and Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy ; <sup>2</sup>Humanitas Clinical and Research Hospital, Neurosurgery, Rozzano Milan, Italy

#### Purpose or Objective

The local control of large brain metastases is a crucial issue. Treatment options include whole-brain irradiation (WBRT), surgery, and stereotactic radiosurgery (SRS). As single-modality, none of these treatments are effective in controlling large brain metastases and a combined treatment is recommended. Surgery followed by WBRT was the standard treatment but it is burdened by a high risk of decline in neurocognitive functions. More recently surgery followed by SRS on the tumor bed is under investigation, but results are still poor. Based on this background we designed a prospective phase II study aimed to assess the benefit of surgical resection followed by hypofractionated radiosurgery (FSRS) on the tumor bed, instead of postoperative WBRT, for patient with single large brain metastases from solid tumor. Primary endpoint was local control rate; secondary endpoints toxicity, brain distant failure, and patients overall survival.

#### Material and Methods

Adults patients with primary diagnosis of solid tumors, KPS  $\geq 70$ , controlled extracranial disease, single brain metastasis  $\geq 2.1$ , or smaller but conditioning mass effect and/or neurological deficits and/or massive edema, and estimated survival  $\geq 3$  months were enrolled. Patients underwent previous WBRT were excluded. Surgical resection was performed with the aim to maximally (>95%) remove the tumor. Within 1 month from surgery, a fractionated SRS was performed on the tumor bed for a total dose delivered of 30 Gy in 3 daily fractions. Response was assessed according to RANO criteria, and toxicity using CTCAE scale. Incidence of radionecrosis was evaluated employing perfusion MRI and neurocognitive function with Milano Biccoca battery.

#### Results

Between 2014 and September 2018, 135 patients were enrolled, 63 female and 72 male with a median age of 49 years. The most common primary tumor was Non-Small Cell Lung Cancer (47%), followed by breast cancer (27%) and melanoma (10%). The median follow-up was 25 months (range 7-52 months). The 1,2-year LC rate were 98%, and 98%. Forty-two (34%) patients had new BDP at a median time of 19 months.

The median 1,2-year overall survival were 24 months, 91.3% and 73%. At the last observation time, 30 patients

(22%) were dead and 105 patients (78%) were alive. No detrimental effect on neurocognitive functions was recorded. Grade II radionecrosis occurred in 13% of patients and grade III 6% of cases treated.

#### Conclusion

Fractionated SRS after surgical resection is a safe and feasible option in patients with large brain metastases and oligometastatic disease.

#### PO-0741 Active spot-scanning proton therapy for intracranial meningiomas: CNAO experience

E. D'ippolito<sup>1</sup>, A. Iannalfi<sup>1</sup>, M. Bonora<sup>1</sup>, B. Viscioni<sup>1</sup>, M.R. Fiore<sup>1</sup>, S. Ronchi<sup>1</sup>, V. Vitolo<sup>1</sup>, A. Barcellini<sup>1</sup>, R. Petrucci<sup>1</sup>, A. Mirandola<sup>1</sup>, D. Maestri<sup>1</sup>, G. Magro<sup>1</sup>, A. Facoetti<sup>1</sup>, G. Viselner<sup>2</sup>, M. Ciocca<sup>1</sup>, L. Preda<sup>2</sup>, F. Valvo<sup>1</sup>, R. Orecchia<sup>1,3</sup>

<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ; <sup>2</sup>National Center of Oncological Hadrontherapy, Diagnostic Imaging Unit, Pavia, Italy ; <sup>3</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

#### Purpose or Objective

Meningiomas are the most common primary intracranial tumors. If therapy is necessary, the standard treatment is gross total surgical resection. Proton therapy (PT) is an alternative therapeutic option for unresectable meningiomas, mostly located in the skull-base that are difficult to access, and a complementary treatment for complex and irregular tumors and lesions located in close proximity of critical organs at risk (OAR) as optic-pathways and brainstem where only subtotal or partial resection is possible. Aim of the study was to evaluate treatment results and toxicity in patients (pts) with meningiomas treated with active spot-scanning PT

#### Material and Methods

79 pts (29 men and 50 women) with a median age of 54 years (range 15-85) with intracranial meningioma (histologically proven 50/79) were treated with PT between October 2012 to December 2017 at CNAO. Pts, tumor and treatment characteristics were summarized in Tab 1. 59 pts had skull-base lesions. 44 pts were treated as primary treatment (exclusively PT= 32 pts, postoperative PT = 12 pts), 35 pts were treated for recurrence after surgery. For pts with histological diagnosis, 33 pts had a diagnosis of World Health Organization (WHO) Grade I, 13 of WHO Grade II and 4 of WHO Grade III respectively, while 29 pts had radiological diagnosis (28/29 skull-base lesions) and in all these cases <sup>68</sup>Ga-DOTATOC-PET was performed before treatment. All pts were treated using pencil-beam active scanning PT. The median administered dose was 55.8 Gy (relative biological effectiveness -RBE) (range, 50.4- 66) at 1.8-2.0 Gy RBE per fraction. Gross tumor volume (GTV) ranged from 2.3-205.71 cm<sup>3</sup> (median 22.8, mean 36.5). Late toxicity was assessed according to Common Terminology Criteria for Adverse Events -CTCAE- V4.03 scale

Tab 1. Patients, tumor and treatment characteristics

Characteristics	N. of patients (%)
<b>Total</b>	79 (100)
<b>Sex</b>	
Male	29 (37)
Female	50 (63)
<b>Age (years): median (range)</b>	57 years (range, 14-86)
<b>Histologic classification</b>	
WHO Grade I	33 (42)
WHO Grade II	13 (16)
WHO Grade III	4 (5)
No histology	29 (37)
<b>Clinical timing</b>	
Newly diagnosed tumors	44 (56)
Post surgery recurrence	35 (44)
<b>Tumor site</b>	
Skull-base meningioma*	59 (75)
Non-skull-base meningioma	20 (25)
<b>GTV (cm<sup>3</sup>): median (range)</b>	22.8 (2.3-205.71)
<b>Total (and fraction) doses (Gy RBE)</b>	
50.4 (L8)	3 (4)
54 (L8)	11 (14)
55.8 (L8)	31 (39)
56 (2)	2 (3)
57.5 (L8)	4 (5)
59.4 (L8)	9 (11)
60 (2)	7 (9)
64 (2)	1 (1)
66 (2)	11 (14)

## Results

Median follow-up was 17 months (range, 4.8-62.3). Very low rates of side-effects developed, including headaches, nausea and dizziness during treatment. No high-grade (grade 3-4) treatment-related toxicity was observed. Local control was 99%. Only one patient, affected by atypical meningioma, had local recurrence 22 months after the end of the treatment. Two pts with atypical and anaplastic meningioma respectively had "out-of-field" recurrence 20 and 8 months after the end of the treatment

## Conclusion

PT is a safe and effective treatment for pts with intracranial meningiomas, and it allows to deliver high local doses even in complex anatomy (as skull-base lesions) while sparing critical OARs

## PO-0742 The survival impact of the time between surgery and chemo-radiotherapy in Glioblastoma patients

O. Kaidar-Person<sup>1</sup>, I. Zur<sup>1</sup>, T. Tzuk-Shina<sup>1</sup>

<sup>1</sup>Rambam Health Care Campus - Faculty of Medicine, Oncology Institute, Haifa, Israel

## Purpose or Objective

Glioblastoma multiforme (GBM) is the most common primary CNS malignancy. Although multimodality therapy, it is bears grave prognosis. While importance of current treatment protocol is well-known and practiced, it is still unclear what is the optimal waiting time between surgery and the initiation of radio-chemotherapy (CRT). The aim of the current study is to evaluate the impact of the waiting time of initiation of CRT after surgery on disease outcome.

## Material and Methods

After IRB approval, we conducted a retrospective study of all medical records of GBM patients treated at our institution between 2005-2014. Data collected included: demographics, degree of surgical resection, performance status, dates and treatment protocols, and outcome. For data analysis, patients were divided into 3 groups according to the time-gap from surgery to initiation of CRT: < 4 weeks (47 patients), 4-6 weeks (72) and > 6 weeks (84). Univariate and multivariate analysis were performed. Overall survival (OS) and progression free survival (PFS) were analyzed using the Kaplan-Meier method and Cox proportional hazard model.

## Results

A total of 465 high-grade Glioma cases were reviewed, 261 were excluded. Only patients who were diagnosed with

GBM (not grade III) and were treated with surgery followed by CRT (temozolomide, TMZ) were included in the analysis. Median age was 60 years (23-79 years) with predominance male gender (61.7% vs. 38.3%). On a multivariate analysis: ischemic heart disease, degree of surgical resection, total radiation dose, number of TMZ cycles, and CRT waiting-time were significant for survival. A significant difference in OS (HR=0.49, p-value=0.002, 95% CI: 0.32-0.78) and PFS (HR=0.51, p-value= 0.003, 95% CI: 0.33-0.79) in the group who were CRT was initiated > 6 weeks after surgery, compared with the other two groups tested, favoring longer waiting times.

## Conclusion

According to our study, a time-gap of > 6 weeks for initiation of CRT after surgical resection was associated with better survival outcome. As our study represents retrospective "real-world data" from a tertiary hospital, the full report of the study analyzes the potential factors and biases that might have influenced our results and have significance in the daily practice.

## PO-0743 Single dose versus FSRT for brain metastases: a retrospective study.

C. De la Pinta Alonso<sup>1</sup>, E. Fernández<sup>1</sup>, M. Martín<sup>1</sup>, R. Hernandez<sup>1</sup>, C. Vallejo<sup>1</sup>, M. Martín<sup>1</sup>, A.B. Capúz<sup>2</sup>, J.A. Rojo<sup>3</sup>, I. Villodre<sup>3</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Ramon y Cajal Hospital, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Ramon y Cajal Hospital, Medical Physics, Madrid, Spain ; <sup>3</sup>Ramon y Cajal Hospital, Radiotherapist, Madrid, Spain

## Purpose or Objective

Radiosurgery is increasing being employed for the treatment of brain metastases, both as an adjuvant to surgical resection, and also as a primary treatment modality. The aim of this study is to evaluate the efficacy and tolerability of radiosurgery in patients with brain metastases comparing two different treatment regimens, single-dose radiosurgery(SRS) and fractionated stereotactic radiotherapy(FSRT).

## Material and Methods

Between 2004-2018 we analyzed 97 patients with 135 brain metastases. Fifty-six patients were treated with SRS, and forty-one were treated with FSRT. The median doses were 16 Gy(12-20Gy) for the SRS group and 30 Gy in 5 fractions for the FSRT group. FSRT was used for large lesions or lesions located near critical structures. Kaplan Meier curves were constructed for overall survival and local control.

## Results

Median age was 61,9 years(32- 89 years). Patients had Karnofsky-performance status>70 in 72,8%. Median survival was 10 months for all patients(1-68). With a median of 10 months no significance differences between overall survival between groups(p=0,21). Local control for all patients was 67%. Local progression-free survival(LPFS) at 6 months and 1-year were 71% and 60%, respectively, for the SRS group and 80% and 69%, respectively, for the FSRT group(p = 0.129). Despite the fact that FSRT was used for large lesions and lesions in adverse locations LPFS was not inferior to SRS. We observed acute toxicities grade 1-2 consisted of brain edema(22p) and crisis without sequels(3p). Late complications consisted of radionecrosis(3p), post-radiation syndrome(1p), chronic crisis(5p), pan-hypopituitarism(1p) and insipid diabetes(1p). Acute toxicity was more frequently observed in the FSRT-group than in the SRS-group(29% vs. 23%, p=0.63) and chronic toxicity was more frequently observed in the FSRT-group than in the SRS-group(19,5% vs. 7,1%, p=0.11). Brain recurrence occurred in 37,5% and 14,6% FSRT vs SRS-group respectively(p=0.06).

## Conclusion

Because patients treated with FSRT exhibited similar survival times and LPFS rates with a lower risk of toxicity in comparison to those treated with SRS, despite the fact

that FSRT was used for large lesions and adverse locations, we find that FSRT can particularly be beneficial for patients with large lesions or lesions located near critical structures. Further investigation is warranted to determine the optimal dose/fractionation.

**PO-0744 Efficacy of single-fraction or fractionated SRS combined with CPIs in melanoma brain metastases**

G. Minniti<sup>1</sup>, D. Arzellini<sup>2</sup>, C. Reverberi<sup>2</sup>, F. Bianciardi<sup>1</sup>, B. Tolu<sup>1</sup>, C. Scaringi<sup>1</sup>, M. Osti<sup>2</sup>, P. Gentile<sup>1</sup>

<sup>1</sup>UPMC San Pietro FBF, Radiation Oncology, Roma, Italy ; <sup>2</sup>Sant' Andrea Hospital- University Sapienza- 00100 Rome, Radiation Oncology, Rome, Italy

**Purpose:** to investigate efficacy and safety of concurrent stereotactic radiosurgery (SRS), either single-fraction SRS s-fSRS; 18-22 Gy) or fractionated (fSRS; 3x9 Gy) SRS and ipilimumab or nivolumab in patients with untreated melanoma brain metastases.

**Patients and Methods:** Eighty consecutive patients with 326 melanoma BM, receiving SRS in combination with ipilimumab or nivolumab, were analyzed. Concurrent systemic treatment was generally started within 5 days before SRS and consisted of intravenous nivolumab or ipilimumab until disease progression or unacceptable toxicity. Primary endpoint of the study was intracranial progression-free survival (PFS). Secondary endpoints were extracranial PFS, overall survival (OS), and toxicity.

**Results:** Eighty patients were analyzed. Forty-five patients received SRS and ipilimumab (SRS+ipilimumab), and 35 patients SRS and nivolumab (SRS+nivolumab). With a median follow-up of 15 months, the 6-month and 12-month intracranial PFS rates were 69% (95%CI,54-87%) and 42% (95%CI,24-65%) in SRS+nivolumab group and 48% (95%CI,34-64%) and 17% (95%CI,5-31%) in SRS+ipilimumab group ( $p=0.02$ ), respectively. Similarly, patients treated with SRS and nivolumab had better 6-month extracranial PFS and 12-month OS (SRS+nivolumab, 57% and 37%; SRS+ipilimumab, 42% and 17%). Stratification for type of SRS showed that combined CPIs and fSRS were associated with better intracranial PFS; 6-month and 12-month rates were 70% and 40%, respectively, for patients receiving fSRS and 46% and 10%, respectively, for those undergoing sf-SRS ( $p=0.01$ ). As for intracranial PFS, fSRS resulted in better extracranial PFS. Grade 3 treatment-related adverse events occurred in 24% of patients receiving SRS and ipilimumab and 17% of patients receiving SRS and nivolumab.

**Conclusions:** In conclusion, concurrent SRS and CPIs show meaningful intracranial activity and acceptable toxicity in patients with either asymptomatic and symptomatic melanoma BM, particularly when fSRS is combined with nivolumab. Further studies need to investigate the potential stronger synergistic effect of fractionated radiation schedules and CPIs.

**PO-0745 Fractionated SRS (fSRS) or surgery plus fSRS to resection cavity for NSCLC large brain metastases**

G. Minniti<sup>1</sup>, C. Scaringi<sup>1</sup>, D. Arzellini<sup>2</sup>, F. Bianciardi<sup>1</sup>, B. Tolu<sup>1</sup>, R. Morace<sup>3</sup>, M. Osti<sup>2</sup>, P. Gentile<sup>1</sup>

<sup>1</sup>UPMC San Pietro FBF, Radiation Oncology, Roma, Italy ; <sup>2</sup>Sant' Andrea Hospital- University Sapienza, Radiation Oncology, Roma, Italy ; <sup>3</sup>IRCCS Neuromed-, Neurosurgery, 86077 Pozzilli IS, Italy

**Purpose or Objective**

To investigate clinical outcomes in patients with NSCLC brain metastases <4 cm in size undergoing complete surgical resection plus fractionated stereotactic radiosurgery to the resection cavity (fSRS) or fSRS alone.

**Material and Methods**

Two hundred and twenty-seven patients with 246 brain metastases receiving surgery plus fSRS (S+fSRS) or fSRS alone were analyzed. All lesions evaluated in the study were treated with a dose of 27 Gy given in 3 fractions over

three consecutive days. Cumulative incidence analysis was used to compare local control (LC), distant brain failure (DBF), and radiation-induced brain necrosis (RN) between groups from the time of SRS.

**Results**

At a median follow-up of 13 months, median OS and 1-year survival rates were comparable: S+fSRS, 13.5 months and 59%; fSRS, 15.2 months and 68% ( $p=0.2$ ). Median DBF did not differ significantly, being 12 and 14 months for S+fSRS and fSRS, respectively. Eighteen patients undergoing S+fSRS and 17 patients treated with fSRS recurred locally ( $p=0.4$ ). Six-month and 1-year LC rates were 92% and 85% in S+fSRS group and 96% and 91% in fSRS group, respectively ( $p=0.1$ ). Stable extracranial disease, systemic therapy with TKIs, a single brain metastasis, adenocarcinoma histology and KPS >70 emerged as significant independent indices of prolonged OS. Controlled extracranial disease and TKI therapy resulted to be the most significant independent prognostic factors.

**Conclusion**

In conclusion, fSRS is an effective treatment option for large NSCLC brain metastases, resulting in a similar local control and reduced risk of RN compared to S+fSRS.

**PO-0746 The utility of functional magnetic resonance imaging in target delineation of high-grade gliomas**

L. Qian<sup>1</sup>, Q. Fei<sup>1</sup>, Y. Zhang<sup>1</sup>, W. Guo<sup>1</sup>, X. Bian<sup>1</sup>, L. Yin<sup>1</sup>, P. Yan<sup>1</sup>, T. Wang<sup>1</sup>, P. Qian<sup>1</sup>, Z. Guo<sup>2</sup>, X. He<sup>1</sup>

<sup>1</sup>Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research & The Affiliated Cancer Hospital of Nanjing Medical University, Department of Radiation Oncology, Nanjing, China ; <sup>2</sup>Jiangsu Cancer Hospital & Jiangsu Institute of Cancer Research & The Affiliated Cancer Hospital of Nanjing Medical University, Department of Radiology, Nanjing, China

**Purpose or Objective**

This study explored the different survival outcomes and failure patterns of high-grade glioma (HGG) patients by comparing the combination of functional imaging technology (fMRI: perfusion weighted imaging (PWI), diffusion-tensor imaging (DTI)) and contrast-enhanced MRI (CE-MRI) imaging (enhanced T1) with CE-MRI alone in guiding the delineation of radiotherapy target area.

**Material and Methods**

102 patients with postoperative HGG between 2012 and 2016 were included in our study. All patients were treated with IMRT in combination with the standard STUPP regimen. MRI (plain scan + enhancement), MR spectroscopy (MRS), DTI and PWI were performed before radiotherapy for postoperative patients. 50 (cohort A) were delineated based on fMRI (PWI, DTI) and CE-MRI (enhanced T1). The other 52 (cohort B) were delineated based on CE-MRI (enhanced T1, FLAIR/T2) as controlled. Survival analysis was performed using the Kaplan-Meier method, and the difference between two groups were evaluated by log-rank test.  $p < 0.05$  was considered statistically significant.

**Results**

All clinical characteristics were comparable between the two cohorts. At a median follow-up of 20 months, 80 (78%) patients had died. The median survival benefit was 6 months. The median survival was 24 months in cohort A and 18 months in cohort B. The 2-year OS, PFS, and LRC rates were 48% vs 25% ( $p = 0.005$ ), 42% vs 13.46% ( $p = 0.0003$ ), and 40% vs 13.46% ( $p = 0.0007$ ) for cohort A and cohort B, respectively. Two cohorts had similar rates of disease progression and recurrence (62% vs 63.5%,  $p = 0.879$ ), while the proportion of failure patterns was different. In cohort A, 28 (90.3%) patients experienced recurrence within the irradiated field (50-60Gy); 4 (9.7%) experienced out-field failure (2 cases of marginal failure, 1 case of pituitary metastasis, 1 case of cerebrospinal fluid metastasis). In cohort B, 26 (78.8%) patients experienced

recurrence within the irradiated field (50-60 Gy); 7 (21.2%) experienced out-field failure (2 cases of marginal failure, 2 cases of corpus callosum metastasis, 1 case of pineal gland metastasis, 1 case of contralateral brain metastasis, 1 case of distant intraparenchymal metastasis).

#### Conclusion

This study was the first to explore the clinical value of fMRI in the delineation of radiotherapy target volume for HGG. It suggested that combination of fMRI and CE-MRI may improve the survival outcome compared to the traditional guidelines, and may reduce the risk of distant metastasis for HGG patients.

#### PO-0747 Results at long-term after linac-based radiosurgery of vestibular schwannomas

P. Anselmo<sup>1</sup>, M. Casale<sup>1</sup>, F. Trippa<sup>1</sup>, F. Arcidiacono<sup>1</sup>, S. Fabiani<sup>1</sup>, A. Di Marzo<sup>1</sup>, L. Draghini<sup>1</sup>, S. Terenzi<sup>1</sup>, E. Maranzano<sup>1</sup>

<sup>1</sup>Ospedale Santa Maria, Radiotherapy Oncology Centre, Terni, Italy

#### Purpose or Objective

Vestibular Schwannomas (VS) are benign tumors generally arising from vestibular component of the vestibulocochlear nerve. Hearing loss is the most common initial presenting symptom. This report regards patients with sporadic VS undergone linac-based radiosurgery (SRS) with a follow-up > 10 years.

#### Material and Methods

Between August 2002 and January 2008, 53 patients with 53 sporadic VS were treated. Patients not able to discriminate words or not hearing at all, were scored as 'non-serviceable hearing'. Trigeminal and facial nerve functions were assessed asking the patient about facial pain/paraesthesia. Median dose of SRS was 16.5Gy (range, 13-20Gy).

#### Results

Male/female ratio was 27/26. The median age was 59 years (range, 23-83). The median tumor volume was 1,7 cc (range, 0.09-7.4). Surgery has been performed before SRS in 14 (26%) patients (total or subtotal resection 5-9% and 9-17% patients, respectively). In these cases SRS was performed as salvage therapy for recurrent or progressive tumors. Other 39 (74%) patients underwent SRS alone. Fifty (94%) of patients had hearing loss as an initial symptom and 27 (51%) a "non-serviceable" hearing function. Ataxia, tinnitus, trigeminal neuralgia and facial pain/paraesthesia were presenting symptoms in 10 (19%), 8 (15%), 4 (7.5%) and 10 (19%) of the patients, respectively. Considering that 5 patients were lost to follow up, 48 (92%) patients were evaluable. At a median follow-up of 12 years (range, 2-16), 10 patients (21%) had an objective improvement of their initial symptoms with a MRI response classifiable as stable, partial or complete remission in 6, 3 and 1 patient, respectively. Twenty-one (44%) patients had stable symptoms, with a MRI showing stable disease, transient enlargement due to central tumor necrosis, or partial remission in 10, 3, 8 patients, respectively. Seventeen (35%) patients worsened their pre-treatment symptoms. This deterioration was transient in 12 patients and persistent in 5. In "serviceable-hearing" patients, 10-year hearing preservation rate was 92%. Four of 38 (11%) patients without pre-SRS facial toxicity, developed incomplete facial nerve palsy, that regressed in a median time of 6 months. Eleven of 44 (25%) patients without pre-SRS trigeminal neuralgia developed trigeminal toxicity which was transient or stable/mild during follow-up in 10 (23%) patients (median tumor size 18mm, median dose of 17Gy). In only 1 case (2%) trigeminal toxicity was severe and appeared 12 months after SRS (tumor size was 18.8mm and prescribed dose 16,5Gy). Crude radiologic tumor control rate was 100%.

#### Conclusion

Long-term follow-up confirmed the excellent tumor control associated to SRS of VS. Although the median administered dose was rather high, iatrogenic toxicity was acceptable and similar to that reported in literature.

#### PO-0748 Prognostic factors of distant brain failure free survival after stereotactic RT for brain metastasis

Y. Pin<sup>1</sup>, M. Loo<sup>1</sup>, A. Paix<sup>1</sup>, P. Meyer<sup>2</sup>, D. Antoni<sup>1</sup>, F. Proust<sup>3</sup>, G. Noël<sup>1</sup>

<sup>1</sup>Centre de Lutte Contre le Cancer, Radiation Oncology, Strasbourg, France ; <sup>2</sup>Centre de Lutte Contre le Cancer, Medical Physic, Strasbourg, France ; <sup>3</sup>Strasbourg University Hospital, Neurosurgery, Strasbourg, France

#### Purpose or Objective

Brain metastasis (BM) is a frequent evolution in patients with solid cancer. Treatments with whole brain radiotherapy (WBRT) demonstrated a benefit in overall survival (OS) but their indications are becoming controversial due to the induced cognitive impairment. The reduction of the use of WBRT is for the benefit of the stereotactic radiation therapy (SRT). Nevertheless, SRT rarely improved significantly the OS provided by the WBRT and suffers of higher distant metastasis rates. In this study, we tried to find prognosis factors of distant brain failure free survival (DFS) that might permit to refine the indications of the use of WBRT in patients treated for BM with SRT.

#### Material and Methods

Clinical, biological and imaging factors were retrospectively recorded from patients referred for upfront stereotactic radiotherapy of one to three BMs. Those factors included a new edema descriptor, the *Edema Theoretical Thickness* (ETT) defined by the difference of radius between a first perfect sphere which volume corresponds to the sum of BMs volumes and a second perfect sphere which volume corresponds to the sum of brain edemas volumes. DFS was studied in function of these factors with the Cox proportional hazards regression model. Relevant factors were selected by an univariate analysis. The most relevant non-colinear factors were selected using the Farrar-Glauber test. Then, the multivariate analysis was performed to find the significant factors predicting the DFS.

#### Results

Between January 2012 to December 2017, 182 patients were included. Factors found significant by the multivariate analysis on the DFS were the ETT (HR = 0.92,  $p = .022$ ) with a better DFS in patients with an ETT > 7.5 mm ( $p$  logrank = .011), the melanoma histologic type (2.67,  $p = .034$ ) and the BM local relapse after SRT (2.65,  $p = .018$ ).

#### Conclusion

In this study, we found that the survival free of distant brain failure is independently correlated to the melanoma histologic type, the local failure after SRT and the ETT. ETT appeared to reflect a potential abscopal-like effect in case of SRT for BM and should be included in further studies. The combination of BMs SRT with immunotherapy could be a further way of research.

#### PO-0749 New aspects regarding the treatment of glioblastoma

C. Matuschek<sup>1</sup>, B. Tamaskovics<sup>1</sup>, E. Boelke<sup>1</sup>, W. Budach<sup>1</sup>, F. Djiepmo<sup>1</sup>, J. Hausmann<sup>1</sup>, A. Kumar<sup>2</sup>, H. Pokhylevych<sup>2</sup>, D. Schomer<sup>2</sup>, A. Hayman<sup>2</sup>

<sup>1</sup>University Hospital Düsseldorf, Radiation Oncology, Düsseldorf, Germany ; <sup>2</sup>MD Anderson, Neuroradiology, Houston, USA

#### Purpose or Objective

Since 60 years no accurate classification system exists for glioblastoma. Furthermore, the treatment results are still very poor with a low survival rate. To understand the

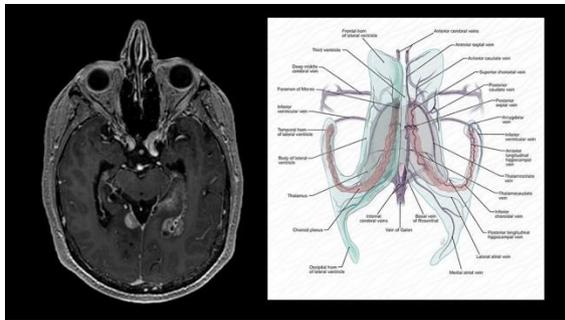

spread patterns of glioblastoma will help to define the clinical target volume for radiation therapy.

#### Material and Methods

After receiving IRB approval from MD Anderson, Houston Teys, the clinical MR imaging of 1250 cases of glioma were studied for 10 years using an anatomic software program developed by the authors (Anatom-e, Houston Texas). The final 3 years of the project was devoted to reorganizing venous anatomy to make it responsive to clinically relevant consultations and data mining. This was accomplished by developing deformable anatomic templates (DAT) which could overlay the venous territory maps on the clinical scans. The system also contained a drawing tool which embed the tumors shape into a DAT template. The software was also able to store and compare the shape and location of a single glioma between exams or across a group of tumors.

#### Results

The highly variable MR appearance of glial tumors and their complicated spread patterns strongly infer the existence of previously undescribed perivenous compartment in the cerebral hemispheres.

The only natural anatomic structure of the brain that is compatible with the shape and location of gliomas, regardless of their histology, is venous anatomy. The otherwise inexplicable tumor spread of certain multicentric gliomas to the contralateral hemisphere reflects perivenous spread along the deep venous network. Multicentric gliomas with corresponding venous maps will be presented. For example, we analyzed the case of a multicentric GBM (Figure 1) that spreads along the inferior chorooidal vein to the basal vein and then crosses the midline along the peduncular vein

#### Conclusion

DAT is capable of correctly explaining the complicated spread patterns of glioblastoma. It seems that the superficial and deep peri-venous compartments are responsible for the spread patterns of glioblastoma. Clinical imaging of gliomas strongly supports the existence of perivenous space which is capable of storing and spreading glial tumor cells throughout the brain. This new concept can be used to develop a new classification system for glial tumors and can be used to predict tumor growth

#### PO-0750 VMAT for CNS Tumors and alopecia: results of an observational study and new constraints for the SCALP

S. Scoccianti<sup>1</sup>, R. Grassi<sup>1</sup>, P. Marco<sup>1</sup>, F. Terziani<sup>1</sup>, G. Simontacchi<sup>1</sup>, C. Talamonti<sup>2</sup>, G. Caramia<sup>1</sup>, M. Lo Russo<sup>1</sup>, M.A. Teriaca<sup>1</sup>, E. Scoccimarro<sup>1</sup>, C. Saieva<sup>3</sup>, L. Cosi<sup>1</sup>, S. Pallotta<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Radiation Oncology, Firenze, Italy ; <sup>2</sup>Azienda Ospedaliera Universitaria Careggi, Medical Physics Unit, Firenze, Italy ; <sup>3</sup>Istituto per lo Studio- la Prevenzione e la rete Oncologica, SC Epidemiologia of Risk Factors and Lifestyles, Florence, Italy

#### Purpose or Objective

To define a dose-response relationship for alopecia when using conventionally fractionated VMAT.

#### Material and Methods

The scalp was defined as a region of interest. At the moment of the end of RT and during the follow-up, the areas of scalp where alopecia developed were defined. Grade of alopecia was assessed according to CTCAE version 4.0. A treatment planning system-based dosimetric evaluation of areas of acute alopecia was performed. The following dosimetric parameters were registered for the whole scalp and the areas of alopecia: dose received by 0.1 cc ( $D_{0.1cc}$ ), mean D ( $D_{mean}$ ), volumes that received 16, 20, 25, 30, 35, 40 and 43 Gy ( $V_{16 Gy}$ ,  $V_{20 Gy}$ ,  $V_{25 Gy}$ ,  $V_{30 Gy}$ ,  $V_{35 Gy}$ ,  $V_{40 Gy}$  and  $V_{43 Gy}$ ). Receiver operating characteristics (ROC) curve analysis was used to identify dosimetric parameters associated with high risk of acute and chronic hair loss. Time from end of radiotherapy to alopecia recovery was analyzed. Kaplan Meier analysis and Cox regression analysis were performed in order to assess clinical and dosimetric factors impacting on the recovery probability.

#### Results

A total of 101 patients were included in the study. All the patients received a limited-volume RT with conventionally fractionated VMAT technique. 5 patients who were treated for deep tumors did not develop any area of alopecia. Their scalp received very low doses (mean  $D_{mean}$  3.1 Gy; mean  $D_{0.1cc}$  19.7 Gy). At the end of RT, 96/101 patients developed acute alopecia (G1 only n=11; G2 only n=52; G1+G2 n=33). The whole scalp of the patients with G1 and G2 alopecia received mean  $D_{mean}$  equal to 10.6 Gy and 11.8 Gy with mean  $D_{0.1cc}$  equal to 40.2 and 47.3 Gy, respectively.  $D_{0.1cc}$ ,  $D_{mean}$ ,  $V_{16 Gy}$ ,  $V_{20 Gy}$ ,  $V_{25 Gy}$ ,  $V_{30 Gy}$ ,  $V_{35 Gy}$ ,  $V_{40 Gy}$  and  $V_{43 Gy}$  were significantly different if compared with the same parameters of patients who did not developed acute alopecia ( $p < 0.05$ , Mann-whitney test). Mean  $D_{mean}$  in areas of alopecia G1 and alopecia G2 at end of RT was 16.5 Gy and 20.3 Gy, respectively ( $p < 0.05$ , Mann-whitney test). Mean  $D_{0.1cc}$  in areas of alopecia G1 and alopecia G2 at end of RT was 33.4 Gy and 44.6 Gy, respectively ( $p < 0.05$ , Mann-whitney test). Trichological follow-up was available for 74/101 patients. 65 patients (92.8%) had an intact scalp. Median time to recover was 5,9 months. The actuarial rate of hair recovery was 87.0% and 98.1% at 9, and 18 months after the end of RT. At ROC curve analysis,  $V_{16 Gy} \geq 16.7 cc$  and  $V_{20 Gy} \geq 5.2 cc$  were the strongest predictors of risk of acute alopecia, whereas  $V_{40 Gy} \geq 5.4 cc$  and  $V_{43 Gy} \geq 2.2 cc$  were the strongest predictors of risk of chronic alopecia. Kaplan Meier analysis and Cox regression showed that age,  $D_{0.1cc}$ ,  $D_{mean}$ ,  $V_{30 Gy}$ ,  $V_{35 Gy}$ ,  $V_{40 Gy}$  and  $V_{43 Gy}$  are related to recovery probability.

#### Conclusion

By treating patients with this scalp-sparing approach, in most patients complete recovery from alopecia was obtained within some months. By maintaining the doses lower than the dosimetric cut-off values we identified, further reduction of the risk of alopecia may occur.

#### PO-0751 Neutrophil lymphocyte ratio and Platelet lymphocyte ratio as a prognostic factor in brain metastases

A. Niiya<sup>1</sup>, K. Murakami<sup>2</sup>, R. Kobayashi<sup>2</sup>, K. Toyofuku<sup>2</sup>, E. Nishimura<sup>3</sup>, M. Kato<sup>2</sup>, Y. Ozawa<sup>4</sup>, H. Shinjo<sup>4</sup>, K. Miyaura<sup>2</sup>, M. Morota<sup>1</sup>, T. Serizawa<sup>5</sup>, Y. Ito<sup>2</sup>, A. Imai<sup>4</sup>, Y. Kagami<sup>2</sup>

<sup>1</sup>Showa University Koto Toyosu Hospital, Radiation Oncology, Koto-ku, Japan ; <sup>2</sup>Showa University Hospital, Radiation Oncology, Shinagawa-ku, Japan ; <sup>3</sup>Showa University Hospital, Radiology, Shinagawa-ku, Japan ; <sup>4</sup>Showa University Fujigaoka Hospital, Radiation Oncology, Yokohama, Japan ; <sup>5</sup>Tokyo Gamma Unit Center- Tsukiji Neurological Clinic, Neurosurgery, Chuo-ku, Japan

### Purpose or Objective

Brain metastases (BM) occurs in 10-30 % in adult cancer patients, and it is an important factor affecting patient survival rate and quality of life.

In recent years, neutrophil lymphocyte ratio (NLR) and platelet lymphocyte ratio (PLR) have been reported to correlate with overall survival (OS) in various cancers. However, few reports have verified the NLR and PLR in patients with BM. The purpose of this study is to evaluate whether NLR and PLR is a prognostic factor for OS, using in Japanese BM patients our hospital.

### Material and Methods

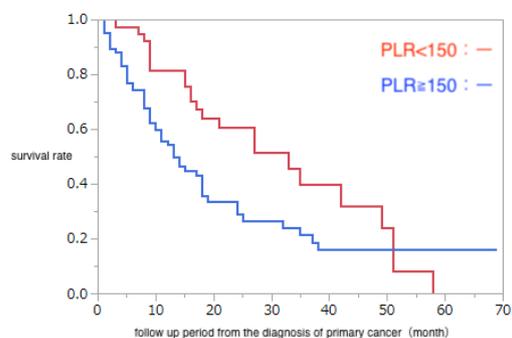

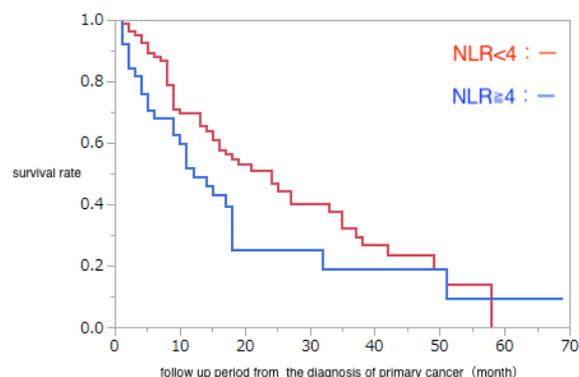

We retrospectively compiled the NLR and PLR in patients who received radiotherapy in our hospital from March 2011 to December 2017. Neutrophils, platelet and lymphocytes were calculated based on absolute values and analyzed with the OS. The absolute values of neutrophils, platelet and lymphocytes were obtained at the time of diagnoses of primary cancer and BM. For the data of BM, we didn't exclude patients who underwent chemotherapy or molecular targeted drugs for primary tumor.

### Results

The number of patients is 256, and primary sites were 150 lung, 66 breast, 15 gastrointestinal, 7 urological, and 18 others. The median age of the patient cohort at diagnosis of primary cancer was 65 years (range: 20-87 years), and BM was 66 years (range: 24-87 years). The patient group contained 136 males and 120 females, median KPS of BM detection was 70 (range: 10-100). Radiation therapy was 227 patients of whole brain irradiation (20-40 Gy) and 29 patients of stereotactic radiotherapy (15-32 Gy). The median follow up period was 19 months (mo.) from cancer diagnosis (range: 1-236 mo.), and 5 mo. from BM detection (range: 1-83 mo.). The median survival time (MST) from cancer diagnosis was 33 mo. and MST from BM detection was 9 mo.

Patients with NLR <4.0 at the diagnosis of primary cancer had better MST compared with patients with NLR  $\geq$ 4.0 (24 mo. vs. 12 mo.;  $P=0.0116$ ). Patients with PLR <150 at the diagnosis of primary cancer had better MST compared with patients with PLR  $\geq$ 150 (33 mo. vs. 13 mo.;  $P=0.0012$ ). Patients with NLR <4.0 at the time of BM detection had better MST compared with patients with NLR  $\geq$ 4.0 (12 mo. vs. 4 mo.;  $P<0.001$ ). Patients with PLR <150 at the time of BM detection had better MST compared with patients with PLR  $\geq$ 150, but there was no significant difference (15 mo. vs. 7 mo.;  $P=0.0538$ ).

Utilizing Multivariate analysis, age  $\geq$ 65 and PLR  $\geq$ 150 at the diagnosis of primary cancer were significantly correlated with survival (HR2.30;  $P=0.0008$ , HR2.17;  $P=0.0043$ ). KPS and NLR  $\geq$ 4 at the time of BM detection were significantly correlated with survival (HR1.53;  $P=0.0201$ , HR2.28;  $P<0.001$ ).

### Conclusion

NLR and PLR at the diagnosis of primary cancer might be prognostic factors. Furthermore, this tendency was also showed at the time of BM detection. To our knowledge, our study was the first report about NLR and PLR with BM patients who underwent radiation therapy. We are planning a prospective study to validate the results.

### PO-0752 Hypofractionated stereotactic radiotherapy for inoperable arteriovenous malformations

T. Takahashi<sup>1</sup>, T. Yamano<sup>2</sup>, K. Nishimura<sup>1</sup>, S. Ueno<sup>2</sup>, K. Washizu<sup>1</sup>, R. Soda<sup>1</sup>, S. Kondo<sup>1</sup>, N. Utsumi<sup>1</sup>, M. Shimbo<sup>1</sup>, S. Hatanaka<sup>1</sup>, M. Hariu<sup>1</sup>  
<sup>1</sup>Saitama Medical Center- Saitama Medical University, Radiation Oncology, Kawagoe, Japan ; <sup>2</sup>Saitama Medical Center- Saitama Medical University, Radiation Oncology, Kawagoe, Japan

### Purpose or Objective

In our institute, we performed hypofractionated stereotactic radiotherapy (HSRT) for inoperable arteriovenous malformations (AVM) whose Spetzler-Martin grade was mainly more than grade III. In this time, we investigated therapeutic efficacy and obliteration rate of our HSRT from the view point of prescription doses and dose fractionations, retrospectively.

### Material and Methods

We examined 23 patients of inoperable AVM who underwent HSRT at our institute between 2003 and 2014. Spetzler-Martin grade III was 90 % in patients. Mean nidus volume was 7.95 ml. At the beginning of HSRT, patients' median age was 30.5 years old (4 - 68 years old). Median observation periods were 56 months (4 - 117 months). A median dose was 33.8 Gy (20 - 40 Gy). Median fractionations were 6.8 fractions (4 - 13 fractions).

### Results

The occlusion rate at 2 years after HSRT was 57.1%, and 4 years 87.5 %, respectively. There is no evidence of obvious late adverse events of more than 3 grade. No significant difference in the occlusion rate of nidus volume was found between more than 14 ml and less than 14 ml. There was no significant difference in the occlusion rate between patients who received more than 7 Gy and less than 7 Gy, in a fractional dose. On the other hand, significant difference of obliteration rate of the nidus was found between patients who received more than 100 Gy and less than 100 Gy, in biological effective doses (BED) with  $\alpha/\beta=3$ . Patients who received more than 100 Gy in BED 3 resulted in favourable outcome ( $p=0.02$ ).

### Conclusion

In the past, stereotactic radiosurgery (SRS) has been mainly reported about radiotherapy for inoperable AVM. Although the therapeutic results of SRS is favorable, there is a tendency to reducing prescription doses for the patients who have large nidus volume, in consideration of adverse events. Our results suggest that HSRT also have been performed favorably and safely for patients whose nidus volumes were larger than 14 ml. Recently, some studies about HSRT occur in various reports, however suitable doses remain a subject of future investigation.

**PO-0753 radiotherapy quality assurance-POLCA trial-patients with anaplastic oligodendroglial tumors**

L. Feuvret<sup>1</sup>, H. Douzane<sup>2</sup>, C. Jenny<sup>1</sup>, A. D'Hombres<sup>3</sup>, L. Padovani<sup>4</sup>, M. Aumont<sup>5</sup>, G. Noel<sup>6</sup>, J. Jacob<sup>1</sup>, F.G. Riet<sup>1</sup>, C.H. Canova<sup>1</sup>, C. Dehais<sup>2</sup>, F. Fauchon<sup>7</sup>, Y. Meng<sup>8</sup>, F. Dhermain<sup>9</sup>

<sup>1</sup>Hôpital Pitié-Salpêtrière, RADIATION THERAPY, Paris, France ; <sup>2</sup>Hôpital Pitié-Salpêtrière, Neuro Oncology, Paris, France ; <sup>3</sup>Hôpital Lyon Sud, Radiation Therapy, Lyon, France ; <sup>4</sup>APHM, Radiation therapy, Marseille, France ; <sup>5</sup>René Gauducheau, Radiation Therapy, Saint Herblain, France ; <sup>6</sup>Paul Strauss, Radiation Therapy, Strasbourg, France ; <sup>7</sup>Centre des Hautes Energies, Radiation Therapy, Nice, France ; <sup>8</sup>Hôpital d'Argenteuil, Radiation Therapy, Argenteuil, France ; <sup>9</sup>Gustave Roussy, Radiation Therapy, Villejuif, France

**Purpose or Objective**

The ongoing phase III POLCA trial (NCT02444000) was designed to determine whether treating patients with newly diagnosed 1p/19q-codeleted anaplastic gliomas with PCV alone can increase overall survival without neurocognitive deterioration as primary endpoint. The control group treatment is intensity-modulated radiation therapy (IMRT) followed by 6 cycles of PCV chemotherapy and the experimental group treatment 6 cycles of PCV chemotherapy (radiotherapy being deferred at the time of progression) (October 2018: 60 patients in each arm). We report the results of retrospective individual case reviews (ICRs) for the first patients randomized to assess the study protocol compliance.

**Material and Methods**

All institutions were required to submit the radiotherapy plan of their first randomized patients. Full digital datasets uploaded to the CD rom were assessed by three independent reviewers through the "POLCA quality assurance" ANOCEF group (GRANOCEF). The software Artiview® (Aquilab SAS, France) package allowed experts to review and assess multimodality imaging and radiotherapy treatments.

**Results**

Forty-four ICRs from 14 centers were received and assessable. Twenty-three were evaluated as per protocol (53%), 5 as acceptable variation (11%) and 16 as unacceptable variations (36%). Most common unacceptable variations were related to the target volumes delineation (11 cases; 25%), OARs delineation (5 cases; 11%), dosimetric process (4 cases; 9%), dosimetric MRI (1 case; 2%) and no using IMRT (1 case; 2%).

**Conclusion**

The ICR analysis showed a significant number of major deviations with potential impact on toxicity profile and/or tumor control. OARs delineation dummy-run, guide book "list of main deviations", participation to "POLCA quality assurance" ANOCEF group, customized confidential reports may improve quality of radiotherapy technique. Prospective ICRs could prevent and correct protocol violations before starting treatment for future studies.

**Purpose or Objective**

Intensity-modulated radiation therapy (IMRT) treatment plans for head and neck cancer typically use a high number of radiation fields and may be associated with new beam-path non-target tissue toxicities, particularly nausea and vomiting. The dorsal vagal complex (DVC), including the area postrema, the nucleus of the solitary tract and the dorsal motor nucleus of the vagus, is a little known structure of the brainstem which may be implicated in the radiation-induced nausea and vomiting (RINV). The objective of our project was to define consensus guidelines for delineating the DVC.

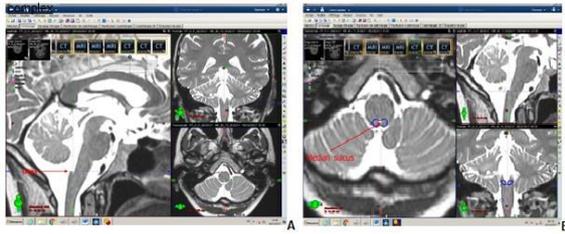

**Material and Methods**

The DVC was identified on autopsy sections and endoscopic descriptions. Anatomic landmarks and boundaries were used to establish radio-anatomic correlations on CT and Magnetic Resonance Imaging (MRI). The DVC delineation was performed on MRI images and reported on CT scans. Next, guidelines were provided to eight radiation oncologists (the working group, WG) for delineation guidance of this structure on DICOM-RT images of two patients being treated for a nasopharyngeal carcinoma. The evaluation of the variability of contours was benchmarked using a "experts' reference contour" (delineated with the help of three experts of the brainstem: HMD, DH, and ML). Firstly, each volume submitted by the eight radiation oncologists was compared with the reference volume. Secondly, different indices reflecting the correlation of the volume with the "experts' reference contour" were calculated: the Volume Ratio (VR), the Common Delineated Volume (CDV), and the Additional Delineated Volume (ADV). Then, the kappa index (KI) and the Overlap Volume (OV) were calculated.

**Results**

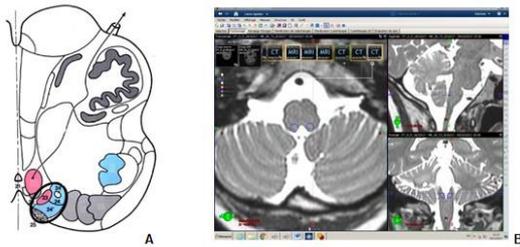

The DVC was defined with a concise description of its main anatomic boundaries. The caudal limit of the DVC is easily determined on a MRI sagittal view of the brainstem and must be delineated in the transversal plane of the obex, which is also in the plane of the central canal aperture (Fig 1). The DVC is located on both sides of the median sulcus of the medulla oblongata. In order to be more reproducible, we proposed delineating a 4-mm diameter circle which included the different parts of the DVC (Fig 2). The craniocaudal length of the DVC is 5 mm. The interobserver analysis showed that the DVC delineation was reproducible. The average volume and height of the DVC delineated by the WG were not significantly different from that of the expert with a result of 0.13 cm<sup>3</sup> (95% CI: 0.12-0.14) ( $p = 0.5$ ) and 0.5 cm ( $p = 1$ ), respectively. The different indices obtained by the WG compared to the expert were 0.98 (95% CI: 0.64-1.08) for the VR, 71% (95% CI: 44-87) for CDV, 27% (95% CI: 16-38) for the ADV, 0.58 (95% CI: 0.33-0.84) for the OV and 0.72 (CI 95%: 0.50-0.91) for the KI.

Fig. 1 Caudal limit of the dorsal vagal complex (DVC)

1 A: Sagittal view of the medulla oblongata showing the obex plane (red arrow). 1 B: The caudal limit of the DVC is a unique volume.

Fig. 2 Transversal view of the medulla oblongata at the level of the Dorsal Vagal Complex (DVC)

2 A: Diagram of a transversal plane of the medulla oblongata at the level of the DVC (Adapted from Duvernoy HM. Human brain stem vessels. Springer, Berlin Heidelberg New York Tokyo 1999; Published with permission). This structure includes the area postrema (25), the nucleus of the solitary tract (24) and the dorsal motor nucleus of the vagus (23). 21: median sulcus. 2 B: Transversal view of the medulla oblongata at the level of the DVC in our atlas. The DVC was indicated by a circle of 4 mm in diameter such that the delineation was reproducible.

## Conclusion

This atlas was feasible and reproducible for the delineation of DVC on planning CT using fused MRI. It will be used to prospectively assess dose-volume relationship for DVC and occurrence of nausea vomiting during intracranial or head and neck irradiation.

## PO-0755 Patterns of Re-irradiation for Recurrent Gliomas and Validation of a Prognostic Score

J. Verhoeff<sup>1</sup>, C. Post<sup>1</sup>, M. Kramer<sup>2</sup>, E. Smid<sup>1</sup>, H. Van der Weide<sup>2</sup>, K. Kleynen<sup>1</sup>, M. Heesters<sup>2</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>UMC Groningen, Radiation Oncology, Groningen, The Netherlands

## Purpose or Objective

Re-irradiation (ReRT) is a generally accepted method for salvage treatment in patients with recurrent glioma. However, no standard radiation regimen has been defined. This study aims to compare the efficacy and safety of different treatment regimens and to independently externally validate a recently published ReRT risk score introduced by Niyazi et al. (2018).

## Material and Methods

We retrospectively analyzed a cohort of patients with recurrent malignant glioma treated with salvage conventionally fractionated (CFRT; fractional dose <3 Gray), hypofractionated (HFRT; fractional dose 3-5 Gray) or stereotactic radiotherapy (SRT; fractional dose ≥5 Gray) between 2007 and 2017 at the University Medical Centers of Utrecht and Groningen.

## Results

Of the 121 patients included, 60 patients (50%) underwent CFRT, 22 (18%) HFRT and 39 (32%) SRT. The primary tumor was grade II-III in 52 patients and grade IV in 69 patients with median Overall Survival (mOS) since first surgery of 113 [Interquartile range: 53.2-137] and 39.7 [24.6-64.9] months respectively and mOS from first day of ReRT of 8.5 [6.5-11.6] and 11.3 [6.3-28.5] months respectively. Overall, mOS post ReRT was 9.7 months [6.5-14.6]. No significant difference in mOS was found between the treatment groups using log-rank test (p=0.17) and multivariate Cox regression (p=0.79) (mOS CFRT: 10.0

[6.9-17.6], HFRT: 7.7 [5.7-10.3] and SRT: 9.7 [6.2-14.9] months (Figure 1)). In multivariate analysis, Karnofsky performance scale ≥70% (p<0.01), ReRT for first recurrence (p=0.02), longer time interval between RT start dates (p<0.01) and smaller planning target volume (p<0.05) were significant favorable prognostic factors (Table 1). Eight patients (12.5%) developed severe, hospitalization required, acute toxicity and five cases (7.7%) of radionecrosis were reported in the UMC Utrecht dataset (n=65). The ReRT risk score showed good calibration by corresponding results of the Cox regression and Kaplan-Meier estimators (mOS of the prognostic groups in our cohort: 14.6, 9.76, 5.32 months versus Niyazi's development cohort 14.2, 9.1 and 5.3 versus Niyazi's validation cohort 13.8, 8.8 and 3.8 months). Discrimination performance of the score is modest (c-index: 0.65).

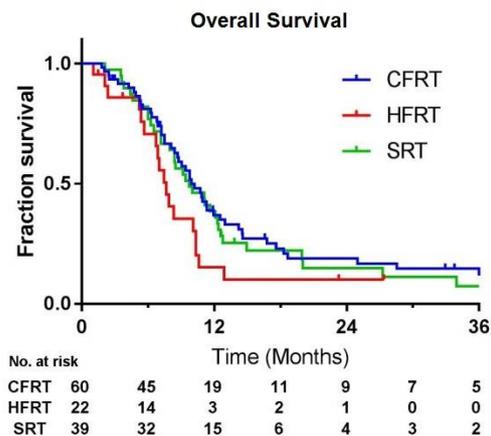

Figure 1. Kaplan-Meier curves showing overall survival from first day of re-irradiation (time in month) according to SRT (green line), HFRT (red line) and CFRT (blue line). Log-rank test was not significant (p=0.173). Pairwise comparison was also not significant (CFRT vs HFRT p=0.060; CFRT vs SRT p=0.735; SRT vs HFRT p=0.162).

Table 1. Univariate and multivariate Cox regression analysis of prognostic factors for overall survival in 121 patients receiving re-irradiation (16 censored, 20 cases with missing values). Data are expressed as hazard ratios and p-values.

Variable	Univariate analysis			Multivariate analysis		
	HR	95% CI	P-value	HR	95% CI	P-value

Time interval <sup>c</sup>	0.982	0.974-0.989	<0.001*	0.981	0.969-0.993	0.002*
PTV	1.002	1.000-1.004	0.027*	1.002	1.000-1.004	0.047*
EQD2 <sub>app-10</sub> <sup>d</sup> cumulative	0.992	0.971-1.014	0.476	-	-	-

Abbreviations: CI: Confidence interval; EQD2: equivalent dose at fractionation of 2 Gy; HR: Hazard ratio; KPS: Karnofsky performance scale; NS: not significant; PTV: planning target volume; RT: radiotherapy; ReRT: re-irradiation; TMZ: temozolomide concurrent at initial therapy.

\*p value of <0.05 was considered significant; <sup>a</sup>Reference group: <sup>b</sup>Number of recurrences occurred before re-irradiation; <sup>c</sup>Surgery within 2 months prior to re-irradiation; <sup>d</sup>Time interval between start date of initial radiotherapy and start date of re-irradiation; <sup>e</sup>Calculated with  $\alpha/\beta = 10$  for tumor tissue.

## Conclusion

In our series, mOS after ReRT was sufficient to justify use of this modality. Until a reliable treatment decision tool is developed based on larger retrospective research, the decision for ReRT schedule should remain personalized and based on a multidisciplinary evaluation of each patient.

**PO-0756 Evaluating the DS-GPA in patients with 1-10 brain metastases treated with stereotactic radiosurgery**

S. Nagtegaal<sup>1</sup>, A. Claes<sup>1</sup>, T. Snijders<sup>2</sup>, J. Verhoeff<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>UMC Utrecht, Neurology, Utrecht, The Netherlands

**Purpose or Objective**

There are multiple prognostic models for predicting survival after treatment for brain metastases. One of them, the diagnosis-specific Graded Prognostic Assessment (DS-GPA), has been developed to predict the median survival for brain metastases from the most frequent primary sites. Our objective is to compare the survival predicted by the DS-GPA to actual survival in patients treated with SRS for 1-10 brain metastases. We will both evaluate the ability of the DS-GPA to predict the survival on an individual level, as well as its success in dividing a group of patients into different prognostic strata.

**Material and Methods**

We identified a consecutive cohort of patients treated with SRS for brain metastases in our institute. DS-GPA scores were calculated for each patient, and the median survival for each DS-GPA group was calculated. Differences in survival between DS-GPA groups were tested with Kaplan-Meier curves.

**Results**

Out of a total of 401 patients treated with SRS from 2012-2017, 366 patients with calculable DS-GPA were identified. Waterfall plots showing the difference between predicted median and actual survival per patient are shown in Figure 1, stratified by the number of brain metastases. The proportion of the survival times within each predicted quartile was 26.6%, 30.7%, 24.9% and 17.8% (for Q1-Q4, respectively). Figure 2 shows the Kaplan-Meier curves of the disease groups with a statistically significant difference between the DS-GPA strata.

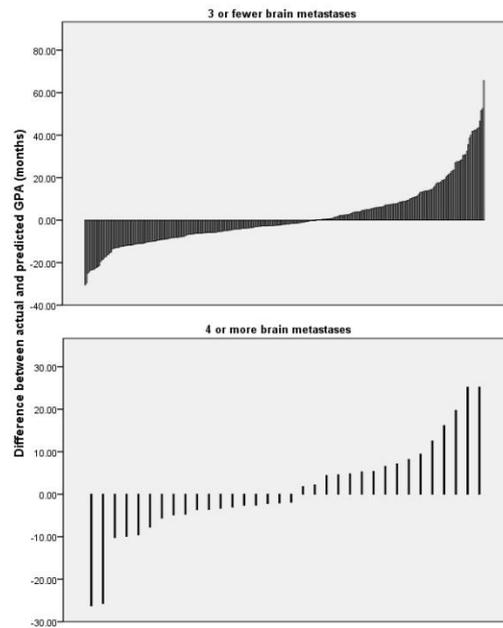

Figure 1 Waterfall plots showing the differences between the predicted and the actual survival on an individual level, stratified by the number of brain metastases

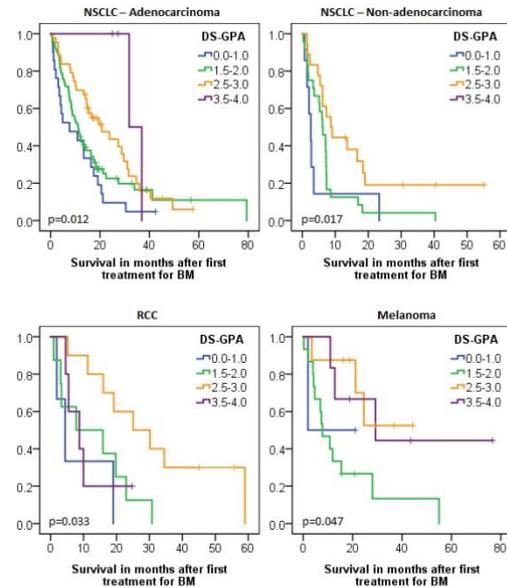

Figure 2 Survival curves for the disease subgroups with a statistically significant difference between the DS-GPA strata

**Conclusion**

DS-GPA seems to be a reliable tool for brain metastases patients treated with SRS. Although the differences between the predicted median and the actual survival difference can be large, the distribution of the actual survival within the predicted quartiles is as expected. This means that, although the DS-GPA doesn't give a point prediction of survival, it is able to accurately predict the range in which the survival will fall.

Furthermore, the DS-GPA is also useful in dividing the renal cell carcinoma, melanoma and both NSCLC disease groups into strata with different survival. This allows physicians to place a patient in a certain prognostic group, which may help to determine the most optimal treatment and the duration and frequency of follow-up.

The way physicians and other health professionals discuss the results of the DS-GPA score is important. The fact that it results in a median survival and not a point-predicted survival is an important distinction. Patients should not be told that the DS-GPA gives a precise prediction of the expected survival. Instead, a patient needs to be told that around half of the patients with similar clinical characteristics reach the median age, but that the other half dies before that time. This corresponds with our findings. Additionally, the window of survival that applies to half of the patients, i.e. the interquartile range, is another important message for patients, which is also something we have found in this study.

**PO-0757 Radiosurgery for cranial and spinal haemangioblastomas: monoinstitutional analysis.**

V. Pinzi<sup>1</sup>, A. Viola<sup>2</sup>, E. De Martin<sup>3</sup>, C. Iezioni<sup>4</sup>, M. Cerniauskaite<sup>1</sup>, M. Marchetti<sup>1</sup>, L. Fariselli<sup>1</sup>  
<sup>1</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Neurosurgery- Unit of Radiotherapy, Milan, Italy ; <sup>2</sup>University of Milan, Radiation Oncology, Milan, Italy ; <sup>3</sup>Fondazione IRCCS Istituto neurologico C. Besta, Health Department, Milan, Italy ; <sup>4</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Neurosurgery-Radiotherapy Unit, Milan, Italy

**Purpose or Objective**

Hemangioblastomas (HB) of the central nervous system are rare indolent WHO grade I vascular tumors of controversial origin that may occur sporadically or in association with von Hippel-Lindau (VHL) disease. Though primary therapy for HB is surgical resection, for patients

with subtotally excised or unresectable lesions and for patients with poor clinical status who are not good candidates for surgery, as well as those wishing a minimally invasive approach, radiotherapy (RT) or radiosurgery (SRS) can be an effective alternative. RT and SRS have been associated with good rates of local control in a 60-90% range, especially in patients with VHL. The aim of this study is to evaluate the efficacy and safety of SRS for patients with diagnosis of intracranial and spinal HB in terms of local control and toxicity.

#### Material and Methods

We conducted a retrospective analysis of 22 patients with a total of 37 HB: 23 intracranial HB and 14 spinal HB treated at our Institute from January 2012 until February 2017.

A regular clinical and radiological follow-up with MR imaging was scheduled at 4-6 month intervals after SRS procedure. The toxicity was recorded based on CTCAE 3.0v. The radiosurgical procedures were performed using a CyberKnife system, characterized by a 6MV linac mounted on a robotic arm for multiple, non-isocentric, non-coplanar beams sets delivery. Statistical analysis was carried out using SPSS 21.

#### Results

Twenty-two patients were followed for a median of 42 months (range 3-72 months). Median age at the time of SRS was 44 years (range 19-79), 8 patients were female and 14 male.

The diagnosis of HB was based on the histological findings, except in 7 patients without surgical removal. Seven patients had multiple lesions and 30 patients had a single lesion. The median tumour volume pre-SRS was 417 mm<sup>3</sup> (range, 40-15779 mm<sup>3</sup>). The mean prescription dose was 18 Gy (range, 10-25 Gy) in 1-5 fractions with median isodose line of 81% (range, 73-88%).

Two patients (9%) developed a recurrence, 12 patients (55%) showed stable disease and 8 (36%) partial response. There was no significant toxicity after treatments.

**Conclusion**  
SRS, both in single and multi-fractions settings, is potentially attractive for patients with VHL disease where multiple HB may develop either concurrently or sequentially and may be difficult to treat or retreat with repeated surgery and/or conventional radiation techniques without the risk of toxicity. Our results show that SRS can be considered a safe and effective treatment for intracranial and spinal HB.

#### PO-0758 Whole brain RT plus concomitant Temozolamide in PCNSL after MTX-HD: a prospective phase II study

F. Catucci<sup>1</sup>, S. Chiesa<sup>2</sup>, M. Giraffa<sup>2</sup>, E. Maiolo<sup>3</sup>, F. Beghella<sup>2</sup>, T. Zinicola<sup>2</sup>, S. Hohaus<sup>3</sup>, V. Rufini<sup>4</sup>, V. Valentini<sup>2</sup>, M. Balducci<sup>2</sup>

<sup>1</sup>Istituto di Radiologia- Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Radiologiche- Radioterapiche ed Ematologiche, Roma, Italy; <sup>2</sup>Istituto di Radiologia- Fondazione Policlinico Universitario A. Gemelli IRCCS- Università Cattolica del Sacro Cuore, Dipartimento di Scienze Radiologiche- Radioterapiche ed Ematologiche, Roma, Italy; <sup>3</sup>Istituto di Ematologia - Fondazione Policlinico Universitario A. Gemelli IRCCS- Università Cattolica del Sacro Cuore, Dipartimento di Scienze Radiologiche- Radioterapiche ed Ematologiche, Roma, Italy; <sup>4</sup>Istituto di Medicina Nucleare - Fondazione Policlinico Universitario A. Gemelli IRCCS- Università Cattolica del Sacro Cuore, Dipartimento di Scienze Radiologiche- Radioterapiche ed Ematologiche, Roma, Italy

#### Purpose or Objective

To evaluate the overall survival (OS) in patients affected by primary cerebral lymphoma (PCNSL) treated with radiotherapy (RT) plus Temozolamide (TMZ) after treatment with high dose methotrexate (HD-MTX).

#### Material and Methods

Patients with an histological diagnosis of PCNSL, previously treated HD-MTX, were enrolled to receive TMZ concomitant to RT. The whole brain up to C2 leptomeninges received 30 Gy (2 Gy/die), while the total dose to initial site of disease or residual mass, if present, was modulated according to the response to HD-MTX (Complete response = 6 Gy, partial response = 10 Gy, progression disease = 16 Gy). According to our previous dose escalation study, concomitant TMZ was administered at a safety dose level of 75 mg/mq.

#### Results

From March 2004 to December 2017, 33 patients were enrolled: 18 males and 15 females. The median age was 64.5 yrs (range 50-76). Twenty-two patients received two cycles of HD-MTX, while 9 only one cycle (because of hematological toxicity) and 2 patients did not received any cycle (due to poor performance status). Nine patients were subjected to macroscopic surgical excision while the remaining patients were only subjected to biopsy. Twenty-five patients were treated with RT plus concomitant TMZ. The median follow up was 80 months (range 3-169), currently, 9 out of 33 patients (27%) are alive (7 without disease and 2 with stable disease), 22 patients died because of disease and 2 patients because of other causes. The median OS of the whole group was 23.1 months with at 1 years OS of 64% and at 3 years OS of 43%. The concomitant use of TMZ showed a significant impact on OS (p = 0.004).

#### Conclusion

Although with a limited patients selection, this prospective study demonstrated that the use of TMZ at a dose of 75 mg/mq concomitant to radiotherapy shows better results in terms of OS than radiotherapy alone.

#### Purpose or Objective

The indications for post-operative radiation therapy (PORT) after primary systemic treatment (PST) for stage I-

II breast cancer (BC) are unclear. Therefore, we conducted a prospective cohort study from 2011-2014 in the Netherlands (RAPCHEM: NCT01279304), to evaluate the 5-year locoregional recurrence rate for BC patients treated with PST, surgery, and PORT given according to strict study-guidelines (SG). The aim of the current analysis is to evaluate adherence to these SG.

#### Material and Methods

Between January 2011 and January 2015, all patients with cT1-2N1 (four or more suspicious nodes at imaging excluded) BC, treated with PST in the referral area of 18 Dutch RT centres were included. Trained clerks of the Dutch Cancer Registry registered tumour and treatment characteristics. Surgery consisted of breast conserving therapy (BCT) or mastectomy with a sentinel node (SN) biopsy and/or an axillary lymph node dissection (ALND). SG recommended whole breast RT for patients treated with BCT and adapted chest wall/nodal RT based on three risk categories, mainly based on the ypN status:

1. Low-risk (ypN0): breast RT in case of BCT/no chest wall RT in case of mastectomy;
2. Intermediate-risk (ypN1): chest wall/breast RT;
3. High-risk (ypN2): chest wall/breast RT with regional RT (level I-IV).

In 2013, an amendment was developed taking into account new insights in axillary treatment: in case of a positive SN, additional ALND could be replaced by axillary RT.

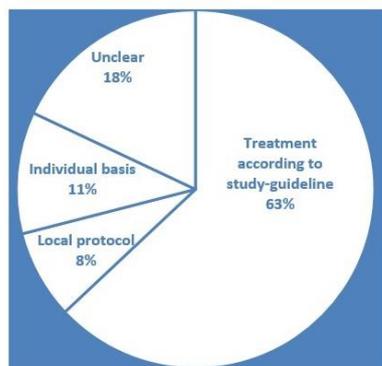

#### Results

From 2011-2014 we included 853 patients: 291 in the low-, 378 in the intermediate-, and 184 in the high-risk groups, respectively. 160 (19%) patients did not undergo an ALND. Overall, 63% of the patients were treated according to the SG (66% after BCT, 60% after mastectomy). Almost 10% received RT to fewer target volumes than recommended in the SG, and almost 25% received RT to more extensive target volume (Table). These percentages remained stable over the inclusion period. The largest variation was seen in the intermediate risk group (ypN1), where only 54% were treated according to the SG and where 16% received less and 27% received more RT than the SG. In half of the patients not treated according to the SG, the reason for deviation was unclear; in the other half, 60% deviated on an individual basis, whereas 40% were treated according to the local institutional protocol, since the radiation-oncologists did not agree with the SG (Figure).

Table showing percentage of patients treated according to study-guidelines, receiving more or less extensive RT than study-guidelines or just different than study-guidelines.

Risk group	RT according to study-guideline	Less RT than study-guideline	More RT than study-guideline	Different RT than study-guideline	Total
Low risk (ypN0)	61.5%	0.3%	37.5%	0.7%	100%
Intermediate risk (ypN1)	54%	16.4%	27%	2.7%	100%
High risk (ypN2)	85.3%	11.4%	0%	3.3%	100%
Total	63.3%	9.9%	24.7%	2.1%	100%

Figure showing reasons for not adhering to study-guidelines

#### Conclusion

The SG of the RAPCHEM study were followed in only 63% of patients. The largest variation in applied post-operative RT was observed in patients with ypN1 disease (intermediate risk group); deviation of the SG more often

resulted in more extensive RT than recommended by the SG. Future analyses will be aimed at evaluating the outcome of these patients in relation to risk factors and the actual RT given.

#### PO-0760 Heterogeneity of Radiosensitivity, Recurrence, and PD-L1 in Breast Tumor Single Cell RNA-Seq Data

B. Jang<sup>1</sup>, W. Han<sup>2</sup>, I.A. Kim<sup>3</sup>

<sup>1</sup>Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University-College of Medicine, Surgery, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University-College of Medicine, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

Tumor heterogeneity has been recently revealed in an advent of single-cell RNA sequencing. At a single cell level, heterogeneity of intrinsic tumor radiosensitivity, recurrence-risk, and their relationship remain unknown in breast cancer. In this study, we investigate the heterogeneity of intrinsic tumor radiosensitivity and recurrence risk in breast cancer patients.

#### Material and Methods

We investigated single cell mRNA sequencing data from GEO database (GSE75688) to profile 281 primary breast tumor cells. Subtypes of each tumor cell were classified by using PAM50 gene signature. OncoType DX and Endopredict gene signatures were used to estimate enrichment score and to assess the recurrence risk for each cell. To explore radiosensitivity, Gene Set Variation Analysis (GSVA) were performed across cells using radiosensitivity gene signatures including both RSI (Radiosensitivity Index) and 31-gene. PD-L1 expressed tumor cells were profiled as well.

#### Results

GSVA analysis showed that mean recurrence risk score of cells were different according to PAM50 breast cancer subtype, and cells were classified as basal subtype demonstrated higher risk recurrence score compared to those of other subtypes ( $P < 0.001$ ). Heterogeneity of recurrence risk was observed more frequently in luminal A subtype compared to basal/HER2 positive subtypes. Radioresistant tumor cells, representing high enrichment score of RSI, were more commonly found in basal type compared to those of other subtypes ( $P = 0.029$ ). RSI score was varied among cells from patient to patient, indicating the heterogeneity of intrinsic tumor radiosensitivity. There were significant correlations in a single cell resolution between RSI and 31-gene radiosensitivity (Pearson's  $r = 0.25$ ), between RSI and Endopredict risk score ( $r = 0.26$ ), and between OncoType DX and Endopredict enrichment scores ( $r = 0.61$ ), respectively. Most of the PD-L1 expressed cells were classified into high-risk recurrence group (92.8% for Endopredict and 100% for OncoTypeDX).

#### Conclusion

Tumor cells having various subtype or recurrent-risk coexisted regardless of individual pathologic subtype in a single cell level. Most radioresistant tumor cells showed basal subtype or PD-L1 expression. PD-L1 expressed cells were enriched in the high-risk or basal/HER2/luminal B subtype. Our results demonstrated the heterogeneity of intrinsic tumor radiosensitivity and recurrence risks in breast cancer patients.

#### PO-0761 Hypofractionated whole breast irradiation safety after breast-conserving surgery for young patients

I. Meattini<sup>1</sup>, Y. Kirova<sup>2</sup>, C. Saieva<sup>3</sup>, L. Visani<sup>1</sup>, E. Olmetto<sup>1</sup>, V. Salvestrini<sup>1</sup>, J. Kim<sup>4</sup>, W. Jung<sup>4</sup>, I. Desideri<sup>1</sup>, A. Fourquet<sup>2</sup>, P. Poortmans<sup>2</sup>, L. Livi<sup>1</sup>, K. Kim<sup>4</sup>  
<sup>1</sup>University of Florence - Azienda Ospedaliero Universitaria Careggi, Radiation Oncology Unit - Oncology Department, Florence, Italy ; <sup>2</sup>Institut Curie, Department of Radiation Oncology, Paris, France ;

<sup>3</sup>Institute for cancer research- prevention- and clinical network ISPRO, Cancer Risk Factors and Lifestyle Epidemiology Unit, Florence, Italy ; <sup>4</sup>Ewha Womans University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

Whole breast irradiation (WBI) ± boost on the primary tumour bed is the standard of care after breast-conserving surgery (BCS). For decades, conventionally fractionated WBI (CF-WBI) has been widely used. Pivotal phase 3 trials on hypofractionated-WBI (HF-WBI) showed comparable results in terms of efficacy with lower rates of acute side effects in favour of hypofractionation. However, due to the relatively low proportion of younger patients enrolled in these studies, HF-WBI is not broadly adopted for these patients. The aim of this retrospective case-control study is to confirm the safety of hypofractionation in younger patients.

### Material and Methods

Between 2007 and 2016, a total of 786 patients aged less than 60 years old with early stage breast cancer was treated with WBI after BCS in three leading breast cancer centres: 340 underwent HF-WBI while 446 cases were treated with CF-WBI. All patients were homogeneously scored following the acute and late RTOG/EORTC scales by treating expert physicians. Acute side effects were evaluated by scoring the maximum grade of oedema, erythema/pigmentation, and wet desquamation at the end of the WBI. Late toxicity was evaluated by scoring the maximum grade of oedema, erythema/pigmentation, desquamation, and breast fibrosis at 6, 12, 24, and 36 months.

### Results

At univariate analyses, hypofractionation showed a significant protective effect in terms of acute oedema (p=0.0001), acute wet desquamation (p=0.009), chronic oedema (p=0.0001), chronic erythema/pigmentation (p=0.0001), and chronic fibrosis (p=0.0002). Main results are summarized in Figure 1. At multivariate analysis independent factors for acute oedema were hypofractionation (HR 0.09, 95%CI 0.02 to 0.48; p=0.005), and adjuvant chemotherapy (HR 2.09, 95%CI 1.10 to 3.97; p=0.024); independent factors for chronic fibrosis were breast volume (HR 2.64, 95%CI 1.50 to 4.65; p=0.001), extensive intraductal component (HR 2.15, 95%CI 1.17 to 3.98; p=0.014), and tumour grade (HR 0.29, 95%CI 0.11 to 0.74; p=0.01). Major results are summarized in Figure 2.

Figure 1. Significant association between individual characteristics and toxicity in 786 breast cancer cases. P-values from univariate logistic models.

≤107%	455	0.58 (0.37-0.91)	0.017	1.00 (0.44-2.27)	0.99

### Conclusion

HF-WBI showed significantly better outcome in terms of main acute and late skin side effects. Longer follow-up is needed to confirm efficacy results. In line with recently updated international guidelines, the use of HF-WBI after BCS should be strongly encouraged and may largely replace CF-WBI independently of age.

### PO-0762 Low predictive value of mean heart dose for coronary artery dosimetry in breast cancer radiotherapy

S. JACOB<sup>1</sup>, J. Camilleri<sup>2</sup>, S. Derreux<sup>3</sup>, V. Walker<sup>1</sup>, O. Lairez<sup>4</sup>, M. Lapeyre<sup>5</sup>, E. Bruguière<sup>5</sup>, A. Pathak<sup>6</sup>, M. ### Purpose or Objective

In many studies that investigated radiation-induced cardiac toxicity of breast cancer radiotherapy, doses are described as those received by the entire heart and the mean heart dose is used as the reference dose for analyzing dose-response relationship. However the specific relationships between doses to cardiac sub-structures, in particular coronary arteries, and subsequent toxicity have not been well defined. Detailed individual dosimetry information for the heart and its sub-structures is required to better understand cardiac damage from radiation exposure. The aim of this dosimetric study was to analyze the distribution of individually-determined radiation exposure, in a population of breast cancer patients treated with three dimensional conformal radiation therapy (3D-CRT), and clarify whether mean heart dose is a good surrogate parameter for the dose to coronary arteries, in particular the left anterior descending artery.

### Material and Methods

Patients with left or right unilateral breast cancer (BC) treated with 3D-CRT between 2015 and 2017 were included (BACCARAT clinical study). Before RT, a coronary computed tomography angiography (CCTA) was performed. Registration of the planning CT and CCTA images allowed precise delineation of the coronary arteries on the planning CT images. Using the 3D dose matrix generated during treatment planning and the added coronary contours, dose distributions were generated for the following cardiac structures: whole heart, left main coronary artery (LMCA), left anterior descending artery (LAD), left circumflex artery (LCX) and right coronary artery (RCA). A descriptive analysis of the physical doses in Gray (Gy) was performed.

#### Results

Dose distributions were generated for 89 left-sided BC and 15 right-sided BC patients. The treatment schedule with tangential beams was either 50 Gy delivered in 25 fractions of 2 Gy or 47 Gy in 20 fractions of 2.35 Gy, with or without irradiation of regional lymph nodes. Additional beams to tumor bed (boost) were used, if clinically indicated. The mean heart dose (Dmean Heart) was  $2.9 \pm 1.5$  Gy for left-sided BC and  $0.5 \pm 0.1$  Gy for right-sided BC. For left-sided BC patients, the mean ratio Dmean LAD/Dmean Heart was around 5. All other ratios were below 1 except for RCA in right-sided BC patients (ratio=2.7). However, the coefficients of determination  $R^2$  indicated that the proportion of the variance in Dmean LAD or Dmean RCA predictable from Dmean Heart was low ( $R^2=0.45$  and  $0.36$  respectively). For left-sided BC patients with lower exposure (Dmean Heart < 3Gy), 56% of patients received doses > 40Gy to 20% of the LAD volume on average (V40Gy).

#### Conclusion

Our study illustrates that the predictive value of the mean heart dose was not good enough for coronary arteries, in particular for LAD, illustrating the importance of considering the distribution of doses within these cardiac substructures rather than just the mean heart dose to enhance knowledge on the risk of radiation-induced cardiotoxicity in breast radiotherapy.

#### PO-0763 Prognostic role of platelets-to-lymphocytes and neutrophil-to-lymphocytes ratio in breast cancer

I.R. Scognamiglio<sup>1</sup>, M. Tirozzi<sup>1</sup>, A. Romano<sup>1</sup>, M. Caroprese<sup>1</sup>, E. Zanella<sup>1</sup>, E. Scipilliti<sup>1</sup>, R. Mancuso<sup>1</sup>, A. Farella<sup>1</sup>, R. Solla<sup>2</sup>, C. Oliviero<sup>1</sup>, S. Clemente<sup>1</sup>, R. Pacelli<sup>1</sup>, M. Conson<sup>1</sup>

<sup>1</sup>University "Federico II" School of Medicine, Department of Advanced Biomedical Sciences, Napoli, Italy ;

<sup>2</sup>National Research Council, Institute of Biostructure and Bioimages, Napoli, Italy

#### Purpose or Objective

Breast cancer (BC) is the most common cancer and the first leading cause of cancer related death among women. Nowadays, many prognostic factors are available in clinical practice for BC patients, but ongoing efforts are made by the scientific community to identify new biomarkers for prognostic models' improvement. Inflammation is a hallmark of cancer and in the tumor-microenvironment it contributes to many cancer-promoting effects. Platelet-to-lymphocyte ratio (PLR) and neutrophil-to-lymphocyte ratio (NLR) are related to systemic inflammation and associated with prognosis in many solid tumors. The aim of this study is to verify the prognostic role of PLR and NLR in no metastatic BC patients who underwent radiotherapy (RT).

#### Material and Methods

Between January 2010 and December 2012, 229 consecutive BC patients treated in our department with adjuvant RT were analysed. 3D conformal RT with conventional fractionation schedule was administered. Clinical, pathological, and treatment characteristics of all patients are reported in Table 1. PLR and NLR were

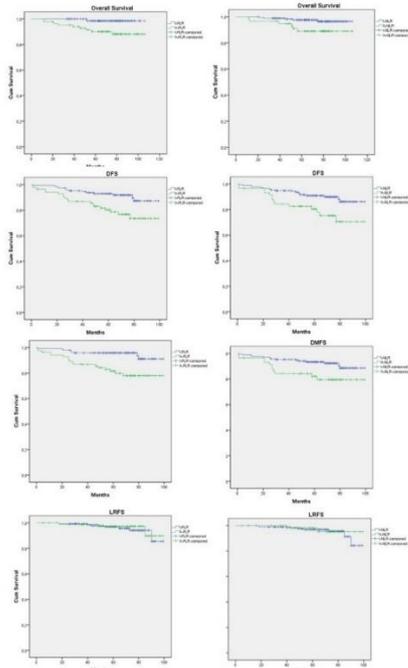

calculated as the absolute platelet count divided by the absolute lymphocyte count, and absolute neutrophil count divided by absolute lymphocyte count, respectively. The blood-count values were collected before RT. PLR and NLR were dichotomized and the cut-off values were 180 (namely, h-PLR $\geq$ 180, l-PLR<180) and 3 (namely, h-NLR $\geq$ 3, l-NLR<3), respectively. Actuarial 5 years overall survival (OS), disease free survival (DFS) were calculated. The impact of PLR and NLR along with patients clinical, pathological, and treatment characteristics on survival endpoints was evaluated. To this end, univariate and multivariate analyses were performed.

Table1 Patient characteristics

#### Results

Median age was 55 years (range 25-84). At a median follow-up time of 70 months (range 5-99), 218 patients (95.2%) were alive. Eight patients (3.5%) died for disease progression, while 3 deaths (1.3%) were non-cancer related. There were 32 (14%) relapses of disease. At the univariate analysis, 5y-OS was 98.4% for l-PLR patients and 90.1% for h-PLR ( $p<0.002$ ). 5y-DFS was 98.4% for l-PLR patients and 88.9% for h-PLR ( $p<0.001$ ). h-PLR and h-NLR resulted significantly associated with higher distant recurrence rates, while it was not observed for locoregional recurrence rates. The results are reported in Figure 1. Among patients clinical, pathological, and treatment characteristics, stage III age < 55 years, triple negative status negatively affected 5y-OS and DFS. At multivariate analysis, only h-PLR and stage III resulted associated with poorer prognosis, with a significantly higher rate of distant recurrences.

DMFS and LRFS of 229 patients divided into l-PLR (PLR<180) and h-PLR (PLR≥180) group

### Conclusion

High PLR is associated with poor prognosis in breast cancer patients. This biomarker might be implemented in clinical practice to improve recurrence risk estimation.

### PO-0764 The effect of automatic heart contouring on model performance in predicting acute coronary events

D. SPOOR<sup>1</sup>, F. Peters<sup>1</sup>, V. Van den Bogaard<sup>1</sup>, A. Van der Schaaf<sup>1</sup>, B. Ta<sup>1</sup>, R. Vliegthart<sup>2</sup>, R. Kierkels<sup>1</sup>, H. Langendijk<sup>1</sup>, J. Maduro<sup>1</sup>, M. Sijtsema<sup>1</sup>, A. Crijs<sup>1</sup>  
<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Vroomshoop, The Netherlands ; <sup>2</sup>University Medical Center Groningen, Radiology, Vroomshoop, The Netherlands

### Purpose or Objective

Breast cancer irradiation is associated with an increased risk of cardiac toxicity. The relationship between cardiac dose and toxicity was described by prediction models with the mean heart dose (MHD) as predictive variable. To determine the MHD the heart volume has to be delineated. Delineation of the heart can be done manually, but this is a time consuming method. Alternatively, methods for automatic contouring of the heart have been developed and the geometric overlap with manual contours has been studied. However, the effect of the contouring method on model performance has never been studied. In this study, the performances of NTCP models containing MHD based on automatic and manual generated contours of the heart were analyzed.

### Material and Methods

The study cohort consisted of 927 consecutive female breast cancer patients treated with radiotherapy after breast-conserving therapy. Manual contours of the whole heart were made routinely by technicians. Automatic contouring was performed with an in house developed multi-atlas based automatic segmentation (MABAS) tool for the heart. This tool has previously been proven to be an accurate and efficient method for automatic contouring of the heart on non-contrast planning CT scans. The NTCP model for acute coronary events (ACE) 9 years after radiotherapy by van den Boogaard et al. was refitted based on individual reconstructed MHD based on auto-contours (MABAS fit) and manual-contours (manual fit)

using Cox regression. Model performance was evaluated for both model fits by the -2 log likelihood and the c-statistic. The correlation between predicted risks of an ACE for both model fits was calculated. Calibration of both model fits was performed by plotting predicted risk of an ACE against observed ACE rates for different subgroups. These subgroups were created by stratification of patients by predicted risk of an ACE (0-5%, 5-10%, 10-15%, 15-20% and >20%) in both groups.

### Results

Model performance of the MABAS fit was comparable to the manual fit. The -2 log likelihood of the MABAS fit was 1.4 lower than the manual fit (323.2 vs. 324.6 respectively). The c-statistic of the MABAS fit and the manual fit were 0.82 (0.63-0.91) and 0.81 (0.72-0.90) respectively. Figure 1 shows that predicted risks for both model fits are highly correlated ( $r=0.994$ ). Despite an overestimation of the risk of an ACE due to limited follow-up, Figure 2 shows that the accuracy of the predictions for the MABAS fit and the manual fit are similar.

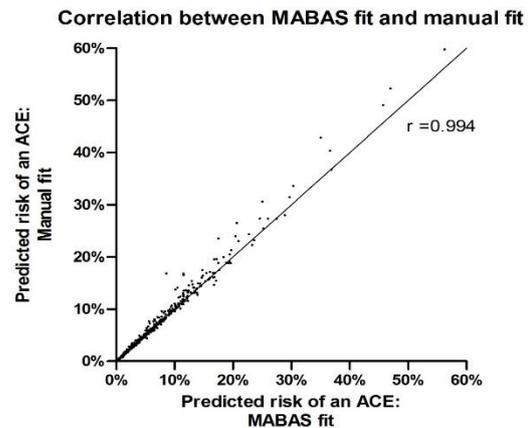

Figure 1: Correlation between predicted risks of an ACE for MABAS fit and manual fit

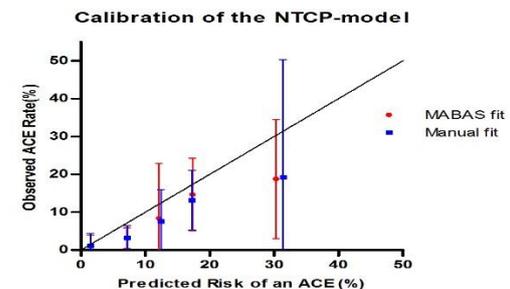

Figure 2: Calibration plot showing the predicted ACE rates 9 years after breast cancer radiotherapy as a function of observed ACE rates for two model fits; one dataset using MABAS derived MHD and the other using manual derived MHD.

### Conclusion

Refitting of the model by van den Bogaard et al. with datasets using MABAS and manual derived MHD results in highly correlated predictions and a comparable model performance.

### PO-0765 Oncological and cosmetic outcome after IOERT as a boost in a large cohort of breast cancer patients.

M. Machiels<sup>1</sup>, R. Weytjens<sup>1</sup>, K. Erven<sup>1</sup>, J.M. Westerhoff<sup>1</sup>, S. Amrouch<sup>1</sup>, J. Bosiers<sup>1</sup>, L. Verkinderen<sup>2</sup>, J. Hauspy<sup>2</sup>, P. Van Dam<sup>3</sup>, P. Dirix<sup>1</sup>, M. Vos<sup>1</sup>, P. Huget<sup>1</sup>, L. Dirix<sup>4</sup>, P. Meijnders<sup>1</sup>, S. Van Laere<sup>4,5</sup>, P.B. Vermeulen<sup>4,5</sup>, C. Billiet<sup>1,6</sup>  
<sup>1</sup>Iridium Kankernetwerk, Radiation Oncology, Antwerp,

Belgium ; <sup>2</sup>GZA Hospitals, Gynaecology, Antwerp, Belgium ; <sup>3</sup>Antwerp University Hospital, Multidisciplinary Oncologic Centre Antwerp MOCA, Edegem, Belgium ; <sup>4</sup>GZA Hospitals, Oncology, Antwerp, Belgium ; <sup>5</sup>University of Antwerp, Center for Oncological Research, Antwerp, Belgium ; <sup>6</sup>Oncology Center GZA, Translation Cancer Research Unit, Antwerp, Belgium

### Purpose or Objective

Advantages of using intraoperative radiotherapy with electrons (IOERT) as a boosting modality in breast-conserving therapy, include the direct visualization of the tumor bed, patient convenience, and allows a reduced dose to the skin, which may lead to a more favorable cosmetic outcome. We aimed to report oncological outcome, postoperative complication rate, mammographic changes on follow-up imaging, late toxicity and cosmetic outcome in women treated at our institution with IOERT as a boost modality in breast-conserving therapy for early invasive breast carcinoma or ductal carcinoma in situ (DCIS).

### Material and Methods

Between January 2007 and June 2018, 763 unselected patients of any risk group with early breast carcinoma or DCIS, treated at the GZA Hospitals were enrolled. During breast-conserving surgery, an IOERT boost of 9 Gy (90% reference dose) was applied, followed by whole breast irradiation (WBI). In a subset of patients (n=230) late toxicity and cosmetic outcome were scored prospectively using the LENT-SOMA breast questionnaires.

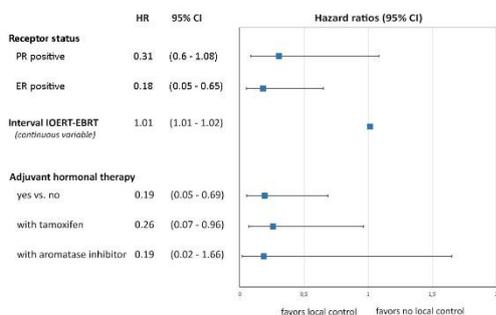

### Results

At a median follow-up of 62.2 months (range: 0.5 - 135), only 12 in-breast recurrences were observed, yielding a local tumor control rate of 98.4% at 5 years. A DFS of 95.1% at 5 years and OS of 97.2% at 5 years were noted. In univariate analysis, negative ER status, adjuvant hormonal therapy and interval between IOERT and EBRT predicted ipsilateral locoregional recurrence (Figure 1), albeit in multivariable analysis none reached significance. From the 12 patients with an in-breast recurrence, 9 were located within the initially involved quadrant and 3 outside this quadrant.

A total of 27 (3.5%) patients developed postoperative complications (e.g. hematoma, infection, wound dehiscence). None of the tumor characteristics nor any of the IOERT technical parameters were predictive for postoperative complications.

Ninety-nine percent of patients received follow-up imaging with a frequency < 2/year (median 0.92/y, range: 0 - 5.5). On follow-up imaging, 179 patients with mammographic changes were found of which 57% (n=102) required a biopsy.

After a median follow-up of 35 months (range: 22-64), the most prevalent G2 toxicities were breast fibrosis (29.5%) and breast pain (6.9%). Only 5.4% of patients reported any kind of G3 toxicity. A total of 78.8% patients had an excellent to good cosmetic outcome.

**Figure 1.** Forest - Plot: Hazard ratios (HR) and 95% confidence intervals (CI) obtained from univariable Cox

proportional hazards regression model of ipsilateral locoregional recurrences. Only significant characteristics are presented. Abbreviations: PR = progesterone receptor; ER = estrogen receptor.

### Conclusion

A 9 Gy IOERT boost combined with post-operative WBI provided outstanding local control rates, comparable to all trials with similar length of follow up. Furthermore, this is the largest cohort reporting on late toxicity and cosmetic outcome; our results demonstrate IOERT boost to be well-tolerated, with limited late toxicity and an excellent cosmetic outcome.

### PO-0766 The Italian Society of Radiation and Clinical Oncology (AIRO): snapshot on breast cancer management

F. Gregucci<sup>1</sup>, A. Fozza<sup>2</sup>, S. Falivene<sup>3</sup>, D. Smaniotto<sup>4</sup>, A. Morra<sup>5</sup>, A. Daidone<sup>6</sup>, R. Barbara<sup>7</sup>, A. Ciabattini<sup>8,9</sup>

Ascalesi, Radiation Oncology, Napoli, Italy ; <sup>4</sup>Policlinico Universitario A. Gemelli IRCCS - Università Cattolica del Sacro Cuore - Istituto di Radiologia, Radiation Oncology, Roma, Italy ; <sup>5</sup>Istituto Europeo di Oncologia - IRCCS, Radiation Oncology, Milano, Italy ; <sup>6</sup>P.O. Abele Ajello, Radiation Oncology, Mazzara del Vallo, Italy ; <sup>7</sup>AO San Giovanni Addolorata, Radiation Oncology, Roma, Italy ; <sup>8</sup>Ospedale San Filippo Neri, Radiation Oncology, Roma, Italy ; <sup>9</sup>on the behalf of Italian Society of Radiation and Clinical Oncology AIRO Breast Group, Radiation Oncology, Italy, Italy

### Purpose or Objective

To investigate the actual attitude of the Italian Radiation Oncologists in the management of breast cancer (BC) concerning some controversial issues.

### Material and Methods

A nationwide, 21-points questionnaire was distributed online via Survey Monkey to the Italian Radiation Oncologists.

### Results

78 Centers answered the Survey for 34164 patients (pts) affected by BC. In most centers, the pts number treated was superior to 200/year and in almost all cases an experts multidisciplinary discussion was performed to choose the best treatment for each patient. 16734 (49%) pts were treated with hRT. The 95% of centers used this treatment approach as clinical practice after breast-conserving surgery (BCs) for early stage BC, mostly in women older than 50 years (40%) affected by invasive ductal carcinoma (IDC) (89%). Dose prescription ranged between 34-45Gy with high use of moderate hRT (40Gy/15fr and 42.4Gy/16fr in 62% of cases). In locally advanced BC, the post-mastectomy or regional nodal hRT was still rarely applied, 13% and 15% respectively. In early stage BC, the 60% of centers used partial breast RT (PBI) with different techniques. 216 (0.6%) pts received rRT after BC recurrence. In 80% of cases, the rRT was given more than 5 years after primary RT. The age factor was not related with the rRT choice (68% of answer were "all age") and the most frequent histological type was IDC (82%) alone or associated with other histology. Regarding RT volumes are so representative below: 54% total rRT (WBI/chest wall irradiation) and 94% PBI (including 42% of tumor bed RT). 3879 (11%) pts received RT after NAC. In the 55% of cases a clinical disease evaluation was performed at the end of NAC and in 40% before. Disease staging included sentinel node biopsy before and after NAC in 40% and 60% respectively. The chest wall and the ipsilateral lymph nodes RT is a shared choice by most of the Italian Radiation Oncologists in case of locally advanced BC at the disease onset (cT3-T4 and/or cN2-N3), regardless of the kind of response obtained after NAC (complete response vs partial response) and also independently by the axillary

surgical approach (SLB vs axillary lymph node dissection-ALND). In case of disease onset with limited lymph node involvement (cN1), the same therapeutic option is chosen based on the response obtained after NAC but not based on the axillary surgical approach: in case of residual disease after NAC (ypN+), post-mastectomy RT is performed in the 79% and 76% of cases after SLB or ALND, respectively. In this setting, breast RT was administered in 97% of pts after BCs, with hRT in 49% of cases.

#### Conclusion

This survey demonstrated the high interest for breast RT in the majority of Italian Centers. Some practices as rRT and RT omission in particular clinical settings need further verification before entering in current clinical practice. Future national clinical collaborative studies are advocated in order to investigate these controversial topics about BC RT.

#### PO-0767 Long-term results of adjuvant hypofractionated radiotherapy for breast cancer in elderly patients.

M.J. García Anaya<sup>1</sup>, I. García Ríos<sup>1</sup>, S. Segado<sup>1</sup>, Á. Fernández Forné<sup>1</sup>, C. Jódar López<sup>1</sup>, J.A. Medina Carmona<sup>1</sup>

<sup>1</sup>Hospital Universitario Virgen de la Victoria, Radiation Oncology, Malaga, Spain

#### Purpose or Objective

Radiotherapy is an important treatment for the local control of breast cancer. More than 30% of breast cancer cases occur in women 70 years of age or older, but adjuvant radiation therapy is often omitted in older women due to comorbidities, sociofamilial problems or difficulty to attend the radiotherapy sessions. Traditionally, whole-breast radiation therapy (WBRT) after surgery has been delivered over 5 weeks using a conventionally fractionated schedule (2 Gy daily) to a total dose of 50 Gy. This is a logistic issue, particularly for an elderly population, which affects radiotherapy accessibility and comprises a major determinant of its eventual underutilization. We need radiotherapy fractionation schedules adapted to elderly patients. Hypofractionation (HFRT) allows to administer a lower total dose delivered in fewer although larger fractions. The objective of this study is to evaluate local control, acute and late toxicity and disease-free survival of elderly breast cancer patients treated with once-weekly adjuvant whole-breast radiation therapy.

#### Material and Methods

A consecutive series of 240 breast cancer elderly patients underwent once-weekly hypofractionated WBRT after breast conservative surgery, mastectomy or only *biopsy*, from January 2006 to September 2017. Patients were primarily selected to take into account older age, poor medical condition and/or logistic issues. They were given 32.5 Gy in 5 fractions (6.5 Gy once a week) until October 2011. Subsequently, they were administered 28,5 Gy in 5 fractions (5,7 Gy once a week). The modification of the fractionation to a lower dose per fraction was chosen according to the approach of the UK FAST randomized trial.

#### Results

The median aged was 78 years (35-89). 204 (85%) patients underwent breast-conserving surgery, 34 (14.2%) radical surgery and 2 (0.8%) no surgery. The clinical stage distribution was as follows: I in 92 (38.3%), II in 98 (40.8%), III in 49 (20.4%). Axillary lymph nodes were positive in 40.3 % of cases. Adjuvant hormone therapy and chemotherapy was given in 83.3% and 16.7% respectively. There was no interruption of the treatment. Early skin reactions were tolerable. Late effects, mainly subcutaneous fibrosis, were recorded in 115 patients; they were classified as grade 1 in 94 cases, grade 2 in 24 cases and grade 3 in 7 patients (figure 1). No late toxicity in 115 patients. The patients with 32.5 Gy showed a worse cosmetic result

what the patients with 28.5 Gy. There were no differences in locoregional control between both treatment schedules. Locoregional control was 94.2% at 5 years (figure 2) and progression-free survival was 84.5% at 5 years. At a median follow-up of 46.3 months, 178 patients (74.2%) was alive and disease free and 30 (12,5%) patients die and disease free.

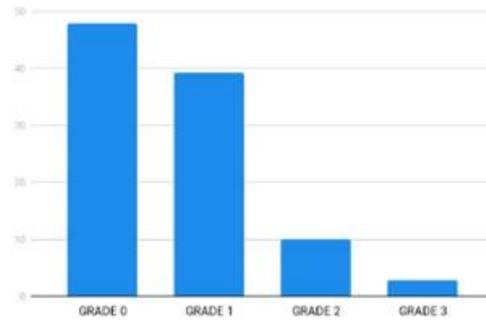

Figure 1: late toxicity (RTOG)

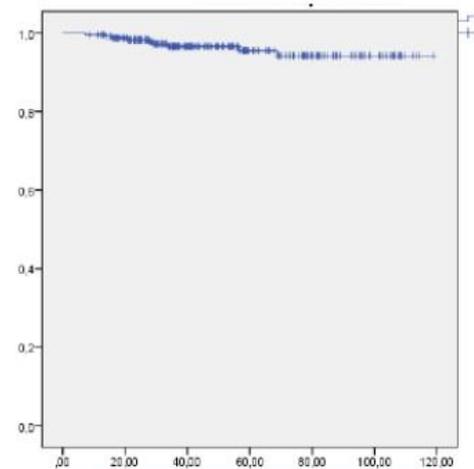

Figure 2: 5-years locoregional control: 94.2%

#### Conclusion

According to the findings from this retrospective study, HFRT schedule is effective and well tolerated in the elderly patients, with toxicity equivalent to other schemes of radiotherapy treatment and with a high level of compliance.

#### Poster: Clinical track: Lung

#### PO-0768 High Heart Dose Affects Overall Survival in Lung Cancer Patients Undergoing Radiation Therapy.

M. Fatyga<sup>1</sup>, S. Schild<sup>1</sup>, J. Niska<sup>1</sup>, M. Herman<sup>2</sup>, J. Li<sup>3</sup>, X. Liu<sup>3</sup>

<sup>1</sup>Mayo Clinic Arizona, Radiation Oncology, Phoenix, USA ;

<sup>2</sup>Mayo Clinic Rochester, Radiation Oncology, Rochester, USA ;

<sup>3</sup>Arizona State University, School of Computing-Informatics- Decision Systems Engineering, Tempe, USA

#### Purpose or Objective

To determine if radiation induced cardiac toxicity influences overall survival (OS) in stage III lung cancer patients undergoing radiation therapy (RT).

#### Material and Methods

A single institution database of 134 stage III Non Small Cell Lung Cancer patients, treated with RT, was retrospectively analyzed in this study. Survival status was obtained for each patient from the institutional tumor registry. Patients were treated with conventionally fractionated 3D Conformal and Intensity Modulated Radiation Therapy. The heart structure was contoured for each patient within the Varian Eclipse Treatment Planning System. A range of dose volume histogram (DVH) indices was computed from the whole heart cumulative DVH, and used together with patient specific characteristics in a family of Multivariate Cox Regression models. Each model used a single DVH index and all patient specific characteristics. The Akaike Information Criterion was used to find significant predictors in each model. We used this methodology to systematically search within a wide range of DVH indices for indices which may be predictive for a decrease in overall survival. Only one DVH index was used in each model because of strong correlations between indices. Subsequently, each heart was digitally subdivided into four segments along sup-inf and left-right axes. The same analysis was repeated using cumulative DVHs in each sub-part separately. Prescription dose, age before RT, mean lung dose, V20 lung dose, tumor location and laterality, stage, chemotherapy and surgery were used as patient specific characteristics.

#### Results

80 (60%) patients presented with stage IIIA and 54 (40%) with stage IIIB cancer. Doses prescribed were  $61.9 \pm 6.8$  Gy in 2Gy fractions, and 113 (77%) patients also received chemotherapy. 53 (40%) patients were alive at the last followup, while 81 (60%) were not. High doses to the heart were found to be significant predictors for the decreased overall survival, specifically: V%<sub>55Gy</sub> ( $p=0.01$ ) and V%<sub>60Gy</sub> ( $p=0.04$ ). Three patient characteristics were also found to be predictive for overall survival in all models: cancer stage (IIIA/IIIB,  $p=0.02$ ), chemotherapy ( $p<0.01$ ) and age before RT ( $p=0.02$ ). The analysis of digitally subdivided heart structures showed that V%<sub>55Gy</sub> ( $p=0.01$ ) and V%<sub>60Gy</sub> ( $p=0.02$ ) in the right-superior portion of the heart were significant predictors for the overall survival, while doses to the remaining three segments of the heart were not predictive. The index V%<sub>D</sub> indicates the percentage of the volume receiving dose 'D', or greater.

Whole Heart DVH index	V%5	V%10	V%15	V%20	V%25	V%30
p-value	0.63	0.613	0.648	0.531	0.446	0.554
Whole Heart DVH index	V%35	V%40	V%45	V%50	V%55	V%60
p-value	0.98	0.611	0.257	0.051	<b>0.011</b>	<b>0.039</b>

#### Conclusion

High doses to the heart in radiation therapy for lung cancer were associated with decline in overall survival, especially doses to the superior right segment of the heart. Minimizing high doses to the superior-right segment of the heart may potentially improve the overall survival for lung cancer patients and permit higher therapeutic doses.

#### PO-0769 Lung Organ-at-Risk volumes - The need for a better definition in the era of 4DCT

S. Vinod<sup>1</sup>, C. Choong<sup>1</sup>, P. Vial<sup>1</sup>, T. Kron<sup>2</sup>, D. Ball<sup>2</sup>  
<sup>1</sup>SWSLHD Liverpool Hospital, Cancer Therapy Centre, Liverpool BC, Australia ; <sup>2</sup>Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia

#### Purpose or Objective

Accurate volume delineation is crucial to correct interpretation of lung dose volume histograms (DVHs). However the studies on which current lung DVH constraints are based were all conducted in the 3DCT era with varying definitions for lung volume for DVH calculation ie Lungs alone, Lungs - PTV, Lungs - GTV. These volume definitions have not been updated in the era of 4DCT.

#### Material and Methods

We undertook a survey of all Australian departments in 2018 to evaluate how lung OAR risk volumes were being defined in clinical practice. To assess the clinical impact of different volume subtractions, we calculated lung DVHs on a cohort of 10 consecutive patients who had completed IMRT for Stage II-III NSCLC to a dose of 60-66Gy/30-33 fractions. We calculated mean lung dose (MLD), V20 and V30 for "Lungs - PTV", "Lungs - CTV", "Lungs - ITV" and "Lungs - GTV\_EX (expiratory phase)", where "Lungs" were delineated on the average of the 4DCT. These parameters were also calculated for "Lungs - ITV" where "Lungs" were delineated on the average, inspiratory and expiratory phases.

#### Results

Of the 27/88 responses received, 1 department used "Lungs alone", 6 used "Lungs - PTV", 2 used "Lungs - CTV", 6 used "Lungs - ITV", 5 used "Lungs - GTV in one phase of the respiratory cycle" and 7 departments stated the volumes used varied according to individual radiation oncologists.

The different tumour volume subtractions resulted in a difference in MLD ranging from 0.9Gy to 4.15Gy (Figure 1), V20 from 1.5% to 6.6% (Figure 2) and V30 from 1.34% to 7.11%. Four patients had a difference in MLD greater than 2Gy, 7 patients a difference in V20 greater than 2% and 8 patients in V30 greater than 2%. Subtraction of the PTV resulted in the lowest DVHs. The largest difference between subtraction of GTV\_EX and ITV was 0.32Gy, 0.43% and 0.46% for MLD, V20 and V30 respectively.

Subtraction of the ITV from the lungs as defined on different datasets resulted in a difference in MLD ranging from 0.2Gy to 2.88Gy and V20 from 0.37% to 5.61%. One patient had a difference in MLD greater than 2Gy and 4 patients a difference in V20 greater than 2%. There was no consistent dataset for lung volume definition which was associated with lower DVHs.

Figure 1 - Mean lung dose (Gy) calculated for different tumour volume subtractions in 10 patients

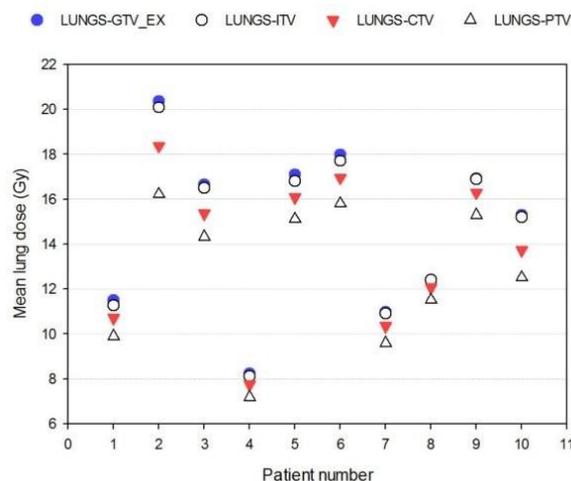

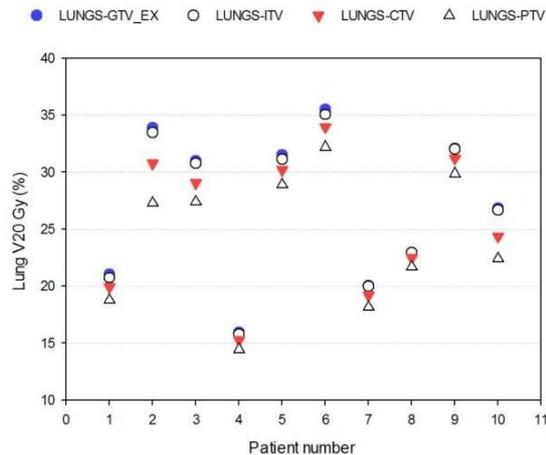

Figure 2 - Lung V20Gy (%) calculated for different tumour volume subtractions in 10 patients

### Conclusion

There is variability in definition of Lung OAR volumes. Clinically significant differences in lung DVH parameters are seen depending on the volume being subtracted. A robust definition of lung OAR volumes, applicable to both 3DCT and 4DCT simulation is needed. We suggest using “Lungs (average) - ITV” for 4DCT and “Lungs - GTV” for 3DCT simulation for Lung DVH calculation. Ideally these definitions should be used in clinical trial protocols to clarify the association between lung DVHs and toxicities and aid in translation of trial results into clinical practice.

### PO-0770 Clinical Outcomes of Concurrent Chemoradiation vs RT alone in Elderly Patients with Stage III NSCLC

D.Y. Kim<sup>1</sup>, J. Kim<sup>2</sup>, C. Song<sup>2</sup>, J.S. Lee<sup>3</sup>

<sup>1</sup>Seoul national university hospital, Radiation oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University Bundang Hospital, Radiation oncology, Seongnam, Korea Republic of ; <sup>3</sup>Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea Republic of

### Purpose or Objective

In elderly patients with stage III Non-Small Cell Lung Cancer (NSCLC), there are no solid conclusions about which treatment modality is better for concurrent chemoradiotherapy (CCRT) or radiotherapy (RT) alone, considering combined comorbidity or poor treatment tolerance. This study evaluated clinical outcomes between CCRT and RT alone in patients  $\geq 70$ -year old in a single institution clinical practice

### Material and Methods

A total of 94 patients with unresectable stage III NSCLC treated with at Seoul National University Bundang Hospital between 2004 and 2016 were reviewed. We analyzed 82 patients with curative intent to compare the tolerance ( $\geq$  EQD2 54Gy and no unplanned break of RT more than 5days or no hospitalization due to severe toxicities) by chi-square test and overall survival (OS), locoregional recurrence (LRR) and distant metastasis (DM) between two treatments using Kaplan-Meier method. Also, we evaluated patients who had died within 4 months after RT and causes of deaths. Furthermore, we performed subgroup analyses of factors which affect OS and 4-month survival in each treatment group by stepwise cox regression model.

### Results

Median follow-up time was 20.1 months. Patients received CCRT (65.9%) and RT alone (34.1%), and induction chemotherapy was done in 68.5% and 50.0%, respectively. Treatment tolerance was significantly worse in CCRT (87.0%) compared to RT alone (100.0%) (P=0.046). Median survival was 21.1 months and 18.1 months for CCRT and RT alone group, which was not statistically significant. LRR

and DM also showed no significantly difference between two treatment modalities. Though there was no statistical significance, deaths within 4 months after RT (4-month death) were higher in CCRT than RT alone group. Most of 4-month deaths in CCRT were related to non-cancer related mortality, such as pneumonia. In toxicity analysis, acute esophagitis of grade 2 or higher occurred more frequently in CCRT than in RT alone (P=0.017). On multivariate analysis, OS was significantly associated with Charlson comorbidity index (CCI) of 5 or greater (HR 2.00, 95% CI 1.10-3.61, P=0.022) and weight loss of 5% or more after treatment (HR 2.46, 95% CI 1.33-4.54, P=0.004). The factors affecting 4-month survival were also CCI score $\geq$ 5 (HR 6.46, 95% CI 2.18-19.21, P=0.001) and treatment modality (HR 0.26, 95% CI 0.07-0.98, P=0.047). Furthermore, in patients with CCI score 5 or greater, RT alone showed significantly better survival than CCRT at 4 months of follow up (P=0.038).

### Conclusion

We found that there were no significant differences in OS, LRR and DM between CCRT and RT alone, rather poorer tolerance and higher incidence of acute esophagitis grade 2 or higher in CCRT group. In case of the elderly patients with CCI score 5 or more, RT alone seems to be favorable with low possibility of early death after the treatment, mostly due to non-cancer related mortality.

### PO-0771 Cardiac event after radical radiotherapy for lung cancer - initial results from a multi-centre study

F. Sun<sup>1</sup>, K. Banfill<sup>2</sup>, S. Falk<sup>2</sup>, M. Alan<sup>2</sup>, L. John<sup>1</sup>, W. Robert<sup>1</sup>, A. Azadeh<sup>2</sup>, S. Matthias<sup>2</sup>, V.H. Marcel<sup>2</sup>, F. Corinne<sup>2</sup>, F. Kevin<sup>1</sup>

<sup>1</sup>St James Institute of Oncology, Oncology, Leeds, United Kingdom ; <sup>2</sup>Christie Hospital- Manchester, Clinical Oncology, Manchester, United Kingdom

### Purpose or Objective

Lung cancer is the leading cause of cancer mortality worldwide. Radical radiotherapy plays a pivotal role in the management of early and locally advanced disease. Recent studies suggest adverse cardiac events post treatment may worsen survival outcome for patients. This study aims to identify risk factors which predispose patients to cardiac events post radiotherapy and we present the initial results from the initial 107 patients.

### Material and Methods

All patients who received radical dose of radiotherapy for lung cancer between 01/01/2010 to 30/12/2016 in Leeds and Manchester are to be included. 1709 patients have been identified. From these cohorts patients were excluded if they had multiple courses of radiotherapy to the chest. Individual patient clinical information was retrieved from the hospitals electronic patient record (EPR). Patient and cancer demographics have been collected. Pre-existing cardiac conditions, Charlson's Comorbidity index and Qrisk 3 scores were calculated. Post radiotherapy cardiac events were recorded, survival times were calculated.

### Results

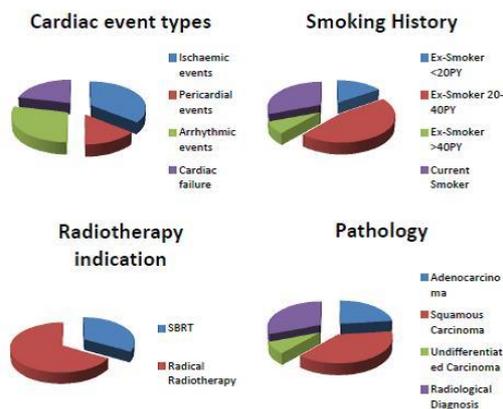

107 patients have been analysed so far. Median follow up is 26 months. Patient, tumour and radiotherapy characteristics are summarised in table 1. In the patients studied 30% had pre-existing cardiac conditions and 13% of patients experienced a cardiac events following radiotherapy (83% of these patients had pre-existing cardiac conditions). The median time from treatment to cardiac event was 13 months post radiotherapy. Patient characteristics of those who experienced cardiac toxicity are summarized in charts 2.

Charts 2

Patients who had cardiac toxicity following radiotherapy

### Conclusion

A substantial proportion of patients had a cardiac event following radical radiotherapy for lung cancer. A large proportion of these patients had pre-existing cardiac conditions. Cardiac events occur much sooner after lung cancer radiotherapy than post-radiotherapy for breast cancer or lymphoma. Further work is on-going to expand

the patient numbers, examine risk factors and correlate cardiac events/survival with radiotherapy dosimetry.

### PO-0772 Role of Prophylactic Cranial Irradiation in Extensive Disease Small Cell Lung Cancer

J. Chung<sup>1</sup>, S.Y. Kang<sup>2</sup>, G.J. Cheon<sup>2</sup>, H. Wu<sup>1</sup>, Y.S. Weo<sup>1</sup>, D. Kim<sup>3</sup>, H.J. Kim<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University Hospital, Department of Nuclear Medicine, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea Republic of

### Purpose or Objective

The role of prophylactic cranial irradiation (PCI) remains controversial in extensive disease small cell lung cancer (ED-SCLC). This study is performed to identify the risk factors of symptomatic brain metastasis and to evaluate the impact of PCI on brain metastasis-free survival (BMFS) and overall survival (OS) according to the risk of symptomatic brain metastasis in ED-SCLC.

### Material and Methods

From 2006 to 2017, a total of 190 patients diagnosed with ED-SCLC who underwent FDG-PET and brain MRI prior to treatment were enrolled in this retrospective study. Among these patients, 53 (27.9%) received PCI and 137 (72.1%) did not. Prognostic index predicting a high risk of symptomatic brain metastasis was calculated in the observation group (137/190) on Cox regression model and the prognostic index was generated by summing significant factors weighted by hazard ratio of each. The role of PCI in each risk group was analyzed by using Kaplan-Meier survival analysis.

### Results

Median follow-up time was 10.6 months. 1-year and 2-year symptomatic BMFS and OS were 86.9%, 52.5% and 49.8%, 12.7%, respectively. Multivariate Cox regression analysis showed that 4 risk factors were associated with high risk of symptomatic brain metastasis: presence of extrathoracic metastases ( $P=0.005$ ), FDG-PET uptake in bone marrow (BM) or spleen ( $P < 0.001$ ), progressive disease (PD) after chemotherapy ( $P=0.010$ ), and high hemoglobin (Hb) level ( $P=0.006$ ). The prognostic index significantly divided patients into two subgroups of high and low-risk of symptomatic brain metastasis ( $P < 0.001$ ). PCI significantly improved BMFS in high-risk patients ( $P=0.002$ , 1-year rate 95.5% vs. 61.8%), but not in low-risk patients ( $P=0.522$ , 1-year rate 100.0% vs. 91.9%). However, PCI did not improve OS in patients at a high risk for symptomatic brain metastasis ( $P=0.736$ , 1-year rate 45.0% vs. 50.0%).

### Conclusion

Four prognostic factors are associated with a high risk of symptomatic brain metastasis in ED-SCLC: presence of extrathoracic metastases, FDG-PET uptake in BM or spleen, PD after chemotherapy, and high Hb level. PCI is beneficial for patients at a high risk of symptomatic brain metastasis in terms of BMFS, but not OS. Therefore, selective use of PCI in ED-SCLC according to risk stratification is recommended.

### PO-0773 CBCT is not valid for response evaluation after chemoradiotherapy for locally advanced NSCLC

### Purpose or Objective

The PACIFIC trial showed a remarkable overall survival benefit with the adjuvant immune checkpoint inhibitor durvalumab after concomitant chemoradiotherapy (cCRT) for stage III non-small cell lung cancer (NSCLC). Inclusion criteria in the study were performance status (PS) 0-1 and no progression after cCRT. The adjuvant therapy was initiated within 42 days after the last radiotherapy (RT) fraction. There was a statistically significant advantage of starting adjuvant treatment early versus late within the 42 days, emphasizing the value of early response evaluation. We examined if response evaluation based on cone beam CT scans (CBCT) can be used to select patients for adjuvant therapy after cCRT. Furthermore, we assessed the fraction of patients eligible for adjuvant treatment with immune checkpoint inhibitor.

### Material and Methods

Patients with stage III NSCLC who received cCRT with cis- or carboplatin and vinorelbine in two prospective studies (2014-17) on deep inspiration breath-hold (DIBH) radiotherapy (RT) were included in the analysis. PS was prospectively registered at baseline and at completion of cCRT. CBCT response evaluation was performed retrospectively comparing the CBCT of the last fraction to the planning CT. Clinical response evaluation was done with contrast enhanced CT and compared to the planning CT. To avoid bias, CBCT evaluation was performed prior to assessing the CT evaluation. RECIST 1.1 criteria were used to evaluate if there was progression.

### Results

Ninety-four patients were included in the two trials. After the planning FDG-PET/CT, 18 patients were upstaged and received palliative treatment, two patients were downstaged and had stereotactic body RT or resection, and one patient died. Seventy-three patients proceeded to cCRT. Two patients progressed during cCRT (both brain metastases) and four patients were lost to follow-up before the evaluation CT, leaving 67 patients (46% men / 54% women), for analysis.

Median age was 65 (range 49-85) years and median baseline PS was 1. Pathology was adenocarcinoma (58%), squamous carcinoma (36%) and others (4%). Fifty-one (76%) patients received RT in DIBH and 16 (24%) patients in free breathing.

CBCT response evaluation revealed local progression in one patient and CT response evaluation found progression in seven patients. Furthermore, two patients were diagnosed with brain metastases on MR between end of RT and CT evaluation. Table 1 summarizes the progressing patients. CT evaluation was performed at median 57 (range 0-123) days after end of treatment.

Seventeen (25%) patients were in PS0, 41 (61%) patients in PS1 and nine (13%) patients in PS 2 at end of RT.

### Conclusion

CBCT cannot be recommended for treatment evaluation as most progressions (67%) were outside the CBCT field of view. Fifty (75%) patients were in PS 0-1 and without progression on CT evaluation after cCRT and thus candidates for adjuvant immune checkpoint inhibitor therapy.

Patient nr	Site of progression	Found on CBCT	Found on CT	Within CBCT FOV <sup>1</sup>	RT to CT time span <sup>2</sup> (days)

### PO-0774 Outcomes of IMRT/VMAT vs 2D/3D-conformal thoracic radiation in limited stage small-cell lung cancer

T.S. Toh<sup>1</sup>, A. Bang<sup>2</sup>, D. Pinto<sup>3</sup>, H. Katrina<sup>4</sup>, C. Brown<sup>4</sup>, W. Xu<sup>5</sup>, G. Liu<sup>4</sup>, B. Lok<sup>2</sup>

<sup>1</sup>University of Sheffield, Faculty of Medicine- Dentistry and Health, Sheffield, United Kingdom ; <sup>2</sup>Princess Margaret Cancer Centre, Radiation Medicine Program, Toronto, Canada ; <sup>3</sup>McMaster University, McMaster Faculty of Health Sciences, Hamilton, Canada ; <sup>4</sup>Princess Margaret Cancer Centre, Division of Medical Oncology and Hematology, Toronto, Canada ; <sup>5</sup>Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada

### Purpose or Objective

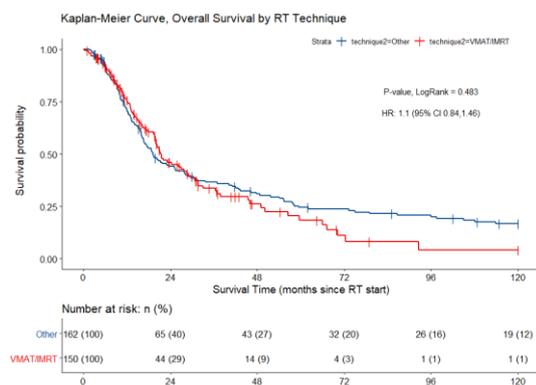

To compare the efficacy and toxicity between IMRT/VMAT and 2D/3D-conformal radiation techniques in limited-stage small-cell lung cancer (LS-SCLC) patients treated with curative intent.

### Material and Methods

A retrospective cohort of LS-SCLC patients treated with curative intent chemoradiation at the Princess Margaret Cancer Centre (1997-2018) were reviewed for patterns of efficacy/toxicity by radiation technique. Efficacy of different radiation techniques utilized overall survival (OS) from date of treatment initiation, censored at 10 years post-treatment start. The logrank test and Cox model were used to compare differences in survival by radiation technique. Toxicity rates (Grade  $\geq 2$  and  $\geq 3$  pneumonitis or esophagitis) were compared in a subset of patients (n=178) using logistic regression.

### Results

Of 312 LS-SCLC patients, the median age was 66 years (range: 39-85 years); 56% were males. 150 patients received IMRT (n=146) or VMAT (n=4). 162 received other forms of radiotherapy (27 3D conformal and 135 opposed AP/PA). Median follow-up was 16.6 months for all patients and 22.2 months for all living patients. Median OS was 20.5 months (95% CI: 18.8-25.3 months). The unadjusted hazard ratio comparing IMRT/VMAT versus other radiation techniques was 1.11 (95% CI: 0.84-1.46; p=0.48) for OS. Of the 178 patients in the toxicity-analyzable subset, 53% experienced Grade  $\geq 2$  esophagitis (9% Grade  $\geq 3$ ) and 10% experienced Grade  $\geq 2$  radiation pneumonitis (5% Grade  $\geq 3$ ). The unadjusted odds ratios comparing IMRT/VMAT vs. other radiation techniques were 0.69 (95% CI: 0.35-1.34; p=0.27) for grade 2+ esophagitis and 0.69 (95% CI: 0.24-1.98; p=0.49) for grade 2+ pneumonitis.

### Conclusion

With the advent of highly conformal radiotherapy techniques for the treatment of LS-SCLC patients, no difference in OS was identified. Lower rates of esophagitis and pneumonitis was observed, but this was not statistically different. Future work will be conducted to correlate dosimetric parameters with toxicity and outcomes.

### PO-0775 Palliative lung radiotherapy: audit of prescribing practice and survival analysis

T. Lewis<sup>1</sup>, J. Kennedy<sup>1</sup>, G. Price<sup>1</sup>, T. Mee<sup>2</sup>, K. Kirkby<sup>2</sup>, N. Kirkby<sup>2</sup>, D. Woolf<sup>1</sup>, N. Bayman<sup>1</sup>, C. Chan<sup>1</sup>, J. Coote<sup>1</sup>, C. Faivre-Finn<sup>1</sup>, M. Harris<sup>1</sup>, A. Hudson<sup>1</sup>, L. Pemberton<sup>1</sup>, A. Salem<sup>1</sup>, H. Sheikh<sup>1</sup>, H. Mistry<sup>1</sup>, D. Cobben<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom ;

<sup>2</sup>University of Manchester, Division of Cancer Sciences- School of Medical Sciences- Faculty of Biology- Medicine & Health, Manchester, United Kingdom

### Purpose or Objective

Choosing the optimal palliative lung radiotherapy (RT) regimen is challenging. The Royal College of Radiologists (RCR) guidance recommends treatment stratification based on patients' performance status (PS). The aim of palliative treatment is to alleviate symptoms, but evidence suggests higher radiotherapy doses are associated with survival benefits. Here, we present the effects of fractionation regimen and additional factors on the survival of palliative lung cancer radiotherapy patients.

### Material and Methods

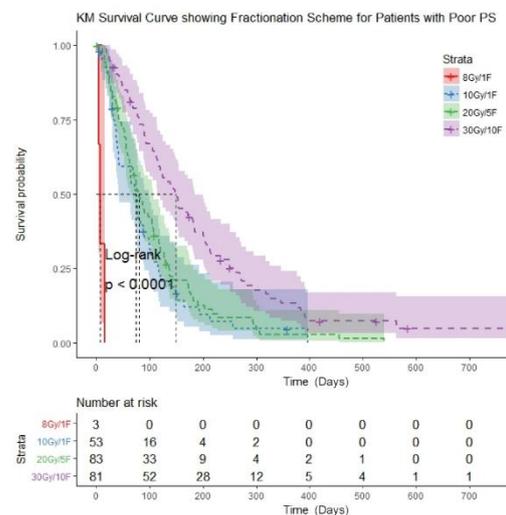

An audit comparing palliative non-small cell lung cancer (NSCLC) radiotherapy prescription with RCR guidance was conducted in a retrospective patient cohort (N=664) treated between 2013 and 2018 at a large cancer centre. Multivariable analysis of the prognostic significance of baseline patient characteristics and treatment prescription on overall survival was performed on a combined NSCLC and small cell lung cancer patient cohort (N=422). The percentage of patients dying within 30 days of treatment was calculated. Covariates investigated included: sex, age, PS, histology, comorbidities, stage, tumour location, tumour side, smoking status, pack year history, primary RT technique and fractionation scheme (8Gy/1F, 10Gy/1F, 20Gy/5F, 30Gy/10F).

### Results

80.8% of patients were treated according to RCR guidance. 2.6% good PS patients were under-dosed (i.e. lower dose and/or fractionation compared to RCR recommendations) and 16.6% poor PS patients were over-dosed. 85 patients (9.2%) died within 30 days of treatment.

Univariable analysis revealed that PS ( $p < 0.0001$ ), fractionation scheme ( $p < 0.0001$ ) and comorbidities ( $p = 0.03$ ) were significantly associated with survival. Univariable subset analysis results are displayed in Graph 1.

Multivariable analysis: better PS ( $p = 0.003$ ) and increased dose/fractionation regimens of up to 30Gy/10F ( $p < 0.0001$ ) were the only covariates that significantly correlated with increased survival.

Graph 1. Univariable subset analysis revealed that increased fractionation was associated with longer survival through every PS strata. Median overall survival (OS) of poor PS strata patients increased by 74 days when comparing those who received 30Gy/10F to 10Gy/1F.

### Conclusion

RCR guidance for palliative lung radiotherapy was followed for the majority of patients. Increased fractionation regimens (up to and including 30Gy/10F) were associated with better survival regardless of performance status.

### PO-0776 Neutrophil-to-lymphocyte ratio dynamics predict for survival in lung cancer treated with SBRT

M. Chowdhary<sup>1</sup>, R. Dhawan<sup>1</sup>, J. Switchenko<sup>2</sup>, S. Tian<sup>2</sup>, K. King<sup>1</sup>, M. Batus<sup>3</sup>, M. Fidler<sup>3</sup>, P. Bonomi<sup>3</sup>, N. Sen<sup>1</sup>, K. Patel<sup>4</sup>, M. Khan<sup>2</sup>, M. Gaurav<sup>1</sup>

<sup>1</sup>Rush University Medical Center, Radiation Oncology, Chicago, USA ;

<sup>2</sup>Emory University School of Medicine, Radiation Oncology, Atlanta, USA ;

<sup>3</sup>Rush University Medical Center, Medical Oncology, Chicago, USA ;

<sup>4</sup>Yale School of Medicine, Therapeutic Radiology, New Haven, USA

### Purpose or Objective

Systemic inflammation is known to play an important role in cancer progression. Neutrophil-to-lymphocyte ratio (NLR) may be a surrogate for systemic inflammatory response and tumor microenvironment. Indeed, high baseline levels of NLR has been shown to be a poor prognostic factor in various malignancies. Stereotactic body radiotherapy (SBRT) has been linked to systemic antitumor T-cell response via immune stimulation. The aim of this study is to assess percent (%) change in NLR, before and after SBRT, as a prognostic factor for survival in patients with early-stage lung cancer.

### Material and Methods

After IRB approval, patients treated with SBRT for Stage I-II lung cancer from 2012-2018 were retrospectively identified. Pre- and post-treatment NLR were calculated from blood counts obtained in closest proximity to SBRT delivery. Percent change in NLR was defined as  $([pre - post-SBRT NLR] / [pre-SBRT NLR])$ .

Overall survival (OS) was calculated using the Kaplan-Meier method. Intra- and extra-thoracic outcomes were calculated using the cumulative incidence model with competing risks for death. Multivariable Cox models were applied to adjust for confounders.

## Results

A total of 62 patients with evaluable % change NLR were available for analysis. The median time interval between blood draw and SBRT was 33 and 55 days for pre- and post-SBRT NLR, respectively. The overall median follow-up was 25.4 months.

Of the 62 patients, 38 (61.3%) demonstrated an increase in NLR following SBRT. Key patient characteristics (age, gender, race, KPS, smoking, comorbidities, steroid use, peripheral/central location, stage, mutation status) were well balanced, except for higher rates of hyperlipidemia and less involvement of right upper lobe in the NLR % change >0 cohort. Treatment characteristics (number of fractions, dose/fraction, total dose, BED) did not differ by cohort.

A statistically significant OS advantage was seen in patients when stratified by NLR % change: 12-, 24- and 36-month OS rates were 100% vs. 78.1%, 95.7% vs. 50.0%, and 87.7% vs. 45.0%, amongst patients with NLR % change ≤0 vs. >0, respectively. On univariate analysis, NLR % change (p=0.001), female gender (p=0.047), KPS (p=0.047), COPD (p=0.031), and total dose (p=0.013) were significant factors for OS. NLR % change >0 remained significant for predicting inferior OS (Hazard Ratio: 6.16 [95% CI: 1.70-22.28], p=0.006) on multivariable analysis confirmed; all other factors were not significant.

Other disease outcomes were not significantly associated with % change NLR: 2-year lobar recurrence (0% vs. 7.0%), nodal recurrence (4.4% vs. 18.2%), second primary (0% vs. 7.1%), or distant recurrence (13.3% vs. 22.7%) [all NLR % change ≤0 vs. >0].

## Conclusion

The percent change in NLR after SBRT, a potential marker for radiation-induced inflammatory response, is inversely related to OS in patients with early-stage lung cancer. If prospectively validated, NLR is a simple, systemic marker that can be easily used to guide subsequent management.

## PO-0777 Predicting overall survival after radiotherapy for brain metastases in patients with NSCLC

N. Knotter<sup>1</sup>, N. Horeweg<sup>1</sup>, I. Coremans<sup>1</sup>, R. Wiggeraad<sup>2</sup>, Y. Van der Linden<sup>1</sup>

<sup>1</sup>Leiden University Medical Center LUMC, Department of Radiotherapy, Leiden, The Netherlands; <sup>2</sup>Haaglanden Medical Center, Department of Radiotherapy, Leidschendam, The Netherlands

## Purpose or Objective

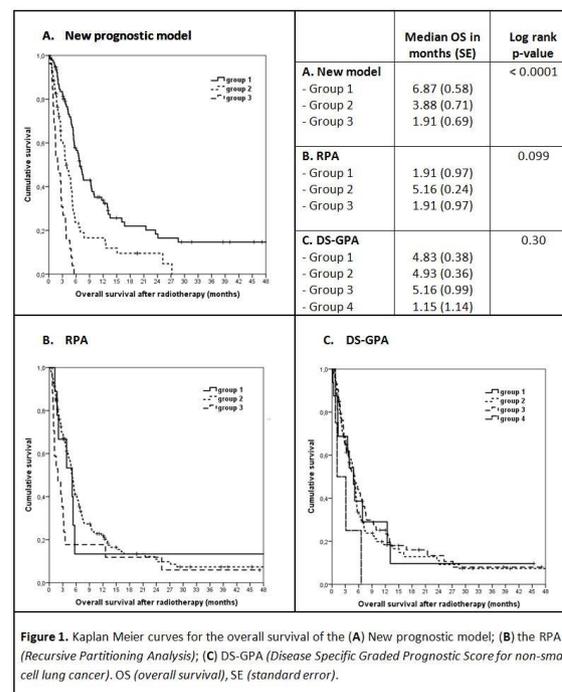

Brain metastases (BM) are common in non-small cell lung cancer (NSCLC) patients. The current standard treatment is palliative radiotherapy (RT), although its effect on symptoms and survival is debatable. The QUARTZ study suggested that only patients with a good performance status and expected prolonged survival benefit [1]. To aid in predicting overall survival (OS), recursive partitioning analysis (RPA) and Diagnosis specific graded prognostic score (DS-GPA), based on USA trial patients, were developed. Their use is currently widespread [2, 3, 4]. A recent Dutch study reported that OS in patients outside of trials is worse than these models suggest [5]. We therefore investigated whether these models correctly predict OS, and searched for additional prediction factors. Subsequently, a prognostic model was constructed to fit NSCLC patients with BM.

## Material and Methods

Retrospective cohort study of all patients with NSCLC treated with RT for BM at Leiden University Medical Center (2011-2018). Patient characteristics, data concerning fractionation schemes and follow-up were extracted from electronic patient charts. Kaplan-Meier's methodology was used to estimate OS. Uni- and multivariable Cox regression analyses were performed to identify significant prognostic factors and to define our prediction model. Performance of the three models was compared using the log-rank test.

## Results

188 patients were included. Mean age was 65 years, 50% was male, 69% had adenocarcinoma. Seventy percent received whole-brain RT (95% 20Gy/5#, 2% 25Gy/10# and 3% 39Gy/13#) and 30% underwent stereotactic RT (84% a single fraction of 15, 18, 20 or 21Gy). Ninety-one percent had a KPS ≥70, 70% had extracranial metastases at the time of brain metastases diagnosis. Forty-one percent had 1-2 BM, 46% 3-10 and 13% had >10 BM. Median OS was 4.9 months. The RPA and DS-GPA models did not show significant differences in OS between the risk groups (fig 1). Independent significant risk factors for mortality were non-adenocarcinoma, KPS <70, brain metastases (1-2 vs. 3-10 or >10) and age ≥65 years. Treatment type (whole-brain or stereotactic RT), fractionation schemes, extracranial metastases or mutation status (EGFR, KRAS, ALK/Ros) were not prognostic. Next, the LUMC-BM score was composed using these risk factors and classified patients into three risk groups (tab 1). The median OS for groups 1 (n=94), 2 (n=52) and 3 (n=26) were 6.9, 3.9 and 1.9 months (log rank p<0.0001), respectively. The hazard ratio's for mortality in group 2 and 3, relative to group 1, were 2.1 (95% CI 1.4-3.1) and 5.9 (95% CI 3.6-9.8) respectively.

**Figure 1.** Kaplan Meier curves for the overall survival of the (A) New prognostic model; (B) the RPA (Recursive Partitioning Analysis); (C) DS-GPA (Disease Specific Graded Prognostic Score for non-small cell lung cancer). OS (overall survival), SE (standard error).

**Table 1.** New prognostic model for overall survival in patients with NSCLC and brain metastases

Prognostic factor	Scoring criteria		
	0	1	2.5
Histology	Adenocarcinoma	Non-adenocarcinoma	N.A.
KPS	≥ 70	< 70	N.A.
No. of BM	1 - 2	3 - 10	> 10
Age, years	< 65	≥ 65	N.A.

Risk Groups: 1 = 0 - 1 points; 2 = 2 - 2.5 points; 3 = 3 - 5.5 points  
N.A. (not applicable)

## Conclusion

Our new prognostic model more accurately predicts OS in NSCLC patients with brain metastases outside of trials than current widespread used RPA and DS-GPA prediction models. The validation study of our model is currently being performed.

**PO-0778 New prognostic factors in the SBRT treatment of early stage non-small cell lung cancer**

J. Di Muzio<sup>1</sup>, S. Badellino<sup>1</sup>, M. Levis<sup>1</sup>, L. Delsedime<sup>2</sup>, C. Mantovani<sup>1</sup>, M. Volante<sup>2</sup>, M. Papotti<sup>2</sup>, U. Ricardi<sup>1</sup>  
<sup>1</sup>University of Turin - Città della Salute e della Scienza, Radiation Oncology, Torino, Italy ; <sup>2</sup>University of Turin and Città della Salute e della Scienza Hospital, Pathology Unit- Department of Medical Sciences, Torino, Italy

**Purpose or Objective**

The indication of SBRT in operable patients affected by early stage NSCLC who refuse surgery is always increasing, with the need to identify prognostic factors for disease control. Our study aims to identify histological and molecular biology factors for a prognostic stratification of these patients.

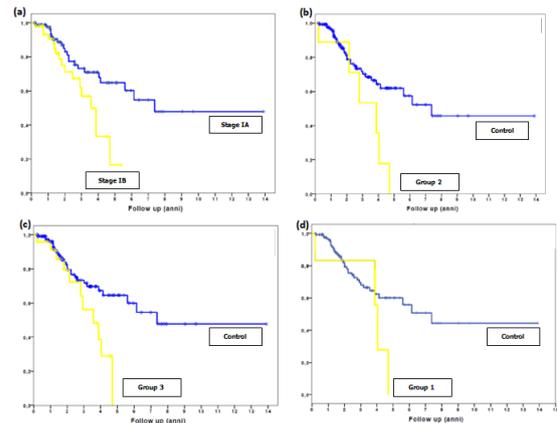

**Material and Methods**

The database of the radiotherapy institute of the University of Turin was retrospectively reviewed in search of patients underwent SBRT for early stage NSCLC from January 2003 to October 2017. Only patients with histological typing performed at the Pathology Unit of the University of Turin were included in the analysis. Patient and tumor data were collected together with immunohistochemistry and molecular biology data. Molecular biology data detected were EGFR mutation, ALK translocation, KRAS, ROS1 and BRAF mutation. The patients were analysed according to the subdivision into 3 groups. The first with the only KRAS positive, the second (unfavorable) with KRAS positive, ROS1 negative and BRAF positive, the third (very unfavorable) with the presence of the previous factors but EGFR and ALK negative. Total dose of treatment was prescribed at 80% isodose and risk-adapted treatment schedules were used. All patients were treated with a minimum BED of 100 Gy.

**Results**

142 patients were included in the analysis with a median follow-up of 22 months. Patient characteristics are listed in Table 1. Median progression free survival was 49 months. Stage ( $p = 0.008$ ) and molecular biology factors (KRAS  $p = 0.007$ , unfavorable  $p = 0.004$  and very unfavorable  $p < 0.001$ ) were statistically significant with univariate analysis. Stage ( $p = 0.02$ ) and the very unfavorable group ( $p < 0.001$ ) were confirmed at the multivariate analysis. Median cancer specific survival was 73.7 months. Stage ( $p = 0.02$ ) and molecular biology factors (KRAS  $p = 0.009$ , unfavorable  $p = 0.025$ , very unfavorable  $p = 0.027$ ) were statistically significant in the univariate analysis as clinical predictors. Stage ( $p = 0.03$ ) and the unfavorable group ( $p = 0.06$ ) were confirmed in multivariate analysis. Local control at 12, 24 and 36 months was 95.8%, 83.6%, 80.1%, respectively. Stage ( $p = 0.005$ ) and the very unfavorable group ( $p = 0.001$ ) proved to be predictive for univariate analysis. Both factors were confirmed in multivariate analysis ( $p$  respectively of 0.01 and 0.008). Systemic control at 12, 24 and 36 months was 90.1%, 72.5% and 67.7%, respectively. Stage ( $p < 0.001$ ), histology ( $p = 0.04$ ) and molecular biology factors (KRAS  $p < 0.001$ , unfavorable  $p < 0.001$  and very unfavorable  $p < 0.001$ ) proved to be predictive for univariate analysis. Only stage and the very unfavorable group were confirmed at the multivariate analysis ( $p$  of 0.03 and 0.002, respectively).

**Cancer Specific Survival**

**Conclusion**

Molecular biology and histological parameter, such as KRAS, could select a population of patients with more aggressive tumor. These patients may be deserving of greater personalization of therapy by dose intensification or integration with systemic therapies.

**PO-0779 Current management of limited-stage SCLC and CONVERT trial impact: an EORTC LCG survey**

A. Levy<sup>1</sup>, L.E.L. Hendriks<sup>2</sup>, C. Le Pêchoux<sup>1</sup>, S. Falk<sup>3</sup>, B. Besse<sup>4</sup>, S. Novello<sup>5</sup>, A.C. Dingemans<sup>2</sup>, B. Hasan<sup>6</sup>, M. Reck<sup>7</sup>, T. Berghmans<sup>8</sup>, C. Faivre-Finn<sup>3</sup>  
<sup>1</sup>Gustave Roussy, Radiation Oncology, Villejuif, France ; <sup>2</sup>Maastricht University Medical Center, Pulmonary Diseases, Maastricht, The Netherlands ; <sup>3</sup>The Christie NHS Foundation Trust, Radiation Oncology, Manchester, United Kingdom ; <sup>4</sup>Gustave Roussy, Medical Oncology, Villejuif, France ; <sup>5</sup>AOU San Luigi, Oncology Department, Turin, Italy ; <sup>6</sup>European Organisation for Research and Treatment of Cancer, Statistics, Brussels, Belgium ; <sup>7</sup>LungenClinic Grosshansdorf, Pulmonology,

Grosshansdorf, Germany ; <sup>8</sup>Jules Bordet, Intensive Care and Oncological Emergencies & Thoracic Oncology, Brussels, Belgium

### Purpose or Objective

The CONVERT trial (NCT00433563: once-daily (OD) vs. twice-daily (BD) thoracic chemoradiotherapy (CRT)) confirmed that BD radiotherapy (RT) should continue to be considered the standard of care but impact on CRT regimens in daily care is unknown. A European survey was launched to evaluate current practice in good performance status (PS) limited-stage small-cell lung cancer (LS-SCLC) patients suitable for chemo-radiotherapy (CRT) to 1) assess the impact of the CONVERT trial and 2) identify relevant research questions for future clinical trials

### Material and Methods

An European Organisation for Research and Treatment of Cancer (EORTC) Lung Cancer Group (LCG) survey containing 28 questions on LS-SCLC was distributed between April 2018 and October 2018 to the EORTC LCG and several European thoracic oncology societies' members.

### Results

188 responses were analyzed (radiation oncologists: 50% [n=94], pulmonologists: 15% [n=28], medical oncologists: 23% [n=35]); 84% with >5 years' experience of treating SCLC. Italy (18%, n=34), Spain (16%, n=31), and the UK (15%, n=28) contributed the most. 87% (n=164) were aware of the CONVERT trial and 20% (n=38) included patients in the trial. Concurrent CRT is favoured (n=169, 90%) compared to sequential treatment. OD is the most commonly used regimen, but the use of BDRT increased after the CONVERT publication (n=120, 64% prior to and n=107, 57% after the publication) (Table 1). 60-66 Gy in 30-33 fractions is the most commonly prescribed OD RT regimen (n=73/120, 61%). The main reasons for not implementing BD after the CONVERT publication are logistical issues (n=84, 45%) and inconvenience for patients (n=55, 29%). 139 respondents (74%) deliver 4 cycles of chemotherapy and 45 deliver 6 cycles (24%) routinely in the context of CRT. G-CSF (granulocyte colony-stimulating factor) is used by 39%, either routinely or as secondary prophylaxis. Prophylactic cranial irradiation (PCI) is routinely used in patients who have not progressed after CRT (n=178, 95%). The most commonly prescribed PCI dose is 25 Gy in 10 fractions (n=150, 80%) and more than half of respondents do not apply an upper age limit (n=100, 53%). The main research questions of interest for LS-SCLC are 1) integrating novel targeted therapies-immunotherapies (151, 80%) and 2) PCI (+/- hippocampal sparing) vs. MRI surveillance (134, 71%).

Table 1: Type of preferred radiotherapy delivered in the concurrent setting.

	Before CONVERT Total=176* N (%)	After CONVERT Total=180* N (%)
<b>OD</b>	120 (68)	107 (59)
Preferred regimen	60-66 Gy: 73/120 (61)	60-66 Gy: 70 (65)
Preferred regimen	45 Gy: 55/56 (98)	45 Gy: 72 (99)

\*excluding respondents that never used concurrent CRT

### Conclusion

Although the CONVERT trial confirmed that BD radiotherapy should be considered the standard of care, OD (60-66 Gy in 30-33 fractions) remains the most prescribed radiotherapy fractionation.

### PO-0780 Prognostic value of PD-L1 expression in locally advanced NSCLC treated with chemoradiotherapy

Tufman<sup>4</sup>, R.M. Huber<sup>4</sup>, M. Orth<sup>1</sup>, S. Reu<sup>5</sup>, M. Niyazi<sup>1</sup>, C. Belka<sup>1</sup>, F. Manapov<sup>1</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>LMU University Hospital Grosshadern, Department of Pathology, Munich, Germany ; <sup>3</sup>LMU University Hospital Grosshadern, Department of Nuclear medicine, Munich, Germany ; <sup>4</sup>Thoracic Oncology Centre Munich Ludwig-Maximilians University, Division of Respiratory Medicine and Thoracic Oncology Department of Internal Medicine V, Munich, Germany ; <sup>5</sup>University Hospital Wuerzburg, Department of Pathology, Wuerzburg, Germany

### Purpose or Objective

Immune checkpoint inhibitors (CPIs) are an integral part of multimodal treatment approach in locally-advanced stage non-small cell lung cancer (LA-NSCLC). Purpose of the present study was to investigate prognostic value of PD-L1 expression on tumor cells and tumor-infiltrating lymphocytes (TILs) in a single-center patient cohort treated with chemoradiotherapy.

### Material and Methods

We collected tumor tissue samples and clinical characteristics of 37 LA- NSCLC patients treated with chemoradiotherapy between 2000 and 2004. The analyzed tissue was taken before therapy and immunostaining was performed by experienced pathologist. VENTANA PD-L1 (SP263) Rabbit Monoclonal Primary Antibody was used to detect PD-L1 in formalin-fixed, paraffin-embedded tissue through the OptiView CC1. The samples were pretreated for 64 minutes, the antibody incubation time measured 16 minutes. Dilution was not necessary (Ready-to-use, RTU). The histological staining was carried out by the Benchmark Ultra. Tumor cells and lymphocytes were analyzed separately. Based on PD-L1 expression (0%, 1-5%, >5%) 3 groups were defined.

### Results

All patients were treated with definitive chemoradiotherapy (CRT). Follow-up data of all patients until death was available. One patient was diagnosed in UICC stage II, 31 patients in stage III and 5 patients in stage IV. Absolute majority (35 patients, 95%) were treated with concurrent cisplatin- and taxane-based CRT. 23 patients (62%) received consolidative chemotherapy. A total of 30 males (81%) and 7 females (19%) were evaluated, 11 of which (30%) were non-smokers, 26 (70%) had at least 20 pack years. Patients without (0%) and very low expression (1-5%) of PD-L1 on tumor cells showed a significantly better overall survival compared to the subgroup showing PD-L1 expression over 5% with 13.8 versus 6.6 months as well as one-year survival rate of 67.7 versus 33.3%, respectively (p=0.039). Expression of PD-L1 on the TILs showed no significant impact on overall survival (p=0.808).

### Conclusion

PD-L1 expression on tumor cells correlates significantly with reduced overall survival in patients with LA-NSCLC treated with CRT. In contrast, PD-L1 expression on tumor-infiltrating lymphocytes has no impact on overall survival in our study.

### PO-0781 30 Gy single dose SBRT: Outcome in a large series of patients with lung oligometastatic disease

University of Rome, Department of Radiology, Rome, Italy

### Purpose or Objective

To evaluate local control (LC), long term adverse effects and survival in a series of patients with oligometastatic to the lung disease who received 30Gy in single dose with stereotactic technique.

### Material and Methods

Between December 2008 and April 2017, a total of 160 lung metastases in 123 patients affected by oligometastatic disease were treated, at our Institution, with stereotactic body radiotherapy (SBRT) delivered in a single dose of 30 Gy. The primary tumors in most cases were non small-cell lung cancer and colon-rectum cancer (46.3% and 29.2%, respectively). Prognostic factors were also assessed.

### Results

The median follow-up was 38 months. Twenty-three (14.3%) lesions in 20 patients progressed locally. Intra-thoracic progression (new lung lesions or thoracic lymph node metastases) occurred in 58 (47.1%) patients. Distant progression occurred in 43 (34.9%) patients after a median time of 14 months. The 3- and 5-year local relapse-free survival (LPFS) were 80.3% and 79.5% (median not reached), respectively. Late toxicity was evaluated in 148 patients (follow-up >6 months): 50 (33.7%) had grade  $\leq 2$  fibrosis, 10 (6.7%) experienced grade 3 fibrosis. Two (1.3%) cases of rib fracture occurred. One case of toxic death (grade 5) has been reported. Median OS was 39 months. Prognostic factor at the univariate analysis was: lesion diameter  $\leq 18$  mm correlated significantly with a longer LPFS ( $p=0.001$ ). Prognostic factors at the multivariate analysis were: lesion diameter  $< 18$  mm was predictive for longer LPFS ( $p=0.006$ ); oligometastases from primary colon cancer predicted significantly for worse LPFS ( $p=0.041$ ) and progression-free survival ( $p=0.04$ ).

### Conclusion

To our knowledge, the current study represents the largest series on the use of SBRT 30 Gy single dose for lung metastases. The proposed schedule showed to be effective and safe, when administered in selected oligometastatic patients. These results could be evaluated in further prospective series with the aim of investigating the safety of this schedule in selected candidates.

### PO-0782 External validation of NTCP models for pneumonitis in lung cancer patients receiving proton therapy

A. Niezink<sup>1</sup>, V. Jain<sup>2</sup>, O. Chouvalova<sup>1</sup>, R. Wijsman<sup>1</sup>, C. Muijs<sup>1</sup>, M. Frick<sup>2</sup>, A. Doucette<sup>2</sup>, C. Simone<sup>3</sup>, C. Chinniah<sup>2</sup>, J. Widder<sup>4</sup>, J. Langendijk<sup>1</sup>, A. Van der Schaaf<sup>1</sup>, A. Berman<sup>2</sup>

<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands; <sup>2</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA; <sup>3</sup>University of Maryland School of Medicine, Radiation Oncology, Baltimore, USA; <sup>4</sup>Medical University of Vienna, Radiation Oncology, Vienna, Austria

### Purpose or Objective

Concurrent chemo-radiotherapy (CRT) is the standard of care for patients with locally advanced non-small cell lung cancer (LA-NSCLC). Pneumonitis is the most frequently observed treatment related toxicity which can have significant impact on quality of life. Proton beam therapy (PBT) offers advantages over photon beam therapy by reducing radiation dose to healthy tissues. However, not all dose reductions are clinically relevant. Therefore a method to select patients that are most likely to benefit from this modality is warranted. One such approach is using normal tissue complication probability (NTCP) models for plan comparison. However, the currently available models are exclusively based on photon data. In this study, we investigated the validity of three photon

based NTCP models for radiation pneumonitis (RP) in patients that underwent CRT using PBT for LA-NSCLC.

### Material and Methods

The validation cohort consisted of 99 consecutive patients with LA-NSCLC (Stage III) treated with definitive CRT using PBT (pencil beam scanning and double scattering) between 2011-2016. Patients were treated to a total dose of 56-74cGy, assuming an RBE of 1.1 for PBT. RP was scored at 3 and 6 months post treatment (CTCAE v4.0). We evaluated the performance of the QUANTEC pneumonitis (QP) model, the QUANTEC model adjusted for clinical risk factors (AQP), as well as a newer and updated QP (NQP) model (ESTRO 2017, which has a steeper slope and includes current smoking). A closed testing procedure (CTP) was performed to test the need for model updating, either by calibration-in-the-large (re-estimation of model intercept), recalibration (re-estimation of intercept and slope) or model revision (re-estimation of all coefficients).

### Results

There were 21 events (21%) of Grade  $\geq 2$  RP in the PBT cohort. On univariable analysis, mean lung dose was significantly associated with RP ( $p=0.01$ ), as well as several DVH parameters ranging from V5 to V50, with the strongest association for V40 ( $p<0.01$ ). The CTP did not detect major deviations of the data from the models, but recommended adjustment of the intercept only for the photon-based AQP and NQP models. The apparent steepness of the dose-response relationship was larger in the PBT data than in the QP and AQP models, but lower than in the NQP model. However, these deviations were not significant, therefore the CTP did not recommend updating the slope or other model parameters. Redeployment of a new model using mean lung dose, V40, and smoking status (current smoking is a protective factor) did not improve the existing models (with update after validation).

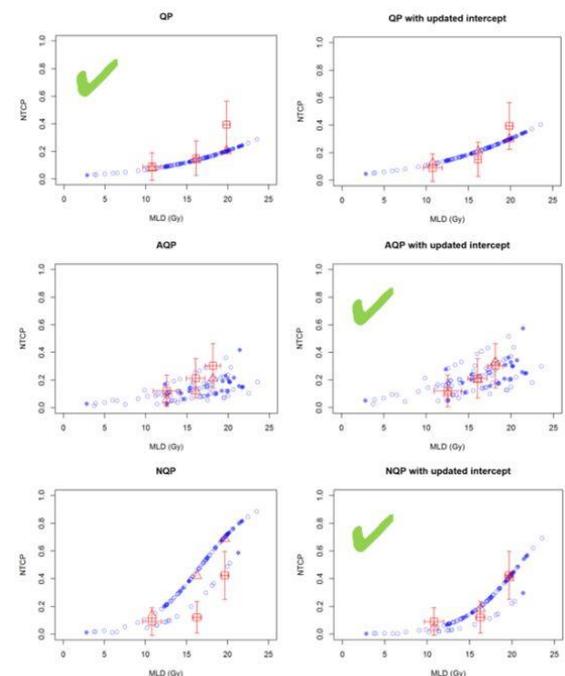

Figure 1: Predicted and observed NTCP as a function of mean lung dose (MLD) for three different models. Left = original models. Right = models with updated intercept. Blue circles = NTCP prediction for individual patients. Filled circle = patient with observed complication (pneumonitis). Red squares with error bars = average observed toxicity in 3 risk groups (grouped according to NTCP of the corresponding model). Red triangle = predicted average toxicity for each risk group. The green mark indicates recommended models by CTP.

### Conclusion

Three photon based NTCP models for RP were externally validated in a cohort of patients with LA-NSCLC treated

with PBT. The models performed well in this cohort and only small adjustments of the model intercepts were needed. This study indicates that photon based NTCP models are applicable among patients treated with protons.

### PO-0783 Standardizing mediastinal nodal CTV delineation in Stage III NSCLC: results of a two-phase dummy run

F. Chartier<sup>1,2,3</sup>, V. Remouchamps<sup>3,4</sup>, M. Lambrecht<sup>5</sup>, X. Geets<sup>3,6</sup>, E. Hortobágyi<sup>3,5</sup>, Y. Lievens<sup>3,7</sup>, L. Moretti<sup>1,3</sup>  
<sup>1</sup>Institut Jules Bordet, Department of Radiation Oncology, Brussels, Belgium ; <sup>2</sup>Université Libre de Bruxelles, Radiation Oncology, Brussels, Belgium ; <sup>3</sup>on behalf of the Belgian College for Physicians in Radiation Oncology, Radiation Oncology, Brussels, Belgium ; <sup>4</sup>CHU UCL Namur - site Ste Elisabeth, Department of Radiation Oncology, Namur, Belgium ; <sup>5</sup>University Hospitals Leuven, Department of Radiation Oncology, Brussels, Belgium ; <sup>6</sup>Cliniques Universitaires Saint-Luc, Radiotherapy Department, Brussels, Belgium ; <sup>7</sup>Ghent University Hospital, Department of Radiation Oncology, Ghent, Belgium

#### Purpose or Objective

Lymph node delineation in stage III non-small cell lung cancer (NSCLC) remains the subject of discussion as the inclusion or omission of a lymph node or station can have an important impact on both oncological outcome and toxicity. The Belgian College for Physicians in Radiation Oncology aims to improve the quality of radiotherapy in Belgium. Within this framework the Project on Cancer of the Lung (ProCaLu) focuses on standardizing delineation for locally advanced NSCLC. A two-phase contouring dummy-run on a single test case was performed to analyze the baseline interobserver variability on target definition and delineation and evaluate the effects of a national consensus before the start of a peer-review program for routine clinical practice.

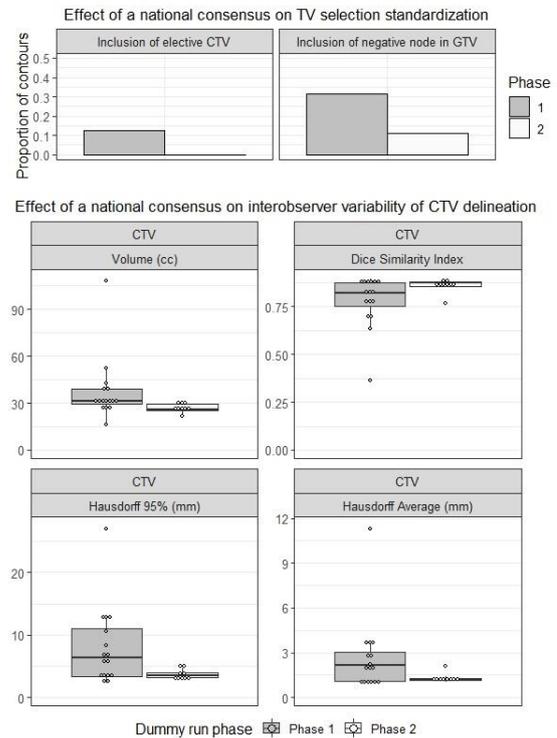

#### Material and Methods

All 25 radiotherapy centers in Belgium and Luxembourg were invited to take part in a delineation dummy-run by sending contours from at least one radiation oncologist (RO) dedicated to lung cancer treatments. The case consisted of a squamous cell carcinoma of the right upper lobe with nodal extension to station 4R staged cT1bN2M0 (TNM 7). The results of chest CT, PET/CT and endoscopic samplings were provided to participants and the planning CT was made available through a secure transfer platform. RO's were asked to delineate and upload back the GTV and CTV for the nodal disease. More than a year later and after the formulation of a national consensus based on current ESTRO guidelines (inclusion of only involved nodes with a 5 mm CTV margin) [Maarten L1] the case was resent to all centers with the same purpose. On all received contours, a description of the TV definition and delineation was obtained through visual inspection. Using an open-source software (3D Slicer with SlicerRT), the DICE Similarity Index and Hausdorff distances were analyzed to compare the delineations. To allow an evaluation of uniformity with these metrics, independent GTV and CTV contours by the first author were used as reference.

#### Results

At the first phase, 16 contours sent by 14 RT centers were analyzed. Important variations were due to the inclusion of a negative node in GTV (n=5) or elective CTV (n=2). The median volumes and interquartile ranges (IQR) were 11.9cc (10.4-14.1) for GTV and 31.2cc (29.3-39) for CTV. A preliminary analysis of the second phase was performed on 9 contours from 9 centers, 4 of which did not participate in phase 1. Median GTV and CTV volumes were 9.3cc (8.2-11.1) and 25.7cc (25.4-29.1) resp. One center included a negative node and none included elective CTV. The reference volumes were 11.4cc for GTV and 27.7cc for CTV. The volume comparisons demonstrated a reduction

in IQR for all metrics ranging from 22% to 90%. Most variations are due to target definition (GTV or CTV). Cropping patterns to other structures is also associated with variability.

	Phase 1 (n=16)		Phase 2 (n=9)		Difference IQR <sup>*</sup> reduction
	Median	IQR <sup>*</sup>	Median	IQR <sup>*</sup>	
<b>GTV</b>					
Volume (cc)	11.9	[10.4 - 14.1]	9.3	[8.2 - 11.1]	22%
DICE Similarity coefficient*	0.84	[0.76 - 0.87]	0.83	[0.79 - 0.87]	27%
Hausdorff Average (mm)*	1.4	[0.9 - 1.9]	1	[0.9 - 1.2]	70%
Hausdorff 95% (mm)*	4.4	[2.9 - 11.3]	3.2	[2.8 - 4.3]	82%
Hausdorff Maximum (mm)*	9.9	[6.2 - 20.3]	6.6	[6.5 - 8.6]	85%
<b>CTV</b>					
Volume(cc)	31.2	[29.3 - 39]	25.7	[25.4 - 29.1]	62%
DICE Similarity coefficient*	0.82	[0.75 - 0.88]	0.87	[0.86 - 0.88]	85%
Hausdorff Average (mm)*	2.1	[1.1 - 3]	1.2	[1.1 - 1.3]	89%
Hausdorff 95% (mm)*	6.3	[3.4 - 11.1]	3.5	[3.2 - 4]	90%
Hausdorff Maximum (mm)*	11.5	[7.4 - 20.3]	7.7	[6.4 - 8.8]	81%

\* Independent contour used as reference to evaluate uniformity.

<sup>\*</sup> Interquartile range (1st and 3rd quartiles)

Table 1: Uniformity of delineations through dummy run phases

#### Conclusion

The preliminary results of this dummy run hint that uniformity in target definition and delineation in NSCLC can reasonably be pursued. Full results will be reported.

### PO-0784 Repeat Stereotactic Body Radiation Therapy for Salvage of Local Failure after Definitive Lung SBRT

W. Kennedy<sup>1</sup>, P. Gabani<sup>1</sup>, J. Nikitas<sup>1</sup>, C. Robinson<sup>1</sup>, J. Bradley<sup>1</sup>, M. Roach<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Radiation Oncology, St. Louis, USA

#### Purpose or Objective

Stereotactic body radiation therapy (SBRT) for early-stage non-small cell lung cancer (NSCLC) provides high rates of local control. However, the optimal management of local failures after SBRT is unknown, and data describing the role of reirradiation with additional courses of SBRT for isolated local recurrences after previous lung SBRT are sparse. The purpose of this study is to investigate the safety and efficacy of repeat lung SBRT as salvage for patients with local failures after previous definitive SBRT for NSCLC.

## Material and Methods

Patients with primary NSCLC treated with salvage SBRT for local recurrence after previous definitive SBRT for early-stage NSCLC were identified using a prospective institutional review board-approved SBRT registry. Both initial and salvage SBRT courses were given in 3 to 5 fractions with a biologically effective dose (BED) of at least 100 Gy. Local failure was defined as either failure in the involved lobe within 1 cm of the initial planning target volume (PTV) or with significant treatment overlap of the  $\geq 25\%$  isodose lines. Lobar failures  $>1$  cm beyond the PTV, without overlap of at least the 25% isodose lines, or with other sites of recurrence were excluded from this study. Kaplan-Meier analysis was used to estimate survival outcomes.

## Results

We identified 21 patients who received salvage SBRT for salvage of local recurrence after initial SBRT for non-metastatic NSCLC treated between 2008 and 2017. Interval from initial to salvage SBRT was a median of 23 months (range, 7 - 52 months). The median age at salvage was 75 years (range, 59 - 89), median Karnofsky performance status was 80 (range, 60 - 100), and median age-adjusted Charlson comorbidity index was 6 (range, 2 - 11). Median tumor diameter was 1.4 cm (range, 1.0 - 2.5 cm). Median follow-up from time of salvage SBRT was 23 months (range, 2 - 59 months). Median survival after salvage SBRT was 24 months (range, 3 - 60 months). After salvage SBRT, two-year primary tumor control was 81%, distant control was 75% and overall survival was 68%. Four patients developed new lung primaries; 3 of these were new NSCLC while 1 patient developed small cell lung cancer. Grade 2 pneumonitis was observed in 2 patients (9%) and grade 2 chest wall toxicity was observed in 3 patients (14%). No grade 3+ toxicity was observed in this cohort.

## Conclusion

Reirradiation with SBRT for salvage of local failures after initial definitive SBRT for early-stage, medically-inoperable NSCLC appears to be a safe treatment modality associated with low rates of treatment-related toxicity and encouraging rates of tumor control observed in our series.

## PO-0785 Clinical significance of treatment related lymphopenia in lung SBRT and a method to ameliorate them

K. Wijesooriya<sup>1</sup>, J. Colen<sup>2</sup>, T. McMullen<sup>2</sup>, S. Liyanage<sup>3</sup>, C. Alonso<sup>1</sup>, K. Romano<sup>1</sup>, S. Peach<sup>1</sup>, P. Read<sup>1</sup>, J. Larner<sup>1</sup>

<sup>1</sup>University of Virginia, Radiation Oncology, Charlottesville, USA ; <sup>2</sup>University of Virginia, Physics, Charlottesville, USA ; <sup>3</sup>Albemarle High School, High School, Charlottesville, USA

## Purpose or Objective

Treatment related lymphopenia (TRL) is a side-effect of radiation therapy. Moderate to severe TRL decreases immunological function, causing suppression of immunoresponse to tumors as well as increased susceptibility to infection. Severity of TRL has been shown to correlate with inferior outcomes for patients in multiple prior studies. Even though SBRT provides over 90% local tumor control for patients with early stage inoperable non-small cell lung cancer (NSCLC), long-term OS at 3 years post SBRT remains suboptimal at 38%. Thus there is opportunity for improvement. This work focusses on TRL due to lung SBRT, and its effects on hospitalizations, and overall survival. This work also describes the first algorithm for predicting TRL for lung SBRT treatments as a potential strategy to minimize TRL.

## Material and Methods

We conducted an Institutional Review Board (IRB) approved retrospective analysis of 92 patients treated with Lung SBRT in the absence of chemotherapy where, RT treatment plans met all dosimetric criteria from RTOG

0915 and 0813. Kaplan-Meier curves, log-rank analysis and cox regression were performed to assess for survival differences associated with severe TRL in SPSS. We have developed a simulation for thorax RT to model circulating blood in treatment planning. In this we considered radiation dose to circulating blood by coupling the time-dependence of the radiation delivery with a blood flow transport model that considers the transient time in the regional structures as well as the mixing of irradiated and non-irradiated blood volumes.

## Results

On average, the patients saw a sharp decrease in absolute lymphocyte counts from 0- 25 days following SBRT to lung. By day 30, the mean ALC was only 58% of baseline. When the post RT lymphocyte count reduction falls in to (0.75 - 1.0)  $\times 10^9$  cells/L category, hospitalization within 5 months of SBRT increased by a factor of two compared to the lower lymphocyte depletion cohorts. Patients with severe TRL (less than  $0.5 \times 10^9$  cells/L) had worse overall survival (log rank,  $\chi^2=7.62$ ,  $p=0.006$ ). On multi-variate cox regression, minimum absolute lymphocyte count was directly related to survival, with a hazard ratio of 0.613 ( $p=0.034$ ). Predictive model results: a) predict the post treatment absolute lymphocyte value to better than 16% across all variables of interest: age, pre-Tx LYA value, post Tx blood draw day, treatment delivery time, tumor volume size, and location of the tumor. b) model has a sensitivity and a specificity to predict a patient having a post RT lymphocyte value of  $<0.8 \times 10^9$  cells/L with an the area under the curve (AUC) of Receiver Operating Characteristic (ROC) of 0.83 .

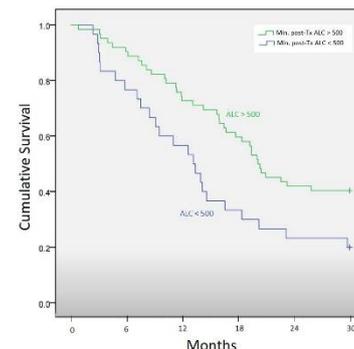

Figure 1 Overall survival up to 30 months post lung SBRT: Kaplan-Meier curve stratified by post lung SBRT absolute lymphocyte count of  $0.5 \times 10^9$  cells/L.

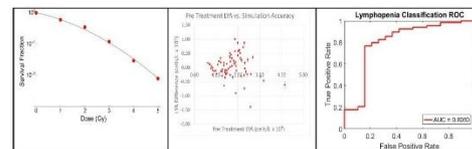

Figure 2: (left): simulation predicted cell survival compared to Nakamura data, (middle): difference of simulation predicted and measured post Tx lymphocyte count, (right): ROC curve for the preliminary simulation to predict post Tx LYA  $<0.8 \times 10^9$  cells/L.

## Conclusion

TRL due to lung SBRT treatments can have a clinically significant impact on overall survival and frequency of hospitalizations due to immune suppression. The predictive algorithm we have developed has an accuracy that could enable treatment plan design and optimization to reduce TRL.

Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

**PO-0786 Hemostasis radiotherapy for inoperable gastric cancer: A prospective study**

O. Tanaka<sup>1</sup>, A. Sugiyama<sup>2</sup>, T. Omatsu<sup>3</sup>, T. Taniguchi<sup>1</sup>, K. Ono<sup>1</sup>, Y. Kunishima<sup>4</sup>, M. Matsuo<sup>5</sup>

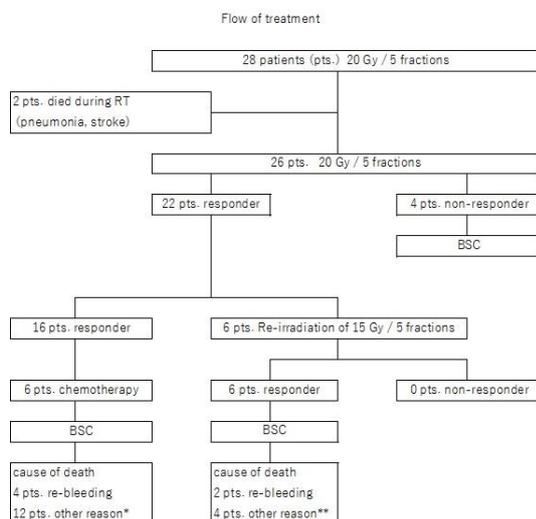

<sup>1</sup>Asahi University Hospital, Department of Radiation Oncology, Gifu, Japan ; <sup>2</sup>Gifu Municipal Hospital, Department of Radiation Oncology, Gifu city, Japan ; <sup>3</sup>Asahi University Hospital, Department of Gastroenterology, Gifu, Japan ; <sup>4</sup>Asahi University Hospital, Division Of Nursing, Gifu, Japan ; <sup>5</sup>Gifu University Hospital, Department of Radiology, Gifu city, Japan

**Purpose or Objective**

Standard treatment for progressive gastric cancer with bleeding includes hemostasis radiotherapy (RT). However, no prospective study of the ideal dosage has been conducted. We thus clarified the utility of RT for gastric cancer at a fixed dose and field.

**Material and Methods**

A total of 28 patients with gastric cancer with bleeding were enrolled in this study. The flow of treatment was shown in Figure 1. The initial RT plan was whole stomach irradiation. Although the examination indicated tumor spread, it was difficult to determine the border between normal tissue and malignancy tissue. We contoured the outer wall of the stomach with an injection of butylscopolamine on an empty stomach. The initial dose was 20 Gy / 5 fractions for full stomach. Hemostasis was achieved when hemoglobin levels in the blood tests stabilized within two weeks of irradiation. If re-bleeding occurred, patients decided whether or not to undergo re-irradiation. The salvage re-irradiation dose was 15 Gy / 5 fractions. Before RT, three or four clips were placed near the gastric tumor by endoscopy. The radiation oncologist contoured the tumor, CTV and PTV under guidance with clips. CTV was not for the whole stomach and only the partial stomach was irradiated. We scored the adverse events (AEs) each day during RT and one week after treatment.

\* reasons (pneumonia, DIC, liver disfunction, hear fairure, renal fairure, unknown)

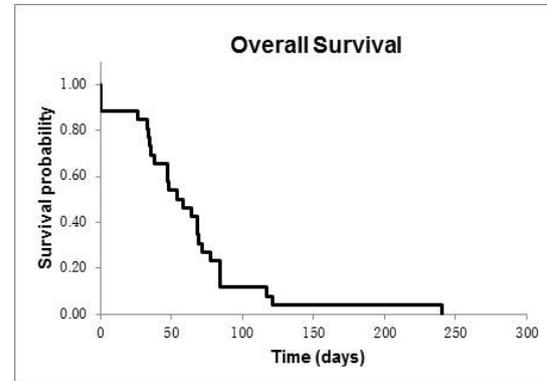

\*\* reasons (pneumonia, liver disfunction, unknown)

BSC: Best Supportive Care

**Results**

Two patients were excluded because they did not complete RT due to stroke and pneumonia. The response ratio of initial RT was 85% (22/26 patients). Six patients underwent re-irradiation, all of which responded (100%).

The median overall survival (OS) was 52 days (Figure 2). The median OS values of the non re-irradiation (one-time) and re-irradiation groups were 54 days and 36 days, respectively, which was not a statistically significant difference. There were no grade three or higher adverse events.

**Conclusion**

Re-irradiation followed by initial RT was effective for reducing adverse events and did not cause adverse events. OS did not differ between the one-time irradiation and re-irradiation groups. No predictive factors were identified. It may be necessary to determinate the ideal dose and fraction number of initial irradiation, which is preferably lower than 20 Gy.

**PO-0787 Adjuvant chemoradiation in resected gallbladder cancer: A prognostic model for overall survival**

C. Solé<sup>1</sup>, L. Vargas<sup>2</sup>, V. Solé<sup>2</sup>, F. Larsen<sup>2</sup>, S. Solé<sup>2</sup>

<sup>1</sup>Instituto de Radiaciones Médicas, Radiotherapy, Santiago, Chile ; <sup>2</sup>Clinica IRAM, Santiago, Chile

**Purpose or Objective**

Patients with gallbladder cancer (GBC) have a dismal prognosis. We investigated outcomes and risk factors for overall survival (OS) in patients treated with radical surgery and adjuvant chemoradiotherapy (CRT).

**Material and Methods**

A total of 212 patients with LAGC ( $\geq$ pT3 59% and/or pN+ 52%) were studied. The primary endpoint of the analysis was OS. We constructed a risk scoring system in which points were assigned to each risk factor by dividing each  $\beta$  coefficient in the final model by the lowest  $\beta$  coefficient and rounding to the nearest integer. A risk score was assigned to each subject by adding up the points for each risk factor present. Subjects were then divided into three risk groups based on their risk scores (0 points=low risk, 1-2 points= intermediate risk, 3-6 points= high risk).

**Results**

Median follow-up was 46.2 months (2-235). Five-year OS for the entire cohort was 53%. In multivariate analysis higher pT stage [HR: 2.43 (1.29-3.68),  $p = 0.01$ ], R1 resection [HR 5.06 (3.12-8.19),  $p < 0.001$ ], and number of surgical procedures [HR 1.41 (1.01-2.16),  $p = 0.05$ ] were associated with an increased risk of death. Five-year OS for patients with low (n=63), intermediate (n=94) and high (n=55) risk was 79.1%, 51.2% and 9.5%, respectively.

**Conclusion**

Overall results after multimodality treatment of GBC are promising. A risk model was generated to determine a prognostic index for individual patients with GBC. Classification of risk factors for death has contributed to propose a prognostic index that could allow us to guide risk-adapted tailored treatment.

**PO-0788 Preliminary analysis of PET/CT imaging on radiation field and relapse rates in esophageal cancer**

E. Jimenez-Jimenez<sup>1</sup>, P. Mateos<sup>2</sup>, N. Aymer<sup>3</sup>, R. Roncero<sup>3</sup>, I. Ortiz<sup>3</sup>, J. Pardo<sup>3</sup>, S. Sabater<sup>1</sup>

<sup>1</sup>Complejo Hospitalario Universitario de Albacete, Radiation Oncology Department, ALBACETE, Spain ;

<sup>2</sup>Clinica IMQ Zorrotaurre, Medical Physics Department, Bilbao, Spain ; <sup>3</sup>Hospital Universitari Son Espases, Radiation Oncology Department, Palma de Mallorca, Spain

#### Purpose or Objective

Our study analyzed the impact of pretreatment PET/CT uptake on pattern of relapse with respect to the volume encompassed by the radiotherapy field among patients with esophageal cancer.

#### Material and Methods

Fifty-six patients with stage II-IIIc esophageal cancer who received definitive or neoadjuvant radio/chemotherapy were analyzed. Patients underwent standard follow-up every 4 to 6 months.

Loco/regional failures were classified as "in-field", "borderline-field" and "out-field". The exact site of the disease recurrence was noted and accurately compared with the volume encompassed by the radiotherapy field.

#### Results

All patients underwent PET/CT scan before treatment. The median of follow-up was 23 months. The first site of relapse was metastatic recurrence and, secondly, local recurrence of primary tumor. The most frequent were "in-field" local (30.4%) and regional (17.9%) recurrence.

We observed a statistically significant relationship between patients classified-N1 by PET/CT and out-field nodal recurrence ( $p = 0.024$ ). In addition, there was a relationship between patients -N2 by PET/CT and in-field nodal recurrence ( $p=0.024$ ). However, no relationship was observed between location of involved nodes by PET or SUVmax values of the metastatic lymph nodes and regional recurrences.

The total number of relapses and location of relapses within the RT field were also analyzed. However, only the number of PET-positive nodes was an independent significant prognostic predictor for relapse (hazard ratio = 4.87,  $p < 0.001$ ).

#### Conclusion

Our results show that only FDG-PET/CT can provide useful information and it could modify radiation treatment. A larger number of enrolled patients with a longer follow-up is needed.

#### PO-0789 Evaluation of Hepatic Toxicity after Repeated Stereotactic Body RT for Hepatocellular Carcinoma

S.M. Yoon<sup>1</sup>, S. Lee<sup>2</sup>, H. Kim<sup>2</sup>, J. Jung<sup>2</sup>, J. Kwak<sup>2</sup>, B. Cho<sup>1</sup>

<sup>1</sup>Asan Medical Center- University of Ulsan College of Medicine, Radiation Oncology, Seoul, Korea Republic of ;

<sup>2</sup>Asan Medical Center, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

This study aimed to evaluate the hepatic toxicity after repeated stereotactic body radiation therapy (SBRT) for recurrent hepatocellular carcinoma (HCC) using deformable image registration (DIR).

#### Material and Methods

Between January 2007 and December 2015, 85 patients who received two sessions of SBRT for HCC treatment were retrospectively analyzed. A DIR technique was used to calculate the cumulative dose of the first and second SBRT to the normal liver by matching the two computed tomography simulation images. The Dice similarity coefficient (DSC) index was calculated to evaluate the DIR accuracy. Radiation-induced liver disease (RILD) was defined as the worsening of the Child-Pugh score by  $\geq 2$  or elevation of transaminases or alkaline phosphatase of at least 5-fold or that of bilirubin of at least 3-fold compared to either the upper normal limit or the pretreatment

levels without an evidence of disease progression within 3 months of completing each SBRT.

#### Results

Median follow-up time was 45 months and median interval time between two SBRT sessions was 15 months (interquartile range [IQR], 7-24). Before the first and second SBRT, 6 (7.1%) and 12 (14.1%) patients were Child-Pugh class B, respectively. Median tumor size was both 1.7 cm before both SBRT treatments. Mean DSC index value was 0.93, being  $>0.9$  in 79 (92.9%) registrations. Median cumulative mean liver dose (MLD) was 9.3 Gy (IQR, 7.6-11.7). RILD was developed in three patients, and two of them, with Child-Pugh class B, experienced irreversible liver function deterioration following the second SBRT. Grade 3 or higher biliary stricture was not observed during the follow-up period.

#### Conclusion

The DIR method provided reliable information regarding cumulative doses to the liver. In patients with Child-Pugh class A liver function, repeated SBRT for small recurrent HCC could be safely performed with acceptable hepatic toxicity. The safety of repeated SBRT at a cumulative MLD around or above 13 Gy in patients with Child-Pugh class B hepatic function needs further evaluation.

#### PO-0790 A nationwide analysis evaluating a role of local treatment including external RT for BCLC C HCCs

C.H. Rim<sup>1</sup>, L. Jeongshim<sup>2</sup>

<sup>1</sup>Korea University Ansan Hospital, Radiation Oncology, Ansan- Danwon-gu, Korea Republic of ; <sup>2</sup>Inha University Hospital, Radiation Oncology, Incheon, Korea Republic of

#### Purpose or Objective

Sorafenib was recommended as a standard treatment for hepatocellular carcinoma (HCC) with Barcelona Clinic of Liver Cancer (BCLC) C. However, local treatment including radiation therapy (LRT) is also widely administered in practice. The aim of our study was to define the role of LRT among BCLC C patients using a nationwide cohort.

#### Material and Methods

From 2008 to 2014, 3401 patients with HCC BCLC C stage were identified from Korea Liver Cancer Study Group cohort. Among them, patients with information on initial therapy were extracted, and classified with 3 initial treatment groups: LRT, sorafenib, and no treatment.

#### Results

1486 HCC patients with BCLC C were inclusive in this study. Of these, 266 were assigned to LRT (17.9%), 316 to sorafenib (21.3%), and 904 to no treatment group (60.8%). Median survival time of the sorafenib group was shorter than that of the LRT group (3.8 vs. 7.6 months,  $p < 0.001$ ). In multivariable analysis, sorafenib group showed significantly higher risk related to mortality compared to RT group, not only among all patients (Hazard ratio [HR] 1.50, 95% confidence interval [CI] 1.23-1.84) but also between subgroups cohorts with portal invasions (1.55, 1.23-1.84), with lymph node metastases (2.42, 1.53-3.83), without distant metastases (1.43, 1.10-1.87) and with distant metastases (1.57, 1.13-2.19). Additionally, no treatment group showed the worst survival among three treatment groups not only in all patients, but also in all subgroup's patients (All  $P_s < 0.001$ ).

#### Conclusion

LRT as an initial treatment showed survival benefit as compared to sorafenib in HCC patients with BCLC C disease.

#### PO-0791 Neoadjuvant treatment potentially improves outcome in resectable pancreatic cancer: meta-analysis

E. Versteijne<sup>1</sup>, J.A. Vogel<sup>2</sup>, M.G. Besselink<sup>2</sup>, O.R. Busch<sup>2</sup>, J.W. Wilmink<sup>3</sup>, J.G. Daams<sup>4</sup>, C.H. Van Eijck<sup>3</sup>, B. Groot Koerkamp<sup>5</sup>, C.R. Rasch<sup>1</sup>, G. Van Tienhoven<sup>1</sup>

<sup>1</sup>Amsterdam UMC, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>Amsterdam UMC, Surgery, Amsterdam,

The Netherlands ; <sup>3</sup>Amsterdam UMC, Medical Oncology, Amsterdam, The Netherlands ; <sup>4</sup>Amsterdam UMC, Medical Library, Amsterdam, The Netherlands ; <sup>5</sup>Erasmus MC, Surgery, Rotterdam, The Netherlands

### Purpose or Objective

Current standard treatment for patients with (borderline) resectable pancreatic cancer is resection followed by adjuvant chemotherapy. Several retrospective studies have suggested a benefit of neoadjuvant treatment, but suffer from selection bias as they only report the outcome of patients who ultimately underwent a resection. Evidence from randomized controlled trials reaching full accrual is lacking and the final results of the Dutch Pancreatic Cancer Group multicenter randomized PREOPANC trial are still awaited. The aim of this meta-analysis is to report survival by intention to treat in a comparison of upfront surgery versus neoadjuvant treatment in (borderline) resectable pancreatic cancer.

### Material and Methods

A systematic review of literature on Medline, EMBASE and the Cochrane Library was performed to identify studies reporting median overall survival (mOS) by intention to treat in patients with (borderline) resectable pancreatic cancer treated with or without neoadjuvant treatment. Two authors screened the articles independently for eligibility. Secondary outcomes included resection rate, reasons for no resection, R0 resection rate, positive lymph node rate and toxicity of the neoadjuvant treatment.

### Results

Overall, 3484 patients with (borderline) resectable pancreatic cancer were included from 38 studies, of whom 1738 (49.9%) received neoadjuvant treatment. The weighted mOS by intention to treat was 18.8 months after neoadjuvant treatment versus 14.8 months after upfront surgery. In the subset analysis among patients that actually underwent resection, the difference was larger (26.1 versus 15.0 months respectively). The overall resection rate was 66.0% with neoadjuvant treatment compared with 81.3% after upfront surgery ( $P < 0.001$ ), but the R0 rate was higher in (86.8 versus 66.9%;  $P < 0.001$ ) with neoadjuvant treatment. Positive lymph nodes were seen in 43.8% after neoadjuvant treatment versus 64.8% in the upfront surgery group ( $P < 0.001$ ). Of the patients who had neoadjuvant treatment, 17.8% did not undergo exploratory surgery, mostly due to progression of disease. Toxicity ( $\geq$ grade III) was reported in up to 64% of the patients receiving neoadjuvant therapy.

### Conclusion

This meta-analysis of neoadjuvant treatment versus upfront surgery by intention to treat suggests improved survival, R0 resection and less lymph node positivity with neoadjuvant treatment in patients with (borderline) resectable pancreatic cancer. The lower resection rate after neoadjuvant treatment suggests that this treatment selects patients who might not benefit from harmful large surgery because of early progression. The final results of the randomized PREOPANC trial are awaited.

**PO-0792 A randomized clinical trial on radiosensitizer effects of LMWH in Chemoradiation of esophageal SCC**  
S.A. Javadinia<sup>1</sup>, A. Taghizadeh Kermani<sup>2</sup>, S. Hosseini<sup>2</sup>, A. Fanipakdel<sup>2</sup>, M. Joudi Mashhad<sup>2</sup>, A. Gholami<sup>2</sup>

<sup>1</sup>Mashhad University of Medical Sciences, Student Research Committee, Mashhad, Iran Islamic Republic of ;

<sup>2</sup>Mashhad University of Medical Sciences, Department of Radiation Oncology- Omid Hospital, Mashhad, Iran Islamic Republic of

### Purpose or Objective

Current treatment approaches for esophageal cancer are associated with a poor survival, and there are ongoing efforts to find new and more effective therapeutic strategies. There are several reports on the anti-tumoral effects of low molecular weight heparin (LMWH). We have

assessed the possible survival benefit of LMWHs in esophageal malignancies.

### Material and Methods

This was a randomized, single blind, multi-center, phase II clinical trial on non-metastatic esophageal cancer candidate for neoadjuvant chemoradiotherapy. Patients were randomly assigned to the chemoradiotherapy-only arm (n=32) or chemoradiotherapy plus enoxaparin arm (n=37) using 1:1 allocation. Radiotherapy was delivered in 1.8-Gy daily fractions to a dose of 50.4 Gy in both groups. Paclitaxel 50 mg/m<sup>2</sup> and carboplatin (AUC2) were administered weekly concurrent with radiotherapy. In the intervention group, patients received enoxaparin (40 mg) daily as well as chemoradiation. Four to six weeks after treatment, all patients underwent esophagectomy.

### Results

Both groups were similar in term of age, gender, ECOG performance score, tumor grade, and location tumor (Table 1).

Table 1. Patient and tumor characteristics per treatment group

Variables	CRT+enoxaparin		CRT alone	P value
	Frequency (%)	Frequency (%)	Frequency (%)	
Age (years) <sup>1</sup>	60-61:	13 (35.1)	8 (25)	p=0.4
	61-:	24 (64.9)	24 (75)	
Gender <sup>2</sup>	Female:	18 (48.7)	13 (40.8)	p=0.8
	Male:	19 (51.3)	17 (53.2)

	R1 res	0 (0)	0 (0)	
	R2 res	0 (0)	0 (0)	

CCR: complete clinical response, SCR: significant clinical response, PCR: poor clinical response, pCR: pathologic complete response, PD: persistent disease, RM: residual mass, res: resection. Classification of clinical response based on CCR vs SCR+PCR. <sup>2</sup>Chi-Square test revealed no significant difference. <sup>3</sup>Fisher's exact test revealed no significant difference.

After a median follow up of 7 months, estimated one year disease free survival in the intervention and control groups was 78.9% and 70% respectively ( $p=0.5$ ). Toxicity from the experimental arm was minimal and there were no treatment-related deaths.

### Conclusion

Overall, the results of this study showed that the clinical and pathological response of squamous cell carcinoma of esophagus to the neoadjuvant chemoradiation was improved by the addition of enoxaparin to the treatment, although the difference was not significant. Also, there was an insignificant improvement in one year disease free survival of chemoradiotherapy patients receiving enoxaparin. Data from our study indicate that concurrent enoxaparin with radiotherapy and weekly paclitaxel/carboplatin chemotherapy was associated with minimal toxicity. The effects of LMWHs on survival of cancer patients, is probably due to a combination of direct anti-tumoral effects, antiangiogenic and immunomodulatory effects, beside indirect effects on the coagulation system. Most of these direct and indirect effects may have clinical efficacy in the treatment of SCC and gastroesophageal adenocarcinoma, although the

current data on this are contradictory and the observed benefits have been mostly from cellular and in-vitro investigations. Considering that treatment with LMWHs has few side effects, it is recommended that efforts to define the mechanisms of this group of these drugs in affecting tumor growth in the cellular level, and also clinical trials on the benefits of the anticoagulant and anti-tumoral effects, should be continued. However, it must be noted that the new generation of LMWHs lack the oligosaccharide segment and thus part of the antitumoral effects of these drugs may be limited.

**PO-0793 Nodal CTV selection according to primary tumor location and pT-stage for biliary tract cancers**

J. Socha<sup>1</sup>, D. Surdyka<sup>2</sup>, L. Kepka<sup>1</sup>  
<sup>1</sup>Military Institute of Medicine, Radiation Oncology, Warsaw, Poland ; <sup>2</sup>Cancer Center of the Lublin Region, Radiation Oncology, Lublin, Poland

**Purpose or Objective**

In adjuvant radiotherapy for biliary tract cancer there are no guidelines on nodal CTV selection in relation to primary tumor location and pT-stage. To assist radiation oncologists in determining the nodal CTV for each subsite of biliary tract, we aimed to formulate such recommendations based on the analysis of incidence and location of metastatic lymph nodes.

**Material and Methods**

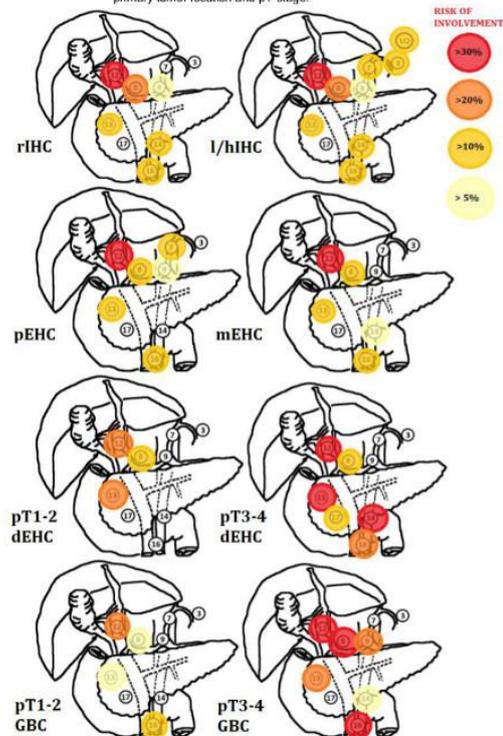

Systematic review was performed, using the “PubMed” and “Google Scholar” databases, to determine the rate of pathological nodal involvement of the respective lymph node stations (LNS) as a function of the primary tumor pT-stage (pT1-2 vs. pT3-4), separately for: right intrahepatic cholangiocarcinoma (rIHC), left/hilar intrahepatic cholangiocarcinoma l/hIHC), proximal extrahepatic cholangiocarcinoma (pEHC), middle extrahepatic cholangiocarcinoma (mEHC), distal extrahepatic cholangiocarcinoma (dEHC) and gall bladder cancer (GBC). A 5% or higher risk of involvement was assumed to justify inclusion of the LNS into CTV.

**Results**

Data on the rate of involvement for each LNS according to the pT-stage was available only for dEHC (6 studies, 522 patients) and GBC (5 studies, 338 patients); rate of involvement for each LNS was available separately for mEHC (5 studies, 132 patients) and pEHC (5 studies, 591 patients) and also separately for rIHC (4 studies, 74 patients) and l/hIHC (4 studies, 156 patients), Table 1. Based on the results, the following LNS should be included into nodal CTV (Figure 1):

1. pT1-2 dEHC: common hepatic artery (CHA), hepatoduodenal ligament (HDL) and posterior pancreaticoduodenal (PPD) LNS;
2. pT3-4 dEHC: CHA, HDL, pPD, superior mesenteric artery (SMA), paraaortic (Ao) and anterior pancreaticoduodenal (aPD) LNS; Celiac artery (CA) LNS risk of involvement in dEHC is below 5%, irrespective of the pT-stage.
3. pT1-2 GBC: CHA, HDL, pPD and Ao LNS;
4. pT3-4 GBC: CHA, HDL, pPD, Ao, CA, and SMA LNS;
5. mEHC: CHA, HDL, pPD, Ao and SMA LNS, risk of involvement for CA LNS is < 5%;
6. pEHC: CHA, HDL, pPD, Ao, CA and left gastric artery (LGA) LNS, risk of involvement for SMA LNS is < 5%;
7. rIHC: CHA, HDL, pPD, Ao, SMA and CA LNS;
8. l/hIHC: as for rIHC + additionally LGA, lesser curvature, and paracardial LNS - risk of involvement for these LNS is > 10%.

Figure 1. Risk of involvement of the respective lymph node stations in relation to primary tumor location and pT-stage.

Lymph node stations classification (according to JSHBPS - Japanese Society of Hepato-Biliary-Pancreatic Surgery):  
 8 - CHA: common hepatic artery, 9 - CA: celiac artery, 12 - HDL: hepatoduodenal ligament, 13 - pPD: posterior pancreaticoduodenal, 14 - SMA: superior mesenteric artery, 16 - Ao: paraaortic, 17 - aPD: anterior pancreaticoduodenal, 7 - LG: left gastric, 3 - LC: lesser curvature, 1/2 - PC: paracardial.  
 rIHC - right intrahepatic cholangiocarcinoma; l/hIHC - left/hilar intrahepatic cholangiocarcinoma; pEHC - proximal extrahepatic cholangiocarcinoma; mEHC - middle extrahepatic cholangiocarcinoma; dEHC - distal extrahepatic cholangiocarcinoma; GBC - gallbladder cancer; pT - pathological tumor stage.

Table 1. Risk of nodal stations involvement according to primary tumor location and pT-stage in biliary tract cancers

Location within	RISK OF LNS INVOLVEMENT													
	8 CHA	12 HDL	9 CA	13 pPD	14 SMA	16 Ao	17 aPD	7 LG	3 LC	1/2 PC	Total LNS+ pts (n)			
rIHC	100	100	100	100	100	100	100	100	100	100	100	100	100	100
l/hIHC	100	100	100	100	100	100	100	100	100	100	100	100	100	100
pEHC	100	100	100	100	100	100	100	100	100	100	100	100	100	100
mEHC	100	100	100	100	100	100	100	100	100	100	100	100	100	100
dEHC	100	100	100	100	100	100	100	100	100	100	100	100	100	100
GBC	100	100	100	100	100	100	100	100	100	100	100	100	100	100

All rates given are the pooled rates (random effect). \* significant heterogeneity; random model used for the proportion analysis  
 LNS - lymph node stations (according to JSHBPS - Japanese Society of Hepato-Biliary-Pancreatic Surgery Classification); 8 - CHA: common hepatic artery; 12 - HDL: hepatoduodenal ligament; 9 - CA: celiac artery; 13 - pPD: posterior pancreaticoduodenal; 14 - SMA: superior mesenteric artery; 16 - Ao: paraaortic; 17 - aPD: anterior pancreaticoduodenal; 7 - LG: left gastric; 3 - LC: lesser curvature; 1/2 - PC: paracardial.  
 rIHC - right intrahepatic cholangiocarcinoma; l/hIHC - left/hilar intrahepatic cholangiocarcinoma; pEHC - proximal extrahepatic cholangiocarcinoma; mEHC - middle extrahepatic cholangiocarcinoma; dEHC - distal extrahepatic cholangiocarcinoma; GBC - gallbladder cancer; pT - pathological tumor stage.

**Conclusion**

This systematic review provides evidence-based strategy for nodal CTV selection in biliary tract cancer according to primary tumor location and pT-stage. CA LNS that is usually included into CTV in clinical practice, has a low risk of involvement and can be omitted for pT1-2 GBC, for dEHC irrespective of pT-stage and for mEHC. Ao and SMA LNS that are usually omitted, have a high risk of involvement. Ao LNS should be routinely included for all the subsites except for pT1-2 dEHC, pT1-2 GBC and pEHC. LGA, lesser curvature, and paracardial LNS should be routinely included for l/hIHC.

**PO-0794 Postoperative Chemoradiotherapy in Gastric Cancer with Poor Response to Neoadjuvant Chemotherapy**

Y. Kundel<sup>1</sup>, B. Brenner<sup>1</sup>, G. Perel<sup>1</sup>, N. Gordon<sup>1</sup>, R. Levin<sup>1</sup>  
<sup>1</sup>Beilinson Hospital, Davidoff cancer center, Petach Tikva, Israel

**Purpose or Objective**

Current standard of care for patients (pts) with locally advanced gastric cancer (LAGC) includes perioperative

chemotherapy (CHT) and surgical resection. According to this approach, all pts receive the same CHT regimen in the neoadjuvant and postoperative setting, regardless of their tumors' pathological response. The CRITICS trial, comparing perioperative CHT with preoperative CHT followed by postoperative chemoradiotherapy (CRT), failed to demonstrate an improved overall survival (OS) with the addition of CRT, but subgroup analysis based on pathologic response to neoadjuvant CHT was not reported yet. The current study aims to evaluate treatment outcomes in pts with poor pathologic response to neoadjuvant CHT, who received postoperative CRT according to our institutional policy.

#### Material and Methods

A retrospective study on pts with LAGC in whom initial treatment strategy was perioperative CHT (ECX, EOX or ECF) and surgery (R0 or R1), but due to poor pathologic response, in their primary tumor and/or regional lymph nodes, to neoadjuvant CHT were treated with postoperative CRT. CRT consisted of 45 Gy in 25 fractions of 1.8 Gy, combined with capecetabine 825 mg/m<sup>2</sup> twice daily on radiotherapy days or continuous infusion of 5FU. Radiation treatment planning was IMRT.

#### Results

Between 2011-2017, 20 pts were treated. Median age was 60 years. Thirteen pts (65%) had proximal gastric tumors, 10 (50%) had diffuse subtype and 13 (65%) had signet ring cell histology. Clinical stages were IIA-III. All pts underwent surgery with D1-D2 lymphadenectomy. R0 resection was achieved in 10 pts (50%). Pathological stage was IIA in 2 pts (10%), IIB in 3 (15%), III in 14 (70%) and IVA in 1 (5%). Eighteen pts (90%) had pT3-T4 tumors and 14 (70%) had N2-N3 disease. Fifteen pts (75%) received also adjuvant chemotherapy before postoperative CRT (same or another regimen as in the neoadjuvant setting). Treatment was well tolerated; it was stopped in only one pt, due to grade 4 vomiting. With a median follow-up time of 32.0 months (range: 12-112 months), recurrences were documented in 11 pts (55%): 5 regional, 4 distant, and 2 combined regional and distant recurrences. Median progression-free survival (PFS) was 20 months (range: 18-21 months) and median OS has not been reached. Estimated 5-year PFS and OS were 42% and 56%, respectively.

#### Conclusion

In our small retrospective study, pts with LAGC assumed to have dismal prognosis due to poor pathologic response to neoadjuvant CHT, achieved a relatively good outcome following the addition of postoperative CRT, compared to reference arms in randomized trials (perioperative CHT arms in MAGIC and CRITICS). These results support the evaluation of an individualized treatment approach, tailored according to pathological response to neoadjuvant CHT, in future studies in this setting. Additional data, on more pts and longer follow-up, will be presented at the meeting.

#### PO-0795 Prediction of severe lymphopenia during chemoradiotherapy for esophageal cancer

P. Van Rossum<sup>1,2</sup>, W. Deng<sup>2</sup>, D. Routman<sup>3</sup>, A. Liu<sup>4</sup>, C. Xu<sup>2</sup>, Y. Shiraishi<sup>2</sup>, M. Peters<sup>1</sup>, K. Merrell<sup>3</sup>, C. Hallemeier<sup>3</sup>, R. Mohan<sup>4</sup>, S. Lin<sup>2</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA; <sup>3</sup>Mayo Clinic, Radiation Oncology, Rochester, USA; <sup>4</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

#### Purpose or Objective

In esophageal cancer patients, occurrence of grade 4 radiation-induced lymphopenia during chemoradiotherapy (CRT) has been associated with worse progression-free survival (PFS) and overall survival (OS). The aim of this study was to develop, internally and externally validate a

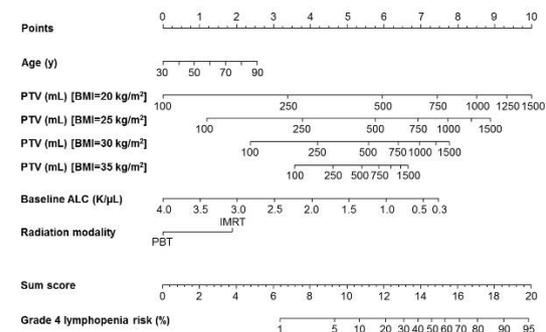

pretreatment clinical nomogram for the prediction of grade 4 lymphopenia to guide individualized treatment decision-making.

#### Material and Methods

Consecutive patients who underwent CRT for esophageal cancer at one center between 2004 and 2017 were identified. Absolute lymphocyte counts (ALCs) were obtained prior to, and weekly during CRT. Grade 4 lymphopenia was defined as ALC nadir <0.2 x10<sup>3</sup>/μL. Potential pretreatment predictors were selected based on literature and clinical reasoning. After multiple imputation, final predictors were selected using multivariable logistic regression with backward stepwise elimination. Internal validation of the final model was performed using bootstrapping. The model was evaluated in terms of calibration and discrimination, corrected for optimism, and presented as nomogram yielding 4 risk groups based on individual nomogram sum scores. External validation was performed by applying the model to an independent cohort of esophageal cancer patients who underwent CRT at another institution between 2015 and 2017. Finally, the relationships between nomogram-based risk groups and PFS and OS were assessed.

#### Results

Among 860 included patients, 322 (37%) experienced grade 4 lymphopenia during CRT. Higher age, larger planning target volume (PTV) in interaction with lower BMI, photon- rather than proton-based therapy, and lower baseline ALC were predictive for grade 4 lymphopenia in the final model yielding a corrected c-statistic of 0.76. The resulting nomogram is presented in Figure 1. External validation of the nomogram in 144 patients from another institution, in whom 58 (40%) had grade 4 lymphopenia, yielded a c-statistic of 0.72. Applying the nomogram sum score (0 to 20), patients were divided into 4 risk groups yielding predicted grade 4 lymphopenia risk rates of 10%, 24%, 43%, and 70%, respectively, which were in good agreement with observed incidences. Risk groups showed statistically significant associations with survival, with 5-year PFS rates of 54%, 50%, 41%, and 40%, respectively, and 5-year OS rates of 55%, 49%, 44%, and 37%, respectively.

#### Conclusion

A pretreatment clinical nomogram for the prediction of grade 4 radiation-induced lymphopenia during CRT for esophageal cancer with a good model performance was developed and validated, both internally and externally. The nomogram allows for prediction of the risk of grade 4 radiation-induced lymphopenia for each individual patient, which in turn is associated with PFS and OS. The nomogram can aid in the selection of patients suitable for mitigating treatment strategies or potential future therapeutic approaches, which may ultimately improve survival.

#### PO-0796 Carbotaxol definitive chemoradiotherapy for inoperable oesophageal cancer: UK multicentre study

R. Owens<sup>1</sup>, C. Cox<sup>2</sup>, S. Gombert<sup>3</sup>, S. Prince<sup>4</sup>, T. Bird<sup>5</sup>, N. Dorey<sup>6</sup>, U. MacGregor<sup>7</sup>, H. Al-Chamali<sup>8</sup>, C. Hurt<sup>2</sup>, S.

Mukherjee<sup>1</sup>

<sup>1</sup>Oxford University Hospital NHS Trust, Oncology, Oxford, United Kingdom ; <sup>2</sup>Cardiff University, Centre for Trials Research, Cardiff, United Kingdom ; <sup>3</sup>Guys and St Thomas Hospital, Oncology, London, United Kingdom ; <sup>4</sup>Univeristy Hospital Southampton, Oncology, Oxford, United Kingdom ; <sup>5</sup>Royal Marsden Hospital, Oncology, London, United Kingdom ; <sup>6</sup>Royal Devon and Exeter Foundation NHS Trust, Oncology, Exeter, United Kingdom ; <sup>7</sup>NHS Highland, Oncology, Inverness, United Kingdom ; <sup>8</sup>Royal Berkshire Hospital, Oncology, Reading, United Kingdom

### Purpose or Objective

The CROSS trial established weekly carboplatin (CP) based CRT as standard of care for pre-operative treatment of oesophageal cancer. Given the promising outcome and low toxicity profile, this regimen is being increasingly used internationally as a component of definitive CRT (dCRT) for inoperable oesophageal cancer, although no large studies demonstrate benefit or equivalence over standard cisplatin fluoropyrimidine (CF) based dCRT. In the UK, a national questionnaire demonstrated that although CF-dCRT remained treatment of choice, CP-dCRT was being offered to elderly patients, less fit patients and in those whom CF-dCRT was contra-indicated. We present the outcomes of CP-dCRT from a UK-wide national audit in this selective patient group.

### Material and Methods

Appropriate UK centres were identified through a national questionnaire. All patients were treated with weekly carboplatin (AUC2) and paclitaxel (50mg/m<sup>2</sup>) dCRT with curative intent between 2011-2018. Patient and tumour demographics, indication for CP-dCRT, toxicity, response rates (as per endoscopy and imaging), recurrence and overall survival were collected.

### Results

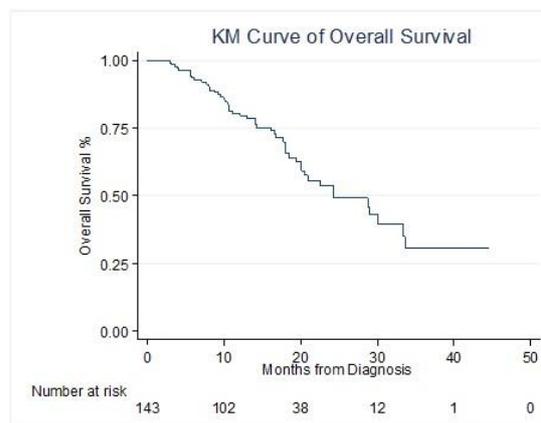

143 patients from 7 centres were included. Patient and tumour demographics are shown in Table 1.

Table 1

		n	%
Sex	Male	85	40.6%
	Female	58	59.4%
Age	Median (IQR, range)	73 ((64,78), 42-91)	
	70+	87	60.8%
	80+	25	17.5%
T stage	1	5	3.5%
	2	31	21.7%
	3	85	59.4%
	4	20	14.0%
	Missing	2	1.4%
N stage	0	59	41.3%
	1	59	41.3%
	2	21	14.7%
	3	4	2.8%
Site	Lower third	74	51.8%
	Middle third	58	40.6%
	Upper third	11	7.7%
Performance status	0	36	25.2%
	1	88	61.5%
	2	19	13.3%
Disease length (cm)	Median (IQR, range)	4.5 ((3.0, 6.1), 1-13)	
Histology	SCC	66	46.2%
	Adeno	77	53.8%

Median age was 73 years (range 42-91; 60.8% >70yrs; 17.5% >80 yrs). Indications for CP-dCRT included co-morbidities (48.3%), clinician choice (32.9%), poor tolerance/progression on induction chemo (18.9%). 43.4% received induction chemotherapy (commonly CF). 71.3% received IMRT, and 75.5% received 50Gy/25 fractions (dose range 41.4/23-64/32#). 96.5% completed RT and 85.3% completed ≥4 weekly infusions of CP. 36% of

patients experienced at least one grade 3+ toxicity (haematological-12%, non-hematological-34%). The most common grade 3 non-haematological toxicities were nausea and vomiting (8%). There were 2 recorded deaths during treatment (oesophageal hemorrhage, duodenal perforation). At the post-treatment response assessment, 91 patients had an endoscopy, 121 had imaging, and 12 patients died prior to this point. 69.2% had complete response (CR) on endoscopy, 86.0% had CR/Partial response (PR)/Stable disease (SD) on imaging and 70.3% had combined CR on endoscopy with CR/PR/SD on imaging. In all patients, median follow-up was 17.2 months (95% CI 14.7-20.5), median OS was 24.3 months (95% CI 20.0-33.5), median overall/local/distant relapse free survival were 16.8 (95% CI 14.2-24.3)/20.3 (95% CI 16.8-28.8)/24.3 (95% CI 16.8-33.1) months respectively, and 31% of patients had relapsed.

Median overall survival: 24.31 months (95% CI: 20.01, 33.45)

Median duration of follow up: 17.22 months (95% CI: 14.65, 20.47)

In patients that had a post-treatment endoscopy (n=91), treatment response (CR on endoscopy with CR/PR/SD on imaging) was associated with superior survival on multivariate cox regression (HR 4.79 (95% CI 1.83-12.55, p=0.001)).

### Conclusion

CP-dCRT is safe and deliverable in elderly and “poor performance” patients who would have otherwise received palliative treatment. The outcomes are comparable to CF based dCRT, and should be considered as the preferred treatment option in this patient group.

### PO-0797 Impact of <sup>99m</sup>Tc-GSA SPECT image-guided inverse planning on DFH parameters for SBRT planning for HCC

R. Toya<sup>1</sup>, T. Saito<sup>1</sup>, Y. Kai<sup>2</sup>, S. Shiraishi<sup>3</sup>, T. Matsuyama<sup>1</sup>, T. Watakabe<sup>1</sup>, F. Sakamoto<sup>3</sup>, N. Tsuda<sup>3</sup>, Y. Shimohigashi<sup>2</sup>, Y. Yamashita<sup>3</sup>, N. Oya<sup>1</sup>

<sup>1</sup>Kumamoto University Hospital, Radiation Oncology, Kumamoto, Japan ; <sup>2</sup>Kumamoto University Hospital, Radiological Technology, Kumamoto, Japan ; <sup>3</sup>Kumamoto University Hospital, Diagnostic Radiology, Kumamoto, Japan

### Purpose or Objective

A radiopharmaceutical tracer, <sup>99m</sup>Tc-labeled diethylene triamine pentaacetate-galactosyl human serum albumin (<sup>99m</sup>Tc-GSA), that binds specifically to the hepatic asialoglycoprotein receptor is used to assess hepatic function. Single-photon emission computed tomography (SPECT) using <sup>99m</sup>Tc-GSA provides three-dimensional information about regional liver function, and its findings suggest that regional function of patients with liver tumors is inhomogeneous because of previous treatments, such as radiofrequency ablation and transarterial

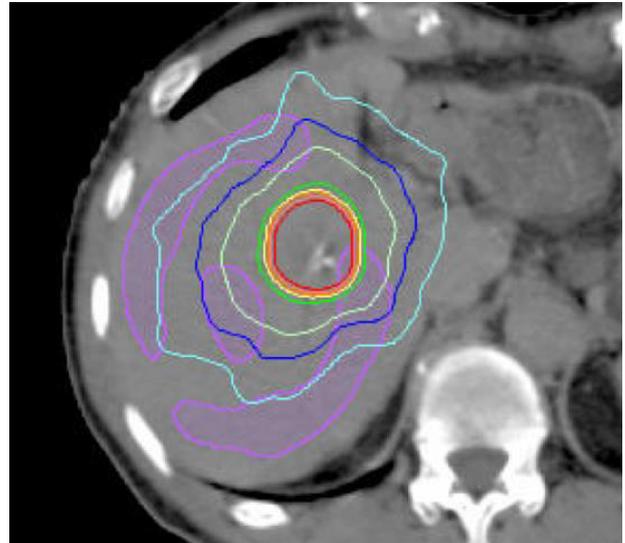

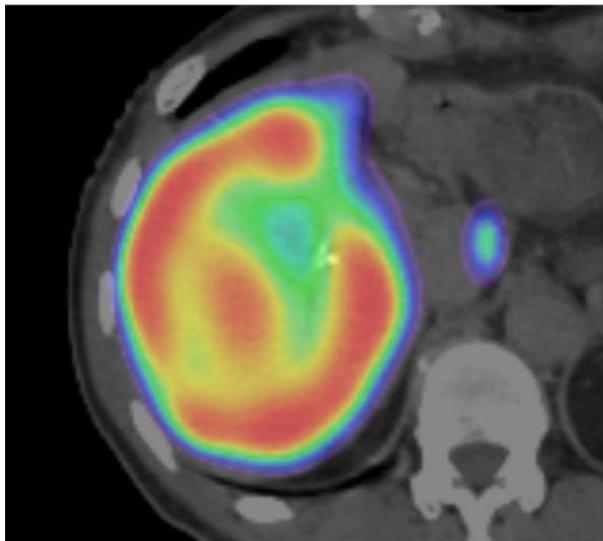

chemoembolization. A recent study revealed that a dose-function histogram (DFH) using  $^{99m}\text{Tc}$ -GSA SPECT provides dosimetric information of the liver function of HCC patients who underwent SBRT. Introduction of functional information of  $^{99m}\text{Tc}$ -GSA SPECT for use in inverse planning for IMRT might be a reasonable approach to spare liver function. We evaluated the impact of  $^{99m}\text{Tc}$ -GSA SPECT image-guided inverse planning on the DFH parameters of SBRT planning in HCC patients.

#### Material and Methods

Eleven patients with HCC were enrolled in this study. We used a SPECT/CT system (Symbia T16; Siemens Healthcare, Erlangen, Germany) for the SPECT/CT imaging. Attenuation-corrected SPECT and CT images and planning CT images were transferred to a Velocity AI (version 3.0.2; Varian Medical Systems, Palo Alto, CA, USA). We registered the SPECT/CT images onto the planning CT images: a rigid image registration followed by a non-rigid deformable registration. The functional liver structure (FLS) as an avoidance structure for optimization was derived from SPECT thresholds of 60%-80% of the maximum pixel value. Two treatment plans optimized without FLS (plan C) and with FLS (plan F) were designed for 50 Gy in 5 fractions to the planning target volume (PTV) by using a 2-arc RapidArc (Clinac iX; Varian Medical Systems, Palo Alto, CA, USA). DFH parameters were calculated as follows:  $F_x = (\text{sum of the counts within the liver volume receiving a dose } >x \text{ Gy} / \text{sum of the counts within the whole liver volume}) \times 100$ . Other parameters for the PTV included the absorbed dose received by 95% of the PTV ( $D_{95}$ ), mean dose, conformity index (CI), and homogeneity index (HI).

#### Results

In comparison with plan C, plan F significantly reduced the DFH parameters of  $F_5$  to  $F_{40}$  ( $p < 0.05$ ), and plan F did not significantly increase  $F_{45}$  and  $F_{50}$ . There were no significant differences in the DVH parameters of  $D_{95}$ , mean dose, CI, and HI for the PTV between plans C and F. There were no significant differences in the parameters of the OARs of the stomach, duodenum, spinal cord, and kidneys between plans C and F. There was no significant difference in the MUs between plans C and F.

#### Conclusion

DFH analyses revealed that  $^{99m}\text{Tc}$ -GSA SPECT image-guided inverse planning provided dosimetric benefits related to sparing of liver function while maintaining coverage of the PTV and may reduce hepatic toxicities.

#### PO-0798 Response assessment to neoadjuvant chemoradiotherapy for esophageal cancer using PET/CT and DW-MRI

<sup>1</sup>UMC Utrecht, Radiation Oncology and Surgical Oncology, Utrecht, The Netherlands ; <sup>2</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>3</sup>UMC Utrecht, Surgical Oncology, Utrecht, The Netherlands ; <sup>4</sup>Holland PTC, Holland Particle Center, Delft, The Netherlands ; <sup>5</sup>The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands ; <sup>6</sup>The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Radiology, Amsterdam, The Netherlands ; <sup>7</sup>The University of Texas MD Anderson Cancer Center, Imaging Physics, Houston, USA ; <sup>8</sup>The University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA

#### Purpose or Objective

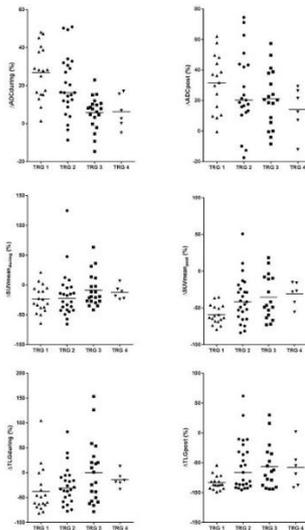

Around one third of the patients have a pathologic complete response (pCR) after neoadjuvant chemoradiotherapy (nCRT) for esophageal cancer. Accurate preoperative identification of this group could omit esophagectomy in these patients. The purpose of this prospective multicenter study was to evaluate the distinct and combined value of  $^{18}\text{F}$ -FDG PET/CT and DW-MRI during and after nCRT to predict pathologic response in esophageal cancer patients.

#### Material and Methods

In this prospective multicenter study, patients scheduled to receive nCRT followed by esophagectomy for resectable esophageal cancer underwent  $^{18}\text{F}$ -FDG PET/CT and DW-MRI scanning prior to start of nCRT, during nCRT and 0-2 weeks before esophagectomy. Response to nCRT was measured using the tumor regression grading system based on histopathological evaluation of the resection specimen (TRG1-4). Relative changes in  $^{18}\text{F}$ -FDG PET/CT ( $\Delta\text{SUV}$  and  $\Delta\text{TLG}$ ) and DW-MRI ( $\Delta\text{ADC}$ ) parameters were compared between patients with a pCR (TRG1) and non-pCR (TRG2-4) groups (Figure 1). Multivariable logistic regression analysis with bootstrapped 95% confidence intervals and

corresponding concordance measurements were calculated to evaluate the complementary value of <sup>18</sup>F-FDG PET/CT and DW-MRI.

Figure 1: Comparison of relative changes in <sup>18</sup>F-FDG PET/CT and DW-MRI imaging parameters during and after neoadjuvant chemoradiotherapy between histopathologic tumor regression grades (TRG). The solid horizontal lines represent group medians.

**Results**

A total of 69 patients with 203 <sup>18</sup>F-FDG PET/CT and 199 DW-MRI scans were eligible for analysis. A pCR was found in 26.1% (18/69). Relative changes in <sup>18</sup>F-FDG PET/CT parameters after nCRT ( $\Delta$ SUV<sub>mean,post</sub> [median, IQR] -63% (-68%, -49%) for pCR versus -42% [-58%, -16%] for non-pCR, p = 0.018 and  $\Delta$ TLG<sub>post</sub> [median, IQR] -86% [-93%, -81%] for pCR versus -65% [-88%, -32%] for non-pCR, p = 0.036), as well as changes in DW-MRI parameters during nCRT ( $\Delta$ ADC<sub>during</sub> [median, IQR] 28% [15%, 39%] for pCR versus 11% [3.7%, 17%] for non-pCR, p = 0.006) were significantly different between pathologic complete responders and non-responders in esophageal cancer (Table 1). A c-statistic of 0.74 for  $\Delta$ SUV<sub>mean,post</sub> alone, of 0.77 for  $\Delta$ ADC<sub>during</sub> alone and of 0.81 for the combination of  $\Delta$ ADC<sub>during</sub> with  $\Delta$ SUV<sub>mean,post</sub> was obtained in classifying patients as pCR and non-pCR.

Table 1. Relative changes in <sup>18</sup>F-FDG PET/CT and DW-MRI parameters between pathologic complete response (TRG 1) and non-pathologic complete response (TRG 2-4).

		Median (IQR)		p-value*	Holm-Bonferroni adjusted p-value	c-statistic
		pCR (TRG 1) (n=18)	non-pCR (TRG 2-4) (n=51)			
During treatment	$\Delta$ SUV <sub>mean,post</sub> (%)	-27 (-38, -8.8)	-19 (-33, -2.5)	0.246	0.492	0.59
	$\Delta$ SUV <sub>max</sub> (%)	-29 (-46, -8.1)	-23 (-35, -2.1)	0.408	0.492	0.57
	$\Delta$ TLG <sub>post</sub> (%)	-54 (-64, -23)	-20 (-50, 9.8)	<b>0.020</b>	0.100	0.69
	$\Delta$ ADC <sub>during</sub> (%)	28 (15, 39)	11 (3.7, 17)	<b>0.001</b>	<b>0.006</b>	0.77
Post treatment	$\Delta$ SUV <sub>mean,post</sub> (%)	-63 (-68, -49)	-42 (-58, -16)	<b>0.003</b>	<b>0.018</b>	0.74
	$\Delta$ SUV <sub>max</sub> (%)	-68 (-78, -58)	-54 (-71, -31)	<b>0.026</b>	0.103	0.68
	$\Delta$ TLG <sub>post</sub> (%)	-86 (-93, -81)	-65 (-88, -32)	<b>0.006</b>	<b>0.036</b>	0.72
	$\Delta$ ADC <sub>during</sub> (%)	34 (13, 46)	20 (10, 38)	0.139	0.417	0.63

\* p-value calculated based on Mann-Whitney U test

ADC apparent diffusion coefficient; c-statistic concordance statistic; IQR interquartile range; pCR pathologic complete response; SD standard deviation; SUV standardized uptake volume; TLG tumor lesion glycolysis; TRG tumor regression grade

**Conclusion**

This prospective multicenter study demonstrates that changes in <sup>18</sup>F-FDG PET/CT parameters after nCRT ( $\Delta$ SUV<sub>mean,post</sub> and  $\Delta$ TLG<sub>post</sub>) and early treatment-induced changes on DW-MRI during nCRT ( $\Delta$ ADC<sub>during</sub>) discriminate between pathologic complete responders from non-

responders in esophageal cancer. Moreover, <sup>18</sup>F-FDG PET/CT and DW-MRI are of complementary value in the assessment of histopathological response.

**PO-0799 Treatment outcomes of nodal positive unresectable thoracic esophageal carcinoma**

T. Huang<sup>1</sup>, S. Li<sup>2</sup>, Y. Chen<sup>2</sup>, H. Lu<sup>3</sup>, C. Lo<sup>3</sup>, F. Fang<sup>1</sup>, S. Chou<sup>1</sup>, Y. Wang<sup>1</sup>

<sup>1</sup>Kaohsiung Chang Gung Memorial Hospital and Chang Gung University School of Medicine, Proton and radiation therapy center, Kaohsiung, Taiwan ; <sup>2</sup>Kaohsiung Chang Gung Memorial Hospital and Chang Gung University School of Medicine, Department of Hematology-Oncology, Kaohsiung, Taiwan ; <sup>3</sup>Kaohsiung Chang Gung Memorial Hospital and Chang Gung University School of Medicine, Department of Thoracic & Cardiovascular Surgery, Kaohsiung, Taiwan

**Purpose or Objective**

The prognosis of unresectable (T4b) thoracic esophageal cancer (EC) is extremely poor and the optimal treatment strategy remains controversial. The present study investigated the treatment outcomes and prognostic factors of nodal positive (N+) T4b thoracic EC patients treated by curative intent concurrent chemoradiotherapy (CCRT).

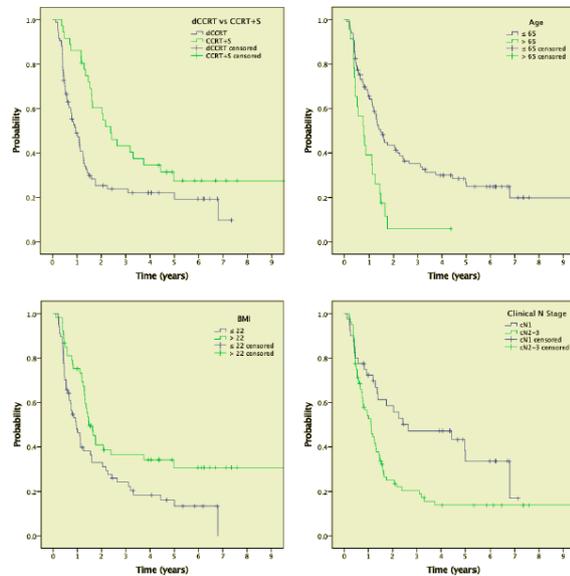

**Material and Methods**

A retrospective review of 1120 EC patients treated at our institution between 2009 and 2017 was conducted. One hundred and twenty T4b N+ thoracic EC patients without distant metastasis who underwent curative CCRT were identified for the following study. Among these patients, 84 patients were treated by definitive CCRT only (dCCRT) while salvage esophagectomy was performed in 36 patients (CCRT+S). All clinical factors were put into analysis. Survival analysis was calculated using Kaplan-Meier method with log-rank test, and prognostic factors were examined by Cox proportional hazards model.

**Results**

The median survival for the entire group of 120 patients was 15.5 months. The 1-year, 3-year, and 5-year overall survival (OS) was 60.2%, 29.5%, and 22.5%, respectively. Multivariable analysis revealed that CCRT+S (p = 0.014), age <= 65 (p = 0.001), Pre-CCRT body mass index (BMI) > 22 (p = 0.001), and clinical N1 (cN1) disease (p = 0.005) were significant independent prognostic factors. Tumor location (upper/middle/lower) and different invasion structures (great vessels, airway, or both) had no significant influence on OS.

Variable	Univariable analysis			Multivariable analysis		
	HR	95% CI	p value	HR	95% CI	p value
<b>Overall Survival</b>						
Surgery (No vs Yes)	1.976	1.236-3.160	0.004*	1.837	1.134-2.977	0.014*
Age (<=65 vs >65)	2.301	1.388-3.815	0.002*	2.504	1.449-4.325	0.001*
BMI (<=22 vs >22)	1.776	1.152-2.736	0.009*	2.166	1.372-3.419	0.001*
Lymph Node (cN2-3 vs cN1)	1.982	1.232-3.191	0.005*	2.018	1.232-3.304	0.005*
<b>Tumor Invasion</b>						
(Great Vessels/Airway/Both)				N.S.		
<b>Tumor Location</b>						
(Upper/Middle/Lower)				N.S.		

### Conclusion

Our study revealed that long-term survival is still achievable for patients with cT4b N+ EC. Patients with younger age, higher BMI, and cN1 disease tended to have better OS while salvage esophagectomy may further improve the outcomes.

### PO-0800 Radiation dose escalation in pancreatic cancer: a propensity-score matching study

X. Zhu<sup>1</sup>, C. Yangsen<sup>1</sup>, Z. Xianzhi<sup>1</sup>, S. Yuxin<sup>1</sup>, J. Xiaoping<sup>1</sup>, Q. Shuiwang<sup>1</sup>, C. Fei<sup>1</sup>, J. Zhen<sup>1</sup>, F. Fang<sup>1</sup>, G. Lei<sup>1</sup>, Z. Huojun<sup>1</sup>

<sup>1</sup>Changhai Hospital, Radiation Oncology, Shanghai, China

### Purpose or Objective

For patients with locally advanced pancreatic cancer, standard therapy consists of different combinations of chemotherapy and radiotherapy. Additionally, chemoradiotherapy may be the alternative option for those with resectable or borderline resectable but medically inoperable pancreatic cancer though there was no consensus about the optimal therapy. However, fewer studies have evaluated the association of radiation dose and survival or local control. Therefore, the aim of the study was to investigate the role of dose escalation in non-operable pancreatic cancer.

### Material and Methods

Consecutive patients with resectable or borderline resectable but medically inoperable due to comorbidities and locally advanced pancreatic cancer receiving SBRT and chemotherapy were included. Patient demographic and treatment information were stratified by a BED<sub>10</sub> of 60 to 70Gy versus a BED<sub>10</sub> >70Gy. Factors predictive of overall survival (OS), progression free survival (PFS) and local control (LC) were identified by multivariate analysis. OS, PFS and LC were further compared using propensity score matching.

### Results

Four hundred and thirty-three patients were included; 330 received 60 to 70Gy and 107 received doses >70Gy. Univariate analysis showed that tumor stage and CA19-9 response correlated with OS and PFS, while tumor stage, CA19-9 response and ECOG was associated with LC. After multivariate analysis, both tumor stage and CA19-9 response were predictive of OS, PFS and LC (P<0.001 for all analyses). Therefore, these two factors were used to develop matched cohorts. One hundred and seven patients in each group were included after propensity-score matching. Patients with a BED<sub>10</sub> >70Gy had a superior OS, PFS and LC compared with those with a BED<sub>10</sub> of 60 to 70Gy (OS: 13.7 months vs. 17.6 months, P<0.001; PFS: 9.4

months vs. 13.8 months, P<0.001; LC: 10.5 months vs. 15.0 months, P<0.001).

### Conclusion

BED escalation >70Gy may provide survival benefits and better local control in patients with pancreatic cancer but require further validation in prospective studies.

### PO-0801 Esophageal Cancer: One Organ, Two Histologies, One Treatment Strategy: Why?

<sup>1</sup>C.H.U. - Sart Tilman, Department of Radiotherapy, Liège, Belgium ; <sup>2</sup>Institut Jules Bordet, Department of Radiotherapy, Brussels, Belgium ; <sup>3</sup>C.H.U. - Sart Tilman, Department of Medical Oncology, Liège, Belgium ; <sup>4</sup>C.H.U. - Sart Tilman, Department of Gastroenterology and Digestive Oncology, Liège, Belgium

### Purpose or Objective

Neoadjuvant radiochemotherapy (NRTC) is recommended for Adenocarcinoma (ADK) and Squamous Cell Carcinoma (SCC) of the esophagus for patients with good performance status and tumor located in the lower third of the esophagus. While often treated as a sole and unique entity, esophageal cancer could be viewed as two different pathologies based on tumor histology, pathogenicity and patient related co-morbidities. The aim of this study was to assess the Overall Survival (OS), median OS (mOS), Local and Distant Recurrences (LR/DR) in regard of tumor histology.

### Material and Methods

We retrospectively reviewed a cohort of patients with histological proven SCC or ADK esophageal cancer who received either definitive RTC or NRTC from 01/01/08 to 10/15/16. For definitive RTC patients received 50,4Gy in 28 fractions concomitantly with Cisplatin and 5FU or Carboplatin and Taxol. For NRTC they received 45Gy in 25 fractions with Carboplatin and Taxol. Patients who were not electable for NRTC due to co-morbidities, tumor stage or tumor location were treated by RCT and salvage surgery.

### Results

We identified 112 patients, 74 SCC and 38 ADK. NRTC was administrated to 9 SCC and 24 ADK, all the others received RTC. With a median follow up of 40 months, the 3 and 5y OS and mOS for all the cohort are for RTC 33%, 25,4% and 21,1 mo and for NRTC 38,5% 38,5% and 24,3mo, respectively (p=ns). Among 74 SCC (Ratio M/F=2), 85,1% were former smokers and 64% were still active and 71,6% had alcoholic habits at diagnosis. The 3 and 5y OS for RTC are 38% and 32% with 21,8mo mOS. For NRTC the 3y OS is 22,4% and 22,4mo mOS. Recurrences occurred in 40 % patients (LR alone 11%, LR and DR 5%, DR 24%). Most recurrences occurred (74%) during the first year after treatment and 70% of those patients died within the year of the relapse. Among 38 ADK (Ratio M/F=8,5), 65,8% were former and 47,4% were still active smokers and 26,3 % had alcoholic habits at diagnosis. Most of the patients (63%) were treated with NRCT. Recurrences occurred in 50 % patients (LR alone 5%, LR and DR 5%, DR alone 39%) and 58% of these relapses occurred within the first year. The mOS of RTC was 8,25 months without any survivors at 3 years. NRCT approach showed a mOS of 24,3 mo and 3 years OS of 40 %. Due to limited number of patients the 5 years OS is not reliable. More details are featured in Table

### Conclusion

Both in ADK and SCC we achieved a good local control (>85%). There was no significant differences in OS between treatments. We showed that ADK were mostly treated with NRTC and SCC with RTC illustrating the difficulties of NRTC on SCC. Worth noticing, the OS of SCC treated with RTC demonstrated an OS as good as surgical series despite the advanced tumor stage of those patients (> 50% stage III) and tobacco / alcohol related comorbidities. These results, good tumor local controlled and OS for locally advanced tumors questioned the place of surgery as a standard of treatment for SCC.

### PO-0802 Lung dose was associated with severe lymphopenia in esophageal cancer undergoing trimodality therapy

J. Lin<sup>1</sup>, J. Lee<sup>2</sup>, C. Cheng<sup>3</sup>, T. Chang<sup>4</sup>, Y. Chen<sup>2</sup>  
<sup>1</sup>Changhua Christian Hospital, Radiation Oncology, Changhua, Taiwan ; <sup>2</sup>MacKay Memorial Hospital, Department of Radiation Oncology, Taipei, Taiwan ; <sup>3</sup>Changhua Christian Hospital, Department of Thoracic Surgery, Changhua, Taiwan ; <sup>4</sup>Changhua Christian Hospital, Department of Radiation Oncology, Changhua, Taiwan

### Purpose or Objective

Previous studies had reported lymphopenia was associated with poorer outcomes in esophageal cancer. The lung was reservoir of hematological stem cell. Radiotherapy and chemotherapy might destroy the hematological stem cells in the lung and could contribute to lymphopenia. This

study aimed to identify whether lung dosimetric parameters were predictive for severe lymphopenia in esophageal cancer patients.

### Material and Methods

A total 117 patients with esophageal cancer underwent neoadjuvant chemoradiotherapy followed by surgery during 2010 and 2015 in two academic centers were analyzed. With majority male gender, current smoker, squamous cell carcinoma histology, and clinical stage III disease, all patient underwent neoadjuvant therapy consisted of 2-3 course of cisplatin and 5-fluorouracil concurrent with radiotherapy (median dose 44 Gy). Patients with severe lymphopenia, defined as absolute lymphocyte count  $\leq 500$  during neoadjuvant therapy were compared to those without this toxicity. The logistic regression was used to identify predictive treatment-related and dosimetric factors for severe lymphopenia. Factors with a  $p$  value  $<0.05$  were considered significant. Further receiver-operating characteristic (ROC) curve was performed for these dosimetric parameters to obtain best cutoff values.

### Results

The mean heart dose of all patients was 18.06 Gy [standard deviation (SD): 6.67Gy]. The mean lung volume receiving 5 Gy or more (V5), lung V10, and lung V20 was 72.8% (SD: 21.1%), 52.2% (SD:17.8%), 20.3% (SD:6.5%), respectively. Lung V5 (odds ratio [OR]: 1.03, 95% confident interval [CI]: 1.00-1.06,  $p = 0.04$ ) and ECOG performance status (0 vs. 1, OR: 3.30, 95% CI: 1.15-9.44,  $p = 0.03$ ) were associated with severe lymphopenia when adjusting for pre-treatment feeding jejunostomy, cisplatin intensity, gross tumour volume, gross tumour dose, and lung V10. The ROC curve analysis generated best cutoff value of lung V5 of 75% (the area under the curve: 0.75,  $p < 0.001$ ). High probability of severe lymphopenia in patients with lung V5  $\geq 75\%$  compared to those with lung V5  $< 75\%$  (55.74% vs. 16.07%,  $p < 0.001$ ).

### Conclusion

Higher lung V5 was associated with severe lymphocyte declined in esophageal cancer patients underwent neoadjuvant chemoradiotherapy followed by surgery. Constraints for low dose lung volume may avoid severe lymphopenia in these patients.

### PO-0803 Endoluminal brachytherapy with induction chemotherapy and definitive chemoradiation in Ca. Esophagus

S. Raghunath<sup>1</sup>, R. Tiwari<sup>1</sup>, G. Narayanan<sup>1</sup>, B. Vishwanathan<sup>1</sup>, R. Sultana<sup>1</sup>  
<sup>1</sup>Vydehi Institute of Medical Sciences and Research Center, Radiation Oncology, Bangalore, India

### Purpose or Objective

#### Need for the Study:

Over 75% of people with cancer worldwide have no access to safe surgery. Access is worse in low income countries where 95% of people with cancer do not receive basic cancer surgery.

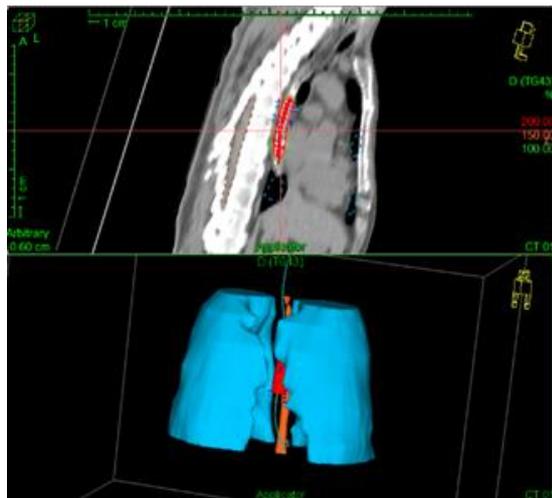

Patients in remote areas in Rural India, South Asia, Africa and Poorer EU Member States do not have access to surgical infrastructure or qualified personnel to deliver high quality surgery in locally advanced esophageal carcinoma. Further, Esophageal Cancer has an abysmal response despite multimodality treatment. Endoluminal Brachytherapy is an under-utilized modality in the curative setting and an elegant tool to escalate the dose to improve the clinical response and clinical symptoms.

This study examines if Dose Escalation with Endoluminal Brachytherapy after Induction Chemotherapy and Definitive Chemoradiation is feasible in the background of the above scenarios in underserved populations.

#### Objective:

To evaluate Dysphagia Free Interval (DFI), Disease Free Survival (DFS), Overall Survival (OS) and Toxicity Profile in

### Endoluminal Brachytherapy in Ca. Esophagus with Induction Chemotherapy and Definitive Chemoradiation. Material and Methods

31 patients with biopsy proven Esophageal Carcinoma Stage IIA-IVA with Node (-) Status were enrolled at our Institute from June 2007 to July 2018. ILRT 10Gy/2# was delivered following Definitive CTRT 50.4Gy/28# with 3-weekly CDDP/5-FU after 6-10 cycles of Paclitaxel/Carboplatin.

Proximal and Distal borders were marked from the Prechemotherapy tumor volume on OGD. Patients were simulated in a GE Multislice CT scanner to confirm accurate coverage of the pre-chemotherapy disease.

Positions were marked and secured on the Ryles Tube to prevent any shift in placement before and during treatment.

ILRT Dose was prescribed to 1 cm from the center of the source.

Swallowing Status was established on follow up. OS and DFS was censored at death or last follow up. Statistical Analysis was performed using SPSS.

#### Results

Patient Characteristics	
Total No. of Patients	31
Median Age of Recruitment	62.5 years
Distribution by Sex	
Male	20
Female	11
Distribution by Stage	
T2N0M0	3.22%
T3N0M0	87.09%
T4N0M0	9.6%
Histology	
Squamous Cell Carcinoma	87.09%
Adenocarcinoma	12.91%

- Median Age of Recruitment was 62.5 years. All 31 Patients completed treatment and were clinically stable at discharge. 83.97% Completed Chemotherapy, 96.77% completed Radiation Therapy according to protocol. 35.48% patients were alive on last follow up.
- Median OS was 21 months. OS at 2 years was 53.6%. Median DFI was 10.7 months. Those with a Cumulative EQD2 >60 Gy had a significant 5 year OS of 59.1% vs. 33.3% for those who received EQD2 <60 Gy (p=0.061, CI=76.3-91.4). 5 year DFS for EQD2 >60 Gy was 56.1% vs. 16.7% for those who received Cumulative EQD2 <60Gy (p=0.079, CI=74.2-93.8).
- There were no Grade III/IV acute toxicities. There were no Fistulas on follow up. 2 patients required stenting within 1 year of treatment and died within 2 months thereafter. 2 Patients developed CHF at 4 years. 1 Patient Developed Left Breast Fibrosis at 4.5 years.

#### Conclusion

Endoluminal Brachytherapy with Induction Chemotherapy and Definitive Chemoradiation is a feasible option in the absence of conventional alternatives.

#### PO-0804 Re-irradiation with SBRT for In-field Recurrence of Pancreatic Cancer After Prior SBRT

Y. Shen<sup>1</sup>, X. Zhu<sup>1</sup>, X. Ju<sup>1</sup>, Y. Cao<sup>1</sup>, S. Qing<sup>1</sup>, F. Cao<sup>1</sup>, H. Zhang<sup>1</sup>

<sup>1</sup>Changhai Hospital Affiliated to Second Military Medical University, Department of Radiation Oncology, Shanghai, China

#### Purpose or Objective

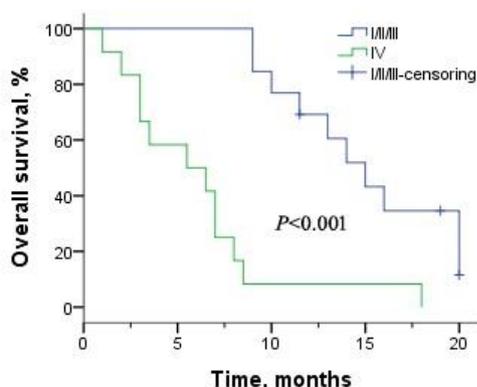

Stereotactic body radiation therapy (SBRT) is a promising alternative for pancreatic cancer with an excellent local control and acceptable toxicity. However, the safety and efficacy of SBRT for in-field recurrence after the initial SBRT remains unknown. Therefore, the aim of the study was to investigate the feasibility of re-irradiation with SBRT for local recurrent pancreatic cancer after the first SBRT.

#### Material and Methods

Twenty-six consecutive patients with pancreatic cancer received re-irradiation with SBRT after prior SBRT in our center between November 2013 and December 2016. One patient was lost to follow-up. Thirteen and twelve patients had limited disease (M0) and distant metastasis (M1) at the time of re-irradiation. Outcomes, including survival, disease control and toxicity, after treatment were evaluated in details.

#### Results

The median time between the first and second SBRT was 12.5 months (range, 6-29 months). The median prescription dose of the initial SBRT was 36Gy (range, 32-45Gy in 5-8 fractions), and of the re-irradiation with SBRT was 32Gy (range, 25-40 Gy in 5-8 fractions). The median OS of patients with M0 was 15 months (range, 9-20 months) from re-irradiation and 25 months (range, 12-42 months) from the first SBRT. Six months after re-irradiation, the percentage of disease control rate (DCR) was 77.3%. Whether patients received chemotherapy or not, CA19-9 levels declined dramatically after re-irradiation (P=0.002, 0.018). Thirteen of 18 patients (72.2%) had pain relief after re-irradiation. No Grade 4 or 5 toxicity was found during the whole treatment. One patient (4.2%) experienced late Grade 3 upper gastrointestinal hemorrhage.

### Conclusion

Re-irradiation with SBRT can provide effective analgesia and disease control with tolerable toxicity after prior SBRT for in-field recurrence, which is feasible for local relapsed pancreatic cancer. But it should be employed in highly selected patients with distant metastasis.

### PO-0805 Analysis of esophageal cancer patients treated with neoadjuvant therapy who never made it to surgery

<sup>1</sup>KU Leuven - University of Leuven, Department of Oncology - Laboratory Experimental Radiotherapy, B-3000 Leuven, Belgium ; <sup>2</sup>UZ Leuven - University Hospitals Leuven, Department of Radiation Oncology, B-3000 Leuven, Belgium ; <sup>3</sup>KU Leuven - University of Leuven, Department of Chrometa, B-3000 Leuven, Belgium ; <sup>4</sup>UZ Leuven - University Hospitals Leuven, Department of Thoracic Surgery, B-3000 Leuven, Belgium ; <sup>5</sup>UZA - University Hospital Antwerp, Department of Oncology, B-2000 Antwerp, Belgium

### Purpose or Objective

Neoadjuvant treatment (NT) followed by esophagectomy is standard practice in patients with locally advanced resectable esophageal cancer (EC). However, not all patients who start NT will undergo esophageal resection. The aim of this study was to evaluate the group of patients, scheduled for NT followed by esophagectomy, who never made it to surgery.

### Material and Methods

We performed a retrospective institutional analysis of patients treated for locally advanced EC with NT (2002-2015), who did not undergo esophagectomy. Tumor (histology, cTNM, tumor location), patient (age, gender) and treatment related (NT regimen) characteristics were collected. The reason for cancellation of surgery and the proportion of patients with a clinical complete response (cCR) were reviewed. Subanalysis was performed according to the time period (2002-2010 vs 2011-2015) and histology (adenocarcinoma (AC) vs squamous cell carcinoma (SCC)). Median overall survival (OS) was calculated for the entire patient cohort and according to the two time frames and histology.

### Results

In 116 of 681 patients (17.0%), surgery was not performed after NT. NT treatment included chemoradiotherapy in 95 (81.9%) and chemotherapy alone in 21 (18.1%) patients. The median age of the patients not undergoing surgery was 66 years (IQR 60-70). The predominant clinical tumor stage was cT3 (75.9%) and most patients were clinically node positive (89.7%). A cCR was obtained in 23 patients (19.8%). Reasons for cancellation of surgery were disease progression in 50 (43.1%), poor general condition in 26

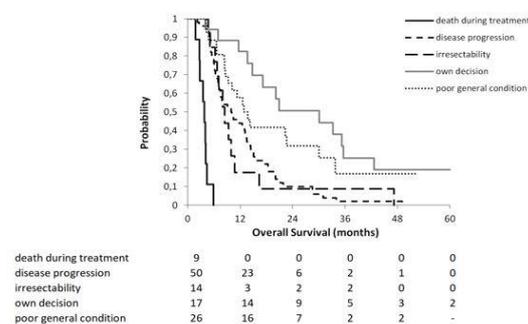

(22.4%), irresectability in 14 (12.1%), patients' own decision in 17 (14.7%); 10 of them had a cCR) and death during NT in 9 (7.8%) patients (Table 1). Patients refusing surgery had an improved median OS compared to those in whom esophagectomy was cancelled for other reasons (30.1 vs 13.8 months;  $p < 0.0001$ ) (Figure 1). In the second time period, irresectability decreased (17.4% vs 5.7%;  $p = 0.0279$ ). Median OS was not different over time (9.2 vs 12.6 months;  $p = 0.897$ ). Irresectability ( $p = 0.031$ ), patients' refusal ( $p = 0.015$ ) and poor general condition ( $p < 0.001$ ) were more frequent as reasons for cancellation in SCC patients. Median OS was 12.9 and 9.9 months for patients with an AC and a SCC ( $p = 0.485$ ), respectively. Median OS of patients in the surgery and non-surgery group was 36.5 and 10.8 months ( $p < 0.0001$ ).

Table 1: Reasons for cancellation of esophagectomy according to time period and histology.

AC = adenocarcinoma; SCC = squamous cell carcinoma

Reasons	2002-2010		2011-2015		Total (% of patient cohort without surgery)	Total (% of entire patient cohort)
	AC	SCC	AC	SCC		
Death during neoadjuvant treatment	0	4	4	1	9/116 (7.8)	9/681 (1.3)
Disease progression	14	13	15	8	50/116 (43.1)	50/681 (7.3)
Irresectability	3	8	2	1	14/116 (12.1)	14/681 (2.1)
Own decision	4	6	2	5	17/116 (14.7)	17/681 (2.5)
Poor general condition	3	8	6	9	26/116 (22.4)	26/681 (3.8)
<b>Total number of patients without surgery</b>	<b>24</b>	<b>39</b>	<b>29</b>	<b>24</b>	<b>116</b>	
<b>Total number of patients without surgery/with surgery</b>	<b>63/337 (18.7)</b>		<b>53/344 (15.4)</b>			<b>116/681 (17.0)</b>

Figure 1: Overall survival in the cohort of patients with cancelled esophagectomy

### Conclusion

One in six patients starting NT for EC never made it to surgery. Over time, irresectability as reason decreased. As a result, medical reasons became more important, indicating the paramount importance for upfront testing of medical operability. Cancellation of surgery was significantly more common in SCC patients. Reasons were medical inoperability and patients' own decision, besides a higher number of irresectable tumors. Patients who refused esophagectomy, often because of cCR, had a significant survival benefit compared to those who did not undergo esophagectomy because of other reasons.

### PO-0806 Impact of Hospital Volume and Trimodality in Survival Outcomes for Esophageal Cancer

M. Bringel oliveira duarte<sup>1</sup>, J. Barreto Campello Carvalheira<sup>2</sup>, E. Baldon Pereira<sup>1</sup>

<sup>1</sup>Hospital de Clinicas - Universidade Estadual de Campinas, Radiation Oncology, Campinas, Brazil ;

<sup>2</sup>Hospital de Clinicas - Universidade Estadual de Campinas, Clinical Oncology, Campinas, Brazil

### Purpose or Objective

Hospitals with a low volume of surgeries for esophageal cancer usually present a proportionally higher rate of complications for this procedure. However, it is unclear whether limited access to hospitals with a high volume of surgeries could influence the therapeutic plan for locally advanced esophageal squamous cell carcinoma (ESCC) in underdeveloped countries. Thus, in this population-based study, we assessed the influence of the number of treated

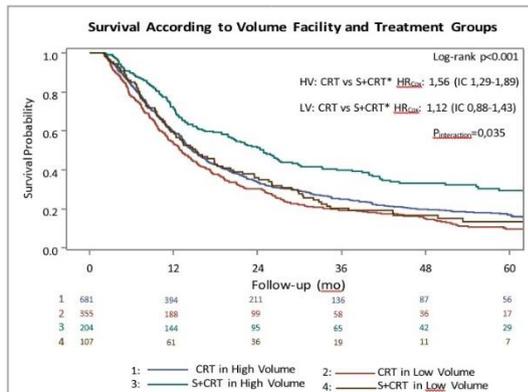

patients per hospital in the survival of patients with locally advanced ESCC submitted to chemoradiotherapy plus surgery (S+RCT) or definitive chemoradiotherapy (RCT).

#### Material and Methods

We used the Fundação Oncocentro de São Paulo (FOSP) database to identify 18 years old or older patients who received a diagnosis of stage II, or III (non-T4) ESCC between 2000 and 2013 (1347 patients and 64 hospitals). Treatments initiated 365 days after diagnosis, without T and N definition and with early mortality (until 60 days of diagnosis) were excluded. Descriptive variables were first accessed with chi-square test after categorizing hospitals as high (HH) or low volume (LH), 100 surgeries per year was used to divide the groups. Overall survival (OS) was compared with a log-rank test and with a Cox proportional hazards method, adjusting for all variables, then we tested the possible interaction between treatment type and volume facility.

#### Results

66% of patients were treated in HH hospitals, and 23% were treated with S+RCT without significative difference between facility's surgery volume and treatment performed ( $p=0,96$ ). There were more stage III ESCC treated in LH (46,1 vs 34,3%  $p<0,01$ ), more treatment initiated after 60 days of diagnosis in HH (61,0 vs 38,3%  $p<0,01$ ) and no significative age difference in volume facilities groups ( $p=0,48$ ). Median OS in months was 14,7 in HH/CRT, 24,9 in HH/S+RCT, 13,1 in LH/CRT and 15,1 in LH/S+RCT with positive association in log-rank test ( $P_{rank}<0,001$ ).

CRT: Chemoradiotherapy; HV: High Volume Hospital; LV: Low Volume Hospital; IC: Interval Confidence (accounting  $\alpha=0,05$ ); Log-rank test accounted treatment and facilities modalities; Cox Regression accounted for all variables, a Wald test was used for interaction.

In Cox analysis, female sex (HR 0,76  $p<0,01$ ) and treatment in HH (HR 0,82  $p<0,01$ ) were associated with better overall survival. Patients treated with RCT had worst OS (HR 1,38  $p<0,001$ ). After performing sensitivity analysis for treatment type and facility's surgery volume, we note a significative worst OS in those treated with CRT in HH (HR: 1,56; IC: 1,28-1,89) and no difference in that treated with CRT in LH (HR: 1,23; IC: 0,88-1,43), ( $P_{interaction}=0,035$ ).

#### Purpose or Objective

Patients with localised esophageal and gastroesophageal junction (GEJ) cancer are offered definite chemoradiotherapy if considered non-resectable or medically inoperable. Despite treatment with curative intent a median survival of less than 20 months and a 5-year survival of 15-25% were found in clinical trials. Survival is affected by several factors, including lack of locoregional control with failures located in the treated target volumes.

A national randomized phase II study to investigate FDG-guided dose escalation in order to improve locoregional control and survival in this patient cohort is planned. Prior to final design of the randomized study, all centres participated in a delineation workshop and a treatment planning study; data from these are presented here.

#### Material and Methods

In the delineation workshop 5 patients were delineated by participants from all enrolment centres. For the treatment planning study, a common delineation was used. A homogenous dose of 50 Gy/25 fractions (fx) prescribed to the PTV is planned as the standard arm. In the experimental arm, the dose is escalated heterogeneously to the FDG-PET avid tumour volume (defined as 50% of SUV<sub>peak</sub>), with mean dose up to 63 Gy/25 fx for the most PET avid volumes of the primary tumour, and 60 Gy/25 fx for all malignant lymph nodes. The escalation dose is limited in favour of OAR constraints. A standard and an experimental treatment plan will be optimized for each patient prior to randomization. Mean dose to lungs and heart in the experimental plan must be kept within  $\pm 1$ Gy corresponding doses in the standard plan.

#### Results

Data from the target delineation workshop is presented in Table 1. Consistency of the delineated GTV-T, GTV-N and CTV volumes were acceptable. The two patients with the smallest target volumes had the largest relative range.

In the treatment planning study, the dose escalated FDG-PET avid part of tumour (PET<sub>GTV-T</sub>) constituted in median 45% (range 32% - 57%) of the GTV-T and received an average mean dose of 62.3 Gy. This resulted in an average mean dose to the GTV-T of 59.9 Gy. For the GTV-N, the average mean dose was 59.6 Gy. The combined clinical target volume (CTV-total) received an average mean dose of 55.3 Gy. Normal tissue doses were similar for the experimental and standard plan, with a difference in mean lung dose and mean heart dose in the two arms of 0.1 Gy and 0.2 Gy, respectively. The maximum dose for the standard plans was 55 Gy (110%). Higher doses up to 67 Gy were applied for the experimental plans, but only to small volumes respecting the strict normal tissue constraints (see figure)

Table 1: Median and range of target volumes for the five patients included in the delineation workshop

	GTV-T, median [range] cm <sup>3</sup>	GTV-N, median [range] cm <sup>3</sup>	CTV, median [range] cm <sup>3</sup>
Patient 1	121.7 [104.7–129.7]	4.9 [4.2–5.3]	406.1 [298.4–452.4]
Patient 2	109.0 [96.1–120.7]	No GTV-N	392.1 [337.0–466.2]
Patient 3	12.8 [11.0–40.1]	10.5 [5.9–14.1]	163.7 [129.6–313.0]
Patient 4	43.9 [41.0–43.3]	24.5 [20.6–33.0]	303.8 [246.5–326.3]
Patient 5	9.1 [7.0–14.1]	No GTV-N	71.5 [37.5–93.5]

#### Conclusion

Data from a target delineation workshop and a pilot treatment planning study suggest that FDG-guided dose

escalation in definitive radiotherapy for esophageal and GEJ cancer is feasible with similar normal tissue doses compared to standard treatment. A randomized dose escalation trial will be designed based on this knowledge.

#### PO-0808 Definitive involved-field radiotherapy for esophageal cancer: are we missing the target?

C. Viveiros<sup>1</sup>, G. Fernandez<sup>1</sup>, C. Pedro<sup>1</sup>, A. Pimenta<sup>1</sup>, L. Mirones<sup>1</sup>, M. Fortunato<sup>1</sup>, F. Santos<sup>1</sup>

<sup>1</sup>Instituto Português de Oncologia de Lisboa Francisco Gentil- EPE, Radiotherapy, Lisboa, Portugal

#### Purpose or Objective

Definitive concurrent chemoradiotherapy became the standard of care for patients with esophageal cancer not candidates to surgery. However, it is still controversial whether radiotherapy requires elective nodal irradiation (ENI) or only involved-field irradiation (IFI). The purpose of this study was to analyze failure patterns and survival in patients receiving IFI.

#### Material and Methods

Retrospective study of patients with pathologic proven esophageal cancer, not candidates to surgery, who have received IFI with curative intent, with or without concurrent chemotherapy, between January 2013 and December 2017. Comparing the target volume with radiological response, patterns of failure at the first recurrence were defined as in-field, regional out-of-field and distant failure. Response to treatment was also assessed and persistence disease was noted. Demographic data, tumor characteristics, imaging and treatment factors were recorded. Survival and disease-control outcomes were calculated from the first day of treatment with Kaplan-Meier method.

#### Results

105 patients were included, 95% with esophageal squamous cell carcinoma and 71.4% with lymph node involvement. All radiation treatments were delivered as three-dimensional conformal radiation therapy (3D-CRT) with standard fractionation (1.8Gy fraction). 93.3% with a total dose of 50.4Gy and a median overall treatment time of 39 days. 94.3% patients received concurrent chemotherapy.

With a median follow-up of 13.2 months, 33 patients (31.4%) had persistent disease, most of whom evolved with distant metastasis (11) and out-of-field recurrences (4). Amongst the patients with complete response (72), there were 5 cases of out-of-field recurrences (only 2 of which were isolated out-of-field relapses, and both were in regions that would not have been included in ENI), 9 with in-field recurrences and 22 with distant metastasis. The median dose at sites where out-of-field relapse occurred was 13.8Gy (1-44 Gy). 21 patients (20%) had mixed failure patterns on the first evidence of disease failure (persistence and/or recurrence).

Median overall survival (OS) was 11.6 months (95% CI 8.2-14.9 months). There were significant differences in OS for patients with and without disease persistence (median OS 10.2 months vs 13 months,  $p < 0.05$ ). Median time to in-field, out-of-field and distant recurrences was 17.3 months (CI 95% 0-38 months), 9.7 months (CI 95% 0-25months) and 8.2 months (CI 95% 6.8-9.7 months), respectively.

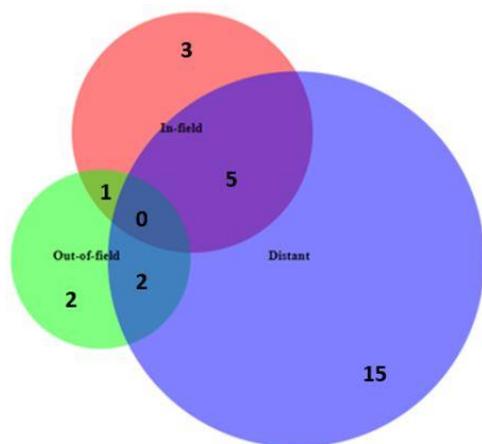

Figure 1. Failure patterns amongst patients with complete response

## Conclusion

Tumor persistence and distant recurrence were the main patterns of lack of disease control. Persistence after (chemo)radiotherapy negatively impacted survival. Out-of-field was the least frequent recurrence pattern. It is acceptable to maintain IFI technique.

## Purpose or Objective

Variations in volume delineation in pancreatic cancer have been reported in previous studies. Thanks to the high soft tissue resolution, Magnetic Resonance Imaging (MRI) could improve the accuracy of tumor delineation in pancreatic cancer compared to Computed Tomography (CT). Since recommendations for pancreatic cancer contouring using MRI have been recently provided, a multi-institutional contouring dummy-run study was proposed to evaluate the impact of MRI on inter-observer agreement in Gross Tumor Volume (GTV).

## Material and Methods

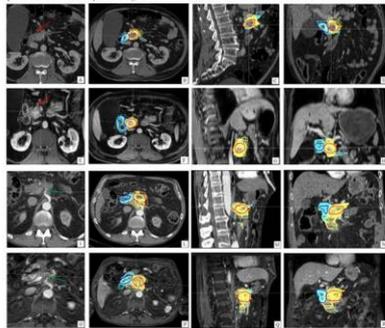

The study group for gastrointestinal cancers of the Italian Association of Radiation Oncologists (AIRO) proposed a multicenter contouring study to the centers interested in pancreatic cancer treatment. Two clinical cases of borderline resectable (Case 1) and locally advanced unresectable (Case 2) pancreatic cancer were selected by two radiologists and two radiation oncologists expert in pancreatic cancer. In two sequential steps, diagnostic contrast-enhanced CT scan and 1.5T MRI sequences were

sent to the participating centers. CT-GTVs were contoured while blinded to MRI data sets. Dice Similarity Index was used to evaluate the spatial overlap accuracy of both GTVs of all centers with respect to a national benchmark, identified on the basis of per-year high volume pancreatic cancer treatment center.

### Results

Thirty-one radiation oncologists from different Institutes joined the study and submitted the delineated volumes for both cases on CT scans and MRI images, respectively (Figure 1). CT- and MRI-GTV volumes were  $21.6 \pm 9.0 \text{ cm}^3$  and  $17.2 \pm 6.0 \text{ cm}^3$ , respectively for Case 1, and  $31.3 \pm 15.6 \text{ cm}^3$  and  $33.2 \pm 20.2 \text{ cm}^3$ , respectively for Case 2. MRI-GTV mean volume resulted significantly smaller than CT-GTV in the borderline resectable case ( $p < 0.05$ ), whereas no significant GTV differences between the two different imaging modalities were reported in Case 2. A substantial agreement was shown by the median DICE index for CT- and MRI-GTV resulting as 0.74 (IQR: 0.67-0.75) and 0.61 (IQR: 0.57-0.67) for Case 1; a moderate agreement was instead reported for Case 2: 0.59 (IQR: 0.52-0.66) and 0.53 (IQR: 0.42-0.62) for CT- and MRI-GTV, respectively.

Figure 1. Graphic representation on axial (Panels A, B, E, F, I, L, O and P), sagittal (Panels C, G, M and Q) and coronal (Panels D, H, N and R) planes of inter-observer variation between 31 Centers for CT (Panels A, B, C and D) and MRI (Panels E, F, G and H) GTV and duodenum of Case 1 (borderline resectable) and for CT (Panels I, L, M and N) and MRI (Panels O, P, Q and R) GTV and duodenum of Case 2 (unresectable). GTV and duodenum benchmark delineations are represented in red and blue solid outline, respectively. Yellow and light blue solid outlines represent GTVs and duodenum contours of the remaining 30 participating Centers. Panels A, E, I and O represent axial CT and MRI images of Case 1 (borderline resectable) and Case 2 (unresectable) without contours. Panels A and E: borderline resectable case for the encasement of the superior mesenteric vein (red arrow); Panels I and O: unresectable case for the tumor infiltration of the colon trunk (green arrow).

### Conclusion

DICE index for GTV delineation agreement was acceptable in the borderline resectable case, whereas a larger overlap deviations was recorded in the unresectable case, suggesting that the major issues in the outlining of macroscopic disease are present when vascular structures are more involved. Based on these results, CT scan, thanks to its high definition of tumor vessels infiltration, can still be considered as the gold standard for volume delineation in pancreatic cancer, especially in unresectable patients. Instead, since diagnostic MRI resulted in smaller GTV in borderline resectable case, the integration of the two imaging methods could offer an improved accuracy of target delineation when radiotherapy is delivered with more conformed techniques such as IMRT, VMAT and/or SBRT.

### PO-0810 Outcome following definitive radiotherapy in oesophageal cancer: A single UK centre experience.

S. Mehta<sup>1</sup>, A. Mcpartlin<sup>1</sup>, C. Hodgson<sup>1</sup>, G. Radhakrishna<sup>1</sup>, L. Bhatt<sup>1</sup>, H. Sheikh<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

### Purpose or Objective

Definitive chemo radiotherapy (dCRT) is the standard of care for inoperable oesophageal cancer patients, however, a large proportion are not suitable due to multiple factors such as co-morbidities or poor performance status. For this group definitive radiotherapy (dRT) alone may be considered. The consensus guidelines are lacking in this regards with wide variation in doses/ techniques of radiotherapy. Here we report our

experience of patients treated with dRT at one of the largest cancer centre in UK.

### Material and Methods

A total of 138 patients who received dRT for oesophageal cancer at the Christie hospital, Manchester, UK, from December 2009 to October 2013 were considered for the analysis. Radiotherapy was initially delivered using 3 field 3D conformal radiotherapy (3D-CRT) and subsequently 5-8-field intensity modulated therapy (IMRT) as practice evolved. Patients were followed up routinely in outpatient clinic after treatment at 3 monthly intervals for one year and then less frequently. Routine re-staging was not performed but investigations were carried out for concerning new or unresolving symptoms. Statistical analysis was performed using SPSS version 21. Survival was calculated from the first day of radiotherapy using the Kaplan-Meier technique and effect of disease characteristics tested using the log rank test. There was a minimum of 12 months follow up following completion of treatment.

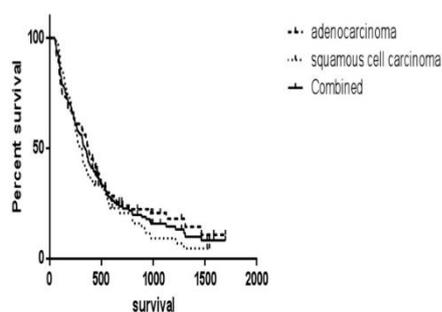

### Results

All patients commenced a course of 55 Gray (Gy) in 20 daily fractions over four weeks, with the exception of seven patients who received 50.4 Gy in 28 daily fractions over five and one half weeks due the volume of stomach involved by GOJ tumours. IMRT was received by 92.0% (127) of patients with the remaining 8.0% (11) treated with 3D-CRT. The demographics of patients and tumour characteristics are shown in table-1. The median follow up time was 22.9 months (range 11.9-55.8) in the 23 survivors at time of analysis and 11.1 months (range 1.5-55.8) in all patients. Post treatment swallow function was recorded at four to twelve weeks post radiotherapy in 78% (80) of patients with dysphagia at initial presentation. Improvement was noticed in 55% (44), stable swallow in 13% (11) and worsened swallow in 32% (26). Of the 138 patients treated, 4 failed to complete the intended radiotherapy course. The symptomatic oesophagitis was experienced by 81.6% (112) with strong opioid analgesics required during treatment or in the six weeks post treatment by 35.5% (49) of patients. Median overall survival (OS) from the start of radiotherapy was 11.1 months with a four year OS of 8.2%. There was no significant difference observed based on histology e.g. median OS for adenocarcinoma and squamous cell carcinoma was 12.1 vs. 9.8 months respectively (log rank,  $p = 0.27$ ) (figure-1).

Table 1: Patient characteristics

## Purpose or Objective

Stereotactic body radiation therapy (SBRT) has emerged as a safe and effective treatment for patients with hepatocellular carcinoma (HCC), but its role in advanced HCC is not well defined. In this study we aim to assess the efficacy of SBRT in comparison to sorafenib treatment in patients with advanced HCC.

## Material and Methods

We included 901 patients treated with sorafenib at six tertiary centers in Europe and Asia and 122 patients treated with SBRT from thirteen centers in Germany and Switzerland. Medical records were reviewed including laboratory parameters and treatment characteristics. Propensity score matching was performed to adjust for differences in baseline characteristics. The primary endpoint was overall survival (OS) and progression-free survival (PFS).

## Results

Median OS of SBRT patients was 18.1 [10.3 - 25.9] months compared to 8.8 [8.2 - 9.5] months in patients treated with sorafenib. After adjusting for different baseline characteristics, the survival benefit for patients treated with SBRT was still preserved with a median OS of 17.0 [10.8 - 23.2] months compared to 9.6 [8.6 - 10.7] months in patients treated with sorafenib. SBRT of intrahepatic lesions in patients with extrahepatic metastases was also associated with improved OS compared to patients treated with sorafenib in the same setting (17.0 vs 10.0 months,  $p=0.012$ ) whereas in patients with portal vein thrombosis (PVT) there was no survival benefit in patients with SBRT.

## Conclusion

In this retrospective comparative study, SBRT was superior compared to sorafenib in patients with advanced HCC.

## PO-0812 Pathological validation of endoscopically placed fiducials on tumor borders in esophageal cancer.

<sup>1</sup>Amsterdam UMC- locatie AMC, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>Amsterdam UMC- locatie AMC, Pathology, Amsterdam, The Netherlands ; <sup>3</sup>Amsterdam UMC- locatie AMC, Upper GE Surgery, Amsterdam, The Netherlands ; <sup>4</sup>Amsterdam UMC- locatie AMC, Gastroenterology, Amsterdam, The Netherlands

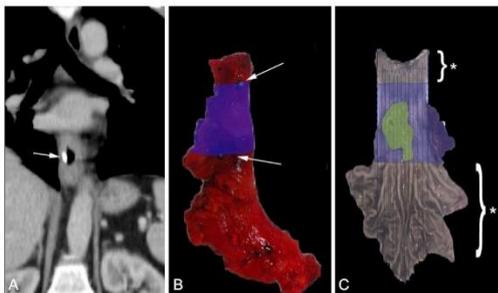

### Purpose or Objective

The microscopic tumor extension beyond the macroscopic tumor borders of esophageal cancer is scarcely investigated. Nonetheless this information is crucial for determining the clinical target volume (CTV) in radiation therapy [1]. Modern innovations in gross tumor volume (GTV) determination allow delineation with the aid of (echo)endoscopically placed fiducial markers on the tumor borders. The question arises whether the current voluminous clinical target volume (CTV) margins of 3-5 cm around the GTV to account for microscopic extension - based on one study solely - are still accurate [1]. In the present study, we analysed microscopic spread beyond the (echo)endoscopically determined tumor border (EDTB) with the use of fiducial markers at the tumor borders. Furthermore, we validated the use of fiducial markers placed on the EDTB as a surrogate for macroscopic tumor borders.

### Material and Methods

Thirty-two consecutive esophageal cancer patients were included in this study. All patients were treated with neoadjuvant chemoradiotherapy and fiducial markers were (echo)endoscopically implanted before treatment at the cranial and caudal tumor borders. The surgical specimens of all patients were collected from the operation room, fiducial marker positions were detected under CT guidance and demarcated with beads, and subsequently analysed at the pathology department for macroscopic and microscopic spread beyond the demarcations (EDTB) (Figure 1). Per specimen a shrinkage rate was calculated (i.e., distance between fiducial markers ex-vivo divided by distance between fiducial markers in-vivo). A logistic regression analysis was performed to determine predicting factors for microscopic spread beyond EDTB (significance level  $\alpha=0.05$ ).

**Figure 1.** A: Pre-operative CT scan of patient 3 in coronal view with caudal fiducial visible. Arrow indicates fiducial marker. B: Esophageal specimen exterior of patient 3 with blue inked area: (echo)endoscopically determined tumor area between both (echo)endoscopically determined tumor borders. Arrows indicate fiducial positions cranially and caudally, demarcated externally with green bead. C: Esophageal specimen interior of patient 3. Blue inked area: (echo)endoscopically determined tumor area. Green overlay: residual tumor left. Asterix indicates area examined for macroscopic and microscopic tumor spread.

### Results

A total of 60 EDTB were examined in 32 patients. As listed in Table 1, 16/32 (50%) of patients had a Mandard 3 or higher (i.e., residual tumor group) and were included for analysis of microscopic tumor spread analysis. In the residual tumor group, only 3/16 (19%) patients had microscopic spread beyond the cranial EDTB, and 4/16 (25%) had microscopic spread beyond the caudal EDTB. The mean microscopic spread beyond EDTB was 7 mm cranially (range: 6 - 9 mm) and 13.5 mm caudally (range:

5.8 - 20 mm). This extension was corrected for each individual determined shrinkage rate (mean: 93%). The presence of microscopic spread of cancer beyond EDTB was only significantly associated with initial tumor length ( $p = 0.028$ ). None of the patients had macroscopic tumor spread beyond the EDTB.

**Table 1.** Tumor, fiducial marker implantation and pathologic characteristics. Abbreviations: EDTB = (echo)endoscopically determined tumor border; GEJ = junctiontumor; EUS = echoendoscopy.

### Conclusion

No macroscopic tumor was found beyond the EDTB. Only 19% and 25% of respectively the cranial and caudal EDTB, were traversed with a mean of 7 mm - 13.5 mm, and a maximum of 20 mm microscopic tumor. Our results indicate that current recommended CTV margins around the GTV to compensate for microscopic tumor along the esophageal wall can be reduced when the GTV is determined with the aid of fiducial markers.

### PO-0813 A Phase I/II Study of durvalumab and stereotactic radiotherapy in locally advanced pancreatic cancer

R. Tuli<sup>1</sup>, N. Nisen<sup>2</sup>, S. Lo<sup>3</sup>, V. Placencio<sup>1</sup>, G. Gresham<sup>3</sup>, A. Hendifar<sup>3</sup>

<sup>1</sup>Cedars-Sinai Medical Center, Radiation Oncology, los angeles, USA ; <sup>2</sup>Cedars-Sinai Medical Center, Surgery, Los Angeles, USA ; <sup>3</sup>Cedars-Sinai Medical Center, Medicine, los Angeles, USA

### Purpose or Objective

Previous studies targeting the PD-1/PD-L1 pathway in varying tumor types have shown blockade of this pathway can enhance the efficacy of radiotherapy (RT). However, no such data is available in pancreatic cancer (PC) and no significant responses have been seen in this disease with immune checkpoint blockade. Our group and others have observed the effect of both chemotherapy and RT is enhanced in PC by targeting the PD-1/PD-L1 pathway, and the degree of this response is dependent upon the native expression of PD-1/PD-L1. These data led us to hypothesize that the clinical efficacy of RT in PC can be enhanced with concurrent PD-L1 blockade. Herein, we report interim results of an ongoing phase 1/2 clinical trial in locally advanced (LA) and borderline resectable (BR) PC (NCT03245541).

### Material and Methods

Patients with LA or BR PC treated with standard of care gemcitabine and nab-paclitaxel for 3 to 6 cycles were enrolled. Treatment consisted of durvalumab (750 mg Q14

days) on D1. Stereotactic ablative radiotherapy (SABR; 6.6 Gy/fraction) was delivered every other day x 5 fractions beginning D8. Durvalumab continued as maintenance Q14 days until resection or progression. The run-in phase 1 utilized a standard 3+3 design prior to phase 2 expansion. Dose limiting toxicities (DLTs), adverse events (AEs) and serious adverse events (SAEs) were assessed during the first 10 weeks of study treatment. CT scans were obtained every 2 months for response assessment. Endoscopic research biopsies were obtained pre- and 6-8 weeks post-SABR, and weekly blood samples were obtained on D1, weekly for 10 weeks, and then every 2 months until resection or progression to assess for immune correlates of response.

### Results

Since 8/2017, 15 of 30 planned patients were enrolled of which 9 (60%) are LA and 6 (40%) were BR. Median age was 70 and 8 (53%) were female. No DLTs were identified in the phase 1 run in and enrollment in the phase 2 study continues. Grade 3 toxicities have been identified in 2 patients (nausea, anorexia). Ten patients have discontinued study treatment due to surgery (n=6) and disease progression (n=4; local = 1, distant = 2, local+distant = 1). All resections have been margin-negative. Objective response rates (RECIST 1.1) included SD (n=9) and PR (n=6). Two patients have died. Median PFS has not been reached.

### Conclusion

To our knowledge, this is the first report of a PD-L1 inhibitor-RT combination in LA PC. The regimen was safe, well tolerated and appears to be clinically active with high rates of margin-negative resection.

## Poster: Clinical track: Lower GI (colon, rectum, anus)

### PO-0814 Clinical target volume in radiation therapy for organ preservation in T2 rectal cancer

J. Socha<sup>1</sup>, L. Pietrzak<sup>2</sup>, A. Zawadzka<sup>3</sup>, A. Paciorkiewicz<sup>3</sup>, A. Krupa<sup>2</sup>, K. Bujko<sup>2</sup>

<sup>1</sup>Military Institute of Medicine, Department of Radiotherapy, Warsaw, Poland; <sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Centre, Department of Radiotherapy I, Warsaw, Poland; <sup>3</sup>Maria Skłodowska-Curie Memorial Cancer Centre, Medical Physics Department, Warsaw, Poland

#### Purpose or Objective

There are no guidelines on clinical target volume (CTV) delineation for cT2 rectal cancer treated with organ preservation.

#### Material and Methods

A systematic review and meta-analysis were performed to determine the extent of distal mesorectal (DMS) and distal intramural spread (DIS), the risk of lateral lymph node (LLN) metastases in pT2 tumours, and regional recurrence pattern after organ preservation.

#### Results

The rate of DMS >1 cm was 1.9% (95% CI: 0.4%-5.4%), maximum extent: 1.3 cm. The rate of DIS >0.5 cm was 4.7% (95% CI: 1.3%-11.5%), maximum extent: 0.8 cm. The rate of LLN metastases was 8.2% (95% CI: 6.7%-9.9%) for tumours below or at peritoneal reflexion and 0% for higher tumours. Regional nodal recurrences alone (i.e. without concomitant intraluminal recurrences) were recorded in 1.1% (95% CI: 0.5%-1.7%) of patients after watch-and-wait and in 2.1% (95% CI: 1.2%-3.4%) after preoperative radiotherapy and local excision. Thus, the following rules for CTV delineation are proposed: caudal border 1.5 cm from the tumour to account for DMS or 1 cm to account for DIS, whichever is more caudal; cranial border at S2/S3 interspace; inclusion of LLN for tumours at or below peritoneal reflexion (see Table 1, Figure 1). A planning study was performed in eight patients to compare dose-

volume parameters obtained using these rules to that obtained using current guidelines for advanced cancers. The proposed rules led to a mean 18% relative reduction of planning target volume, which resulted in better sparing of at-risk organs.

### Conclusion

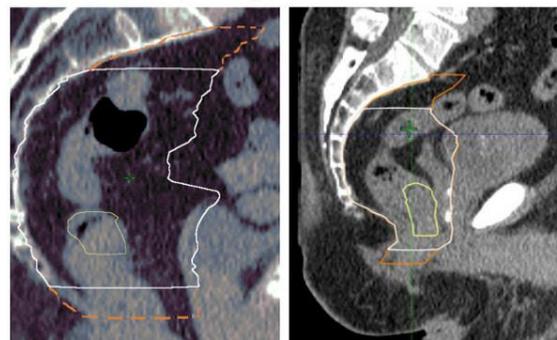

This meta-analysis suggests a smaller CTV for cT2 tumours than the current guidelines designed for advanced cancers.

Table 1. Proposed CTV borders in radiation therapy for organ preservation in patients with cT2 tumour.

Caudal border	1.5 cm caudally from the tumour to account for DMS or 1 cm caudally from the tumour to account for DIS, whichever is more caudal (see Figure 1).
Cranial border	S2/S3 interspace.
Lateral border	Pelvic wall for tumours with lower border located below or at the peritoneal reflexion to include LLNs. Mesorectal fascia for tumours with lower border located above the peritoneal reflexion.

DMS - distal mesorectal spread; DIS - distal intramural spread, LLN - lateral lymph node.

Figure 1. Comparison of clinical target volume (CTV) obtained after applying the proposed rules to that obtained after using the current guidelines.

A: cT2 cancer situated 6 cm from the anal verge. CTV<sub>proposed</sub>: white; CTV<sub>standard</sub>: orange.  
B: cT2 cancer situated 3 cm from the anal verge. CTV<sub>proposed</sub>: white; CTV<sub>standard</sub>: orange.

### PO-0815 Stereotactic radiation therapy in colorectal cancer brain metastasis: a multicentric cohort

A. Paix<sup>1</sup>, F. Thillays<sup>2</sup>, J. Biau<sup>3</sup>, N. Vulquin<sup>4</sup>, I. Pop<sup>5</sup>, K. Debbi<sup>6</sup>, A.L. Grosu<sup>5</sup>, G. Noël<sup>1</sup>

<sup>1</sup>Centre Paul Strauss, Radiothérapie, Strasbourg, France; <sup>2</sup>Institut Cancérologique de l'ouest, Radiothérapie, Saint Herblain, France; <sup>3</sup>Centre Jean Perrin, Radiothérapie, Clermont-Ferrand, France; <sup>4</sup>Centre Georges-François Baclesse, Radiothérapie, Dijon, France; <sup>5</sup>Universitätsklinikums, Klinik für Strahlenheilkunde, Freiburg, Germany; <sup>6</sup>Centre Henry Kaplan - CHU Tours, Radiothérapie, Tours, France

#### Purpose or Objective

Colorectal cancer (CRC) is the third most common cancer in western countries, but brain metastases only occur in 1% of CRC patients. Overall survival in CRC patients rises as new systemic drugs became available. Thus the incidence of brain metastases in CRC patients will likely increase. We conducted a multicentric analysis to evaluate and compare the outcomes of stereotactic radiosurgery (SRS) and hypofractionated stereotactic radiotherapy (HFSRT) in CRC brain metastasis management.

#### Material and Methods

On behalf of the association of French-speaking neuro-oncologist (ANOCEF), we retrospectively collected individual data of patients treated with SRS or HFSRT for CRC brain metastases in 6 hospitals in France and Germany.

The primary endpoint of the study was the radiological response rate define as a complete response, partial response or stability of the metastasis according to RANO

BM criteria. A Bayesian multivariate logistic regression was performed to evaluate the influence of several factors on the probability of response. Secondary endpoints included overall survival (OS) and brain progression-free survival (BPF5).

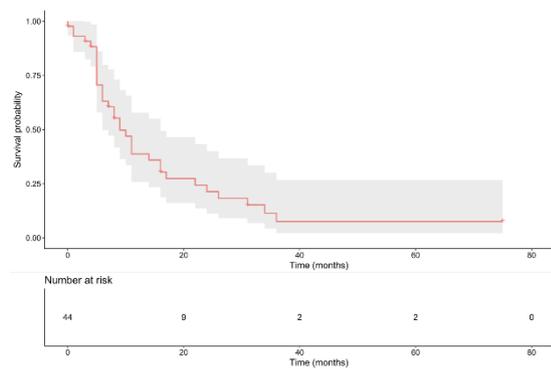

### Results

This international, multicentric retrospective analysis involved 58 patients and 69 metastases.

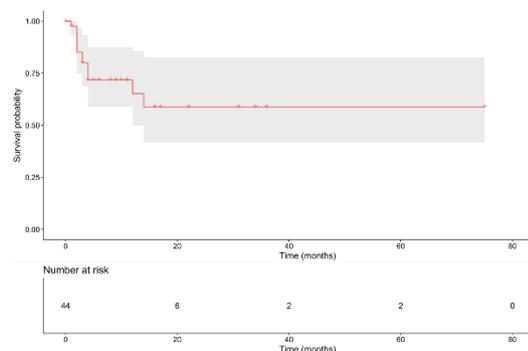

The median response rate for metastasis treated was 65.9% (CI 95% [51.9% - 79.9%]) and was positively influenced by SRS whereas multiple brain metastases were related to poorest response rates. The results of the Bayesian multivariate logistic regression are reported in Table 1.

	Odds Ratio	Standard deviation	2.5%	95%	p(OR<1)	p(OR>1)
Disease controlled	0.73	0.51	0.17	2.05	79%	21%
Multiple brain metastasis	0.72	0.52	0.16	2.05	80%	20%
PTV (mL)	0.99	0.03	0.94	1.04	70%	30%
SRS	3.27	4.12	0.36	13.5	21%	79%

The median follow-up from initial treatment was 31 months. The median overall survival (OS) from initial treatment was ten months (CI 95% [5 - 22]), the Kaplan-Meier survival curve is reported in Figure 1. OS was negatively influenced by extra-cranial metastases, male gender, whereas it influenced positively by brain progression-free survival (BPF5).

Median BPF5 was not met. BPF5 Kaplan Meier survival curve is reported in Figure 2.

### Conclusion

We report the results of one of the largest cohort of CRC brain metastasis treated with stereotactic radiotherapy.

This analysis suggests that CRC metastases have an overall poor response rate to stereotactic radiotherapy. However, it seems that SRS should prefer over HFSRT in patients with limited CRC brain metastases. Moreover, it demonstrates that BPF5 directly impact OS.

### PO-0816 Adaptive radiotherapy concomitant with chemotherapy as preoperative treatment for rectal cancer

<sup>1</sup>Ospedale San Raffaele IRCCS, Radiation Oncology, Milan, Italy ; <sup>2</sup>Ospedale San Raffaele IRCCS, Medical Physics, Milan, Italy ; <sup>3</sup>Ospedale San Raffaele IRCCS, Medical Oncology, Milan, Italy ; <sup>4</sup>Ospedale San Raffaele IRCCS, Radiology, Milan, Italy ; <sup>5</sup>Ospedale San Raffaele IRCCS, Surgery, Milan, Italy

### Purpose or Objective

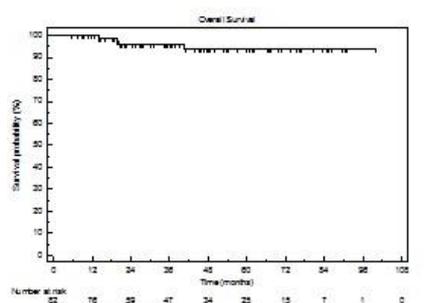

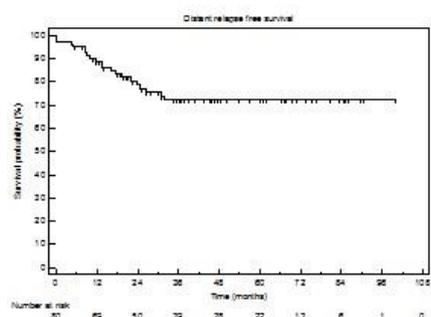

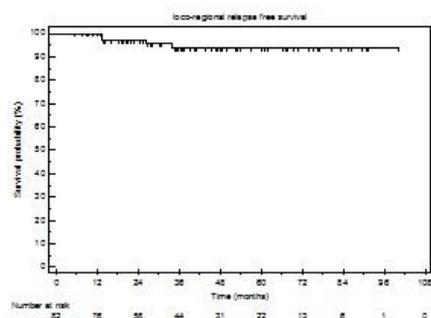

To report our clinical experience with hypofractionated, adaptive radiotherapy (RT) concomitant with chemotherapy (ChT) as preoperative treatment for rectal cancer.

### Material and Methods

Patients (pts) with T3/T4N0 or any TN+ rectal adenocarcinoma were included in an observational study. Chemotherapy consisted of Oxaliplatin 100mg/m<sup>2</sup> on days -14, 0, +14 and c.i. 5FU 200mg/m<sup>2</sup>/day or oral capecitabine 825mg/m<sup>2</sup>x2/day (from 2015 on) from day -14 to the end of RT. RT started on day 0, was delivered by Tomotherapy, and was divided into two phases of 12 and 6 fractions (Frs), respectively. Pts were positioned on Comby-Fix<sup>®</sup> and underwent a simulation CT and MR, subsequently matched. In the first RT phase CTV included mesorectum, perineum in case of tumor < 6cm from anal canal, and regional lymph-nodes. PTV was defined as CTV with a margin of 0.5 cm and received 27.6 Gy in 12 fractions (2.3 Gy/Fr). A simulation CT and MR were repeated after two cycles of ChT and 9 Frs of RT. Two new volumes were considered: GTVadaptive, defined as the residual tumour (T and N) visible on the intermediate MR images, and PTVadaptive, created from GTVadaptive with a margin of 0.5 cm. In the second RT phase, the adaptive phase, PTV again received 2.3 Gy/fr x 6 Frs (total dose 41.4 Gy in 18 Frs), while PTVadaptive received a simultaneous integrated boost of 3.1 Gy/Fr x 6 Frs (total dose 46.2 Gy in 18 Frs).

### Results

From 9/2009 to 5/ 2017, 82 pts were prospectively enrolled, T2=5, T3=72, T4=5, N+=67. Median distance from anal canal was 6.5 cm (0 cm in 18 pts), median cranium-caudal tumor length was 5 cm (1.2-11 cm). No G4 toxicity occurred; G3 toxicity consisted of diarrhoea in 10/82 pts (12%) and proctitis in 4 pts (5%). Diarrhoea always occurred before the adaptive phase. Eighty pts (97%) completed RT; median duration of RT was 25 days. Fifty-seven (70%) and 74 (84%) received > 75% of oxaliplatin and 5FU dose, respectively. Two pts achieved complete clinical response and refused surgery, 1 pt was lost, 1 pt had early distant progression. Seventy-eight pts were resected (73 R0, 5 R1), 72 pts had conservative surgery, 6 pts had abdominal-perineal amputation. Twenty-two pts (28%) had pathological complete response, 23 pts (29%) had TRG3 with 1-5% of residual vital cells. Fifty-two pts received adjuvant chemotherapy. At a median follow up of 30 months, calculated from the end of chemoradiotherapy to the last clinical check or death, 3 pts had local and 20 pts distant relapse. Local-regional-relapse free survival, distant metastasis free survival, and overall survival were 96.5%, 75.7% and 95.7%, respectively.

### Conclusion

Hypofractionated, adaptive RT concomitant with oxaliplatin and fluoropyrimidines is feasible with acceptable G3 toxicity and provides a very interesting response rate. There could be room for further dose escalation on the residual tumor with the aim of increasing pCR and/or cCR rates.

Radiotherapy Unit, Campobasso, Italy ; <sup>8</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy ; <sup>9</sup>Ospedale Bellaria, Radiotherapy Department, Bologna, Italy

### Purpose or Objective

Aim of this study was to evaluate the pathological complete response (pCR) rate in locally advanced rectal cancer (LARC) after adaptive high-dose neoadjuvant radiation therapy (RT) with concomitant plus sequential boost based on [18F]FDG-PET/CT performed two weeks after the start of RT.

### Material and Methods

Patients (pts) with biopsy proven LARC were included. Primary end-point was pCR rate. Secondary objectives included acute and late toxicity. The sample size was calculated based on the Simon's two-stage design. All pts underwent [18F]FDG-PET/CT at baseline (PET0) and after 2 RT weeks (PET1). Intensity modulated RT (IMRT) technique was delivered with concurrent capecitabine. The Gross Tumor Volume (GTV) was defined using a gradient-based delineation method and the maximal standardized uptake values (SUVmax) were recorded. The dose to rectum, mesorectum, and pelvic lymph nodes was 45 Gy (1.8 Gy/fr). A simultaneously integrated boost (SIB) was delivered to GTV+2 cm margin with a total dose of 50 Gy (2 Gy/fr). A sequential boost was delivered to GTV+5 mm margin with a total dose of 5 Gy in 2 fractions (2.5 Gy/fr) for a total dose of 55 Gy using cone-beam CT. Pathological response was scored based on the American College of Pathologist Tumor Regression Grading (TRG). Toxicity was scored according to the CTCAE v4.03 scale.

### Results

Eighteen pts (13 M, 5 F; median age 58.1 years) were enrolled. According to UICC TNM Staging (8th edition) classification the clinical stage was: T2N1M0 (2 pts), T3N1M0 (11 pts), T3N2M0 (2 pts), and T4N1M0 (3 pts). Nine-10 weeks since the end of neoadjuvant treatment all pts except one, who refused surgery after evidence of clinical complete response, underwent surgical resection. Six pts (35.3%) showed TRG=0 (pCR), 5 pts (29.4%) TRG=2, and 6 pts (35.3%) TRG 3. GTV measured at PET0 was 22 mL (range: 1.2-90.9) and at PET1 9.8 mL (range: 0-62.4) ( $p < 0.05$ ). Median GTV reduction was 60.2% (range: 0-100): 61.5% (range: 13.9-100) for responders (pCR) pts and 59.5% (range: 0-94.5) for non-responders ( $p = 0.91$ ). Median SUVmax of the rectal lesions was 15.1 (range 5.7-45) at PET0 and 8.3 (range: 0-20.4) at PET1 ( $p = 0.098$ ). Median SUVmax reduction was 40.4% (range: 0-100): 50% for responder pts and 35.2% for non-responders (both ranges: 0-100) ( $p = 0.39$ ). Most pts showed G1 GI and GU toxicity. Only one pt had acute GI G3 toxicity.

### Conclusion

Despite the delivery of the sequential boost on a reduced volume, adapted based on an early 18F-FDG-PET/CT, the pCR rate was 35.3%. This regimen was well tolerated.

### PO-0818 Comparison of three different approaches for bowel delineation in patients with rectal cancer.

E. Rijkmans<sup>1</sup>, B.B.D. Otto<sup>1</sup>, J.R.N. Van der Voort van Zyp<sup>2</sup>, R.Th. Zinkstok<sup>1</sup>, F.P. Peters<sup>1</sup>, C.A.M. Marijnen<sup>1</sup>  
<sup>1</sup>Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands ;  
<sup>2</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Acute gastro-intestinal (GI) toxicity is one of the main dose-limiting toxicities in radiotherapy for rectal cancer. Previous studies showed a dose-response relationship for small bowel and acute GI toxicity. However, different contouring methods have been used, and there is no consensus on which is best suitable for clinical practice. This study aims to compare different bowel delineation

definitions and their association with toxicity in patients with locally advanced rectal cancer (LARC) treated with neo-adjuvant chemoradiotherapy.

**Material and Methods**

Data from a historical cohort study including all consecutive patients with LARC treated with chemoradiotherapy in our institute from 2003-2010 was used for this analysis. Patients were treated with a 3D conformal four-field technique. In all patients, bowel structures were delineated using three different techniques; individual small bowel loops (SBL), bowelbag following EMBRACE criteria and the RTOG bowel cavity (Fig 1). Delineations were performed by two observers (JVZ and BO) and checked by a second observer (ER/FP). An experienced radiologist was consulted if needed. Acute toxicity was scored according to CTCAE v4.0. Volumes receiving 5Gy-50Gy with an interval of 5Gy (V5-V50) of the different contours were correlated with occurrence of grade  $\geq 2$  acute diarrhea, using a Mann-Whitney U tests.

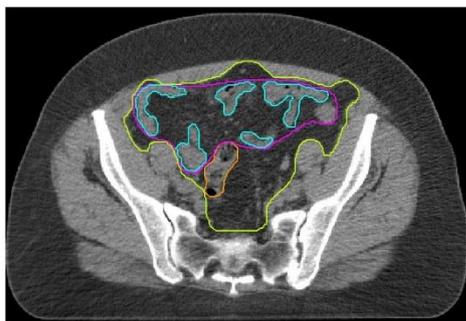

Figure 1. Example of different delineation contours. Small bowel (sky blue); Bowelbag (pink); RTOG (yellow green); Sigmoid (orange); Individual bowel loops (purple); Outer contour of small and large bowel, excluding rectosigmoid; All abdominal contents starting from the most inferior axial slice with small or large bowel loops or above the rectum.

**Results**

Planning CTs and acute toxicity data were available for 90 patients. Grade  $\geq 2$  acute diarrhea occurred in 33 out of 90 patients (36.7%) of which grade 3 in 10 patients (11.1%), no grade 4 or 5 diarrhea occurred. An association was found for all three techniques between irradiated bowel volume and the development of grade  $>2$  acute diarrhea. This association was most pronounced for low dose regions and for SBL and bowelbag compared to the RTOG bowel cavity (Fig 2). The strongest association was observed for the V15 of the bowelbag with a median V15 of 314cc for patients with  $<$  grade 2 diarrhea and a median V15 of 410cc in patients with grade  $\geq 2$  diarrhea ( $p=0.04$ ). Interestingly approximately 50% of volume of the bowelbag consisted of small bowel loops, while this was only approximately 13% for the RTOG bowel cavity (Fig 2).

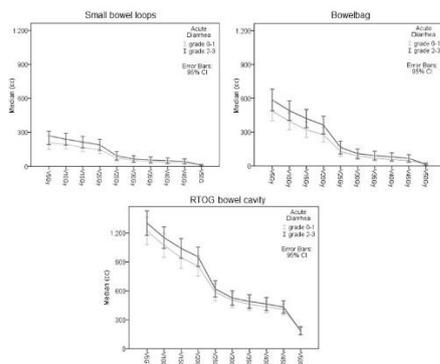

Figure 2. Association of V5-V50 of small bowel loops, bowelbag and RTOG bowel cavity with grade  $\geq 2$  acute diarrhea.

**Conclusion**

The bowelbag V15 was the best predictor for acute diarrhea grade  $\geq 2$  in patients treated with neo-adjuvant chemoradiation for rectal cancer. Further research is needed to assess the value of the bowelbag V15 in modern radiation techniques such as intensity modulated or volumetric arc therapy and in relation to late GI-toxicity.

**PO-0819 Stereotactic Radiation Therapy in Oligometastatic Colorectal Cancer: 102 patients and 150 lesions**

<sup>1</sup>IEO European Institute of Oncology- IRCCS, Division of Radiotherapy, Milan, Italy ; <sup>2</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy ; <sup>3</sup>University Hospital Centre "Mother Theresa", Department of Oncology, Tirana, Albania ; <sup>4</sup>Medical University of Gdansk, Department of General- Endocrine and Transplant Surgery, Gdansk, Poland ; <sup>5</sup>IEO European Institute of Oncology- IRCCS, Division of Medical Physics, Milan, Italy

**Purpose or Objective**

To evaluate local control (LC), progression free survival (PFS), overall survival (OS), toxicity and failure predictors in patients with oligometastatic colorectal cancer (CRC) treated with stereotactic radiation therapy (SRT) in a single institution.

**Material and Methods**

Patients with oligometastatic CRC disease (with 1-5 metastases) were analyzed retrospectively. Treatments were performed using VERO® (BrainLab) and CyberKnife® (Accuray) systems. The SRT prescribed dose was dependent on the volume of the lesions and its location. Treatment characteristics are summarized in table 1.

Table 1: SRT treatment characteristics (N=150 lesions)

	N-150	%
Region of lesions		
Chest	100	66.7
Upper abdomen	30	20
Pelvis	13	8.6
Head and neck	7	4.7
Site of lesions		
Lung	97	64.6
Other*	18	12
Liver	15	10
Lymph-node	13	8.7
Head and neck	7	4.7
PTV (cm <sup>3</sup> )	Median (q1, q3)	15.9 (9.1, 41.8)
Equivalent dose (BED) (Gy)	Median (q1, q3)	129 (45, 129)
Total dose (Gy)	Median (q1, q3)	45 (26, 45)
Dose/fraction (Gy)	Median (q1, q3)	15 (8, 15)

\*Other includes urinary bladder lesions, bone lesions, bronchus lesions, solid abdominal and pelvic lesions.

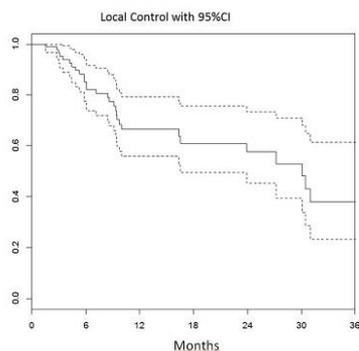

Legend: KPS: Karnofsky performance status; PTV: planning target volume; q1, q3: interquartile range

**Results**

102 consecutive oligometastatic CRC patients (150 lesions overall) were included for this study. They underwent SRT between February 2012 and December 2015. Median prescription dose was 45 Gy (median dose/fraction was 15 Gy delivered in 3 fractions and corresponding BED<sub>10</sub> was 112.5 Gy). Median follow-up was 11.4 months. Acute and late G1 toxicities were observed in 10% and 1.4% of patients, respectively. No patients experienced G3 and G4 toxicity. Considering the radiological response at 3 months and best radiological response, no progression was found in 82% and 85% out of 150 evaluable lesions, respectively.

Actuarial 6-month, 1-year, 2-year LC rates were 85%, 67%, 58% (image 1), respectively, whereas OS rates were 95%, 90% and 90%, respectively and PFS rates were 63%, 37% and 27% respectively. Pattern of failure was out-field in 35% and in-field in 31% of patients. Progressive disease was

significantly correlated with biological equivalent dose (BED) with a significant better LC when BED was  $\geq 75$  Gy ( $p < 0.0001$ ). Moreover, in multivariate analysis, LC was significantly higher in lesions with a Planning Target Volume (PTV) volume  $< 42$  cm<sup>3</sup> and treated with a BED  $\geq 75$  Gy. Patients with Karnofsky performance status (KPS)  $< 90$  showed a significantly higher out-field progression than the ones with KPS  $\geq 90$ .

### Conclusion

Patients with oligometastatic CRC are considered candidates for curative treatment because long-term survival can be expected. Recent studies have shown that SRT in oligometastatic CRC is an excellent option for local treatment of metastases with a good outcome and low toxicity profile. Our study confirms that SRT is an effective treatment with low treatment-associated morbidity. It should be considered as a valid option for properly selected patients. Further studies should be focused to clarify which patient subgroup will benefit most from this treatment modality. Furthermore, researchers should aim to define the optimal dose in order to improve tumor control while maintaining low toxicity profile.

### PO-0820 Effect of short-course radiotherapy on postoperative complications in locally advanced rectal cancer

S. Hoendervangers<sup>1</sup>, C. Sparreboom<sup>2</sup>, H. Van Grevenstein<sup>3</sup>, L. Verkooijen<sup>1</sup>, J. Lange<sup>2</sup>, P. Doornebosch<sup>4</sup>, M. Intven<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands ;

<sup>2</sup>Erasmus MC, Surgery, Rotterdam, The Netherlands ;

<sup>3</sup>UMC Utrecht, Surgery, Utrecht, The Netherlands ;

<sup>4</sup>IJsselland hospital, Surgery, Capelle a/d IJssel, The Netherlands

### Purpose or Objective

Neoadjuvant short-course radiotherapy (5x5 Gy) with a prolonged interval to surgery (SCRT-delay) is regularly used as an alternative for neoadjuvant chemoradiation (CRT) in frail patients with locally advanced rectal cancer (LARC). However, evidence based data on management of LARC in the frail population is scarce. Consequently, there are no clear guidelines for the treatment of this group, and decision-making for the type of neoadjuvant therapy differs per center. With the increasing aging population, there is an urgent need for more evidence to justify the choice of neoadjuvant treatment in frail patients with LARC. Therefore, the aim of this study is to investigate the patient characteristics on which treatment deviation is based and to assess the effect on postoperative outcomes.

### Material and Methods

This is an observational study with data from the Dutch ColoRectal Audit (DCRA), a national audit in which clinical outcomes of patients undergoing primary colorectal surgery are registered. Non-metastatic LARC patients who

underwent surgery between May 2014 and May 2016 after an interval of  $\geq 6$  weeks were included. Missing values were replaced by multiple imputation. Differences in baseline characteristics between SCRT-delay and CRT were evaluated by  $\chi^2$ -test for categorical variables and t-test for continuous variables. The association between the different types of neoadjuvant treatment and postoperative complications was analyzed by multivariable logistic regression.

### Results

2,888 patients with LARC were included; 333 patients were treated with SCRT-delay and 2,555 with CRT. Mean age was higher in the SCRT-delay group compared to the CRT group (73.87 vs. 64.33,  $p < 0.001$ ). Also, prevalence of comorbidities was higher in the SCRT-delay group (81% vs. 66%,  $p < 0.001$ ). There were no statistically significant differences in tumor stage, surgical approach, the occurrence of postoperative complications, length of hospital stay or length of ICU stay. Patients in the SCRT-delay group more often received a permanent colostomy ( $p < 0.001$ ).

Table 1. Multivariable analysis of the association between neoadjuvant short-course radiotherapy with delayed surgery (SCRT-delay) or chemoradiation (CRT) and postoperative complications  $< 30$  days after surgery

	Adjusted OR (95% C.I.)	p-value

- Proctocolectomy	2.07	0.24
- Other	3.45	0.02
Primary anastomosis	0.81	0.06

### Conclusion

Despite the higher age and the higher prevalence of comorbidities, postoperative complications were not significantly higher in the SCRT-delay group. Short-course radiotherapy was not associated with increased postoperative complications and seems to be a good alternative neoadjuvant treatment option for frail LARC patients.

#### Purpose or Objective

Organ preservation strategy with local excision (LE) or watch and wait (W-W) in selected patients (pts) with locally advanced rectal cancer (LARC) who achieve a major (mCR) or complete clinical response (cCR) after preoperative chemoradiotherapy (CRT) may offer an opportunity to avoid major surgery and its effects on anorectal, sexual and urinary functions and quality of life. We report the long term outcome of pts undergoing pre-operative CRT and LE at our Institution

#### Material and Methods

Between January 1998 and July 2017 LE was proposed to pts as an alternative to TME after CRT when mCR or cCR were assessed at DRE, endoscopy with biopsy and MRI. CT-PET was used since 2002 in staging and restaging to characterize also metabolic response. LE was performed using either the traditional transanal approach or Transanal Micro Invasive surgery (TAMIS). Pathologic response was defined as pT stage and Mandard Tumor Regression Grade (TRG). Pts who achieved TRG1 or TRG2 were going to follow-up, whereas was planned for pT1-3, TRG3-5. Long term outcome was assessed by Log-Rank test in terms of 5 and 10yrs OS, DFS and local DFS (LDFS) and Colostomy Free Survival (CFS).

#### Results

Seventy-four pts (M/F: 47/27 ; median age 66 yrs, range 25-85) underwent to LE. Clinical stage at presentation was I in 10 pts, II in 39 and III in 25. Median distance from anal verge was 3.5 cm (range 2-8 cm). Radiotherapy (RT) consisted of 45-50.4 Gy in 25-28 frs in 50 pts and 45-54 Gy in 25 frs (IMRT-SIB) in 24 pts. Concomitant 5-FU or Capecitabine based chemotherapy was associated to RT in all pts. Pathologic T stage after LE was available for 70 pts; 4 pts with cCR entered in a W-W program. pT0 was achieved in 39 pts (56%), pT1-3 in 31 (44%). Overall 50 pts (71%) achieved TRG1 or TRG2 and 20 TRG3-5. Twelve of 20 TRG 3-5pts underwent to TME while 8 pts refused radical surgery. With a minimum follow up of 2 yrs (range 2-20yrs), the 5 and 10-yrs LDFS, DFS and OS in the overall 74 pts were 88.1% and 88.1%, 77.3% and 71.5%, and 88.2% and 74.4%, respectively. For the 43 T0 pts, including 39 pT0 and 4 cCR in W-W program, the 5 and 10-yrs LDFS, DFS and OS were 94.7% and 94.7%, 84% and 73.5%, and 91.6% and 73.2%, respectively. No significant difference of outcome were found between TRG1-2 and TRG3-5 pts, most receiving radical TME. At the same median follow up, 17 pts (24%) needed colostomy, 7 (14%) in TRG1-2 group and 10 (50%) in TRG3-5 respectively. The 10yrs CFS was 87.8% in TRG1-2 group and 52.7% in TRG3-5 and it was significantly different ( $p=0.001$ ) in these two subset of pts. No major complication were reported; 3 pT0 pts needed colostomy for fecal incontinence (2pts) or rectal stenosis (1pt) after LE.

#### Conclusion

Organ preservation with LE after CRT appears safe with favourable long-term outcome for selected LARC patients who achieve mCR or cCR. TME performed after LE don't get worse outcome in TRG3-5 pts. LE confirms a valid approach in organ preservation to improve quality of life in these pts.

<sup>1</sup>MacKay Memorial Hospital, Radiation Oncology, Taipei, Taiwan ; <sup>2</sup>Changhua Christian Hospital, Radiation Oncology, Changhua, Taiwan ; <sup>3</sup>MacKay Memorial Hospital, Obstetrics and Gynecology, Taipei, Taiwan

#### Purpose or Objective

Treatment-related toxicities and decreased levels of patient performance during cancer therapy might contribute to body composition changes and thereby impact outcomes. However, the effect of longitudinal body composition changes on outcomes in patients with advanced endometrial cancer is unknown. This study investigated the association between body composition changes during staging surgery and adjuvant chemoradiotherapy and outcomes in patients with stage III endometrial cancer.

#### Material and Methods

Pre- and post-treatment computed tomographic (CT) images of 131 patients with stage III endometrial cancer who were treated at 2 tertiary centers between 2008 and 2016 were analyzed. The skeletal muscle index (SMI), skeletal muscle radiodensity (SMD), and total adipose tissue index (TATI) were measured from 2 sets of CT images obtained at the level of the L3 vertebra. Patients with a reduction or increase in the SMD of  $\geq 5.0\%$  were classified as having 'SMD loss' or 'SMD gain', respectively. Predictors of overall survival (OS) and progression-free survival (PFS) were identified using Cox regression models.

#### Results

The median follow-up was 50.6 (range, 12.1-117.0) months. Overall, patients lost an average of 2.1% per 210 days (95% CI: -4.0 to -0.2;  $p = 0.03$ ) of SMD and 0.2% per 210 days (95% CI: -1.5 to 1.0;  $p = 0.70$ ) of SMI. Patients gained an average of 3.2% per 210 days (95% CI: -0.2 to 6.7;  $p = 0.07$ ) of TATI. Changes in SMD did not correlate with weight change (Spearman's  $\rho$  for SMD, -0.13;  $p = 0.13$ ). Changes in SMI and TATI positively correlated with weight change (Spearman's  $\rho$  for SMI, 0.20;  $p = 0.02$ ;  $\rho$  for TATI, 0.40;  $p = 0.001$ ). The 5-year OS for patients with SMD loss, stable SMD, and SMD gain were 59.7%, 94.0%, and 90.5%, respectively ( $p < 0.001$ ; Figure 1); the corresponding PFS were 55.9%, 92.8%, and 85.7%, respectively ( $p < 0.001$ ; Figure 1). On multivariable analysis, an SMD loss  $\geq 5.0\%$ /210 days of treatment was independently associated with poorer OS (hazard ratio: 10.20, 95% confidence interval: 2.24-46.42;  $p = 0.003$ ) and PFS (hazard ratio: 7.36, 95% confidence interval: 2.09-25.95;  $p = 0.002$ ). Pretreatment myosteatosis and sarcopenia, as well as changes in SMI and TATI during treatment, were not associated with survival. The pretreatment skeletal muscle gauge was associated with treatment modifications such as delays, dose reductions, and discontinuation of chemotherapy.

PO-0822 Muscle density loss during cancer therapy for advanced endometrial cancer portends poor survival  
J. Lee<sup>1</sup>, J. Lin<sup>2</sup>, C. Chang<sup>3</sup>, M. Wu<sup>1</sup>, Y. Chen<sup>1</sup>

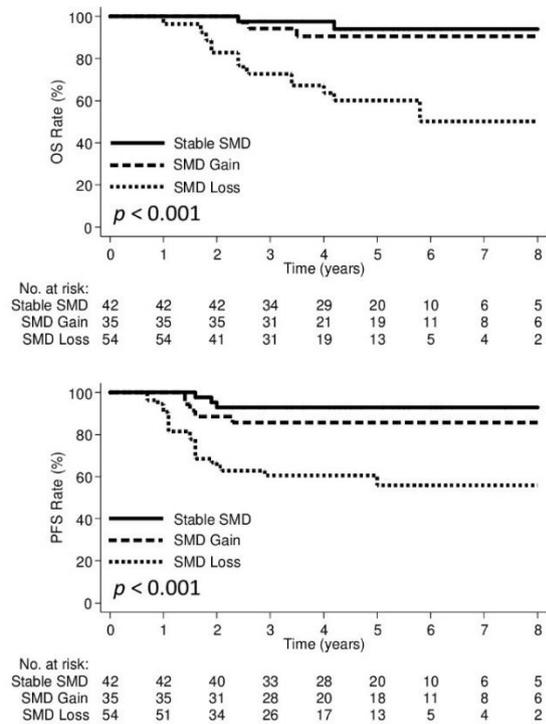

Figure 1 Kaplan-Meier curve demonstrating overall survival and progression-free survival according to skeletal muscle radiodensity change groups.

#### Conclusion

SMD decreased significantly during treatment and was independently associated with poorer survival in patients with stage III endometrial cancer who underwent staging surgery and adjuvant chemoradiotherapy. Furthermore, SMD loss was occult and occurred independently of weight change. Future studies are required to devise interventions aimed at preserving muscle based on individual body composition phenotypes to improve outcomes in advanced endometrial cancer.

#### PO-0823 Relevance of time interval and thermal dose for the clinical outcome of cervical carcinoma patients

M. Kroesen<sup>1</sup>, T. Mulder<sup>2</sup>, N. Holthe<sup>2</sup>, A. Aangeenbrug<sup>2</sup>, J.W. Mens<sup>2</sup>, L. Van Doorn<sup>3</sup>, M. Paulides<sup>4</sup>, E. Oomen-de Hoop<sup>2</sup>, R. Vernhout<sup>2</sup>, L. Lutgens<sup>5</sup>, G. Van Rhooen<sup>2</sup>, M. Franckena<sup>6</sup>

<sup>1</sup>Erasmus MC- University Medical Center Rotterdam, Radiation Oncology, Rotterdam, The Netherlands ;

<sup>2</sup>Erasmus MC- University Medical Center Rotterdam, Department of Radiation oncology, Rotterdam, The Netherlands ;

<sup>3</sup>Erasmus MC- University Medical Center Rotterdam, Department of Obstetrics and Gynaecology, Rotterdam, The Netherlands ; <sup>4</sup>Eindhoven University of Technology, Department of Electrical Engineering, Eindhoven, The Netherlands ;

<sup>5</sup>University Medical Centre Maastricht, Department of Radiation Oncology Maastricht, Maastricht, The Netherlands ; <sup>6</sup>Erasmus MC- University Medical Center Rotterdam, Department of Radiation Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

Addition of deep hyperthermia to radiotherapy results in improved local control (LC) and overall survival (OS) compared to radiotherapy alone in locally advanced cervical carcinoma patients. Previously, we have shown that the thermal dose of hyperthermia significantly correlates with LC and disease specific survival (DSS). Besides thermal dose, the effect of the time interval

between radiotherapy and hyperthermia is expected to influence treatment outcome. Therefore, we investigated the effect of the time interval on treatment outcome. In addition, we investigated the effect of thermal dose in a more recent cohort, including patients treated with image guided brachytherapy (IGBT).

#### Material and Methods

We included all primary cervical carcinoma patients treated with thermoradiotherapy at our institute between 1996 and 2005. For these patients, patient and follow-up data, but not the time interval, were collected previously. In addition, we included all primary cervical carcinoma patients treated between 2005 and 2016. Data on patients, tumors and treatments, including thermal dose parameter TRISE and the use of IGBT, were collected. Follow-up data on LC, disease free survival (DFS), DSS, OS and late toxicity were collected or updated. Kaplan Meier and Cox proportional hazards analyses were used for statistical analyses.

#### Results

400 patients were included. Kaplan Meier and univariate Cox proportional hazard analysis showed no effect of the time interval (range 30-230 minutes) on any of the clinical outcome measures. In multivariate Cox analysis, the thermal dose parameter TRISE (HR 0.649; 95% CI 0.501-0.840) and the use of IGBT (HR 0.432; 95% CI 0.214-0.972), but not the time interval, were significant predictors of LC. In a more recent cohort of 227 patients, treated since our previous analysis of the effect of thermal dose, the independent effect of TRISE on LC in multivariate analysis (HR 0.43; 95% CI 0.28 - 0.68) could be replicated. Moreover, in the 66 patients treated with IGBT from 2012 onwards, the thermal dose parameter TRISE remained to have a significant effect (HR 0.33; 95% CI 0.12 - 0.96) on LC in univariate analysis. The 17 patients having a higher than median radiation dose to the High-Risk CTV in combination with a higher than median thermal dose (TRISE), experienced an excellent 5-year LC, DFS and DSS of 100 percent.

#### Conclusion

The time interval between radiotherapy and hyperthermia, up to 4 hours, has no effect on clinical outcome. The positive association between thermal dose and clinical outcome is replicated in an independent, more recent, cohort of cervical carcinoma patients. Importantly, in patients receiving state-of-the-art IGBT, the additive effect of thermal dose on clinical outcome remains.

#### PO-0824 Postoperative VBT vs EBRT/VBT in patients with early stage of uterine carcinoma - our update results

A. Masarykova<sup>1</sup>, D. Scepanovic<sup>1</sup>, M. Pobjakova<sup>1</sup>, A. Hanicova<sup>1</sup>, M. Fekete<sup>1</sup>

<sup>1</sup>National Cancer Institute, Radiation Oncology, Bratislava, Slovakia

#### Purpose or Objective

Background. - In different trials, like PORTEC-2, Vaginal Brachytherapy (VBT) alone did not make a significant difference in the overall or disease-free survival when compared to patients treated with External Beam Radiotherapy (EBRT) only. However, there are no randomized trials comparing VBT alone with EBRT plus VBT.

Purpose/Objective. - The purpose was to show our update results of VBT alone versus EBRT plus VBT in preventing the vaginal recurrences in patients with early stage of uterine carcinoma, as well as disease-free survival and overall survival of these patients.

#### Material and Methods

Total of 307 patients with early stages of the uterine carcinoma have performed postoperative radiotherapy during the period from 2006 to 2010. There were two groups of patients: 55 patients with VBT alone and 252

patients with combined of EBRT/VBT. In the group with VBT alone, 96% of patients received 5x6Gy HDR Ir-192, however, in the group with combined of EBRT/VBT, 52% of patients received 46Gy and 48% over 46Gy (up to 50.4Gy) by EBRT and the various fractionation regimens by VBT, the most of these patients received 3x6Gy (62%) and 2x6Gy (28%) HDR Ir-192.

#### Results

Ten-year risk of locoregional recurrence was 3.2% in the EBRT/VBT group and 2% in the group of patients with VBT alone ( $p=1$ , Fisher's exact test). However, the 10-year risk of distant metastases was 10.2% in combined EBRT/VBT group and 3% in VBT alone group of patients ( $p=0.2085$ ). During the median follow-up time of 72 months, 89% of patients with VBT alone lived and 79% of patients with combined of EBRT/VBT ( $p=0.1827$ ). The rate of late toxicity, in particular genitourinary was significantly lower in the VBT alone than in the combined of EBRT/VBT group (7.6% vs. 29%) ( $p=0.0057$ ). Ten-year DFS was 76% for the VBT alone group and 70% for group of patients with combined of EBRT/VBT and 10-year OS was 80% for VBT alone versus 77% for combined of EBRT/VT group of patients ( $p=0.8686$ ,  $p=0.7310$ , respectively).

#### Conclusion

Also, our update results showed that VBT alone is as effective as combined of EBRT/VBT in preventing the vaginal recurrences and achieving comparable survival rates as adjuvant settings in patients with early stage uterine carcinoma.

#### PO-0825 Differential impact of GLUT1 overexpression between HPV16-positive and -negative cervical cancer

B.H. Kim<sup>1</sup>, J.H. Chang<sup>1</sup>

<sup>1</sup>SMG-Seoul National University Boramae Medical Center, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

Glucose transporter-1 (GLUT1) has been reported as a poor prognosticator associated with radioresistance and immune evasion through metabolic communication in various cancers, but little data is available on cervical cancer. Meanwhile, most cervical cancer is known to be caused by human papilloma virus (HPV), but treatment response and prognosis according to the HPV subtype are also unknown. This hypothesis-generating study was conducted to investigate the prognostic impact of GLUT1 in cervical cancer, in conjunction with HPV subtype.

#### Material and Methods

Clinicopathologic factors along with mRNA expression data were obtained using The Cancer Genome Atlas database. Tumor HPV status and immune cell abundance scores were extracted from previous publications. Total 298 patients with appropriate information were analyzed.

#### Results

High GLUT1 expression was associated with old age, squamous cell carcinoma, high tumor stage, pelvic lymph node metastases, and low hysterectomy rate. HPV16 positivity itself was not associated with other factors, except low tumor grade. Multivariate survival analysis revealed that high GLUT1 expression (HR 2.57,  $p = 0.002$ ) and HPV16 subtype (HR 0.56,  $p = 0.033$ ) were independent prognostic factors for OS. In the subgroup analysis, poor prognostic impact of high GLUT1 expression was maintained in the HPV16 (+) group ( $p < 0.001$ ), but not in the HPV16 (-) group ( $p = 0.495$ ). Decreased immune cell abundance scores of B cells, CD8 T cells, and Th1 cells by high GLUT1 expression were observed only in the HPV16 (+) group.

#### Conclusion

Despite of heterogenous treatments, our results suggested that GLUT1 expression and HPV16 subtype may have an independent prognostic value in cervical cancer. Especially in the HPV16 (+) group, GLUT1-mediated immunomodulation might be an important cause of treatment failure. Further proof-of-concept study is

warranted to identify novel immunometabolic targets to overcome radioresistance.

#### PO-0826 On the value of a prognostic tumour score in locally advanced cervical cancer

J.C. Lindegaard<sup>1</sup>, P. Petric<sup>1</sup>, A.M. Lindegaard<sup>1</sup>, K. Tanderup<sup>1</sup>, L.U. Fokdal<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

#### Purpose or Objective

Staging of cervical cancer is primarily based on clinical examination using the FIGO staging system. In early stage disease subjected to surgery pathology is included. However, imaging and particularly MRI may provide important additional prognostic information on local tumour extension not incorporated in FIGO. As these findings may be of significance in locally advanced cervical cancer (LACC) treated with definitive radiotherapy and brachytherapy, the aim of the present study was to investigate the feasibility of a simple but wide-ranging tumour score for methodical reporting and detailed prognostication.

#### Material and Methods

400 pts with LACC FIGO stage IB-IVA treated between 2005-2018 with external beam radiotherapy +/- concomitant cisplatin and image guided adaptive brachytherapy were included. The diagnostic work-up included clinical examination, FDG PET-CT and T2 weighted MRI. FIGO stage distribution was IB-IIA 9%, IIB 61% and III-IV 30%. The degree of involvement of 8 anatomical locations (cervix, left parametrium, right parametrium, vagina, bladder, ureter, rectum and uterine corpus) was scored according to a ranked ordinal scale with 0-3 points (Table 1). The total sum of points was calculated (T-score). Uni- and multi-variate analysis of the T-score in relation to age, performance status (WHO), comorbidity, histology, nodal-stage (PET-CT) and FIGO-stage was performed using Cox regression (SPSS). Endpoints were overall survival (OS), disease free survival (DFS), cancer specific survival (CSS) and local control (LC).

#### Results

The median T-score for all pts was 6 (range of 0-20). Potential prognostic findings not included in FIGO were involvement of the uterine corpus 41%, bladder wall 10%, and mesorectum/rectal wall in 12% (Table 1). Vaginal involvement was unaccounted for in 50% (IIB, IIB, IVA). In addition, bilateral parametrial invasion was found in 51% and bilateral hydronephrosis in 14%. Proximal only versus distal parametrial involvement was found in 41% and 27%, respectively. Based on the frequency distribution of the T-score, 4 equally sized risk groups were formed: 0-4, 5-6, 7-9 and >9 points (Table 1). The T-score was highly significant in both univariate and multivariate analysis and outperformed FIGO stage for all endpoints (OS, DFS, CSS and LC). When analysing the 245 pts with FIGO stage IIB (Figure 1) the T-score demonstrated a progressively worse OS with increasing score ( $p=0.021$ ). Similar results were obtained in 36 pts in stage IB-IIA ( $p<0.001$ ) and 119 pts in stage III-IV ( $p=0.041$ ).

#### Conclusion

The use of a tumour score based on both clinical examination and conventional MRI provided significant information capable of intra FIGO-stage prognostication. Confirmation of the results and tuning of the T-score in relation to the relative prognostic importance of the individual anatomical locations require analysis of an independent and larger cohort including especially more pts in stage IB-IIA.

**Table 1**

Anatomical locations used for scoring of local tumour extension in 400 patients with locally advanced cervical cancer. The degree of tumour involvement of the cervix, parametria, bladder, ureter, rectum, corpus uteri and vagina was scored from the integrated information obtained from gynaecological examination, endoscopy and MRI. The total score (T-score) was calculated by adding the points obtained from each location

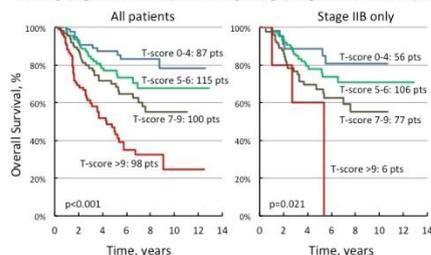

Location	Points	Scale	No of pts
Uterine cervix	0	Diameter <sup>§</sup> <20 mm	2 (0.5%)
	1	Diameter <sup>§</sup> 20-40 mm	7 (1.5%)
	2	Diameter <sup>§</sup> > 40 mm	4 (1%)
	3	Open*	387 (97%)
Parametrium left	0	Not involved	87 (22%)
	1	Proximal	161 (40%)

## Purpose or Objective

To evaluate differences in local stage by using the FIGO system (only gyn examination, ± endoscopy) compared to the T(NM) system based only on MRI in pats. with locally advanced cervical cancer treated with primary CCRT and MR-based IGABT within the EMBRACE study and to assess the uncertainties of FIGO staging next to available MRI.

## Material and Methods

All 1416 pats. from EMBRACE I based on data dump (08/2017) were considered for analysis. Pats. were examined through gyn exam and MRI before treatment. Recto- and/or cystoscopy were optional. Tumour width, height and thickness in millimeter, infiltration of vagina, left and/or right parametrial tissue, pelvic wall, and rectum and/or bladder were reported as assessed through gyn exam ± endoscopy only and based on MRI only. For each pat. independent re-staging was performed through the investigators based on the database: (1) local FIGO stage (FIGO Cancer Report 2012/2015) based on clinical findings only; (2) T-stage (8<sup>th</sup> edition, 2017) on MRI only. Descriptive statistics were used to sum up FIGO- and T-stages and cross tables to evaluate the differences in local staging.

## Results

Data was available from 1338 pats.: FIGO stage was IB in 264 (19.7%) pats., IIA in 83 (6.2%), IIB in 755 (56.4%), IIIA in 15 (1.1%), IIIB in 191 (14.3%), and IVA in 30 (2.2%). T-stage was T1b in 207 (15.5%) pats., T2a in 75 (5.6%), T2b in 834 (62.3%), T3a in 12 (0.9%), T3b in 125 (9.3%) and T4a in 85 (6.4%) (table 1).

Differences in local tumour staging were found in overall 388 pats. (28.9%) (table 1): 141 pats. (10.5%) had a lower T-stage compared to FIGO, whereas 247 pats. (18.5%) had a higher T-stage. In FIGO IIB, 95/755 (12.5%) had a change in T-stage, ranging from T1b1 to T4a. In overall FIGO IB, 128/264 (48.5%) changed to another T-stage. For FIGO IB1, change of stage was in 50.4%, to T1b2 and T2b. For FIGO IB2, change was in 46.3%, mainly to T2b. For FIGO IIA (n=83), change of T-stage was in 66% (T2a1 to T2a2; and to T2b). For FIGO IIIB change of stage was in 100/191 (52.4%) with 62 classified as T2b and 35 as T4a. The small group of FIGO IVA pats. (n=30) changed in 13.3% to another T-stage (T2b/T3b). Change of stage between FIGO and T-stage varies considerably between the different FIGO stages from min 12.5% in FIGO IIB to max 69.2% in FIGO IIA1.

FIGO staging as performed primarily through the centers was different from FIGO re-staging through the investigators in 154/1338 pats. (11.5%).

	T stage									change of stage/total
	1b1	1b2	2a1	2a2	2b	3a	3b	4a		
IB1	70	24	4	0	43	0	0	0		71/141 (50,4%)
IB2	9	66	0	4	40	0	4	0		57/123 (46,3%)
IIA1	4	0	12	15	8	0	0	0		27/39 (69,2%)
FIGO IIA2	1	4	4	17	15	1	0	2		27/44 (61,4%)
stage IIB	22	8	7	8	660	2	28	20		95/755 (12,5%)
IIIA	0	0	1	1	3	8	0	2		7/15 (46,7%)
IIIB	0	0	0	2	62	1	91	35		100/191 (52,4%)
IVA	0	0	0	0	2	0	2	26		4/30 (13,3%)
										388/1338 (28,9%)

Table 1: Cross table showing all EMBRACE patients evaluable (n=1338) with FIGO and T-stages as re-staged through investigators based on clinical findings only and MRI findings only: stage and change of stage are indicated in absolute numbers in detail and overall when classified either based on FIGO (clinical exam) or on T-staging (MRI) criteria.

### Conclusion

When comparing FIGO based on gyn exam only and T-stages based on MRI only in the frame of a primarily unblinded FIGO assessment, about one third of pats. could be classified differently. Upstaging is more frequent than downstaging. To minimize these uncertainties, a comprehensive knowledge of the differential value of clinical and MRI findings for the different areas of tumour spread is necessary to integrate these findings into one comprehensive final local T-stage at diagnosis "T<sub>clinical, imaging</sub>" as suggested by the recent ESGO ESTRO ESP recommendations.

### PO-0828 Chronic Lower Extremity Lymphedema in Gynecologic Cancer Patients : EBRT versus Brachytherapy

W.L. Chang<sup>1</sup>, H. Kang<sup>1</sup>, H.J. Kim<sup>1</sup>, K.S. Seo<sup>2</sup>, H.S. Kim<sup>3</sup>  
<sup>1</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University College of Medicine, Rehabilitation Medicine, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University College of Medicine, Obstetrics and Gynecology, Seoul, Korea Republic of

#### Purpose or Objective

The goal of this study is to compare the risks of chronic lower extremity lymphedema (LEL) between pelvic external beam radiation therapy (EBRT) and brachytherapy and further identify risk factors for chronic LEL in gynecologic cancer patients who underwent adjuvant radiotherapy after radical hysterectomy.

#### Material and Methods

FIGO stage I-III gynecologic cancer patients who underwent adjuvant RT between January 2013 and December 2017 after radical hysterectomy were reviewed retrospectively. After ruling out other causes of lower extremity edema, patients suspected for LEL were diagnosed as LEL when circumference difference between both legs was 2 cm or more. Patients diagnosed as LEL before RT were regarded as acute lymphedema. One-to-one case-matched analysis was conducted with propensity scores generated from patient, tumor and treatment characteristics.

#### Results

Of 252 patients who met the inclusion criteria, 216 (85.7%) patients were treated with pelvic EBRT with or without brachytherapy and 36 (14.3%) patients were treated with brachytherapy alone. Overall, 34 (13.5%) patients were diagnosed with LEL with a median follow-up of 30.6 months (range, 12.0 - 67.7 months). Median interval from surgery to the onset of LEL was 5.0 months (range, 1.1 - 31.7 months). The proportion of patients who were diagnosed with LEL in 6 months and one year was 55.9%

and 85.3%, respectively. In multivariate analysis, para-aortic lymph node dissection (HR, 2.537; 95% CI, 1.247 - 4.859; p=0.009), harvesting more than 30 pelvic lymph nodes (HR, 2.167; 95% CI, 1.050 - 4.472; p=0.037) and laparoscopic surgery (HR, 2.548; 95% CI, 1.127 - 5.760; p=0.025) were identified as independent risk factors for chronic LEL. After propensity score matching, EBRT group showed significantly higher chronic LEL rate than brachytherapy group (3-year LEL rate: 27.8% vs 10.8%, p=0.034).

### Conclusion

Chronic LEL was relatively common in patients with gynecologic cancer, especially during the first year after surgery. Para-aortic lymph node dissection, laparoscopic approach and harvesting more than 30 pelvic lymph nodes during surgery were risk factors for chronic LEL. Compared with brachytherapy, adjuvant pelvic EBRT was also significantly associated with an increased risk of chronic LEL.

### PO-0829 MRI-based texture analysis of lymph node for predicting clinical outcome in cervical cancer patients

S. PARK<sup>1</sup>, M.H. Hahm<sup>2</sup>, S. Na<sup>3</sup>, G.O. Chong<sup>4</sup>, S.Y. Jeong<sup>5</sup>, J.E. Lee<sup>1</sup>, M.K. Kang<sup>1</sup>, M.Y. Kim<sup>6</sup>, J. Kim<sup>1</sup>

#### Purpose or Objective

The aim of this study was to evaluate the feasibility of MRI-based texture analysis of metastatic lymph nodes for predicting survival of node-positive cervical cancer.

#### Material and Methods

We enrolled 89 patients with node-positive cervical cancer with initial magnetic resonance imaging (MRI) for staging. All patients were treated with definitive chemoradiotherapy in our institution, from 2006 to 2016. The criterion for a metastatic lymph node was defined as a maximum short axis diameter of  $\geq 8$  mm on pretreatment MRI. T2-weighted image (T2WI) and contrast-enhanced image (CE) of metastatic lymph nodes were segmented semi-automatically. Voxel based texture analysis of mathematical parameters in addition to first order statistics for semi-automatically segmented metastatic lymph nodes were done. The local progression-free survival (LRFS), regional progression-free survival (RPFS), distant metastasis-free survival (DMFS), disease-free survival (DFS), and overall survival (OS) were estimated using the Kaplan-Meier method, and the differences were compared using log-rank tests. P values of < 0.05 were considered statistically significant.

#### Results

First order statistics including median (p = 0.023), entropy (p = 0.021) and uniformity (p = 0.015) and parameters of gray level co-occurrence matrix including homogeneity (p = 0.023) and normalized inverse difference (p = 0.023) were significantly associated with RPFS. Entropy (p = 0.012) and uniformity (p = 0.030) were found to be associated with DFS. Median value from first order statistical method was associated with OS (p = 0.023).

#### Conclusion

MRI-based texture analysis of metastatic lymph node could provide quantitative and objective assessment for predicting clinical outcome in node-positive cervical

cancer patients treated with definitive chemoradiotherapy.

### PO-0830 Assessment of setup margins and additional subsite anisotropic margin expansions in cervical IGRT.

P. Naga CH<sup>1</sup>, U. Mahantshetty<sup>1</sup>, A. Nachankar<sup>1</sup>, Y. Ghadi<sup>1</sup>, L. Scaria<sup>1</sup>, D. Aravindakshan<sup>1</sup>, S. Sastri<sup>1</sup>, L. Gurram<sup>1</sup>, S. Shrivastava<sup>1</sup>, P. Naga CH<sup>1</sup>

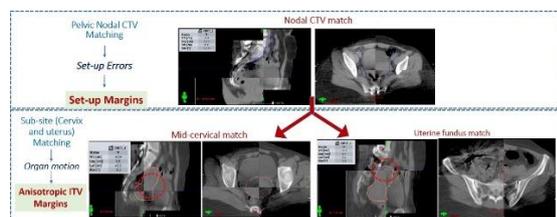

<sup>1</sup>Tata memorial hospital, Radiation oncology, Mumbai, India

#### Purpose or Objective

The movements of utero-cervical complex, variation in organ filling (rectal and bladder), tumor regression and set-up uncertainties during the course of radiation pose a major challenge for the use of conformal radiation techniques in the treatment of cervical cancers. This prospective, observational study aimed to assess of set-up margins and further sub-site anisotropic margin expansions by quantifying set-up errors and organ motion, respectively in cervical cancer image-guided radiation therapy (IGRT).

#### Material and Methods

Patients with locally advanced cervical cancer undergoing definitive pelvic radio (chemo) therapy between April 2011 and April 2017 were included. Daily pre-treatment 3D-volumetric kilo-voltage, cone-beam computed tomography (kV-CBCT) of pelvic region was acquired. Initially co-registration of daily CBCT with the planning CT images was done to match pelvic vessels/CTV pelvic nodal region after initial rigid alignment based on bony anatomy. Subsequently, soft-tissue matching was done to record the residual set-up errors to assess organ motion at the levels of mid-cervical canal and uterine fundus, separately (Figure 1).

**Figure 1** : Representative sagittal and axial images illustrating CBCT matching at nodal-region CTV, mid-cervical and uterine fundus. Mean translational displacements, systematic, and random errors of the study population for matching at three levels were calculated. Set-up margins for clinical target volume (CTV) to planning target volume (PTV) and additional sub-site an-isotropic margin expansions for cervix and uterine region were derived separately using published margin recipes.

#### Results

Data acquired from 1389 kV-CBCT scans of 70 patients was considered for analysis. The recorded mean ( $\pm$ SD) displacements, systematic error ( $\Sigma$ ), random error ( $\sigma$ ) distribution along the six directions [left (X+) & right-lateral (X-), anterior (Y+) & posterior (Y-) directions and superior (Z+) & inferior (Z-)] in millimeter for pelvic nodal CTV region, mid-cervix, and uterine fundal matching is tabulated in Table 1. The calculated CTV-to-PTV margin and sub-site an-isotropic margin recipe for 95% coverage were 7.0 & 8.9 (bilaterally), 10.3 & 7.2 (antero-posteriorly) and 8.5 & 9.8 (supero-inferiorly), respectively. The obtained an-isotropic margin expansions for mid-cervix is 7.3 & 7.7, 8.5 & 6.7 and 9.5 & 8.5, respectively. Similarly, for uterine region, 7.3 & 7.6, 10.2 & 10.4 and 20.9 & 12.6, respectively (Table 1).

	Set-up errors (mm)				Organ motion (mm)									
	CTV pelvic nodal region				Cervix				Uterus					
	Mean ( $\pm$ SD)	$\Sigma$	$\sigma$	Margin	Mean ( $\pm$ SD)	$\Sigma$	$\sigma$	Margin	Mean ( $\pm$ SD)	$\Sigma$	$\sigma$	Margin		
X+	4.5 ( $\pm$ 3.4)	2.0	2.8	7.0	X+	4.5 ( $\pm$ 3.4)	2.1	3.0	7.3	X+	4.2 ( $\pm$ 3.1)	2.2	2.7	7.3
X-	4.5 ( $\pm$ 3.6)	2.7	3.3	8.9	X-	4.6 ( $\pm$ 3.4)	2.3	2.9	7.7	X-	4.6 ( $\pm$ 3.8)	2.3	2.7	7.6
Y+	5.3 ( $\pm$ 4.6)	3.0	4.1	10.3	Y+	5.4 ( $\pm$ 4.0)	2.3	4.0	8.5	Y+	6.6 ( $\pm$ 4.8)	2.7	4.8	10.2
Y-	4.9 ( $\pm$ 3.7)	1.9	3.5	7.2	Y-	5.1 ( $\pm$ 3.6)	1.8	3.1	6.7	Y-	7.4 ( $\pm$ 5.2)	3.0	4.3	10.4
Z+	5.1 ( $\pm$ 4.2)	2.4	3.5	8.5	Z+	5.5 ( $\pm$ 4.8)	2.7	3.9	9.5	Z+	12.1 ( $\pm$ 9.4)	6.6	6.2	20.9
Z-	4.7 ( $\pm$ 4.4)	2.9	3.6	9.8	Z-	4.7 ( $\pm$ 4.0)	2.3	3.8	8.5	Z-	6.6 ( $\pm$ 4.7)	4.0	3.8	12.6

**Table 1** : The mean, SD of target-motion along with systematic error ( $\Sigma$ ), random error ( $\sigma$ ) distribution and calculated margin (mm) recipe for 95% coverage in all three translational directions.

#### Conclusion

Our prospective study suggests set-up margins (CTV to PTV) to account for daily set-up uncertainties and an additional anisotropic margin for the cervical and uterine regions to account for organ motion during cervical cancer radiotherapy. Further research is warranted to evaluate various adaptive strategies for cervical cancer radiotherapy.

### PO-0831 Effect of pre-treatment hematological indices on survival in cervical cancer

U. Mahantshetty<sup>1</sup>, P. Naga CH<sup>1</sup>, L. Gurram<sup>1</sup>, R. Hawaldar<sup>2</sup>, S. Chopra<sup>3</sup>, S. Gupta<sup>4</sup>, J. Ghosh<sup>5</sup>, J. Bajpai<sup>5</sup>, S. Gulia<sup>5</sup>, J. Agarwal<sup>1</sup>

<sup>1</sup>Tata Memorial Hospital, Radiation Oncology, Mumbai, India ; <sup>2</sup>Tata Memorial Hospital, Clinical Research Secreteriat, Mumbai, India ; <sup>3</sup>ACTREC- Tata Memorial Centre, Radiation Oncology, Navi Mumbai, India ; <sup>4</sup>ACTREC- Tata Memorial Centre, Medical Oncology, Navi Mumbai, India ; <sup>5</sup>Tata Memorial Hospital, Medical Oncology, Mumbai, India

#### Purpose or Objective

Recent emerging evidences support that certain systemic indices of immune inflammation can act as independent prognostic factors for various cancers including cervical cancer. In this study, we investigate prognostic implications of pre-treatment hematological factors/indices in locally advanced cervical cancers treated with radical chemoradiation.

#### Material and Methods

The electronic medical records of 1051 cervical cancer patients of FIGO stage IB2 - IVA treated with chemoradiation in prospective studies between 2003 and 2017 were reviewed. All clinical parameters such as age, stage, histological type, nodal involvement and hematological parameters (haemoglobin, platelets, absolute neutrophil count, absolute lymphocyte count, absolute monocyte count) were recorded. Neutrophil/lymphocyte ratio (NLR), platelet/lymphocyte ratio (PLR) and lymphocyte/monocyte ratio (LMR) and prognostic nutritional index (PNI, defined as  $10 \times$  albumin concentration (g/dl)+0.005  $\times$  total lymphocyte count ( $\mu$ l)) were calculated. Univariate and multivariate (Cox regression) analyses was performed to evaluate impact of these factors on disease free survival (DFS) and overall survival (OS).

#### Results

With a median follow-up of 57 months (range, 3-169 months), the 5 years DFS and OS were 65% and 66.5%, respectively. **Table 1** shows in detail the outcome of univariate and multivariate analyses. On multivariate analysis, FIGO stage (HR, 1.57;  $p=0.000$ ) and LMR (HR: 0.92;  $p=0.007$ ) significantly affected DFS while FIGO stage (HR, 1.79;  $p=0.000$ ), LMR (HR, 0.92;  $p=0.008$ ), PNI (HR, 0.97;  $p=0.024$ ) and haemoglobin (HR, 0.93;  $p=0.039$ ) significantly affected OAS. Apart from FIGO Stage, LMR had a significant impact on both DFS and OAS.

Table 1: Univariate and multivariate survival analysis (n=1051).

		Univariate analysis (P-Value)		Multivariate analysis (P-Value)					
		DFS	OS	DFS			OS		
				P value	HR	95%CI	P value	HR	95%CI
<b>Clinico-pathological characteristics</b>									
Age (yrs)	≤50 Vs >50	0.272	0.471	0.088	0.99	0.97-1.00	0.33	0.99	0.98-1.00

PLR	≤142 Vs >142	0.001*	0.000*	0.307	1.00	0.99-1.00	0.156	1.00	1.00-1.003
LMR	≤4.4 Vs >4.4	0.000*	0.000*	0.007*	0.92	0.86-0.98	0.008*	0.92	0.86-0.98
PNI	≤41 Vs >41	0.000*	0.000*	0.276*	0.99	0.96-1.01	0.024*	0.97	0.94-0.99

\*Statistically significance set at p ≤0.05

**Conclusion**

In cervical cancer patients treated with chemoradiation, LMR over and above established prognostic factors including FIGO Stage, hemoglobin and nutritional status seems to be an important independent prognostic factor for DFS and OAS. Further research to get more insights and clinical relevance is warranted.

**PO-0832 Para-aortic lymphadenectomy and recurrence patterns in locally advanced cervical cancer**

M.M. Soraya<sup>1</sup>, D.C. Moreno Santiago<sup>1</sup>, J. Giral Lopez de Sagredo<sup>1</sup>, R. Verges Capdevilla<sup>1</sup>

<sup>1</sup>Vall D'Hebron, radiation oncologist, Barcelona, Spain

**Purpose or Objective**

The aim of this study is to investigate the impact of primary para-aortic lymphadenectomy (PAL) on recurrence patterns in locally advanced cervical cancer patients.

**Material and Methods**

Data of all patients with cervical cancer treated in curative intent with external beam and brachytherapy +/- chemotherapy from 2001 to 2016 in our center were included in this retrospective study. Surgical staging was routinely performed before definitive treatment. However, there were some situations according to patient-related, tumor-related or logistic-related in which the surgical staging was not performed. Radiation was delivered to a clinical target volume comprising the uterus, cervix, vagina, parametrial tissues and pelvic nodes. Para-aortic region irradiation was performed only when there were prove of involved nodes by image or surgical staging.

**Results**

A total of 207 patients were included. The median follow-up was 39.6 months. Table 1 details clinical characteristics of the population according to surgical staging. Loco-regional and distant image staging was evaluated with MRI (97.1% of patients) and PET-CT (32.7% of patients, n=67), finding in MRI 46% of the patients with nodal affection and 55.2% (37) in PET-TC, without significative differences in the surgical vs non surgical groups. Para-aortic lymphadenectomy (PAL) via laparoscopic was done in 141 patients (68.1%). Globally 108 (54.5%) patients were diagnosed with pelvic positive and/or PA nodal involvement of which 35 received extended volume radiotherapy, 19% of them without surgical staging and 23% of those operated, without significant differences.

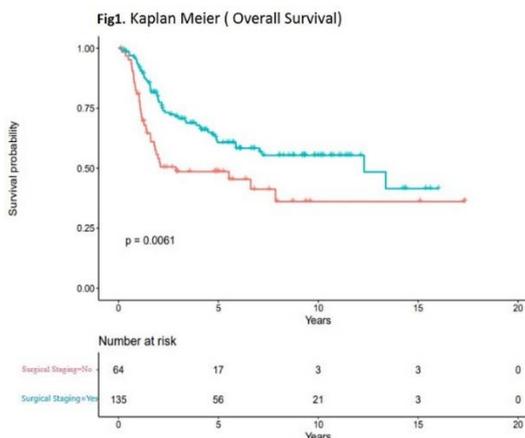

Recurrence happened in 68 patients (34%), 23 (35.4%) without surgical staging and 45 (33.3%) with PAL (p=ns). Local recurrence was described in 38.2% (39.1% and 37.8%, without and with PAL respectively; p=ns). The regional recurrence was 38.2%, 30.4% and 42.2 % respectively without significant differences between groups. The distance recurrence appeared in 52.9% to all group, 56.5%

for non-surgery group and 51% for surgery group, again without differences between the groups.

However overall survival (OS) was 46.87% in the non surgical group vs 60.75% in the surgical (p=0.0061) (Fig.1), probably due to the worse clinical features related with age, performance status and stage of tumor in the non surgical group (p<0.005).

Table 1: Main characteristics and recurrence patterns in patients with cervical cancer according to surgical staging

Characteristics	ALL n=206	Surgical Staging NO n=66	Surgical Staging YES n=141	p value
<b>Age</b>	52 (43.0-64.2)	65.5 (50.2-77.0)	49.5 (41.0-58.0)	<0.005
<b>ECOG</b>				<0.005
ECOG 0-1	193 (96.0%)	58 (87.9%)	135 (100%)	
ECOG 2-3	8 (4.0%)	8 (12.1%)	0 (0%)	
<b>FIGO stage</b>				<0.005
FIGO IB2-IIA2	80 (39.4%)	14 (21.2%)	66 (48.2%)	
Other FIGO stages	123 (60.6%)	52 (78.8%)	71 (51.8%)	
<b>Type of recurrence</b>	ALL n=68	Surgical Staging NO n=23	Surgical Staging YES n=45	p value
<b>Local failure</b>	26 (38.2%)	9 (39.1%)	17 (37.8%)	NS
<b>Regional failure</b>	26 (38.2%)	7 (30.4%)	19 (42.2%)	NS
Pelvic failure	17 (25%)	2 (8.7%)	15 (33.3%)	
PA failure	11 (16.2%)	5 (21.7%)	6 (13.3%)	
<b>Distant failure</b>	36 (52.9%)	13 (56.5%)	23(51.1%)	NS

**Conclusion**

In our group, those patients who underwent surgical staging had a better overall survival. However, Primary PAL does not demonstrate an improvement in loco-regional and distant control. This data suggest that PAL without prophylactic extended volume irradiation does not change the patterns of recurrence in patients with locally advanced cervical cancer.

**PO-0833 Development of a nomogram for predicting overall survival in patients with Cervical cancer**

A.B.A. Osong<sup>1</sup>

<sup>1</sup>Maastricht University, Maastr, Hasselt, Belgium

**Purpose or Objective**

The International Federation of Gynecologists and Obstetricians (FIGO) stage is a prominent prognostic factor for estimating patient's survival in cervical cancer. However, several studies have shown that additional clinical and pathologic variables further improve the prognostic performance of patient survival models. These survival models can be graphically represented in nomograms, enabling the estimation of a patient's overall survival (OS) probability based on these factors. However, these models should be contemporary to the additional routine clinical data. In this work, we developed and internally validated a nomogram to predict OS for cervical cancer patients treated with radiotherapy, optionally in combination with hyperthermia or chemotherapy.

**Material and Methods**

This study included a cohort of 494 patients treated primarily with radiotherapy between 1978 and 2015 with a curative intent. We analyzed five clinical variables, i.e. FIGO stage (IB - IIB), age, tumor diameter (<4cm and > 4cm), histologic type (squamous or adenocarcinoma), treatment (Radiotherapy (XRT), XRT and Chemotherapy, XRT and Hyperthermia). The outcome of interest is OS defined as the time between first treatment and death or last follow-up. Univariate analyses consists of Kaplan-Meier plots and log-rank test. The final multivariate Cox proportional hazard regression model used to build the nomogram included only variables with a statistical significance (p<0.05). The nomogram's performance was assessed by comparing the predicted values of the surviving and non-surviving patients to the observed values in a bootstrapped-internal calibration plots and the concordance index (C-index) where a C-index = 1 indicates a perfect prediction and C-index = 0.5 is comparable to a random guess.

**Results**

We excluded 64 patients with incomplete data reducing the cohort to 430 patients. The mean age in this cohort was 60 (29 - 93) years; Table 1 shows the variable distribution for this study cohort, including the univariate and multivariate statistical significance. The 5 and 10-year overall survival rate since first treatment was approximately 82% and 80% with a median survival period of 90 and 101 months respectively. The model had a C-index of 0.64 with a standard error of 0.024. Figure 1 shows the nomogram representation of the model and the bootstrapped calibration plot. The calibration plot shows an agreement between the models' predicted values and the observed values since most of the points are close to the diagonal line, which indicates perfect prediction.

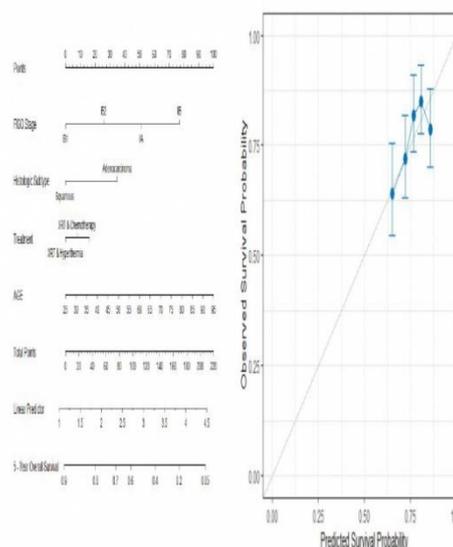

Figure 1: Nomogram for 5-year overall survival(Left) and Calibration curve of the nomogram for 5-year survival(Right)

**Conclusion**

We developed and internally validated a nomogram to predict 5 and 10 - year overall survival for patients with cervical cancer who were treated with radiotherapy, optionally combined with hyperthermia or chemotherapy.

Table 1: Univariate and multivariate analyses

Factors	Levels(n)	Univariate			multivariate		
		HR	95% CI	P-value	HR	95% CI	P-value

**Poster: Clinical track: Prostate**

**PO-0834 Virtual imaging for patient information on radiotherapy planning and delivery for prostate cancer.**

J. Sulé-Suso<sup>1</sup>, J. Bisson<sup>1</sup>, S. Jassal<sup>1</sup>, M. Martínez<sup>2</sup>, N. Huxley<sup>1</sup>, C. Ellis<sup>1</sup>, D. Chambers<sup>1</sup>, K. Fields<sup>1</sup>, C. O'Donovan<sup>1</sup>, C. Edwards<sup>2</sup>, S. Vengalil<sup>1</sup>, R. Bhana<sup>1</sup>  
<sup>1</sup>University Hospital of North Midlands, Oncology Department, Stoke on Trent, United Kingdom ;  
<sup>2</sup>University Hospital of North Midlands, Physics- Oncology department, Stoke on Trent, United Kingdom

**Purpose or Objective**

To assess whether provision of information on RT planning and delivery with a virtual reality (VR) system (VERT) improves, apart from patient's satisfaction<sup>1</sup>, patient's compliance to RT (holding better their water prior to each RT session), and reduces side effects.

**Material and Methods**

This was a randomised study where patients were allocated to group 1 (information on RT planning and delivery using the VERT system was given prior to starting RT) or group 2 (information on RT planning and delivery using the VERT system was given after the last day of RT). Ninety-two patients with prostate cancer receiving radical RT were included in the study. The study was approved by the local ethics committee. For each study patient, their planning CT Scan images and RT plan were uploaded onto the VERT system using the Digital Imaging and Communication in Medicine (DICOM) standard. Patients and relatives were shown using VERT and on a one-to-one basis with a radiographer, a standard room where RT is given, a linear accelerator, and how RT is planned and delivered using their own planning CT Scans. Emphasis was put on the area to be treated and the organs around it. Bladder volumes were calculated from the planning CT Scan (prior to RT) and then on days 1, 2, 3 and then weekly

from the cone beam CT (CBCT) Scans. At the end of the exercise, patients were asked to fill in a quality of life questionnaire (EORTC QLQ-PR25) prior to RT, half-way through RT, on the day of the last fraction of RT and at 3 and 6 months after RT to assess side effects. Radiotherapy was performed using 10 or 6 MV photons delivered from a Varian 2100IX linear accelerator. Treatment planning was performed on the 'Eclipse' system using CT scans. A dose of 74 Gy in 37 fractions was delivered. Every patient completed the prescribed treatment.

#### Results

There were no differences in the number of CBCT scans between group 1 (39.0 CBCT scans per patient) and group 2 (38.5 CBCT scans per patient). No differences were seen either in the reduction of bladder volumes between groups 1 and 2. The percentages of the bladder volume for group 1 and group 2 patients when compared to the pre-RT bladder volume were 81.8 %  $\pm$  25.2 and 80.2 %  $\pm$  37.9 respectively at week 4, and 84.7 %  $\pm$  35.7 and 76.5 %  $\pm$  34.1 respectively on the last day of RT. Finally, based on the answers from the quality of life questionnaire, no differences in early or late side effects were seen between both groups of patients.

#### Conclusion

Providing information on RT planning and delivery using 3D imaging systems rather than 2D helped patients and relatives to better understand the complexity of RT planning and delivery<sup>1</sup>. However, no differences were seen regarding patients' compliance to RT or side effects from RT.

<sup>1</sup>A.O.U. Città della Salute e della Scienza, Oncology-Radiation Oncology, Torino, Italy; <sup>2</sup>A.O.U. Città della Salute e della Scienza, Medical Sciences- Nuclear Medicine Unit, Torino, Italy; <sup>3</sup>A.O.U. Città della Salute e della Scienza, Surgical Sciences- Division of Urology, Torino, Italy

#### Purpose or Objective

<sup>68</sup>Ga-PSMA-11 PET/CT is nowadays the most promising PET tracer in the detection of prostate cancer recurrence. The aim of this study is to assess the detection rate of this technique in patients with prostate cancer biochemical recurrence (BCR) with low PSA levels, and to evaluate which are the predictors of PET positivity.

#### Material and Methods

We prospectively enrolled patients referred to our Center between November 2016 and March 2018 with BCR, after primary treatment. All patients underwent <sup>68</sup>Ga-PSMA-11 PET/CT; in case of PSA >1.5 ng/ml the exam was performed only if previous choline PET/CT were negative. Clearly positive <sup>68</sup>Ga-PSMA-11 PET/CT findings were considered as true positive; dubious findings were explored by other imaging techniques and defined as true positive or true negative by a multidisciplinary consensus. Association between PET positivity and clinical patterns was evaluated by univariate and multivariate logistic regression models.

#### Results

A total of 140 <sup>68</sup>Ga-PSMA-11 PET/CT scans were performed; in 76 (54.3%) patients after radical surgical treatment only, in 3 (2.1%) patients after radiotherapy only and in 61 (43.6%) patients after radical surgery and adjuvant or salvage radiotherapy. Gleason Score (GS) was  $\leq$ 3+4 in 59 (42.1%),  $\geq$ 4+3 in 78 (55.8%) and not known in 3 (2.1%) patients, respectively. T stage was T1c-T2b-c in 69

(49.3%), T3a-b in 66 (47.1%) and not known in 5 (3.6%) patients, respectively. Median PSA value at the moment of PET/CT was 0.73 ng/ml (range 0.23-8.90); in particular, PSA was >0.2 and <0.5 ng/ml in 44 (31.5%), >0.5 e <1 ng/ml in 49 (35%), >1 and <1.5 ng/ml in 23 (16.4%) and >1.5 ng/ml in 24 (17.1%) patients, respectively. Median PSA doubling time and PSA velocity were 8.7 months (range 0.6-264.8) and 0.6 ng/ml/yr (range 0-30.2), respectively. <sup>68</sup>Ga-PSMA-11 PET/CT was considered positive in 57 cases (40.7%); recurrence was located in prostate bed (n=10), loco-regional lymph nodes (n=30), lymph nodes and bone (n=4), and distant sites (n=13). A significant association was observed for PSA velocity (median 0.9 in PET+ vs 0.35 ng/ml/yr in PET-, p<0.001), the 3 main risk factors for PET positivity were the last absolute PSA value before <sup>68</sup>Ga-PSMA PET/CT > 1 ng/ml (OR 5.64, 95% CI 2.23-14.26, p<0.001), a PSA doubling time  $\leq$ 8,7 month (OR 3.13, 95% CI 1.53-6.42, p 0.002) and a T3 stage (OR 4.33, 95% CI 2.06-9.10, p<0.001), both in univariate and multivariate logistic models. Patient management was modified in 29 cases (21%) on the basis of <sup>68</sup>Ga-PSMA-11 PET/CT findings.

#### Conclusion

Preliminary data suggest that <sup>68</sup>Ga-PSMA-11 PET/CT results may be clinically useful to detect prostate cancer recurrence at low PSA values, when dealing with the most aggressive disease patterns. In this setting, a proper selection of the patients that could really benefit of <sup>68</sup>Ga-PSMA-11 PET/CT is mandatory, in order to reach a more cost-effective profile. Larger prospective trials are needed.

#### PO-0836 Outcomes and factors by risk group after prostate brachytherapy: Cohort study in 2316 patients N. Katayama<sup>1</sup>, K. Nakamura<sup>2</sup>, A. Yorozu<sup>3</sup>, T. #### Purpose or Objective

The nationwide prospective cohort study in Japan (J-POPS) resulted in excellent biochemical freedom from failure (bFFF) among all patients who were treated during the first 2 years. Here we report the bFFF by risk group and treatment modality and the associated factors of bFFF by risk group in those patients with prostate cancer undergoing permanent seed implantation (PI) with or without external beam radiation therapy (EBRT).

#### Material and Methods

A total of 2,316 patients in 42 institutes were evaluated. bFFF was evaluated using the Phoenix definition (prostate-specific antigen (PSA) nadir + 2.0 ng/mL). If the PSA subsequently fell to  $\leq$ 0.5 ng/mL without intervention, this was considered a PSA bounce. The scheduled follow-up assessments were conducted every 3 months for the first 2 years, and every 6 months thereafter for 5 years after completion of radiation therapy. We estimated the bFFF by the Kaplan Meier method. We also identified the factors associated with the bFFF by the Cox proportional hazard model.

#### Results

The median age was 69.0 (range, 45-89) years. Median PSA was 6.8 (range, 1.6-42.0) ng/ml. 2,103 patients (23.4%)

had clinical stage T2a or less and 1,309 (56.5%) had Gleason score (GS) less than 7. 542 patients (23.4%) received supplemental EBRT and 1,137 (49.1%) received hormonal treatment (HT). Median follow-up period was 60.0 months (interquartile range, 58.7-60.9 months). The 5-year bFFF rate in all patients, 1028 low risk (LR) patients, 1114 intermediate risk (IR) patients and 133 high risk (HR) patients were 93.6%, 94.9%, 92.7% and 91.1%, respectively (Fig. 1). The 5-year bFFF rate in PI group and EBRT combination therapy group were 93.7% and 93.3%, respectively. On multivariate analysis, older age, GS and the percent volumes of the prostate receiving 100% of the prescribed dose (prostate V100) ( $p = 0.0003$ ,  $<0.0001$  and  $0.0107$ , respectively) in all patients, older age, PSA and prostate V100 ( $p = 0.0002$ ,  $0.0048$  and  $0.0012$ , respectively) in LR patients, and GS and HT ( $p = 0.0003$  and  $0.0077$ , respectively) in IR patients were significantly associated with bFFF. There were no significant predictors in HR patients (Table 1).

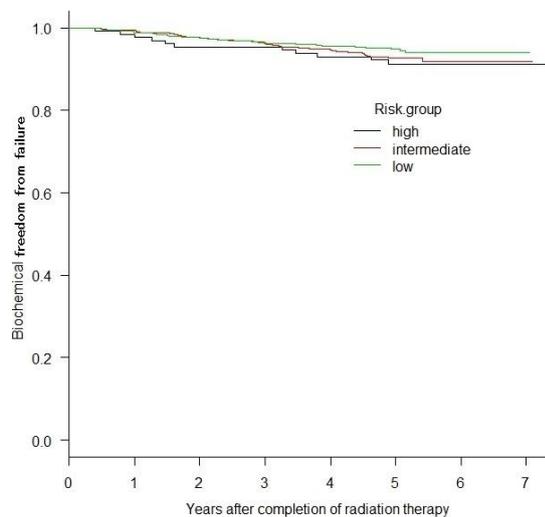

Table 1 Multivariate analyses for biochemical freedom from failure

## Purpose or Objective

Assessing predictors of patient-reported incontinence (INC) 1-year after post-prostatectomy IMRT, focusing on the impact of dose.

## Material and Methods

390 patients (pts) treated during 2012-2018 with adjuvant (ADV) or salvage (SALV) intent were enrolled in a registered (ClinicalTrials.gov) multi-centric cohort study aimed to assess predictors of intestinal, haematological and urinary toxicity. IMRT was delivered with conventional (n=228, 66-77.4Gy) or moderate hypo-fractionation (n=162, 65-75Gy, 2.2-2.7Gy/fr). Clinical and dosimetry data were prospectively collected including ICIQ-SF questionnaire for INC evaluation at baseline, half-RT, end-RT and every 6 months up to 5 years after IMRT. At the time of analysis, mature 1-year data were available; four ICIQ-based end-points were considered: a) "subjective" severe INC: ICIQ-SF>12; b) "subjective" moderate INC: ICIQ-SF>5; c) daily leakage: ICIQ3 (i.e. the score of question 3)>2; d) objective moderate INC: ICIQ3+4 (i.e. the sum of the scores of questions 3 and 4) >4. Predictors of 1-year prevalence were assessed through uni- (UVA) and multi-variable (MVA) logistic regression: potential clinical predictors included age, time from surgery, intent (ADV vs SALV), comorbidities and patient habits, type of surgery and baseline INC. The prescribed EQD2 (i.e.: PTV D<sub>mean</sub>) was also considered by applying alpha-beta values equal to 5 and 1Gy (EQD2\_5/EQD2\_1), reported in literature for late urinary toxicity. UVA/MVA were repeated excluding pts with the investigated symptoms at baseline.

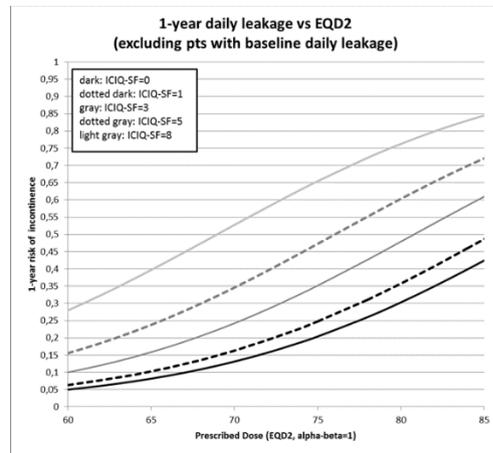

## Results

In total, 356/390 pts filled in baseline ICIQ-SF and 238/356 pts the 1-year ICIQ-SF. Pts experiencing a, b, c, d were 44 (18%), 131 (55%), 124 (52%) and 124 (52%) respectively. The corresponding baseline values were 33 (14%), 114 (48%), 102 (43%) and 103 (43%). For all end-points, baseline ICIQ-SF was the strongest predictor ( $p<0.0001$ , OR: 1.30-1.33), even excluding pts with baseline symptoms ( $p<0.0001$ , OR: 1.25-1.37). When excluding pts with symptoms at baseline, EQD2\_1 was predictive of both objective end-points c and d ( $p=0.02$ , OR: 1.089-1.090). At MVA, ICIQ-SF and EQD2\_1 were independent predictors: the resulting two-variable models well fit data (H&L test: 0.60-0.70) with good calibration (slope= 0.96,  $R^2=0.93$ ). The 1-year risk of daily leakage (n=132 patients, 42 daily leakage: 32%) is plotted in the figure against EQD\_1 for

few baseline ICIQ-SF values: ORs for EQD\_1 and ICIQ-SF were 1.11 ( $p=0.008$ ) and 1.28 ( $p=0.002$ ) respectively.

#### Conclusion

Baseline ICIQ-SF is the major predictor of 1-year INC. Despite the short follow-up, a dose-effect was found for objective INC when excluding pts with symptoms at baseline: the dose relationship was modulated by mild-moderate baseline symptoms. The association between EQD2\_1 and INC (not found for EQD2\_5,  $p>0.30$ ) is a confirmation of the previously reported high sensitivity to fractionation for INC, suggesting extreme caution in using moderate hypo-fractionation in the post-operative setting.

**PO-0838 Castrate testosterone predicts biochemical relapse free survival in non-metastatic prostate cancer**  
G. Ozyigit<sup>1</sup>, P. Hurmuz<sup>1</sup>, D. Yuze<sup>2</sup>, F. Akyol<sup>1</sup>  
<sup>1</sup>Hacettepe University- Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey ; <sup>2</sup>Hacettepe University- Faculty of Medicine, Department of Preventive Oncology, Ankara, Turkey

#### Purpose or Objective

We evaluated the effect of two different castrate testosterone levels, <50 and <20 ng/dL, on biochemical relapse free survival (BRFS) in patients with non-metastatic intermediate and high risk prostate cancers (PC) receiving definitive radiotherapy (RT) and androgen deprivation therapy (ADT).

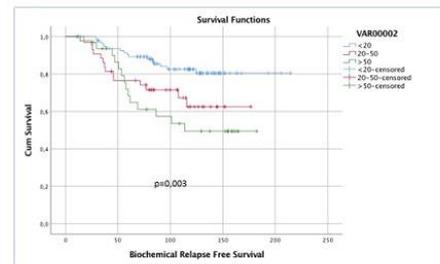

#### Material and Methods

We have a prospective treatment protocol for the definitive treatment of PC patients which was approved by the institutional ethical review board. Herein we included subset of patients with intermediate and high risk disease according to D'Amico risk group stratification. Between April 1998 and February 2011 173 patients with median age of 69 (range, 50-82 years) were treated. Radiotherapy was delivered by either three dimensional conformal technique (3DCRT) to a total dose of 73.4 Gy at the ICRU reference point or intensity modulated radiotherapy technique (IMRT) to a total dose of 76 Gy with daily fraction dose of 2 Gy. All the patients received 3 months of neoadjuvant ADT followed by RT and additional 6 months of ADT. ADT was delivered in the form of total androgen blockade (TAB): GnRH agonist plus antiandrogen. Testosterone levels were measured at each clinical follow-up visits. ASTRO Phoenix definition (nadir PSA+2 ng/dl) was used to define biochemical relapse. All patients should have at least 12 months of follow up.

#### Results

Median follow up duration was 125 months. Median initial PSA level was 14.2 ng/dL (range, 2-100 ng/dL) and median GS was 7 (range, 3-9). The characteristics of the patients

are shown in Table 1. All of the patients received 9 months of planned TAB. Nightly six patients (56%) had castrate testosterone level < 20ng/mL and 139 patients (80%) had castrate testosterone level < 50 ng/mL. Median testosterone recovery time after TAB cessation was 6 months (range, 6-30 months). Both cutoff values are valid at predicting BRFS. However patients with castration testosterone value <20 ng/dL have significantly better BRFS compared to other patient groups ( $p=0.003$ ) (Figure 1). When we compare two cutoff values using receiver operating characteristic curve (ROC) analyses, it was found that using 20 ng/dL is better than 50 ng/dL in predicting the BRFS (AUC= 0.63 versus 0.58, respectively).

Characteristics	Number (%)
AJCC 2010 T stage	
T1	3 (2%)
T2a	74 (43%)
T2b	14 (8%)
T2c	16 (9%)
T3a	40 (23%)
T3b	17 (10%)

Gleason score (median)	7 (3-9)
Initial PSA (median)	14 ng/dL (2-100 ng/dL)

D'Amico risk group	
intermediate	52 (30%)
High	121 (70%)
Perineural invasion	
Absent	103 (60%)
Present	56 (32%)
Unknown	14 (8%)
Percent positive core biopsy percentage	
≥50%	76 (44%)
>50%	59 (34%)
unknown	38 (22%)
Radiotherapy dose	
70 Gy	145 (84%)
75 Gy	16 (16%)

#### Conclusion

Castration testosterone level of less than 20 ng/dL achieved after primary RT plus ADT is associated with better BRFS. Using castration cut off value of 20 ng/dL is better in estimating the BRFS compared to 50 ng/mL. Further studies using current standard of care of high dose IMRT and longer ADT duration might support these findings.

**PO-0839 Correlation of recalculated-dose based on CBCT and toxicity in postoperative prostate cancer VMAT**

P. Buranaporn<sup>1</sup>, T. Jaikuna<sup>1</sup>, P. Dankulchai<sup>1</sup>  
<sup>1</sup>Faculty of Medicine Siriraj Hospital- Mahidol University, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand

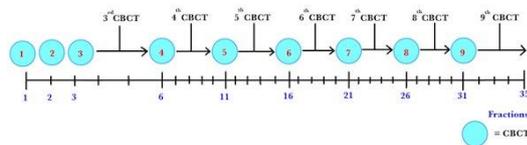

#### Purpose or Objective

To study relationship between GI and GU toxicity and estimated actual volume using recalculated-dose based on CBCT of deformable organs, rectum and bladder, receiving VMAT for postoperative prostate cancer patients.

#### Material and Methods

115 postoperative prostate cancer patients treated with VMAT technique from 2014-2017 were studied retrospectively. Rectum and Bladder were delineated on each CBCT image. Estimated actual dose on CBCT available fraction was recalculated on each CBCT image based on CBCT-calibration curve and was used as a

representative until next CBCT available fraction (as the figure shown). Recalculated dose was deformed into planning CT image by using deformable image registration from Velocity AI software version 3.2 to accumulate estimated actual dose in the treatment course. Dosimetric parameters were then studied, including V50, V60, V65, V70 and V75 for rectum and V65, V70, V75 and V80 for bladder based on QUANTEC study. Clinical toxicities of each case were reviewed from the patient records according to CTCAE version 5.0. Differences of mean volume between patients with grade 0-1 and grade 2-5 toxicities were compared using student T-test. Relationships between toxicities and volumes receiving doses were analyzed using logit analysis.

## Results

All patients with acute rectal toxicity grade 2 or more showed significant increase in volume receiving 50, 60, 65, 70, and 75 Gy radiation compared to those with acute rectal toxicity grade 0 and 1 ( $p=0.002$ ,  $0.007$ ,  $0.008$ ,  $0.021$ , and  $0.018$  respectively), while in late rectal toxicity grade 2 or more showed significant increase in volume receiving 50, 60, 70 and 75Gy radiation compared to group with late rectal toxicity grade 0 and 1 ( $p=0.011$ ,  $0.011$ ,  $0.011$ ,  $0.003$  respectively). For the correlation between rectal volume receiving 75 Gy and acute and late toxicities, the significant dose-response relationships were exhibited ( $p<0.001$ ). The probability for developing toxicities of 10%, 15% and 20% were related with volume receiving 75 Gy dose of 10.9, 15.7 and 19.3 cc in acute rectal toxicity and 10.9, 14.7 and 17.5 cc in late rectal toxicity. Acute and late bladder toxicity revealed no significant relationship with volume receiving radiation in all doses (65, 70, 75 and 80 Gy).

Probability of Grade 2-4 Acute Rectal Toxicity				
Volume (cc)	10%	15%	20%	p value
V50	46.5 (44.7 - 48.7)	51.8 (49.6 - 54.6)	55.8 (53.2 - 59.1)	1.000
V60	32.3 (31.0 - 33.8)	36.4 (34.8 - 38.3)	39.4 (37.6 - 41.7)	0.996
V65	24.0 (23.0 - 25.2)	27.3 (26.0 - 28.8)	29.7 (28.2 - 31.5)	0.650
V70	15.8 (14.5 - 17.6)	19.6 (18.0 - 21.7)	22.5 (20.5 - 24.9)	1.000
V75	10.9 (8.2 - 16.4)	15.7 (11.8 - 23.7)	19.3 (14.5 - 29.2)	0.000

Probability of Grade 2-4 Chronic Rectal Toxicity				
Volume (cc)	10%	15%	20%	p value
V50	45.5 (43.5 - 48.0)	52.226 (49.5 - 55.6)	57.2 (54.0 - 61.3)	0.920
V60	32.6 (30.8 - 34.8)	38.1 (35.8 - 41.0)	42.2 (39.5 - 45.8)	1.000
V65	25.2 (23.3 - 27.7)	30.8 (28.2 - 34.3)	35.0 (31.9 - 39.2)	1.000
V70	16.6 (15.0 - 18.8)	21.3 (19.1 - 24.2)	26.8 (22.1 - 28.4)	1.000
V75	10.9 (8.6 - 15.1)	14.7 (11.5 - 20.4)	17.5 (13.7 - 24.4)	0.000

## Conclusion

Estimated actual volume of rectum receiving high dose (V75) from CBCT-based recalculation was significantly related with grade 2-5 acute and late rectal toxicities in dose-response relationship. Adaptive planning should be considered for a novel approach in order to reduce toxicity.

## PO-0840 Two StereoTactic Ablative Radiotherapy Treatments for Localized Prostate Cancer (2STAR)

Department of Radiation Oncology- University of Toronto, Toronto, Canada ; <sup>4</sup>Department of Radiation Oncology- Odette Cancer Centre- Sunnybrook Health Sciences Centre, Department of Radiation Oncology- University of Toronto- Institute of Health Policy-Measurement & Evaluation- University of Toronto, Toronto, Canada

## Purpose or Objective

Ultra-hypofractionation is appealing for prostate cancer (PCa) due to the low  $\alpha/\beta$  ratio, and increasing the dose per fraction could improve the therapeutic index. Here we report the outcomes of a phase II trial in prostate SABR using a two-fraction protocol.

## Material and Methods

Patients had low or intermediate risk prostate cancer. Three gold fiducials were implanted for image guidance. The clinical target volume (CTV) included the prostate only, and the planning target volume (PTV) was a 3mm expansion on the CTV, enabled through the use of a rectal immobilization device. The dose prescribed to D99 CTV was 26 Gy in 2 weekly fractions (EQD2 110 Gy<sub>1.4</sub>). The primary endpoint was quality of life using the EPIC questionnaire, and the minimal clinically important change (MCIC) was defined as an EPIC QOL decrease  $> 0.5$  SD. Biochemical failure (BF) was defined as nadir  $+2$ . Four-year PSA response rate (4yPSARR) was defined as  $< 0.4$  ng/ml.

## Results

30 patients were accrued in 2014 with a median follow-up of 49.3 months. 10% had low-risk, 33% had favourable intermediate-risk and 56% had unfavourable intermediate-risk PCa. Five patients received a short course of ADT. Median nPSA was 0.2 ng/ml. One patient had BF and is being observed. 56.6% of patients had a 4yPSARR. The mean EPIC QOL change from baseline was -1.1 for the urinary domain, -1.04 for the bowel domain, and -3.8 for the sexual domain. Six patients had a MCIC in the urinary or bowel domain, and 3 had a MCIC in the sexual domain. The cumulative rate of grade 3-4 late GI/GU toxicity was 3%, one patient had a grade 3 hemorrhoid and one had a grade 3 urinary retention.

## Conclusion

Two-fraction SABR in prostate cancer is safe and feasible, with a minimal change in QOL experienced by patients and a low rate of late grade 3-4 toxicity. The PSA kinetics and biochemical control rates are encouraging given that the majority had unfavourable intermediate-risk disease, although longer follow-up is required.

## PO-0841 Salvage SBRT for local prostate cancer recurrence after radiotherapy: a GETUG retrospective study

### Purpose or Objective

After external beam radiotherapy (EBRT) for prostate cancer, the most common site of recurrence is the prostate. The aim was to assess the efficacy and safety of salvage stereotactic body radiotherapy (SBRT) for local prostate cancer recurrence after radiotherapy.

### Material and Methods

We retrospectively reviewed patients with biopsy proven local prostate cancer recurrence after EBRT or brachytherapy in centers from the French Genito-Urinary Group (GETUG) and in the European Institute of Oncology in Milan. Disease extension was assessed by pelvic multiparametric MRI and choline PET in 87% and 94% of patients, respectively. Treatment was proposed by multidisciplinary team in each center and delivered every other day. Median SBRT dose was 36 Gy (range, 25-36.25 Gy) in 6 fractions (range, 5-6). The primary endpoint was second biochemical recurrence-free survival defined according to the Phoenix criteria. Toxicity was assessed according to CTCAE v.4.03.

### Results

Between April 2010 and January 2017, 99 patients were treated with salvage SBRT with a median follow-up of 22.8 months (range 2.4-88.8 months). Twenty-two, 36 and 41 patients presented with low, intermediate and high risk at first diagnosis according to D'Amico classification. All patients presented with biopsy proven recurrence. The median time interval between first radiotherapy and salvage SBRT was 7.5 years (range 2-18 years). Median age at salvage SBRT was 71.2 years (SD 6.4 years) and median PSA at recurrence was 4.3 ng/mL (range, 2-38 ng/mL). Thirty four percent of patients were treated with androgen deprivation therapy for a median duration of 12 months. Whole gland, half prostate and focal treatment was delivered in 48, 18 and 33 patients respectively. Median nadir PSA after salvage SBRT was 0.5 ng/mL, obtained after a median time interval of 10.7 months. Second biochemical recurrence-free survival rates at 2 and 3 years were 72% [95% CI: 60%-81%] and 52% [95% CI: 39%-64%], respectively. Overall survival rates at 2 and 5 years were 96% [95% CI: 87-99] and 87% [95% CI: 71-95], respectively.

The initial D'Amico prognostic group was the only prognostic factor of biochemical recurrence-free survival ( $p=0.025$ ).

No patient developed grade  $\geq 2$  acute gastro-intestinal toxicity; grade 2 and 3 acute genito-urinary toxicity were 8% and 1%, respectively. Late toxicity included urinary events (fifteen grade 2 and one grade 3) and rectal events (two grade 2). One patient presented a neuritis of grade 3.

### Conclusion

With a short follow up, this largest series shows that salvage SBRT allows for good biochemical control and acceptable toxicity, with the key advantage of non-invasiveness of SBRT. This treatment is not a standard, and has to be administered with caution in competent centers. Further prospective studies are necessary to confirm these preliminary results <sup>1</sup>

Australia ; <sup>4</sup>Calvary Mater Newcastle Hospital, Department of Radiation Oncology, Newcastle, Australia ; <sup>5</sup>Westmead Hospital, Crown Princess Mary Cancer Centre, Sydney, Australia ; <sup>6</sup>Liverpool Hospital, Liverpool and Macarthur Cancer Therapy Centres, Sydney, Australia ; <sup>7</sup>Peter MacCallum Cancer Centre, Department of Physical Sciences, Melbourne, Australia ; <sup>8</sup>Peter MacCallum Cancer Centre, Department of Radiation Oncology, Melbourne, Australia ; <sup>9</sup>University of Sydney, NHMRC Clinical Trials Centre, Sydney, Australia

### Purpose or Objective

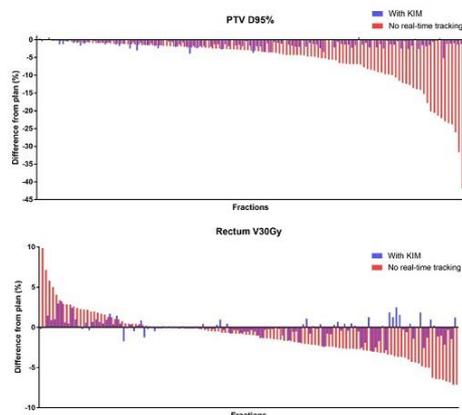

Kilovoltage Intrafraction Monitoring (KIM) is an emerging real-time target tracking technology for standard linear accelerators without the need for additional in-room hardware. In the TROG 15.01 Stereotactic Prostate Ablative Radiotherapy (SABR) with KIM (SPARK) trial, KIM was used to enable real-time target tracking in a multi-institutional setting. We test the primary hypothesis that real-time target tracking improves prostate dose distributions.

### Material and Methods

Forty-eight men with prostate cancer were treated with KIM-guided SABR delivering 36.25 Gy to the prostate in five treatments. During treatment the prostate (target) motion was corrected in real-time by implementing KIM-guided beam gating with couch shifts or multileaf collimator tracking. A dose reconstruction method was used to evaluate the dose to the target and organs at risk (OARs) with real-time KIM target tracking. The same dose reconstruction method was used to evaluate the dose that would have been delivered without real-time target tracking. Thus, all cases acted as their own internal controls. A treatment was considered a success if the target and rectal dose with real-time target tracking were closer to the planned dose than the target and rectal dose estimated without real-time target tracking. The prostate dose was represented by the dose to 95% of the planning target volume. The rectal dose was represented by the rectal volume receiving above 30 Gy. The trial was designed with 90% power and 95% confidence to rule in a KIM success rate of 2/3 in favour of the futility rate of 1/3.

### Results

Motion correction via beam gating or multileaf collimator tracking occurred in 51% (121/235) of the treatments where real-time target tracking was performed. The proportion of motion-corrected treatments with an improvement in dose distribution to both the prostate and rectum was 72% (87/121 treatments), significantly higher than the 33% prospectively defined futility cutpoint ( $p<0.0001$ ,  $\chi^2$ ). The prostate dose with KIM was closer to the plan by an average of 4.6% (range -1.7% to 41%). The rectal dose with KIM was closer to the plan by an average of 1.5% (range -1.2% to 9.7%). Waterfall plots of the prostate and rectal doses are shown in Figure 1.

**Figure 1.** Waterfall plots of the difference in dose from the plan for the treatments with interventions with KIM (blue) and without KIM (red) (top) prostate (PTV D95%) and (bottom) rectum (V30Gy).

## Conclusion

The analysis of the SPARK trial primary outcome measure showed that the KIM real-time target tracking is clinically useful in improving the prostate and rectal dose in the presence of target motion.

## PO-0843 Toxicity of a brachytherapy boost for prostate cancer patients

L. Bokhorst<sup>1</sup>, S. Van der Pol<sup>2</sup>, C. Niël<sup>2</sup>, C. Hoekstra<sup>2</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>Radiotherapiegroep, Radiation Oncology, Deventer, The Netherlands

### Purpose or Objective

To compare potency, urinary, and gastro-intestinal toxicity in men with prostate cancer receiving brachytherapy, external beam radiation therapy (EBRT), or EBRT with a brachytherapy boost (both low and high dose rate (LDR/HDR)).

### Material and Methods

From 2000-2018 all patients treated for prostate cancer in our institute were regularly followed and toxicity was prospectively collected at each follow-up visit using predefined questionnaires. For this analysis we compared IPSS score ( $\geq 20$  versus  $< 20$ ), potency score ( $\geq 5$  versus  $< 5$ ), on a 0 to 8 point scale with 8 being completely impotent and a score  $\geq 5$  being comparable with a CTCAE  $\geq 3$ ), urinary incontinence ( $> 1$  pad use per day), and rectal soiling (any pad use) between men receiving either brachytherapy alone (I-125, 145Gy), EBRT ( $\geq 76$ Gy), EBRT + LDR brachytherapy (50Gy + 100/110Gy), and EBRT + HDR brachytherapy (68Gy + 1x10-15Gy). Men receiving salvage treatment were excluded from this analysis.

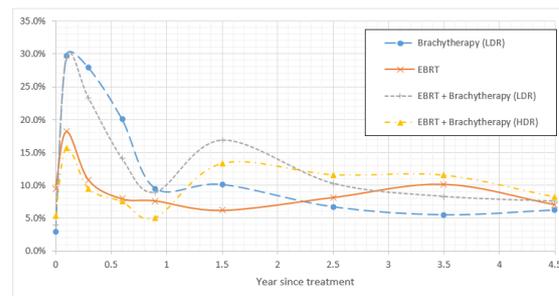

### Results

During follow-up 3291 patients were treated (59% EBRT, 23% brachytherapy, 10% EBRT + LDR, 8% EBRT + HDR) received a total of 28877 follow-up visits (1000 patients were followed more than 7 years). Data completeness differed per questionnaire but ranged from 77% for urinary incontinence up to 86% for potency scores.

The largest difference in IPSS scores were seen in the first year after treatment, with more and longer urinary problems for men receiving LDR brachytherapy with or without EBRT versus EBRT alone of combined with HDR brachytherapy (figure 1).

After 2.5 and 4.5 years of follow-up overall urinary incontinence was 2.7% and 3.6% respectively, overall impotency (in men receiving no (neo)adjuvant hormonal therapy) was 38.3% and 49.9% respectively, and rectal soiling was reported by 0.5% and 0.5% respectively. There were no significant differences in potency score, urinary incontinence or rectal soiling between the different treatment groups during follow-up (table 1).

**Figure 1.** Percentage of men with IPSS score  $\geq 20$  during follow-up for the different treatment options.

**Table 1.** Cox-proportional hazard models predicting impotency (potency score  $\geq 5$ ), urinary incontinence ( $> 1$  pad use per day), and rectal soiling (any pad use).

	Hazard ratio (95% CI)	p-value
<b>Impotency</b>		
<b>Treatment</b>		
EBRT	Reference	
Brachytherapy (LDR)	1.10 (0.93 - 1.30)	0.27

EBRT + HDR	1.11 (0.93 - 1.32)	0.26
<b>Hormonal therapy (HT)</b>		
No HT	Reference	
Neo-adjuvant HT	1.04 (0.90 - 1.21)	0.57
Adjuvant HT	1.30 (1.06 - 1.60)	0.01
Potency score at baseline	1.26 (1.24 - 1.29)	<0.001
Age at baseline	1.01 (1.00 - 1.01)	0.02
	<b>Hazard ratio (95% CI)</b>	<b>p-value</b>
<b>Urinary incontinence</b>		
<b>Treatment</b>		
EBRT	Reference	
Brachytherapy (LDR)	1.20 (0.77 - 1.84)	0.42
EBRT + LDR	1.41 (0.84 - 2.37)	0.19
EBRT + HDR	1.50 (0.81 - 2.78)	0.20
<b>Hormonal therapy (HT)</b>		
No HT	Reference	
Neo-adjuvant HT	1.26 (0.92 - 1.73)	0.14
Adjuvant HT	1.19 (0.63 - 2.24)	0.59
TURP at baseline	4.45 (3.30 - 6.00)	<0.001
Age at baseline	1.00 (0.99 - 1.01)	0.77
IPSS score at baseline	1.02 (1.01 - 1.04)	<0.001
	<b>Hazard ratio (95% CI)</b>	<b>p-value</b>
<b>Rectal soiling</b>		
<b>Treatment</b>		
EBRT	Reference	
Brachytherapy (LDR)	0.80 (0.55 - 1.16)	0.24
EBRT + LDR	0.81 (0.51 - 1.30)	0.39
EBRT + HDR	0.68 (0.38 - 1.22)	0.20
<b>Hormonal therapy (HT)</b>		
No HT	Reference	
Neo-adjuvant HT	1.15 (0.86 - 1.54)	0.34
Adjuvant HT	1.26 (0.74 - 2.12)	0.39
Age at baseline	1.00 (1.00 - 1.01)	0.32

## Conclusion

Adding a brachytherapy boost (either LDR and HDR) did not increase long-term potency urinary, or gastrointestinal toxicity as compared to EBRT or brachytherapy (LDR) alone.

## PO-0844 Target motion mitigation and dose painting in prostate cancer SBRT: results from a Phase II study

C. Greco<sup>1</sup>, O. Pares<sup>1</sup>, N. Pimentel<sup>1</sup>, V. Louro<sup>1</sup>, B. Nunes<sup>1</sup>, J. Sroom<sup>1</sup>, S. Viera<sup>1</sup>, D. Mateus<sup>1</sup>, Z. Fuks<sup>1</sup>  
<sup>1</sup>Fundação Champalimaud, Radiation Oncology, Lisboa, Portugal

### Purpose or Objective

to report biochemical, MR response and patient-reported quality of life (QoL) after extreme SBRT (9Gyx5) in patients with histologically proven organ-confined adenocarcinoma of the prostate using target motion mitigation and OARs dose painting.

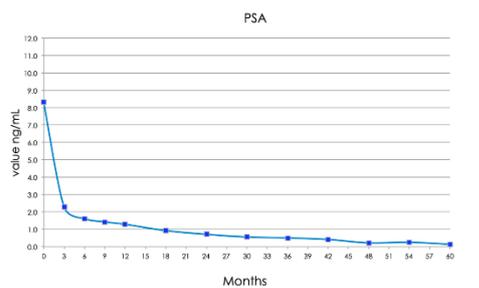

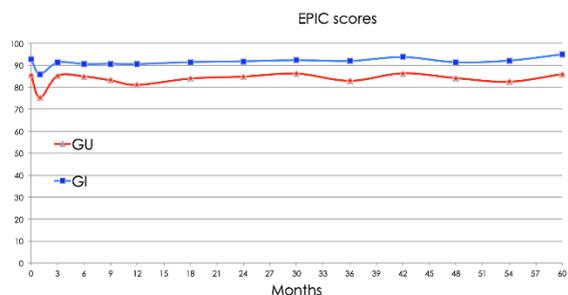

### Material and Methods

Between May 2013 and September 2017, 207 men were enrolled in an IRB-approved phase II prospective study to receive 45Gy in 5 consecutive daily fractions of 9Gy with critical tissue sparing (urethra, urogenital diaphragm and neurovascular bundles). Treatment planning was based on VMAT-IGRT with a negative dose-painting technique to fulfil organ-specific dose-volume constraints The CTV and

OARs were segmented on a fused CT/MR set acquired with organ motion-mitigation devices in place, namely, an endorectal air-filled balloon (150 cc) and a transponder-loaded Foley catheter. The CTV included the prostate gland and seminal vesicles and an isotropic 2 mm margin was added for the PTV. Validation a 2 mm margin expansion was performed in the first 60 patients. The urethral wall was anatomically identified through the catheter. All the other OARs were clearly identified on the MR image set. Strict QA procedures to validate the plan were carried out before final approval. At the time of treatment, anatomical reproducibility was achieved by recapitulating the positioning of the endoluminal devices. Precise PTV targeting was performed by CBCT and real-time motion management was obtained via beacon transponders, ensuring treatment delivery within the 2 mm PTV margin. Toxicities were graded according to the NCI CTCAE v.4, and QoL was assessed by EPIC and IPSS questionnaires. Tumor response was assessed by PSA and MRI at 6 and 12 months post-treatment.

### Results

On-line tracking with 2 mm motion tolerance was achieved in all cases. At a median follow-up of 33 months (range, 12-62), acute G2 GU and GI toxicities were 2% and 0%, respectively. Late G2 GU and GI toxicities were 1% and 0%, respectively. No G3 toxicity occurred. An initial 11% and 6% drop in the GU and GI EPIC domain scores, respectively, was observed at 1 month post treatment, returning to baselines by 3 months. Similarly, at one month median IPSS values increased from 7 to 11 also returning to baseline by 3-months. Post-treatment PSA kinetics show a rapid decline, reaching a median  $\leq 1$  ng/mL by 18 months. A total of 8 patients have relapsed biochemically (Phoenix definition). All relapses occurred in patients with intermediate risk disease between 24 and 36 months post-treatment. Actuarial probability of freedom from biochemical relapse at 48 months is 100% and 97% for low and intermediate risk patients, respectively. MR response at 6 months post-treatment correlated with long term bNED. 60 months bNED was 99% in patients with a negative DW-MR vs. 82% for those with persistent disease, respectively ( $p < 0.01$ ).

### Conclusion

These trial outcomes indicate that 5x9Gy SBRT can be consistently and safely delivered and is associated with excellent biochemical, imaging and QoL measures.

### PO-0845 What is the dosimetric benefit of daily position control imaging for prostate cancer radiotherapy?

M. Splinter<sup>1,2,3</sup>, T. Bostel<sup>2,4</sup>, C. Lang<sup>1,2,3</sup>, P. Häring<sup>1,2,3</sup>, N. Bougatf<sup>5</sup>, J. Debus<sup>2,3,6</sup>, N.H. Nicolay<sup>2,7</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Division of Medical Physics in Radiation Oncology, Heidelberg, Germany; <sup>2</sup>German Cancer Research Center, Clinical Cooperation Unit "Radiation Oncology", Heidelberg, Germany; <sup>3</sup>Heidelberg Institute for Radiooncology, National Center for Radiation Research in Oncology, Heidelberg, Germany; <sup>4</sup>University Medical Center Mainz, Department of Radiation Oncology, Mainz, Germany; <sup>5</sup>Heidelberg Ion Beam Therapy Center, Department of Radiation Oncology, Heidelberg, Germany; <sup>6</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany; <sup>7</sup>Freiburg University Medical Center, Department of Radiation Oncology, Freiburg, Germany

### Purpose or Objective

For prostate cancer patients, interfractional differences in bladder and rectum volumes as well as positioning inaccuracies result in dose deviations in the target volume (TV) and OARs; however, regarding the dose exposure associated with regular CT imaging, the optimal compromise between dose sparing and positioning accuracy remains to be elucidated. Therefore, the influence of daily vs. weekly CT-based positioning imaging on dosimetric deviations between accumulated applied and prescribed doses was analyzed.

### Material and Methods

The data of twenty prostate carcinoma patients (ten patients with primary radiation therapy for prostate cancer, ten patients with salvage treatments to the prostatic bed after previous prostatectomy), who underwent treatment (IMRT plan, 76.5Gy in 34fx for primary and 68Gy in 34fx for salvage treatments) were investigated (680 fractions in total). Prior to each daily fraction, position-control imaging (fx-CT) was carried out using a diagnostic in-room CT scanner (SOMATOM® Emotion Syngo, SIEMENS). For each patient, both daily and once-a-week (d1, d8, d15, d22, d29) fx-CTs were rigidly registered to the planning CT using the position correction vectors. TVs and all OARs were contoured and volumetrically compared to the structures of the planning CT. By using a deformable registration algorithm, doses were tracked, and applied dose were compared to the planned dose for each structure in dependence of the frequency of CT positioning imaging. Gamma analyses of the total dose distribution were performed at the tolerance level of 3%/3 mm for the  $\gamma < 1$  test, within the region receiving doses >10% of the maximum dose.

### Results

Volumetric changes and positional variations especially of the bladder revealed significant dose deviations between accumulated applied dose and planned dose for primary treatments and salvage treatments.

dose difference between applied dose and planned dose [Gy]	primary treatments		salvage treatments		
	daily fx-CTs	once a week fx-CTs	daily fx-CTs	once a week fx-CTs	
PTV	D50	-0.07±0.66	-0.61±0.77	0.11±0.65	-0.41±0.84
	D95	-8.94±6.14	-13.73±11.06	-2.88±4.70	-5.85±6.33
Bladder	D50	2.80±5.59	1.58±5.12	4.94±6.05	6.07±7.53
	D95	0.35±3.48	2.75±3.86	0.77±5.19	0.63±5.87

Doing once-a-week fx-CTs effected a decrease of the applied D<sub>50</sub> (0.54±0.45Gy; 4.79±7.84Gy) and D<sub>95</sub>

( $0.52 \pm 0.39$  Gy;  $2.97 \pm 2.88$  Gy) to the PTV compared to doing daily fx-CTs for primary and salvage treatments, which lead to a worse target volume coverage. For primary treatments, the applied  $D_{50}$  to the bladder was reduced ( $1.22 \pm 1.32$  Gy) by doing weekly fx-CTs instead of daily fx-CTs, while the applied  $D_{50}$  to the rectum was increased ( $2.40 \pm 2.21$  Gy). For salvage treatments, the applied  $D_{50}$  to the bladder was increased ( $1.13 \pm 3.64$  Gy) by doing weekly fx-CTs instead of daily fx-CTs, while the applied  $D_{50}$  to the rectum was reduced ( $0.14 \pm 1.47$  Gy). Doing once-a-week fx-CTs affected a decrease (3%) of the gamma passing rate compared to doing daily fx-CTs.

#### Conclusion

The observed variability resulted in significant dose increases and decreases of the  $D_{50}$  to the bladder and rectum, respectively. It could be shown that the dose decreases of the  $D_{50}$  and  $D_{95}$  to the PTV were statistically significant. Doing daily fx-CTs affected a higher gamma passing rate. Adaptive treatment planning may help to minimize the observed dosimetric deviations.

#### PO-0846 Dosimetric effects of a novel concept of adaptive radiotherapy for prostate cancer patients

M. Splinter<sup>1,2,3</sup>, T. Bostel<sup>2,4</sup>, C. Lang<sup>1,2,3</sup>, P. Häring<sup>1,2,3</sup>, J. Debus<sup>2,3,5</sup>, N.H. Nicolay<sup>2,6</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Division of Medical Physics in Radiation Oncology, Heidelberg, Germany; <sup>2</sup>German Cancer Research Center, Clinical Cooperation Unit "Radiation Oncology", Heidelberg, Germany; <sup>3</sup>Heidelberg Institute for Radiooncology, National Center for Radiation Research in Oncology, Heidelberg, Germany; <sup>4</sup>Mainz University Medical Center, Department of Radiation Oncology, Mainz, Germany; <sup>5</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany; <sup>6</sup>Freiburg University Medical Center, Department of Radiation Oncology, Freiburg, Germany

#### Purpose or Objective

Interfractional variations in bladder and rectal anatomy challenge current concepts of high-precision radiotherapy for prostate cancer patients, as the delivered dose may deviate from the planned dose. As the precise effects of these dose deviations are largely unknown and therefore plan adaptation strategies are difficult to evaluate, this analysis was aimed at investigating dosimetric consequences of a novel method for adaptive radiotherapy using an individualized plan database.

#### Material and Methods

The data of ten patients with prostate carcinoma (salvage radiotherapy to the prostatic bed, 68Gy in 34 fx, step-and-shoot IMRT) were investigated. Prior to each fraction, a diagnostic position-control-CT (fx-CT) was performed using a diagnostic in-room CT scanner (SOMATOM® Emotion Syngo, SIEMENS). Based on the daily fx-CT, the target volume and all OARs were contoured and volumetrically compared to the structures of the planning CT. One treatment plan was calculated based on the planning CT, and two additional plans were calculated based on the bladder filling observed using the first five fx-CTs, thereby creating a plan database that contained plans for low, intermediate and high bladder volume for each patient. Using a deformable registration algorithm for each daily fx-CT, applied doses were tracked and analyzed against the planned doses. The dosimetric effects were quantitatively compared.

#### Results

The use of a plan database did not result in significant benefits for all cases. In 9 of 10 cases, a better PTV coverage was reached. In 6 of these 9 cases, better sparing of the bladder and in 5 of these 6, better sparing of the rectum was achieved. A plan database was useful for 9, 6 or 5 cases of the cohort, depending on the maintained criteria. A plan database seemed particularly useful for patients with large or medium bladder volume (compared

to the first 5fx) at treatment planning. Interfractional variabilities resulted in an increase of  $D_{50}$  ( $0.40 \pm 0.38$  Gy) and a decrease of  $D_{95}$  ( $2.03 \pm 5.40$  Gy) to the PTV. The bladder volume showed the biggest interfractional volume variability ( $286 \pm 168$  ml), effecting a dose deviation of at mean  $7.76 \pm 6.05$  Gy of the  $D_{50}$ . By using a plan database, the applied dose of the bladder could be reduced by  $4.55 \pm 5.81$  Gy. The  $D_{50}$  of the PTV was marginally lower ( $-0.23 \pm 0.31$  Gy) and the  $D_{95}$  of the PTV was marginally higher ( $1.0 \pm 0.9$  Gy) than without using plan database and thus closer to the planning value.

#### Conclusion

The observed variability resulted in significant dose increases of the  $D_{50}$  to the bladder, whereas in the PTV, only small non-significant dose deviations could be detected. By including the bladder volume in the daily choice of the treatment plan - especially for patients with a challenging organ situation - a significantly lower dose to the OAR was achieved, while the target volume coverage was virtually unchanged. Further analyses will reveal a potential correlation of the observed dosimetric benefits with reduced clinical toxicities.

#### PO-0847 Rapid modulation of PSMA expression by ADT: Serial PSMA PET in men commencing androgen blockade.

L. Emmett<sup>1</sup>, V. Chalasani<sup>2</sup>, A. Kneebone<sup>3</sup>, G. Hruby<sup>3</sup>, A.M. Joshua<sup>4</sup>

<sup>1</sup>St Vincent's Hospital- Sydney- Australia, Department of Theranostics, Sydney, Australia; <sup>2</sup>Royal North Shore Hospital- Sydney, Urology, Sydney, Australia; <sup>3</sup>Royal North Shore Hospital, Radiation Oncology, Sydney, Australia; <sup>4</sup>St Vincent's Hospital Sydney, Oncology, Sydney, Australia

#### Purpose or Objective

Prostate specific membrane antigen (PSMA) can be targeted for both imaging and therapy purposes in the management of prostate cancer (PCa). In pre-clinical models, androgen blockade appears to increase expression of PSMA in both hormone sensitive and castrate resistant xenotypes. The aim of this study was to prospectively evaluate the effect on PSMA PET in men with measurable metastatic disease commencing initial androgen blockade in the hormone sensitive cohort or those commencing a novel antiandrogen (enzalutamide or abiraterone) in the castrate resistant cohort.

#### Material and Methods

Serial PSMA PET scans were performed at baseline, and days 9, 18 and 28 in 8 men with measurable metastatic hormone sensitive PCa commencing ADT (cohort 1) and 7 men with castrate resistant PCa commencing either enzalutamide or abiraterone (cohort 2). Gleason score (GS), age, time since diagnosis and prior treatments were documented. Testosterone and PSA (ng/ml) were measured at baseline and at all imaging time points. PET/CT was quantitatively analysed using MIM® software for number of lesions, SUV max, SUV mean and total tumour volume.

#### Results

**Cohort 1:** A mean 25% (IQR) reduction in intensity (SUV max) of PSMA by day 9 post androgen blockade (AB). This reduction in PSMA SUV max was seen in 88 % (7/8) men by day 9, with an associated PSA response in 100% men. There was more heterogeneity on day 18 and 28 PSMA with an increase in PSMA SUV max in 2/8 (25%) men, although overall tumour volume reduced in all men. **Cohort 2:** A mean 28% (IQR) increase in intensity of PSMA SUV was recorded by day 9 post AB. All men demonstrated an increase in both the intensity of uptake and volume on PSMA PET compared to baseline. This increase in quantitative parameters occurred by day 9 in all men, and had reduced by day 18 and 28 imaging. PSA responses were more delayed in cohort 2, with 2/7 men demonstrating PSA progression on the study.

	Baseline(Cohort 1)	Day 9(Cohort 1)	Baseline(Cohort 2)	Day 9(Cohort 2)
PSA (median)ng/m	52 ± 82	31 ± 23	53 ± 257	32 ± 407
SUV max	23 ± 14	14 ± 10	52 ± 23	87 ± 34
SUV mean	6 ± 3.6	4 ± 3.5	7.7 ± 2.2	10.5 ± 3.9
Total volume (mls)	28 ± 40	12 ± 48	290 ± 1141	290 ± 1585

### Conclusion

PSMA is a manipulable receptor with rapid dichotomous in-vivo response on PSMA PET to androgen blockade dependent on hormone sensitive versus castrate resistant PCa phenotype. This has important implications for the interpretation of PSMA PET imaging, and in the timing/sequencing of PSMA targeted therapy.

### PO-0848 Early mortality of prostatectomy vs. radiotherapy as a primary treatment for prostate cancer

D. Medenwald<sup>1</sup>, K. Medenwald<sup>1</sup>, A. Glowka<sup>1</sup>, D. Vordermark<sup>1</sup>, C. Dietzel<sup>1</sup>

<sup>1</sup>Martin Luther University Halle-Wittenberg, <sup>1</sup>Department of Radiation Oncology, Halle/Saale, Germany

### Purpose or Objective

To assess the extent of early mortality and its temporal course after prostatectomy and radiotherapy in the general population.

### Material and Methods

Data from SEER-database and German epidemiologic cancer registries were used for the years 2005-2013. Metastasized cases and deaths from bladder cancer were excluded (avoiding incidental cases after bladder cancer). Analysing overall mortality, year-specific Cox regression models were used for German and US-American data after adjusting for age (including age squared), risk stage and grading. To estimate temporal hazards we computed year-specific conditional hazards for surgery and radiotherapy after propensity-score matching and applied constant proportional hazard models.

### Results

In German and US-American populations we observed higher initial three-month mortality odds for prostatectomy (USA: 7.4-fold risk, 95% CI: 6.1-9.0; Germany: 8.5, 95% CI: 4.5-16.0) approaching the null effect value not before 20 months after diagnosis (used as a cut-off for the observational period defining early mortality).

During the observational period we observed an increasing hazard ratio for the 20-month mortality in the US-population (2005: 1.4, 95% CI: 1.2-1.6; 2013: 1.8, 95% CI: 1.4-2.1) for the surgery/radiotherapy comparison. In the German population the effect remained virtually constant (2005: 1.5, 95% CI: 1.0-2.3; 2013: 3.4, 95% CI: 2.1-5.7). Considering low-risk cases, the adverse surgery effect appeared stronger.

### Conclusion

There is strong evidence from two independent populations of a considerably higher early mortality after prostatectomy compared to radiotherapy extending the time of early mortality considered by previous studies up to 20 months.

### PO-0849 Pattern of Relapse After Metastases Directed Therapy in Oligorecurrent Prostate Cancer

I. San Miguel<sup>1</sup>, D. Büchser<sup>1</sup>, F. Suarez<sup>1</sup>, F. Casquero<sup>1</sup>, I. Fernandez<sup>2</sup>, E. Rodeño<sup>2</sup>, R. Ortiz de Zarate<sup>1</sup>, R. Llarena<sup>3</sup>, J. Garcia Olaverri<sup>3</sup>, L. Martinez-Indart<sup>4</sup>, P. Bilbao<sup>1</sup>, A. Gomez De Iturriaga<sup>4</sup>

<sup>1</sup>Cruces University Hospital, Radiation Oncologist, Baracaldo, Spain ; <sup>2</sup>Cruces University Hospital, Nuclear Medicine, Baracaldo, Spain ; <sup>3</sup>Cruces University Hospital, Urology, Baracaldo, Spain ; <sup>4</sup>Cruces University Hospital / Biocruces Health Research Institute, Radiation Oncologist, Baracaldo, Spain

### Purpose or Objective

A better knowledge of the pattern of recurrence after metastases directed therapy (MDT) in patients with oligometastatic disease might be useful to select the most appropriate candidates. The aim of this study is to report in a prospective cohort of oligorecurrent prostate cancer patients factors associated with the pattern of relapse and disease control after MDT.

### Material and Methods

From 2012 to 2017, 104 lesions diagnosed with Ch-PET in 53 consecutive oligometastatic-recurrence prostate cancer patients have been treated. Biochemical failure was defined using the nadir+2 ng/mL definition; a DFS event was defined as evidence of disease by any clinical, pathological or radiological method. Reassessment with Ch-PET imaging was performed in case of biochemical failure or if clinically indicated to rule out local or distant metastatic progression. Patterns of first progression following MDT were recorded. In case of an oligometastatic recurrence outside the previous PTV field, a retreatment with SBRT or IMRT was offered. Descriptive analyses were done. Chi-square and Fisher-exact tests were performed to evaluate the influence of patient, tumor, and treatment characteristics on the pattern of relapse. A p<0.05 considered statistically significant

### Results

The different subsites of metastatic involvement before 1<sup>st</sup> MDT were lymph-nodes in 67.9% and bone in 32.1% of patients. The treatments administered to the initial oligo-recurrence sites were IMRT (49%) and SABR (51%) +/- short course ADT. After a median follow-up of 28 months (6-54 months), 89% of the patients remain alive and only 3 deaths were related to prostate cancer. At last follow-up 34% of the patients were free from disease progression. Twenty-five patients with biochemical failure after 1<sup>st</sup> MDT presented distant recurrence on re-staging Ch-PET and 64% (16/25) were again oligometastatic relapses allowing for a 2<sup>nd</sup> MDT in 12 patients. In terms of relapse site, 7/7 (100%) patients with initial bone disease presented a subsequent bone relapse, 10/18 (56%) patients with initial nodal disease presented a nodal relapse and 8/18 (44%) a bone relapse. At diagnosis, a PSA pre-PET<4.5ng/mL was associated with higher probability of presenting with nodal oligometastases (p=0.049). The variables with significant association with nodal relapse after MDT were a pre-MDT PSA<10ng/mL (p=0.049) and initial nodal oligometastatic site (p=0.02). A PSADT>12 months before MDT was the only factor statistically associated with higher disease control (p=0.011).

### Conclusion

Long-term disease control is still possible in oligometastatic patients who receive MDT. At relapse, most patients are again oligometastatic allowing for repeated MDT. The pre-MDT PSA and initial nodal oligometastatic site are associated with a further nodal relapse. Patients presenting with a PSADT>12 months and a PSApre-PET<4.5ng/mL may have a better prognosis.

## Purpose or Objective

The fear of treatment induced urinary incontinence is one of the treatment sequelae mainly advising against post-prostatectomy. Purpose of this study was to compare the risk and trend over time of acute patient-reported urinary incontinence (PRUI) after adjuvant (ADV) or salvage (SALV) IMRT.

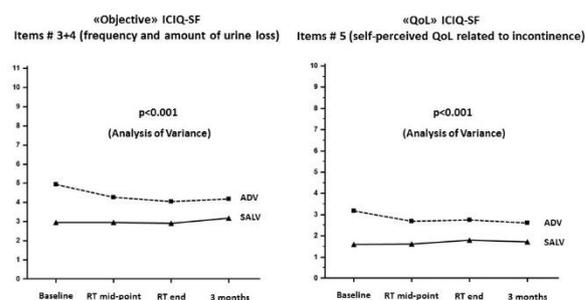

## Material and Methods

An ongoing multicentric observational trial, registered at ClinicalTrials.gov, is evaluating PRUI in pts treated with IMRT for prostate cancer. The ICIQ-SF questionnaire (ICIQ) has to be filled-in by pts at baseline, at RT mid-point and end, 3 and 6 months after RT end and thereafter every 6 months up to 5 years. IMRT is delivered at both conventional (CF) or moderate hypo-fractionation (HYPO). Complete ICIQ at baseline, RT mid-point and end were available for 316 pts (266 at 3 months). Pts characteristics in ADV (n=140) and SALV (n=176) cohorts were: time to RT (TTRT) 4 vs 24.4 months, EQD2 RT dose for a/b=10 Gy 72 vs 74 Gy, HYPO 53% vs 33%, median # of RT fractions 35 vs 37, hormonal therapy 58% vs 33%, Tomotherapy (TOMO) vs VMAT vs static-field IMRT (SS-IMRT) 46%/50%/4% vs 38%/48%/14%, open vs robotic vs laparoscopic surgery 68%/26%/6% vs 60%/28%/12%.

## Results

Two ICIQ-based end-points were considered: "objective PRUI" (OBJ=sum of the scores of items #3 and #4, frequency and amount of urine loss, respectively, score 0-11) and the impact on QoL as reported by pts (item #5, score 0-10). Overall, the mean and median scores for both end-points were significantly higher at baseline, during and immediately after irradiation in the ADV cohort (Table 1 and Figure 1). Nevertheless neither ADV nor SALV RT led to OBJ nor QoL worsening. Of the 266 with ICIQ at baseline and at 3 months, 2/55 (4%) and 12/107 (11%) with a baseline OBJ score <5 exhibited a corresponding score ≥5 at 3 months. The end-point for logistic regression analysis was set as an OBJ score ≥5 at 3 months. Among the variables investigated (age, BMI, TTRT, HORM, type of surgery, dose/fraction at PB, seminal vesicles bed, lymph-nodal PTV, EQD2 to PB, RT intent, baseline OBJ and RT

technique) only those with a p-value ≤0.20 were entered into a multivariable model. In the overall population the only two covariates predictive of OBJ ≥5 at 3 months were baseline OBJ (OR 2.65, p<0.0001) and RT intent (OR 0.35, reference ADV, p=0.008) (AUC: 0.92 95% 0.88-0.95%) while in the subset of pts with a baseline OBJ<5 only baseline OBJ retained the statistical significance (OR 3.01, p=0.003, AUC 0.83 95% 0.76-0.89%).

«Objective» ICIQ-SF (median scores)				
	Baseline	RT mid-point	RT end	3 months
Adjuvant	5	4	4	4
Salvage	3	3	3	3

«Objective» ICIQ-SF (mean scores)				
	Baseline	RT mid-point	RT end	3 months
Adjuvant	4.82	4.19	4.05	4.20
Salvage	3.02	3.02	3.01	3.17
p-value (t-student)	<math><0.0001</math>	0.0004	0.002	0.005

«QoL» ICIQ-SF (median scores)				
	Baseline	RT mid-point	RT end	3 months
Adjuvant	2	2	2	1
Salvage	0	1	1	1

«QoL» ICIQ-SF (mean scores)				
	Baseline	RT mid-point	RT end	3 months
Adjuvant	1.66	1.70	1.89	1.72
Salvage	3.10	2.68	2.76	2.60
p-value (t-student)	<math><0.0001</math>	0.001	0.007	0.009

## Conclusion

Baseline OBJ score was the major predictor of PRUI 3 months after post-prostatectomy RT. Pts receiving ADV IMRT exhibited significantly higher OBJ and QoL scores in the 3 months after RT start, but the overall levels of PRUI and QoL impairment were rather low. Contrarily to what commonly believed, neither ADV nor SALV RT led to any worsening of post-prostatectomy OBJ or QoL in the first 3 months after RT, despite the relatively high delivered dose.

### Purpose or Objective

To determine the evolution of Quality of Life (QoL) within the 1st year after RT for prostate cancer (PC) and its relationship with RT-related urinary and bowel symptoms (symp).

### Material and Methods

Patients (pts) in a multicenter observational study aimed at evaluation of symp and QoL after WPRT were included. Bowel toxicity was scored by means of the Inflammatory Bowel Disease Questionnaire (IBDQ), including QoL scales evaluating both social (SWB) and emotional (EWB) wellbeing. In IBDQ scales (range 1-7) lower scores indicate worse outcome. Moreover, QoL was also measured through the Hospital Anxiety and Depression Scale (HADS), which scores anxiety (ANX) and depression (DEP) separately (range 0-21 for both, greater values mean increased severity, score  $\geq 8$  indicating ANX/DEP mood). Urinary toxicity was scored through both the IPSS (range 0-35) (range 0-21), with greater scores indicating increased symptom's severity for both questionnaires. Longitudinal evaluation of QoL in the 1st year after RT was analyzed by means of ANOVA for multiple measures. Associations between urinary/bowel symp and 1.worsening of SWB/EWB of at least 2 points compared to baseline and 2.presence of ANX/DEP mood at 1 year were evaluated by means of logistic regression (LR).

### Results

304 pts were available for longitudinal evaluation, 38% treated with conventional RT and 62% with moderate hypofractionation with radical (28%), adjuvant (33%) or salvage (39%) intent. Median EQD2Gy (a/b=3Gy) to prostate/prostatic bed was 74Gy, that to pelvic nodes 50Gy.

Evolution of QoL over time was characterized by a quadratic trend for SWB & EWB ( $p > 0.001$ ), with significant worsening at RT end and subsequent recovery after RT completion. Conversely, ANX & DEP could be described by a linear decreasing trend ( $p = 0.002/p = 0.01$ ), reaching the lowest average values at 1 yr (see Figures 1 and 2). At multivariate LR, SWB worsening (23 pts) was associated to urinary obstructive symp (OR=1.09 for 1-point IPSS increase,  $p = 0.006$ ), while EWB worsening (9 pts) was associated to bowel symp (OR=5 for 1-point IBDQ decrease,  $p = 0.001$ ).

ANX mood (30 pts) was independently associated with both urinary obstructive symp (OR=1.12 for 1-point IPSS increase,  $p = 0.001$ ) and bowel symp (OR=3.2 for 1-point IBDQ decrease,  $p = 0.0007$ ). DEP mood (18 pts) was associated to urinary incontinence (OR=1.14 for 1-point ICIQ increase,  $p = 0.001$ ).

ANX/DEP at 1 year were highly negatively correlated with EWB ( $r = -0.79/-0.71$ ,  $p < 0.001$ ).

Figure 1: Quality of life scores as a function of time.

Open circles represent all data points, solid squares represent mean values, while bars represent 68% confidence intervals for the mean.

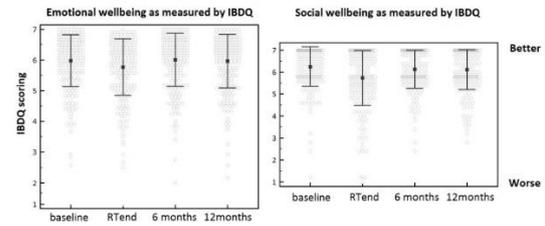

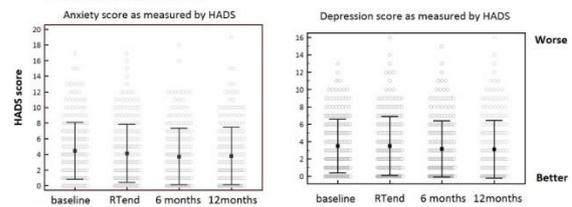

Figure 2: Anxiety and depression as a function of time.

Open circles represent all data points, solid squares represent mean values, while bars represent 68% confidence intervals for the mean.

### Conclusion

SWB & EWB after WPRT for PC are both decreased shortly after RT completion but recover within 1 year, with a limited number of pts reporting worsening SWB/EWB scores at 1 year, mainly associated with persistent bowel and obstructive urinary symp.

ANX/DEP decrease over time, suggesting their being more related to emotional upset following PC diagnosis rather than to treatment and side effects. Residual presence of ANX/DEP mood is significantly associated to both bowel and urinary symp.

### PO-0852 Stereotactic Body Radiation Therapy for Unfavorable Prostate Cancer: Large institutional experience.

N. Aghdam<sup>1</sup>, S. Katarian<sup>1</sup>, M. Danner<sup>1</sup>, M. Ayoob<sup>1</sup>, T. Yung<sup>1</sup>, S. Lei<sup>1</sup>, D. Kumar<sup>2</sup>, B.T. Collins<sup>1</sup>, J. Lischalk<sup>1</sup>, A. Dritschilo<sup>1</sup>, S. Suy<sup>1</sup>, J. Lynch<sup>3</sup>, S.P. Collins<sup>1</sup>

<sup>1</sup>Georgetown University Hospital, Department of Radiation Medicine, Washington DC, USA ; <sup>2</sup>North Carolina Central University, Julius L. Chambers Biomedical/Biotechnology Research Institute BBRI, Raleigh, USA ; <sup>3</sup>Georgetown University Hospital, Department of Urology, Washington DC, USA

### Purpose or Objective

External beam radiation therapy plus brachytherapy boost is a highly effective treatment for unfavorable prostate cancer. However, utilization of brachytherapy in the United States is declining and not all patients are ideal candidates for this treatment approach due to technical reasons. Stereotactic body radiotherapy (SBRT) has emerged as a standard high dose option for low and favorable intermediate risk prostate cancer patients. In this report, we present the biochemical disease free survival for unfavorable prostate cancer treated with SBRT in a large single institution cohort.

### Material and Methods

All patients with unfavorable intermediate risk (more than one intermediate risk factor, GS 4+3, or greater than 50% positive biopsy cores) and high risk prostate cancer treated with SBRT at a single institution were eligible for this study. Treatment was delivered using the robotic SBRT with doses of 35-36.25 Gy in five fractions or 19.5 Gy in three fractions followed by fiducial-guided supplemental IMRT (45-50.4 Gy). In general, patients with high grade, non-organ confined disease received supplemental IMRT. Patient's characteristics were

extracted from a prospective institutional quality of life trial (IRB 09-510). Biochemical failure free survival (BFFS) was determined using the Kaplan-Meier method.

#### Results

A total of 751 patients from 2008 to 2017 were eligible for analysis, of which 427 with UF-IR disease and 324 had HR disease. Fifty percent of the patients received short term ADT (81% HR, 24% UF-IR). At median follow up of 36 months BFFS was 89% for all patients, and 93% and 84% for UF-IR and HR patients respectively (p=0.015). Patients treated with SBRT alone had 91% BFFS as compared to those treated with supplemental IMRT with 86%.

#### Conclusion

SBRT plus or minus supplemental IMRT for high risk prostate cancer shows similar early biochemical responses as alternative dose escalated radiation therapy treatments. In the authors' opinions, SBRT is a reasonable option for unfavorable prostate cancer when a longer course of EBRT is not possible due to logistical challenges.

#### PO-0853 Bladder and urethra subregions predicting urinary toxicity after prostate cancer radiotherapy

E. Mylona<sup>1</sup>, O. Acosta<sup>1</sup>, T. Lizee<sup>1</sup>, J. Castelli<sup>2</sup>, C. Lafond<sup>2</sup>, G. Crehange<sup>3</sup>, N. Magne<sup>4</sup>, S. Chiavassa<sup>5</sup>, S. Supiot<sup>5</sup>, R. De Crevoisier<sup>1,2</sup>

<sup>1</sup>INSERM U1099 - University of Rennes, Laboratoire Traitement du Signal et de l'Image, Rennes, France ; <sup>2</sup>Centre Eugène Marquis, Radiotherapy department, Rennes, France ; <sup>3</sup>Centre Georges François Leclerc, Radiotherapy department, Dijon, France ; <sup>4</sup>Lucien Neuwirth Cancer Institute, Radiotherapy department, St Priest en Jarez, France ; <sup>5</sup>Institut de Cancérologie de l'Ouest, Medical Physics Department, Nantes, France

#### Purpose or Objective

To apply a voxel-based analysis on the planning 3D dose distribution in order to identify symptom-related subregions (SRSs) of the bladder/urethra associated with acute and late urinary toxicity in prostate cancer radiation therapy (RT).

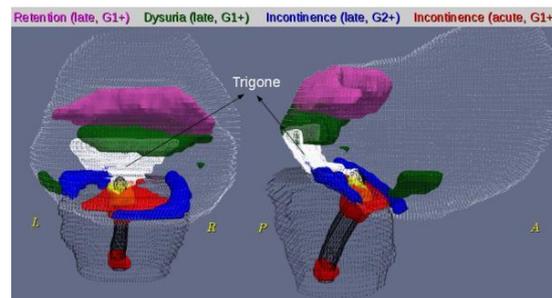

#### Material and Methods

Overall, 272 prostate cancer patients treated with IMRT/IGRT from two multicentric prospective phase III trials were analyzed. Each patient's organ contours (bladder, urethra and prostate) were spatially normalized to a common coordinate system (CCS) via non-rigid registration. The obtained 3D deformation fields were used to propagate the planning dose distributions from the native space of each patient to the CCS. A voxel-based statistical analysis was applied to generate 3D dose-volume maps for different urinary symptoms and identify corresponding SRSs with statistically significant dose differences between patients with/without toxicity. All the identified SRSs were propagated from the CCS back to the native space of each individual and DVHs for the SRSs and the whole bladder were computed. Dose bins of significant dose difference between patients with/without urinary toxicity were identified. Logistic regression was used to estimate the DVH prediction capability (1Gy bin-wise) of the SRSs compared to the whole bladder.

#### Results

A local dose-effect relationship was found in the bladder and the urethra. SRSs of significant dose differences (p-value<0.01) were identified for four endpoints: acute and late incontinence in the urethra and the trigone, late retention and dysuria in the posterior part of the bladder, with average dose differences ranging from 1.26 to 9.28 Gy. Figure 2 shows these SRSs on the template. The DVHs of the SRSs were significantly predictive of toxicity with maximum areas under the ROC curve (AUC): 71% for acute incontinence, 80% for late incontinence, 68% for late retention and 79% for late dysuria. The DVH of the bladder was predictive only for late incontinence and late dysuria (AUC=70%). Table 1 shows the prediction capability of the

DVH for the SRSs and the whole bladder in the native space.

A. Acute toxicity					
Symptom	Region	Most predictive DVH bin (Vx)	AUC	p-value	OR (95% CI)
Incontinence	Acute incontinence SRS	V81	70.9	<0.01	1.05 (1.02-1.09)
	Whole bladder	-	-	NS	-
B. Late toxicity					
Symptom	Region	Most predictive DVH bin (Vx)	AUC	p-value	OR (95% CI)
Incontinence	Late incontinence SRS	V79	79.7	0.01	1.04 (1.01-1.07)
	Whole bladder	V80	70.2	0.01	1.21 (1.05-1.43)
Retention	Late retention SRS	V37, V62	68	<0.01	1.02 (1.01-1.04)
	Whole bladder	-	-	NS	-
Dysuria	Late dysuria SRS	V53	78.7	<0.01	1.06 (1.02-1.09)
	Whole bladder	V63	70.1	0.02	1.04 (1.01-1.07)

Abbreviations: SRS= symptom-related subregion, OR= odds ratio, AUC= area under the ROC curve, Vx= volume receiving at least x Gy, CI= confidence interval, NS= Non-significant

#### Conclusion

The dose delivered to the urethra, the trigone and the posterior region of the bladder was predictive of acute and late incontinence, late retention and late dysuria. These SRSs appear more predictive than the whole bladder, suggesting that identification of radiosensitive subregions can improve the prediction capabilities for urinary toxicity and may be spared in order to decrease urinary symptoms. Additionally, this study provides the first evidence that explicitly correlate the true 3D dose to the urethra with urinary toxicity following EBRT.

#### PO-0854 Extreme vs moderate hypofractionation for localized Pca: a Propensity Score Matching Analysis

G. Marvaso<sup>1</sup>, D. Ciardo<sup>1</sup>, S. Gandini<sup>2</sup>, G. Riva<sup>1</sup>, E. Frigo<sup>3</sup>, D. Zerini<sup>1</sup>, S. Comi<sup>4</sup>, R. Cambria<sup>4</sup>, O. De Cobelli<sup>5</sup>, R. Orrecchia<sup>6</sup>, B.A. Jereczek-Fossa<sup>1,3</sup>

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Radiotherapy, Milan, Italy ; <sup>2</sup>IEO- European Institute of Oncology IRCCS, Epidemiology and Biostatistics, Milan, Italy ; <sup>3</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy ; <sup>4</sup>IEO- European Institute of Oncology IRCCS, Medical Physics, Milan, Italy ; <sup>5</sup>IEO- European Institute of Oncology IRCCS, Urology, Milan, Italy ; <sup>6</sup>IEO- European Institute of Oncology IRCCS, Scientific Directorate, Milan, Italy

#### Purpose or Objective

The aim of this study is to compare clinical outcome and toxicity of 2 cohorts of clinically localized prostate cancer (PCa) patients treated with 2 different radiotherapy (RT) regimens: Extreme hypofractionation (EH, 35Gy or 32.5Gy in 5 fractions) vs moderate hypofractionation (MH, Fox-Chase regimen, 70Gy in 26 fractions) both using image-guided intensity modulated RT (IG-IMRT).

#### Material and Methods

Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer criteria (RTOG/EORTC) and Houston definition (nadir+2) were used for toxicity and biochemical failure evaluation, respectively. Multivariate proportional Hazard Cox

models, stratified for propensity score strata, were used to compare the 2 populations in term of overall survival (OS), clinical progression free survival (cPFS), biochemical PFS (bPFS) and gastro-intestinal (GI) toxicity and genitourinary (GU) toxicity. Propensity scores reflect the probability that a patient received MH or EH based on his baseline characteristics. Patients receiving MH were matched on a one-to-one basis with subjects receiving EH. Matching was performed based on nearest-neighbor matching. The analyses were applied on the matched cohorts and on the whole cohorts, stratifying the analyses by risk strata identified with the propensity scores (Table 1).

### Results

The analysis included 227 PCa patients treated in 2007-2015, receiving MH-IG-IMRT and 194 patients treated with EH-IG-IMRT in 2012-2015. Median age was 75 years (range: 50-89). Median follow-up was 43 months. A statistically significant difference in distribution regarding Gleason score (GS) and risk group was found between the 2 groups ( $p=0.004$  and  $p=0.002$ , respectively). 226 patients with good matching characteristics and balance (113 men per group) were selected after propensity score matching. A multivariate Cox analysis performed on the pre-matched cohort showed that bPFS, cPFS and OS were not statistically different between the 2 treatment groups ( $p=0.439$ ,  $p=0.317$ ,  $p=0.906$ , respectively), after adjusting for prognostic variables and confounding factors (Figure A,B,C). These results were confirmed in the matched population analysis. As concerning GI toxicity, compared with EH, in MH acute  $G>1$  events were significantly more (3% vs 9%,  $p=0.007$ ). As concerning GU toxicity, compared with EH, in MH, acute  $G>1$  events were registered in 11% vs 26% ( $p<0.001$ ). Multivariate Cox regression models showed no significant differences between the cohorts in term of late GI and GU toxicity. Acute GU/GI toxicities in the matched cohort were confirmed to be worse in the MH ( $p=0.002$  and  $p<0.001$ ). The GU/GI toxicity detected at last follow-up were both in line with those emerged from the pre-matched analyses ( $p=0.43$  and  $p=0.08$ ).

### Conclusion

Utilizing the Propensity Score Comparison there was no difference in terms of oncological outcome at a median follow-up of 43 months comparing the 2 RT modalities. Moreover, the 2 RT regimens were associated with similar toxicity profiles.

### PO-0855 Development and Validation of a Prostate Cancer Patient Decision Aid: Towards Participative Medicine

Oelke<sup>6</sup>, A. Dekker<sup>1</sup>, P. Lambin<sup>7</sup>, R. Fijtten<sup>1</sup>, A. Bertlang<sup>8</sup>

<sup>1</sup>Maastricht University, Knowledge Engineering, Maastricht, The Netherlands ; <sup>2</sup>Maastricht University, Radiotherapy, Maastricht, The Netherlands ; <sup>3</sup>Fontys University of Applied Sciences, n/a, Eindhoven, The Netherlands ; <sup>4</sup>Maastricht University Medical Centre+, Urology, Maastricht, The Netherlands ; <sup>5</sup>Zuyderland Medical Center, Urology, Sittard, The Netherlands ; <sup>6</sup>St. Antonius-Hospital Akademisches Lehrkrankenhaus der WWU Münster, Urology, Gronau, Germany ; <sup>7</sup>Maastricht University, The D-Lab- Research Institute GROW, Maastricht, The Netherlands ;

<sup>8</sup>Maastricht University, n/a, Maastricht, The Netherlands

### Purpose or Objective

Prostate cancer is the second most prevalent cancer in men in the Western world. Insufficient information on the different treatment options often results in suboptimal treatment choices that could lead to poor quality of life and additional costs. A Cochrane meta-analysis proved the value of patient decision aids (PDAs) in improving patient knowledge and enabling values clarification to facilitate shared decision making, yet poor design is a major

implementation barrier.

We develop an interactive web-based PDA based on user-centered design for better integration into the care pathway. In this approach, users are involved early and often in order to improve quality, reliability, usability of the PDA, and build ownership.

### Material and Methods

PDA development consisted of five rounds of semi-structured interviews and usability tests with, urologists (n=8), radiation oncologists (n=4), nurses (n=2), general practitioners (n=8), ex-patients (n=19), usability experts (n=4) and male test volunteers (n=11). The PDA was continuously tested and refined based on user feedback. Interview topics included informational needs, PDA requirements and possible implementation barriers. We tested usability with surveys and heuristic evaluation by experts.

### Results

Initial versions focused on clinical details (anatomy, complications, contra-indications) but as the rounds progressed the PDA was updated to reflect non-clinical factors that influenced patients' choices: treatment logistics, the impact of side-effects on daily life and uncertainty. Patients tended to choose aggressive surgery due to fear and lack of knowledge, underlining the need for more balanced information, particularly on radiotherapy. Usability experts suggested navigational and visual changes, e.g. a sidebar menu, neutral color palette, more white space and less textual clutter to improve readability (Fig. 1 and 2).

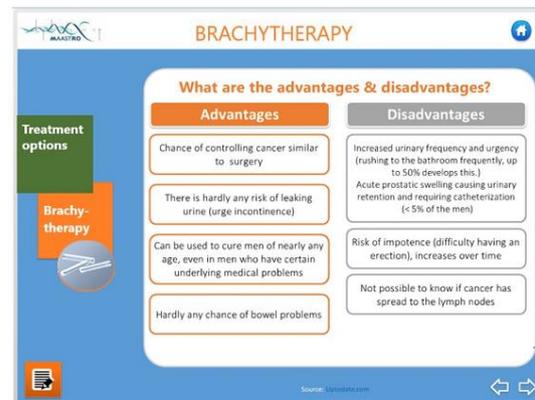

Figure 1: Treatment information about brachytherapy in the initial versions of the PDA

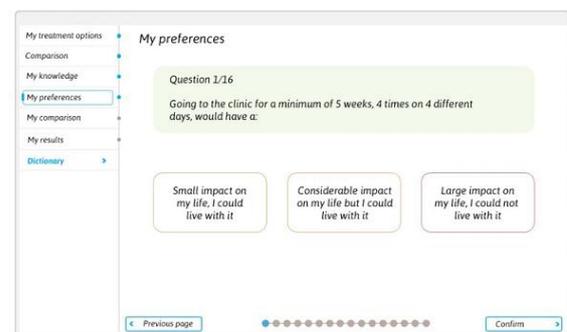

Figure 2: An example of values clarification in the final version of the PDA

The final PDA ([www.beslissamen.nl](http://www.beslissamen.nl)) contains seven sections:

1. **Introduction:** a 2-minute video priming patients for using the PDA.
2. **My treatment options:** textual and visual information (diagrams, videos) on each treatment option (brachytherapy, external radiation, surgery and active surveillance).

3. **Comparison:** a table listing pros and cons of each treatment side-by-side.
4. **My knowledge:** Ten true/false questions to confirm the patient's understanding.
5. **My preferences:** 16 values clarification questions about treatment experience, quality of life, and uncertainty.
6. **My comparison:** four questions asking the patient to select treatment aspects that are least desirable.
7. **My results:** a tabular overview of the values clarification. This can be printed for use in the consultation to guide the SDM talk in accordance with patient values.

### Conclusion

User-centered design provided valuable insights into PDA requirements but resulted in a time-consuming process and a diverse range of perspectives that were challenging to integrate. The PDA is currently being evaluated in a clinical trial (NCT03278197).

**PO-0856 Metastasis-directed therapy for oligoprogressive castration refractory prostate cancer**  
**C. Berghen<sup>1</sup>, S. Joniau<sup>2</sup>, P. Ost<sup>3</sup>, K. Poels<sup>1</sup>, W. Everaerts<sup>2</sup>, K. Haustermans<sup>1</sup>, G. De Meerleer<sup>1</sup>**  
<sup>1</sup>University Hospital of Leuven, Radiation Oncology, Leuven, Belgium ; <sup>2</sup>University Hospital of Leuven, Urology, Leuven, Belgium ; <sup>3</sup>University Hospital of Ghent, Radiation Oncology, Ghent, Belgium

### Purpose or Objective

In metastatic castration refractory prostate cancer (mCRPC) state-of-the-art treatment consists of a systemic treatment with second-line hormones, chemotherapy or bone seeking agent in addition to palliative androgen deprivation therapy (pADT). Clinical progression is the signal to switch to next-line systemic treatment (NEST). A subgroup of these progressive patients shows oligoprogression, defined as the progression of a limited number of metastatic spots while the majority of metastases are controlled by ongoing systemic therapy. We hypothesized that metastasis directed therapy (MDT) against these oligoprogressive lesions might defer the need for NEST. Therefore, we performed this retrospective analysis.

### Material and Methods

We analyzed the outcome of patients who were treated with MDT for mCRPC oligoprogressive disease, defined as either the progression of  $\leq 3$  existing oligometastatic sites and/or the appearance of  $\leq 3$  new metastasis and/or local recurrence. In total, the number of progressive/new lesions was  $\leq 3$ . All patients were under systemic therapy with pADT whether or not combined with second-line systemic treatment. The time frame of the study was from 1/2012 until 3/2018. Primary endpoint was NEST-free survival (NEST-FS). Secondary endpoints were progression-free survival (PFS) and toxicity scoring.

### Results

A total of 35 cases of oligoprogression were included who received MDT consisting of SBRT (n=22), metastasectomy (n=2), or local treatment with more conventionally fractionated radiotherapy (n=11). A total of 51% in the MDT-group had upfront metastatic disease, from which 61% had upfront oligometastatic disease. At the time of oligoprogression the majority had bone lesions (69%). Others had nodal disease or a combination of both or local recurrence. There were no patients with oligoprogressive visceral metastasis. Most patients were on systemic treatment with pADT only. The median follow-up time was 30 months (IQR 9-42). There was a median NEST-free survival (NEST-FS) of 16 months (CI 95% 12-31) and PFS of 12 months (CI 95% 7-18). SBRT or surgery-related toxicity was minor, with limited grade 1 and 2 toxicity and only one patient experiencing acute grade 3 toxicity after treatment for local relapse in the prostate.

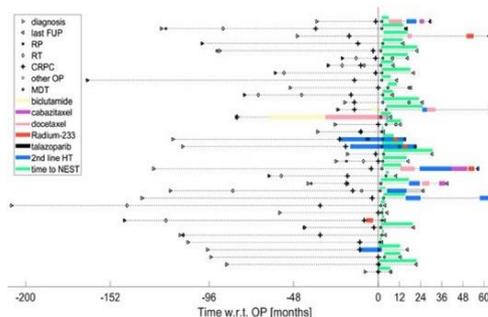

Figure 1. Overview of therapies pre- and post-diagnosis of oligoprogression  
 Oligoprogression is defined as the zero point on x-axis; FUP: follow-up; RP: radical prostatectomy; RT: radiation therapy; CRPC: castration refractory prostate cancer; OP: oligoprogression; MDT: metastasis-directed therapy; NEST: next-line systemic treatment.

Table 1: Patient Characteristics		MDT group (n=35)
<b>Time point: initial diagnosis prostate cancer</b>		
Median age in years (IQR)		64 (57-70)
Median PSA (ng/ml) (IQR)		12 (7-16)
Gleason 8-10 (%)		24 (69)
Metastatic disease (%)		18 (51)
Local treatment (%)		28 (80)
ADT (%)		19 (54)
<b>Time point: oligoprogression</b>		
Median age in years (IQR)		70 (66-76)
Median PSA (ng/ml) (IQR)		3 (1-10)
Time period being on ST (months) (IQR)		24 (22-52)
<b>Number of progressive lesions (including LCR)</b>		
1		20 (58)
2		10 (28)
3		5 (14)
<b>Type of lesion</b>		
Lymph node		5 (14)
Bone		24 (69)

grade 2		2 (6%)
grade 3		1 (3%)
grade 4		0
grade 5		0
<b>Outcome</b>		
Median follow-up, months (IQR)		17 (8-25)
Median progression free survival, months (95% CI)		12 (7-18)
Median NEST-free survival		16 (12-31)

Legend: IQR: interquartile range; PSA: prostate specific antigen; ADT: androgen deprivation therapy; ST: systemic therapy; LCR: local recurrence; NEST: next-line systemic treatment

### Conclusion

Our data demonstrate an important deferral of NEST with a median NEST-FS of 16 months in 35 cases of patients treated with MDT. These data are unique and may induce a paradigm shift in the treatment of these patients. Prospective clinical trials are warranted to further define the patient characteristics and treatment outcomes.

**PO-0857 MRI-derived radiomics to select patients with high-risk prostate cancer for adjuvant radiotherapy**

<sup>1</sup>CHRU Brest, Radiation Oncology, Brest, France ;

<sup>2</sup>Université de Bretagne Occidentale, LaTIM UMR 1101

INSERM, Brest, France ; <sup>3</sup>CHRU Brest, Urology Unit,

Brest, France ; <sup>4</sup>CHRU Brest, Radiology, Brest, France

### Purpose or Objective

Radical prostatectomy (RP) is one of the treatments of choice for patients with prostate cancer (PCa) but biochemical recurrence (BCR) after RP occurs in 50% of patients, particularly in those who harbor high risk features like locally advanced disease (T3-4), positive margins (R1) or high Gleason score. Adjuvant radiotherapy

(RT) has been proven effective to prolong biochemical control, but is associated with a higher risk of grade  $\geq 2$  toxicity. We aimed to develop and validate a magnetic resonance imaging (MRI)-based radiomics signature with prognostic value in patients with high risk PCa, in order to guide patients management especially regarding the use of adjuvant RT.

#### Material and Methods

One hundred-seven patients with histologically proven PCa with high-risk features namely pT3-4, and/or R1, and/or Gleason 8-10 and treated with RP with or without lymphadenectomy from 2010 to 2016 at our institution, and with available preoperative pelvic MRI were included. Adjuvant treatment, postoperative PSA > 0.04 ng/mL and c/pN1 were exclusion criteria.

Prostatic tumors were delineated on both the ADC and T2 MRI sequences using 3D Slicer® v4.8.0 and IBSI-validated radiomic features were extracted. The cohort was randomly split into training (n=70) and testing (n=37) sets. The selection of a subset of 10 radiomics features was performed in the training set using an aggressive false discovery reduction procedure relying on stability and correlation checks and robustness score. Correlation with BCR was assessed using ROC curves and Cox regression analysis was performed to identify independent predictive variables.

#### Results

After a median follow-up of 52.0 months, 17 (16.0%) patients experienced BCR. In the training set, none of the clinical features was significantly correlated with BCR. Amongst the 10 radiomic features pre-selected, an ADC feature outperformed the others with an AUC of 0.85 to predict biochemical relapse-free survival (bPFS) ( $p = 0.0001$ ).

In the testing set, this feature remained significantly predictive of BCR (AUC of 0.76) and prognostic of bPFS ( $p = 0.0236$ ).

#### Conclusion

One ADC radiomic feature appeared to be strongly predictive of BCR following RP. This feature could help in redefining the population who would mostly benefit from treatment intensification such as adjuvant RT.

#### PO-0858 Dosimetric correlation analysis of observed toxicities in prostate cancer patients treated with SBRT

N. Pienimäki<sup>1</sup>, K. Vuolukka<sup>2</sup>, J. Heikkilä<sup>2</sup>, J. Palmgren<sup>2</sup>, J. Seppälä<sup>2</sup>

<sup>1</sup>University of Eastern Finland, Department of Applied Physics, Kuopio, Finland ; <sup>2</sup>Kuopio University Hospital, Centre of Oncology, Kuopio, Finland

#### Purpose or Objective

The aim of this study was to investigate the correlation between dosimetric parameters and registered toxicities in ultra-hypofractionated radiotherapy of prostate cancer (PCa).

#### Material and Methods

Between the years 2012 and 2015 220 patients received ultra-hypofractionated radiotherapy (5x7.0 Gy / 7.25 Gy) delivered with CyberKnife robotic system for the radical treatment of PCa at Kuopio University Hospital, Finland. Toxicities were observed in 36 patients which were divided in four different groups; Intermediate-term Genitourinary toxicities (GU, n=19), intermediate-term rectal toxicity (GI, n=7), Infectious problems toxicity (INF, n=7) and Acute toxicity (ACUTE, n=4). Comparison groups of patients were formed for each toxicity group by selecting similar patients without any toxicity according to age, size of PTV and hormonal treatment. Average DVH curves (Fig.1) for rectum and bladder were produced for each group and were used to choose representative dose-volume parameters for correlation analysis. In correlation analysis the mean values of absolute volume doses, mean values of relative volume doses and relative volumes for

dose in percentage was studied. The results were further analysed by using Wilcoxon rank sum test. Analysis was done separately per each toxicity group and its comparison group.

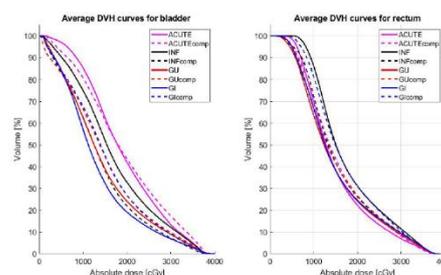

Figure 1: Average DVH curves of bladder and rectum for each toxicity group and comparison groups.

#### Results

For the INF patients significant differences between the groups were discovered for the higher doses of bladder (D5% ( $p=.007$ ) and D10% ( $p=.005$ )). In addition, for bladder the results between INF patients and comparison group differed significantly with V35 ( $p=.0006$ ) and somewhat notably with V30 ( $p=.07$ ). When investigating the doses delivered to rectum, significant differences were observed with medium dose value V10 ( $p=.038$ ). Also, with V15 ( $p=.07$ ) and D50% ( $p=.07$ ) some notable differences were observed.

For the GI patients in the analysis for rectum, it was observed that the doses of D5cc ( $p=.07$ ) and D10cc ( $p=.05$ ) differed remarkably between the groups. When analysing relative volumes for dose in percentage, it was observed that for rectum V15 ( $p=.07$ ) the volumes for doses were remarkably different. Further research is still needed in order to verify the significance of these observed values. Significant correlation between toxicity symptoms and dosimetric values were not found for the GU and for the ACUTE groups, respectively. All the notable results are presented in Table 1.

Toxicity Group	Structure	Variable	Toxicity patients Dose [Gy $\pm$ SD]	Comparing group Dose [Gy $\pm$ SD]	P value
GI	Rectum	D5cc	31.0 $\pm$ 2.5	28.6 $\pm$ 2.9	0.073
GI	Rectum	D10cc	25.2 $\pm$ 3.1	22.2 $\pm$ 3.1	0.053
INF	Bladder	D5%	35.5 $\pm$ 1.2	34.1 $\pm$ 1.7	0.073
INF	Bladder	D5%	34.2 $\pm$ 1.3	31.4 $\pm$ 2.2	0.007
INF	Bladder	D10%	30.5 $\pm$ 2.4	26.2 $\pm$ 4.0	0.053
INF	Rectum	D50%	15.1 $\pm$ 1.4	13.0 $\pm$ 2.8	0.073
Toxicity Group	Structure	Variable	Toxicity patients Volume [% $\pm$ SD]	Comparing group Volume [% $\pm$ SD]	P value
GI	Rectum	V15	39 $\pm$ 11	50 $\pm$ 13	0.073
INF	Rectum	V15	50 $\pm$ 8	42 $\pm$ 14	0.073
INF	Rectum	V10	86 $\pm$ 9	73 $\pm$ 15	0.038
INF	Bladder	V35	5 $\pm$ 2	2 $\pm$ 0	0.001
INF	Bladder	V30	12 $\pm$ 6	7 $\pm$ 3	0.073

Table 1: The most remarkable mean values of dose per volume and volumes for dose in percentage for bladder and rectum for GI and INF toxicity patients and their comparison group.

#### Conclusion

High maximum doses to critical organs was found to correlate strongly with observed INF and GI toxicities for the PCa patients treated with ultra-hypofractionated radiotherapy. For the GU and ACUTE groups no correlation between the groups in toxicity and dose distributions was found. For the medium range doses there were only slight differences between toxicity and control group, respectively. The daily variation of the treated anatomy could have an effect for the non-significance of the lower doses since dose received by the critical organs of may vary by fraction.

#### PO-0859 Validation of genetic variants associated to late severe toxicity after prostate cancer RT

A. Cicchetti<sup>1</sup>, T. Rancati<sup>2</sup>, F. Ballarini<sup>3</sup>, M. Dispinzieri<sup>4</sup>, T. Giandini<sup>5</sup>, B. Avuzzi<sup>4</sup>, C. Cozzarini<sup>6</sup>, C. Fiorino<sup>7</sup>, R. Valdagni<sup>8</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori and University of Pavia, Prostate cancer program/Department of Physics, Milan, Italy ; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate cancer program, Milan, Italy ; <sup>3</sup>University of Pavia, Physics Department INFN-Section of Pavia, Pavia, Italy ; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy ; <sup>5</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy ; <sup>6</sup>San Raffaele Scientific Institute, Radiation Oncology, Milan, Italy ; <sup>7</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy ; <sup>8</sup>University of Milan and Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Oncology and Hemato-oncology / Prostate cancer program & Radiation Oncology 1, Milan, Italy

### Purpose or Objective

To validate the impact of single nucleotide polymorphisms (SNPs) on radio-induced toxicity (tox) after curative RT for prostate cancer (PC).

### Material and Methods

Comprehensive literature search for SNPs associated to increased risk for tox after PC RT was carried out. A panel of 8 SNPs was established.

A cohort of PC patients (pts) from a prospective trial on RT-induced toxicity was identified.

They were treated with radical IMRT to a total dose of 78Gy at 2Gy/fr or to 65-74.2Gy with 2.55-2.65Gy/fr.

Blood samples were collected during the follow up (fup) for DNA extraction (Oct2016-May2017).

Selected endpoint was overall moderate-severe late tox assessed at 3 year-fup, i.e. scoring of at least one symptom among the following: grade $\geq$ 2 rectal bleeding (CTCAE), chronic faecal incontinence (FI) (CTCAE average grade $>$ 1 during whole fup), severe urinary dysfunction (15-point worsening in IPSS questions #1to#7), hematuria, stricture and moderate-severe urinary incontinence (by 2-point worsening in ICIQ question #3).

Association of selected SNPs with overall late tox was investigated through logistic regression (LR).

Confirmed SNPs (similar Odds Ratios) were later included into a LR model together with Equivalent Uniform Dose (EUD) for bladder and rectum, as computed from DVHs corrected with a/b=3Gy). For both bladder and rectum, volume parameters n for overall late tox were determined by literature search.

### Results

108 pts were included in the study. Overall late tox was scored in 37 pts (34%).

3/8 investigated SNPs were confirmed: rs3931914CG, rs2293054GA and rs845552AG (De Langhe Rad&Onc 2014, see Fig. 1 for details).

From literature search, we identified a volume parameter n=0.1 for bladder (p=0.003, i.e. bladder acting as serial organ for late urinary tox) and n=0.25 for rectum (p=0.007, i.e. relevance of medium to high doses is kept, correctly matching the presence of 2 distinct patterns in late rectal tox, which includes both bleeding, affected by small volumes receiving high doses, and FI, affected by mean rectal dose).

The final LR model included: bladder EUD (fitted OR=1.10), rectal EUD (fitted OR=1.09) and SNPs (literature OR=2.59, 0.23 and 5.3 for rs845552AG, rs2293054GA and rs3931914CG ). Total p=0.015, calibration slope=0.83 and AUC=0.70, details on calibration in fig 2b.

Fig 2a presents the nomogram derived from LR model, where the genetic risk score is reported as the number of SNPs harboured by the single patient. The nomogram highlights that given the same dose to organs at risk (i.e. same bladder EUD+rectal EUD) presence of 1 SNP is increasing tox risk by 5%, while presence of 2 or 3 SNPs increases tox risk by more than a factor 2.

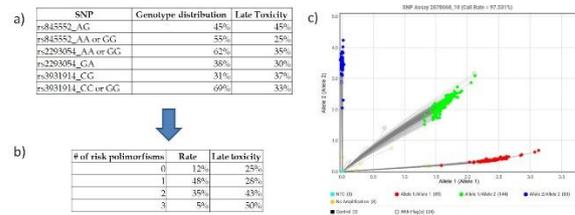

Fig. 1: Panel a) Genotype distribution among the patients and rate of late toxicity in the dichotomized categories, panel b) patients classification by number of risk polymorphisms, panel c) example of rs845552 distribution before the dichotomization.

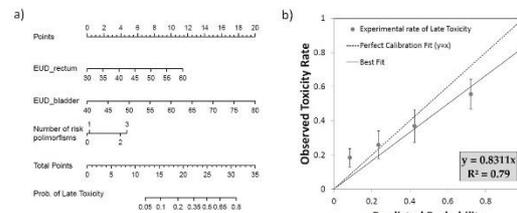

Fig. 2: Panel a) Predictive nomogram of Late Overall Toxicity with genetic risk score reported as number of risk polymorphisms, panel b) Calibration Plot for the predictive model with EUD+SNPs (with coefficients showed in De Langhe et al.)

### Conclusion

3 SNPs previously identified as associated with increased risk of RT-induced tox were confirmed in this validation study. **Late overall tox incidence was well described by a data+literature driven model** (effect size of SNPs and volume parameters for EUD calculations from literature, effect size for bladder and rectal EUD fitted on data).

### PO-0860 Improving consistency of proximal seminal vesicle delineation for prostate SBRT

K. Morrison<sup>1</sup>, N. Van As<sup>1</sup>

<sup>1</sup>Royal Marsden NHS Trust, Radiotherapy, London, United Kingdom

### Purpose or Objective

Accurate and consistent clinical target volume (CTV) delineation is important in stereotactic body radiotherapy (SBRT). The proximal 1 - 2 cm seminal vesicles (pSV) are included in the CTV for low/ intermediate risk prostate cancer, however there is no clear consensus on how this should be defined. Within the PACE SBRT trial, inconsistent pSV delineation has been demonstrated between centres. The aim of this study is to investigate a delineation method which will improve consistency in further trials.

### Material and Methods

21 experienced prostate radiotherapy clinicians (consultants and trainees), were identified at a national uro-oncology conference, and invited to participate in a contouring exercise. Using fused CT and MRI imaging from one selected intermediate-risk prostate cancer case, participants were instructed to contour: superior prostate (partial contour provided); full seminal vesicles (SV); and proximal 1cm SV as defined by the clinician (pSV method A). A further pSV contour was defined by creating a 1cm circumferential prostate margin, and including the section of SV within this region (pSV method B). For each method, investigational contours were compared to a set of reference contours, using measured volume (cc) and calculated conformity indices: DICE similarity coefficient; Geographical Miss Index (GMI); and Discrepancy Index (DI). Results for methods A and B were compared to analyse differences in consistency, using paired t-test to measure statistical significance.

### Results

19 sets of contours were complete and analysable. For pSV method A, the mean investigational contour volume was 11.07 cc (95% CI 9.04 - 13.11) compared to the reference contour 8.65 cc. For method B, the mean investigational

volume was 5.91 cc (95% CI 5.49 - 6.34) compared to the reference contour volume of 6.46 cc. The mean DICE similarity coefficient (ideal value 1) for method A was 0.67 (95% CI 0.63 - 0.71), and was significantly higher for method B at 0.81 (95% CI 0.78 - 0.84,  $p < 0.0001$ ), demonstrating greater concordance with the reference contour. The mean DI (ideal value 0) was 0.35 (95% CI 0.28 - 0.43) for method A, and was significantly lower for method B at 0.15 (95% CI 0.11 - 0.18,  $p < 0.0001$ ) indicating a lower possibility of excessive contouring with this method, in comparison to the reference contour. The was not a significant difference in mean GMI (ideal value 0), at 0.24 (95% CI 0.16 - 0.32) for method A, and 0.23 for method B (95% CI 0.18 - 0.27,  $p = 0.7$ ).

#### Conclusion

Consistency of pSV delineation is improved by the use of a circumferential prostate margin to define the extent of the seminal vesicles to be included in the target volume. This method is recommended for use in future prostate radiotherapy trials, and will be adapted for the PACE C trial which will compare SBRT with conventional radiotherapy in higher risk patients, including 2cm pSV within the CTV.

#### PO-0861 Analysis of nodal and prostatic bed RT in oligorecurrent PC patients treated with PSMA-PET-guided RT

S. Kirste<sup>1</sup>, S. Kroeze<sup>2</sup>, C. Henkenberens<sup>3</sup>, N. Schmidt-Hegemann<sup>4</sup>, M. Vogel<sup>5</sup>, J. Becker<sup>6</sup>, H. Christiansen<sup>7</sup>, S. Combs<sup>8</sup>, A. Müller<sup>9</sup>, C. Belka<sup>10</sup>, M. Guckenberger<sup>2</sup>, A. Grosu<sup>11</sup>

<sup>1</sup>University Hospital Freiburg, Radiooncology, Freiburg, Germany ; <sup>2</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland ; <sup>3</sup>Medical School Hannover, Department of Radiooncology and Special Oncology, Hannover, Germany ; <sup>4</sup>University Hospital LMU Munich, Department of Radiation Oncology, Munich, Germany ; <sup>5</sup>Technical University Munich, Department of Radiation Oncology, Munich, Germany ; <sup>6</sup>University Hospital Tübingen, Department of Radiooncology, Tübingen, Germany ; <sup>7</sup>Medical School Hannover, Department of Radiotherapy and Special Oncology, Hannover, Germany ; <sup>8</sup>Technical University Munich, Department of Radiooncology, Munich, Germany ; <sup>9</sup>University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany ; <sup>10</sup>University Hospital LMU Munich, Department of Radiooncology, Munich, Germany ; <sup>11</sup>University of Freiburg, Department of Radiooncology, Freiburg, Germany

#### Purpose or Objective

Patients with prostate cancer and PSMA-PET/CT detected oligo-recurrent disease are a very heterogeneously treated group of patients. Various treatment regimens are currently practiced in different institutions in an individual approach to this patient group; in particular, there are no clear recommendations concerning doses, treatment fields and radiation techniques (conventional versus hypofractionated versus stereotactic body radiotherapy). This study's aim is to investigate treatment patterns at different institutions and to analyze the influence of target volume concepts on progression-free-survival (PFS).

#### Material and Methods

Data of 305 patients from 6 different academic centers that were treated with definite radiotherapy (RT) because of oligorecurrent 68Ga-PSMA -positive prostate cancer between 04/2013 and 01/2018 were evaluated. To describe treatment regimen at different institutions descriptive statistics was used. PFS was analyzed using Kaplan-Meier survival curves and log rank testing. Uni-, and multivariate analyses were performed to determine influence of treatment parameters on PFS.

#### Results

According to the pretreatment PSMA-PET/CT 92 patients (30.2%) had a recurrence in the prostate bed only, 134 (43.9%) had recurrence in the lymphatics with or without prostate bed recurrence and 79 patients (25.9%) had distant metastasis. RT was directed to the PET/CT-positive lesions only, without elective RT in 85 patients (27.9%). The prostate bed was irradiated in 234 patients (76.7%) either electively (103 patients) or because of a PSMA-PET/CT detected recurrence (131 patients). 71 patients (23.3%) received treatment to other lesions without irradiation of the prostate bed. If the prostate bed was electively irradiated the median dose was 66.6 Gy (range, 48 - 70 Gy) in single doses of 1.8 - 2 Gy. If pelvic lymphatics were electively irradiated median dose was 47.5 Gy (range, 42-56 Gy) in single doses of 1.8 Gy (1.5 - 2 Gy). Most patients were treated with conventional RT 155 (50.8%) or conventional RT with a simultaneous integrated boost (SIB) technique 122 (40%). SBRT was used in 18 (5.9%) and combined SBRT and conventional RT in 10 (3.3%) patients. Patients who did not receive elective RT of the prostate bed had a 3- year biochemical free survival of 38% compared to 57% of patients who received RT of the prostate bed. Median biochemical free survival was 24 vs. 32 months ( $p=0.03$ ). Dose to the prostate bed or lymph nodes had no influence on PFS. Elective RT to the pelvic or paraaortic lymph nodes did not result in a statistically significant difference in PFS (25 vs. 30 months). In multivariate analysis location of recurrence and type of radiotherapy (conventional RT vs. SBRT and combined conventional/SBRT) were significantly associated with PFS.

#### Conclusion

Treatment regimens for PSMA-positive oligorecurrent prostate cancer in 6 academic institutions vary substantially in terms of treatment fields and technique. Patients who did not receive elective irradiation of the prostate bed had a significantly worse PFS than patients who received elective irradiation of the prostate bed.

#### PO-0862 P2 RCT of Home-based physical activity in pts treated by ADT and EBRT for localised prostate carcinoma

C.P. Doyle<sup>1</sup>, P. Thirion<sup>2</sup>, B. O'Neill<sup>2</sup>, M. Dunne<sup>2</sup>, V. Curtis<sup>3</sup>  
<sup>1</sup>Trinity Biomedical Science Institute, Medicine, Dublin, Ireland ; <sup>2</sup>St Lukes Radiation Oncology Network, Radiation Oncology, Dublin, Ireland ; <sup>3</sup>The London School of Hygiene and Tropical Medicine, Disease Control, London, United Kingdom

#### Purpose or Objective

To assess the feasibility and efficacy of a home-based moderate-to-vigorous physical activity walking exercise intervention (MVPA-WEI) in patients (pts) with localised prostate cancer treated by protracted (6-8 weeks) fractionated External Beam Radiotherapy (EBRT) and short-term (< 1 year) Androgen Deprivation (ADT).

#### Material and Methods

A Phase 2 randomised trial compared standard of care versus home-based MVPA-WEI, consisting of a prescription of 3000 steps in 30 minutes on 5 days each week, i.e. a cadence of 100 steps/minute (in addition to patient pre-determined habitual step/day) for the duration of radiotherapy (7-8 weeks).

Patients treated radically for localised prostate carcinoma by a combination of AD and EBRT, having completed a minimum of 3 month of induction and requiring concomitant AD during EBRT, in addition to having a sedentary life style were eligible for recruitment.

Intervention feasibility was evaluated through quantitative and qualitative methods. The efficacy endpoints were: **Adherence to exercise prescription** (pedometer and logbook [walking frequency, intensity and time]), **Fatigue** (Brief Fatigue Inventory [0-90]), **Health Related Quality of Life** (FACT-P [0-156]), **Anthropometric measures** (Weight [kg], % Body fat, % Muscle mass, Waist

circumference [cm]) and Functional Fitness [2 minute step test and 30 second sit-to-stand test]).

Patient were recruited at planning CT scan and randomised at fraction 6 of EBRT. Assessments were conducted at baseline (planning CT), mid EBRT, end of EBRT, and at 1 month post EBRT.

#### Results

From 02/2014 to 04/2014, 24 pts were recruited (12 per arm). All pts were evaluable. The overall MVPA-WEI adherence rate in the intervention group was 81.8%. 33% of pts in the control group increased their average daily step count. When compared to baseline, pts allocated to the intervention group experienced at 1 month post EBRT, greater and persistent improvements in 1) fatigue [mean Fatigue score difference: -20.17 vs. +5.75], 2) quality of life [Improved FACT-P score only noted in the intervention group], 3) anthropometric measurements [mean weight difference: -1.7 Kg vs. + 1.7 Kg, mean % body fat difference: - 1.1% vs. +1.1%, mean waist circumference difference: -0.9 cm vs. + 3.4 cm, mean % muscle mass difference: +0.5% vs. - 0.8%] and 4) physical performance [2min step performance difference: +55.8% vs. + 30%, Sit-to-stand test performance difference: +25.3% vs. 9.0%]

#### Conclusion

This preliminary evidence suggests that a pragmatic home-based MVPA-WEI is feasible and has potential clinical benefits in pts treated by EBRT+ADT, and thus provides a strong rationale for a Phase 3 randomised trial.

#### PO-0863 Adaptive radiotherapy for carcinoma of the urinary bladder: Long term outcomes with dose escalation

P. Gupta<sup>1</sup>, V. Murthy<sup>1</sup>, K. Baruah<sup>1</sup>, R. Krishnatry<sup>1</sup>, G. Bakshi<sup>1</sup>, G. Prakash<sup>2</sup>, M. Pal<sup>2</sup>, A. Joshi<sup>3</sup>, K. Prabhaskar<sup>3</sup>  
<sup>1</sup>Tata Memorial Centre, Dept of Radiation Oncology, Mumbai, India ; <sup>2</sup>Tata Memorial Centre, Dept of Urology, Mumbai, India ; <sup>3</sup>Tata Memorial Centre, Dept of Medical Oncology, Mumbai, India

#### Purpose or Objective

This study was done to assess the clinical outcomes with dose escalated, image guided adaptive radiation therapy (ART) in patients of muscle invasive bladder cancer (MIBC), as a part of trimodality treatment approach for bladder preservation.

#### Material and Methods

Patients with non-metastatic MIBC treated with ART were analysed. After maximal resection of bladder tumor, they were treated with radical chemoradiation. For ART, 3 anisotropic planning target volumes were concentrically grown (PTVs small, medium and large) around the bladder. A library of intensity modulated radiotherapy (IMRT) plans was created for each patient. A dose of 64 Gy in 32 fractions to the whole bladder and 55 Gy to the pelvic nodes was planned. In selected patients with solitary tumor or two tumors in close proximity, without any in situ carcinoma component, dose escalation to tumor bed to 68 Gy (equivalent dose for 2-Gy fractions assuming  $\alpha/\beta$  of 10 [EQD2]<sub>10</sub> = 68.7 Gy) was planned. Simultaneous integrated boost was used for dose escalation and these patients were treated with a comfortably full bladder. On-board daily megavoltage imaging was used every day to choose the most appropriate PTV encompassing the bladder ('Plan-of-the-day' approach) for each fraction.

#### Results

A total of 106 patients were analysed. Most patients had T2 (68%) or T3 (19%) disease. Twenty three patients (22%) received neoadjuvant chemotherapy and 76% received concurrent weekly chemotherapy (platinum-based in 63%, gemcitabine-based in 35%). Ninety two patients (87%) completed the planned dose of 64 Gy to the whole bladder

while sixty three patients (59%) received 68 Gy to the tumor bed as boost. With a median followup of 26 months, 3-year locoregional control (LRC), disease-free survival (DFS), and overall survival (OS) were 74.3%, 62.9%, and 67.7% respectively. 82% retained a disease-free bladder, while another 8.5% had non muscle invasive recurrences managed conservatively. Patients receiving dose escalation to 68 Gy showed no difference in OS and DFS compared to those receiving <68 Gy. Acute and late Radiation Therapy Oncology Group (RTOG) grade III/IV genitourinary (GU) toxicity was seen in 7.5% and 6.5% patients respectively. Acute and late RTOG grade III gastrointestinal (GI) toxicity was seen in 0% and 3.8% patients respectively. The incidence of grade III/IV acute or late GU or GI toxicity was not found to be associated with dose escalation.

#### Conclusion

Dose escalation with adaptive plan-of-the-day approach for bladder irradiation is clinically safe and effective. A high bladder preservation rate can be achieved without compromising on survival or toxicities using plan of the day ART.

#### PO-0864 Normal tissue sparing with diffusion weighted MRI informed tumour boost in bladder radiotherapy

K. Chan<sup>1</sup>, K. Warren-Oseni<sup>2</sup>, H. Abdel-Aty<sup>3</sup>, A. Dunlop<sup>2</sup>, D. McQuaid<sup>2</sup>, M. Koh<sup>3</sup>, A. Sohaib<sup>3</sup>, R. Huddart<sup>3</sup>, S. Hafeez<sup>3</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom ; <sup>2</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom ; <sup>3</sup>The Institute of Cancer Research - The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom

#### Purpose or Objective

Partial bladder radiotherapy for the radical treatment of muscle invasive bladder cancer (MIBC) can be utilized with no adverse effect on local control [1, 2]. Studies however have failed to show improved toxicity. This may be due in part to uncertainty in CT based GTV delineation. DWI has an established diagnostic role in local MIBC staging with improved accuracy over CT. Here we evaluate the use of DWI to inform GTV delineation and its impact on normal tissue sparing.

#### Material and Methods

Twenty-one patients with unifocal T2-T3N0M0 MIBC recruited to an ethics approved phase I dose escalation radiotherapy protocol (NCT01124682) were evaluated. For treatment the tumour boost volume (GTV) was delineated on the radiotherapy planning CT (GTV<sub>CT</sub>). Pre-radiotherapy DWI was performed on a 1.5T system using b values 0, 50,100, 250, 500 and 750s/mm<sup>2</sup>. GTV was drawn on 750 s/mm<sup>2</sup> image (GTV<sub>DW-MRI</sub>) using in-house software (Adept, Institute of Cancer Research, London), was imported into the TPS (Raystation 6.99, RaySearch Laboratories, Stockholm, Sweden) and registered to the radiotherapy planning CT scan (using anatomical information from T2 and b0 image). The GTV and CTV (whole bladder) was expanded anisotropically (1.5cm anteriorly and superiorly, 1.0cm posteriorly and 0.5cm laterally and inferiorly) to create PTV<sub>boost-CT</sub>, PTV<sub>boost-DW-MRI</sub>, and PTV<sub>bladder</sub>. Two VMAT plans were created (for five patients), each treating PTV<sub>bladder</sub> to 52Gy and PTV<sub>boost</sub> to 70Gy in 32 fractions using the two different PTV<sub>boost</sub> volumes. Target volumes and dose to normal structures between were compared using Wilcoxon signed rank test where possible.

#### Results

All tumours seen on T2 image were identified on DWI. In 3 patients no tumour was seen on either T2 or DWI. Mean GTV<sub>CT</sub> was 34.1cm<sup>3</sup> (SD 21.1; range 6.7-78.7). Mean GTV<sub>DW-MRI</sub> was 15.6cm<sup>3</sup> (SD 23.4; range 0-104.4). GTV<sub>DW-MRI</sub> was significantly smaller than GTV<sub>CT</sub> (p=0.001).

Table below summaries normal tissues constraints achieved at planning.

Organ at risk	Constraint	*Plan using PTV <sub>boost,CT</sub>			*Plan using PTV <sub>boost,DWI</sub>		
		Median	Range	Median	Range	Median	Range
Rectum	V30<80%	39.2	27.5	44.0	37.6	21.7	43.4
	V50<60%	1.1	0.8	6.4	2.0	0.8	6.7
Other bowel	V30<178 cm <sup>3</sup>	146.5	0.0	352.7	141.8	0.0	316.6
	V45<139 cm <sup>3</sup>	62.9	0.0	144.1	94.2	0.0	206.1
	V50<127 cm <sup>3</sup>	50.5	0.0	115.1	62.6	0.0	137.1
	V55<115 cm <sup>3</sup>	34.2	0.0	66.9	5.2	0.0	24.1
	V60<98 cm <sup>3</sup>	11.9	0.0	39.2	3.1	0.0	17.8
	V65<40 cm <sup>3</sup>	7.1	0.0	31.4	1.1	0.0	13.4
Normal bladder outside PTV <sub>boost</sub>	V60<80%	22.3	15.2	63.9	22.1	8.4	77.9
	V65<50%	33.0	7.9	91.6	11.0	3.6	53.3

\*Where n=5, and corresponding median GTV<sub>CT</sub> was 43.6 cm<sup>3</sup> (range 19.3-76.1), median GTV<sub>DWI</sub> was 10.1 cm<sup>3</sup> (range 4.3-30.7)

## Conclusion

DWI informed boost delineation for bladder radiotherapy planning improved normal tissue sparing at high dose bowel and bladder constraints by >60% compared to CT based GTV delineation. Acquiring DWI for radiotherapy planning may therefore complement target volume delineation and inform non-uniform dose delivery to biological sub-volumes for bladder radiotherapy dose escalation trials. Work is on-going to demonstrate this.

## Poster: Clinical track: Skin cancer / malignant melanoma

### PO-0865 Curative HDR brachytherapy (HDR-BT) for non-melanoma skin cancers (NMSC)

B. Emami<sup>1</sup>, C. Hentz<sup>1</sup>, I. Rashed<sup>1</sup>, K. Stang<sup>1</sup>, A. Gliniewicz<sup>1</sup>, M. Mysz<sup>1</sup>, D. Eilers<sup>1</sup>, R. Tung<sup>1</sup>

<sup>1</sup>Loyola University Medical Center, Radiation Oncology, Maywood, USA

#### Purpose or Objective

NMSC is the most common malignancy. Standard treatments are surgery; radiotherapy: external beam radiotherapy (EBRT) and brachytherapy with HDR-BT and electronic brachytherapy (e-BT) sources.

With some treatment modalities, incompatibility with certain anatomical sites (surgery and e-BT), operational/wound complications (surgery), dosimetric limitations (e-BT), and cosmetic/functional complications (surgery) often result in suboptimal cure rates or unacceptable sequela. In order to overcome these issues, we have used HDR-BT in treatment of selected NMSC patients.

#### Material and Methods

From July 2015 to June 2018, 105 NMSC lesions of basal cell carcinoma (BCC), squamous cell carcinoma (SCC), cutaneous T cell lymphoma (CTCL), or Merkel cell carcinoma in 75 patients were treated using HDR-BT (Iridium-192) using an Elekta Freiburg flap surface applicator according to an internal review board approved prospective protocol.

Targeted lesions with 5-10mm margins were delineated at the time of CT simulation using radiopaque wires attached to thermoplastic mesh. The Freiburg flap is affixed to the mesh surface. A dose of 32-40 Gy in 8-10 fractions was delivered to a depth of 3-5 mm depending on lesion thickness. Patient and treatment characteristics, pain level and medication use, early (<3 month) and late toxicities (CTCAE v4.03), physician- and patient-reported cosmesis, and cancer outcomes were recorded in a prospective manner. Univariate generalized linear mixed effects models were used to estimate odds of suboptimal cosmesis (fair-poor vs. excellent-good).

#### Results

Median age of patients was 82 (range 74-88). Fifty-eight percent of lesions were SCC, 42% BCC. The median lesion size was 4mm (range 4mm - >5cm). Patient comorbidities were also recorded, with 51% of patients with vascular

disease, 26% current or former smokers, and 20% with autoimmune disease. The median follow-up time is 15 months. Results are shown in Table 1 and Figure 1.

Site	Histology	n	Tumor Control (%)	RFS (%)	Acute Skin Toxicity (≥ grade 2)	Late Skin Toxicity (≥ grade 2)	Physician Reported Cosmesis	Patient Reported Cosmesis
H&N	BCC	24	100%	100%	4/30%	0%	Good-Excellent in 100%	Good-Excellent in 95.8%
	SCC	19	100%	100%	0%	0%	Good-Excellent in 100%	Good-Excellent in 100%
Skull	BCC	1	100%	100%	0%	0%	Good-Excellent in 100%	Good-Excellent in 100%
	SCC	17	94%	94%	0%	0%	Good-Excellent in 100%	Good-Excellent in 100%
Extremities	BCC	8	100%	100%	1 of 6	0%	Good-Excellent in 100%	Good-Excellent in 100%
	SCC	24	96%	96%	4%	0%	Good-Excellent in 94%	Good-Excellent in 92%
Other	BCC	1	100%	100%	0%	0%	Excellent 100%	Excellent 100%
	SCC	1	100%	100%	0%	0%	Excellent 100%	Excellent 100%

Table 1. Treatment of selected subtypes, basaloid and squamous. \*Single SCC recurrence in immunosuppressed patient who died of her aggressive metastatic disease.

Figure 1. (a) Pre-treatment tumor (scalp), (b) HDR-BT Treatment Setup, (c) Outcome at completion of treatment, (d) Outcome at 1 year follow-up. Note: After completion of treatment patient underwent hair coloring.

## Conclusion

HDR-BT with surface applicators has important dosimetric and time advantages over other radiation modalities for NMSC. Based on our results, HDR-BT also offers excellent tumor control with exceptional cosmetic results in properly selected patients with NMSC. Future directions include a multi-institutional randomized trial comparing HDR-BT with EBRT.

### PO-0866 Cost-effectiveness analysis of stereotactic radiotherapy in melanoma brain metastases.

A. Paix<sup>1</sup>, F. Thillays<sup>2</sup>, F. Courtault-Deslandes<sup>3</sup>, I. Pop<sup>4</sup>, J. Biau<sup>5</sup>, O. Briard<sup>6</sup>, A.L. Grosu<sup>4</sup>, E.A. Sauleau<sup>7</sup>, G. Noël<sup>1</sup>

<sup>1</sup>Centre Paul Strauss, Radiothérapie, Strasbourg, France ;

<sup>2</sup>Institut Cancérologique de l'Ouest, Radiothérapie, Saint-Herblain, France ;

<sup>3</sup>Centre Georges-François Leclerc, Radiothérapie, Dijon, France ;

<sup>4</sup>Universitätsklinikum Freiburg, Klinik für

Strahlenheilkunde, Freiburg, Germany ;

<sup>5</sup>Centre Jean Perrin, Radiothérapie, Clermont-Ferrand, France ;

<sup>6</sup>Centre Henry Kaplan - Centre Hospitalier Universitaire de Tours, Radiothérapie, Tours, France ;

<sup>7</sup>Centre Hospitalier Universitaire de Strasbourg, Groupe de

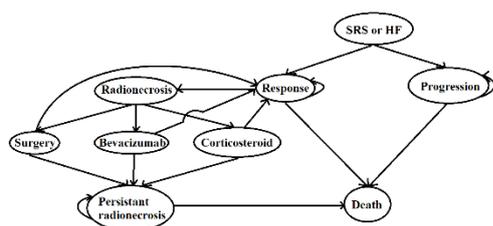

méthodologie et recherche clinique GMRC, Strasbourg, France

#### Purpose or Objective

Melanoma is the third cancer responsible for brain metastases in frequency. To treat these metastases, when a safe surgery could not be performed, there is a global agreement to prefer stereotactic radiotherapy, performed in either one single fraction (SRS) or several fractions (HFSRT), over whole brain irradiation, to preserve cognitive function with a better metastases response to treatment.

#### Material and Methods

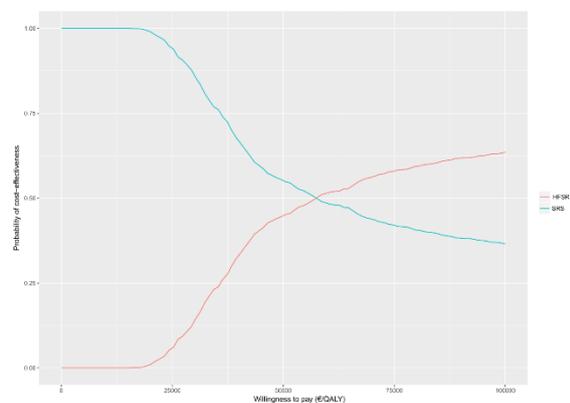

We developed a Markov model, reported in Figure 1, based on retrospectively collected data of treatment delivered in 6 hospitals in France and Germany, to describe survival and treatment-related complications of patients treated for a single melanoma brain metastasis. This analysis was conducted from the French payer perspective on a lifetime horizon. Utility values, recurrence risks, and costs were adapted from the literature. Deterministic (DSA) and probabilistic (PSA) sensitivity analyses were performed to assess the influence of the assumptions made.

## Results

In the base case analysis, SRS and HFSRT total costs were 5,444.68€ and 7,349.83€, and the quality-adjusted life expectancies were 1.4641 and 1.4763.

In the probabilistic sensitivity analysis, SRS and HFSRT were associated with a mean total cost of 5,258.77€ and 7,138.91€, and a quality-adjusted life expectancy of 1.4709 and 1.4928 QALYs, respectively. SRS appeared to be 1,880.14€ cheaper than HFSRT with a decrease of quality-adjusted life expectancy of 0.0219 QALYs. The acceptability curves reported a probability of cost-effectiveness of nearly 85.1% and 36.5% for SRS for willingness thresholds of 30,000 and 100,000€/QALY respectively, as represented in the acceptability curves reported in Figure 2.

## Conclusion

This is the first medico-economic evaluation of SRS and HFSRT in melanoma brain metastases and its results suggest that HFSRT is cost-effective over SRS.

## Poster: Clinical track: Sarcoma

### PO-0867 Prognostic impact of the "Sekhar Grading System for Cranial Chordomas" - an attempt at validation

A. Hottinger<sup>1,2</sup>, B. Bojaxhiu<sup>1</sup>, M. Walser<sup>1</sup>, B. Bachtary<sup>1</sup>, A. Pica<sup>1</sup>, D.C. Weber<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland ; <sup>2</sup>University Hospital Basel, Radiotherapy and Radiation Oncology, Basel, Switzerland

#### Purpose or Objective

Skull base chordomas (SBCs) are rare and heterogeneously behaving tumors. Though still classified as benign they can grow rapidly and are locally aggressive. To adapt the treatment to the specific needs of patients at higher risk of recurrence, a preoperative grading system would be useful.

The aim of this retrospective analysis was to assess the prognostic impact of the "Sekhar Grading System for Cranial Chordomas" (SGSCC; Brito da Silva et al. *Cranial Chordoma: A New Preoperative Grading System*.

*Neurosurgery* 2017;0:1-13) looking at the cohort of patients treated at our institution as to determine if the SGSCC is reproducible in a larger cohort and ultimately to ensure more risk adapted local treatments for these challenging tumors.

#### Material and Methods

Searching our database, we identified patients (n = 142) treated for SBC between 2004 and 2016 with surgery and pencil beam scanning proton therapy. We analyzed the patient specific data focusing on the 5 criteria proposed for the SGSCC (recurrence after prior treatment, tumor size, number of anatomic regions and vessels involved as well as intradural invasion) and sorted them according to their scores (ranging from 2 to 25 points) into three prognostic groups (0-7 points low-risk, 8-12 points intermediate-risk and 13-25 points high-risk). The three groups were then analyzed in regards of local control (LC), local recurrence free survival (LRF5) and overall survival (OS).

#### Results

The mean clinical follow up was 53.7 (range, 3.2-152.3) months; of the entire cohort, 34 (23.9%) patients had a local recurrence (LR), resulting in a LC of 75% at 5 years. OS was 83% at 5 years, 12 (8.5%) patients died due to local progression. The LRF5 at 5 years was 70%. When split into the three SGSCC prognostic groups, the observed LC was 90%, 72% and 64% (p = 0.07) in the low-, intermediate- and high-risk group, respectively. A similar correlation existed for LRF5 with 93%, 89% and 66% (p = 0.05) and for OS with 89%, 83% and 76% (p = 0.65) for the same SGSCC prognostic groups.

#### Conclusion

After splitting our patient cohort into three SGSCC risk groups we found a trend towards better outcome for those SBC patients treated with proton therapy with lower as opposed to higher scores.

### PO-0868 Total Marrow Irradiation in Myeloma Multiple patients candidate to allogeneic transplant

A. Chiara<sup>1</sup>, S. Broggi<sup>2</sup>, M. Pasetti<sup>1</sup>, I. Dell'oca<sup>1</sup>, M. Azizi<sup>1</sup>, G. Salvadori<sup>1</sup>, S. Selli<sup>1</sup>, M. Marcatti<sup>3</sup>, A. Assanelli<sup>3</sup>, J. Peccatori<sup>3</sup>, M. Cattaneo<sup>2</sup>, F. Ciceri<sup>3</sup>, N. Di muzio<sup>1</sup>

<sup>1</sup>Ospedale San Raffaele, Radioterapia, Milano, Italy ;

<sup>2</sup>Ospedale San Raffaele, Fisica Sanitaria, Milano, Italy ;

<sup>3</sup>Ospedale San Raffaele, Ematologia, Milano, Italy

#### Purpose or Objective

Total Body Irradiation (TBI) is as part of the conditioning regimen for haematopoietic stem cell transplantation in haematological diseases. Higher doses of radiation reduce the relapse rate but increase Treatment Related Mortality (TRM). Total Marrow Irradiation (TMI) using Helical Tomotherapy (HT) showed to enhance the therapeutic ratio ( Target dose/Organ At Risk dose) reducing TRM. We report the first results of feasibility, safety and toxicity of myeloablative Treosulfan-based conditioning chemotherapy (cTreoCT) combined with dose-escalating TMI in patients (pts) affected by advanced Multiple Myeloma (MM).

#### Material and Methods

Twelve patients (pts) (5 males and 7 females with a median age 59 yrs), affected by advanced MM, were treated from December 2012 to January 2018. All pts received a cTreoCT combined with TMI using HT. 2 Gy (2 times a day) was delivered with a dose escalation approach from 8 to 14 Gy; the total dose is increased in a triplet approach only if extra-hematological (G<sub>2</sub> ≥ 4 grade) toxicities don't appear in the previous dose patient's group. The treatment was delivered with two different plans: an upper plan from head to half leg (Head First Supine Setup) and with a low plan included the complete legs (Feet First Supine Treatment). Both plans were delivered in helical mode. For each pt a personalized immobilization device, including head, thorax/pelvis and foot masks, was builded.

## Results

All pts received the planned TMI dose (95% of PTV received almost 90% of prescription dose) with a good Organ At Risk (OAR) sparing (the dose at OAR was < 50% of prescription dose); all pts, after the transplant, achieved engraftment with no secondary graft failure. No grade 3-4 extra-hematological toxicity has been registered in the first 30 days. Five deaths have occurred, 2 due to TRM and 3 due to progression disease. With a median follow-up time of 39 months, 3-yr PFS was 38% and 3-yr OS was 48%. Day +100 incidence of grade II-IV aGVHD was 36%; grade III-IV 9%; 1-year incidence of cGVHD was 39%. 3-year relapse incidence was 39%. 7 pts have experienced an extensive/severe cGVHD with significant involvement the lower legs and ankles. This toxicity seems more evident for patients treated with higher doses (>10 Gy), probably correlated also to the skin higher dose delivered with HT technique, in particular at the pretibial level for patients with poor adipose pannicle. The combination effect with the type of cTreoCT and with the type of used GvHD prophylaxis regimen should be better investigated.

## Conclusion

These data show that TMI addition to cTreoCT is feasible and has not demonstrated an addition of at least short-term toxicities. The late toxicity found in the limbs leads us to find solutions to avoid such side effects in patients irradiated at doses above 12 Gy, such as reviewing the PTV contouring at the tibia level or as using different techniques in legs irradiation (like tomodirect) and as improving GvHD prophylaxis regimen.

### PO-0869 Reducing pulmonary and renal toxicity in children receiving TBI with forward planned IMRT

M. Bishr<sup>1</sup>, E. Nicholson<sup>2</sup>, E. Durie<sup>3</sup>, M. Potter<sup>2</sup>, M. Ethell<sup>2</sup>, C. Anthias<sup>2</sup>, C. Messiou<sup>4</sup>, I. Johnson<sup>5</sup>, S. Eagle<sup>3</sup>, W. Ingram<sup>3</sup>, F. Saran<sup>3</sup>, H. Mandeville<sup>5</sup>

<sup>1</sup>Children's Cancer Hospital Egypt, Department of Radiotherapy, Cairo, Egypt; <sup>2</sup>Royal Marsden NHS Foundation Trust, Department of Haematology, London, United Kingdom; <sup>3</sup>Royal Marsden NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom; <sup>4</sup>Royal Marsden NHS Foundation Trust, Department of Radiology, London, United Kingdom; <sup>5</sup>Royal Marsden NHS Foundation Trust, Children and Young People's Unit, London, United Kingdom

#### Purpose or Objective

Total body irradiation (TBI) is an integral part of conditioning regimens prior to haematopoietic stem cell transplantation (HSCT). However, there is a risk of both short term and long term side effects, especially in children. This study evaluates the pulmonary and renal toxicity of a novel forward planned (FP) intensity modulated radiation therapy (IMRT) TBI technique.

#### Material and Methods

We retrospectively identified 65 paediatric patients (≤ 16 years old) who received TBI-based full intensity allogeneic HSCT between July 2009 and March 2018. The whole body was the specified target volume and the dose was prescribed to the 100% with a reduction of the median lung dose by approximately 15% compared to the whole body. All dose modulations were multi-leaf collimator-based and treatment was delivered twice a day using 10 MV photons and a dose rate of 14-19cGy/min. Pulmonary toxicity was subdivided into infective pneumonia (IP), based on the identification of a causative agent in blood or bronchoalveolar lavage, and idiopathic pneumonitis syndrome (IPS) when no organism could be detected. The estimated glomerular filtration rate (eGFR) was calculated using Schwartz's formula and chronic kidney disease (CKD) was defined as eGFR <60 mL/min/1.73m<sup>2</sup> for ≥ 3 months.

## Results

All patients were treated for haematopoietic malignancies, most commonly acute lymphoblastic leukemia (78.5%), at a median age of 8.7 years (range 2-16). TBI doses were 14.4Gy (63%), 13.2Gy (5%) or 12Gy (32%). Patients were followed up for a median of 1.7 years (range 13 days - 8.3 years) and the mean overall survival (OS) was 58 months (95% CI 45.9 - 70). The 2-year OS was 68% (95% CI 54 - 78) and the 2-year progression-free survival (PFS) was 54% (95% CI 40 - 66). The 100 day non-relapse mortality (NRM) in our patients was 14% (95% CI 7 - 23) and 2-year NRM was 23% (95% CI 13 - 35). None of the patients developed CKD at 5 years and a total of 31 patients (47.7%) developed pulmonary toxicity. Only one patient (1.5%) developed grade 1 IPS, while 30 patients (46.2%) had IP, of whom five patients died accounting for 41.6% of NRM. One patient developed bronchiolitis obliterans organizing pneumonia (BOOP) 4 months post-HSCT and another patient developed pulmonary inflammatory myofibroblastic tumor 6.4 years post-HSCT. Compared to males, females had a lower risk of developing pulmonary toxicity (OR 0.25, p-value 0.037). Patients who were cytomegalovirus (CMV)-mismatched from their donors exhibited 3.4-times higher risk of developing pulmonary toxicity as compared to CMV-matched recipients with a trend for significance (p-value 0.08).

## Conclusion

Compared to parallel opposed technique in literature, our novel FP-IMRT-TBI technique for paediatric full intensity HSCT yields lower rates of renal and pulmonary toxicity, specifically IPS. This favourable safety profile supports the adoption of highly conformal radiotherapy techniques to further improve quality of life of long-term survivors after HSCT in childhood.

### PO-0870 Treatment Outcomes for Pediatric Basal Ganglia Germinomas: A single institute experience in Taiwan

Y. Kang<sup>1</sup>, S. Lin<sup>2</sup>, Y. Lee<sup>3</sup>, F. Chang<sup>4</sup>, M. Liang<sup>3</sup>, H. Chen<sup>3</sup>, Y. Liu<sup>1</sup>, T. Wong<sup>3</sup>, Y. Chen<sup>1</sup>

<sup>1</sup>Taipei Veterans General Hospital, Division of Radiation Oncology- Department of Oncology, Taipei, Taiwan; <sup>2</sup>National Yang-Ming University, Faculty of Medicine, Taipei, Taiwan; <sup>3</sup>Taipei Veterans General Hospital, Division of Pediatric Neurosurgery- Neurological Institute, Taipei, Taiwan; <sup>4</sup>Taipei Veterans General Hospital, Department of Radiology, Taipei, Taiwan

#### Purpose or Objective

Pediatric basal ganglia germinoma is a rare and unique disease. Our purpose was to evaluate the clinical outcomes of pediatric basal ganglia germinomas after treatment.

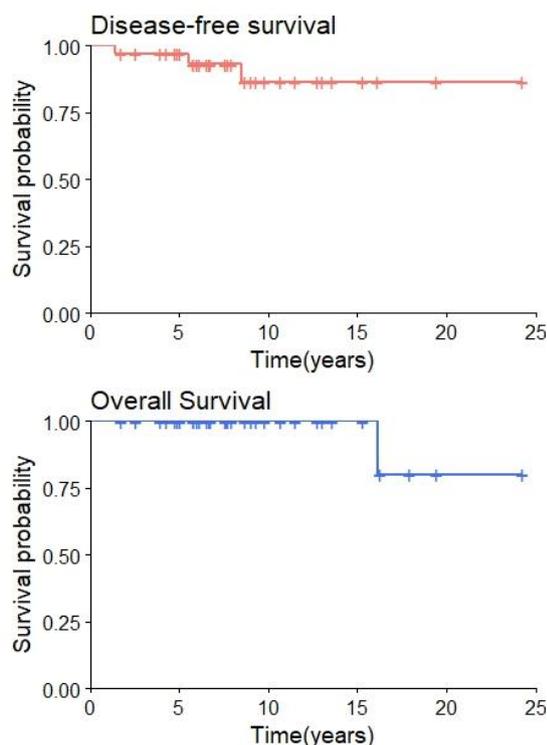

#### Material and Methods

The medical records of 33 children with pediatric basal ganglia germinomas treated at Taipei Veterans General Hospital between 1994 and 2015 were retrospectively reviewed. There were 1 female (3.03%) and 32 males (96.97%) with a median age at diagnosis of 12.18 years (range, 7-19 years old). Age, sex, symptoms, pathological findings, treatment modalities, recurrence patterns, recurrence date, death date, and toxicities were recorded. Survival curves were estimated with the Kaplan-Meier method, and univariate Cox proportional hazards models were used to identify possible risk factors.

#### Results

The median overall survival was 7.77 years (range, 1.76-24.28 years), with 2- and 3-year disease-free survival rates of 97% and 94%, respectively. Thirty patients (90.9%) were treated successfully without recurrence. Three patients (9.1%) suffered from recurrence during follow up, and all of them were treated successfully by salvage treatment. Only one patient (3.0%) died during follow-up because of radiotherapy related sarcoma over scalp. Focal irradiation

showed a trend of lower disease-free survival rate in Kaplan-Meier survival curves ( $p=0.12$ ) when compared to irradiation to whole ventricle, whole brain, or cranial spinal area. There is no disease-free survival difference in risk factors analysis in univariate Cox proportional hazards models, including age, metastatic status at diagnosis, tumor diameter, chemotherapy, and BHCG detection. Patients who received irradiation only to whole ventricle showed lower treatment toxicity and better quality of life during follow-up compared to irradiation to whole brain and cranial spinal area.

### Conclusion

Our results showed excellent disease-free survival and high rate of success of salvage treatment among pediatric basal ganglia germinomas after radiotherapy with or without chemotherapy. Focal irradiation showed a trend of lower disease-free survival, and whole ventricle irradiation showed lower treatment toxicity and better quality of life.

### PO-0871 Efficacy of radiotherapy boost in incompletely resected paediatric ependymoma: a retrospective study

M. Ramos Albiac<sup>1</sup>, B. Gutiérrez<sup>1</sup>, N. Mestre<sup>2</sup>, M. Mota-Foix<sup>3</sup>, S. Pérez-Hoyos<sup>3</sup>, A. Llort<sup>4</sup>, P. Cano<sup>5</sup>, J. Giralt<sup>1</sup>  
<sup>1</sup>Hospital Universitario Vall d'Hebron, Radiation Oncology Department, Barcelona, Spain ; <sup>2</sup>Centro de Regulación Genómica, Centro de Regulación Genómica, Barcelona, Spain ; <sup>3</sup>Vall d'Hebron Institut de Recerca, Unitat d'Estadística i Bioinformàtica, Barcelona, Spain ; <sup>4</sup>Hospital Universitario Vall d'Hebron, Pediatric Oncology, Barcelona, Spain ; <sup>5</sup>Hospital Universitario Vall d'Hebron, Neurosurgery, Barcelona, Spain

### Purpose or Objective

The main objective of the study is to determine whether a radiotherapy boost to residual tumour in incompletely resected paediatric ependymoma confers the same local control (LC) and overall survival (OS) than a complete resection.

### Material and Methods

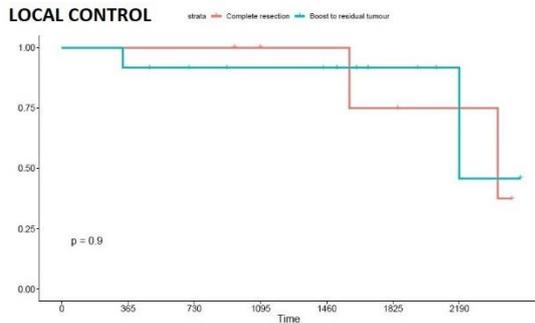

We retrospectively analyzed 23 patients diagnosed with ependymoma and treated with upfront post-operative

radiotherapy in our institution between April 2003 and April 2017. We registered age, sex, location of primary tumour, extent of resection, histological grade, radiation dose to tumour bed, boost dose to residual tumour and radiation technique. We have follow-up data of all patients, having also registered date of first relapse, date of death and/or date of last follow-up. We divided patients in 4 groups according to radiotherapy target volumes: surgical bed in patients with complete resection ( $n=6$ ), surgical bed plus boost to residual tumour ( $n=12$ ), residual tumour only ( $n=4$ ) and tumour bed without boost in one patient with residual tumour. We then compared OS, DFS and LC only for the first two groups using the Kaplan-Meier method. For age and radiotherapy dose, Cox univariate analysis was applied.

### Results

Median follow-up was 4.2 years. The characteristics of the patients are summarized in table 1. Of all 23 patients, 18 of them were alive at the moment of last follow-up, 14 of which were free of disease. 2 patients presented distant failure and 7 patients presented local relapse. We observed non-significant differences in OS, DFS and LC between the complete resection group and the boost group. 2-year OS was 100% and 100% respectively, DFS 100% and 91.7% respectively and LC 100% and 91.7% respectively. 4-year OS was 100% and 87.5% respectively, DFS 100% and 80.2% respectively and LC 100% and 91.7% respectively. We observed statistically significant differences only in DFS for histological grade, response to upfront treatment and age.

Patients characteristics	ALL (N=23)
Age	8.0 [5.75-13]
Sex	
F	11 (47.8%)
M	12 (52.2%)
Location	
Posterior Fossa	14 (60.9%)
Spinal Cord	3 (13%)
Supratentorial	6 (26.1%)
Resection	
Complete	6 (26.1%)
Incomplete	17 (73.9%)
Histological grade	
I	1 (4.3%)
II	6 (26.1%)
III	16 (69.6%)
RT technique	
3DCRT	14 (60.9%)
IMRT	8 (34.8%)
Unknown	1 (4.3%)
Boost (N=12)	
SFRT	7 (58.3%)
SIB	5 (41.7%)
Response	
NER	6 (26.1%)
CR	9 (39.1%)
PR	2 (8.7%)
SD	6 (26.1%)
Relapse location (N=9)	
Local	7 (77.8%)
Distant	2 (22.2%)

### Conclusion

No statistically significant differences in OS, DFS and LC were observed between the complete resection group and the boost group, considering that it is a small series with limited follow-up of some patients. These results are consistent with other published data considering the potential benefit in LC and OS of a radiation boost to residual tumour in incompletely resected ependymoma patients, although further investigation is necessary.

### PO-0872 Hematological toxicity of 3DCRT and VMAT craniospinal irradiation in pediatric medulloblastoma

B. Diletto<sup>1</sup>, E. Pecori<sup>1</sup>, O. Alessandro<sup>2</sup>, S. Meroni<sup>3</sup>, T. Giandini<sup>3</sup>, C. Stucchi<sup>3</sup>, C. Cavatorta<sup>3</sup>, E. Schiavello<sup>4</sup>, V. Biassoni<sup>4</sup>, M. Massimino<sup>4</sup>, E. Pignoli<sup>3</sup>, L. Gandola<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy ; <sup>2</sup>Università degli Studi di Milano, Residency Program in Radiation Oncology, Milan, Italy ; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy ; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Pediatric Oncology, Milan, Italy

### Purpose or Objective

Craniospinal irradiation (CSI) is a milestone of the postoperative treatment of pediatric standard risk (SR) and high risk (HR) medulloblastoma (MB). Advantages of VMAT technique for CSI in term of target coverage and organ sparing have been documented, but it causes exposition of red bone marrow to low doses, worsening hematopoiesis. Aim of the study was the evaluation of hematological toxicity of pediatric SR and HR MB pts treated with 3DCRT or VMAT-CSI.

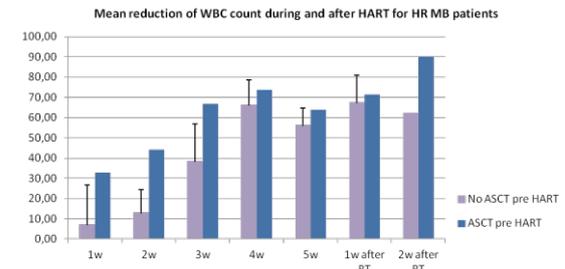

### Material and Methods

RT and clinical details of SR and HR MB pts treated in our Institution were collected. Prescription doses to SR patients: 23.4 Gy/1.8 Gy daily to craniospinal axis, followed by a tumor bed boost up to a total dose of 54 Gy. All SR children then received a standard maintenance chemotherapy (CT). Prescription doses to HR patients: hyperfractionated accelerated RT (HART) with CSI doses of 39 Gy or 31.2 Gy/1.3 Gy bid, depending on age, followed by a boost to the tumor bed up to a total dose of 59.8 Gy when indicated. Before HART all HR pts received high-dose sequential CT. HR pts with persistent disease before HART, were consolidated with 2 courses of myeloablative CT and autologous stem cell transplant (ASCT) before irradiation, while the remaining received standard maintenance CT after HART. Hematological changes were recorded weekly during RT and scored according to RTOG system. Mean RT doses to iliac bones were collected to evaluate dose to red bone marrow.

### Results

Data from 26 patients (SR: 11,HR: 15) were collected (median age 10 y,4-33): 10 pts received 3DCRT (SR: 5,HR: 5), 16 pts VMAT (SR:6,HR:10). 4 HR pts were consolidated with 2 ASCT before HART (3DCRT:1,VMAT:3). Within SR

groups no hematological toxicity differences were observed (4 G3 leuko-neutropenia,3DCRT:2/5,VMAT:2/6). G3 toxicity occurred in all HR pts.G4 (leuko-neutropenia, thrombocytopenia) was recorded in 4 VMAT pts, 3 of whom received ASCT before HART. More use of G-CSF and transfusions during and after RT was required for VMAT pts, and 1 ASCT-VMAT child stopped earlier HART due to hematological toxicity. Pts irradiated with VMAT and undergoing ASCT showed a more pronounced and persistent leukopenia during and after HART (Figure). Evaluation of mean absorbed doses by iliac bones showed a significant difference in pts treated with 3DCRT (0.9 Gy) or VMAT (5.8 Gy).

### Conclusion

Low doses irradiation of red bone marrow during VMAT-CSI has the potential to interfere with hematopoiesis implying a more severe hematological toxicities in HR pts who received ASCT before HART. Hence, to reduce toxicity during VMAT-CSI, at least in this subgroup, iliac bones should be contoured as OAR and a planning effort is strongly recommended to lower mean dose to these structures. Nevertheless, hematological toxicity in our series was never life threatening and always reversible and we continue to recommend VMAT for CSI due to the documented advantages of this technique in sparing higher RT doses to other vital organs such as heart, lungs and liver.

### PO-0873 Associations between vessel volume and neurocognition In children treated with proton therapy

A. Srivastava<sup>1</sup>, J. Contreras<sup>1</sup>, H. Heimos<sup>1</sup>, S. Perkins<sup>1</sup>  
<sup>1</sup>Washington University School of Medicine, RADIATION ONCOLOGY, Saint Louis, USA

### Purpose or Objective

Vasculopathy is a well-recognized late side effect of radiotherapy (RT) in the pediatric population, and RT-induced cerebrovascular injury is thought to induce neurocognitive impairment. In this study we sought to further characterize this relationship by evaluating the effects of proton beam RT (PBT) on volumetric changes in the cerebral vasculature and corresponding changes in neurocognitive function.

### Material and Methods

In this prospective study, we evaluated 13 children, ages 4-21, with a primary CNS malignancy treated with PBT. Magnetic resonance imaging of the brain (bMRI) was obtained pre-treatment and at scheduled follow-up visits post-RT every 3-6 months, and substructures were auto-segmented on MPRage sequences using a well-validated auto-segmentation program. Patients completed neurocognitive testing using the National Institutes of Health Toolbox Cognitive Battery (NIH-TCB) at baseline and during follow-up visits within three months of their bMRIs. Using linear mixed effects models, we evaluated the effects of age, time since PBT, and RT dose on cerebral vessel volumes and TCB metrics.

### Results

The median age at RT was 14 years (range 4-19), and median follow-up time was two years (range 0.5-2.9). The plurality of patients was treated for medulloblastoma

(n=5). Following PBT, cerebral vessel volume (CVV) decreased with time ( $p=0.02$ ), and this effect was more notable in younger patients undergoing RT (interaction variable,  $p<0.01$ ). CVV was also found to be positively associated with language-related TCB domains [composite cognitive function ( $p<0.01$ ), crystallized function ( $p=0.02$ ), and picture vocabulary tests ( $p=0.05$ )], which all decreased from baseline during follow up ( $p<0.01$  for each test) in these patients. On dosimetric analysis, total brain volume receiving 10 Gy (V10) was found to be the strongest predictor of TCB testing with worse outcomes found with higher values of V10.

#### Conclusion

Based on this prospective study, use of RT is associated with decreases in performance in neurocognitive testing, and this may be mediated through declines in cerebral vessel volume. Ultimately, limiting dose to total brain volume and maintaining a low V10 may help to mitigate these changes, though further follow-up and studies are needed.

#### PO-0874 The feasibility of MR-Linac treatment planning in childhood abdominal Neuroblastoma

M. Llewellyn<sup>1</sup>, G. Smyth<sup>2</sup>, N. Lavan<sup>1</sup>, S. Nill<sup>2</sup>, U. Oelfke<sup>2</sup>, H. Mandeville<sup>1</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust, Clinical Oncology, London, United Kingdom ; <sup>2</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust- Sutton- London- UK, Joint Department of Physics, London, United Kingdom

#### Purpose or Objective

Radiotherapy plays an important role in the management of paediatric abdominal malignancies. Treatment planning techniques are often highly complex due to large target volumes, the close proximity of OARs, and the challenge of ensuring uniform future vertebral bone growth. The Elekta Unity MR-Linac (Elekta AB, Stockholm, Sweden) enables highly detailed real-time imaging while avoiding the concomitant doses of daily kV imaging. However, the dosimetric effects of a magnetic field on treatment plan quality for paediatric abdominal radiotherapy are unknown.

This study aims to explore the feasibility of IMRT planning with the presence of a magnetic field for abdominal malignancies. Dosimetric comparisons of target volumes and OARs between conventional linac and MR-Linac based treatment plans are made.

#### Material and Methods

Ten postoperative paediatric patients with abdominal Neuroblastoma were identified and two nine-field IMRT plans were produced for each child. One plan was produced for the MR-Linac, accounting for the effects of the 1.5T magnetic field, and another for a conventional linac (Monaco V5.19, Versa HD, Elekta AB, Stockholm, Sweden). All plans were produced to deliver a median PTV dose of 21 Gy in 14 fractions and were planned to observe clinical dose constraints. Dose calculation was performed using a Monte Carlo dose engine and a calculation uncertainty of 2%, grid size 3x3x3mm. Doses to PTV, adjacent vertebral bodies and OARs were compared and Homogeneity Index (HI) and Conformity Number (CN) were measured for each technique.

#### Results

All plans met required dose objectives and were clinically acceptable; Mean PTV volume was 259.1 cm<sup>3</sup> (range 143-498 cm<sup>3</sup>). There were no significant differences in PTV near maximum (D<sub>2%</sub>) or near minimum (D<sub>98%</sub>) doses between MR-Linac and conventional linac. For those tumour sites where there was a component of lung irradiation (n=7), MR-Linac treatment plans achieved a small but significant reduction in the volume of lung receiving 15 Gy ( $p=0.03$ ) compared to the conventional linac. There were no other statistically significant

differences in dose to OARs and no significant differences in PTV homogeneity or conformity were observed.

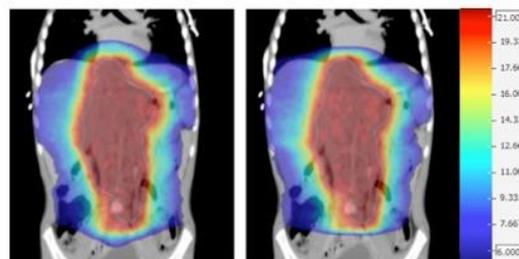

Figure 1. A example of a conventional treatment plan (L) and MRL treatment plan (R)

Metric	Clinical objective	Value mean $\pm$ standard deviation		p-value
		MR-Linac	Conventional Linac	
PTV D <sub>2%</sub> (Gy)	< 22.5	21.7 $\pm$ 0.1	21.6 $\pm$ 0.1	0.4
PTV D <sub>98%</sub> (Gy)	> 18.9	20.1 $\pm$ 0.4	20.1 $\pm$ 0.3	0.7
HI	N/A	0.08 $\pm$ 0.02	0.07 $\pm$ 0.2	0.7
CN	N/A	0.65 $\pm$ 0.05	0.65 $\pm$ 0.03	0.9
Adjacent vertebral body V <sub>15 Gy</sub> (%)	> 95%	98 $\pm$ 0.8	98.3 $\pm$ 1.5	0.6
Combined Kidney V <sub>14 Gy</sub> (%)	< 40%	37.2 $\pm$ 7.6	33.1 $\pm$ 4.9	0.1
Combined Kidney Mean (Gy)	< 15	13.3 $\pm$ 3.3	11.8 $\pm$ 0.6	0.2
Heart Mean (Gy)	< 15	4.1 $\pm$ 2	3.6 $\pm$ 1.7	0.2
Liver V <sub>21 Gy</sub> (%)	< 50%	1.7 $\pm$ 1.1	2 $\pm$ 1.4	0.1
Lung V <sub>15 Gy</sub> (%)	< 10%	4.6 $\pm$ 2.5	5.3 $\pm$ 3	0.03
Lung V <sub>12 Gy</sub> (%)	< 25%	7.4 $\pm$ 8	8 $\pm$ 4.8	0.2
GI Tract (%)	< 100%	3 $\pm$ 2.6	3.1 $\pm$ 2.8	0.8

Table 1. Dose statistics and plan quality metrics for both techniques. Values were judged to be statistically significant for p-values < 0.05

#### Conclusion

MR-Linac treatment planning for upper abdominal malignancies in children is feasible and produces clinically acceptable plans. Achieved dose distributions were comparable to a conventional linac, despite large treatment volumes and the high complexity of plans. Combining plan quality with more accurate visualisation of abdominal soft tissues and improved delineation of target volumes, the MR-Linac has the potential to reduce setup errors and further decrease normal tissue radiation exposure/ integral dose compared with radiotherapy on a conventional linac.

#### PO-0875 Development of pituitary deficits after radiotherapy in pediatric patients after long follow-up.

C. Satragno<sup>1</sup>, E. Tornari<sup>1</sup>, S. Barra<sup>2</sup>, F. Giannelli<sup>2</sup>, L. Belgioia<sup>1</sup>, M. Giaccardi<sup>3</sup>, N. Di Iorgi<sup>3</sup>, M.L. Garre<sup>4</sup>, R. Haupt<sup>5</sup>, R. Corvò<sup>1</sup>

<sup>1</sup>University of Genoa and San Martino Hospital, Health Science Department DISSAL and Radiation Oncology, Genoa, Italy ; <sup>2</sup>San Martino Hospital, Radiation Oncology, Genoa, Italy ; <sup>3</sup>Istituto Giannina Gaslini, Department of Pediatrics, Genoa, Italy ; <sup>4</sup>Istituto Giannina Gaslini, Department of Neurooncology, Genoa, Italy ; <sup>5</sup>Istituto Giannina Gaslini, Epidemiology and Biostatistics Unit, Genoa, Italy

#### Purpose or Objective

To evaluate the risk of developing pituitary deficits in pediatric patients with central nervous system (CNS) tumors treated by radiotherapy.

#### Material and Methods

We retrospectively analyzed patients with brain tumors, younger than 16 years, with a minimum follow up of 2 years after the end of radiotherapy. In this study, we evaluated GH, ACTH and TSH deficiency and if endocrine deficit correlate with pituitary gland and hypothalamic dose.

#### Results

Between 1996-2015, 88 consecutive patients have been identified. Among them, we had to exclude 20 patients because they presented hormone deficiency before starting RT, and 4 more because they had the

endocrinological follow-up in less than 2 years. Therefore, 64 patients were evaluated: 32 medulloblastomas (50.0%), 17 gliomas (26.5%), 7 germinomas (10.9%), 3 ependymomas (4.6%), and 5 other histological types (7.8%) (2 Ewing sarcomas, 1 PNET, 1 pinealoblastoma, 1 ATRT). 61 pts also underwent to chemotherapy and 42 to surgery. The mean pituitary dose in patients with GHD was  $36.5 \pm 9.78$  Gy ( $p < 0.01$ ), TSHD  $38.0 \pm 6.0$  Gy, ACTHD  $34.6 \pm 10.5$  Gy. Patients treated with 3DCRT had a higher risk of developing GHD, ACTHD, and TSHD when compared to those treated with IMRT techniques ( $p < 0.05$ ). The "safe dose" to under which no patient has shown GH deficiency is  $< 10$  Gy while for TSH and ACTH deficit is  $< 20$  Gy.

#### Conclusion

Our data underline the role of pituitary dose on endocrine deficits; IMRT should be the preferred technique in the treatment of paediatric CNS.

#### PO-0876 Stereotactic Body Radiation Therapy for thoracic nodes metastases, a multi-institutional experience

D. Franceschini<sup>1</sup>, F. Bianciardi<sup>2</sup>, R. Mazzola<sup>3</sup>, F. De Rose<sup>1</sup>, P. Gentile<sup>2</sup>, F. Alongi<sup>3,4</sup>, M. Scorsetti<sup>1,5</sup>

<sup>1</sup>Humanitas Research Hospital, RADIO THERAPY AND RADIOSURGERY, Rozzano Milan, Italy; <sup>2</sup>San Pietro Fatebenefratelli Hospital, Radiation Therapy Department, Rome, Italy; <sup>3</sup>IRCCS Sacro Cuore Don Calabria Hospital, Radiation Oncology Department, Negrar-Verona, Italy; <sup>4</sup>University of Brescia, Radiation Oncology Department, Brescia, Italy; <sup>5</sup>Humanitas University, Department of Biomedical Sciences, Rozzano-Milano, Italy

#### Purpose or Objective

To evaluate safety and efficacy of Stereotactic Body Radiation Therapy (SBRT) in patients with thoracic nodes oligometastases

#### Material and Methods

The present study is a multicenter analysis. Oligometastatic patients, affected by a maximum of 5 active lesions in 3 or less different organs, treated with SBRT to thoracic nodes metastases between 2012 and 2017 were included in the analysis. Primary end point was local control (LC), secondary end points were overall survival (OS), progression free survival (PFS), acute and late toxicity. Univariate and multivariate analysis were performed to identify possible prognostic factors for the survival endpoints.

#### Results

76 patients were included in the analysis. Different RT dose and fractionation schedules were prescribed according to site, number, size of the lymph node(s) and to respect dose constraints for relevant organs at risk. Median BED delivered was 75 Gy (interquartile range: 59-86 Gy). Treatment was optimal; one G1 acute toxicity and 7 G1 late toxicities of any grade were recorded. Median follow up time was 23.16 months. Sixteen patients (21.05%) had a local progression, while 52 patients progressed in distant sites (68.42%).

Median LC was not reached, LC at 6, 12 and 24 months was 96.05% (CI 88.26-98.71%), 86.68% (CI 75.86-92.87) and 68.21% (CI 51.89-80.00%), respectively. Median OS was 28.3 months (interquartile range 16.1-47.2). OS at 6, 12, 24 and 36 months was 98.68% (CI 91.03-99.81%), 86.34% (CI 76.07-92.42%), 55.98% (CI 42.61-67.40%) and 41.61% (CI 27.85-54.80%), respectively. Median PFS was 9.2 months (interquartile range 4.1-17.93). PFS at 6, 12 and 24 months was 63.16% (CI 51.29-72.89%), 34.99% (CI 24.22-45.94%) and 16.84% (CI 8.91-26.92%), respectively.

At multivariate analysis, RT dose, colorectal histology, systemic therapies were correlated with LC. Performance

status and the presence of metastatic sites other than the thoracic nodes were correlated both with OS and PFS. Local response was a predictor of OS.

#### Conclusion

SBRT for thoracic nodes was safe and feasible. Higher RT doses were correlated to better LC and should be taken in consideration at least in patients with isolated nodal metastases and colorectal histology.

#### PO-0877 Utilization of short course palliative radiation therapy in breast cancer bone metastasis

P. Gabani<sup>1</sup>, B. Fischer-Valuck<sup>2</sup>, W. Kennedy<sup>1</sup>, L. Ochoa<sup>1</sup>, M. Thomas<sup>1</sup>, M. Daly<sup>1</sup>, I. Zoberi<sup>1</sup>, C. Abraham<sup>1</sup>

<sup>1</sup>Washington University in Saint Louis, Radiation Oncology, Saint Louis, USA; <sup>2</sup>Emory School of Medicine, Radiation Oncology, Atlanta, USA

#### Purpose or Objective

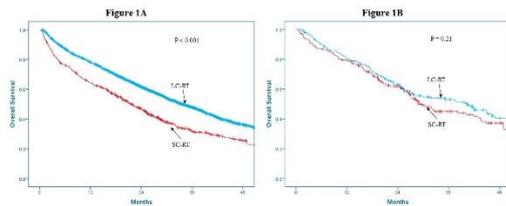

Breast cancer is one of the most common malignancies associated with bone metastasis. Recent evidence suggests equivalent palliative efficacy between short course RT (i.e.  $\leq 5$  fractions) and long course RT ( $\geq 10$  fractions) for the palliation of bone metastasis. Despite this, the uptake of short course RT remains low. This is an observational study of a large national cohort evaluating the patterns of care associated with various palliative RT fractionation schemes for the treatment of breast cancer bone metastases.

#### Material and Methods

Patients with metastatic breast cancer bone metastasis from 2010 - 2015 were obtained from a national cancer database. Patients who were treated with palliative RT to bone lesions with 8 Gy in 1 fx or 20 Gy in 5 fx were categorized as short course RT (SC-RT). Patients who were treated with palliative RT to bone lesions with 30 Gy in 10 fx or 37.5 Gy in 15 fx were categorized as long course RT (LC-RT). Patients receiving other RT fractionation schemes were excluded. Patients receiving RT to the spine for cord compression were excluded. Multivariable logistic regression analysis was used to evaluate factors associated with the receipt of SC-RT. Exact match using propensity score was used to balance the baseline patient characteristics between SC-RT and LC-RT. Overall survival (OS) was estimated with Kaplan-Meier method. Multivariable Cox proportional hazards model was used to evaluate factors associated with OS. Significance was defined at a value of  $p < 0.05$ .

#### Results

A total of 4816 patients were included in the analysis: 737 (15.3%) received SC-RT and 4079 (84.7%) received LC-RT. The median follow up was 24.3 months (range: 0.8 - 84.7). The utilization rate of SC-RT increased significantly from 10.7% in 2010 to 20.7% in 2015 ( $p < 0.01$ ). On multivariable analysis, factors that were associated with a higher likelihood for the receipt of SC-RT were age  $\geq 60$  (ref = age  $< 60$ , OR 1.27 (1.06 - 1.52),  $p = 0.01$ ), treatment to extremities (ref = spine, OR 2.15 (1.69 - 2.74),  $p < 0.01$ ), treatment to ribs (ref = spine, OR 3.15 (1.76 - 5.63),  $p < 0.01$ ), treatment at an academic/research program (ref = community cancer program, OR 1.78 (1.47 - 2.17),  $p < 0.01$ ), and triple negative breast cancer (ref = hormone positive, OR 2.29 (1.72 - 3.04),  $p < 0.01$ ). On multivariable analysis, SC-RT was associated with a worse OS compared to LC-RT (HR 1.38 (1.20 - 1.59),  $p < 0.01$ ). The 3-yr OS was 31.9% in SC-RT vs 47.9% in LC-RT group (Fig 1A,  $p < 0.01$ ). However, after exact match using propensity score, there was no difference in the 3-yr OS between the two groups (53.1% vs. 45.0%, Fig 1B,  $p = 0.21$ ).

### Conclusion

LC-RT remains the most common RT fractionation scheme for palliative treatment of breast cancer bone metastases. However, the use of SC-RT is increasing, particularly in more recent years, and for older patients and treatments at academic/research centers. As observed in multiple randomized trials, we also demonstrate equivalent OS between SC-RT and LC-RT after propensity matching.

### PO-0878 Implementing a dedicated inpatient radiation team with multidisciplinary palliative care rounds

D. MARK<sup>1</sup>, P. Gilbo<sup>1</sup>, S. Joseph<sup>1</sup>, A. Goenka<sup>1</sup>, B. Bloom<sup>1</sup>  
<sup>1</sup>Northwell Health, Radiation Medicine, Lake Success, USA

#### Purpose or Objective

To improve inpatient radiation care in our academic tertiary center, we have initiated a two pronged approach: we implemented daily inpatient multidisciplinary palliative care rounds (MPCR) including radiation oncology, medical oncology, and palliative care to improve interdisciplinary communication, and then started a dedicated inpatient radiation oncology team consisting of an attending and physician assistant to enhance continuity of care. We analyzed the impact of both interventions on number of inpatient treatment courses, recommended number of fractions, treatment completion rates, and length of inpatient stay.

#### Material and Methods

We initially implemented MPCR in July 2017 and then implemented our dedicated inpatient radiation team in January 2018. We retrospectively reviewed records for patients treated at our inpatient facility from 1/2017-6/2018 and recorded demographic data, treatment details, and length of inpatient stay after a radiation oncology consultation. We compared 6 months of baseline data (1/2017-6/2017), to data after the implementation of MPCR (7/2017-12/2017) and after the implementation of a dedicated inpatient care team (1/2018-6/2018).

#### Results

307 inpatient treatment courses were administered during this 18 month interval. There was a 35% increase in number of inpatient radiation treatments courses in the 6 months after development of MPCR (77 compared to 104) and a 63% year-to-year increase in the 6 months after both interventions (77 compared to 126). Number of fractions recommended after both interventions decreased from a mean of 6.1 (1/2017-6/2017) to 4.9 (1/2018-6/2018) which was significant (p=0.02). There was an increase of single fraction treatment courses offered from 7 (1/2017-6/2017) to 21 (1/2018-6/2018), and this trended toward significance (p=0.09). Treatment terminations did not significantly differ between time periods (11.7% initially, 13.5% after MPCR, and 11.1% after implementation of the dedicated team). Lastly, we noted a significant decrease of length of stay after a radiation oncology consultation from a mean of 16.2 days at baseline (1/2017-6/2017), to 14.7 days after the implementation of MPCR (7/2017-12/2017), to 12.3 days after the implementation of a dedicated inpatient radiation oncology team (p=0.004 when comparing 1/2017-6/2017 to 1/2018-6/2018).

#### Conclusion

Through the implementation of daily inpatient multidisciplinary rounds and a dedicated inpatient

radiation oncology team to enhance continuity of care, we noted significant changes in practice patterns. In addition to a continued increase in the number of inpatients treated with radiation, we noted a significant decrease in number of fractions prescribed to our palliative patients and a significant decrease in length of inpatient stay after a radiation oncology consultation. We hypothesize that this is due to enhanced communication between our dedicated inpatient radiation oncology team and allied medical oncology and palliative care providers.

### PO-0879 Mobile health for monitoring of health status in palliative care patients: a feasibility study

M. Pavic<sup>1</sup>, V. Klaas<sup>2</sup>, G. Theile<sup>1</sup>, J. Kraft<sup>1</sup>, G. Tröster<sup>2</sup>, M. Guckenberger<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Radiooncology, Zurich, Switzerland ; <sup>2</sup>Swiss Federal Institute of Technology, Wearable Computing Laboratory, Zurich, Switzerland

#### Purpose or Objective

Discharge from hospital is a vulnerable phase in palliative patients' trajectories resulting in frequent unplanned readmissions. We examined the feasibility of remote monitoring of palliative patients using wearables in form of a smart-phone and a bracelet, aiming to detect deterioration of health status early and to prevent emergency readmissions.

#### Material and Methods

Patients treated with palliative intent in an inpatient setting were recruited for this prospective single-center observational feasibility study. Inclusion criteria were age >18, a severe medical condition (metastatic cancer or severe cardiac/pulmonary disease), ECOG performance status ≤2, no relevant cognitive impairment and good knowledge of German language. Patients were provided with two mobile health devices, an Android smartphone with a pre-installed activity monitoring app developed for this study and a sensor-equipped bracelet that recorded physical and social activity, vital signs and daily subjective ratings of pain and distress. Quality of life was assessed weekly by means of the EORTC QLQ-C30. The follow-up period was 12 weeks and started at discharge from hospital.

#### Results

Between February 2017 and February 2018 68 patients were eligible, of which 31 (46%) patients with a median age of 64 years (range 39-85) consented to participate. All included patients had a cancer diagnosis. Twenty-five patients completed the study period of 12 weeks, 3 died in between, 3 discontinued. On average, the bracelet was worn on 53 % of the study days. Wearing time per study day was on average 63 % (time considered between 8:00 and 20:00). The smartphone was worn at 85 % of the study days and wearing time was 50 % per day (8:00 to 20:00). Completion rate of digital questionnaires for patient reported outcome/subjective ratings (of pain and distress) was 73%. During the study period 8 unplanned hospital readmissions occurred. Patient reported ratings of pain, distress and QLQ-C30 scores were not associated with emergency readmission, whereas heart rate variability (HRV) while resting (root mean square of the successive differences), resting heart rate and speed of steps differed significantly between groups of patients with emergency readmissions versus no readmission.

#### Conclusion

Monitoring of palliative cancer patients using wearables is feasible. First results indicate that features of resting HRV, resting heart rate and speed of steps might be promising mobile health biomarkers to predict unplanned hospital readmission and are more significant than subjective ratings

### PO-0880 Validation of a predictive model for survival in patients receiving radiotherapy for bone metastases

K. Yasui<sup>1</sup>, H. Katagiri<sup>2</sup>, T. Onoe<sup>1</sup>, H. Ogawa<sup>1</sup>, H. Harada<sup>1</sup>, H. Asakura<sup>1</sup>, S. Maki<sup>1</sup>, A. Nakura<sup>1</sup>, Y. Ito<sup>1</sup>, M. Hirata<sup>1</sup>, S. Murayama<sup>1</sup>, Y. Honda<sup>2</sup>, M. Miyagi<sup>2</sup>, J. Wasa<sup>2</sup>, H. Murata<sup>2</sup>, M. Takahashi<sup>2</sup>, T. Nishimura<sup>1</sup>

<sup>1</sup>Shizuoka Cancer Center, Radiation oncology, Nagaizumi - Cho- Shizuoka, Japan ; <sup>2</sup>Shizuoka Cancer Center, Orthopedic surgery, Nagaizumi - Cho- Shizuoka, Japan

#### Purpose or Objective

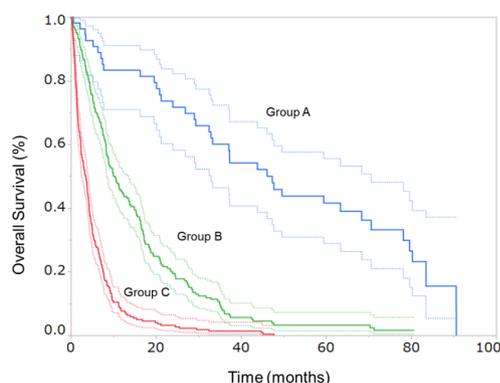

To validate a predictive model for survival in patients with bone metastases who are receiving radiation therapy.

#### Material and Methods

We previously constructed a predictive model for patients' survival using six prognostic factors: the primary lesion, visceral or cerebral metastases, abnormal laboratory data, poor performance status, previous chemotherapy, and multiple skeletal metastases. Each prognostic factor was assigned scores. Each patient was scored from 0-10 and classified into one of three groups: group A (those with scores 0-3), group B (those with scores 4-6), and group C (those with scores 7-10). This model was constructed from the records of 808 patients with bone metastases from 2005 to 2007. To validate the model, we evaluate 497 patients with bone metastases receiving radiotherapy from 2010 to 2012. Survival was estimated by the Kaplan-Meier method. The log-rank test was used to compare the survival times.

#### Results

The median survival was 6.1 months; group A (n = 54) 47.4 months (95% CI, 32.5-68.4 months); group B (n = 207) 10 months (95% CI, 8.4-13.1 months); and group C (n = 236) 3.5 months (95% CI, 2.6-4.0 months). The survival probability at 6, 12, and 24 months was 91%, 83%, 72%, respectively for group A; 70%, 45%, 19%, respectively for group B; and 28%, 8%, 3%, respectively for group C ( $p < 0.001$ ).

#### Conclusion

Our predictive model can be utilized to predict prognosis for patients with bone metastases receiving radiation therapy. External validation is needed in order to confirm our findings.

#### PO-0881 Outcomes of oligometastatic bone disease treated with conventional or stereotactic radiotherapy

S. Van de Ven<sup>1</sup>, J.M. Van der Velden<sup>1</sup>, W.S.C Eppinga<sup>1</sup>, D.H.J.G Van den Bongard<sup>1</sup>, H.M. Verkooijen<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) has become a widely adopted treatment for patients with oligometastatic bone disease, despite limited evidence of superiority. We compared patient-reported pain, quality of life (QoL) and survival outcomes of patients with oligometastatic bone metastases within the prospective

PRESENT cohort, treated with conventional radiotherapy or SBRT.

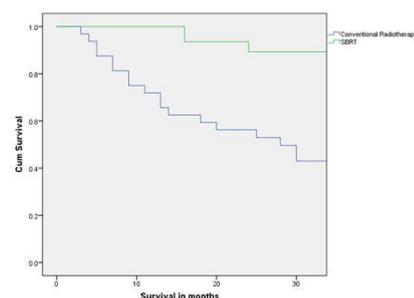

#### Material and Methods

We included all patients with oligometastatic bone disease ( $\leq 5$  metastatic lesions within  $\leq 3$  different organs) enrolled in the PRESENT cohort between June 2013 and September 2017. Since SBRT was only available as a treatment option at our department since December 2014, all patients before that date were treated with conventional radiotherapy (3D-CRT, IMRT or VMAT). Main outcomes were pain response (duration of pain response and best response defined as 'complete', 'partial' or 'stable response'), QoL (EORTC QLQ-BM22 and QLQ-C15-PAL), overall survival (OS), progression free survival (PFS), and time to start of, or switch in systemic treatment (FFSS) after radiotherapy. To control for potential confounders, patients were stratified into bone metastases only yes/no, histology (e.g. 'favorable histology' (breast or prostate) or 'other histology'), interval between diagnoses of the primary tumor and detection of oligometastatic disease  $\leq 12 > 12$  months with correction for age and WHO performance.

#### Results

Of the 131 patients, 66 patients were treated with conventional radiotherapy (1x8 Gy (44%), 5x4 Gy (12%), 10x 3 Gy (36%)) and 65 patients were treated with SBRT (1x 18Gy (35%), 3x10 Gy (30%) and 5x7 Gy (20%)). The median duration of follow-up was 46 and 25 months for the conventional radiotherapy and SBRT group respectively. There was no difference in best reported pain response within the first 12 months after treatment (pain response 81% vs. 84 %,  $p=0.79$ ) or duration of the response (23 weeks (95% CI 1-58) versus 25 weeks (95% CI 0-50),  $p=0.79$  in the SBRT group). All quality of life domains were similar, with the exception of physical functioning which was better in the SBRT group. The SBRT group demonstrated superior median OS (median OS not reached vs. 18 months) and PFS rates (median PFS 12 months (95% CI 5.3-18.6) versus 5 months (95% CI 3.5-6.5,  $p= 0.002$ ), figure 1). After correction for age and WHO performance, treatment with SBRT significantly prolonged OS and PFS in patients with an interval between primary tumor and oligometastatic disease  $>12$  months (table 1). Treatment with SBRT did not affect FFSS in any subgroup within our cohort.

OS= Overall Survival, CRT= conventional radiotherapy, SBRT= stereotactic radiotherapy, HR= hazard ratio, CI= confidence interval, N=number of patients

**Conclusion**

SBRT to oligometastatic bone metastases did not improve QOL or pain response compared to conventional radiotherapy. Only patients with an interval between primary tumor and oligometastatic disease >12 months showed prolonged OS and PFS after treatment with SBRT.

**PO-0882 Outcome and Toxicity of Hypofractionated Image-Guided SABR for Spinal Oligometastases**

C. Billiet<sup>1</sup>, C. Mercier<sup>1,2</sup>, F. Vandaele<sup>1</sup>, P. Vermeulen<sup>3</sup>, S. Van Laere<sup>3</sup>, P. Huget<sup>1</sup>, D. Verellen<sup>1</sup>, P. Dirix<sup>1</sup>

**Purpose or Objective**

To evaluate tumor control and toxicity after high-dose stereotactic hypofractionated intensity modulated radiation therapy for patients with spinal oligometastases.

**Material and Methods**

Between March 2015 and March 2018, 40 consecutive patients with a localized spine metastasis (C1 to sacrum) from a histologically confirmed solid tumor received stereotactic ablative radiotherapy (SABR) to a total of 44 lesions and were followed for at least 6 months. SABR was delivered in three fractions of 8-10 Gy following international consensus delineation guidelines. All patients were treated with linac-based rotational SABR using cone-beam CT image-guidance and online correction of set-up errors in six degrees of freedom. An optical surface monitoring system (OSMS) was used to ensure patient immobilization. Factors associated with progression-free survival were retrospectively investigated by multivariate analysis. Local recurrence was defined as regrowth within the irradiated field or clear exacerbation of symptoms such as pain and motor deficits.

WHO: World health organization; RPA: Recursive partitioning analysis; MR: magnetic resonance; PET: Positron emission tomography; PSMA: Prostate-specific membrane antigen; SPECT: Single Photon Emission Computed Tomography

**Results**

Mean follow up was 69 months for all patients. Patient and tumor characteristics are depicted in Table 1. The 1-year progression free survival (PFS) was 97% for all patients (median PFS 92 months)(Figure 1) . In three patients (6,8%) a local recurrence was observed. No radiation-induced myelopathy was observed. Vertebral compression fractures developed de novo in 4.5% (2/44) of patients. In multivariate analysis, synchronous (vs. metachronous) lesions (p< 0.001; HR= 113.5), older age (p= 0.01; HR= 1.1) and no systemic therapy (p= 0.02; HR= 8.1), were correlated with worse PFS. In subgroup analysis for prostate cancer patients only, synchronous lesions were confirmed as significant predictive factor for PFS in multivariate analysis.

The mean volume of the gross target volume (GTV) was 11 cc and for the clinical target volume (CTV) 32cc. Mean dosimetric parameters D2%, D50% and D98% for the CTV and planning target volume (PTV) were 32.0 Gy, 18.6 Gy, 29.0 Gy and 33.1 Gy, 21.7 Gy, 30.7 Gy respectively.

Figure 1 : Progression free survival for all patients

**Conclusion**

These results show high rates of efficacy and minimal toxicity in patients treated with high-dose stereotactic hypofractionated RT for spinal metastases. Oligometastatic patients with metachronous lesions, younger age and additional systemic therapy seem to

benefit the most from SABR for spinal metastases. Probably, these metachronous lesions are the main reflection of a true oligometastatic state. However, these findings need to be investigated further in larger and prospective trials.

**PO-0883 Phase II trial of stereotactic body radiation therapy for abdomino-pelvic lymph node oligometastases**

C. Franzese<sup>1</sup>, T. Comito<sup>1</sup>, A. Tozzi<sup>1</sup>, F. De Rose<sup>1</sup>, P. Navarra<sup>1</sup>, P. Mancosu<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1</sup>  
<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

**Purpose or Objective**

Stereotactic body radiotherapy (SBRT) is nowadays considered an effective approach for the management of oligometastatic patients. Few data exist on radiotherapy in the context of isolated or limited lymph node metastases. We analyzed clinical results of oligometastatic patients treated with high dose SBRT for lymph node metastases in abdomen and pelvis.

**Material and Methods**

This is a prospective, phase 2 trial. Primary end-point was the assessment of acute and late toxicity; secondary end-points were local control (LC), progression free survival (PFS) and overall survival (OS) The schedule of SBRT was 48 Gy delivered in 4 fractions of 12 Gy each. Inclusion criteria were: Histologically-proven carcinoma of gastro-intestinal, genito-urinary of gynecological primary site, WHO performance status  $\leq 2$ , maximum 3 lymph node sites of disease, maximum diameter  $\leq 5$  cm, abdomen-pelvic site. Physical examinations and toxicity assessments were performed during and after SBRT according to CTCAE v4.0. Tumour response was evaluated on CT-MRI-PET scans using the RECIST modified criteria.

**Results**

From 2015 to 2018, 41 patients with 52 lymph nodes were enrolled. Median age was 69.2 years and 87.8% of patients were male. Most common primary tumour was located in genito-urinary tract (70.7%), and in particular prostate adenocarcinoma (58.8%), followed by gastro-intestinal (26.8%) and gynecological (2.5%) disease. One single lymph node was treated 32 patients, while 2 and 3 lymph node in 7 and 2 patients, respectively. Systemic therapy was administered before SBRT in 43.9% of patients and during SBRT in 14.6%. Median clinical target volume diameter was 15 mm (6 - 49). With a median follow-up of 16.7 months, only 3 patients reported grade 1 acute toxicity, in the form of pain, dysuria and fatigue. In the late setting, chronic pain was observed in 1 patient. In-field progression was observed in 5 (12.2%) patients with a 1- and 2- years rate of 96.4% and 77.1%. Systemic therapy during SBRT was associated with worse LC (HR 8.6, 95%CI 1.41 - 52.7,  $p=0.020$ ). Out-field lymphnodal progression was observed in 17 (41.4%) of cases and distant progressions in 8 (19.5%) cases. Median PFS was 12.8 months. At time of analysis all patients were alive except one with 1- and 2-years OS of 100% and 94.7%.

**Conclusion**

Treatment of lymph node metastases with high dose SBRT can be considered a safe option with high rates of local control in the context of multidisciplinary management of oligometastatic patients.

**PO-0884 Predicting 30-day mortality for palliative radiotherapy**

A. Witztum<sup>1</sup>, S. Wu<sup>1</sup>, E. Gennatas<sup>1</sup>, G. Valdes<sup>1</sup>, T. Solberg<sup>1</sup>, S. Braunstein<sup>1</sup>  
<sup>1</sup>Department of Radiation Oncology, University of California- San Francisco, San Francisco, USA

**Purpose or Objective**

Decision support for cancer patients at end of life is needed to optimize outcome for this population. Currently

there are a limited number of mortality prediction tools such as the TEACHH and Chow models. Here we build a model incorporating multiple factors to predict 30-day mortality for patients treated with palliative radiotherapy (RT) for advanced cancer.

**Material and Methods**

A cohort (n=518) of patients treated with external beam RT to a site of metastatic disease between 2012-2016 was included. Factors that may be associated with death within 30 days of RT treatment, including demographics and clinical and laboratory data were retrospectively collected. Generalized linear models (GLMNET package) were built with no regularization (logistic regression), and with regularization (Lasso and Elastic Net). Random forest (RANGER) and gradient boosting machine (GBM) models were also built to assess non-linearity in the response. Missing data was imputed by replacing values with either the mean or the mode, and adding a variable which indicated which patients had missing data for each variable. All models were built in R using cross validation withholding 25% of the data (test set), and stratified subsampling to account for unbalanced outcome. Each model was seeded in order to enable a pairwise t-test to compare the distribution of test balanced accuracies of each model. The area under the ROC curve (AUC) was also reported. The variable importance for linear models was calculated by multiplying the coefficient with the standard deviation of that variable for normalization.

**Results**

Lung, breast, and prostate cancer accounted for 55% of primary malignancies, with bone and brain accounting for 85% of treatment sites. 125 patients (24%) died within 30 days of RT. A logistic regression model resulted in a mean balanced accuracy (MBA) of 0.76 (AUC = 0.83). Adding Lasso or Elastic Net regularization offered a small improvement in MBA of 0.78 for both models ( $p=0.07$ ,  $p=0.09$ ) and an AUC of 0.83 and 0.84 (Figure 1) respectively. The non-linear models proved worse than logistic regression with random forest having an MBA of 0.74 ( $p=0.01$ , AUC = 0.82) and GBM having an MBA of 0.75 ( $p=0.08$ , AUC = 0.83). The most important variables in the logistic regression model are those indicative of missing data in other variables. Both Lasso and Elastic Net (Figure 2) regularizations, however, result in more interpretable variables such as TEACHH score, performance score, and hospice status. These features also have high importance in both non-linear models. For comparison, the AUC when using TEACHH score alone was 0.69.

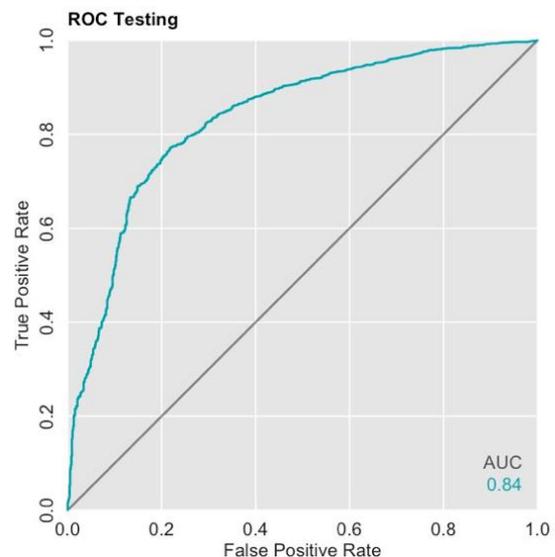

Figure 1: Area under the ROC curve for a generalized linear model with ElasticNet regularization (alpha tuned over 0, 0.3, 0.5, 0.7, 1).

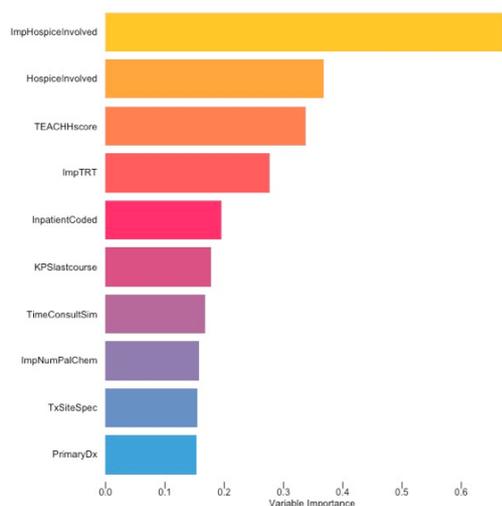

Figure 2: Variable importance for a generalized linear model with ElasticNet regularization (alpha tuned over 0, 0.3, 0.5, 0.7, 1). TRT = Time from referral to treatment, KPS = Karnofsky performance status, NumPalChem = Number of palliative chemo courses, InpatientCoded = Inpatient status at time of consult, TEACHHscore = Score according to TEACHH mortality prediction model, Imp prefix = Variable indicating if data was imputed.

### Conclusion

A linear prediction model was built to predict 30-day mortality for palliative RT patients with advanced cancer. An AUC of 0.84 was obtained (0.15 higher than TEACHH) proving that the problem is well characterized by the features selected. This encourages us to prospectively validate the model with the hope that it can be informative in the physician/patient decision process.

### Purpose or Objective

The constant increase of life expectancy is associated to a higher incidence of cancer diagnosis in the elderly population. For aged patients with early stage Non Small Cell Lung Cancer (es-NSCLC), surgery is not often proposable, so Stereotactic Body Radiotherapy (SBRT) represents an attractive option for elderly subjects unfit or refusing resection, leading to a reduced percentage of untreated patients. In the effort to offer the best tailored approach to this subset of more vulnerable patients, several authors suggest the use of geriatric comprehensive assessment tools in order to facilitate a more customized treatment. Here we report our single-center experience of SBRT for es-NSCLC in  $\geq 65$  years patients, who were evaluated in the pre-treatment setting using G8 screening tool and Charlson Comorbidity Index (CCI).

### Material and Methods

From March 2014 to June 2018 we retrospectively evaluated 42 patients  $\geq 65$ -years with es-NSCLC who were assessed with G8 screening tool and CCI. Median age was 74 years (range, 65-91), 38 were stage I and 4 stage II.

Adenocarcinoma was the most frequent histological subtype, detected in 18 pts, undifferentiated in 3, squamous cells in 8; in 13 cases histological confirmation was not available and diagnosis was made on the evidence of pathological uptake recorded on PET scan. SBRT was performed with Helical Tomotherapy delivering 60-70 Gy in 8-10 fractions for peripheral lesions and 50-60 Gy in 10 fractions for central and ultra-central lesions. Acute and late toxicity assessment was conducted using CTCAE v4.0 scale; for the first year after RT, follow-up was based on quarterly chest CT scans and PET scans if needed. Any clinical correlation was evaluated with Fisher's exact test and Kaplan-Meier method and log-rank test were performed for Local Control (LC) and Overall Survival (OS) estimates.

### Results

Median CCI and G8 scores were 6 (4-11) and 14 (12-17). Median treatment time was 15 days (10-24), with 29 patients treated daily, and 13 every other day. BED<sub>10</sub> $\geq 100$ Gy schedules were administered in 53% (n=22) of cases, for a median BED<sub>10</sub>=105 Gy (75-119). With a median follow-up of 14 months (3-37) we observed 3 cases of acute G2 radiation pneumonitis, resolved after steroids therapy. As regards late toxicity, we reported only one case of G2 non-cardiac chest pain and one case of G2 radiation pneumonitis treated with steroids. At statistical analysis, G8 scores $\leq 14$  were significantly associated with late toxicity rates (p=0.049), no other statistical correlation was found. At the time of the analysis, we detected 4 local failures resulting in 1- and 2-yrs LC rates of 91% and 86%. 12 patients out of 42 died, 6 for non-cancer related causes, resulting in 1- and 2-yrs OS rates of 93% and 80%.

### Conclusion

In our experience the use of the G8 screening tool, for the pre-treatment evaluation of elderly patients candidate to SBRT for es-NSCLC, revealed a predictive power for late toxicity patterns, suggesting its implementation for a more tailored approach.

**PO-0886 Partial tumor irradiation exploiting immunomediated effects: tumor microenvironment as a new oar.**

S. Tubin<sup>1</sup>

<sup>1</sup>KABEG Klinikum- Landeskrankenhaus, Strahlentherapie und Radioonkologie, Klagenfurt, Austria

### Purpose or Objective

In a pre-clinical phase of this translational oncology research, it was proved for the first time that the hypoxic tumor cells show higher potential for induction of the bystander (BE) and abscopal effects (AE) than the normoxic cells: single high-dose irradiation of the hypoxic tumor exclusively resulted in significantly stronger radiation-hypoxia-induced BE and AE. These finding were translated to a clinic. Since BE and AE are mediated by the immune-system cells, we hypothesized that high-dose partial tumor irradiation (PTI), targeting exclusively the hypoxic tumor segment, and leaving the tumor microenvironment intact, would generate an effective tumor-abscopal signaling and antigen release leading to immune-mediated regression of whole partially-irradiated tumor (due to BE) but also of unirradiated metastases (due to AE). Primary endpoint included BE and AE response rates. Secondary endpoints included assessment of toxicity, overall (OS) and disease-specific survival (DSS).

### Material and Methods

Clinical study involved 32 patients whose bulky tumors of the lung, H&N, pancreas, kidney, skin and adrenal glands were partially irradiated. "Bystander Tumor Volume (BTv)" (hypoxic segment) was defined using PET-CT, as a

hypovascularized-hypometabolic junctional zone between the central necrotic and peripheral hypervascularized-hypermetabolic tumor segment. Based on tumor site and volume, BTV was irradiated with 1-3 fractions of 10 or 12 Gy prescribed to 70% isodose, avoiding the tumor microenvironment (Fig.1, 2). No patient received systemic therapy. Immunohistochemistry was performed on the available tissue samples after neoadjuvant PTI and surgery to explore for the modifications within the tumor microenvironment.

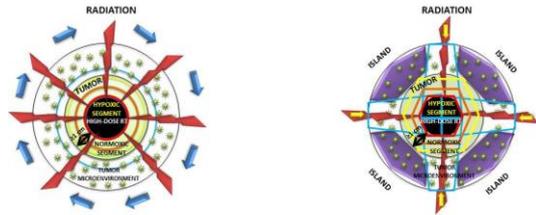

Figure 1A DYNAMIC RADIATION ARCS: Figure shows how a desired high radiation dose (red ring) is delivered by the means of dynamic arcs very precisely and conformally to the hypoxic tumor segment (red/black area). Moving from that high-dose region through the necrotic tumor towards outside of the tumor, the dose will sharply fall off (orange ring-moderate dose, yellow ring-low dose) reaching a very low dose-level (blue ring) outside the tumor at the level of the tumor microenvironment, being at that level very steady and homogeneously distributed. In this case, an acceptably low radiation dose will cover a small volume of the tumor microenvironment closer to the tumor's periphery leaving it viable and functional.

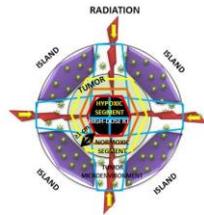

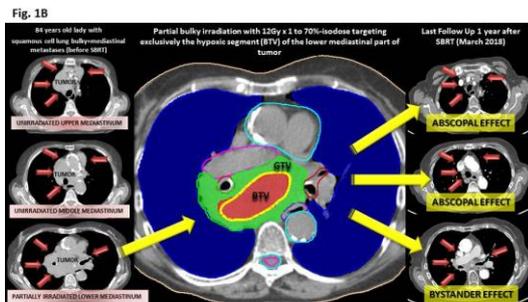

Figure 1B LOW NUMBER OF STATIC RADIATION FIELDS: Figure shows how a desired high radiation dose (red ring) is delivered by the means of a static radiation fields to the hypoxic tumor segment (red/black area) whereby a significant volume of the tumor microenvironment is constantly spared from radiation dose. Moving from that high-dose region through the necrotic tumor towards outside of the tumor, the dose will fall off (orange ring-moderate dose, yellow ring-low dose) reaching a very low dose-level (blue area) outside the tumor, covering a smaller volume of the tumor microenvironment. In this case, a larger volume of the tumor microenvironment remains intact in a form of the islands.

## Results

On an average, the BTV corresponded to 30% of the bulky tumors. With median follow-up of 11 months (range: 2-22) OS and DSS were 71% and 84%, respectively. BE response rate was 95%. Average bulky shrinkage was 60%, with 20% complete responses. AE response rate was 47% with mean reduction of unirradiated metastases of 50% (range: 30-100%). No patient experienced acute or late toxicity of any grade. The immunohistochemical findings after neoadjuvant PTI showed that apoptosis-inducing factor was massively upregulated in the partially irradiated bulky and also at unirradiated-abscopal tumor sites, whereas a dense immune reaction was observed only at the border of the partially irradiated tumor but not at the abscopal site indicating an important role for the tumor-abscopal signaling.

## Conclusion

PTI for bulky tumors was feasible, effective and safe, showing high potential for induction of BE and AE, that could be translated in improved therapeutic ratio.

**Relevance:** PTI showed high *neoadjuvant* potential to convert unresectable into resectable lesions; very convenient *palliative* 1-3 days treatment for patients in poor general conditions, offering an *improved cost-effectiveness profile*; safe *salvage re-irradiation* option in case of relapses.

**PO-0887 Radiation toxicity in patients with collagen vascular disease: Meta-analysis of case-control studies**

<sup>1</sup>West Virginia University, Radiation Oncology, Kentwood, USA ; <sup>2</sup>Geisinger Medical Center, Radiation Oncology, Danville- PA, USA ; <sup>3</sup>Allegheny General Hospital, Internal Medicine, Pittsburgh- PA, USA ; <sup>4</sup>Loyola University Chicago, Radiation Oncology, Maywood- IL, USA ; <sup>5</sup>West Virginia University, Radiation Oncology, Morgantown- WV, USA ; <sup>6</sup>Loyola University Chicago, Radiation Oncology, Chicago- IL, USA

## Purpose or Objective

Several retrospective matched-pair series have reported on late effects of radiotherapy(RT) in patients with collagen vascular disease(CVD). Results have been conflicting and concern remains that patients are at greater risk for late toxicity.

## Material and Methods

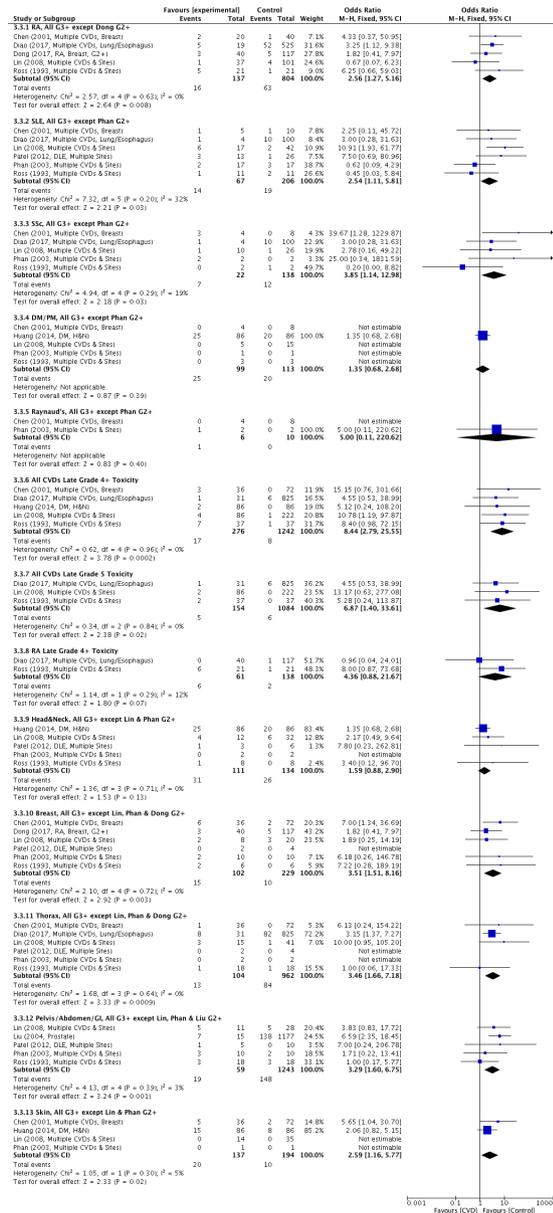

A comprehensive EMBASE and Medline search was performed to identify case-control series reporting RT toxicity in patients with CVDs. Results were synthesized from studies reporting at least grade 2 or 3 (G2/3+) acute and/or late toxicities in patients with rheumatoid arthritis(RA), systemic lupus erythematosus(SLE), scleroderma (SSc), Dermatomyositis/Polymyositis (DM/PM), Raynaud's, Mixed connective tissue disease(MCTD)/Sjogren's. Results were analyzed on the random-effects(RE) model if there was evidence of between-study heterogeneity, otherwise the fixed-effects model(FE) was used. Hazard ratio(HR) was used for overall late toxicity for all CVDs and survival endpoints and odds ratio(OR) for subgroup toxicity analysis.

## Results

10 studies were identified with 4112 patients (CVD=380, control=3732). Grade 2/3+late toxicity was seen in 18.4% (68/370) RT courses in CVD patients vs. 10.1% (262/2588) in control patients (Fig). Pooled data showed significantly worse grade 2/3+ late toxicity in patients with CVD vs. control (HR=2.37; 95% CI 1.71-3.28, p<0.00001, FE). Subgroup analysis showed RA patients had 16/137 (11.7%) RT courses complicated by grade 2/3+ late toxicities vs. 63/804 (7.8%) in control patients (OR=2.56; 95% CI 1.27-5.16, p=0.008). SLE patients had 14/67 (20.9%) RT courses complicated by grade 2/3+ late toxicities vs. 19/206 (9.2%) in control patients (OR=2.54; 95% CI 1.11-5.81, p=0.03, FE). SSc patients had 7/22 (31.8%) RT courses complicated by grade 2/3+ late toxicities vs. 12/138 (8.7%) in control patients (OR=3.85; 95% CI 1.14-12.98, p=0.03, FE). No significant differences were found in late grade 2/3+ toxicity for subgroups of DM/PM or Raynaud's. Late grade 4 and 5 toxicity was significantly higher in CVD patients, 6.2% vs. 0.64% (HR=8.44, p=0.0002) for Grade 4 and 3.2 vs. 0.55% (HR=6.87, p=0.02) for Grade 5. Abdomen/Pelvis had the highest probability of late grade 2/3+ toxicity (32.2%, bowel toxicity) followed by head & neck (27.9%, likely reflecting higher dose) compared to breast, thorax and skin (<15%) anatomic sites. Overall acute G2/3+ was also significantly worse in CVD group (OR 2.0, p<0.0001) and in the subgroups of patients with SLE (OR=2.25, p=0.05) and DM/PM (OR=3.39, p<0.0001). There was statistically significant worse disease-free-survival in CVD patients vs. controls (HR=1.46, p<0.01) but no difference in overall, loco-regional or distant metastases free survival.

## Conclusion

Metanalysis demonstrated significantly higher RT induced late toxicity, including risk of death in irradiated CVD patients, especially in RA, SLE and SSc subgroups and in abdomen/pelvis and head/neck anatomic sites. These findings support further validation in prospective manner.

Material and Methods

Enrolled patients suffered from recurrent VT or electrical storm (ES) refractory to CA and AADs. Before the procedure, an electroanatomic mapping (EAM) was performed to localize the VT substrate (VT-sub). All patients underwent a planning CT co-registered with a cardiac MRI or a cardiac CT to help in volume definition. For each case, the cardiologist delineated the VT-sub according to the EAM data. The distal dipole of the ICD lead was used as a fiducial marker for tracking. The median dose of 25 Gy (range, 20-25 Gy) was delivered to the VT-sub using the Cyberknife® system.

Results

Since September 2017, five patients with VT or ES refractory to AADs and CA were treated. Four patients were elective, while another one, hospitalized in the intensive care unit (ICU), was intubated because of an ES with multiple ICD shocks refractory to CA. VT was due to an ischemic cardiomyopathy in two patients and to a non-ischemic cardiomyopathy in the three others. In all patients, SBRT was successfully delivered using near real-time ICD lead tracking with an average time of 54 minutes. The median ablation volume was 22 cc (range, 19-35 cc). After a median follow-up of 5 months (range, 4-11), the elective patients did not experience any VT recurrence. The ICU patient, suffering from a non-ischemic cardiomyopathy, was extubated 3 days after SBRT and remained free of ICD shocks during 4 months; he presented, however, a new ES episode 19 weeks after the procedure related to a new VT-sub successfully treated by CA. In all patients, the ICD interrogation confirmed that no sustained VT episodes arose from the irradiated site after SBRT. Importantly, no SBRT-related toxicity occurred.

Conclusion

SBRT appears as an efficient tool for the treatment of refractory VT caused by myocardial scarring. Recurrence was observed only in non-ischemic cardiomyopathy remote from the irradiated site.

**PO-0889 Breathing modulation in patients treated for mobile tumours: moving forward to clinical integration**  
 G. Van Ooteghem<sup>1,2</sup>, D. Dasnoy-Sumell<sup>3</sup>, G. Liistro<sup>4</sup>, E. Sterpin<sup>5</sup>, G. Xavier<sup>1,2</sup>

<sup>1</sup>Institut de Recherche Expérimentale et Clinique, Molecular Imaging- Radiotherapy and Oncology MIRO, Brussels, Belgium; <sup>2</sup>Cliniques Universitaires Saint Luc, Radiation Oncology, Brussels, Belgium; <sup>3</sup>Université Catholique de Louvain, ImagX-R, Louvain-La-Neuve, Belgium; <sup>4</sup>Cliniques Universitaires Saint Luc, Pneumology, Brussels, Belgium; <sup>5</sup>Université Catholique de Louvain, Molecular Imaging- Radiotherapy and Oncology MIRO, Brussels, Belgium

Purpose or Objective

We previously demonstrated that mechanically-assisted and non-invasive ventilation (MANIV) can be used safely without sedation on healthy volunteers. MANIV can be used to regularise the breathing pattern by constraining the breathing rate (BR) and the tidal volume (Volume-controlled ventilation mode - VC). Breathing modulation can also be achieved by the shallow-controlled mode (SH) which reduces the breathing amplitude proportionally to the BR increase while the Slow-controlled mode (SL) mimics repeated end-inspiratory breath-holds. To allow the clinical integration of MANIV in radiotherapy, patients' tolerance and the intra- and inter-session reproducibility of the breathing-related tumour motion were thus evaluated.

Material and Methods

In lung or liver cancer patients (cohort A), the tumour motion was assessed with the VC and SH modes and compared to spontaneous breathing (SP). In left breast cancer patients (cohort B), the nipple motion was assessed with the SL mode and compared to spontaneous breath-

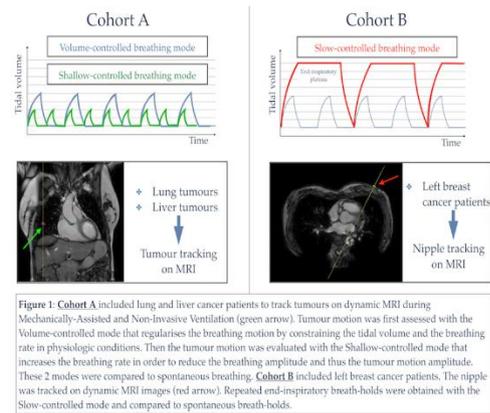

**PO-0888 Stereotactic body radiotherapy for refractory ventricular tachycardia: clinical outcomes**

R. Jumeau<sup>1</sup>, M. Ozsahin<sup>1</sup>, J. Schwitzer<sup>2</sup>, F. Duclos<sup>1</sup>, V. Vallet<sup>3</sup>, M. Zeverin<sup>3</sup>, R. Moeckli<sup>3</sup>, E. Pruvot<sup>4</sup>, J. Bourhis<sup>1</sup>

Purpose or Objective

Ventricular tachycardia (VT) caused by myocardial scarring bears a significant risk of mortality and morbidity that can be partially controlled by the implantation of a cardioverter-defibrillator (ICD). Recently, stereotactic body radiotherapy (SBRT) appeared as a promising tool for the management of VT refractory to antiarrhythmic drugs (AADs) and catheter ablation (CA). We present herein the outcomes of our series of patients treated under an institutional SBRT program for refractory VT.

holds (SPBH) (Figure1).

All the patients underwent one coaching session, one simulation session and then 2 dynamic MRI sessions. Each MRI acquisition lasted for 6 minutes with a first acquisition in SP/SPBH followed by those with MANIV. Patients' objective tolerance was assessed with oxymetric monitoring (SpO<sub>2</sub>, etCO<sub>2</sub>). Subjective tolerance was assessed through questionnaires fulfilled after each session. The motion of the tumour, or the nipple, was tracked and expressed in position, amplitude, period and plateau within each MRI (intra-session analysis) and between MRI (inter-session analysis).

### Results

Five lung cancer patients, 5 liver cancer patients (61-83 years old) and 10 left breast cancer patients (49-77 years old) were included (Table 1).

	Cohort A	Cohort B
Total (n)	10	10
Region of interest (n)	Lung tumour (5) Liver tumour (5)	Left breast nipple (10)

Table 1: Demographic data of Cohort A and Cohort B  
(M = male; F = female; BMI = Body Mass Index; COPD = Chronic Obstructive Pulmonary Disease;  
OAS = Obstructive Sleep Apnea Syndrome; CPAP = Continuous Positive Airway Pressure device)

MANIV was well tolerated without any interruption, nor oxymetric changes. Main reasons of discomfort were the facial mask (47%) and the arms position (29%), before MANIV itself (18%).

In cohort A, the BR in VC and SH were all more stable than in SP in intra- and inter-session analysis. Switching from VC to SH led to a motion amplitude reduction of 0.6mm to 9mm proportional to the BR increase (1.5 to 3.4-fold increase).

The greatest effect was observed in a liver tumour with a spontaneous median amplitude of 28.7mm (IQR 12.8mm) reduced to 17.6mm (IQR 4.8mm) with SH.

In cohort B, the repeated breath-holds in SL were as stable as in SPBH in terms of range within a same plateau (0.7mm in SPBH and 0.9mm in SL) or position between plateaus (0.2mm of median variation for both). Plateaus in SL lasted 16,7sec (IQR=4.6) and 20sec in SPBH.

### Conclusion

This trial demonstrates that MANIV can be used safely in unsedated patients. MANIV may thus be proposed in

clinical practice to improve the current motion mitigation techniques such as margins reduction (SH mode), respiratory gating (SL mode) or tracking (VC mode). Indications still have to be refined and patients well-selected according to appropriate clinical situation.

### PO-0890 Abscopal effects in metastasized cancer patients treated with PD-1 inhibition and radiation therapy

M. Trommer<sup>1</sup>, S.Y. Yeo<sup>2</sup>, T. Persigehl<sup>2</sup>, A. Bunck<sup>2</sup>, M. Schlaak<sup>3</sup>, H. Gröll<sup>2</sup>, S. Theurich<sup>4</sup>, M. Von Bergwelt<sup>4</sup>, J.M. Herter<sup>1</sup>, E. Celik<sup>1</sup>, S. Marnitz<sup>1</sup>, C. Baues<sup>1</sup>

<sup>1</sup>University Hospital of Cologne, Department of Radiation Oncology, Köln, Germany; <sup>2</sup>University Hospital of Cologne, Department of Diagnostic and Interventional Radiology, Köln, Germany; <sup>3</sup>Ludwig Maximilian University, Department of Dermatology and Allergology, Munich, Germany; <sup>4</sup>Ludwig Maximilian University, Department III of Internal Medicine- Hematology and Oncology, Munich, Germany

### Purpose or Objective

Immune-checkpoint inhibitors targeting the programmed death receptor 1 (PD-1) have shown promising results in the fight against several malignancies. Radiation therapy (RT) induces the release of immunogenic targets and the secretion of damage-associated molecules. Subsequent systemic anti-tumor reactions can lead to a regression of non-irradiated lesions, which is called abscopal effect. The aim of this study was to evaluate abscopal effects based on radiological imaging of irradiated cancer patients receiving simultaneously anti-PD1 antibodies.

### Material and Methods

We analyzed 48 patients treated with PD-1 inhibitors and radiotherapy between August 2014 and December 2017. Inclusion criteria were at least one distant metastatic site outside V10% (volume of tissue receiving at least 10% of the prescribed irradiation dose) and start of RT after at least one month of anti-PD1 therapy (pembrolizumab 2 mg/kg every three weeks or nivolumab 3 mg/kg every two weeks) or within one month after the last application. Abscopal effect was defined as shrinkage of one or more non-irradiated lesions outside V10% with no additional treatment. To distinguish the abscopal effect from the systemic effects of immunotherapy alone, radiological imaging had to be performed twice before RT and at least once after completion of RT. In every radiological image taken during radio-immunotherapy, the largest diameter of the lesions was measured. A size change of more than 20 % was considered as significant decrease or enlargement.

### Results

11 patients met the inclusion criteria. We observed lesion shrinkage outside V10% in four out of 11 analyzed cases, one patient demonstrated as case example. In five patients, all lesions progressed during the analyzed period, whereas two patients showed already reduced or stable lesions after immunotherapy alone. Nivolumab was given in four cases and pembrolizumab in seven cases. Patients were irradiated with a mean of 50,67 Gy total dose (median 50 Gy) in the analyzed time period. Seven patients were treated stereotactically using Cyberknife® (20 Gy / 65 %). One out of those received three Cyberknife® treatments, one patient additionally received hypo-fractionated treatment (3 Gy single dose (SD)), two patients additionally hypo-fractionated and normo-fractionated treatment (3 Gy SD and 1,8 or 2 Gy SD). Two patients had only hypo-fractionated (3 Gy SD) and two only normo-fractionated (2 Gy SD) radiotherapy. Three out of four patients showing AE were treated stereotactically, all AE patients received a high total dose (mean: 77,6 Gy, median: 78 Gy).

### Conclusion

We demonstrated that four out of 11 patients who were considered for this analysis showed a regression of lesions

outside the irradiation field. Confirming the clinical evidence of a systemically mediated effect of radiotherapy, our study contributes to understanding the circumstances of its occurrence and assists in developing a setting for the effective use of the synergistic mechanisms of radioimmunotherapy.

#### PO-0891 Radiochromic film based output measurement for radio-biological experiments at low energy photons

N. Tomic<sup>1</sup>, L. Lieng<sup>1</sup>, M. Lecavalier<sup>1</sup>, J. Seuntjens<sup>1</sup>, R. Aparidian<sup>1</sup>, S. Devic<sup>1</sup>

<sup>1</sup>Jewish General Hospital, Radiation Oncology, Montreal, Canada

#### Purpose or Objective

Purpose of radiobiological experiments with small animals is to provide information of the efficacy of dose delivered for the investigated new modalities, for which it is essential to determine exactly the delivered dose. If the experimental setup is simulated before the actual experiment, radiochromic film with high spatial resolution can be used as a calibration tool, providing the spatial output data for future experiments.

#### Material and Methods

We designed experimental setup for radiobiological studies in the irradiation of the mouse abdomen (Fig.1a). It consists of the polyactic acid mouse holder and the half cylinder phantom mimicking the mouse during output measurements, both created using 3D printer (MicroBOT). Irradiation was carried by the Axxent -Xoft (Xoft Inc. Sunnyvale, CA) electronic brachytherapy system and Vaginal Applicator. The applicator was covered with the lead collimator having the 7 mm diameter hole, aligned with the source position within the applicator. Dose range used in the described setup is from 2 to 30 Gy. The irradiator has the beam quality of 50 kVp and the measured HVL of 0.81 mm Al.

We used EBT3 model GAFCHROMIC™ film to estimate the output and the 2D dose distribution. Output of the irradiator at the reference point of measurement in terms of air kerma in air was measured using a calibrated parallel plate (Exradin A20) ionization chamber following AAPM TG-61 protocol. At the same reference point, film pieces were irradiated to create calibration curve for given beam quality in terms of air kerma in air as a function of film response to radiation:  $(PV_0/PV) \cdot -1$  [Aldelaijan et al. *Phys. Med.* **49**,112-118(2018)].

Output of irradiator at the phantom surface mimicking mouse was determined by employing previously described film reference dosimetry system, where dose to water is determined by multiplying air kerma in phantom by the mass-energy attenuation coefficient ratio water to air,  $(m_{en}/r)_{air}^{wat}$ , for a given beam quality [Tomic et al. *Med. Phys.* **37**,1083-1092(2010)].

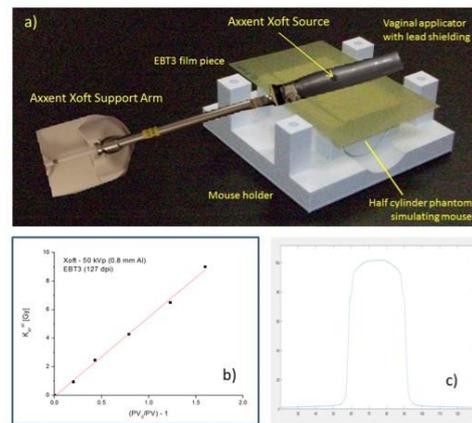

Figure 1: Calibration of the experimental setup for radiobiological studies of mouse irradiation: a) mouse holder with the half cylinder phantom to mimic the mice, Axxent-Xoft electronic brachytherapy system with Vaginal Applicator as an irradiator and the piece of EBT3 film between the irradiator and the surface of the mouse model phantom; b) calibration curves for EBT3 GafChromic™ film based reference dosimetry system at irradiator beam quality (50 kVp, 0.81 mm Al); c) dose profile extracted from the irradiated EBT3 film piece during the irradiation of the mouse model phantom with 7 mm diameter collimator opening aligned with the source position within the applicator.

#### Results

Figure 1.b presents calibration curve for measured beam quality showing linear response in wide dose range. Output of described irradiator at the surface of the animal model phantom in the center of lead opening was found to be  $8.4 \pm 0.1$  Gy/min, and obtained 2D dose distribution was found to be uniform. Profile through the region of irradiation (Fig 1.c) shows dose uniformity to be within 95% from dose in the middle of the profile over 80% of the field diameter defined at 50% of central axis dose. Due to significant energy dependence of the EBT3 film response for effective photon energies below 100 keV, the beam quality has to be determined before using described reference dosimetry protocol.

#### Conclusion

We described method to measure the output and the 2D dose distribution of low energy photons in radiobiological setups with small animals using the EBT3 radiochromic film dosimetry protocol with the uncertainty in measured dose of the order of 5%.

#### PO-0892 On the orientation of ionization chambers in dosimetry of small photon fields

B. Casar<sup>1</sup>, E. Gershkevitch<sup>2</sup>, I. Mendez<sup>1</sup>

<sup>1</sup>Institute of Oncology Ljubljana, Department for Dosimetry and Quality of Radiological Procedures, Ljubljana, Slovenia; <sup>2</sup>North Estonia Medical centre, Medical Physics Service, Tallinn, Estonia

#### Purpose or Objective

The new IAEA Code of Practice TRS - 483 for dosimetry of small static photon fields provides advice on the orientation of various detectors for measurements of beam profiles and field output factors (FOFs). For cylindrical ionization chambers (ICs), it is advised to place the IC with its stem perpendicular to the beam axis for the determination of FOFs, while for the measurement of lateral beam profiles, the recommended orientation is parallel to the beam axis. Accurate positioning of the IC in the center of the field is crucial to obtain accurate values for FOFs. As the most accurate location of the center of the field lies in the middle of two orthogonal lateral beam profiles at FWHM, which is supposed to be obtained in a parallel orientation, recommendations from TRS-483 are somewhat incoherent. We aimed to analyze differences in detector specific output correction factors (OCFs) between parallel and perpendicular orientations of IC and to resolve the ambiguity on how to perform measurements of FOFs with ICs.

### Material and Methods

The measurements were made on Elekta Versa HD linac for 6 and 10 MV beams with and without flattening filter. FOFs were acquired for nine small square fields ranging from 0.5 to 10.0 cm (nominal sizes) shaped with MLC and jaws, at SSD = 90 cm and 10 cm depth in a 3D water phantom. Nominal field sizes were converted to equivalent square field sizes ( $S_{clin}$ ) as  $S_{clin} = (AxB)^{1/2}$ , where A and B correspond to the measured field width and length defined at the FWHM.

Discrete values of FOFs were determined with two reference detectors, Exradin W1 plastic scintillator and EBT3 radiochromic films, fitted with the analytical function  $FOF(S_{clin})$  proposed by Sauer and Wilbert - Eq. (1). EBT3 films were irradiated in an RW3 Solid Water phantom under the same set-up as described above and analyzed with Radiochromic.com software. Four types of ICs - IBA Razor, IBA CC04, PTW 31022 3D PinPoint and PTW 31023 PinPoint - were used in parallel and perpendicular orientations to measure signal ratios  $M(S_{clin})/M(S_{ref})$  between clinical and reference ( $10 \times 10 \text{ cm}^2$ ) fields. The orientation was kept unchanged (parallel or perpendicular) for the scanning procedure and the point measurements. Discrete values of OCFs determined with Eq. (2) were fitted by the function shown in Eq. (3).

$$FOF(S_{clin}) = P_{\infty} \frac{S_{clin}^n}{l^n + S_{clin}^n} + S_{\infty} (1 - e^{-b \cdot S_{clin}}) \quad (1)$$

$$OCF(S_{clin}) = \frac{FOF(S_{clin})}{\frac{M(S_{clin})}{M(S_{ref})}} \quad (2)$$

$$OCF(S_{clin}) = \frac{1 - e^{-\frac{10-a}{b}}}{1 - e^{-\frac{S_{clin}-a}{b}}} + c \cdot (S_{clin} - 10) \quad (3)$$

### Results

For the smallest fields, OCFs were always lower (closer to unity) in parallel than in perpendicular orientation for all ICs, regardless of the beam energy used (Fig. 1).

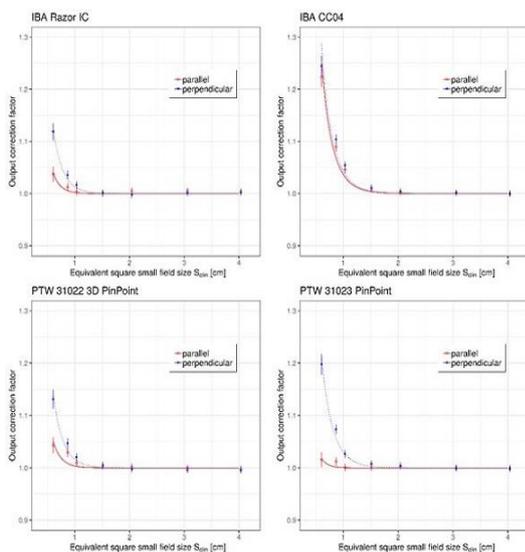

Fig 1: Output Correction Factors (OCF) for four IC obtained in 6 MV WFF photon beam from Elekta Versa HD linac, displayed as discrete points and as curves of analytical function from Eq. (3)

### Conclusion

For the determination of FOFs and OCFs for cylindrical IC, we recommend the orientation with its stem parallel to the beam axis. Our recommendation arises from two main

arguments: (i) the center of the radiation field can be determined from lateral beam profiles using the IC in a parallel orientation as recommended in TRS-483, (ii) OCFs were lower in parallel compared to perpendicular orientation for the smallest fields in all studied ICs.

### PO-0893 Absolute dosimetry with polymer gels - A TLD reference system

A. Schwahofer<sup>1</sup>, P. Mann<sup>1</sup>, C. Karger<sup>1</sup>

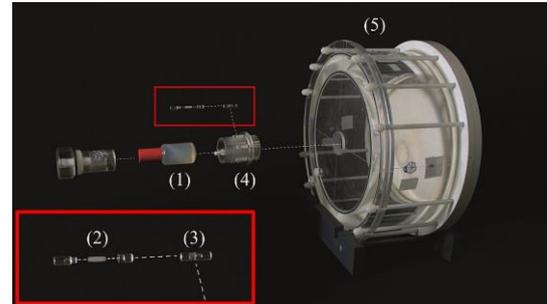

<sup>1</sup>German Cancer Research Center DKFZ, Department of Medical Physics in radiation therapy, Heidelberg, Germany

#### Purpose or Objective

Absolute dosimetry in 3D with polymer gels (PG) is generally complicated and usually requires a second independent measurement with conventional detectors. This is why, PG are often used only for relative dosimetry. To overcome this drawback, we combine PG with a 1D thermoluminescence (TL) detector within the same measurement. The TL detector information is then used as additional information for calibration of the gel.

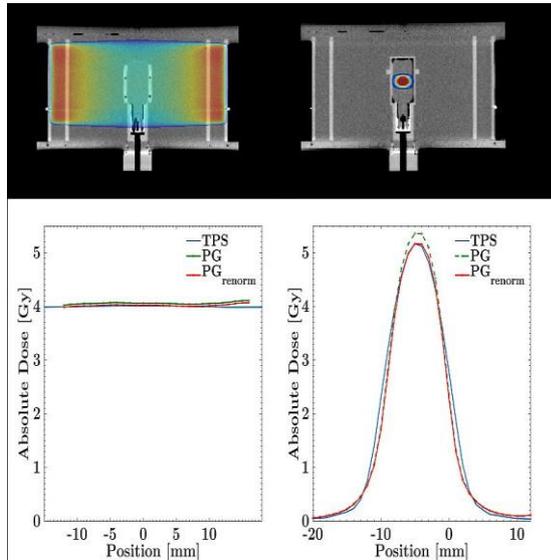

#### Material and Methods

The PAGAT dosimetry gel was used in combination with TLD600 (LiF:Mg,Ti). TL detectors were attached on the surface of the PG container placed inside a cylindrical Phantom (figure 1). To test the usability of this setup, two irradiation geometries were carried out: (a) homogeneous target coverage and (b) small-field irradiation. PG was evaluated with magnetic resonance imaging (MRI) and the TL detectors with a Harshaw 5500 hot gas reader.

### Results

PG dosimetry alone showed deviations of up to 4% as compared to calculations. Including additionally the dose information of the TL detectors for PG calibration, this deviation was decreased to less than 1% for both irradiation geometries (figure 2). This is also reflected by the very high -passing rates of >96% (3%/3mm) and >93 % (2%/2mm), respectively.

### Conclusion

This study presents a novel method combining 3D PG and TL dose measurements for the purpose of absolute 3D dose measurements that can also be applied in complex anthropomorphic phantoms using only a single measurement. The method was validated for two different irradiation geometries including a homogeneous large field as well as a small field irradiation with sharp dose gradients.

### PO-0894 Characterization of a multilayer ionization chamber for relative depth-dose curves in particle beams

A. Vai<sup>1</sup>, D. Maestri<sup>1</sup>, G. Magro<sup>1</sup>, A. Mairani<sup>1,2</sup>, E. Mastella<sup>1</sup>, A. Mirandola<sup>1</sup>, S. Molinelli<sup>1</sup>, S. Russo<sup>1</sup>, M. Togno<sup>3</sup>, S. La Civita<sup>3</sup>, M. Ciocca<sup>1</sup>

<sup>1</sup>National Center for Oncological Hadrontherapy CNAO, Medical Physics Department, Pavia, Italy; <sup>2</sup>Heidelberg Ion Beam Therapy Center HIT, Physics Department, Heidelberg, Germany; <sup>3</sup>IBA Dosimetry, Research and Development, Schwarzenbruck, Germany

### Purpose or Objective

To characterize a commercial multilayer ionization chamber (MLIC) detector primarily designed for measurements of integrated depth-dose (IDD) curves of both proton and carbon ion scanning beams, for QA purposes.

### Material and Methods

The commercial MLIC *Giraffe* (IBA Dosimetry, Schwarzenbruck, Germany) is a device developed for integrated depth-dose (IDD) curves measurements of a central axis pencil-beam, with FWHM ranging between 0.5 to 3 cm. Preliminary, water-equivalent calibration factory values were verified against the reference curves acquired with the Peakfinder water column (PTW GmbH, Freiburg, Germany). For both protons and carbon ion beams, the device was tested in terms of short- and long term repeatability, linearity and dose-rate independence. Accuracy of the detector was tested by evaluating range (distal  $R_{90}$ ) of IDD curves for a set of representative energies for both particle species against reference acquisitions in water. Two modulated proton spread-out Bragg peak (SOBP) were measured and range compared to theoretical values. To increase the native spatial resolution (approx. 2 mm), consecutive acquisitions were acquired respectively with and without build-up PMMA plates. The possibility of a double- (none + 1-mm WET thick) or triple-merge (none + 1-mm + 0.44-mm WET thick) was investigated in terms of accuracy.

### Results

Particle type dependent WET-offset values < 1 mm were measured, while chamber length was found in agreement to the value provided by the vendor. Measurements showed a high repeatability: mean relative standard deviation was within 0.5% for all channels and both particle types. Moreover, the detector response was linear with dose ( $R^2 > 0.99$ ) and independent on the dose rate. The mean deviation over the channel-by-channel readout respect to the reference beam flux was equal to 0.2% and 0.6% for protons and carbon ions respectively. The long-term stability of the gain calibration was very satisfying for both particle types, with values of channel mean relative standard deviation less than 1% for all the acquisitions performed at different times. Merging of measured data with and without 1-mm plate provided the right trade-off between accuracy and measurement time for QA purposes. Against reference curves in water, deviations in BP position were < 1 mm for both particle types in the whole investigated energy range. Similar results were found for modulated SOBPs against expected values.

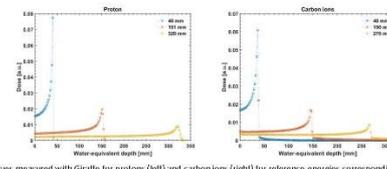

Figure. IDD curves measured with Giraffe for protons (left) and carbon ions (right) for reference energies corresponding to a nominal BP depth of 40-, 151-, 320-mm for protons and 40-, 150-, 270-mm for carbon ions. Curve values are normalized for equal integral dose.

Particle	Energy	Distal $R_{90}$ in water [mm]	Distal $R_{90}$ with Giraffe [mm]	$\Delta R_{90}$ [mm]	$\Delta R_{90}$ [%]
Mono-energetic pencil beam P	72.6 [MeV]	40.5	40.4	-0.1	-0.3%
Mono-energetic pencil beam P	148.8 [MeV]	152.4	152.3	-0.1	-0.1%
Mono-energetic pencil beam P	228.6 [MeV]	322.9	323.3	0.4	0.1%
Mono-energetic pencil beam C + ripple-filters	133.7 [MeV/u]	37.48	37.3	-0.2	-0.5%
Mono-energetic pencil beam C + ripple-filters	279.9 [MeV/u]	147.6	147.4	-0.2	-0.1%
Mono-energetic pencil beam C + ripple-filters	398.8 [MeV/u]	266.7	267.6	0.85	0.3%

Table. Distal  $R_{90}$  measured with the Giraffe device vs reference measurement in water with the Peakfinder for several IDD curves for both proton and carbon ion beams.

### Conclusion

To our best knowledge, this is the first time the detector has been used with carbon ion beams. The Giraffe was proved to be accurate, linearly responding with dose, precise and easy to handle for QA beam energy checks of both protons and carbon ion beams.

### PO-0895 Anthropomorphic breathing phantom with lung and liver components for testing MR-guided radiotherapy

E. Colvill<sup>1</sup>, M. Krieger<sup>1</sup>, Y. Zhang<sup>1</sup>, S. Safai<sup>1</sup>, D.C. Weber<sup>1</sup>, A.J. Lomax<sup>1</sup>, G. Fattori<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland

### Purpose or Objective

Magnetic resonance (MR) imaging is widely recognised as a key element in many new frontiers of radiotherapy such as daily treatment adaptation and motion compensated dose delivery. Currently available phantoms for treatment quality assurance are however limited in realism and provide poor MR imaging texture. Therefore, renewed effort went to develop an anatomical model with good imaging contrast for testing new sequences and image-guided radiotherapy techniques.

### Material and Methods

We expand on an existing anthropomorphic breathing thorax phantom by making use of 3D printing to develop a new, anatomically correct, lung model with improved mechanical properties and tissue characteristics. The respiratory tract including trachea and main bronchi has been segmented from clinical data and used as inlet for ventilation. The lung infill modulated during printing to

mimic the lung parenchyma tissue, embedded with a solid region shaped from a patient's lung tumour and six nitroglycerine capsules as reference landmarks. The full internal mesh structure is covered with a thin layer of polyorganosiloxane gel making the complex pattern visible in MR imaging. The phantom is completed with a liver mould shaped by a thin casing of silicon, filled with gel and elastic plastic internal structures. Once fitted into a pre-existent rib-cage and skin models, stationary and 4D CT and T1 weighted MR imaging sequences were acquired to evaluate the structure visibility and mechanical properties of each component of the phantom.

### Results

Contrast of the 3D printed flexible material and the polyorganosiloxane gel was good on the T1 weighted MRI with image intensities of -500 - -400 and 0 - 100 respectively. The silicon liver casing had an image intensity range of 600 - 800. Good contrast is also confirmed on CT images with 0 - 150 HU for the printed plastic, 50 - 200 HU for gel and 650 - 800 HU for the silicon-based liver casing. The range of motion between exhale and inhale breathing phases evaluated as magnitude of the deformable image registration vector field was around 4 mm at the upper lobes and 15 mm in the inferiors. Similar deformation was seen for the liver and the surface skin, mechanically connected with the lung and ribcage (Figure 1.).

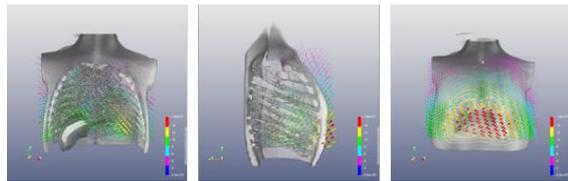

Figure 1 : Time resolved imaging of Lung Cancer phantom: volume rendering from lateral and frontal perspective of 4D MR images. Vector field describes the displacement of voxels between exhale and inhale breathing phases; scale in millimetres goes from no-motion (blue) to 16 mm (red). Coronal (left-hand panel), lateral (central panel) cuts and surface motion (right-hand panel).

### Conclusion

A ventilated thoracic dosimetry phantom has been updated to allow for enhanced imaging with MR and CT by the addition of new lung and liver models. These additions will allow for reliable validation of 4D imaging techniques and treatments as well as deformable image registration quality assurance.

### PO-0896 Motorised 3D printed water tank designed for measurements in MR linear accelerators

H.L. Riis<sup>1</sup>, P.F. Lange<sup>1</sup>, T.L. Schierbeck<sup>1</sup>, L. Gregorius<sup>1</sup>, F. Mahmood<sup>1,2</sup>, U. Bernchou<sup>1,2</sup>, C. Brink<sup>1,2</sup>, A.S. Bertelsen<sup>1</sup>  
<sup>1</sup>Odense University Hospital, Department of oncology, Odense, Denmark ; <sup>2</sup>University of Southern Denmark, Department of clinical research, Odense, Denmark

### Purpose or Objective

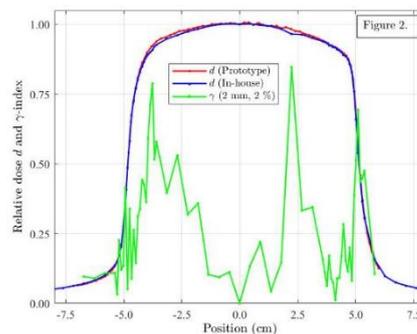

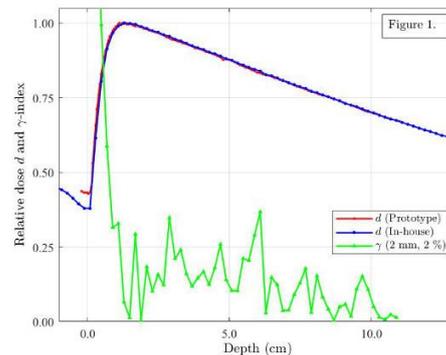

The recent introduction of MR linear accelerators (MR-linacs) for clinical treatment of patients opens new possibilities and challenges in radiotherapy. Beam data collection in a water tank for commissioning of dose planning systems for an MR-linac is more challenging compared to a conventional linear accelerator. The bore diameter, the isocentre height, the lack of room lasers, light field and cross-hair makes the setup of a water tank more complex on an MR-linac. The presence of a strong magnetic field in an MR-linac requires, for safety and handling, that water tanks to be used on MR-linacs are constructed of non-ferromagnetic materials. This work demonstrates that an MR-compatible motorized in-house designed water tank can be used at the high-field MR-linac Unity from Elekta based mainly on 3D printed parts.

### Material and Methods

An in-house designed and developed water tank was produced. The water tank consists of around 60 parts. Three ultrasonic motors manufactured by SHINSEI Corporation, toothed wheels, belts, aluminium spindlers, carbon rods and bearings were bought commercially. Arms and detector holders were printed in plastic using 3D printers. The outer dimension of the tank was 44×33×50 cm<sup>3</sup> with Perspex walls of 12 mm in thickness. Data collection uses Mephysto mc<sup>2</sup> (PTW) as interface in line with data collection on all our conventional accelerators. The data acquired using the in-house water tank was compared with data collected by Elekta, during commissioning, using a prototyped MR-compatible water tank developed in collaboration between Philips, Elekta and PTW. Scans in both water tanks were carried out using a PTW microDiamond detector as field detector and a reference detector. The scans were all performed on the same Elekta Unity MR-linac with 7 MV FFF x-ray energy characterised by a beam quality index of 0.70.

### Results

Depth dose as well as profile scans at gantry 0° at the depths 5 and 10 cm for the square field sizes 2×2, 5×5 and 10×10 cm<sup>2</sup> were carried out at a source-to-surface (SSD) distance of 133.5 cm (SAD=143.5 cm). In Figure 1 and 2, examples of the depth dose and cross-plane profiles at 10 cm are shown, respectively, for a 10×10 cm<sup>2</sup> field. The comparison is evaluated via  $\gamma$ -index calculations using the criteria 2 mm/2 %. The  $\gamma$ -index was found to be < 1 except in the build-up region of the depth dose curve, Figure 1. The two microDiamond detectors seem responding differently in the air to water region resulting in  $\gamma > 1$ . Figures show a good agreement between the data measured in the two water tanks.

### Conclusion

It is demonstrated that it is technically possible to replace a commercial non-MR-compatible water tank with an in-house MR-compatible printed water tank. This work also proves that the accuracy of an in-house built water tank is comparable to a prototyped MR-compatible tank. Furthermore, special requests on design and dimensions as well as an ability of repair and future improvements are in

our view an advantage of in-house fabrication of water tanks.

#### PO-0897 Development of an anthropomorphic lung phantom for imaging and radiotherapy

A. WEIDNER<sup>1,2,3</sup>, A. Runz<sup>1,4</sup>, W. Johnen<sup>1,4</sup>, G. Echner<sup>1,4</sup>

<sup>1</sup>DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>University of Heidelberg, Faculty of Medicine, Heidelberg, Germany ; <sup>3</sup>Mannheim University of Applied Sciences, Faculty of Informationtechnology, Mannheim, Germany ; <sup>4</sup>Heidelberg Institute for Radiation Oncology HIRO, National Center for Radiation Research in Oncology NCRO, Heidelberg, Germany

#### Purpose or Objective

Aim of this work is to develop an anthropomorphic, maneuverable and flexible lung phantom which can be used for end-to-end-tests in the radiation therapy. Furthermore, the lung phantom should be durable and the manufacturing process reproducible.

#### Material and Methods

As a basis for the lung phantom, anonymized CT image data of patients were used, which were downloaded from the following website

"<http://www.cancerimagingarchive.net/>". To achieve CT and MRI characteristics of human lung as well as the flexibility, a silicone is used which was optimized by means of its magnitude of elasticity, stability and imaging properties in MRI and CT. First, the DICOM data was opened in Medical Imaging Interaction Toolkit (MITK) and the lung was segmented and transformed into a virtual model. Based on this model the lung phantom could be constructed with the CAD software AutoCAD Inventor and the tool freeform. The internal structure of the lung, thus the bronchia and the alveola, were carried out by a grid structure. First an outer casting mold was constructed and 3D printed using the Objet30 Pro Polyjet 3D printer. To facilitate the internal structure, a core was constructed as an insertion for the outer casting mold. It consists of a grid structure with 5mm by 5mm by 5mm and was 3D printed with a water soluble polyvinyl alcohol (PVA) material by using the Ultimaker 3 Extended 3D printer (Fig. 1 (a) in red). To realize silicone model with an internal grid structure, the core was placed precisely in the outer casting mold and filed out with silicone. After the silicone was hardened, the silicone lung phantom can be removed from the outer casting mold and put into water to dissolve the core composed of water soluble PVA material (Fig. 1 (b)). Using a catheter, a tumor model was inserted into the lung phantom. Afterwards MRI and CT Imaging were performed using a T2 - sequence for the MRI respectively a thorax sequence for the CT imaging (Fig. 2).

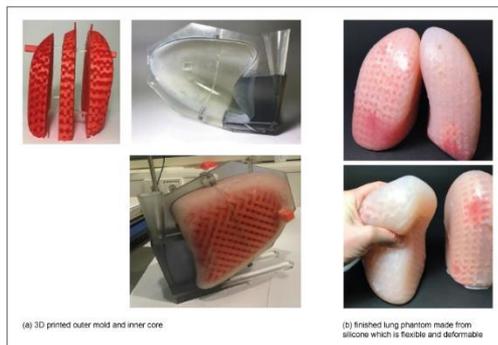

Figure 1: 3D print and finished lung phantom made of silicone

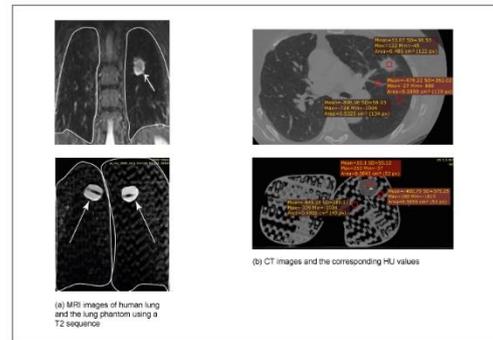

Figure 2: Comparison of human lung and lung phantom with the two imaging methods MRI and CT

#### Results

The HU values of the internal structure of the lung phantom indicate a deviation of 7% compared to the human lung (Fig. 2 (b)). The comparison of the MRI images ((Fig. 2 (a)) shows, that the contrast of the silicone lung phantom is the same as of a human lung.

#### Conclusion

A method to manufacture such an anthropomorphic lung phantom was developed, which allows a reproducible manufacturing process. In this manner the lung model can be used to perform experiments with an implanted tumor model. Due to the reproducibility determined by the steady geometry of the lung model and the consistent manufacturing process, it is possible to achieve constantly good requirements for experiments. Further on, a tumor model in the form of dosimetry gel could be inserted into the lung phantom and normal respiration could be simulated.

#### PO-0898 Advanced Diamond Dosimeter for quality Assurance in Radiotherapy

Casati<sup>5</sup>, S. Calusi<sup>1</sup>, M. Mangoni<sup>1</sup>, S. Pallotta<sup>1</sup>, L. Servoli<sup>2</sup>

<sup>1</sup>University of Florence, Dip Scienze Biomediche Sperimentali e Cliniche, Firenze, Italy ; <sup>2</sup>Istituto Nazionale di Fisica Nucleare, Sezione di Perugia, Perugia, Italy ; <sup>3</sup>University of Florence, Dip Fisica e Astronomia, Firenze, Italy ; <sup>4</sup>Istituto Nazionale di Fisica Nucleare, Sezione di Firenze, Firenze, Italy ; <sup>5</sup>Azienda Ospedaliera Universitaria Careggi, Fisica Medica, Firenze, Italy

#### Purpose or Objective

The aim of this study is to test a novel diamond device, 3DDOSE, to be used for high precision and high reliability machine quality assurance.

#### Material and Methods

3DDOSE is a polycrystalline chemical vapor deposited 3D diamond detector with graphitic in bulk electrodes, fabricated using a pulsed laser technique. Main advantages of such solution are the low voltage working point (tens of V), the all-carbon material presented to the photon beam, the relatively high sensitive volume with respect to the planar electrodes devices ( 0.125 mm<sup>3</sup> for 0.5 mm<sup>2</sup> area) allowing for an higher signal. Also being a volume detector, it should have small dependence from its orientation with respect to the beam. For these reasons it is a good candidate to a dosimeter for beam QA. Tests of the 3DDOSE diamond dosimeter, developed at University of Florence, were performed by means of an Elekta Synergy LINAC at the University Hospital of Florence with conventional 6MV photon beams. The 3DDOSE was placed at the isocenter and inserted in a precisely motorized PMMA phantom at a depth of 10cm with field size variable from 1.6x1.6cm<sup>2</sup> to 10x10cm<sup>2</sup> to be used for relative dose measurements. A very

preliminary dosimetric characterization was performed, the studied parameters were repeatability, response linearity versus absorbed dose and dose rate dependence. In-plane and cross-plane beam profiles were acquired with the setup configuration (SSD=90 cm and depth=10 cm). Beam profiles were acquired scanning the field with 0.1mm step. A comparison with single crystal diamond detector specifically developed for small field (PTW60019) was also performed. Signal ratios were obtained by considering the 3DDOSE charge value for different nominal field size. For each acquisition 100 cGy were delivered at a Dose rate of 430 cGy/min. The 3.2x 3.2 cm<sup>2</sup> FS was used as reference. Values were compared with PTW60019 and a plastic scintillator dosimeter.

**Results**

The 3DDOSE detector was tested for time stability and repeatability showing excellent performance with less than 0.6% signal variation. It also showed a linear response for low dose rates with a deviation from linearity of 2%. As an example in fig.1 the 0.8x0.8 cm<sup>2</sup> in-plane profiles for 3DDOSE, and the single crystal diamond PTW60019 were shown. In table1 the signal ratios as function of the nominal field size are reported and compared with PTW60019 and the plastic scintillator detector EXTRADIN W1 used as reference in the hospital. Even if this study is very preliminary and more works must be done, both on the detector contacts and in testing it for small fields measurements, the obtained results show a good agreement both with the single crystal diamond and the plastic scintillators and are good starting point for developing a new device for QA.

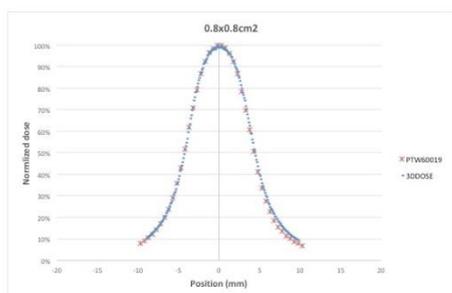

Fig.1 In-plane 0.8 x 0.8 cm<sup>2</sup> 3DDOSE (blue points) and PTW60019 (orange points)

Nominal field size	3DDOSE	PTW60019	W1	deviation 3DDOSE respect to W1	deviation PTW60019 respect to W1
1.6	0.901	0.915	0.910	-1.5%	0.5%
2.4	0.962	0.963	0.966	-0.1%	-0.3%
3.2	1.000	1.000	1.000	0.0%	0.0%
10.4	1.171	1.174	1.174	0.3%	0.0%

Tab.1 3DDOSE, PTW60019 and W1 Signal Ratios normalized to the FS 3.2 x 3.2 cm<sup>2</sup>. Values are compared with single crystal diamond PTW60019 and the plastic scintillator dosimeter Exradin W1

**Conclusion**

3DDOSE demonstrated its potentiality to be used as dosimeter for beam quality assurance, moreover a 3DDose array or a 2D matrix could be realized to speed up QA tests on clinical beams.

**Poster: Physics track: Dose measurement and dose calculation**

**PO-0899 Validation of dose calculation accuracy on daily cone-beam CT scans in the thoracic region**

L. Hoffmann<sup>1</sup>, M. Alber<sup>2</sup>, U.V. Elstrøm<sup>1</sup>, L.P. Kaplan<sup>1</sup>, D.S. Møller<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology-Medical Physics, Aarhus, Denmark ; <sup>2</sup>Heidelberg University Hospital, Department of Radiation Oncology-, Heidelberg, Germany

**Purpose or Objective**

Large anatomical changes may occur during RT of lung cancer. Daily image guidance combined with adaptive RT can correct for these changes. However, the quality of cone-beam CT (CBCT) is often regarded as problematic for dose computation. This study investigates the accuracy of daily dose calculation on CBCT using three different algorithms with the purpose of daily assessment of delivered dose.

**Material and Methods**

Stoichiometric calibration was performed for the CT and CBCT images. Twelve patients were set up using soft tissue matching based on daily CBCTs. All patients had a surveillance CT scan (sCT) at fraction 10. Target and OAR structures were delineated on the sCT and rigidly transferred to CBCT at fraction 10. The treatment plan was recalculated on the sCT and CBCT using the AAA, Acuros (Varian Medical Systems) and Monte Carlo SciMoCa (ScientificRT) algorithms. On CBCT, large regions with HU<950 were seen. Density overrides with HU=900 were performed for these regions followed by recalculation of dose (CBCTlift). Dose to 98% (D<sub>98</sub>), 2% (D<sub>2</sub>) and mean dose to CTV was analyzed in addition to dose to the hottest 1 cm<sup>3</sup> of the spinal cord and oesophagus (D<sub>1cc</sub>). Dose parameters were compared for the algorithms between sCT and CBCT or CBCTlift.

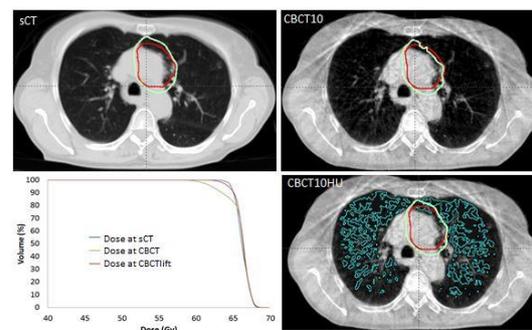

Fig 1. sCT and CBCT for one patient. CTV in red and the 95% isodose level in light green. The segmentation of all lung pixels with HU < 950 is shown in turquoise to the lower right. At sCT no lung pixels with HU < 950 was detected. Dose volume histogram for the CTV is shown to the lower right for dose calculated on sCT (blue), CBCT (green) and CBCT (red) with density override

**Results**

The CTV dose distribution calculated by Acuros is shown for one patient in Fig. 1. A very similar dose distribution is seen, except for underdosage of the CTV on the CBCT in the lung region with low HU density. Density override removes the discrepancy. In Fig. 2, a box plot for CTV dose difference between sCT and CBCT is shown for all 12 patients and all three algorithms. The median difference of the mean dose is <0.5% for all algorithms with a maximum deviation of 1.3%. The dose difference range between the 1<sup>st</sup> and 3<sup>rd</sup> inter quartile ranges (IQR) for D<sub>98</sub> is 6.4%, 5.0% and 2.7% for Acuros, SciMoCa and AAA, respectively. The deviations between sCT and CBCT mainly stem from lung regions with very low HU only in the CBCTs affecting primarily Acuros and SciMoCa. The density override in these regions reduces the IQR to 1.0%, 0.8%

and 0.9%, respectively, showing largest sensitivity to low HU numbers for the Acuros and SciMoCa algorithms. The IQR for  $D_2$  is nearly identical for all algorithms and <0.9% with median values <0.5%. Nearly no difference is seen between CBCT and CBCTlift for these near maximum doses. The median value of dose difference in  $D_{1cc}$  is <0.5% and the IQR is <1.6% for both oesophagus and spinal cord.

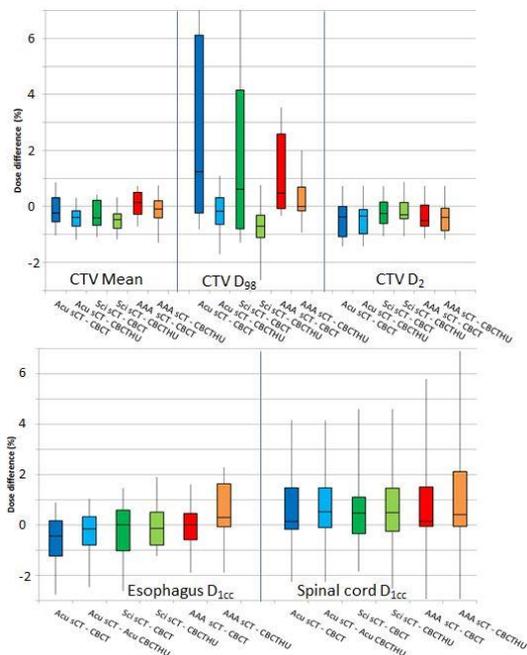

Fig 2: Difference in dose between sCT and CBCT presented as a boxplot. The box shows the range between 1<sup>st</sup> and 3<sup>rd</sup> inter quartile ranges, the vertical line in the middle indicates the median value and the whiskers range from minimum to maximum value.

**Conclusion**

Dose calculation on CBCT images calibrated by a stoichiometric metric and density override of HU values <950 results in clinically acceptable deviations for both target and OARs. A median deviation in target mean dose of <0.5% and IQR for  $D_{98}$  and  $D_2$  <1% was obtained for all algorithms. The lower quality in CBCT has a similar impact for all algorithms if HU override is applied. The CBCT calibration/modification method is readily implemented for automatic decision making for adaptive RT for all three dose computation algorithms

**PO-0900 The magnitude of dose calculation errors as a component of IROC phantom failures**

S. Edward<sup>1</sup>, M. Glenn<sup>1</sup>, P.A. Balter<sup>1</sup>, J.M. Pollard-Larkin<sup>1</sup>, C.B. Peterson<sup>2</sup>, R.M. Howell<sup>1</sup>, D. Followill<sup>1</sup>, S.F. Kry<sup>1</sup>  
<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA ; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Biostatistics, Houston, USA

**Purpose or Objective**

From 2012 to present, 17% of IROC SBRT spine and 15% of IROC moving lung phantom irradiations have failed to meet established acceptability criteria. In this study, we looked at the contribution of dose calculation errors to these failing results.

**Material and Methods**

We evaluated dose calculation errors by comparing the calculation accuracy of institutions' treatment planning systems (TPS) versus IROC-Houston's previously established [add reference] independent dose recalculation system (DRS). Each calculation was compared to the measured dose actually delivered to the phantom; cases where the recalculation was more accurate were interpreted as a deficiency in the

institution's TPS. 188 phantom irradiation plans (128 lung and 60 spine) were recomputed. The spine phantom simulates a highly modulated SBRT case; the lung phantom represents a low-to-none modulation moving target case.

**Results**

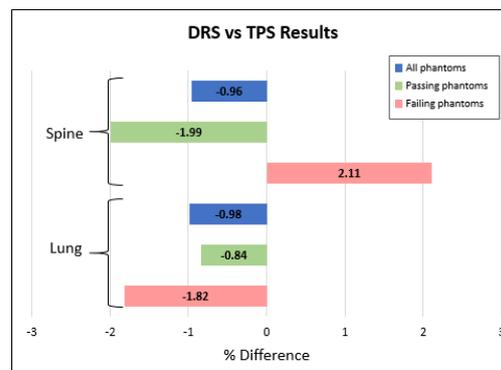

The results of the recalculation comparisons are shown in table 1. Overall, the DRS performed better than the TPS in about 52% of the spine cases. However, in the subset of phantoms that failed IROC criteria, the DRS was more accurate 93% of the time, indicating an error in the institution's dose calculation system. In contrast, the lung phantom DRS recalculations were better only 31% of the time for all cases and 28% of the time in failing lung phantoms, indicating that dose calculation errors were not substantially present.

More accurate calculation	Spine			Lung		
	Pass	Fail	Total	Pass	Fail	Total
DRS	17	14	31	35	5	40
TPS	28	1	29	75	13	88

Table 1. Performance of the dose recalculation system compared with institutions' TPS.

Figure 1 shows the differences between the accuracy of the DRS and TPS. These values represent the average percentage difference over all phantoms within each cohort. A positive difference % value indicates better DRS performance, meaning that the institution TPS is suboptimal. Correspondingly, a negative value indicates better TPS performance (which is the expected outcome if the TPS is well commissioned).

In terms of magnitude of average dose accuracy (instead of frequency), the overall TPS performance surpassed that of the DRS in all cases except the failing spine phantoms which were more than 2% more accurate with the DRS as compared to the institution's calculation. This reiterates the fact that for this phantom, a great majority of the error stems from the institutions' dose calculation systems.

**Conclusion**

For spine phantoms, the institutions' TPS performed better overall, but the DRS was remarkably better among the failing cohort. This indicates substantial room for improvement in many institutions' TPS calculations (likely beam models). In contrast, lung phantom calculations indicated no direct dependence of failure on dose calculation.

**PO-0901 2D solid-state array detectors: a technique for in-vivo dose verification at varying effective area**

G. Biasi<sup>1</sup>, K. Utitsarn<sup>1,2</sup>, M. Petasecca<sup>1</sup>, M. Carolan<sup>3</sup>, V.L. Perevertaylo<sup>4</sup>, W.A. Tomé<sup>3</sup>, M.L.F. Lerch<sup>1</sup>, T. Kron<sup>6,7</sup>, A.B. Rosenfeld<sup>1</sup>  
<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia ; <sup>2</sup>Lopburi Cancer Hospital, Department of Medical Services, Lopburi, Thailand ; <sup>3</sup>Wollongong Hospital, Illawarra Cancer Care Centre, Wollongong, Australia ; <sup>4</sup>SPA-BIT, n/a, Kiev,

Ukraine ; <sup>5</sup>Albert Einstein College of Medicine, Department of Radiation Oncology, New York, USA ; <sup>6</sup>Peter MacCallum Cancer Centre, Department of Physical Sciences, Melbourne, Australia ; <sup>7</sup>University of Melbourne, Sir Peter MacCallum Cancer Institute, Melbourne, Australia

### Purpose or Objective

In the present study, a novel technique for using a high-resolution (2 mm) 2D solid-state detector prototype 'MP512' in transmission mode (TM) is introduced. The technique aimed at using measurements in TM to calculate absolute dose at  $d_{max}$ , in a homogenous phantom of solid water, in effective area ( $A_{eff}$ ) which could be varied in size to best suit that of the monitored target.

### Material and Methods

The MP512 has 512 diode-sensitive volumes, 0.5 mm × 0.5 mm each, uniformly distributed with a pitch of 2 mm over a square area of 52 mm side. Measurements in TM were performed with the MP512 at a surface-to-detector distance (SDD) variable in the range from 0.3 cm to 24 cm and in dose mode (DM) at  $d_{max}$  in a homogenous phantom of solid water (Figure 1). We considered jaw-defined static square fields of 2 cm, 3 cm, 5 cm, 8 cm and 10 cm side produced by a 6 MV flattened beam delivered by a Varian Clinac® iX linear accelerator equipped with a Millennium 120-multi-leaf collimator (MLC). Measurements were used to derive a relationship between the response in DM and the response in TM as a function of SDD and field size. To verify the relationship, we calculated from measurements in TM at 4 cm and 24 cm SDD the response in DM in square fields of 1 cm and 4 cm side and in clinical step-and-shoot IMRT fields. For all IMRT plans, we used the Pinnacle's adaptive convolution-superposition (CS) algorithm implemented into the Pinnacle<sup>3</sup> treatment planning system (TPS) version 14 (Philips Medical Systems, Eindhoven, The Netherlands). Dose calculations were performed at  $d_{max}$  with a 2 mm grid. A gamma index analysis was used to cross-check our dose calculations with TPS calculations and with measurement in DM with the MP512 itself, with Gafchromic™ EBT3 films and with a Farmer ionization chamber.

### Results

Calculations in square fields of 1 cm and 4 cm side agreed with measured values within ±2%. Calculations in IMRT fields (Table 1) had, using acceptance criteria of 3%/3 mm, 2%/2 mm and 1%/1 mm respectively, gamma passing rates (%GP) greater than 96.89%, 90.50%, 62.20% at SDD 4 cm and greater than 97.22%, 93.80%, 59.00% at SDD 24 cm. When considering a 1%/1 mm acceptance criterion, lower %GP between our dose calculations and TPS calculations (Table 1) could be explained by factors such as sub-millimetre misalignments in detector positioning and dose averaging in TPS calculations over a 2 mm grid. This result emphasizes the importance of developing high-spatial resolution dosimetry detectors.

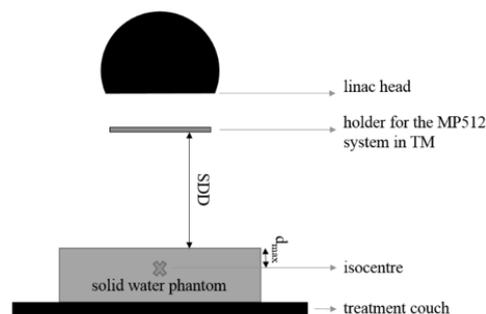

Figure 1. Use of the MP512 system in TM (not to scale).

Table 1. Gamma evaluation for IMRT plan dose calculation at SDD of 4 cm and 24 cm.

SDD [cm]	acceptance criteria											
	3%/3 mm				2%/2 mm				1%/1 mm			
	TPS	MP512, calc. vs EBT3	MP512, calc. vs MP512, meas.	MP512, calc. vs TPS	TPS	MP512, calc. vs EBT3	MP512, calc. vs MP512, meas.	MP512, calc. vs TPS	TPS	MP512, calc. vs EBT3	MP512, calc. vs MP512, meas.	MP512, calc. vs TPS
4	98.14%	96.89%	99.79%	90.50%	92.00%	98.59%	62.20%	69.40%	99.40%			
24	97.22%	97.53%	99.69%	93.80%	93.80%	97.69%	59.00%	71.00%	99.00%			

### Conclusion

We derived a relationship between the response of the MP512 in TM and in DM at  $d_{max}$ , as a function of SDD and field size. As at a different SDD corresponds a different  $A_{eff}$  at  $d_{max}$ , using this relationship measurement in TM could be performed at the SSD producing the  $A_{eff}$  which best fits the size of the monitored target. This study represented also a first step in the development of a real-time high-spatial resolution 3D dose reconstruction technique based on TM measurements with the MP512 prototype.

### PO-0902 The ACDS approach to measuring dose to bone and comparing to TPS reported dose to water and medium

J. Lye<sup>1</sup>, M. Shaw<sup>1</sup>, J. Lehmann<sup>2</sup>, A. Alves<sup>1</sup>, R. Brown<sup>1</sup>, C. Davey<sup>1</sup>, F. Kadeer<sup>1</sup>, J. Kenny<sup>1</sup>, J. Supple<sup>1</sup>

<sup>1</sup>Australian Radiation Protection and Nuclear Safety Agency, Australian Clinical Dosimetry Service, Melbourne- Victoria, Australia ; <sup>2</sup>Calvary Mater Hospital, Physics, Newcastle, Australia

### Purpose or Objective

In clinical dosimetry there is a difference in planned dose to a patient when dose to medium or dose to water is used. This is an issue that is particularly notable when looking at dose to bone treatments such as SABR/SBRT spine (4-12% differences depending on bone type and the definition of dose to water used by a particular TPS). It should also be considered when looking at the smaller (~1%) yet more widespread effect of using either dose to water or dose to muscle/adipose for soft tissue plans. The purpose of this work is to determine a consistent definition of dose and to apply this definition to report the differences between measurements in bone and calculated dose from TPS algorithms.

### Material and Methods

There are three commonly used definitions of dose:

Dose to medium as calculated by Monte Carlo algorithms (dose to medium-in-medium,  $D_{m,m}$ );

Dose to water with variable electron density as calculated by "conventional TPSs" (dose to water-in-water,  $D_{w,w}$ ); and

Dose to water converted from dose to medium using stopping powers: approximates dose to the water material of a cell in an otherwise non-water medium (dose to water-in-medium,  $D_{w,m}$ ).

Of importance is that the two different definitions of dose to water are not equivalent. Our main aim is for consistent definitions, and to use only one definition of absorbed dose to water. The ACDS defines absorbed dose as the dose to medium in a medium approximated by the average J/kg across a voxel (around 1-2mm<sup>3</sup>). Dose to water is then a particular case of this definition where the medium is water. Dose to water is defined as  $D_{w,w}$ . This gives a consistent definition of dose in TPS calculations and reference dosimetry and is closest to the previously used definitions of dose which clinical data is based on.

### Results

The ACDS measures dose to bone in the SABR spine audit with EBT3 film and microdiamond measurements in CIRS cortical and trabecular bone. These measurements are performed with a detector measuring in bone but

calibrated in dose to water in a water phantom. Monte Carlo modelling is required to convert the measurements to either dose to water ( $D_{w,w}$ ) or dose to medium ( $D_{m,m}$ ). The EGSnrc code was used to correct the raw measurements with a microdiamond in trabecular bone as shown in Figure 1. Before correction the measurements were higher than planned doses for both  $D_{w,w}$  and  $D_{m,m}$  with averages of -2.1% and -4.1% respectively. After correction the averages are -0.8% and +0.2% respectively.

**Figure 1** Summary of dose differences ((planned-measured)/measured) from spine point dose in trabecular bone.

For measurements in solid water, an algorithm dependent correction for dose to tissue is planned for TPS reporting dose to medium.

#### Conclusion

For measurements in bone, the ACDS applies Monte Carlo corrections to report  $D_{w,w}$  and  $D_{m,m}$  with a detector calibrated with dose to water. The ACDS does not calculate and report on Dose to water in medium, as determined by applying stopping power ratios to dose to medium calculations.

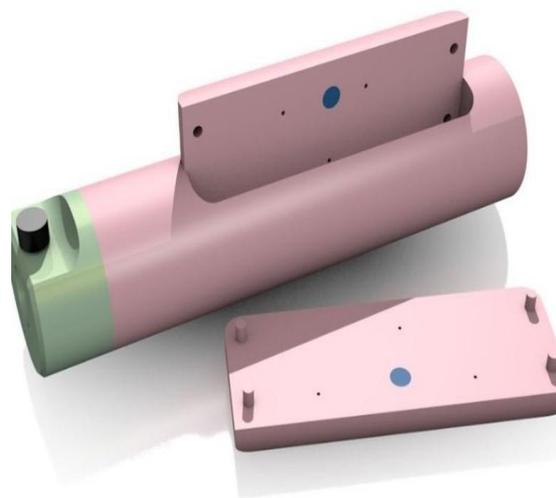

#### PO-0903 AcurosXB dose verification of ultra-small lung lesions with EBT-XD film in a heterogeneous phantom

M. Öllers<sup>1</sup>, A. Swinnen<sup>1</sup>, F. Verhaegen<sup>1</sup>

<sup>1</sup>Maastric Clinic, Medical Physics, Maastricht, The Netherlands

#### Purpose or Objective

Modern type 'c' dose calculation algorithms can predict dose for stereotactic treated lung tumors larger than 4cm<sup>3</sup> with an uncertainty up to 5% (Fogliata et al., 2017). However, the trend to treat tumors with volumes below 1cm<sup>3</sup> with hypofractionation poses a serious challenge even for type 'c' algorithms. Common recommendations for QA and dose verification in SBRT treatments are to use phantoms that are homogeneous: either water-equivalent (e.g. PTW RW3/Octavius, SunNuclear Delta4) or lung-equivalent materials (e.g. CIRS thorax). The CIRS4D thorax phantom provides a lung-equivalent film rod containing a water-equivalent spherical target (figure 1) that provides a more realistic verification set-up. Our aim was to evaluate the accuracy of the AcurosXB dose algorithm with EBT-XD film in a homogeneous and heterogeneous phantom for targets below 1cm<sup>3</sup>

#### Material and Methods

The PTW RW3 and CIRS4D thorax phantom were used to verify the dose distribution of 10 lung cancer patients with GTV volumes below 1cm<sup>3</sup>. EBT-XD film measurements were performed in the RW3 slab phantom at 5 cm depth. Treatment plan verification was performed in the CIRS4D phantom in a film rod containing a 0.1 cm<sup>3</sup> water-equivalent target. All measurements were performed on a 6MV Varian Truebeam STx linac for single fraction doses of 15 or 18Gy. Treatment plans were calculated in Eclipse 15.5 with the AcurosXB 15.5.11 dose algorithm. Films were analyzed using an EPSON 11000 XL film scanner and FilmQA Pro software (Ashland, USA), following a dedicated protocol (Lewis et al., 2012; Lewis et al. 2016).

#### Results

The average GTV volume for the 10 patients was 0.6±0.5 cm<sup>3</sup>. Regarding the homogeneous RW3 verifications, the average difference between maximum dose on film and maximum dose on the corresponding dose plane in the TPS was 2.6±1.6%. Recalculating the patient plans in the CIRS4D phantom in lung with an artificial lung tumor matching the patient tumor size yields differences between maximum dose on film and maximum dose on the corresponding dose plane in Eclipse up to 16.5% with an average overdose of 10.8±4.7%. In general, larger differences were found between measurement and predicted dose by the AcurosXB algorithm as tumor size decreased.

#### Conclusion

Dose verification of small lung tumors should be performed in a heterogeneous phantom incorporating a water-equivalent target that is of a comparable size to the original tumor to be treated. Current verification methods in homogeneous phantoms do not seem suitable for these challenging stereotactic lung treatments. The AcurosXB dose calculation consistently underestimates dose in (very) small lung tumors.

#### PO-0904 Benchmarking of a module for Monte Carlo simulation of proton transport in the PENELPE code

N. Verbeek<sup>1,2,3</sup>, S. Smyczek<sup>1,3,4</sup>, J. Wulff<sup>1,3</sup>, C. Bäumer<sup>1,3,5</sup>, B. Timmermann<sup>1,3,5,6</sup>, L. Brualla<sup>1,2,3</sup>  
<sup>1</sup>University Hospital Essen, West German Proton Therapy Centre Essen WPE, Essen, Germany; <sup>2</sup>University of Duisburg-Essen, Faculty of Medicine, Essen, Germany; <sup>3</sup>University Hospital Essen, West German Cancer Center WTZ, Essen, Germany; <sup>4</sup>Heinrich Heine University

Düsseldorf HHU, Physics, Medical Physics, Germany ;  
<sup>5</sup>German Cancer Consortium DKTK, Radiation Oncology and Imaging, Heidelberg, Germany ; <sup>6</sup>University Hospital Essen, Department of Particle Therapy, Essen, Germany

### Purpose or Objective

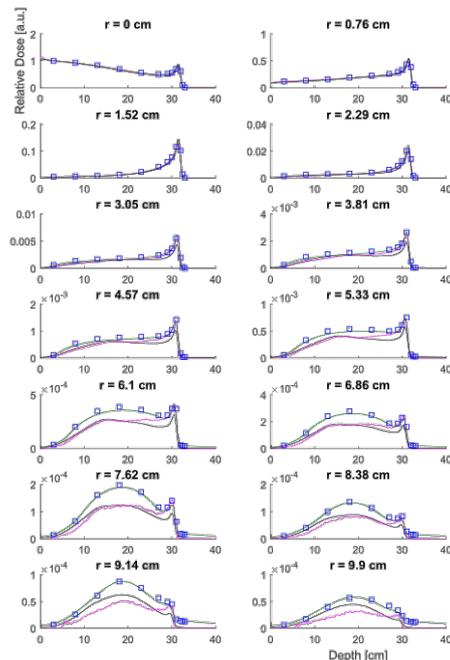

PENH is a recently coded module for simulation of proton transport in conjunction with the Monte Carlo (MC) code PENELOPE [1]. The purpose of this work is to benchmark this module. PENH uses calculated differential cross sections for proton elastic collisions that include electron screening effects as well as nuclear structure effects. Proton-induced nuclear reactions are simulated from information in the ENDF-6 database [2], or from alternative nuclear databases in ENDF format (e.g., TENDL-2017).

### Material and Methods

Results from simulations with PENH are compared with simulation data obtained from TOPAS MC v3.1p2 [3] and RayStation 6 MC [4]. In all simulations a measurement-derived Fermi-Eyges [5] beam model, with nominal energy 225 MeV, was used. The beam model reproduced the phase-space of an IBA pencil beam (PB) scanning dedicated nozzle. The simulated geometry consisted of a water phantom with a 50 cm-thick layer of air upstream of it. Simulated dose results were compared to experimental data obtained with the MatriXX PT 2D detector (IBA Dosimetry) [6].

### Results

Depth dose profiles taken at varying radius from the central axis are shown in figure 1. The radial distance from the central axis at which the profiles are plotted appears above of each subfigure. All plots shown are normalized to the central axis dose at a depth of 3 cm. Excellent agreement is observed among the evaluated codes with the experimental data up to 3 cm from the central axis, that is, at the halo region where the dose drops three orders of magnitude from the maximum dose. Results from RayStation MC were smoothed with a moving average filter. Results from TOPAS MC coincide with experimental data up to six orders of magnitude below the maximum. Results from both RayStation and PENH qualitatively reproduce the experimental behavior in the low dose regions from three to six orders of magnitude below the maximum.

**Figure 1.** Dose Deposition of a 225 MeV Proton PB in a Water Phantom. Comparison between Measurement (squares), TOPAS MC (green line), RayStation MC (magenta) and PENH (black). The average standard statistical uncertainty of the dose distribution taking into account those bins that score more than 50% of the maximum dose is 0.02%, <0.1% and <0.02% for PENH/PENELOPE, RayStation and TOPAS MC, respectively. The combined uncertainty for the experimental data is 2.5%. In all cases uncertainty bars are smaller than the symbols used for experimental data.

### Conclusion

The outstanding agreement between TOPAS MC and experimental data is partly due to the fact that TOPAS MC takes into account neutron transport and PENH does not. However, the differences in the results produced by both codes cannot be fully ascribed to neutron simulation. They arise from the different physics models and tracking schemes. We conclude that the elaborate physics modeling of the PENELOPE/PENH code yields results consistent with measurements.

**PO-0905 Validation of a 4D Monte Carlo optimization and planning feature for CyberKnife lung treatment**  
 S. Trivellato<sup>1,2</sup>, E. Rondi<sup>1</sup>, S. Vigorito<sup>1</sup>, E. Miglietta<sup>3</sup>, F. Castellini<sup>3</sup>, G. Piperno<sup>3</sup>, A. Ferrari<sup>3</sup>, B.A. Jereczek-Fossa<sup>3,4</sup>, F. Cattani<sup>1</sup>

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Unit of Medical Physics, Milan, Italy ; <sup>2</sup>University of Milan, Department of Physics, Milan, Italy ; <sup>3</sup>IEO- European Institute of Oncology IRCCS, Division of Radiation Oncology, Milan, Italy ; <sup>4</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

### Purpose or Objective

In thorax treatments, the management of respiratory motion is mandatory. An available treatment planning

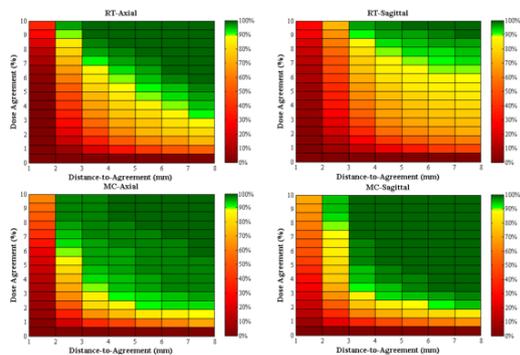

system for the CyberKnife robotic radiosurgery system is offering a 4D treatment planning and optimization feature to take into account tissue motion recorded in a 4D computed tomography (4DCT). The aim of the study is to experimentally validate the 4D Monte Carlo (MC) dose calculation before its use in the clinical routine of not visible lung lesions when tracking is not feasible.

#### Material and Methods

A thorax-moving phantom was used to simulate 3 motion sets amounting to 9 patterns. Two of them were defined with a lesion velocity of 1 mm/s and 2.5 mm/s respectively. The last set was defined to simulate 3 patients' extracting surrogate motions from RPM files (Real-Time Position Management, Varian Medical Systems) while the superior-inferior lesion displacement was measured as the distance between the barycentre of the CTV in the full-inhale and full-exhale phases. The phantom was scanned for a static benchmark (SB) in absence of motion. An 8-respiratory phase binning was performed and images were imported in the Precision® Treatment Planning System (Accuray Inc.): 4D plans were optimized and calculated for all different motion patterns (MP Plans) with an 80% prescription to the PTV. All dose distributions were calculated with the Ray Tracing (RT) algorithm and then recalculated by a MC algorithm with a 1% uncertainty. Plans were delivered to the phantom with axial and sagittal films positioned in the lung insert. A local  $\gamma$ -analysis was performed with the FilmQA Pro software (Ashland) to quantitatively evaluate the agreement between the calculated and measured doses. Treatment plans were considered acceptable if the passing rate ( $P_\gamma$ ) was greater than or equal to 90%. Results for the 3 set of motions have been compared to evaluate the 4D module performances.

#### Results

$\gamma$ -analysis results for the SB plans are reported in Fig. 1. An acceptable  $P_\gamma$  is reached in axial and sagittal planes for the RT plan when the  $\gamma$ -criteria are 7%/3 mm and 8.5%/3 mm, respectively. The MC calculation showed an acceptable  $P_\gamma$  for 3%/3 mm  $\gamma$ -criteria in both directions. On the other hand, MP  $\gamma$ -analysis results are reported in Table 1 in terms of axial, sagittal and overall mean  $P_\gamma$ (3%/3 mm). The overall mean passing rate for the 3 motion sets are 85.3%, 59.9% and 66.2% for RT Plans; 92.7%, 95.9% and 84.1% for MC Plans.

**Figure 1** Graphical representation of the passing rate in the axial and sagittal planes for the RT plan (top) and the MC plan (bottom). The color bar on the right associates the used colors with the percentage of gamma analysis passing pixels.

		RT	MC
Set 1	Axial	92.4%	93.9%
	Sagittal	78.1%	91.4%
	<b>Mean</b>	<b>85.3%</b>	<b>92.7%</b>
Set 2	Axial	68.4%	95.2%
	Sagittal	51.3%	96.5%
	<b>Mean</b>	<b>59.9%</b>	<b>95.9%</b>
Set 3	Axial	70.0%	83.3%
	Sagittal	62.3%	84.9%
	<b>Mean</b>	<b>66.2%</b>	<b>84.1%</b>

**Table 1** Percentage of pixels passing the 3%/3 mm criteria for various motion sets for RT and MC dose calculation.

#### Conclusion

The static benchmark has allowed a definition of minimum 3%/3 mm  $\gamma$ -criteria for following measurements because of the used experimental setup. The 4D feature allows obtaining an acceptable agreement between measured and calculated dose distributions in lung treatments when a MC calculation is performed. Future studies will follow to define a breathing-irregularity cut-off guaranteeing an acceptable passing rate for the third set. The RT calculation resulted in not acceptable accordance with measured dose distributions.

#### PO-0906 Perturbation techniques for optimizing IAEA phase spaces for different medical linacs

J.C. Martins<sup>1</sup>, R. Saxena<sup>1</sup>, S. Neppel<sup>2</sup>, A. Alhazmi<sup>1</sup>, M. Reiner<sup>2</sup>, C. Belka<sup>2</sup>, K. Parodi<sup>1</sup>

<sup>1</sup>Ludwig-Maximilians-Universität München, Chair of Experimental Physics - Medical Physics, Garching b. München, Germany ; <sup>2</sup>LMU Munich, Department of Radiation Oncology - University Hospital, München, Germany

#### Purpose or Objective

Monte Carlo techniques are very accurate for simulating dose distributions in radiotherapy, provided the model is based on detailed geometric information of the linac. Alternatively, validated phase space (PhSp) files (e.g. provided by IAEA) can be used, however these are available for a limited number of linac models. This work proposes a methodology to optimize an existing IAEA PhSp to produce fine-tuned machine-specific PhSp for an Elekta Synergy linac, by tuning the energy and momentum of the particles inside the PhSp.

#### Material and Methods

An Elekta Synergy linac coupled with an Agility collimator was modeled using Geant4. Due to unavailability of geometric information of the linac's head, the IAEA PhSp for Elekta Precise was used as surrogate. Percentage Depth Dose (PDD) and lateral profiles, for different field sizes and 6 MeV photon beams, were measured and simulated under the same conditions. The discrepancies between measurements and simulations were quantified in term of cost values. Initially, the information inside the PhSp was perturbed randomly, aiming at finding correlations with the simulated dose profiles. Subsequent perturbations were performed following identified correlations, in the direction of decreasing cost values. To

optimize the iterative process, the PhSp was cropped into smaller sections, depending on the field size and simulation configuration. The differences in the simulated results using cropped PhSp, in comparison to the corresponding results using the full PhSp, are under 3% (Figure 1), which assures no relevant information was disregarded. Small energy perturbations were applied to cropped PhSp and PDD were simulated. This process was repeated until a minimum cost value was reached and an optimal energy value was found. Next, the momenta of the particles in all three directions were perturbed, following identified constraints and statistical correlations between particle's momentum and lateral profiles. Two distinct optimal perturbation factors were found for particles' momentum in crossline and inline directions.

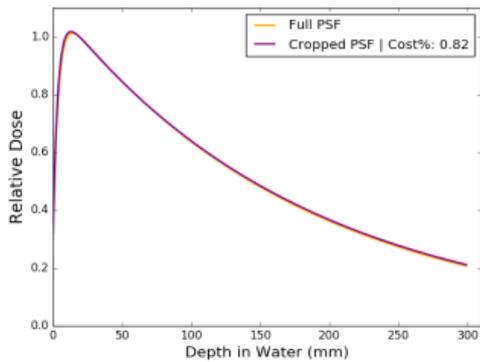

Figure 1 - Comparison of the PDD profiles simulated using the full PhSp (in orange) and the cropped PhSp (in purple), for the 10x10 cm<sup>2</sup> field. For this simulation, the cropping section corresponds to a 20 mm disc, meaning that only the particles positioned inside a 20 mm disc centered in the center of the full PhSp are included in the cropped PhSp. The cost value between both curves is 0.82%. If the cropping is performed correctly, the simulated curves performed with full and cropped PhSp should be similar, yielding a small cost value.

## Results

For validation, the optimal perturbation factors were finally applied to the entire PhSp for different field sizes. For the considered linac, an energy perturbation of 0.32 MeV results in PDD cost values under 1.5% for all fields considered, and improves cost values for lateral profiles in the inline direction (Figure 2). Perturbation factors of 0.61% and 0.05%, when applied separately to the momenta of particles in the crossline and inline direction respectively, yield cost values below 3%. Several approaches to merge both factors and investigate the method with different beam energies are under evaluation.

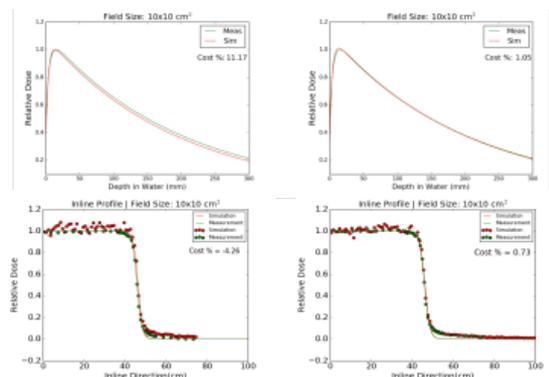

Figure 2 – Percentage Depth Dose (PDD) and Inline profile for a 10x10 cm<sup>2</sup> field (A) before energy optimization and (B) after energy optimization. A better agreement between measured and simulated profiles can be qualitatively seen after energy optimization. Quantitatively, cost values decreased from 11.17 to 1.05 % for PDD and from 4.26% to 0.73% for inline profile.

## Conclusion

A methodology for optimization of an existing PhSp was developed, enabling generation of machine-specific PhSp

based on validated IAEA PhSp. It offers an alternative when neither geometric details nor validated PhSp are available for a specific machine.

**PO-0907 Gafchromic EBT3 film for absolute dosimetry in proton therapy based on averaging of beam quality**  
 A. Resch<sup>1</sup>, P. Heyes<sup>1</sup>, H. Fuchs<sup>1</sup>, D. Georg<sup>1</sup>, P. Hugo<sup>2</sup>  
<sup>1</sup>Medizinische Universität Wien, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria ; <sup>2</sup>MedAustron Ion Therapy Centre, Medical Physics, Wiener Neustadt, Austria

## Purpose or Objective

Gafchromic EBT3 films are a relevant dosimeter for proton therapy due to their high spatial resolution and near water equivalence. Currently their energy dependent relative effectiveness (RE) limits their usage for absolute dosimetry in particle therapy to the beam quality (e.g. the average linear energy transfer (LET)) at calibration. Previously, beam quality correction factors have been proposed based on a fluence averaging over the mixed charged particle field. In this study we investigate the RE for varying energy distributions to provide experimental evidence for a suitable averaging method.

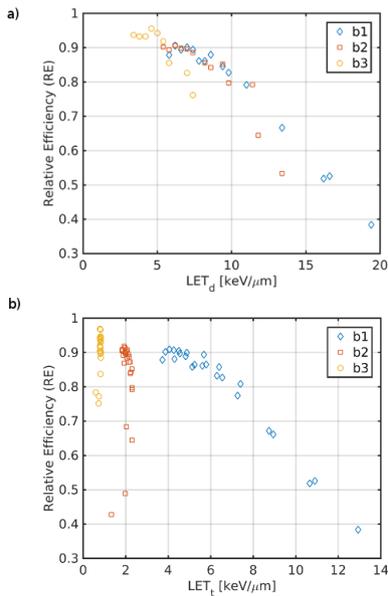

## Material and Methods

The RE as a function of depth was experimentally characterized for two beam types, mono-energetic (initial beam energy) and spread-out Bragg peaks (SOBPs). The initial beam energies ( $E_0$ ) of three single-energy fields were 62, 148 and 252 MeV. Three constant-dose SOBPs ( $E_0$  ranging from 62 to 68 MeV) were created with different energy distributions by superimposing a fraction of low LET protons ( $E_0 = 252$  MeV). Beam 1 (b1) consisted only of the SOBP. In beam 2 (b2) approximately 50% of the initial fluence and in beam 3 (b3) approximately 50% of the dose was contributed by the low LET beam. To ensure lateral charged particle equilibrium a field size of 7x7cm<sup>2</sup> was used.

EBT3 films were calibrated in a low LET region, in the entrance plateau region of a single-energy 179.2 MeV proton beam, for several dose levels. Gate/Geant4 Monte Carlo (MC) simulations employing a validated beam model were used to calculate the absorbed dose to water as well as dose- (LET<sub>d</sub>) and track-average LET (LET<sub>t</sub>). Dose simulated with MC was normalized to measurements with a plane parallel ionization chamber in the SOBP. The RE of the EBT3 response was calculated as the ratio of the film dose relative to MC simulated dose.

## Results

The RE was found to be below unity except for the 62 MeV beam at around LET<sub>d</sub> = 6 keV/μm (corresponding to points shortly before the Bragg peak). RE as a function of LET<sub>d</sub> of all beams was similar up to approximately 5 keV/μm. In Fig.1 the measured RE is shown as a function of LET<sub>d</sub> and LET<sub>t</sub> for the 3 SOBP beams. The RE of b1 to b3 was comparable but differed at high LET<sub>d</sub>. The same experimental RE (but with smaller LET binning) expressed as a function of LET<sub>t</sub> revealed the limitations of the concept of fluence averaging, as there was no one-to-one correlation of LET<sub>t</sub> and RE for beams b2 and b3. The LET<sub>t</sub> for b2 and b3 hardly increased over depth and hence could not reflect the decreasing RE over depth.

## Conclusion

Our experiments indicate that a fluence based beam quality correction function for EBT3 films may be limited in its applications for intensity modulated proton therapy. At high LET there was also a tendency of the RE-LET<sub>d</sub> relation to differ for different initial beam energies and fluences. A single parameter may not be sufficient to represent beam quality with respect to film response. Current work in progress is to develop a formalism for RE of EBT3 film response.

## PO-0908 Determination of surface dose in pencil beam scanning proton therapy

A. Kern<sup>1,2,3</sup>, C. Bäumer<sup>1,3,4</sup>, K. Kröninger<sup>2</sup>, L. Mertens<sup>2</sup>, B. Timmermann<sup>1,3,4,5</sup>, J. Walbersloh<sup>6</sup>, J. Wulff<sup>1,3</sup>

<sup>1</sup>University Hospital Essen, West German Proton Therapy Centre Essen WPE, Essen, Germany ; <sup>2</sup>Technical University Dortmund, Experimental Physics IV, Dortmund, Germany ; <sup>3</sup>University Hospital Essen, West German Cancer Center WTZ, Essen, Germany ; <sup>4</sup>German Cancer Consortium DKTK, Radiation Oncology and Imaging, Essen, Germany ; <sup>5</sup>University Hospital Essen, Department of Particle Therapy, Essen, Germany ; <sup>6</sup>Materialprüfungsamt NRW, Strahlenschutz, Dortmund, Germany

## Purpose or Objective

Quantification of surface dose within the first few hundred μm is challenging, albeit of large interest for proton therapy to study dose effects in the skin. Treatment planning systems are typically limited in their ability to calculate skin dose accurately. Experimental determination on the other hand is affected by the detectors' volume and in case of ionization chambers by the entrance wall. Aim of this study is the estimation of the absorbed dose at and around depth of 70 μm according to ICRU [1] with different dosimetric approaches for surface dose in proton pencil beam scanning.

## Material and Methods

Four different detectors were tested for determination of surface dose in water: EBT3 GAFCHROMIC®, LiF:Mg,Ti TLDs, IBA PPC05 plane-parallel and PTW 23391 extrapolation chamber. The irradiation setup consisted of a monoenergetic extended proton pencil beam with 100 MeV, 150 MeV and 226.7 MeV. Radiochromic films are used within a vertical stack and in wedge geometry and analyzed/calibrated with FilmQA Pro™ (triple channel dosimetry). The extrapolation chamber PTW 23391 was

used as a conventional ionization chamber with a fixed electrode gap of 2 mm. Three Kapton® entrance windows with the thicknesses of 25 μm, 50 μm and 75 μm were employed. TLDs provided as powder pressed onto a piece of aluminium. TOPAS [2] in version 3.1.2 was used to model an IBA PBS Nozzle and score dose to water in voxels of 5x5x5 mm<sup>3</sup> within a cubic phantom.

## Results

Both figures show the relative dose, normalized to a reference depth of 3 cm for the various detectors as a function of depth for 150 MeV. The results in figure 1 show the proton build-up effect. The two ionization chambers, the TLDs and the combination of film and wedge have good agreement with each other, whereas TOPAS and the film stack can deviate from these by up to 1 %. The errors of the mean value are within 1-2 ‰, except for the TLDs, which show larger deviations of up to 2.3 ‰. From the extrapolation chamber and TLD measurements and TOPAS calculations respectively, the skin dose at 70 μm amounted approx. 87 % of the dose at reference depth of 3 cm, see figure 2.

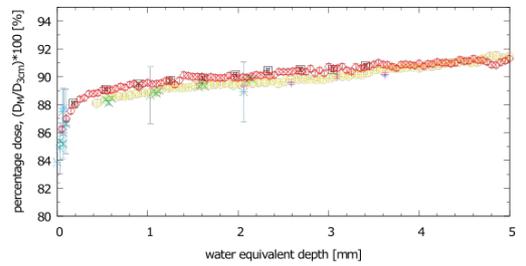

Figure 1: Percentage dose within the first 5 mm of water equivalent depth for 150 MeV

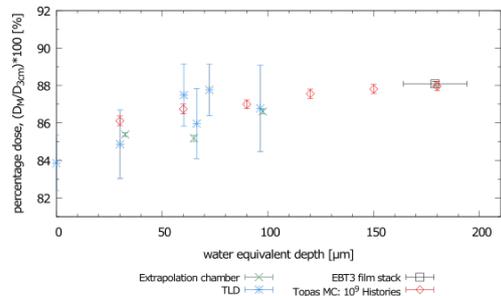

Figure 2: Percentage dose within the first 200 μm of water equivalent depth for 150 MeV

## Conclusion

All measurement methods show a good agreement within the first 5 mm. With the extrapolation chamber, the TLDs and the EBT3 film, data in the micrometer range can be measured. The extrapolation chamber shows the smallest uncertainties and the largest dynamic range. The TLDs have the largest uncertainty. TOPAS MC reproduces the experimental results. With regard to the skin dose, it can be noted that at 70 μm it amounts to approx. 87 % of the total dose from the reference depth in 3 cm. Furthermore, a dose increase of 4 % can be observed in the first 200 μm.

## PO-0909 Development and experimental validation of a user code for time-resolved Monte Carlo simulations

P. Sibolt<sup>1</sup>, C.E. Andersen<sup>2</sup>, C.F. Behrens<sup>1</sup>, R.O. Cronholm<sup>3</sup>, E. Heath<sup>4</sup>

<sup>1</sup>Herlev & Gentofte Hospital, Radiotherapy Research Unit- Department of Oncology, Herlev, Denmark ;

<sup>2</sup>Technical University of Denmark, Center for Nuclear Technologies, Roskilde, Denmark ; <sup>3</sup>Skåne University Hospital, Department of Radiation Physics, Lund, Sweden ; <sup>4</sup>Carleton University, Carleton Laboratory for Radiotherapy Physics, Ottawa, Canada

#### Purpose or Objective

Due to intra-fractional motion in the abdominal and thoracic region of cancer patients, there is a need for solutions to accurately calculate external x-ray beam radiotherapy dose in four dimensions with synchronization between the dynamic beam configuration and deforming anatomy. In order to facilitate determination of time-dependent accuracy of advanced radiotherapy techniques, there is furthermore a need for the advanced dose calculation solution to be time-resolved. The aim of this project was to develop and experimentally validate a user code for time-resolved Monte Carlo (MC) calculations of dose delivered to a dynamic thorax phantom.

#### Material and Methods

Time-resolved Monte Carlo simulations were based on the previously developed 4DdefDOSXYZnrc/EGSnrc MC user code, which scores dose in a time-varying deformable geometry. To improve efficiency of the simulations, photon cross-section enhancement (XCSE) was implemented in a region surrounding the voxel in which dose was scored. One three-dimensional conformal radiotherapy (3DCRT) plan and one volumetric modulated arc therapy (VMAT) plan (both 6 MV) were optimized on and delivered to a set of static and dynamic configurations of an in-house developed dynamic thorax phantom. Time-resolved MC calculations using linac logfile based input files were synchronized with and compared to measurements using a fiber-coupled organic plastic scintillator detector (PSD). Measurements and calculations were conducted in the center of a spherical tumor (PMMA) embedded in a motion controlled cylindrical lung insert (balsa wood), laterally positioned in the body (PMMA) of the thorax phantom.

#### Results

Using the time-resolved MC code with a XCSE factor of 8 and binning the data to a resolution of 100 ms, a statistical uncertainty of approximately 2% was achievable. Comparison with PSD measurements revealed cases with disagreements in low-dose regions and narrow dose peaks, which are attributed to uncertainty in the position of the PSD and currently under investigation. However, a majority of the results indicated good agreement; first of all in the accumulated dose (in most cases within 2-3%) and secondly in the dose as a function of time as indicated by agreements in temporally resolved dose gradients. This applies for both the 3DCRT and VMAT techniques applied to the set of phantom configurations investigated.

#### Conclusion

A novel user code for time-resolved MC calculations of dose delivered to a deforming anatomy was developed and initial validation included indications of good temporal agreements in detecting dose gradients compared to PSD dosimetry in a dynamic thorax phantom. The solution has high potential in assisting in the detection of underlying causes to deviations detected in the accumulated dose as delivered by advanced motion managed radiotherapy techniques.

#### PO-0910 Lumbosacral proton therapy treatment of a patient with large spine metal implants

C. Peucelle<sup>1</sup>, A. Gérard<sup>1</sup>, D. Maneval<sup>1</sup>, M. Vidal<sup>1</sup>, A. Falk<sup>1</sup>, J. Héroult<sup>1</sup>

<sup>1</sup>Centre Antoine Lacassagne, Radiotherapy, Nice, France

#### Purpose or Objective

Metal implants complicate radiotherapy delivery by creating artifacts in CT images. Artifacts, as well as CT-number inaccuracy of very high-density material, may affect range calculation in the TPS for proton therapy and

result in major uncertainties in the delivered dose. Therefore, presence of metal implants is often a determining criterion in deciding to contraindicate proton therapy. This work reports the implemented strategy at the Mediterranean Institute for Proton Therapy (Nice, France) that allowed a patient with lumbosacral chordoma to benefit from proton therapy with the Proteus@ONE IBA system despite large metallic spine implants.

#### Material and Methods

The titanium alloy materials implanted in the patient (screws, nuts, rods) were provided by the manufacturer. The purpose was to quantify the shift in proton range when implants were placed in the beam and compare it to the shift calculated in the TPS used for proton pencil beam scanning treatments (RayStation). EBT3 Gafchromic films were interspersed among 1 cm-thick solid water slabs. The phantom was placed along the beam direction to assess depth dose distributions. Metal implants were positioned at the films entrance. The phantom was irradiated using a 120 MeV-proton scanned field covering a 20 cm<sup>2</sup> area (see figure 1). CT images of the set-up were obtained by scanning the phantom with and without the use of Smart Metal Artifact Reduction (MAR) reconstruction algorithm. In RayStation, irradiation conditions were reproduced based on the CT images. Bragg peak positions measured in the films for each implant were compared to the calculated ones in several configurations: using both uncorrected and MAR-corrected images; overriding or not the density of the delineated implants in the TPS; using both Pencil Beam and Monte Carlo algorithms.

Figure 1: EBT3 film irradiated parallel to the beam direction with a 120-MeV scanned proton field. The Bragg peak is shifted at the implants locations.

#### Results

In all cases, maximum error in TPS range calculation was 18.9 mm. In both CT series, the errors were minimized when implants density was overridden in RayStation. Although MAR-corrected images reduced beam hardening artifacts, they mis-reproduced implant dimensions. Hence, the following planning strategy was adopted: implants were delineated on uncorrected CT and contours were copied on MAR-corrected CT. The metal structure was overridden to a compound defined in RayStation based on Ti with a density of 4,42 g/cc. The range uncertainty parameter of robust optimization in the TPS was set to 5%. To account for maximal errors, 5 mm CTV-to-PTV margins were added to target and organs-at-risk near the implants.

#### Conclusion

In this work, evaluation of the maximum error in calculated proton range allowed to define adapted safety margins and create a robust treatment plan for a patient with lumbosacral chordoma with metal spine implants. The strategy implemented could be re-used in further proton therapy treatments. Besides, the use of a dual energy CT scan could improve the definition of high density structures CT-number, allowing reducing safety margins. Further investigations are ongoing, including absolute dose studies.

#### PO-0911 Choose before you measure. Setting gamma parameters for different QA devices on the basis of ROC.

M. Gizińska<sup>1,2</sup>, D. Błatkiewicz<sup>1</sup>, M. Bukat<sup>1</sup>, M. Gil-Ulkowska<sup>1</sup>, S. Maluszczyk<sup>1</sup>, A. Paciorkiewicz<sup>1</sup>, D.

Szałkowski<sup>1</sup>, A. Walewska<sup>1</sup>

<sup>1</sup> *Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics Department, Warsaw, Poland*; <sup>2</sup> *University of Warsaw Faculty of Physics, Department of Biomedical Physics, Warsaw, Poland*

### Purpose or Objective

An important question which should be answered prior to pre-treatment measurement is whether we want to check linac performance and detect all MLC errors or do we want to detect only those errors with clinically relevant impact on dose distribution. Some groups reported capability of different gamma parameters to detect clinically relevant errors. In our work we propose to use Receiver Operating Characteristic (ROC) in order to compare three different QA devices and choose gamma analysis parameters - especially tolerance level for percent of passing points (PPP).

### Material and Methods

Forty clinical IMRT plans (10 plans for each of tumor localizations: gynecology, prostate, brain, head and neck) were used in our study. All plans were clinically accepted and used for patients treatment. Sixteen known MLC errors of different magnitude were introduced for each plan. Dose distribution was recalculated in TPS (Eclipse AAA 13.6.23) on the patient CT. We created verification plan for all plans (original and with error) for three QA devices: ArcCHECK (SunNuclear), Octavius 729 (PTW), EPID (Varian). In order to do the bias-free evaluation, artificial measurements were created based on the dose calculations in TPS. Artificial measurement is a file created with a Python script on the basis of TPS dicom dose distribution which mimics the real measurement file. All artificial measurements were compared with original verification plan in adequate software (SNCPatient, Verisoft, Portal Dosimetry). Gamma analysis was performed with 5% threshold. Tested parameters were: 3mm/3%, 2mm/2%, 1mm/1% for both max and local evaluation. From dose comparison between the clinical plan and error plans we flagged each of 680 plans with Positive or Negative, where Positive meant clinically relevant change in PTV dose (i.e. D98%<95%, D2%>107% or  $\Delta D_{mean}>2\%$ ). While changing the gamma evaluation percent of passing points tolerance level we calculated sensitivity (True Positive Ratio) and specificity (True Negative Ratio) for all tested devices. ROC curves were evaluated for each site and gamma parameters.

### Results

In Figure 1 ROC curves for 3mm/3% max gamma evaluation are shown. Octavius 2D (with 729 array) performs slightly better than EPID. Area under ROC curve for ArcCHECK is smaller thus showing lower performance in detecting clinically relevant errors. It can be seen that 98% tolerance for Octavius and EPID does not balance between Sensitivity and Specificity. ROC curves obtained for 3mm/3% local gamma evaluation (Figure 2) show that ArcCHECK tolerance level should be set to 90% while EPID and Octavius tolerance levels should be 95%-98%. For these parameter all detectors performed similarly.

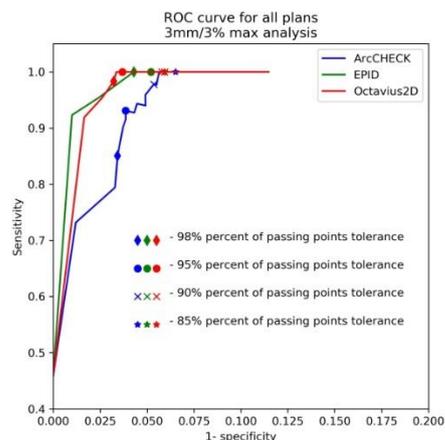

Figure 1. Comparison of ROC curves for 3 tested detectors for 3mm/3% max gamma parameters.

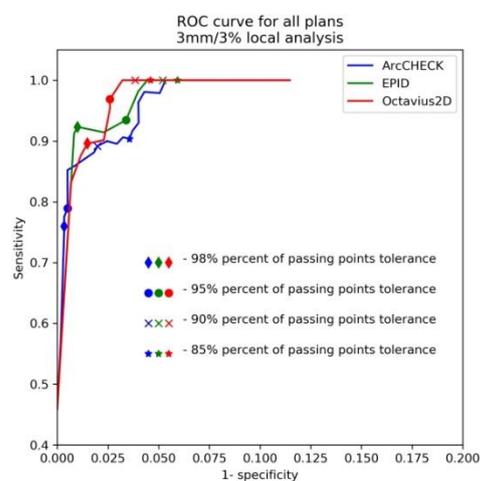

Figure 2. Comparison of ROC curves for 3 tested detectors for 3mm/3% local gamma parameters.

### Conclusion

ROC analysis for pre-treatment QA device can help in setting the tolerance level of PPP for gamma analysis aimed to detect clinically relevant dose distribution change. Our study showed that for 3mm/3% gamma evaluation ArcCHECK tolerance level should be set to lower value than that for Octavius and EPID.

### Purpose or Objective

We previously estimated rates of severe/disabling, life-threatening, or fatal cardiac disease in 24,214 five-year survivors in the Childhood Cancer Survivor Study (CCSS). At doses  $\geq 10$ Gy, a linear dose-response relationship was observed between mean heart doses (MHD) and rates of any cardiac disease, coronary artery disease, and heart failure. For each individual, we reconstructed radiation-therapy-(RT)-treatments on age-specific phantoms. MHDs were calculated for a heart model located between thoracic vertebral bodies T5 and T9 (base heart model). Variability in heart anatomy was not considered, and its effect on the dose-response relationship is unknown. This study explored the impact of this variability on the dose response.

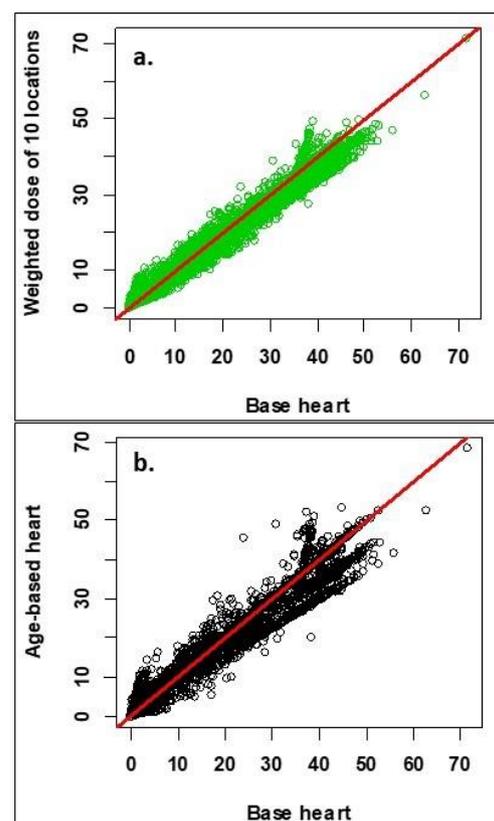

### Material and Methods

CCSS includes individuals diagnosed in 1970-1999 with median age at diagnosis and attained age of 7.0 (range 0-20.9) and 27.5 (range 5.6-58.9) years, respectively. Those treated with RT ( $n = 11,668$ ) received conventional RT without Computed-Tomography-(CT)-based planning; heart positions were unknown. To assess the possible range of heart positions, we documented the superior and inferior aspects of hearts from CT scans in a sample of contemporary pediatric RT patients ( $n=43$ ) and for International Commission on Radiological Protection (ICRP) reference phantoms (ages: 0,1,5,10,15). We classified ten unique heart positions (including that base heart). Nine hearts models were added to our age-specific phantoms. MHDs were calculated for heart models located in ten different positions for each individual. Dose-response relationships were evaluated using weighted piecewise-exponential models adjusting for attained age, sex, age at diagnosis, race, smoking history, year of diagnosis, treatment (alkylating agents, anthracycline, and an interaction between anthracycline and age at diagnosis) where individuals' MHDs were assigned in three ways: (1) base heart; (2) the 10 hearts weighted according to the distribution in the sample group; (3) age-based heart (the heart position of the ICRP phantom of the same age).

### Results

Shown in Figure 1(a-b) are scatter plots comparing the MHDs for the base heart model to the alternate dose-assignment methods; corresponding relative rate estimates of the three cardiac-disease rates by MHD are reported in Table I. The estimates are largely consistent between the established heart model using base heart model and the two alternate models. Consistent with our previous findings, here we report that the relative rates of cardiac toxicity increase with MHD  $\geq 10$  Gy monotonically ( $P<0.005$ ) and agree within 20% regardless of which heart model is used in the analyses.

Mean Heart Dose (Gy)	Any Cardiac Disease Relative Rate (95% CI)

> or = 30	6.5 (4.4 - 9.6)	6.2 (4.1 - 9.3)	6.8 (4.5 - 10.3)

**Figure 1:** Scatter plots comparing mean heart doses (MHD) for base heart (red line) with MHDs for **a.** 10 hearts weighted based on sample group and **b.** age-based hearts (heart position of ICRP phantom of same age).

### Conclusion

These data indicate that the heart model used in our previous analysis is robust and representative of the various possible heart positions that may occur for patients in pediatric cohorts. Based on these data, we have confirmed the soundness of our dose response model for cardiac disease.

### PO-0913 Cancer risk after breast proton therapy considering physiological and radiobiological uncertainties

A. Raptis<sup>1</sup>, J. Ödén<sup>2</sup>, O. Ardenfors<sup>2</sup>, A. Flejmer<sup>1</sup>, I. Toma-Dasu<sup>3</sup>, A. Dasu<sup>1</sup>

<sup>1</sup>The Skandion Clinic, Radiotherapy, Stockholm, Sweden ; <sup>2</sup>Stockholm University, Department of Physics, Stockholm, Sweden ; <sup>3</sup>Stockholm University, Medical Radiation Physics, Stockholm, Sweden

#### Purpose or Objective

To investigate the risk of radiation induced second cancer following breast radiotherapy with protons, to evaluate the impact of the physiological movements and the radiobiological uncertainties and to compare the results with corresponding risks from photon treatments.

#### Material and Methods

Twelve thoracic patients who underwent CT scans in breath hold at inhalation, breath hold at exhalation and free breathing were included in this study. Photon and proton plans aiming at delivering 50 Gy (RBE) in 25 fractions to the delineated whole left breast were generated for all twelve patients assuming a constant RBE of 1.1 for protons. In order to evaluate the plans in terms of second primary cancer risk, two models were employed: a competition model and a plateau-shaped model. The impact of physiological breathing movement was assessed from the dose distributions corresponding to the different breathing phases. The proton treatment plans were evaluated assuming a RBE=1.1 or a variable RBE model, enabling an analysis of the proton radiobiological uncertainty and its influence on the calculated risk of radiation-induced second cancer. The influence of the uncertainty in  $\alpha/\beta$  values was also studied. The integral doses for both modalities and both risk models were calculated and their correlation with risk prediction was investigated.

#### Results

The oesophagus, the contralateral breast and the heart received practically 0 Gy (RBE) for all proton plans, whereas the photon plans resulted in mean doses less than 1.2 Gy to the organs. The lungs received the highest doses with both modalities, with an average of 1.45 Gy for the photon plans and 0.58 Gy (RBE) for the proton plans (RBE=1.1). The average risk of developing a second primary cancer in the lungs according to the competition model was estimated to 0.31% and 0.12% for the photon and proton plans, respectively. The calculated risk was lower for the proton plans compared to the photon plans for all OARs, risk models, breathing phases as well as when considering all the tested values of the parameters of the radiobiological models. The variable RBE model predicted slightly higher risks compared to the constant RBE of 1.1, although the risks were still lower than for the photon plans. The risks for the proton plans did not increase with the integral dose, this was however observed for the photon plans [Figure 1].

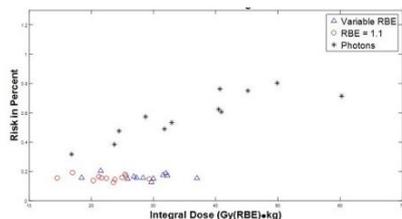

Figure 1: The relationship between integral dose and the total risk for second cancer predicted by the competition (bell-shaped risk) from the photon and proton plans for the patients included in the study.

#### Conclusion

The risk of radiation-induced second cancer following breast radiotherapy was lower for proton therapy in comparison to photon radiotherapy. The uncertainties in physiological movements and radiobiological parameters affected the absolute values of the risk estimates but not

the general trend of higher risk associated with photon therapy than for proton therapy.

### PO-0914 Patient specific organ dose evaluation in cone beam CT

A. Sardo<sup>1</sup>, F.R. Giglioli<sup>1</sup>, E. Gallio<sup>1</sup>, V. Rossetti<sup>1</sup>, C. Fiandra<sup>2</sup>, O. Rampado<sup>1</sup>

<sup>1</sup>A.O.U. Città della Salute e della Scienza di Torino, Medical Physics Department, Turin, Italy ; <sup>2</sup>University of Turin, Radiation Oncology Department, Turin, Italy

#### Purpose or Objective

Daily images from Cone Beam CT (CBCT) could deliver significant dose to the patient, which should be considered and evaluated. It is essential to associate the absorbed dose delivered by the imaging procedures to the treatment of each patient. Aim of this work is to calculate organ doses for patients undergoing CBCT when treated with radiotherapy.

#### Material and Methods

The system in use was an Elekta CBCT (XVI) and the protocols analysed were four: head, pelvis, chest and chest 4D with different parameters. The formula for organ dose calculation, was obtained from Rampado et al. (Med Phys 2016;43(5):2515-26), where dose to organs were evaluated by means of Monte Carlo simulation in phantom; the effect of patient size were also accounted for.

$$D_T = D_{W,1Ph} \cdot (D_T / D_{W,1Ph})_{tab} \cdot a \cdot e^{-bx}$$

In particular  $D_{W,1Ph}$  is the measured dose in a phantom for the specific protocol,  $x$  is the effective diameter of the patient,  $(D_T / D_{W,1Ph})_{tab}$ ,  $a$  and  $b$  are tabulated data from the article cited above. Patients were analyzed from march to june 2017. For each case were registered: the effective diameter from simulation CT, CBCT protocol, number of CBCT scans.

#### Results

Two hundred patients were considered and the mean doses and standard deviation for all the protocols are illustrated in the table .

Protocol	Organ	Mean ± SD [mGy]
H&N S20	Oralmucosa	28.9 ± 2.2
	Salivary glands	30.1 ± 2.3
	Respiratory airways	27.7 ± 2
	Spinal cord	18.8 ± 1.4
PELVIS M20 F1	Colon	425.6 ± 55.9
	Bladder	536.3 ± 57.2
	Ovaries	472.6 ± 84.2
	Prostate	401.0 ± 50.8
CHEST 4D SYMMETRY	Breast	66.4 ± 32.9
	Heart	45.5 ± 21.6
	Lung	38.8 ± 19.1
CHEST M20 F0	Breast	469.3 ± 119.8
	Heart	443 ± 111.0
	Lung	473.2 ± 118.5
CHEST M20 F1	Breast	439.2 ± 97.3
	Heart	550.6 ± 122.0
	Lung	477.3 ± 106.9

For head protocol, the mean CBCT doses were about 26.3±2.1 mGy for all organs. Instead, doses of about 458±60 mGy were evaluated for pelvis protocol. CBCT Doses for Chest 4D protocol were lower than other chest ones (about 50.3±25 mGy vs 461±115 mGy). This difference was due to number of CBCT scans/treatment fractions.

#### Conclusion

Dose from CBCT procedures should be accounted for; based on organ doses calculations, a program of dose optimization could be performed.

PO-0915 Integral multi-scenario robustness evaluation of anatomical robust optimization in head and neck

M. Cubillos Mesías<sup>1</sup>, E.G.C. Troost<sup>1,2,3,4,5</sup>, F. Lohaus<sup>1,2,3</sup>, L. Agolli<sup>2</sup>, M. Rehm<sup>2</sup>, C. Richter<sup>1,2,3,4</sup>, K. Stützer<sup>1,4</sup>

<sup>1</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden - Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany; <sup>2</sup>Faculty of Medicine and University Hospital Carl Gustav Carus, Department of Radiotherapy and Radiation Oncology, Dresden, Germany; <sup>3</sup>German Cancer Consortium DKTK, Partner site Dresden, Dresden, Germany; <sup>4</sup>Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology - OncoRay, Dresden, Germany; <sup>5</sup>National Center for Tumor Diseases NCT, Partner Site Dresden, Dresden, Germany

Purpose or Objective

Classical robust optimization considers uncertainties in patient setup and particle range. Usually plan robustness is evaluated from calculation of perturbed dose distributions based on the planning CT, without considering potential anatomical changes that may occur during the treatment course. Our aim was to compare the overall plan robustness of classical robust optimization (cRO) with the recently proposed anatomical robust optimization (aRO) based on an integral multi-scenario evaluation, considering all types of uncertainties including anatomical variations.

Material and Methods

Datasets for 20 head and neck cancer patients, including a planning CT and weekly control CTs, were analyzed. Two intensity-modulated proton therapy (IMPT) plans were calculated: cRO, using solely the planning CT, and aRO, including additionally the first two control CTs in the plan optimization. For the robustness analysis, perturbed dose distributions with random setup uncertainties and fixed range uncertainty values of -3.5%, 0% and +3.5% were generated, drawing for each fraction  $n$  a random number from a Gaussian distribution around 0 mm with a standard deviation of 2.5 mm for the isocenter shift in each cardinal direction ( $x_n, y_n, z_n$ ). Moreover, in each fraction  $n$  the correspondent weekly control CT was used to consider the anatomical changes during therapy. 33 single-fraction perturbed doses were calculated and summed to generate a perturbed whole-treatment dose distribution. The procedure was repeated 10 times for each of the three range uncertainty values, resulting in 30 perturbed dose distributions per plan (Figure 1).

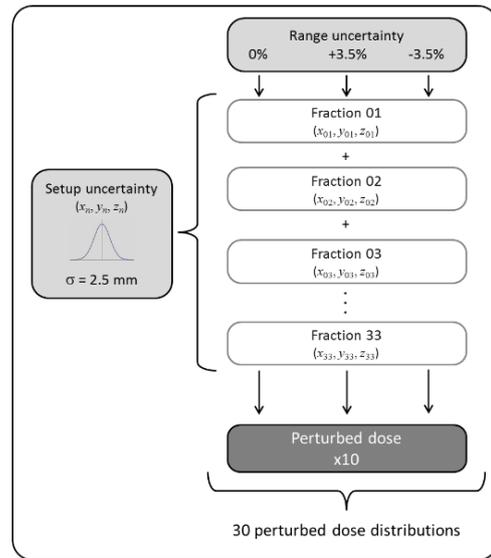

Figure 1. Workflow for the generation of perturbed dose distributions, generating random setup uncertainty values per fraction  $n$  with fixed range uncertainty values. In each fraction  $n$  the anatomy of the correspondent weekly control CT is considered.

Results

Both nominal plans fulfilled the clinical objective for target coverage ( $D_{98\%} \geq 95\%$  of the prescribed dose). The median values calculated from the 30 perturbed dose distributions for each patient showed a reduction in the target coverage for the cRO plan, with mean (minimum) values of 94.9% (88.1%) and 95.4% (89.3%) for the low- and high-risk CTV, respectively, in comparison with 96.6% (92.0%) and 96.8% (93.6%), respectively, for aRO (Figure 2a). The variation in CTV coverage between the 30 scenarios, i.e. the width of the perturbed dose distributions, was found to be larger for cRO plans, with median (maximum) values of 1.9 (8.3) and 1.4 (5.6) for low- and high-risk CTV, respectively, in comparison with 1.4 (3.4) and 0.9 (5.2) for aRO plans, respectively. Moreover, the cRO case showed reduced robustness in comparison with aRO for some patients, where certain scenarios violate the clinical objective, as shown in Figure 2b.

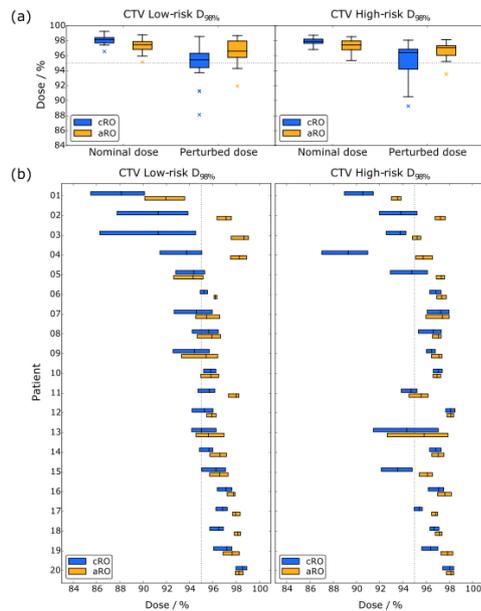

Figure 2.  
(a) Comparison of target coverage for cRO and aRO plans in nominal dose and medians of the perturbed dose distributions for all patients. The dashed line represents the clinical objective (95%).  
(b) Distribution of the generated perturbed dose distributions for target coverage per patient. Central line in each box represents the median value. The dashed line represents the clinical objective (95%).  
Abbreviations: cRO, classical robust optimization; aRO, anatomical robust optimization.

## Conclusion

Anatomical robust optimization showed superior plan robustness in comparison with the classical approach in a comprehensive multi-scenario evaluation. Anatomical variations play an important role in the overall plan robustness together with setup and range uncertainties, therefore their effect should not be underestimated or neglected.

## PO-0916 Energy layer switching sequence optimization algorithm for an efficiency proton arc therapy delivery

X. Ding<sup>1</sup>, X. Li<sup>1</sup>, G. Liu<sup>1</sup>, C. Stevens<sup>1</sup>, D. Yan<sup>1</sup>, P. Kabolizadeh<sup>1</sup>

<sup>1</sup>Beaumont Health, Proton Therapy Center, Royal Oak, USA

### Purpose or Objective

Spot-Scanning Proton Arc therapy (SPArc) has been a great interest of the society because of the improved dosimetric outcome. Due to the magnetic field hysteresis, it costs significant time in the energy layer switching especially switching from low energy to high energy layers. Thus, we presented a new energy layer and delivery sequence optimized SPArc algorithm (SPArc\_seq) to shorten the proton arc delivery time.

### Material and Methods

SPArc\_seq includes an energy layer sorting and control point re-sampling mechanism taking into account of proton arc delivery sequence through the gantry rotation. The SPArc\_seq plan is optimized for high to low energy delivery sequence instead of random layer switching which was introduced in the original SPArc algorithm. Both SPArc and the novel SPArc\_seq were tested on three kinds of disease sites: prostate, lung and brain cancer. Both plan group (SPArc and SPArc\_seq) were delivered at a fixed 0 degree gantry angle simulating the arc delivery sequence and energy switching in clock-wise gantry rotation. Total actual delivery time was recorded and dose measurements were performed using a 2D ion chamber array device, MatriXXONE, at 3cm depth.

### Results

With a similar proton arc plan quality, SPArc-seq optimized plan was able to successfully reduce 56% (beam-on time comparison: 330s vs 756s), 52% (beam-on time comparison: 305s vs 635s) and 55% (beam-on time

comparison: 256s vs 570s) of proton arc delivery time compared to SPArc in prostate, lung and brain cancer respectively. Absolute dose measurements showed within 2% difference compared to the plans. 2D Gamma Index (3%/3mm) showed more than 97% passing rate in both SPArc and SPArc\_seq.

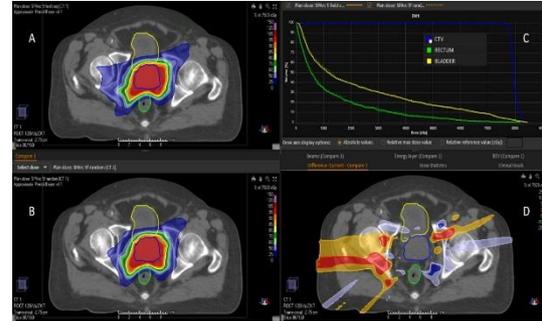

Figure 1. A representative axial view of the dose comparison. (A) SPArc\_seq; (B) SPArc; (C) DVH comparison. Solid line is the SPArc and dotted line is the SPArc\_seq; (D) dose difference between SPArc and SPArc\_seq

Table 1. SPArc Energy layer delivery sequence from gantry 0 to 360 clock-wise

## Conclusion

The new SPArc\_seq optimization algorithm is able to effectively reduce proton arc treatment delivery time by about half compared to the original SPArc algorithm. Such findings in the proton arc delivery efficiency improvement paves the road for future clinical implementations.

## PO-0917 Deep Convolutional Network with transfer learning for dose prediction in VMAT prostate treatments

P.G. Franco<sup>1</sup>, E.M. Ambroa<sup>2</sup>, J. Perez-Alija<sup>1</sup>, M. Ribas<sup>1</sup>, M. Colomer<sup>2</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Medical Physics, Barcelona, Spain; <sup>2</sup>Consorci Sanitari de Terrassa, Medical Physics Unit - Radiation Oncology, Terrassa, Spain

### Purpose or Objective

We believe that the use of Deep convolutional neural networks (DCNN) with transfer learning (widely used in other science fields with good results) offers tremendous opportunities in the field of Medical Physics. We propose its use in radiotherapy to identify suboptimal plans and guide plan optimization. We have focused the study in the prediction of rectum dose-volume histograms (DVH) for VMAT prostate patients.

### Material and Methods

We retrospectively collected data of 134 prostate patients treated with a simultaneous integrated boost VMAT technique (70 Gy and 50.4 Gy in 28 fractions to the prostate and lymph nodes respectively). QUANTEC dose-volume constraints were taken into account as a starting point for treatment planning. VGG-16 (DCNN, ImageNet Large Scale Visual Recognition Challenge 2014) was used as our network architecture. VGG-16 is a DCNN pre-trained with more than 1.2 million natural images of 1000 object categories (ImageNet image dataset). For image classification we dropped the last three fully connected

layers from the VGG-16 and added a new fully connected neural network to properly transfer learning to our data. Our data was split into training, validation and test sets (98, 26 and 10 patients in each set respectively). To apply this DCNN to our problem, for each patient we extracted the contour information included in the CT and feed this data to the modified VGG-16. The model was trained on single slices of the patient instead of a whole 3D image. DCNN output is a 2D rectum DVH for every slice. Rectum DVHs from our test set were compared to DVHs predicted by our model. An actual plan was considered suboptimal if the mean square error (MSE) of the prediction was greater than the MSE of the validation plus 2 standard deviations. If predicted DVH was better than the actual DVH a replan was carried out to study the cause of this discrepancy.

### Results

DCNN with transfer learning successfully predicted rectum DVHs for our test patients. The predicted DVH was comparable to the actual DVH except for two cases (20%) where the model predicted a substantially better DVH (Fig.1). In these two cases, replanning decreases doses to the rectum without worsening the PTVs or any organ at risk.

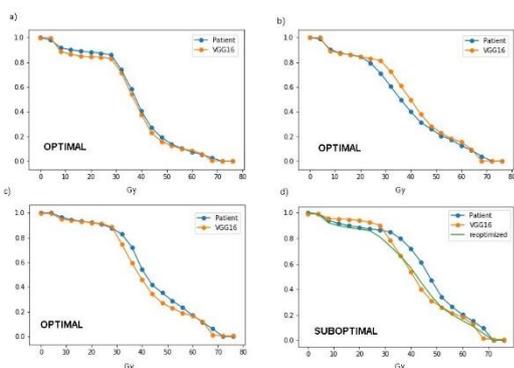

Figure 1. Predicted rectum DVH for 4 patients.

Table I shows a dosimetric comparison between the original plan (blue line), the predicted one (orange line) and the re-optimized plan (green line) for the suboptimal patients. Our replan strategy achieved an improvement of 28.7% and 15.0% in V40 for both patients.

		Dosimetric results comparison				
Patient	Plan	V40Gy (%)	V50Gy (%)	V60Gy (%)	V65Gy (%)	V70Gy (%)
1	Original plan	78.1	45.0	23.1	13.9	3.9
	VGG prediction	42.6	17.6	9.8	5.4	0.3
	Re-optimized plan	49.4	30.1	17.8	11.8	3.7
2	Original plan	71.8	40.4	20.1	13.7	4.8
	VGG prediction	48.0	23.7	14.4	8.2	0.5
	Re-optimized plan	56.8	30.1	15.5	9.8	2.8

Table I

### Conclusion

We successfully used a pre-trained DCNN to predict rectum DVH's for VMAT prostate patients, allowing for effectively detect suboptimal plans and guiding plan optimization to improve dose distribution. To our knowledge this is one of the first attempts to apply the transfer learning of DCNN to dose prediction in radiotherapy. Thus we demonstrate that transfer learning of DCNN is a feasible solution to the lack of training data in radiation oncology. Future work will include DVH prediction for the remaining organs at risk.

### PO-0918 Optimal parameters to perform the Pseudo Skin-Flash on VMAT on breast radiotherapy

M. Lizondo<sup>1</sup>, A. Latorre-Musoll<sup>2</sup>, N. Espinosa<sup>2</sup>, A. Coral<sup>2</sup>, C. Cases<sup>2</sup>, N. Jornet<sup>2</sup>, P. Carrasco<sup>2</sup>, P. Delgado-Tapia<sup>2</sup>, A. Ruiz-Martinez<sup>2</sup>, I. Valverde-Pascual<sup>2</sup>, M. Barcelo<sup>2</sup>, M. Ribas<sup>2</sup>

<sup>1</sup>Institut de Recerca Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain ;

<sup>2</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

### Purpose or Objective

In breast radiotherapy, the use of dynamic techniques (IMRT, VMAT) usually include a skin flash region outside the body contour to ensure correct irradiation of CTV accounting for uncertainties in position, breathing or possible anatomical changes. In VMAT, the common approach consists in optimizing the VMAT plan on an extended CT including a virtual bolus out of the body contour in the area of the PTV.

We present a detailed method to obtain the optimal thickness and HU value assigned to this virtual bolus, regarding plan robustness and dosimetric impact of the strategy.

### Material and Methods

7 bilateral breast patients treated for whole breast radiotherapy were retrospectively selected for the study. For each patient, we defined 16 modified-CT (CT') by adding to the original CT (CT0) all combinations of width (0.5cm & 1.0cm) and HU (from -700 to 0, 100 HU steps) of the bolus.

We optimized a VMAT plan (RapidArc®, Varian Medical Systems, POv13.5.35, AAAv13.5.35) on the CT0 (*NoAction plan*) and on each CT' (*CT' plans*) by using the same optimization objective template per patient and a PTV excluding 5mm of skin. We recalculated CT' plans to CT0 by fixing MU (*CT0 plans*).

For the dosimetric impact of the strategy, CT' plans and CT0 plans were compared on the basis of doses to PTV (Dmean, D98 and D2) and doses to OARs, particularly to heart (Dmean, V30), lungs (V5) and liver (Dmean).

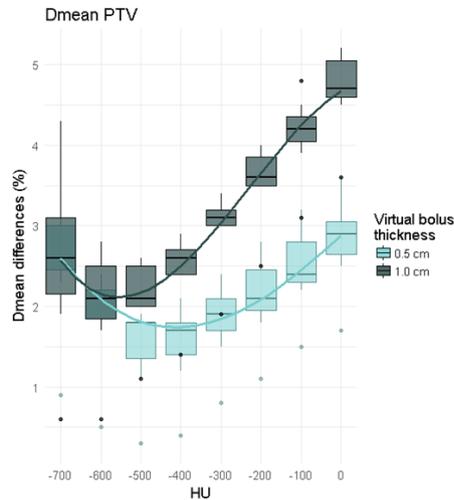

The robustness is assessed by shifting the isocenter 0.5cm and 1.0cm in the breathing direction, and recalculating CT0 plans and *NoAction plan* by fixing MU (*CT0-shifted plans*). *CT0-shifted plans* and *CT0 plans* were compared on the basis of D98 and D2 relative differences on the portion of the PTV in the buildup region (1cm-depth inner margin beneath the skin, PTV<sub>skin</sub>), which is likely to increase the sensitivity of the analysis.

Optimal parameters were those that maximized the plan robustness on CT0 and minimized dosimetric impact of this strategy.

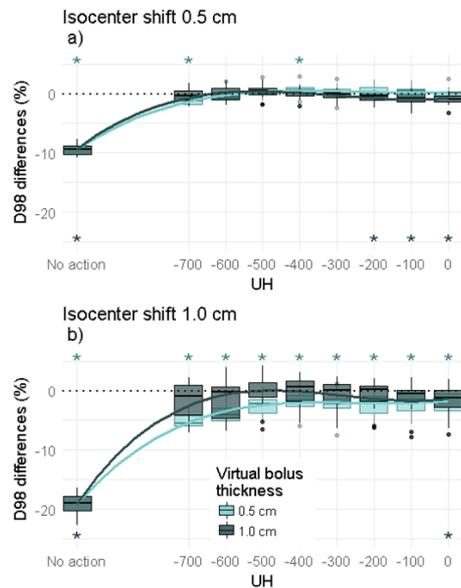

### Results

All PTV dose indexes increased when the re-calculation was made on CT0. Minimum relative Dmean differences were found between -400 and -600 HU depending on the bolus thickness (Fig1). Doses to OARs are not significantly affected.

Regarding to robustness, for shifts of 1.0 cm there are significant differences between choosing a bolus thickness of 0.5 cm or 1.0 cm, which is not observed for shifts of 0.5 cm (Fig2). Best robustness is found for -500 HU and 1.0 cm thickness. It is worth noting that when no pseudo skin flash strategy is applied, relative dose differences up to 20% can be found.

**Figure 1.** PTV Dmean relative variation between *CT* plans and *CT0* plans for each virtual bolus HU assignment.

**Figure 2.** D98 relative variation between the *CT0*-shifted plans and *CT0* plans for each virtual bolus HU assignment and *NoAction* plan, evaluated on PTVskin. Asterisks on the top (related to 0.5 cm of virtual bolus width) and on the bottom (related to 1.0 cm width) inform when the corresponding boxplot is significantly different from zero (t-test, RStudio).

## Conclusion

A virtual bolus of 1.0 cm and a HU-value of approximately -500 HU would maximize plan robustness against movements up to 1.0 cm in the breathing direction. Additionally, this HU-value minimizes the dosimetric impact of the strategy. Therefore in most of the patients it will be no necessary to re-normalize the clinical treatment and if it was, it will be a minor change. The study has been focus at breast radiotherapy but same methodology could be applied on other locations.

## PO-0919 Automatic radiotherapy treatment planning using Particle Swarm Optimization

L.A. Künzel<sup>1</sup>, S. Leibfarth<sup>1</sup>, O.S. Dohm<sup>2</sup>, A. Müller<sup>2</sup>, D. Zips<sup>2,3</sup>, D. Thorwarth<sup>1,3</sup>

<sup>1</sup>Section for Biomedical Physics Department for Radiation Oncology, University Hospital Tübingen, Tübingen, Germany; <sup>2</sup>Department for Radiation Oncology, University Hospital Tübingen, Tübingen, Germany; <sup>3</sup>German Cancer Consortium DKTK partner site Tübingen,

and German Cancer Research Center DKFZ, Heidelberg, Germany

## Purpose or Objective

To investigate the potential of Particle Swarm Optimization (PSO) for automatic planning of VMAT radiotherapy (RT). The aim of this PSO is to formulate an optimal patient individual treatment planning problem, i.e. to define optimal planning constraints leading to the best achievable plan.

## Material and Methods

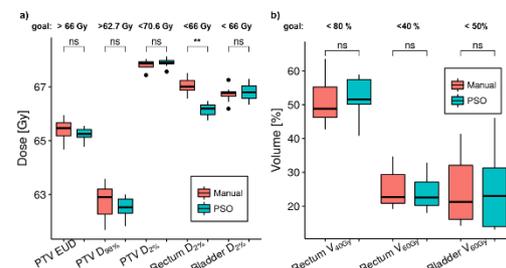

PSO is a statistical, collective and iterative optimization technique which uses the knowledge of each particle about its own best and the swarm's best position to update particle positions for each generation. For automatic RT planning, a particle is considered a plan with its position determined as a vector of planning constraints. To evaluate plan quality, i.e. determine the particle's best positions a scoring function was introduced, based on the sum of individual plan quality scores for dose-volume-histogram (DVH) parameters for planning target volume (PTV) and priority organs at risk (OAR). The plan quality score is defined in a way to increase if the DVH parameter fulfills planning goals and penalizes if the goals are violated.

Automatic treatment planning using PSO was tested for 8 postoperative prostate cases, with a prescribed dose of 66 Gy to the PTV in addition to two rectum and one bladder constraint. N=30 particles were initialized and the PSO was executed for m=100 generations. PSO and manually generated plans were compared dosimetrically with respect to the planning goals, visual inspection of dose distributions and DVHs.

## Results

PSO successfully proposed treatment plans comparable to manually optimized ones in all 8 cases. The mean (range) PTV *EUD* was 65.4 Gy (64.7-65.9) for manual and 65.2 Gy (64.8-65.6) for PSO plans, respectively. Also *D*<sub>98%</sub> for the PTV is slightly higher in manual plans, with 62.8 Gy (61.7-63.6) and 62.5 Gy (61.8-63.0), respectively. On the other hand, PSO plans achieve lower doses in rectum *D*<sub>2%</sub>, 67.0 Gy (66.6-67.5) vs. 66.2 Gy (65.8-66.5, p=0.008). Fig 1 provides an overview of all evaluated planning goals. On average, PSO proposed plans with better OAR sparing but inferior PTV doses. However, this compromise between PTV and OAR doses is directly related to the definition of the scoring function. According to the scoring function used in this study, manual plans had lower plan quality scores compared to PSO plans with -0.61 (-2.41-0.96) vs. 1.41 (-0.84-6.78).

Overall, good convergence of the planning goals and the plan quality score was observed with increasing particle generations (Fig 2a-b). As demonstrated by Fig 2c-d, PSO proposed comparable dose distributions.

**Fig 1:** Boxplots and planning goals for all parameters evaluated by the plan quality score (Wilcoxon signed rank test, ns not significant, \* p < 0.05, \*\* p < 0.01, \*\*\* p ≤ 0.001).

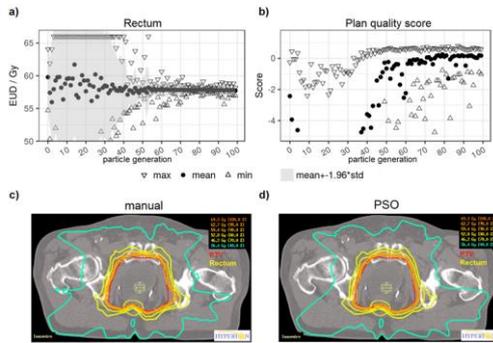

Fig 2: Case PC03: a) shows an example for the evolution of minimum, maximum and mean rectum constraint as a function of particle generation, with a shrinking search area and a stabilization of the mean constraint value. Similarly, the mean quality score converges towards a maximum value during PSO (b). Dose distributions of a representative slice for the manual and the PSO plan are provided in c) and d).

**Conclusion**

PSO allows for automatic generation of VMAT plans with comparable plan quality compared to manually optimized plans. However, further research is needed concerning optimization parameters and the optimal number of particles and generations to fully explore the potential of PSO for automatic planning. The plan quality score has to be further refined to find reasonable and clinical acceptable compromises between PTV and OAR doses.

**Poster: Physics track: Treatment planning: applications**

**PO-0920 Knowledge-based planning significantly reduces dose to organs at risk for lung cancer**

L. Hoffmann<sup>1</sup>, M.M. Knap<sup>2</sup>, D.S. Møller<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Oncology-Medical Physics, Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

**Purpose or Objective**

The introduction of knowledge-based planning has been shown to result in reduced variability in treatment plans and for some patient groups also reduced dose to organs at risk (OARs). RapidPlan (RP) has been introduced into the Eclipse treatment planning system (Varian Medical Systems). The aim of the present study was to investigate if a general reduction in dose to OARs was achievable by using a RP model. Furthermore, for all patients two different beam angle selections were compared.

**Material and Methods**

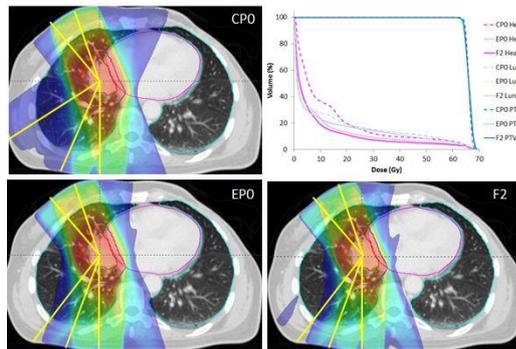

Fig. 1. Treatment plans CPO (clinical plan), EPO (experienced planner plan) and F2 (final plan) for one patient. Dose distributions are shown as dose colour wash for all doses > 10Gy. Yellow lines show beam angles. Upper right: Dose volume histogram showing dose to heart (pink), lung (light blue), esophagus (green) and PTV (dark blue). A clear reduction in dose to all OARs is seen between CPO and EPO. A further reduction is seen for the dose to the heart when applying the RP model (F2).

Seventy-four consecutive lung cancer patients were selected for configuration of the RP model. The patient group consisted of 49 NSCLC patients treated by 60-66 Gy in 30-33 fractions and 25 SCLC patients treated by 45 Gy

in 30 fractions. The median [range] gross tumour volume (GTV) was 29 cm<sup>3</sup> [4-472] and the planning target volume (PTV) was 259 cm<sup>3</sup> [51-1069]. The clinical plans (CPO) consisted of 4-8 IMRT fields. Beam angles were set individually for each patient plan by different dose planners. The plans should comply with constraints for spinal cord (D<sub>max</sub><45Gy), esophagus (D<sub>1cm3</sub><100%), body (D<sub>max</sub><110%), lungs (MLD<19Gy, V20Gy<35% and V5Gy<60%) and heart (V40Gy<30%, V25Gy< 50%). Retrospectively, an experienced planner made 74 new treatment plans (EPO). Beam angles and optimization constraints were selected so that dose to the lungs and heart was minimized, still securing full target coverage (V95%>99%) while minimizing conformity index (CI). These EPO plans were used to generate a RP model (RP1). For each patient, two new plans were made using RP1 (CP1 and EP1) based on the field configurations of CPO and EPO. A second RP model (RP2) was created from the optimal plan (CP1 or EP1) for each of the 74 patients. This final RP model was used to generate the final plan (F2) for each patient. Dosimetric parameters were compared using a Wilcoxon signed rank test. p< 0.05 was considered significant.

**Results**

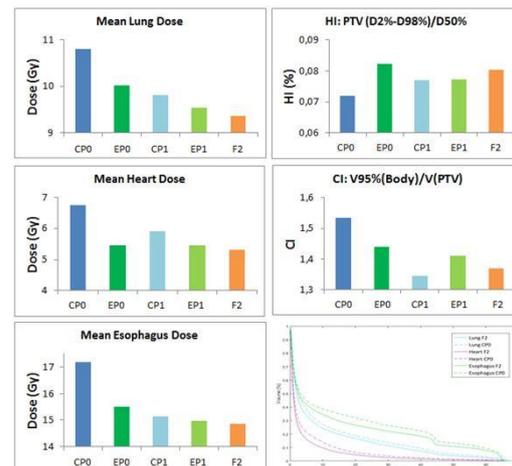

Fig. 2. Bar charts showing the median value of the mean lung/heart/esophagus dose for CPO (dark blue), EPO (dark green), CP1 (light blue), EP1 (light green) and F2 (orange). Lower right: Dose volume histogram showing mean dose for all 74 patients for lungs (light blue), heart (pink) and esophagus (green). The steep change at ~45Gy for esophagus stems from patients treated with 45Gy.

Beam angle selection and dose distribution is shown for one patient in Fig 1, where a clear reduction in dose to heart, lungs and esophagus is seen due to optimal beam directions for EPO vs CPO. Further reduction is obtained by applying the RP model. In Fig. 2, the median value of mean lung/heart/esophagus dose for all 74 patients decreases significantly from CPO to EPO due to optimal beam angle selection. The application of RP1 adds a significant reduction in mean doses to lungs and esophagus (D<sub>CP1</sub><D<sub>CPO</sub>; D<sub>EP1</sub><D<sub>EPO</sub>) and a further significant reduction is seen for all OARs for RP2. The heterogeneity index (HI) increases significantly between CPO and F2. However all plans fulfil PTV<sub>V95%</sub>>99% and Body<sub>D<sub>max</sub></sub><110%. The CI decreases significantly between CPO and F2 or EPO and F2, meaning that the RP model makes the plans more conformal in addition to OARs sparing.

**Conclusion**

Introduction of RapidPlan significantly reduces dose to lungs, heart and esophagus. The highest reduction is seen when RP is combined with optimal beam angles. The conformity index is significantly reduced, while PTV dose coverage is maintained for RP plans. Further reduction is seen by creation of a second RP model (RP2).

**PO-0921 Assessment of CT-based imaging biomarker of COPD in IGRT planning for lung cancer patient**

T. Shiiinoki<sup>1</sup>, Y. Yuasa<sup>1</sup>, K. Fujimoto<sup>1</sup>

<sup>1</sup>Yamaguchi University, Department of Radiation Oncology- Graduate School of Medicine, Ube, Japan

**Purpose or Objective**

One of the most severe complications in radiotherapy of lung cancer is radiation pneumonitis (RP). Chronic obstructive pulmonary disease (COPD) is a recognized risk factor for RP. COPD is a heterogeneous disorder that arises from pathological processes including emphysematous lung tissue destruction, gross airway disease and functional small-airways disease (fSAD) in varying combinations and severity within an individual. It is widely accepted that fSAD and emphysema are two main components of COPD and that a spectrum of COPD phenotypes with varying contributions of these components exists in individual patients. The purposes of this study were to quantify relative lung function using a parametric response map (PRM) as the imaging biomarker of COPD and to assess the dosimetric impact of its integration in treatment planning in volumetric modulated arc therapy (VMAT).

**Material and Methods**

Seven patients who underwent stereotactic body radiotherapy (SBRT) for lung cancer with COPD were enrolled in this study. Four-dimensional CT data sets were acquired around the whole lung with 20-slice CT scanner under free breathing. Next, the entire lung was scanned under breath-hold with a full inspiration. The PRM of quantitative CT as expressed in HU, a measure of tissue density, was determined by imposing two thresholds: (i) -950 HU on full inspiration scan, with values less denoting emphysema, and (ii) -856 HU on normal expiration scan, with values less denoting gas trapping. Therefore, deformable image registration (DIR) was performed from full inspiration to normal exhalation (50%). Classification of voxels with HU values characteristic of lung parenchyma representing normal, fSAD, or emphysema. PRM as imaging biomarker of COPD were calculated for each patient. The VMAT plan was designed based on the total lung. Dosimetric parameters (percent lung volume receiving 5 Gy [V5], V10, V20, and mean lung dose [MLD] to whole lungs (anatomical) versus functional lungs (normal and fSAD)) were compared.

**Results**

Figure 1 showed examples of PRM for two patients. PRM was able to visualize lung function. Red, yellow and green areas indicate emphysema, fSAD and normal lung regions. For all patients, the mean  $\pm$  standard deviation (S.D.) of relative volume of emphysema, fSAD, and normal volume for total lung volume were  $5.4 \pm 8.8\%$  (0.2%-24.6%),  $30.3 \pm 15.2\%$  (8.8%-50.2%) and  $62.5 \pm 20.6\%$  (39.1%-90.8%). Figure 2 indicated an example of dose distribution for patient 3 in coronal and sagittal plane and the mean in V5, V10, and V20 for whole lung, normal, and fSAD, respectively. Mean differences between anatomical and functional lung (normal, fSAD) were 1.9% (0.2%-3.9%), 3.5% (0.3%-10.7%), 1.5% (0.5%-3.5%), 3.6% (0.3%-10.2%), 0.7% (0.2%-1.7%), 1.8% (0.3%-4.1%) and 39 cGy (5.6-67 cGy), 87.5 cGy (22.2-252.2cGy) in V5, V10, V20, and MLD, respectively.

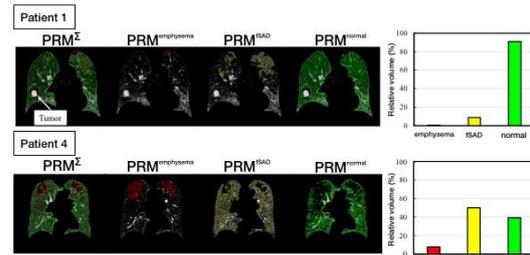

Figure 1. Examples of PRM for two patients

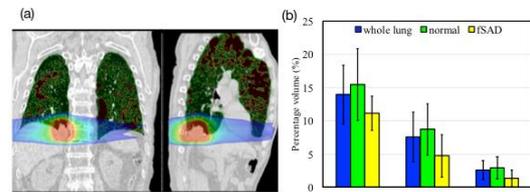

Figure 2. (a) An example of dose distribution for patient 3 in coronal and sagittal plane. (b) The mean in V5, V10, and V20 for whole lung, normal, and fSAD for all patients.

**Conclusion**

It is necessary to evaluate the weighted functional volume in the treatment planning with integration of PRM for functional lung-sparing VMAT.

**PO-0922 Knowledge-based optimization of an adaptive, early-regression-guided, technique for rectal cancer**

R. Castriconi<sup>1</sup>, C. Fiorino<sup>1</sup>, S. Broggi<sup>1</sup>, P. Passoni<sup>2</sup>, N. Di Muzio<sup>2</sup>, R. Calandrino<sup>1</sup>, G.M. Cattaneo<sup>1</sup>

<sup>1</sup>IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy ; <sup>2</sup>IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy

**Purpose or Objective**

The aim of current study is to implement a knowledge-based (KB) optimization strategy to our adaptive (ART) early-regression guided boosting technique in neo-adjuvant radio-chemotherapy for rectal cancer.

**Material and Methods**

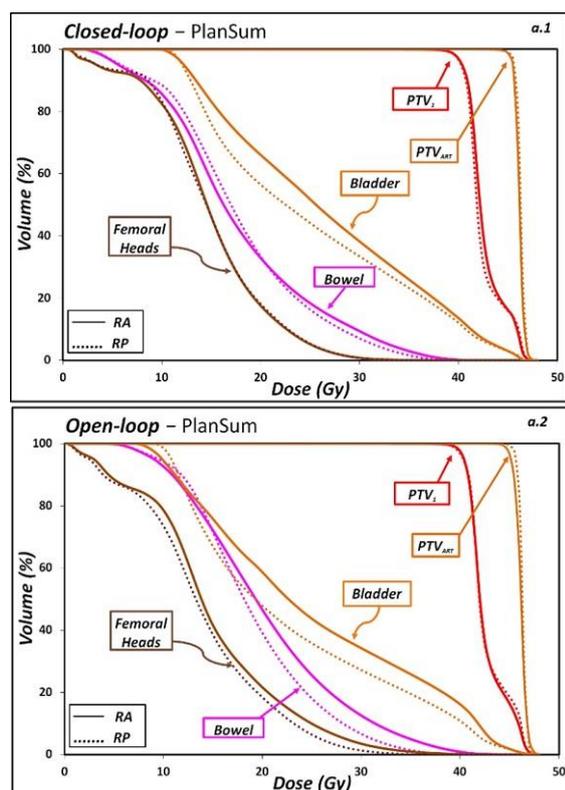

An ART approach for rectal cancer aiming to boost the residual tumor (GTV) in the last part of the treatment was developed and clinically implemented since 2009. The protocol consists of a first phase delivering 27.6Gy to tumor/lymph-nodes, 2.3Gy/fr (PTV<sub>1</sub>); followed by the ART phase concomitantly delivering 18.6Gy (3.1Gy/fr) and 13.8Gy (2.3Gy/fr) respectively to the residual tumor (PTV<sub>ART</sub>) and to PTV<sub>1</sub>. PTV<sub>ART</sub> is obtained by expanding GTV, as visible on MRI taken at fraction 9. Forty VMAT (Varian RapidArc) clinical plans were available and used to generate a KB-model for the first phase using the RapidPlan tool implemented in the Eclipse system (v13.5). Due to the large variability of the size and location of the residual tumor, a robust strategy in order to scale the KB-model of the first phase to the ART one was applied. Twenty clinical plans were retrospectively analysed in terms of PTV<sub>ART</sub> dose distribution: 2cm shell around PTV<sub>ART</sub> (1cm cranial-caudal) was generated for each ART plan. An automatic optimization template for the ART part was obtained by scaling the dose constraints of the first part and including constraints for the shell. An internal (closed-loop) and external (open-loop) validation were performed for both phases, in order to assess the potentiality of the method: all automatic plans (RP) were compared in terms of OARs/PTVs parameters against the original plans (RA).

**Results**

Before assessing best constraints for the shell, shell-DVHs of 20 ART plans were analysed and not found to be correlated with PTV<sub>ART</sub> volume or with the ratio between

PTV<sub>ART</sub> and PTV<sub>1</sub>. Then, the prescribed dose of the PTV<sub>1</sub> was chosen as soft-constraint for  $D_{\text{mean}}$  of the adaptive shell, with lower weight compared to PTV<sub>ART</sub> constraints, optimized to obtain a high dose gradient around PTV<sub>ART</sub> without losing its coverage. The resulting automatic plans were generally better than or equivalent to clinical plans. We reported the comparison of the plan sum (first+second phase) mean-DVH for both internal and external validation (figure 1).

In closed-loop, PTVs coverage and homogeneity were comparable; OARs sparing for RP was slightly improved. In open-loop, coverage and homogeneity of PTV<sub>ART</sub> were improved and OARs sparing for RP was always better with most of the improvements statistically significant ( $p < 0.05$ ): of note,  $V_{30\text{Gy}}$  for bowel was improved of 9% and  $V_{40\text{Gy}}$  for bladder of 8%. Moreover, a reduction of the planning time was obtained in RP plans.

### Conclusion

The suggested KB strategy for automatic planning in the case of ART early-regression guided boosting technique in neo-adjuvant radio-chemotherapy for rectal cancer was found to be satisfactory. The replacement of conventional planning is currently ongoing in our clinical activity.

### PO-0923 How can a limited number of proton slots be optimally used in combined proton-photon treatments?

S. Fabiano<sup>1</sup>, M. Bangert<sup>2</sup>, N. Andratschke<sup>1</sup>, M. Guckenberger<sup>1</sup>, J. Unkelbach<sup>1</sup>

<sup>1</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland; <sup>2</sup>German Cancer Research Center, Department of Medical Physics in Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

Currently, proton treatment slots are a limited resource. Combined proton-photon treatments, in which most fractions are delivered with photons and only a few with protons, may represent a solution to optimize the allocation of proton resources over a patient population. Nowadays, institutions performing combined treatments optimize intensity modulated radiation therapy (IMRT) and

proton therapy (IMPT) plans separately so that each modality delivers the prescribed dose per fraction to the target volume. The aim of this study is to demonstrate how both modalities can be combined to optimally exploit the protons' ability to reduce the integral dose in normal tissues, also addressing the issue of the robustness of combined treatments against proton range uncertainties.

### Material and Methods

We consider treatment sites (a spinal metastasis, a sacral chordoma, and an atypical meningioma) in which organs at risk (OARs) are located within or near the tumor. As an example, Figure 1 shows the spinal tumor case where the target volume entirely surrounds the cauda. Protection of the cauda requires fractionation in the planning risk volume (PRV). Hence, proton and photon fractions should deliver similar doses to this region. Meanwhile, the remaining target volume can be hypofractionated with protons. Such a proton-photon combination was planned by simultaneously optimizing IMRT and IMPT plans while accounting for the fractionation effect through the biologically effective dose (BED) model. A  $BED_{10}$  corresponding to 35.2 Gy in 5 fractions was prescribed to the target volume while limiting the maximum dose in the cauda to the  $BED_2$ -equivalent of 20 Gy in 5 fractions. Stochastic optimization was applied to mitigate range uncertainties.

### Results

Figure 1 illustrates an optimized combination with 1 IMPT and 4 IMRT fractions. Figures 1a and 1b show the IMRT and IMPT dose distributions per fraction. Figure 1c displays the cumulative equieffective dose (EQD) and shows that protons and photons together yield the prescribed BED to the target volume. Protons and photons deliver similar doses to the PRV to protect the cauda through fractionation. Meanwhile, parts of the tumor are hypofractionated with protons. Therefore, the total dose delivered with photons is reduced leading to a reduction of the integral dose to normal tissues. In fact, optimized combinations with 1 or 2 proton fractions achieve 63% and 84% of the integral dose reduction in normal tissues that a 5-fraction IMPT plan yields, compared to 20% and 40% for the simple combinations. However, combined treatments which are optimized without accounting for proton range uncertainties, are very sensitive to errors (Figure 2a). Stochastic optimization leads to robust combinations (Figure 2b) without compromising the benefit over simple combinations.

### Conclusion

A limited number of proton fractions is optimally used in combined proton-photon treatments if protons hypofractionate parts of the tumor while near-uniform fractionation is maintained in serial OARs.

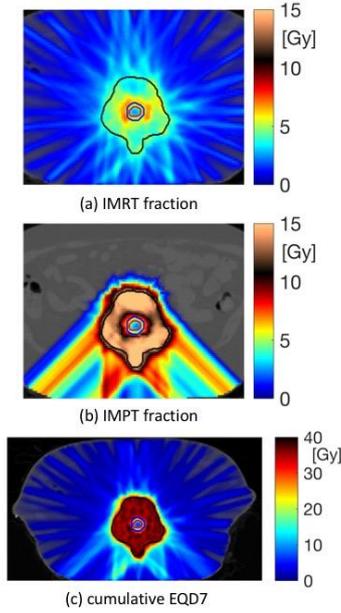

Figure 1: Optimized combined proton-photon treatment with 1 IMPT and 4 IMRT fractions. The contours show the target volume (black), the cauda (red), and the corresponding PRV (blue).

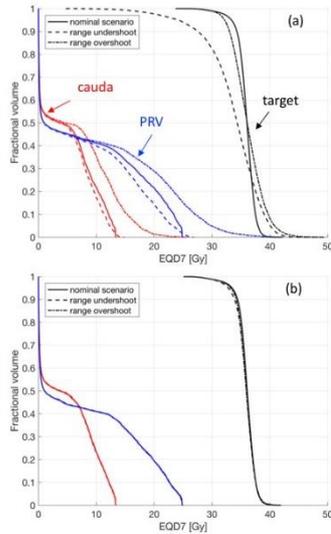

Figure 2: DVHs evaluated for EQD7 from the non-robust (a) and robust (b) optimized combinations with 1 IMPT and 4 IMRT fractions for 3 error scenarios. Range errors were modelled by uniformly scaling the CT Hounsfield units by  $\pm 5\%$ .

**PO-0924 Viability of standardized FFF VMAT TBI treatment plans for extended SSD delivery based on AP-width**

R. Frederick<sup>1,2</sup>, A. Hudson<sup>2,3</sup>, G. Pierce<sup>1,2,3</sup>  
<sup>1</sup>University of Calgary, Department of Physics and Astronomy, Calgary, Canada ; <sup>2</sup>Tom Baker Cancer Centre, Department of Medical Physics, Calgary, Canada ; <sup>3</sup>University of Calgary, Department of Oncology, Calgary, Canada

**Purpose or Objective**

Total body irradiation (TBI) treatments require a large radiation field that often necessitates delivery at an extended source-to-surface distance (SSD), resulting in supplementary set-up procedures that increase treatment

times and patient discomfort. This project aims to decrease planning and treatment time while attaining acceptable dose uniformity by designing stock TBI plans based on patient anterior-posterior (AP) width at umbilicus, and by evaluating the use of flattening filter free (FFF) delivery.

**Material and Methods**

Retrospective examination of 47 TBI patients receiving a prescription of 4Gy/2fx BID was completed using Varian Eclipse™. All patients were treated using our centre's clinical AP/PA VMAT technique at extended SSD with beam spoiler. Patients were stratified into 4 AP width categories: 17-19cm, 19-21cm, 21-23cm, and 23-25cm. The latter two groups were additionally sorted into either short or tall heights. To generate standard FFF VMAT TBI plans, the clinical TBI 6MV 40x10cm<sup>2</sup> open field arcs were used as the plan base with the beam energy substituted with 6MV FFF. Dose homogeneity was achieved through planning MLC leaf positions based on AP midplane lateral dose profiles at eight superior-inferior locations for three patients in each category, and calculated output factors. Custom Python™ code positioned the MLCs at their calculated locations. Two plans (supine, prone) were created for each category for a total of 12 standard plans, and applied to all patients depending on their categorization. The clinical and FFF TBI plans were compared by examining dose-volume histogram (DVH) parameters, dose rates, and beam-on times.

**Results**

Figure 1 presents DVH parameters for all patient categories for the clinical and FFF plans, and Table 1 lists the associated median (range) for each parameter. Significantly similar dose coverage (D98) is seen between the clinical and FFF plans, but the FFF plans have hotspot (D2) and mean lung dose (MLD) distributions that are significantly shifted higher compared to the clinical plans. This decreased dose uniformity still lies within acceptable clinical bounds, and is expected for the standardized FFF plans versus the clinical plans that are tailored to an individual patient. The presented DVH distributions and summarized plan parameters are representative of those for each AP-width category separately.

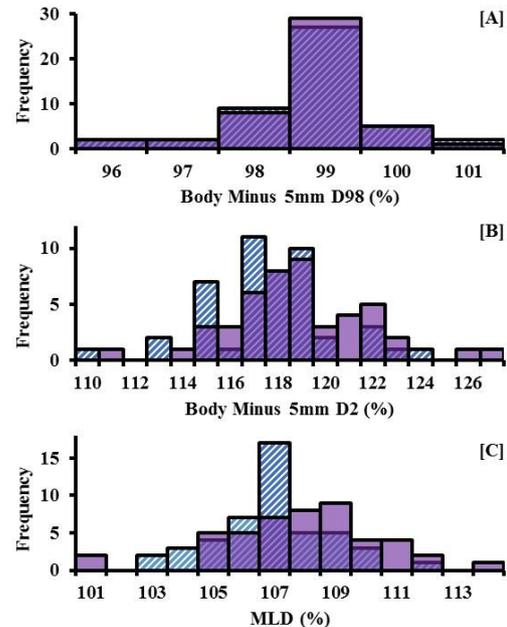

Figure 1. The distribution of clinical and FFF plan dose-volume histogram (DVH) parameters for all 47 patients. [A] Body Minus 5mm D98%, [B] Body Minus 5mm D2%, and [C] Mean Lung Dose (MLD) frequencies.

Table 1. Median (range) of dose-volume histogram (DVH) and various plan parameters for the clinical and FFF TBI plans. Statistical comparison between DVH parameter distribution medians was performed using the Wilcoxon Rank Sum Test. P-values indicating significantly different medians ( $\alpha = 0.05$ ) are bolded.

		Clinical TBI Plans	FFF TBI Plans	P-Value
DVH Parameters	Body Minus 5mm D98 (%)	98.200 (95.125 - 100.680)	98.200 (95.125 - 100.600)	0.9940
	Body Minus 5mm D2 (%)	117.525 (109.150 - 123.650)	118.375 (110.075 - 126.700)	<b>0.0434</b>
	MLD (%)	106.500 (102.275 - 111.350)	107.250 (100.800 - 113.350)	<b>0.0203</b>
Plan Parameters	Average Dose Rate at Midplane (cGy/min)	11.07 (9.85 - 12.24)	18.07 (15.78 - 20.66)	-
	Monitor Units (MU)	10837 (9803 - 12184)	15496 (13552 - 17744)	-
	Beam-On Time (min)	18.06 (16.34 - 20.31)	11.07 (9.68 - 12.67)	-

MLD: mean lung dose

Table 1 lists average dose rates, monitor units (MU), and beam-on times for the clinical and FFF plans for all patient categories. On average, the increase in dose rate and MU are 64.8% and 41.8% respectively for the FFF plans in comparison to the clinical plans. The decrease in beam-on time is 39.2% on average for the FFF plans.

#### Conclusion

The standard AP-width based FFF TBI plans yield a clinically acceptable dose homogeneity that is similar to our current clinical plans while reducing both planning and beam-on time. This technique therefore offers the possibility of decreasing the overall treatment time, and improving patient experience.

#### PO-0925 On the ability of a knowledge based planning process to improve itself

A. Fogliata<sup>1</sup>, G. Reggiori<sup>1</sup>, C. Franzese<sup>1</sup>, D. Franceschini<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>2</sup>, L. Cozzi<sup>2</sup>

<sup>1</sup>Humanitas Research Hospital, Department of Radiation Oncology, Milan-Rozzano, Italy; <sup>2</sup>Humanitas Research Hospital and Humanitas University, Department of Radiation Oncology and Faculty of Biomedical Science, Milan-Rozzano, Italy

#### Purpose or Objective

A knowledge based planning (KBP) engine generates a model from geometric and dosimetric data of a cohort of selected plans, in order to obtain mathematical parameters to estimate the possible DVHs of critical structures, according to the strategy adopted for the plans in the model. Those DVHs are used as optimization objectives for IMRT or VMAT planning for any new patient. As a machine learning process, the KBP is generally able to improve the plan quality. The aim of the present work is to determine if the KBP process RapidPlan (Varian, Palo Alto, CA) can improve itself, i.e. if plans generated by RapidPlan (improved in quality with respect to the clinical plans) can be the source to generate a new RapidPlan model to further improve the plan quality.

#### Material and Methods

Clinical VMAT plans from 83 patients presenting advanced head and neck cancer were selected to build a RapidPlan model. All the plans delivered prescription doses of 54.45 and 69.96 Gy to the elective and boost target volumes, respectively, in 33 fractions with simultaneous integrated boost. The optimization process was manual, using the PRO optimizer. The 83 clinical plans were used to generate a RapidPlan model, named HN-RP-1, using a defined and ad-hoc tuned list of objectives in the model. The HN-RP-1 model was then used to generate new plans for the same 83 patients as above, using the same plan geometry. Those new RapidPlan plans were the input of a new RapidPlan model, named HN-RP-2, having the same list of objectives as HN-RP-1.

A cohort of 20 patients was chosen from the institutional database to validate the two models, HN-RP-1 and HN-RP-2, to assess and compare their plan quality.

#### Results

The HN-RP-2 model presented an improved mathematical process relative to HN-RP-1, showing increased R<sup>2</sup> parameters: 0.634/0.541 (parotids), 0.866/0.599 (oral cavity), 0.756/0.534 (larynx), 0.731/0.204 (spinal cord) for HN-RP-2/HN-RP-1, respectively. Also the regression plots presented general improvements. Regarding the plan quality, D<sub>1%</sub> to the serial organs, spinal cord and brain stem, increased with HN-RP-2 model of 3-4%, not significant. All the parallel organs showed, on the contrary, an improvement with HN-RP-2 relative to HN-RP-1 model, in general around 1% (significant for some structures), with the larynx showing the highest mean dose reduction of 5% (p<0.01). The doses averaged over the 20 validation plans were: 26.3±0.8/26.5±0.8 Gy (parotid mean dose), 40.9±2.3/41.2±2.3 Gy (oral cavity mean), 27.5±2.1/29.0±2.0 Gy (larynx mean), 28.7±0.7/28.0±0.7 Gy (spinal cord D<sub>1%</sub>) for HN-RP-2/HN-RP-1.

#### Conclusion

A second model based on a previous model could improve the plan quality for the parallel organs at risk, and possibly the robustness of the model itself, considering the better mathematical parameters of HN-RP-2 relative to HN-RP-1.

#### PO-0926 A novel approach to automatic planning: robust templates for lung VMAT SBRT

L. Marrazzo<sup>1</sup>, C. Arilli<sup>1</sup>, S. Calusi<sup>2</sup>, M. Casati<sup>1</sup>, C. Talamonti<sup>1,3</sup>, P. Bonomo<sup>4</sup>, L. Livi<sup>3,4</sup>, S. Pallotta<sup>1,3</sup>

<sup>1</sup>Azienda Ospedaliera Universitaria Careggi, Medical Radiation Physics, Firenze, Italy; <sup>2</sup>Istituto Fiorentino di Cura e Assistenza, Medical Physics and Radiation Oncology, Firenze, Italy; <sup>3</sup>University of Florence, Department of Biomedical- Experimental and Clinical Sciences, Firenze, Italy; <sup>4</sup>Azienda Ospedaliera Universitaria Careggi, Radiation Oncology, Firenze, Italy

#### Purpose or Objective

To develop and validate a planning class solution for VMAT SBRT of lung lesions, that achieved target and organs-at-risk (OAR) doses within established constraints using the multicriterial optimization (MCO) of Monaco treatment planning system (Elekta-CMS Software, MO, USA).

#### Material and Methods

The template, containing a list of planning objectives, was first established on a population of 10 lung SBRT patients planned for 55Gy/5fr (peripheral lesions, near to or partly overlapped with the thoracic wall) and refined with a stepwise process. In order to account for anatomical changes between patients, so to achieve personalized results, stage 1 (ideal fluence optimization) was conducted giving priority to OARs and using the MCO. MCO further pushes OARs dose, stopping just before compromising target coverage. To improve gradient and conformity a ring structure around the PTV was set in the list of objectives. Stage 2 (segmentation) was conducted giving priority to PTV coverage. The template was then applied (with no manual intervention) on 20 further patients and the resulting plan was compared with the manual clinical plan. Dose distributions were compared in terms of dosimetric plan parameters (dose to PTV, conformity and gradient index and dose to OARs). Dosimetric verification was performed and evaluated in terms of  $\gamma$  passing rate and point dose measurements, in order to assess that the planned dose distribution could be reliably delivered. Statistical significance of differences between automatic and manual plans was evaluated using paired two-sided Wilcoxon signed-rank test.

#### Results

No statistically significant differences in PTV coverage (p=0.6) and PTV maximum dose (p=0.2) were observed,

while a statistically significant improvement was observed in gradient index ( $p < 0.01$ ) and Paddick conformity index ( $p = 0.01$ ). Data are presented in Table 1.

	PTV $V_{95}$ (%)	PTV $D_{95}$ (Gy)	GI	PCI	Chest wall $V_{30Gy}$	Total lung $V_{20Gy}$ (%)	Heart $D_{10cc}$ (Gy)	Esophagus $D_{50}$ (Gy)	Cord $D_{10cc}$ (Gy)	Cord $D_{1cc}$ (Gy)
MCO auto plan (AVG±SD)	98.0±1.2	59.6±0.4	4.9±0.6	0.83±0.08	22.6±12.7	5.6±3.1	10.5±7.9	9.0±6.0	8.7±4.9	8.1±4.4
Clinical plan (AVG±SD)	97.5±2.0	58.8±2.6	6.6±1.5	0.77±0.12	28.0±14.3	6.5±3.2	12.3±9.6	10.6±3.7	10.7±4.5	9.0±4.3
p	0.6	0.2	<0.01	0.01	<0.01	<0.01	0.2	0.3	0.02	0.2

Table 1. PTV parameters (dose, gradient and conformity) and OARs parameters for MCO auto and clinical manual plans.  $V_{95}$ =volume receiving 95% of the prescription isodose;  $V_{30}$ =volume receiving X Gy;  $D_{10cc}$ =dose to X cc of the considered organ; GI= Gradient Index= volume encompassed by the 50% of the prescription isodose/prescription isodose volume; PCI= Paddick Conformity Index= (target volume in the prescription isodose)/(target volume \* prescription isodose volume).

The improvement in gradient is due to the MCO effectively reducing the constraint on the ring around the PTV. An example of dose distribution is shown in Figure 1.

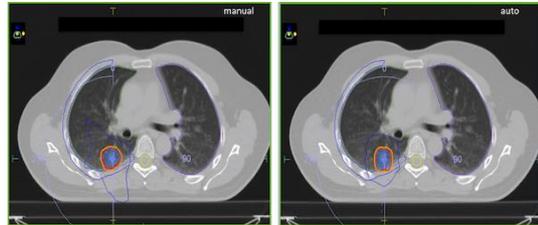

Figure 1. Comparison between manual (left) and automatic (right) dose distributions. In orange the prescription isodose, in blue the isodose relative to the 50% of the prescription isodose.

A general improvement in dose to OARs was observed (Table 1), that resulted to be statistically significant for chest wall  $V_{30Gy}$  and total lungs  $V_{20Gy}$  ( $p < 0.01$ ) and for cord  $D_{0.1cc}$  ( $p = 0.02$ ).

Even a small reduction in doses to OARs, although already below constraints, can be clinically significant in the light of patient retreatment.

Concerning dosimetric verifications, no statistically significant differences were observed in  $\gamma$  passing rates (3%, 3mm, TH10%, local), that were on average (95.4±0.1%) and (96.6±1.4%) for manual and MCO plans, respectively. No manual plan changes were required: all the 20 plans automatically generated were considered clinically acceptable. Average planning time was 10 minutes.

### Conclusion

This study describes a novel approach for automating the planning process and demonstrates the feasibility of developing a class solution for lung VMAT SBRT that produces clinically acceptable plans with a high conformity in a time-efficient manner.

### PO-0927 Lower dose to hippocampi and other OARs with IMPT than with VMAT and IMRT for skull-base meningiomas

M. Florijn<sup>1</sup>, A.W.M. Sharfo<sup>2</sup>, R.G.J. Wiggendaad<sup>3</sup>, J.P.C. Van Santvoort<sup>1</sup>, A.L. Petoukhova<sup>1</sup>, M.S. Hoogeman<sup>4</sup>, M.E. Mast<sup>3</sup>, M.L.P. Dirks<sup>2</sup>

<sup>1</sup>Haaglanden Medical Centre, Medical Physics, Leidschendam, The Netherlands; <sup>2</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands; <sup>3</sup>Haaglanden Medical Centre, Radiation Oncology, Leidschendam, The Netherlands; <sup>4</sup>Holland Proton Therapy Centre, Medical Physics & Informatics, Delft, The Netherlands

### Purpose or Objective

Meningiomas are considered benign in 90% of the cases. When surgery is not feasible radiotherapy (RT) is used, however potential late RT effects include neurocognitive impairment. Proton therapy might be beneficial, especially in case of larger target volumes, because of the steep dose fall-off beyond the target volume. In this study we applied fully automated treatment planning to systematically evaluate the dosimetric differences between intensity modulated proton therapy (IMPT), volumetric modulated arc therapy (VMAT) and intensity modulated radiotherapy (IMRT). The purpose of this study

was to minimize the dose in the organs at risk with specific focus on the hippocampi, while ensuring adequate target coverage.

### Material and Methods

Twenty skull-base meningioma patients with a target volume diameter of > 3 cm were included in this study. A dose of 28x1.8 Gy<sub>RBE</sub> was prescribed, in ten cases to the 100% isodose (conventional), in ten other cases to the 80% isodose (stereotactic). A system for fully automated plan generation was used to calculate a) a coplanar, dual arc VMAT plan, b) an IMRT plan with nine non-coplanar beams with optimized gantry and couch angle, c) an IMPT plan with three patient-specific selected non-coplanar beams. For all plans, the same set of constraints and prioritized objectives was used. The photon plans were generated with 2mm CTV-PTV margin; for IMPT a mini-max robust optimization was used with ±2mm setup and ±3.5% range robustness. For fair comparison, all plans were rescaled to the same target coverage, i.e., 98% of the PTV (IMRT/VMAT) and 98% of the CTV for the worst case robustness scenario (IMPT) should receive 47.88 Gy (conventional), or 50.4 Gy (stereotactic). For statistical comparison, a two-sided p-value ≤ 0.05 was considered statistically significant.

### Results

Compared to IMRT and VMAT, IMPT allowed for a much better dose conformity to the target volume (Figure 1). Consequently, large dose reductions in organs at risk were observed (Figure 2). In particular, with respect to IMRT, the mean dose and D40% in the bilateral hippocampus were on average reduced by 41% and 71% (conventional), and by 64% and 79% (stereotactic), respectively (ANOVA  $p \leq 0.02$ ). Emphasis on conformity during optimization led to a high benefit for the normal brain dose as well. With IMPT, the mean dose in the normal brain and the volumes receiving 10-30 Gy were 28-55% reduced (ANOVA  $p \leq 0.03$ ) compared to IMRT. Also the mean doses in the optic nerves, retina, cochlea, brainstem and cerebellum were significantly lower. When comparing IMPT and VMAT, even larger dose differences were observed, mainly due to the coplanar beam setup in VMAT.

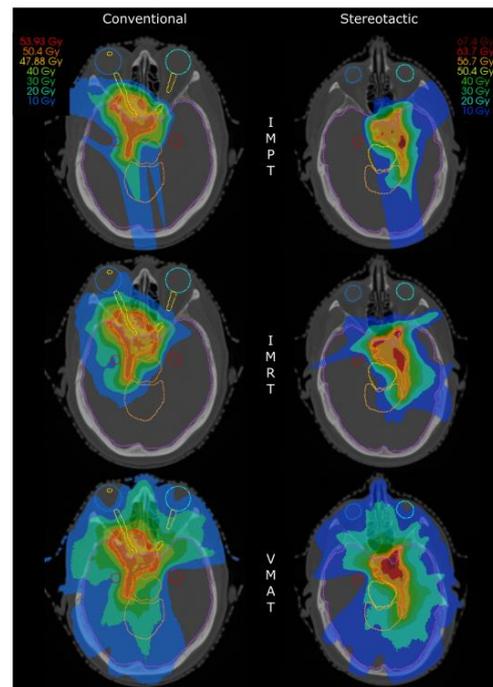

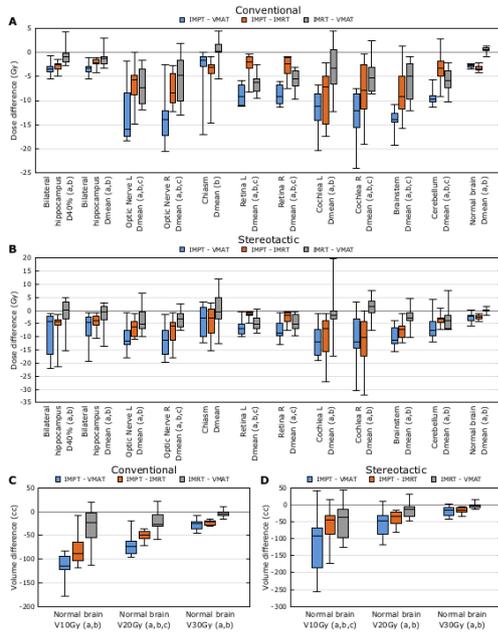

Figure 1. Example of dose distributions for one skull-base meningioma patient treated with conventional prescription (left) and one with stereotactic prescription (right) for IMPT, IMRT and VMAT.

**Figure 2** Differences in dosimetric values for organs at risk between IMPT and VMAT, IMPT and IMRT, and IMRT and VMAT. The central line of each box represents the median value for the 10 study patients with conventional prescription (A and C) and with stereotactic prescriptions (B and D), its upper and lower edge the 25th and 75th percentiles. The whiskers extend to the minimum and maximum differences per group. Negative values indicate lower dose for IMPT (blue/orange) or IMRT (grey); a, b and c indicate statistically significant differences ( $p < 0.5$ ) for IMPT vs VMAT, IMPT vs IMRT and IMRT vs VMAT, respectively.

**Conclusion**

For skull-base meningiomas IMPT allows for a considerable dose reduction in the hippocampi and normal brain compared to both IMRT and VMAT, which may lead to a clinically relevant reduction of late neurocognitive side effects.

**PO-0928 Treatment plan quality assessment for focal dose escalation in prostate cancer**

M. Van Schie<sup>1</sup>, T. Janssen<sup>1</sup>, D. Eekhout<sup>1</sup>, I. Walraven<sup>1</sup>, A. Kotte<sup>2</sup>, L. Kerkmeijer<sup>2</sup>, C. Draulans<sup>3</sup>, K. Haustermans<sup>3</sup>, R.J. Smeenk<sup>4</sup>, U. Van der Heide<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>3</sup>University Hospitals Leuven, Radiation Oncology, Leuven, Belgium ; <sup>4</sup>Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands

**Purpose or Objective**

In a multicenter randomized trial of focal prostate dose escalation up to 95 Gy was prescribed to the tumor in the dose escalation arm, with 77 Gy to the entire prostate in both arms. However, as the dose constraints to normal tissue surrounding the target volume were leading, we investigated what extent of dose escalation to the tumor was achieved.

In clinical practice, it can be challenging to assess whether a treatment plan is optimal in terms of achieved boost dose and dose to organs at risk (OARs). Therefore we developed a predictive model to identify treatment plans in which a higher boost dose could be achieved for the specific patient's anatomy. **Material and Methods**

We analyzed planning CT scans and clinical delineations together with co-registered planned dose distributions of 531 patients from 4 institutions. We compared dose characteristics for the standard and dose-escalated arms. For the latter we determined the percentage of plans with an  $D_{50\%}$  and  $D_{98\%}$  above 82.4 Gy (107 % of 77 Gy), and quantified the correspondence with prescribed dose using the following parameters:

- Quality Factor<sup>[1]</sup>:  $QF = 1/n * \sum |1 - D_{planned}/D_{prescribed}|$ ,

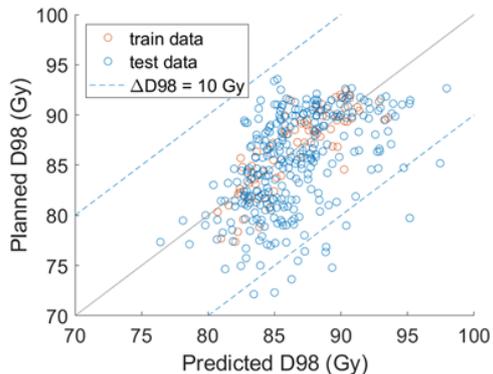

- Homogeneity Index<sup>[2]</sup> (CTV - GTV only):  $HI = (D_{2\%} - D_{98\%}) / D_{50\%}$ ,
- Conformation Number<sup>[3]</sup> (GTV only):  $CN = GTV_{95\%}/GTV * GTV_{95\%}/V_{95\%}$ .

Plans with above-median QF and HI and below-median CN were selected to train a linear regression model to predict  $D_{98\%}$  in the GTV using a 5-fold cross validation scheme. Training was performed on the first 3 principle components (PCs) per Overlap Volume Histogram (OVH) of PTV, GTV, bladder and rectum (in total 10 OVHs). Subsequently, the model was applied to the remaining plans to identify treatment plans with more than 10 Gy difference between planned and predicted dose in the GTV. **Results**

Dose-volume parameters are shown in Table 1.  $D_{50\%}$  and  $D_{98\%}$  were above the threshold of 82.4 Gy in 99 and 71% of the GTVs, respectively. We observed comparable bladder and rectum dose-volume parameters between both arms of the trial. Median QF and HI of all dose-escalated plans were 5.4% and 26.9%, median CN of all GTVs was 0.25. Seventy-eight out of 374 GTVs were selected to train both models. For  $D_{98\%}$  the best predictive model included 5 PCs. Eleven GTVs were identified with a planned  $D_{98\%}$  more than 10 Gy lower than predicted, corresponding with 9 treatment plans. Figure 1 displays the predicted versus planned  $D_{98\%}$  in the GTVs of both training and test data.

**Table 1.** Dose-volume parameters (median and 95% confidence interval) for PTV, CTV, GTV, Bladder and Rectum in the standard and dose-escalated arm.

Structure	Dose-volume parameters	Standard Arm (n = 271)	Study Arm (n = 260)	Constraints
PTV	$V_{95\%}$ (%)	98.3 (90.9 – 99.5)	97.1 (86.9 – 99.0)	> 99%
CTV - GTV	$D_{2\%}$ (Gy)	79.3 (77.5 – 81.1)	91.3 (83.1 – 95.5)	
	$V_{125\%}$ of 77 Gy (%)	2.5 (0.0 – 21.7)	28.1 (11.4 – 59.9)	
	$D_{98\%}$ (Gy)		84.7 (77.1 – 91.4)	
GTV	$D_{50\%}$ (Gy)		93.1 (84.9 – 95.4)	
	$D_{98\%}$ (Gy)		84.7 (77.1 – 91.4)	
	$V_{95\%}$ of 95 Gy (%)		78.2 (0.00 – 99.6)	
	$D_{2\%}$ (Gy)	75.5 (73.2 – 78.5)	76.3 (73.4 – 80.4)	
Bladder	$D_{2\%}$ (Gy)	74.7 (72.0 – 78.1)	75.2 (72.7 – 78.7)	
	$V_{125\%}$ (%)	4.2 (1.0 – 10.7)	4.8 (0.9 – 11.0)	< 10%
	$V_{150\%}$ (cm <sup>3</sup> )	0.0 (0.0 – 0.0)	0.0 (0.0 – 0.7)	< 1 cm <sup>3</sup>
	$D_{2\%}$ (Gy)	74.1 (72.4 – 75.8)	75.2 (72.2 – 78.0)	
Rectum	$D_{2\%}$ (Gy)	73.5 (70.7 – 75.2)	73.7 (71.0 – 76.1)	
	$V_{150\%}$ (%)	33.7 (12.8 – 62.1)	33.0 (17.3 – 59.1)	< 50%
	$V_{125\%}$ (%)	4.1 (1.6 – 8.1)	4.0 (1.6 – 7.2)	< 5%
	$V_{175\%}$ (cm <sup>3</sup> )	0.0 (0.0 – 0.2)	0.3 (0.0 – 1.5)	< 1 cm <sup>3</sup>
	$D_{2\%}$ (Gy)	74.7 (72.0 – 78.1)	75.2 (72.7 – 78.7)	

**Figure 1.** Predicted versus planned  $D_{98\%}$  of the training (orange) and test data (blue). Dotted lines indicate a dose difference of 10 Gy.

**Conclusion**

In this study we observed that a relevant dose escalation above 82.4 Gy was realized in the majority of patients. Meanwhile we showed no differences in OAR dose between both arms of the trial. Although limited dose escalation to a large extent can be assigned to unfavorable anatomy, we developed a model that identified treatment plans where nonetheless a higher boost dose was predicted to be achievable.

### PO-0929 Focal boost dose escalated prostate SBRT on the Halcyon fast-rotating O-ring linac

R. De Roover<sup>1</sup>, W. Crijns<sup>1</sup>, S. Michiels<sup>1</sup>, C. Draulans<sup>1</sup>, K. Poels<sup>1</sup>, K. Haustermans<sup>1</sup>, T. Depuydt<sup>1</sup>

<sup>1</sup>Catholic University of Leuven, Department of Oncology, Leuven, Belgium

#### Purpose or Objective

A commercially available fast-rotating O-ring linac, Varian Halcyon (HA), has been shown to improve the time-efficiency of conventionally fractionated volumetric modulated arc therapy (VMAT). The dual-layer multi-leaf collimator's (MLC) 10 mm leaf-width, however, may limit its use for stereotactic body radiotherapy (SBRT). In this study, HA is compared with a SBRT-dedicated C-arm linac for the planning and delivery of focal boost dose escalated prostate SBRT.

#### Material and Methods

Sixteen patients with intermediate or high risk prostate cancer were planned for whole-gland prostate SBRT with a focal boost to the macroscopic tumor using VMAT. Prescription was 35 Gy to the prostate (PTV<sub>prostate</sub>), 30 Gy to the seminal vesicles (PTV<sub>sv</sub>), and 40 Gy to the focal boost (GTV<sub>boost</sub>) in 5 fractions. The GTV<sub>boost</sub> should be aimed to receive up to 50 Gy as long as the organ at risk (OAR) sparing is not at risk. Plans were generated for HA using 6MV flattening filter free (FFF) dual arc (HA2) and triple arc (HA3) VMAT. Field shaping was performed by both MLC layers independently (10 mm leaf-width, with a 5 mm offset between the staggered layers). The collimator angles were 10°/80° and 10°/45°/80° for dual arc and triple arc respectively. For comparison, plans were generated on a Varian TrueBeam STx (2.5 mm leaf-width) using 6MV dual arc (TB2) VMAT, with collimator angles 10°/80°. The Photon Optimizer and Anisotropic Analytical Algorithm were used in Varian Eclipse (v15.6) for each plan. Identical optimization objectives were used for each plan within a patient. Plans were normalized to 35 Gy covering 95% of PTV<sub>prostate</sub>.

PTV coverage and OAR sparing were compared between HA2, HA3 and TB2 using a two-sided Wilcoxon matched-pairs signed-rank test. Pre-treatment quality assurance (QA) was performed using portal dosimetry using a 2%(local)/2mm gamma evaluation with a low dose exclusion threshold set to 20% of the prescribed dose. The time needed to deliver the plans in auto-sequencing mode was recorded.

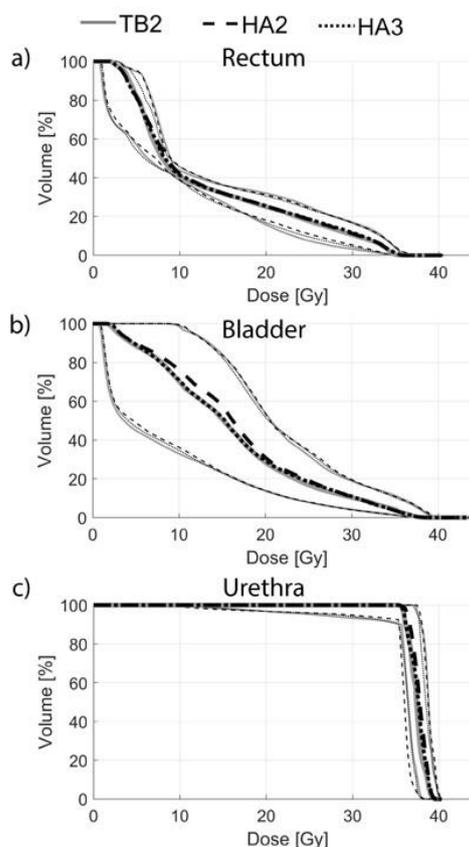

#### Results

Median target coverage, OAR doses and plan properties are compiled in Table 1. Figure 1 shows the median dose-volume histogram for a selection of OARs. Both HA2 and HA3 achieved similar target coverage and focal boost dose escalation compared to TB2. All OAR doses were well within our clinical criteria. Similar urethral sparing was obtained for HA2 and HA3 compared to TB2. Increased D<sub>max</sub> to rectum and bladder was observed for HA2 and HA3 (median increase of 0.6 Gy and 0.4 Gy respectively). The median plan delivery time was reduced with of 34 sec and 16 sec for HA2 and HA3, respectively. All plans passed pre-treatment QA with gamma agreement scores above 94.6%.

**Table 1.** Target coverage, OAR doses and plan properties for the studied patient population (N = 16). The median values are shown together with the minimum and maximum value within brackets. HA2 and HA3-results yielding p < 0.05 for a two-sided Wilcoxon matched-pairs signed-rank test compared to TB2 are indicated in bold.

		TB2	HA2	HA3

Abbreviations: OAR = organ at risk; TB2 = VMAT on a Varian TrueBeam STx using 2 arcs, HA2 & HA3 = VMAT on a Varian Halcyon using 2 and 3 arcs respectively; QA = quality assurance; γAS = gamma agreement score.  
<sup>a</sup>maximum point dose (D<sub>max</sub>) defined as the dose at 0.035 cc volume.  
<sup>b</sup>different absolute dose calibrations were used for both systems: 1 MU corresponds to 0.8 cGy for TB and 1.0 cGy for HA, both delivered at 10 cm depth by a 10 × 10 cm<sup>2</sup> field at 90 cm source-surface distance.  
<sup>c</sup>gamma analysis was performed using 2%(local)/2mm gamma criteria and a low dose exclusion threshold set to 20% of the prescribed dose.

**Figure 1.** Dose-volume histogram for a selection of organs at risk for the three VMAT solutions. Median DVHs and the DVH range (minimum to maximum DVH) are computed over the whole studied patient population (N=16).

#### Conclusion

Compared to a SBRT-dedicated C-arm linac, HA achieved clinically comparable quality for focal boost dose escalated prostate SBRT planning. This study demonstrates the potential of a mainstream fast-rotating O-ring linac to deliver increasingly used prostate SBRT treatments.

### PO-0930 Knowledge-based planning of head and neck cancer; comparisons of target and normal tissue parameters

A.I.S. Holm<sup>1</sup>, L. Kaplan<sup>1</sup>, U.V. Elstrøm<sup>1</sup>, S.S. Korreman<sup>2</sup>  
<sup>1</sup>Aarhus University Hospital, Department of oncology, Aarhus C, Denmark ; <sup>2</sup>Aarhus University Hospital, Department of oncology and Danish Center for Particle Therapy, Aarhus C, Denmark

**Purpose or Objective**

Knowledge-based planning (KBP) has the potential to improve plan quality. We have recently implemented KBP (Rapidplan, Eclipse, Varian Medical Systems), in our clinic. Here we report on comparison between non-KBP and KBP treatment plans for advanced head and neck cancer (HCN) patients.

**Material and Methods**

The KBP model was validated on twenty HNC patients. Three target volumes (TV) are covered by a SIB plan, with prescribed doses (PD) of 66Gy (PTV1), 60Gy (PTV2) and 50Gy (PTV3). Two planning strategies were applied: one with optimization parameters from a generic HNC template and one with patient specific KBP optimization parameter. All plans were three-arc VMAT plans. The two plans were compared using quantitative metrics for target coverage, homogeneity and conformity, steep dose fall-off at PTV1, Integral dose, low-dose bath and mean doses to the brainstem, salivary glands, oral cavity, lips, thyroid, and swallowing structures. P-values were calculated using Wilcoxon signed rank test with  $p < 0.05$  considered significant.

**Results**

Target parameters are shown in fig. 1. No differences were observed for target coverage (data not shown). Target homogeneity was slightly higher for KBP than non-KBP plans. Three out of the four metrics for target conformity show that at least PTV1 and PTV3 are less conformal for KBP than non-KBP. The steep dose-fall of PTV1 is higher for KBP than non-KBP. Comparisons for normal tissues are shown in fig. 2. Using KBP decreases the mean doses to the pharyngeal constrictor muscles (PCM), the glottis larynx and the thyroid gland, whereas the remaining OAR mean doses remain unchanged. The volumes receiving 10 Gy and 15 Gy are decreased by KBP and the integral dose decreases slightly from 127.0J [min: 54.0J; max: 226.3J] to 126.0J [52.9J; 224.1J] by KBP (p-value: 0.018).

Fig. 1. Comparisons of target parameters. Non-KBP data are given in red and KBP data in blue. All values are mean values with error bars showing the maximum and minimum values. Between two bars the corresponding p-value is given and significant differences are framed by green boxes. The specific target parameter and its corresponding definition are given in the labels below.

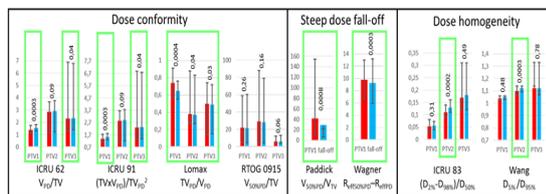

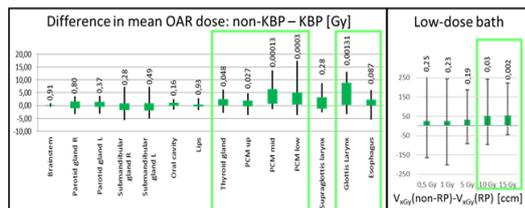

Fig. 2. Comparisons of normal tissue parameters: mean doses to OAR and low-dose bath. All data are given as differences between the non-KBP and KBP plans. Mean doses to OAR in a box-plot, with the 1<sup>st</sup> and 3<sup>rd</sup> quantile, and maximum and minimum values. For the low-dose bath values are given as mean values with error bars showing the maximum and minimum values. Above the data the corresponding p-value is given and significant differences are framed by green boxes.

**Conclusion**

KBP gives similar target coverage as previously accepted clinical plans, with the advantage of reducing the mean doses to a number of OAR, slightly lowering the volume receiving 10 Gy and 15 Gy as well as the integral dose. Since the conformity of PTV3 is decreased, the OAR benefits are due to the steeper dose gradient.

**PO-0931 Application of a thin, energy-layer specific multi-leaf collimator for proton pencil beam scanning.**  
C. Winterhalter<sup>1,2</sup>, G. Meier<sup>1</sup>, D. Oxley<sup>1</sup>, D.C. Weber<sup>1,3,4</sup>, A. Lomax<sup>1,2</sup>, S. Safai<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland ; <sup>2</sup>ETH Zurich, Physics Department, Zurich, Switzerland ; <sup>3</sup>University Hospital of Zurich, Radiation Oncology Department, Zurich, Switzerland ; <sup>4</sup>University Hospital of Bern, Radiation Oncology Department, Bern, Switzerland

**Purpose or Objective**

For pencil beam scanning (PBS) proton therapy, lateral fall-off has been shown to be inferior when compared to passive scattering proton therapy. For shallow tumours adjacent and close to critical structures, this might lead to unnecessary high doses to organs at risk. As such, collimation could potentially improve PBS proton dose distributions.

**Material and Methods**

For four patients with tumours located close to the brainstem, we have investigated the potential advantages of the use of a thin, multi-leaf collimator for energy-level specific collimation. By thin, we mean a collimator with a thickness just sufficient to stop protons with ranges in water of up to 15 cm, beyond which lateral penumbra is anyway determined by scattering in the patient. Additionally, two different pencil beam placement techniques - rectilinear grids (4 mm spacing, clinical approach) or contour scanning - have been analysed with and without collimation using different expansions for the contour scanning scenarios (0mm, 1mm, 2mm, 3mm, see Meier et al (Phys. 2017 Med. Biol. 62; 2398)). For the optimization process, both collimated and un-collimated pencil beams have been included in an analytical dose calculation, but all final dose distributions have been calculated using Monte Carlo (TOPAS).

**Results**

Figure 1 shows the improvement in penumbra when moving from grid to collimated contour scanning for an example patient field. For this case, grid scanning combined with collimation reduced the V30% outside the target by 20% in comparison to the un-collimated grid scenario. For contour scanning alone, a maximal V30% reduction outside the target of 26% was achieved (0mm contour expansion) which increased to 33% with collimation (2mm contour expansion). These improvements however come at the cost of reduced target dose homogeneity. As such, the best un-collimated/collimated dose distributions (i.e. scenarios retaining dose homogeneity while reducing dose to the normal tissue) were achieved with a 1mm/3mm contour expansion, without and with collimation respectively (c.f. figure 1). Finally, for four patients, collimated (shallow) and un-collimated (deep) fields have been combined and compared to the best un-collimated approach (Table 1), showing that the use of a collimator could reduce the V30% by 0.8-8.0% and the mean dose to the brainstem by 1.5-3.3% for such combined plans.

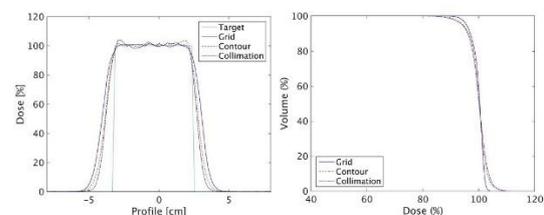

Figure 1: Example profiles in the patient geometry (a) and dose volume histogram for the target volume (b) for the clinical grid scanning (blue), the uncollimated contour scanning (contour extension 1 mm, red), and the collimated contour scanning (contour extension 3 mm, black)

	P 1	P 2	P 3	P 4
Collimated/total fields	3/3	2/3	1/3	2/4
V30	-7.9%	-8.0%	-0.9%	-0.8%
Mean dose to brainstem	-2.1%	-3.3%	-3.1%	-1.5%

**Table 1:** For four patients, V30 (doses outside the target) and mean dose to the brainstem are compared between the best collimated and the best uncollimated plan. All values are given in percentage of the uncollimated result, and negative values indicate a reduction when applying collimation.

### Conclusion

For patients treated in the cranium region, MC simulations of the use of a thin, energy-layer specific multi-leaf collimator have shown to lower doses to normal tissues in comparison to grid and un-collimated contour scanning, especially the brainstem. Best dose results are obtained when combining collimation with pencil beam placements following the target contour. Further improvements are expected either by improving the model in the optimization and/or by using different contour expansions within the same field, or even optimizing the expansion and beam placement itself.

### PO-0932 Identification of modes of tumour changes in NSCLC during radiotherapy

L.M. Amugongo<sup>1</sup>, E. Vasquez Osorio<sup>1</sup>, A. Green<sup>1</sup>, D.

Cobben<sup>1</sup>, V.H. Marcel<sup>1</sup>, A.M. Alan<sup>1</sup>

<sup>1</sup>University of Manchester, Division of Cancer Sciences- Faculty of Biology- Medicine and Health- University of Manchester, Manchester, United Kingdom

### Purpose or Objective

Cone-beam computed tomography (CBCT) is routinely used to set up and verify patient position during radiotherapy (RT) of non-small cell lung cancer (NSCLC) patients. CBCT images can be used to assess tumour changes during RT. This information is currently used qualitatively to inform treatment adaption. However, uncertainty exists regarding the mode of tumour change (elastic or non-elastic) and therefore the safety of adapting treatment. This study introduces a novel approach based on shells around the tumour boundary to automatically distinguish different modes of tumour change.

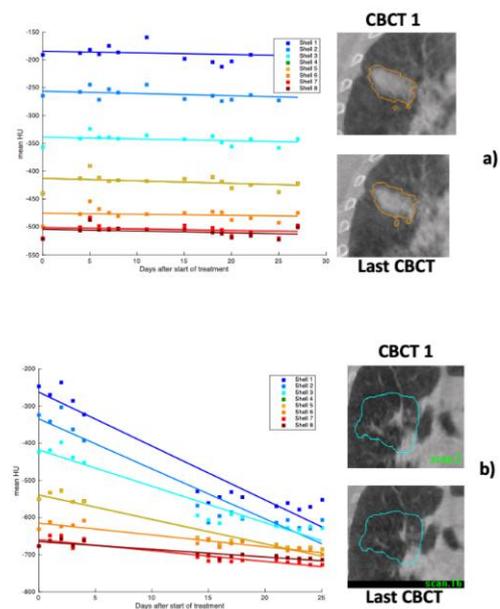

### Material and Methods

CBCT images of 80 NSCLC patients were collected and registered to the planning CT scan using a two-step alignment process. (1) Rigid registration of the bones to remove gross translation and rotations; (2) Localised soft tissue registration, translation only, on a slightly expanded gross tumour volume (GTV). Intensity normalisation was then applied to the CBCTs. Eight shells, 1mm thick and extending 4 mm inwards and outwards from the planning CT GTV surface, were created. The external shells were constrained to the lung/tumour boundary. Typically, shells 1-3 describe gross target volume changes, 4-5 tumour/lung boundary changes and 6-8 show changes to the local lung tissue. From each shell, the mean intensity was extracted across all normalized CBCTs. Linear fits of the mean intensities for each shell were plotted. Affinity propagation, an unsupervised clustering method, was used to explore whether modes of tumour change could be identified based on the gradients of these fits.

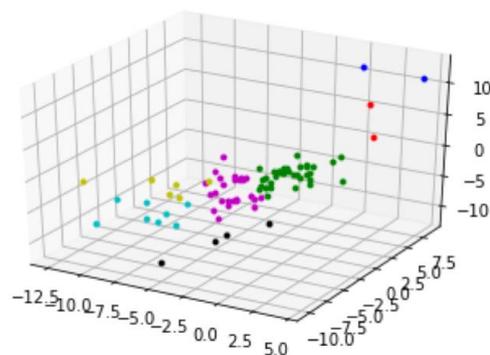

### Results

All CBCTs were successfully registered to the planning CT scan and shells were visually verified to ensure they avoided mediastinum/chest wall. Distinct modes of tumour changes could be seen in the intensity gradients of the CBCT. The majority of patients showed small density changes during the course of treatment (figure 1a), but some showed large changes (figure 1b). Affinity propagation clustered the patients into 7 groups, shown in

figure 2, suggesting definite modes of tumour shrinkage can be identified from our approach.

**Fig 1:** Example of patient with little changes a) and patient with major density changes b).

**Fig 2:** Clustering based on slope of density of shells inside, at the border and outside of the target volume as observed in different patients.

### Conclusion

Our novel methodology automatically identified distinct modes of tumour changes for lung cancer patients from routine on-treatment CBCT imaging. Future work will include more patients, to optimise the clusters, identify and validate the mode of change for each group, e.g., related to histopathology.

### PO-0933 Single isocenter SRS for multiple brain metastases: dosimetric comparison of DCAT and VMAT

J. Hofmaier<sup>1</sup>, R. Bodensohn<sup>1</sup>, S. Garny<sup>1</sup>, M. Reiner<sup>1</sup>, M. Eder<sup>1</sup>, Y. Dinc<sup>1</sup>, S. Corradini<sup>1</sup>, C. Belka<sup>1,2</sup>, M. Niyazi<sup>1</sup>  
<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>German Cancer Consortium DKTK, partner site Munich, Munich, Germany

### Purpose or Objective

For a long time whole brain radiotherapy (WBRT) has been the only treatment option for multiple cerebral metastases whereas a few lesions (usually up to four) were treated with SRS. In the recent decade SRS has become an option also for patients with more lesions. The Elements™ Multiple Brain Mets SRS (MBMSRS) tool (Brainlab, Munich, Germany) enables the simultaneous treatment of up to 15 metastases on LINACs with a single isocenter using non-coplanar dynamic conformal arcs (DCAT). This study compares the dosimetric properties of this technique with non-coplanar volumetric modulated arc therapy (VMAT) (Elekta Monaco®).

### Material and Methods

Datasets of 20 patients with a total of 66 lesions who were treated with MBMSRS version 1.5 at an Elekta Versa HD™ were included in this comparison. A single fraction dose of 15-20 Gy was prescribed to the 80% isolevel encompassing 98% of the PTV (GTV plus a margin of 1mm). All patients were re-planned using VMAT in Elekta Monaco® 5.11. For all plans, the total number of monitor units and the volume of the brain receiving more than 4, 5 and 8 Gy were compared using the Wilcoxon signed rank test (WSRT). Using a density based clustering algorithm, dose clouds of 10 Gy, 12 Gy and half of the prescription dose were identified and assigned to the corresponding lesion. The V10Gy and V12Gy around each lesion were compared using WSRT. Targets with overlapping 10 Gy clusters were joined and treated as one lesion (2 lesions joined: 5 times, 3 lesions joined: once). Paddick conformity index and gradient index (GIPTV) were calculated and compared only for lesions which could be separated in the clusters corresponding to their half prescription dose. To identify a possible predictor for VMAT being superior, the correlation of the differences between V10Gy and V12Gy for both techniques with the sphericity (a measure of similarity to a perfect sphere) of the corresponding PTV was assessed using Spearman's rank correlation coefficient.

### Results

The MBMSRS plans showed superior results in all the investigated metrics (see Table 1). All differences were significant ( $p < 0.05$ ). A moderate correlation of the difference of the V10Gy and V12Gy between the two techniques with the PTV sphericity (Spearman's rho = 0.27 and 0.30, for V10Gy and V12Gy, respectively and  $p < 0.05$  for both parameters) was found. Lesions with higher sphericity tended to have a better healthy brain sparing with MBMSRS.

	MBMSRS DCAT median (range)	#plans MBMSRS superior	Monaco® VMAT median (range)	#plans VMAT superior	P (Wilcoxon SR)
<b>Plan data N=20</b>					
Cumulative MU	4569 (3543-7790)	17	5840 (4089-10769)	3	<0.05
V4Gy (brain) [ccm]	45.6 (18.5-215.9)	19	123.1 (37.5-418.6)	1	<0.05
V5Gy (brain) [ccm]	33.7 (13.0-120.5)	19	69.1 (26.0-273.6)	1	<0.05
V8Gy (brain) [ccm]	17.4 (6.3-52.6)	19	26.6 (10.6-86.4)	1	<0.05
<b>PTV data N=59</b>					
V10Gy (healthy brain) [ccm]	3.2 (0.4-19.3)	55	4.9 (1.0-19.9)	4	<0.05
V12Gy (healthy brain) [ccm]	2.1 (0.1-13.1)	53	3.1 (0.5-13.9)	6	<0.05
<b>PTV data without overlapping N=53</b>					
Paddick CI	0.75 (0.58-0.89)	30	0.73 (0.38-0.88)	22	<0.05
GIPTV	5.99 (3.50-15.73)	48	7.17 (3.35-33.00)	5	<0.05

Table 1 - Investigated metrics for the 20 treatment plans, the 59 lesions and the 53 lesions for which the target indices were computed.

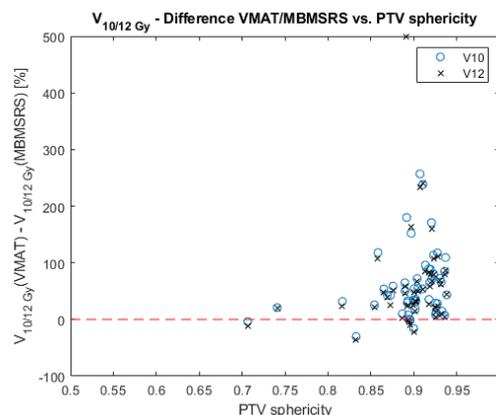

Fig. 1 - Difference in V10Gy and V12Gy scattered against the sphericity of the respective PTV. A sphericity value of 1 corresponds to a perfect sphere, values <1 to shapes deviating from a sphere.

### Conclusion

In most cases, MBMSRS can generate plans with steeper dose gradients, superior healthy brain sparing and less MU as compared to VMAT. In particular cases where the shape of the treated lesions deviates substantially from a sphere, VMAT can be superior.

**PO-0934 Physical and biological doses with increasing number of proton beams for pediatric brain irradiation**  
 L. Toussaint<sup>1</sup>, D.J. Indelicato<sup>2</sup>, K.S. Holgersen<sup>1</sup>, J.B.B. Petersen<sup>1</sup>, C.H. Stokkevaag<sup>3</sup>, Y. Lassen-Ramshad<sup>4</sup>, O. <sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark; <sup>2</sup>University of Florida Health Proton Therapy Institute, Department of Radiation Oncology, Jacksonville, USA; <sup>3</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway; <sup>4</sup>Danish Center for Particle Therapy, Department of Oncology, Aarhus, Denmark; <sup>5</sup>Instituto Português de Oncologia Francisco Gentil, Department of Radiotherapy, Lisbon, Portugal; <sup>6</sup>Aarhus University, Department of Biomedicine, Aarhus, Denmark; <sup>7</sup>Aarhus University Hospital, Department of Pediatrics, Aarhus, Denmark

### Purpose or Objective

Dose conformity and normal tissue sparing of photon-based radiotherapy has improved considerably with the introduction of arc delivery techniques. The concept of proton arc therapy is just becoming commercially/clinically available. Besides the potential for improved physical dose conformity, proton arc therapy might also lessen the concern of elevated linear energy transfer (LET) and relative biological effectiveness (RBE) at the end of the proton range. The aim of this project was therefore to simulate the effects of proton arc therapy for pediatric brain irradiation with respect to dose coverage and conformity, including LET-weighted biological doses.

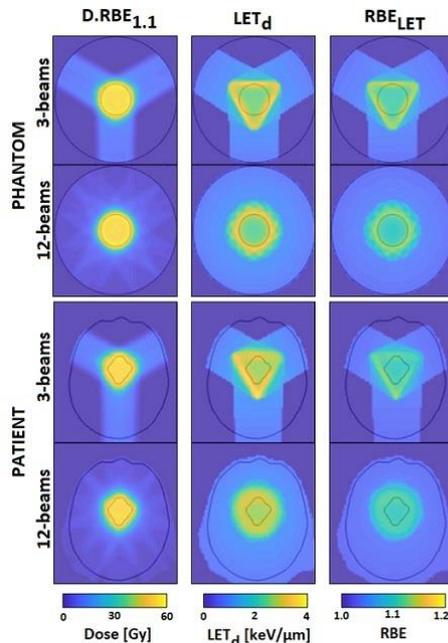

### Material and Methods

Two cylindrical phantoms were used to create a series of treatment plans with varying number of equiangular coplanar beams (2, 3, 4, 6, 8, 10 and 12), where a dose of 54 Gy was prescribed to a cylindrical target. CTs and target volume delineations of three pediatric brain tumor patients were used to construct plans with 3, 6 and 12 equiangular coplanar beams. Doses delivered to a large

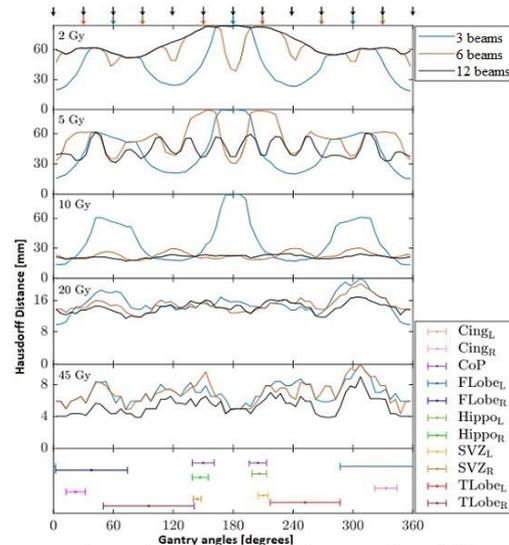

number of manually segmented brain structures associated with cognition were evaluated. Conformity relative to the target was assessed by using both the Conformity Index (CI) and Hausdorff Distance (HD) for multiple isodose levels in both the phantoms and patients. Biologically corrected dose distributions were calculated and compared across plans using two RBE strategies: (1)  $RBE_{1,1}$ , corrected assuming uniformly 10% higher effectiveness of the proton plans, and (2)  $RBE_{LET}$ , calculated using a LET/RBE research script (Eclipse treatment planning system), with the LET distributions normalized to achieve an average  $RBE_{LET} = 1.1$  within the target.

### Results

The CI improved in the phantom plans with up to six beams while no further benefit was observed with larger number of beams. The 3-beam plans showed high-LET and high-RBE regions at the distal edge of each beam while the 12-beam plans resulted in a more uniform distribution of LET and RBE, with the RBE closer to 1.1 (Fig. 1). Similar patterns were seen in both phantoms and patients. Compared to the 3-beam plans, the 12-beam plans had approximately 2 mm lower HD between the target and the 45 Gy isodose surfaces in all directions. The plans with increased number of beams had a more uniform HD between the target and intermediate dose surfaces (10 and 20 Gy) across all directions while the corresponding HD for the 3-beam plans were highly depending on beam direction. The 3-beam plans had the smallest low-dose 'bath' (at 2 and 5 Gy; Fig. 2).

**Figure 1:** Biological dose distributions calculated using an RBE of 1.1 (left column), the LET distribution (central column) and the LET-based RBE distribution calculated as  $1 + c \times LET$ , for plans using three (first row) and twelve beams (second row) in both a phantom (top panel) and a patient (bottom panel). The high-LET patterns are more evident in the phantom plans since these were optimized with only generic normal tissue constraints while the patient plans were optimized using several specific constraints for a range of organs at risk.

**Figure 2:** The Hausdorff Distance between the target surface and different isodose surfaces (2, 5, 10, 20 and 45 Gy) as a function of the gantry direction for the treatment plans indicated by the arrows on top of the panel: three beams (blue), six beams (orange) and twelve beams (black). The bottom panel shows the extensions of the different OARs in the central plane of the beam's eye view as a function of the gantry angles, showing e.g. the cingulum (Cing), Circuit of Papez (CoP), frontal lobes (FLobe), hippocampus (Hippo) and temporal lobes (TLobe).

### Conclusion

The *physical* conformity at high-dose levels in both phantom and patient plans improved when adding up to six fields, suggesting a potential for proton arc therapy. Increasing the number of beams also resulted in more uniform *biological* dose distributions, due to the reduced high-LET volumes. However, increasing the number of beams also enlarged the low-dose 'bath' (<5 Gy) with possible implications for secondary cancer risks.

### PO-0935 Implementation of an in-house solution for motion management-based treatment planning

D. Dechambre<sup>1</sup>, A. Delor<sup>1</sup>, F. Vanneste<sup>1</sup>, X. Geets<sup>1</sup>  
<sup>1</sup>Cliniques Universitaires Saint-Luc, Radiotherapy department, Brussels, Belgium

### Purpose or Objective

No commercial system provides an approach to 4DCT treatment planning with mid-ventilation (MidV) or mid-position (MidP) as respiration-induced target motion strategies. Therefore clinics have to develop their own and often complicated solution using mostly third party software (e.g. Reggui). The aim of this study was to evaluate the feasibility of using an in-house treatment planning system-based (TPS) script to replace, simplify and automatize our current and complex MidP workflow.

### Material and Methods

Scripting was edited in RayStation (RS) system v8 using IronPython v2.7. A graphical user interface (GUI) was designed using XAML which allows for flexible and interactive data visualization.

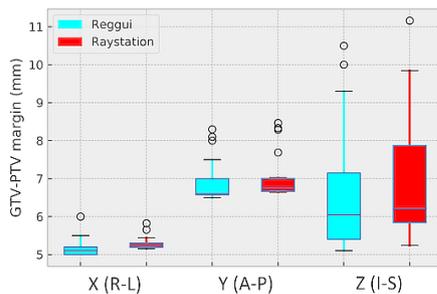

Prior GTV delineation was performed on a single 4DCT phase. Hybrid deformable registration was processed with the remaining phases and the resulting displacement fields were used to map the tumour contour. Given the impossibility to reconstruct the MidP CT from RS using diffeomorphic deformations, MidV-like approach was developed where the selected 4DCT phase minimizes the 3D vector between GTVs and MidP centers of mass (CoM). Chosen MidV\_GTV is then transferred onto the time-average CT and translated to the MidP CoM coordinates, correcting for the hysteresis movement within the GTV rigidity hypothesis. Corresponding 4DCT phase was used for the organs-at-risk delineation.

To validate the methodology, twenty consecutive lung SBRT cases treated in our institution were retrospectively

processed using the RS script. Spatial and volumetric comparison of the resulting PTV was performed against the Reggui-generated one. Statistical significance was assessed using a paired t-test at a 0.05 significance level.

### Results

Patient population consisted in 15 peripheral and 5 central lesions with average 3D motion vector of 10.2 (SD 6.6) mm. The spatial position of the gravity centre showed no statistical differences (<0.1mm) between the Reggui and RS-based PTV. While the script-generated target volume was systematically larger by an average value of 0.42 (0.85) cc ( $p<0.05$ ), the GTV to PTV margin was found significantly larger only in the right-left and anterior-posterior direction by an average of 0.1 (0.1) mm and by 0.2 (0.5) mm in inferior-superior (Figure 1).

### Conclusion

MidP-like solution was successfully integrated into the treatment planning system using built-in scripting capabilities. Hence, workflow was simplified while user inputs and manual interventions were minimized. The development of a tumour deformation handling solution is currently ongoing.

### PO-0936 To be or not to be homogeneous in SBRT plans? a systematic multi-planning study

P. Mancosu<sup>1</sup>, G. Reggiori<sup>1</sup>, A. Gaudino<sup>1</sup>, F. Lobefalo<sup>1</sup>, L. Paganini<sup>1</sup>, V. Palumbo<sup>1</sup>, A. Stravato<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1,2</sup>

<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Oncology, Rozzano Milan, Italy; <sup>2</sup>Humanitas University, Biomedical Sciences, Rozzano Milano, Italy

### Purpose or Objective

In stereotactic body radiation therapy (SBRT) delivered with modulated plans, two opposing approaches could be followed. ICRU 83 recommends to normalize modulated plans at mean dose to the target (homogeneous approach - HOM). AAPM WG 101 recommends to normalize SBRT plans at a specific isodose (inhomogeneous approach - INH). The new ICRU91 for stereotactic treatments does not recommend an explicit normalization but it advises to report doses at near maximum (D2%), minimum (D98%) and mean dose to the target. In this study, a systematic study on the dosimetric effect of the two approaches was performed.

### Material and Methods

Four patients were randomly selected by the internal database of candidates to lung SBRT. Internal Target Volume (ITV) was generated as the union of clinical target volumes (CTV) contoured on 4D-CT series. Planning target volume (PTV) was defined as ITV+5mm in the 3 directions. Volumetric modulated arc therapy (VMAT) plans were optimized by seven experts who performed two different plans on each patient: HOM (normalization at mean dose to PTV; objectives: CTV-V98%>98%, PTV-V95%>95%, PTV-V105%<5%, hotspots only inside ITV) and INH (normalization at PTV-V98%=98%; objectives: PTV-D2%<150%, PTV-D2%>140%). Plans were all prescribed to 48 Gy in 4 fractions. Daily image guided radiotherapy by CBCT

was performed before each fraction. Plans were recalculated on the maximum inspiration and expiration phases of the 4D-CT series, and on CBCTs. Statistical significance was examined using a Wilcoxon signed rank-test for related samples and set at  $p\leq 0.05$ . The computations were carried out with the STATA 13.0.

### Results

A total of 392 plans were calculated and analyzed. All plans fully accomplished the objectives. Example of dose distributions for the two approaches is reported in figure 1. A general higher variability between planners was found for INH (the highest differences for ITV-D50%). Excluding obvious results, HOM plans resulted in higher body V50% sparing ( $P=0.16$ ), lower total MU ( $P<0.001$ ), lower gradient index ( $GI=\text{body V50\%/V95\%}$ ) with  $GI_{\text{HOM}}=4.1\pm 0.3$  and  $GI_{\text{INH}}=3.8\pm 0.1$  ( $P<0.001$ ), lower PTV-D98% ( $95.1\pm 0.3\%$  vs  $98\%$  -  $P<0.001$ ). In the 4D-CT series, CTV-D98% was relatively reduced of  $2.1\pm 0.3\%$  and  $9.3\pm 3.5\%$  for HOM and INH ( $P<0.001$ ), however absolute CTV-D98% values were higher for INH. In the CBCT series, a similar behavior for both approaches was observed with patient and day-by-day variations.

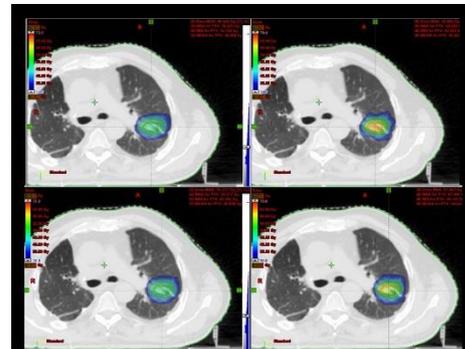

Figure 1: Axial views for (Left) HOM and (Right) INH approaches for two planners. Colorwash ranging between 30-70Gy

### Conclusion

The HOM approach resulted in more reproducible dose distribution between different planners and lower mean dose to the body. The INH approach, however, produced significantly higher mean doses to the target and steeper dose gradients. When defining a clinical protocol, physicians should be aware of advantages and drawbacks of the two approaches.

### PO-0937 Can butterfly VMAT in DIBH reduce dose of LAD in left breast cancer radiotherapy?

M. Maffei<sup>1</sup>, S. Bou Selman<sup>1</sup>, S. Hofer<sup>2</sup>, M. Haller<sup>2</sup>, P. Ferrari<sup>2</sup>

<sup>1</sup>Azienda sanitaria dell'Alto Adige, Servizio di radioterapia oncologica, Bolzano, Italy; <sup>2</sup>Azienda sanitaria dell'Alto Adige, Servizio di fisica sanitaria, Bolzano, Italy

### Purpose or Objective

to assess the feasibility of a multi partial arc in deep inspiration breath hold to minimize dose of left anterior descending coronary artery (LAD) and compare dose between conformal 3D and VMAT both in free breathing and deep inspiration breath hold conditions.

### Material and Methods

21 patients underwent left breast cancer radiotherapy were considered, prescribed dose was 56 Gy in 28 fractions. A total of four treatment combinations were compared (84 plans): 3D-conformal free-breathing (FB), 3D-conformal deep inspiration breath hold (DIBH), 2 partial arcs (from arc angle 290° to 160° clockwise and counterclockwise) free-breathing VMAT (VMAT) and 4 partial arcs using butterfly technique (20 sec per arc, from arc angle 290° to 350°, 120° to 160°, both clockwise and counterclockwise), in order to warranty the treatment

in deep inspiration breath hold (VMAT-DIBH). Conformity and Homogeneity index were calculated. Statistical analysis was performed. Data were expressed as mean  $\pm$  standard deviation. Unpaired Student's t-test was used to compare inter-group means. A P-value equal to or less than 0.05 was considered significant.

#### Results

Conformity and Homogeneity index were significantly better for VMAT compared to 3D plans. 4 partial arcs in VMAT-DIBH were appropriate for patients in breath hold, preserving efficacy of PTV coverage. Dose comparison showed a statistically significant reduction in heart and ventricle mean dose respectively from FB  $3.8 \pm 1.9$  Gy  $5.9 \pm 3.4$  Gy, to VMAT  $3.0 \pm 0.8$  Gy  $4.1 \pm 1.3$  Gy and DIBH  $1.6 \pm 0.8$  Gy  $2.0 \pm 1.3$  Gy. VMAT-DIBH was comparable with DIBH, heart  $1.7 \pm 0.5$  Gy and ventricle  $2.0 \pm 0.7$  Gy, but significantly reduced maximal dose in LAD (43%) and D2 LAD (42%).

#### Conclusion

DIBH reduced dose compared with FB in left breast cancer radiotherapy. VMAT showed to be the second choice in case of ineligible patient. VMAT-DIBH was feasible and comfortable for patients using small partial arcs in butterfly configuration, with a maximum delivery time of 20 sec per arc. VMAT-DIBH was efficacy adding LAD dose reduction (Dmean, Dmax and D2) to the DIBH advantages, at the expense of a small increase in the dose to the contralateral breast. Butterfly VMAT-DIBH improve heart protection in left breast cancer radiotherapy.

#### PO-0938 Spine SBRT plan comparison for Cyberknife and VMAT delivery incorporating intrafraction PTV margin

T. Oshea<sup>1</sup>, C. Jones<sup>1</sup>, C. Meehan<sup>1</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

#### Purpose or Objective

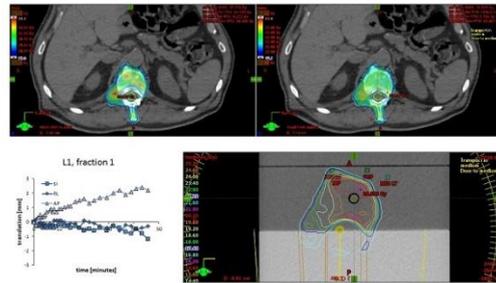

Stereotactic body radiotherapy is an effective method for treatment of spine metastases. At our institute the standard of care is treatment on the CyberKnife (CK) system with kV x-ray based intrafraction motion tracking. We investigate the ability to plan and verify the delivery of treatments using a Varian TrueBeam (TB) Linac with intrafraction motion accounted for in the PTV margin calculation.

#### Material and Methods

Intrafraction motion log data from nine previously treated CK patients (T1 - L2 vertebrae) was analysed and used to calculate PTV margins to account for delineation, phantom transfer and patient motion errors. Two-arc VMAT treatments were planned using the Varian Eclipse treatment planning system (with Acuros version 13.7.14 dose calculation) for 27 to 30 Gy in three fractions with 6FFF beams and 1400 MU/min dose-rate. Plans were compared with clinical CK plans which used a nominal 2.0 mm PTV margin. The deliverability of three plans (T1, T7 and L1) was verified by point dose measurement with a semiflex ionisation chamber in a solid water phantom.

#### Results

Mean ( $\pm$ SD) intrafraction motion using all CK log data was  $0.3 \pm 0.8$  mm (SI),  $0.2 \pm 1.3$  mm (RL) and  $0.7 \pm 0.7$  mm (AP) resulting in PTV margins of 4.0, 4.3, 3.7 mm (which also accounted for delineation, phantom transfer and set-up error estimates). The spinal cord PRV margin was 2.0 mm. The mean PTV coverage for VMAT plans with either 2 mm ( $87.6 \pm 2.7\%$ ) or 4 mm ( $84.3 \pm 2.2\%$ ) PTV margins was not significantly less than CK plans ( $85.9 \pm 4.8\%$ ). CTV coverage was significantly ( $p < 0.05$ ) better for VMAT plans. Risk organ doses were below UK NHS CTe guideline limits in all cases. The three verification plans were delivered to the solid water phantom on a TB Linac with an agreement between measured and calculated dose of  $3.5 \pm 0.1\%$ .

**Figure 1.** L1 vertebra: Comparison of CyberKnife (upper left) and TrueBeam (upper right) planning, example of log-file reconstructed intrafraction motion data used in PTV margin calculation (lower left) and solid water phantom plan verification (lower right).

#### Conclusion

A 4 mm PTV margin can be used to account for translational motion (and other error sources) in the absence of intrafraction motion compensation. PTV coverage for VMAT plans (with 4 mm PTV margin) was not significantly different to CK plans (with 2 mm PTV margin). 2-arc VMAT treatment fractions maintaining maximum dose-rate can be delivered in a much faster time (mean  $< 3.5$  minutes vs. CK  $\sim 40$  minutes) with deliverability verified within our institutes tolerance ( $< 5\%$ ).

#### PO-0939 Suspected impact of linear energy transfer on treatment related toxicities from proton therapy

J. Ödén<sup>1,2</sup>, E. Traneus<sup>2</sup>, P. Witt Nyström<sup>3,4</sup>, I. Toma-

Dasu<sup>1,5</sup>, A. Dasu<sup>3</sup>

<sup>1</sup>Stockholm University, Department of Physics, Stockholm, Sweden ;

<sup>2</sup>RaySearch Laboratories AB, Department of Research, Stockholm, Sweden ;

<sup>3</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden ;

<sup>4</sup>The Danish Centre for Particle Therapy, The Danish Centre for Particle Therapy, Århus, Denmark ;

<sup>5</sup>Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden

#### Purpose or Objective

To analyse dose-averaged linear energy transfer ( $LET_d$ ) and relative biological effectiveness (RBE) distributions for three patients with suspected treatment related toxicity following intracranial proton therapy. Various planning strategies to reduce  $LET_d$ , RBE and normal tissue complication probabilities (NTCP) were also investigated.

#### Material and Methods

Plans for three patients treated with single-field uniform dose plans with fractionation doses of 1.8 Gy (RBE) to the target in 28 or 30 fractions (assuming RBE=1.1) were recalculated in an independent treatment planning system (TPS) with a Monte Carlo dose engine using the original CT-data, CT-calibration and beam data. The resulting physical dose distribution and  $LET_d$  were used as input to calculate the RBE-weighted dose ( $D_{RBE}$ ) using two  $LET_d$ - and  $\alpha/\beta$ -dependent variable RBE-models. For the targets,  $\alpha/\beta$  values of 3 or 10 Gy were used, whereas 2 Gy were assumed for the normal tissues. Resulting distributions of  $D_{RBE}$  and  $LET_d$  were analysed together with NTCP estimations. Following this, four intensity modulated proton therapy (IMPT) plans were generated in order to investigate the potential of  $LET_d$ , RBE and NTCP reductions in the critical structures: (1) IMPT with the clinical beam arrangements and only dose objectives, (2) alternative beam arrangements and only dose objectives, (3) clinical beam arrangements with dose and track-end objectives (penalized protons stopping in critical structures), (4) alternative beam arrangements with dose and track-end objectives.

#### Results

The recalculated dose distributions agreed well with the dose distributions calculated in the clinically used TPS. The variable RBE-models predicted an increase of 7-12 Gy (RBE) in the near-maximum  $D_{RBE}$  ( $D_{RBE, 2\%}$ ) for the structures with the observed toxicities resulting in not fulfilling the clinical goals. The NTCP for the structures with the observed toxicities increased from 0.8, 0.0 and 0.1% (RBE=1.1) to 15.5, 3.6 and 1.8% (Wedenberg RBE-model) for the three patients, respectively. All alternative plans produced physical dose distributions which were similar or better than the clinical plans, while also generally allowing for substantial  $D_{RBE}$ ,  $LET_d$ , and NTCP reductions in several critical structures assuming the variable RBE-models. In all cases, alternative plan 4 resulted in the lowest values, with a  $LET_d$  reduction of 50%, or more, compared to the clinical plan.

**Table 1.** Mean and near-max RBE-weighted dose ( $D_{RBE, mean}$ / $D_{RBE, 2\%}$  [Gy (RBE)]), mean and near-max  $LET_d$  ( $LET_{d, mean}$ / $LET_{d, 2\%}$  [keV/ $\mu$ m]) and NTCP [%] for the critical structure with the observed toxicity for each of the three patients. An  $\alpha/\beta=2$  Gy was assumed for all calculations.

<sup>c</sup>s-model. Brainstem:  $D_{50}=65.1$  Gy,  $\gamma=2.4$ ,  $s=1.0$ . Optic nerve:  $D_{50}=65.0$  Gy,  $\gamma=2.3$ ,  $s=1.0$

<sup>d</sup>Clinical beam arrangements. Only physical dose objectives

<sup>e</sup>Alternative beam arrangements. Only physical dose objectives

<sup>f</sup>Clinical beam arrangements. Physical dose objectives and proton track-end objectives

<sup>g</sup>Alternative beam arrangements. Physical dose objectives and proton track-end objectives

**Figure 1.** Representative transversal slice of patient 2 showing  $LET_d$  for the clinical plan and alternative plan 4, with the beam arrangements. The CTV, PTV (black lines), left optic nerve, right optic nerve, chiasm (white lines), brainstem (blue line) and left/right hippocampus (yellow lines) are shown. The  $LET_d$  is shown for doses  $>5\%$  of 54 Gy (RBE).

## Conclusion

Although a study of this size and design could not establish direct causality between RBE and toxicity, the analysis indicates that the enhanced RBE, due to high  $LET_d$ , could be a potential cause of the observed toxicities. Combining IMPT with alternative beam arrangements and/or objectives beyond physical dose allow for  $D_{RBE}$ ,  $LET_d$ , and NTCP reductions in several critical structures for intracranial lesion, without compromising the target dose. Such planning strategies might hence be a future tool in order to maximize the benefit of proton therapy.

## PO-0940 The effects of Bragg curve degradation in proton therapy of bronchial carcinomas

<sup>2</sup>University of Applied Sciences Giessen THM, Institute of Medical Physics and Radiation Protection, Giessen, Germany ;

<sup>3</sup>GSI Helmholtzzentrum für Schwerionenforschung, Biophysics Division, Darmstadt, Germany

### Purpose or Objective

Sub-millimetre-sized heterogeneities like lung parenchyma cause a degradation of the Bragg curve. State-of-the-art treatment planning systems are unable to consider the degradation in the treatment planning process ignoring the influence on the dose distribution. Potentially, this can result in an underdosage of the PTV and an overdosage of distal normal tissue.

In a previous study we presented a strategy to consider this Bragg peak degradation by applying a density modulation to the voxels associated with the lung [1]. In this study we use this tool to analyse the effects of this Bragg curve degradation on CT based phantoms, enabling a thorough investigation of the dependencies of parameters effecting the degradation and present data for five treatment plans on patient CTs.

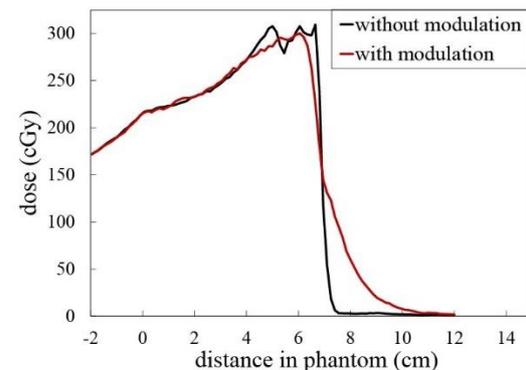

### Material and Methods

Stereotactical proton treatment plans were optimised using the treatment planning system Eclipse (VARIAN) on phantom and patient CTs. Each plan was then recalculated using the Monte Carlo toolkit TOPAS [2]. In a first scenario, the treatment plans were recalculated using the original density values from the treatment planning CT which correlates to the dose distribution predicted by the treatment planning system.

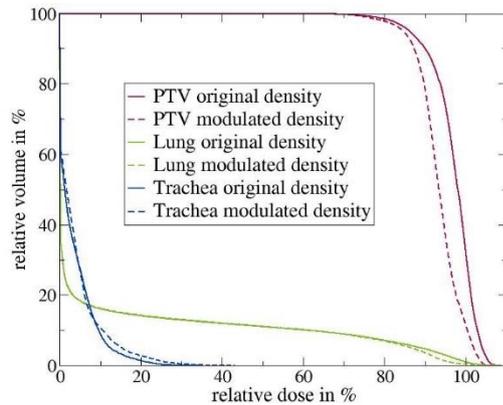

In a second scenario, the density values of each voxel within the lung were modulated using a mathematical model [1], thus giving the actual dose distribution in the patient.

The phantoms that were used covered a range of different distances of the treatment volume in lung as well as various tumour volumes.

### Results

In Figure 1 an exemplary depth-dose curve through one of the phantom dose distribution shows the effect of the Bragg peak degradation in comparison to the curve predicted by the treatment planning system.

In Figure 2 the dose-volume histograms of a patient plan with and without the modulation is presented. It shows an underdosage for the PTV (red) and an overdose in the distal tissue (here: the trachea in blue).

The results from the phantom study show an increase in the dose difference as the distance in lung increases and the volume decreases. Underdoses from a few percent up to 12% for distances up to 15cm in lung were found in a conservative approach. For patients plans, the PTV underdosage ranges between 1% and 5% in comparison to the plan calculated with the treatment planning system.

#### Conclusion

We are able to analyse the effects of Bragg curve degradation due to lung parenchyma in the treatment planning process of lung cancer patients. As the inclusion of this Bragg peak degradation cannot be easily implemented in treatment planning routines, this study gives a conservative approximation for the underdose in the PTV, when it is not accounted for.

#### PO-0941 Can dose gradient-based plan optimisations compete with autoplanning for optimal prostate plans?

D. Schuring<sup>1</sup>, A. Van Nunen<sup>1</sup>, F. Van Aarle<sup>1</sup>, T. Jongsmavan Nunen<sup>1</sup>, T. Budiharto<sup>1</sup>  
<sup>1</sup>Catharina Hospital, Department of Radiation Oncology, Eindhoven, The Netherlands

#### Purpose or Objective

Multiple studies have shown that autoplanning improves consistency and optimal OAR sparing for individual patients in treatment planning [1]. These inconsistencies in OAR sparing are often caused by the use of mean dose or DVH objectives in the inverse optimisation, which are sensitive to anatomical variations in patients and require adjustments by the treatment planner. By optimising on the dose gradients inside the OAR, more consistent results can be obtained as these objectives are less sensitive to these variations. This was tested by replanning clinical prostate patients using these gradient-based objectives and comparing the resulting OAR doses to the clinical plans using the "traditional" optimisation approach.

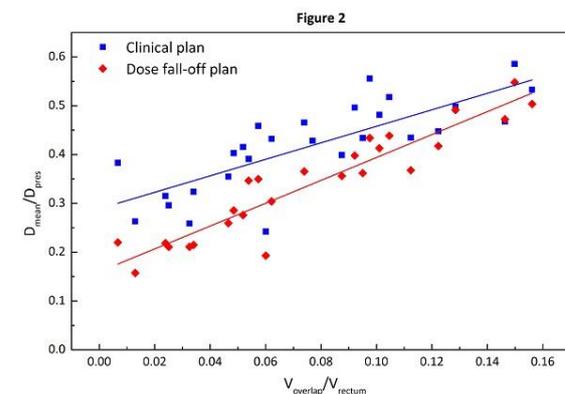

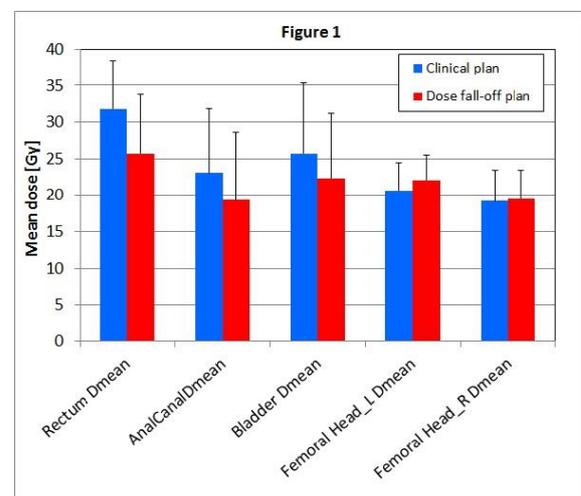

#### Material and Methods

27 patients with prostate cancer receiving a total dose of 76 Gy were randomly selected from the clinic. These patients were then replanned with a new class solution that uses dose fall-off objectives on the OAR in the RayStation TPS. During re-optimisation no manual adjustments to the objectives were allowed. For the

clinical as well as the dose fall-off plans, PTV and OAR dose parameters (rectum, anal canal, bladder, femoral heads) were evaluated to check if OAR sparing improved. In analogy to knowledge-based approaches, consistency of the the rectum sparing was analysed by plotting the mean dose against the fraction of rectum volume overlapping the PTV [1] for both the clinical and dose fall-off treatment plans.

#### Results

For all patients, the new optimisation approach resulted in clinically acceptable plans with a reduction of the dose in the rectum, anal canal and bladder (fig. 1), while maintaining similar PTV coverage and conformity and only a slight increase of the dose in the femoral heads. The largest improvement in OAR sparing was observed for the rectum and anal canal (an average reduction of the mean dose of 19.1 and 16.3% respectively). This was mostly achieved by a reduction of the intermediate dose to these OAR (< 45 Gy). Fig. 2 shows the normalized mean rectum dose as a function of the fraction of the rectum volume overlapping the PTV. Over the whole range of overlap a reduction of the mean rectal dose was achieved, with the largest gains at smaller overlaps fractions. For these patients, the dose constraints can be easily achieved, and larger manual adjustments are needed to achieve optimal sparing. The dose fall-off based optimisations furthermore resulted in a more consistent OAR sparing, reflected by a reduction of the spread of the rectum dose as a function of the overlap fraction.

#### Conclusion

When using a new class solution with dose-gradient objectives for the OAR, a significant improvement of rectum, anal canal and bladder sparing for prostate patients was achieved without manual adjustments of the planning objectives. Similar to autoplanning approaches, this results in more consistent sparing of the OAR with

varying patient anatomy, and less sensitivity to planner experience and skills.

**PO-0942 Optimization of adaptive aperture margins in robustly optimized pencil beam scanning proton plans**  
G. Vilches Freixas<sup>1</sup>, M. Unipan<sup>1</sup>, I. Rinaldi<sup>1</sup>, J. Martens<sup>1</sup>,  
C. Ares<sup>1</sup>, G. Bosmans<sup>1</sup>

<sup>1</sup>*Maastric Clinic, Department of Radiation Oncology, Maastricht, The Netherlands*

**Purpose or Objective**

At the end of the beam line of the Mevion S250i proton therapy system there is an adaptive aperture to reduce lateral penumbra, especially at low energies, by laterally trimming the spots at the edge of the treatment field. The goal of this study was to determine the optimal aperture margin (AM) from the CTV in a robust optimized plan for different anatomical sites, treatment volumes, and number of beams.

**Material and Methods**

In a water phantom, a L-shaped volume simulating a CTV with 10 cm the largest x, y and z dimensions was placed at different depths from 1 up to 15 cm from the phantom surface. In the first phase of the study, nominal non-robust Monte Carlo (MC) 60 Gy(RBE) (2 Gy(RBE) x 30 fractions) plans were created. Using the scripting module in Raystation 8.A, plans varying from single-beam up to 4 beams were generated for every target volume depth. In each plan, the AM margins from the target volume were varied from 2 mm to 10 mm in 2 mm steps. In the second part of the study, 120 robust optimized MC plans taking into account 4 mm setup uncertainty (SU) and 3.5% range uncertainty were created with different AMs. In a robust optimized plan, the SU uncertainties should also be taken into account in the aperture margin. For this reason, the AM in a robust optimized plan (AM\_RO) are defined as the AM in a nominal plan plus the SU:  $AM_{RO} = AM_{nominal} + SU$ . Moreover, to check this hypothesis, extra 2 mm margins were added and subtracted to the AM\_RO in a robustly optimized plan.

Plan robustness, after plan optimization, was further evaluated with the previous robustness settings (4 mm setup and 3.5% range uncertainties, respectively) by calculating 28 different scenarios of combined uncertainties via an automated script. In both phases of the study, the following metrics were used to drive a decision: Homogeneity Index (HI), D98%, D2%, D95% and the Conformity Index (CI). The results were benchmarked against 6 head and neck and 9 central nervous system brain tumour patients.

**Results**

The effect of the AM was more predominant at shallow depths, as expected. More beams allow tighter AMs. The optimal AM was found to be: 4 mm + SU for 1 to 3 beams, 2 mm + SU for 4 beams, and 6 mm + SU for 1 to 2 beams in the case of shallow tumours (Fig. 1 and 2). For the last situation, AM had to be enlarged to improve target coverage. Furthermore, based on the clinical validation, an AM of 6 mm + SU was found to be optimal also for small tumours close to air cavities.

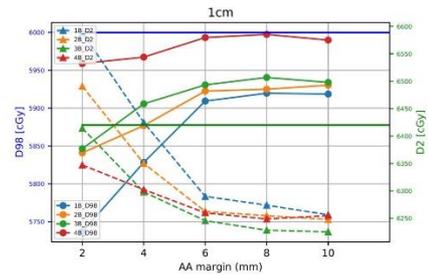

Figure 1. Results of the first phase of the study: nominal non-robust MC plans. D98 and D2 for the 1 cm depth tumour as a function of the AM. D98 (circles) is expected to be as close as possible to the prescribed dose (blue line) and, at the same time, D2 (triangles) below 107% of the prescribed dose (green line).

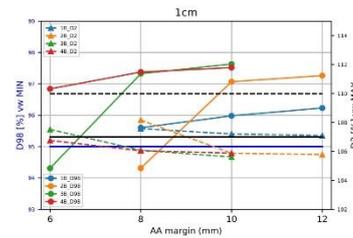

Figure 2. Results of the second phase of the study: robustly optimized and evaluated MC plans. D98 in the robust evaluation distribution (w/ MIN) and D2 in the robust evaluation distribution (w/ MAX) for the 1 cm depth tumour as a function of the AM. D98 (circles) is expected to be above 95% of the prescribed dose (blue line) and, at the same time, D2 (triangles) below 107% of the prescribed dose (black solid line). The discontinuous black line in the right axis represents the 107% of the prescribed dose.

**Conclusion**

Optimal AMs for robustly optimized pencil beam scanning (PBS) proton plans for the Mevion S250i were derived and validated for 15 patient cases. The use of apertures in PBS improves lateral penumbra and potentially reduces the dose to the organs at risk.

**Purpose or Objective**

Clinical evidence for the advantage of proton therapy (PT) is still limited. To show superiority larger scale clinical trials in a collaborative network must be performed. A collaborative network between PT centres in Trento in Italy, Poland, Austria, Czech Republic and Sweden (IPACS) was founded to implement those trials and harmonize PT.

This is the first report of IPACS with focus on proton therapy treatment planning of head-and-neck patients.

### Material and Methods

CT-data sets of five patients were included. During several face-to-face and online meetings a common treatment planning protocol was developed having objectives for target coverage and organ at risk (OAR) sparing together with their mutual prioritization as well as a definition of robustness evaluation. Each centre used its own treatment planning system (TPS) and planning approach with some restrictions specified in the treatment planning protocol. In addition, volumetric modulated arc therapy (VMAT) photon plans were created.

### Results

For CTV1 the average  $D_{98\%}$  was  $54.6 \pm 2.3$  Gy(RBE) for protons and  $54.9 \pm 0.5$  Gy(RBE) for VMAT (aim was 56 Gy(RBE)). For CTV2 the average  $D_{98\%}$  was  $60.8 \pm 5.7$  Gy(RBE) for protons and  $61.6 \pm 3.4$  Gy(RBE) for VMAT (aim was 70 Gy(RBE)). The average  $D_{2\%}$  for the spinal cord was  $25.1 \pm 8.5$  Gy(RBE) for protons and  $47.6 \pm 1.4$  Gy(RBE) for VMAT (see also Figure 1). The average  $D_{2\%}$  for chiasm was  $46.5 \pm 4.4$  Gy(RBE) for protons and  $50.8 \pm 1.4$  Gy(RBE) for VMAT respectively. Robust evaluation was performed and showed the least robust plans for plans with a low number of beams (see Figure 2).

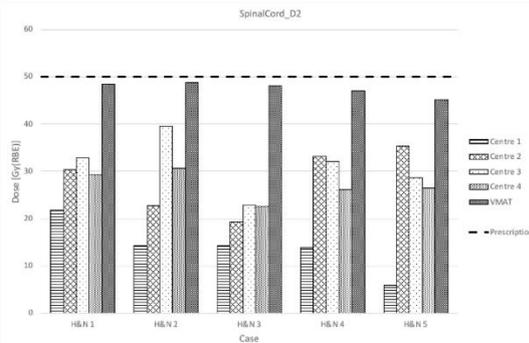

Figure 1: For the nominal plans, the  $D_{2\%}$  for the spinal cord for all 5 head and neck cases from each centre and the VMAT plan is shown. The planning aim was achieved by all plans. The dashed line shows the objective for spinal cord  $D_{2\%}$  which was  $< 50$  Gy (RBE).

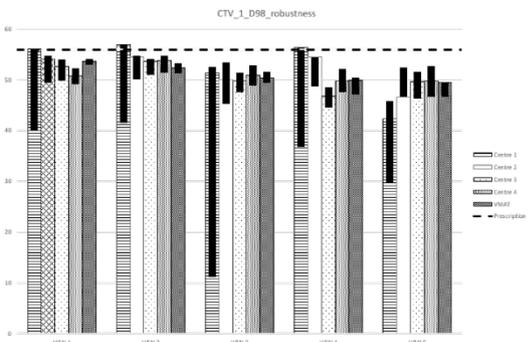

Figure 2:  $D_{98\%}$  for CTV1 in the first treatment phase for the nominal plans and the results of the robustness analysis for all 5 head and neck cases from each centre and the VMAT plan is shown. The black bars show the band width (max and min) of  $D_{98\%}$  for all the robustness scenarios. The dashed line shows the planning aim for CTV1  $D_{98\%}$  which was 56 Gy (RBE) respectively.

### Conclusion

Despite the detailed treatment planning protocol, differences in dose distribution and reported parameter were still identified. Although VMAT is more robust than PT, OAR sparing at intermediate distance from CTVs and

integral dose is worse. In future all OARs that should be included in the optimization need to be specified in order to further harmonize treatment planning.

### PO-0944 Proton therapy for esophageal cancer; variable relative biological effect and heart dose

C. Skinnerup Byskov<sup>1</sup>, A. Ivalu Sander Holm<sup>1</sup>, S.S. Korreman<sup>1</sup>, L. Hoffmann<sup>1</sup>, M. Nordmark<sup>2</sup>, D. Sloth Møller<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Medical Physics, Aarhus C, Denmark ; <sup>2</sup>Aarhus University Hospital, Oncology, Aarhus C, Denmark

### Purpose or Objective

For patients with esophageal cancer the standard treatment is radiotherapy (RT) and concomitant chemotherapy, possibly followed by surgery. Dose to the organs at risk (OAR) can be substantially reduced by proton therapy (PT), and a recent study has shown that posterior field directions constitute the most robust beam configuration for PT [Møller et al., RO 2018]. These PT studies were based on a constant proton relative biological effect (RBE) of 1.1 which disregards data suggesting that RBE varies with linear energy transfer (LET), physiological and biological factors. Heart dose has been found to increase the risk of heart toxicity [Darby et al., NEJM 2013]. The aim of this study was therefore to investigate the effect of variable RBE on dose to the heart in PT for patients with esophageal cancer using posterior field directions.

### Material and Methods

Previously reported robustly optimized proton plans for 23 patients with esophageal cancer were used as baseline plans [Møller et al., RO 2018]. Two field configurations were applied for each patient, using one posterior field (I-plans) or two oblique posterior fields (V-plans) (Figure 1). The linear energy transfer (LET) and relative biological effect (according to the RBE model by McNamara et al. [PMB 2015]) were calculated in Eclipse using an Eclipse script developed by Sanchez-Parcerisa et al. [PMB 2016]. Mean heart dose (MHD), heart volumes receiving 25 Gy (V25Gy) and 40 Gy (V40Gy) and the near maximum dose (D2ccm) were measured and compared for the two different field configurations. Differences were tested using the Wilcoxon signed rank test, with  $p < 0.05$  considered significant.

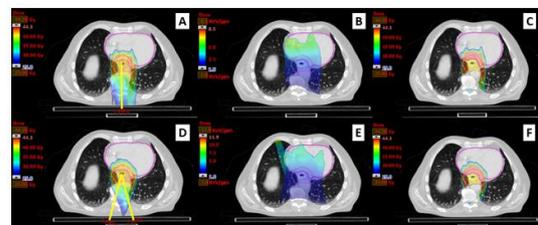

Figure 1: Dose comparisons between the I-plans (top row) and V-plans (bottom row). Field angles shown in yellow. For the RBE = 1.1 dose (A + D) and the McNamara RBE dose (C + F), the minimum dose displayed on the color wash is 25 Gy and all doses above 107% of the prescribed dose (44.3 Gy) are displayed in red. For the RBE weighted dose, only structures that are delineated on the CT scan have calculated doses. In the middle column, the LET distributions are displayed (B + E), the minimum is set to 1 keV/μm and here the maximum values calculated are 6.5 keV/μm for the I-plan and 11.9 keV/μm for the V-plan.

### Results

For the I-plans and the V-plans respectively, the population median MHD was reduced with 7.4 Gy and 6.9 Gy compared to the IMRT plans (Figure 2). When applying the variable RBE model, doses to the heart increased compared to using RBE 1.1. For the I-plans and [V-plans], respectively, the MHD was increased by  $1.0 \pm 0.5$  Gy [ $1.3 \pm 0.7$  Gy], V25Gy was increased by  $1.9 \pm 1.0\%$  [ $2.4 \pm 1.2\%$ ], V40Gy was increased by  $2.3 \pm 1.3\%$  [ $2.9 \pm 1.6\%$ ] and D2ccm was increased by  $3.5 \pm 1.0$  Gy [ $5.0 \pm 1.5$  Gy] (population mean  $\pm$ SD). Significant differences were found between the I-plans and V-plans for V25Gy and D2ccm.

	IMRT	I-plan RBE = 1.1	I-plan McNamara RBE	p-value RBE = 1.1 vs. McNamara RBE	V-plan RBE = 1.1	V-plan McNamara RBE	p-value RBE = 1.1 vs. McNamara RBE	p-value I-plan vs V-plan McNamara RBE
MHD (Gy)	17.0	6.4	9.6	<0.001	8.7	10.1	<0.001	>0.05
V25Gy (%)	23.3	15.9	18.3	<0.001	16.0	18.8	<0.001	<0.05
V40Gy (%)	7.3	6.5	9.2	<0.001	5.9	9.5	<0.001	>0.05
D2ccm (Gy)		42.4	46.2	<0.001	41.9	47.4	<0.001	<0.05

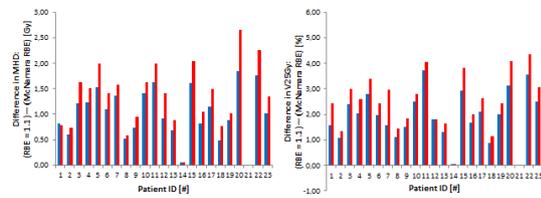

Figure 2: Top: Selected dosimetric parameters for the heart for IMRT, RBE = 1.1 doses and McNamara RBE doses. All values are median values and grey columns are previously published data. Bottom: Differences in dose between McNamara RBE dose and RBE = 1.1 dose for the individual patients. I-plans are shown in blue and V-plans in red.

## Conclusion

Accounting for the variable RBE effect in PT planning with only posterior fields for esophageal patients increases the dose to the heart. The heart exposure is, however, still considerably decreased compared to IMRT. Heart V25Gy and D2ccm were significantly increased when using the two-field configuration compared to the one-field configuration.

## PO-0945 Stochastic Frontier Analysis to predict sparing of organs-at-risk for VMAT-treated prostate cancer

A. Kroshko<sup>1</sup>, O. Morin<sup>2</sup>, L. Archambault<sup>1</sup>

<sup>1</sup>Université Laval, Physique- génie physique et optique, Quebec, Canada ; <sup>2</sup>University of California San Francisco, Department of Radiation Oncology, San Francisco, USA

## Purpose or Objective

Treatment planning of advanced radiation therapy techniques often require compromises between the delivery of the prescribed dose to the volume of interest and the sparing of the neighbouring organs-at-risk (OAR). A novel knowledge-based model was developed based on Stochastic Frontier Analysis (SFA) to predict achievable dosimetric indices for the bladder and the rectum for prostate cancer treated with VMAT.

## Material and Methods

SFA is modeled as an optimum frontier with dosimetric parameters degradation following a normal-half normal distribution. Model can converge into two extremes, a regression or an absolute frontier, otherwise a stochastic frontier is obtained. Seven parameters were used to describe the geometry between each OARs and PTV (e.g. the overlap volume and the Hausdorff distance). They are extracted with an automatized python routine within the 3D Slicer platform. Estimators of the model are determined using a maximum likelihood technique to obtain stochastic frontiers for 9 dosimetric indices (ex. V60Gy) only in terms of the geometric parameters. The model was developed with a database of 152 patients treated between October 2014 and May 2017 with prescribed dose to the PTV between 60 and 78 Gy with the treated volume being prostatic bed or prostate with seminal vesicles. A validation cohort of 20 random patients treated between December 2017 and April 2018 was then used to compare the planned dose to the predicted dose to the OAR. A metric quantifying the similarity between the predicted and the clinical plan is then calculated. It is defined as the sum of the dose difference between predicted and planned divided by the number of dosimetric indices predicted for an OAR. A negative value means that the predicted dose is lower than the one planned. The overall score is the sum of the score for the bladder and the rectum.

## Results

75% of the validation plans have an overall score lower than 5% dose difference between the predicted and the

planned DVH. Thus, the majority of the predicted plans are close to the planned ones or even suggests that further dose reduction is possible for those plans. 68% (27 out of 40) of the organs-at-risk are within the  $\pm 3\%$  dose difference with the planned values. Figure 1 presents the comparison between the planned dose values and the one predicted by our SFA model. The model is well adapted to predict different dosimetric sparing for the OARs and for different dose prescriptions. Considering there is no mathematical relationship between the predicted dosimetric indices the obtained dose-volume curves are quite smooth.

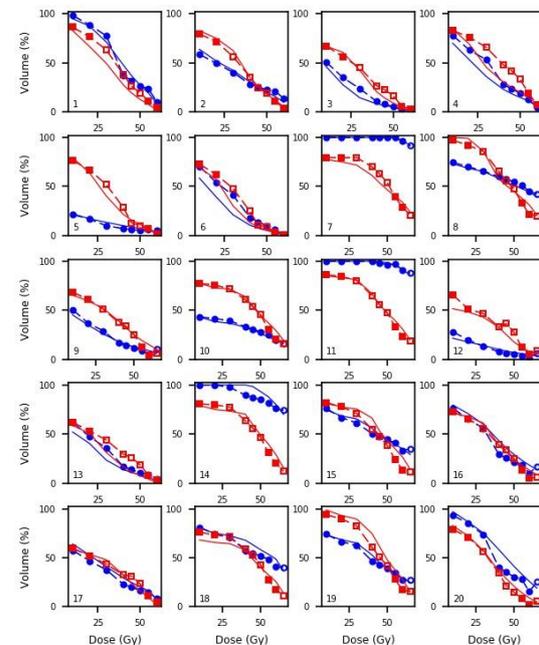

Figure 1: Comparison between the planned dose values (full line) and the predicted (dashed line) for the bladder (blue line - square) and the rectum (red line - circle) for the 20 patients in our validation cohort. Full marker represents a stochastic frontier for this dosimetric indice and an empty marker represents a regression.

## Conclusion

SFA is an adequate model to build a predictive model based on the morphological parameters of a retrospective database. The model is validated with a 20 patients cohort with different dose distribution. We wish to implement this technique into the clinical process of radiation therapy planning in order to maximise the sparing of the OARs.

## PO-0946 Inter-fraction robustness of DECT-based head and neck proton therapy with reduced range uncertainty margins

S. O'Reilly<sup>1</sup>, C. Cheng<sup>1</sup>, A. Lalonde<sup>2</sup>, B. Burgdorf<sup>1</sup>, W.J. Zou<sup>1</sup>, L. Yin<sup>1</sup>, S. Swisher-McClure<sup>1</sup>, A. Fotouhi Ghiam<sup>1</sup>, J.N. Lukens<sup>1</sup>, A. Lin<sup>1</sup>, L. Dong<sup>1</sup>, B.K.K. Teo<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA ; <sup>2</sup>Centre hospitalier de l'Université de Montréal, Radiation Oncology, Montreal, Canada

## Purpose or Objective

The Hounsfield unit (HU) to proton stopping power ratio (SPR) relative to water conversion is a source of uncertainty in proton therapy, with the generally accepted clinically applied range uncertainty for single energy computed tomography (SECT) being 3.5%. However, studies have shown that a range uncertainty of 2% is feasible when using SPR calculated with dual energy computed tomography (DECT). This decrease in range uncertainty leads to a reduction in margins, leading to decreased doses to organs at risk (OAR). This dose reduction can be substantial for head and neck cancer patients, who experience significant acute and late

toxicity. Robustly optimized head and neck plans using SPRs calculated using DECT and SECT were evaluated for OAR sparing and impact of inter-fraction setup variation.

#### Material and Methods

Ten post-operative head and neck patients (2 with SCC of the tongue, 1 parotid, 1 submandibular gland, 5 tonsil, and 1 unknown primary) were used for this study. Patients received a SECT scan followed by a DECT scan in sequential mode (80 kVp and 140 kVp) whereby  $p_e$  and  $Z_{eff}$  images were generated by the scanner software for SPR calculation. Both SECT and DECT calculated SPR images were used for robust optimization and dose calculation. Each plan consisted of 3 fields using multi-field optimization (MFO) to a CTV prescription of 60 or 63 Gy in 30 fractions. The proton plans were robustly optimized for CTV target coverage on SECT (3.5% range uncertainty) and DECT (2% range uncertainty) scans with 3 mm isocenter shifts. Comparison of treated volume outside of CTV- 50%, 70%, and 90% isodose volumes (minus the target volumes) were performed between SECT and DECT plans. Verification scans acquired during the course of treatment were used for forward calculation and evaluated for DECT plan robustness using a 1.5 mm isocenter shift and 2% range uncertainty. The 1.5 mm isocenter shift robustness parameter for the evaluation scans reflect the uncertainty in imaging and treatment isocenter coincidence as well as user dependent variability in image registration.

#### Results

The average reduction in the 50%, 70%, and 90% isodose volumes were 6.8%, 7.3%, and 13.3% respectively. An average decrease in esophagus max of 3.0 Gy (range -8.6 to 1.4 Gy), esophagus mean 0.6 Gy (-1.8 to 0.47 Gy), constrictor mean 1.2 Gy (-2.7 to 1.1 Gy), larynx mean 1.1 Gy (-2.7 to 0.6 Gy), and parotid mean 0.3 Gy (-3.9 to 1.7 Gy) were achieved with DECT plans. CTV coverage (at least 95%-95%) was maintained on each patient's verification scan in the second-to-worst case plan robustness analysis.

#### Conclusion

Using DECT for SPR calculation allows for reduced range uncertainty and margins leading to reduction of dose to regions outside target compared to SECT. Plans with reduced margins of 2% range uncertainty and 3 mm isocenter shifts were robust against inter-fraction setup variations.

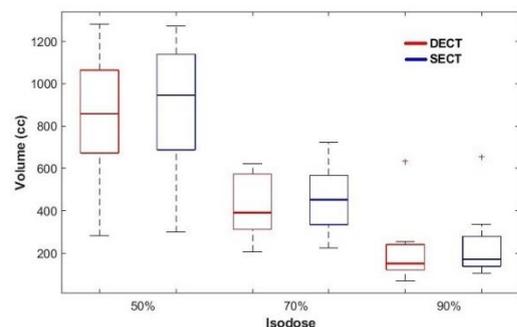

Figure 1. Comparison of treated volume outside of CTV- 50%, 70%, and 90% isodose volumes (minus the target volumes) between SECT (3.5% range uncertainty, 3 mm setup uncertainty) and DECT (2% range uncertainty, 3 mm range uncertainty) plans for ten post-operative head and neck patients.

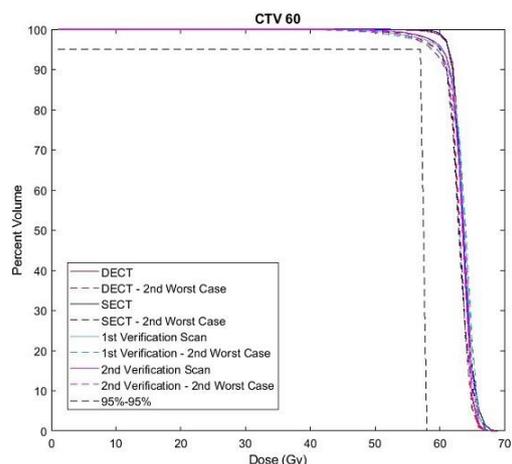

Figure 2. Representative CTV 60 coverage for robustly optimized DECT and SECT plans, compared with coverage for forward calculated plan on two separate verification scans (approximately two weeks apart) taken for a head and neck patient. The second-to-worst case scenario for CTV coverage is provided using 3 mm setup uncertainty for original DECT and SECT plans and 1.5 mm setup uncertainty for verification scans. DECT plans are calculated using 2% range uncertainty and SECT use 3.5% range uncertainty.

##### PO-0947 The impact of dose deviations arising within the dosimetry chain on clinical outcomes

M. Bolt<sup>1</sup>, A. Nisbet<sup>2</sup>, T. Chen<sup>3</sup>, C. Clark<sup>4</sup>

<sup>1</sup>Royal Surrey County Hospital, Radiotherapy Physics, Guildford, United Kingdom ; <sup>2</sup>University of Surrey, Physics, Guildford, United Kingdom ; <sup>3</sup>University of Surrey, Chemical and Process Engineering, Guildford, United Kingdom ; <sup>4</sup>National Physical Laboratory, Radiation and Dosimetry, Teddington, United Kingdom

#### Purpose or Objective

Delivered radiotherapy dose may be compared between clinics due to the traceability of dose between Primary Standards Laboratories (PSL). Uncertainties arise at each point in the calibration chain and thus the actual delivered dose can deviate from that desired. These uncertainties have been quantified for each step; calibration transfer to a secondary standard instrument, transfer to field instruments, and subsequent QA measurement tolerances. Radiobiological modelling has been used to predict the clinical impact of these uncertainties.

#### Material and Methods

Uncertainty in the initial transfer of the calibration from PSL to the clinic was determined from on-site audits performed by the PSL over 2 decades and is normally distributed with a SD of 0.7% [1]. Data from over 24,000 multi-centre beam output measurements was used as a basis of the uncertainty following calibration and had a 0.7% SD [2]. Combining these uncertainties with daily fluctuations (0.2% SD) gives the overall measured uncertainty within the calibration chain of 1.0% SD.

Linear-Quadratic (LQ) and Lyman-Kutcher-Burman (LKB) models were implemented to model the effect of systematic and random deviations in delivered dose. Modelling was developed for prostate (10yr bPFS and grade 2 rectal bleeding) and head and neck (2yr survival and xerostomia induction) cases. The LQ model was used to calculate individual patient response and aggregated to provide population estimates. The clinical cases assessed cover a wide range of dose-response (even some prostate cancers have steep dose response [3]).

#### Results

A systematic dose shift of +2% through the course of treatment was estimated to change TCP by between 6.1-7.0% for the populations. Table 1 shows results for a range

of realistic systematic deviations in delivered dose existing throughout the treatment course.

Dose shift (%)	Modelled change in outcome prediction caused by							
	TCP				NTCP			
	Prostate		Head & Neck		Prostate		Head & Neck	
	RT01 Trial	Fox Chase	PARSPORT	PARSPORT	Rectum	Parotid		
	Ind.	Pop.	Ind.	Pop.	Ind.	Pop.		
-3	-22.2	-10.8	-28.7	-17.3	-26.1	-10.2	-12.8	-4.2
-2	-14.1	-7.2	-18.6	-10.7	-16.7	-6.2	-8.5	-2.8
-1	-6.7	-2.7	-9.0	-5.1	-8.0	-3.8	-4.2	-1.4
0	0	0	0	0	0	0	0	0
1	6.1	2.3	8.2	4.7	7.1	3.1	4.1	1.4
2	11.4	6.1	15.6	8.6	13.5	7.0	8.1	2.8
3	16.2	9.0	22.1	12.1	19.0	9.2	12.0	4.1

**Table 1:** Percentage change in outcome probability for different clinical cases. TCP was calculated for an individual patient with fixed alpha/beta ratio and a population included a variation in alpha/beta ratio across the patient cohort.

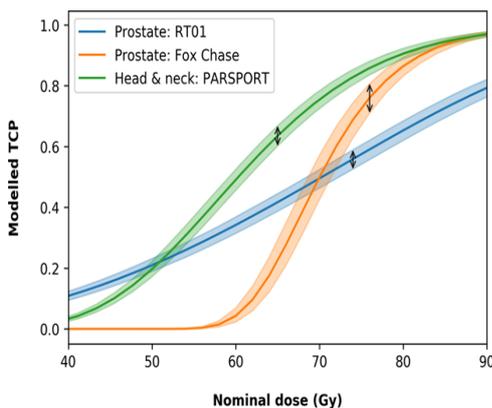

<sup>1</sup>RT01 was a randomised controlled trial comparing 64Gy and 74Gy for prostate cancer [Deaneley et al. 2014, The Lancet Oncology 15(4), 464-473].

<sup>2</sup>Fox chase assessed a range of delivered doses to the prostate between 70-76Gy for medium risk prostate cancer [Hanks et al. 2002, Int. Jour. Of Radiat. Onc. Biol. Phys. 54(2) 427-435].

<sup>3</sup>PARSPORT examined dose sparing of the parotid glands using conformal and IMRT. Here the doses from the IMRT plans are used as these are more comparable to modern treatment techniques [Nutting et al. 2011, The Lancet Oncology, 12(2) 127-136].

Based on treating patients on different machines within a clinic the Fox Chase case, shows the greatest variation in TCP with 5<sup>th</sup> and 95<sup>th</sup> percentiles of 71.0% and 80.7% (range 9.7%). The RT01 prostate case and head and neck case had 5<sup>th</sup> and 95<sup>th</sup> percentiles of 52.5% and 58.9% (range 6.4%), and 60.1% and 66.8% (range 6.7%) respectively. Figure 1 shows variation in predicted outcome for a cohort of patients due only to machine assignment.

Variation in TCP based on machine assignment: Population

**Figure 1:** The simulated variation in TCP for a cohort of patients with spreads in alpha/beta values for the clinical cases detailed in Table 1. The solid line indicates the mean values and shaded regions indicate 5<sup>th</sup> to 95<sup>th</sup> percentiles. Variation in this simulation arises solely due to the machine to which a patient is assigned.

**Conclusion**

This analysis highlights the importance of accurate dosimetry, not only at initial calibration but also with QA. Current recommended action levels of 2% may require revision to reduce this potential difference in clinical outcome. Changes of this magnitude are readily detected; however this information is seldom used routinely. Clinical trials may benefit from reducing uncertainty in delivered dose to provide more robust assessments of response between trial arms, particularly in the context of reduced variation possible with modern treatment techniques.

**PO-0948 Predicting lung function post-RT in lung cancer using multivariate and principal component analysis**

Y. Dong<sup>1</sup>, M. Tawhai<sup>2</sup>, C. Veiga<sup>3</sup>, T. Doel<sup>4</sup>, D. Landau<sup>5</sup>, J. McClelland<sup>3</sup>, K. Burrowes<sup>1</sup>

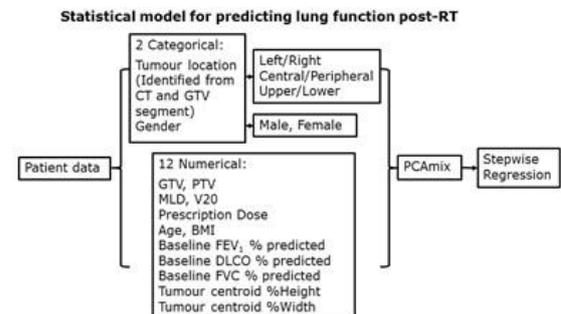

<sup>1</sup>University of Auckland, Chemical and Material Engineering, Auckland, New Zealand ; <sup>2</sup>University of Auckland, Auckland Bioengineering Institute, Auckland, New Zealand ; <sup>3</sup>University College London, Department of Medical Physics & Biomedical Engineering, London, United Kingdom ; <sup>4</sup>University College London, Wellcome EPSRC Centre for International and Surgical Sciences, London, United Kingdom ; <sup>5</sup>University College London, Department of Oncology, London, United Kingdom

**Purpose or Objective**

Radiation therapy to treat lung cancer presents a trade-off between eradicating cancer cells and minimising radiation-induced lung damage (RILD). It is challenging to predict which patients will suffer from RILD due to the large variation in individualised response to RT, due to factors such as age, smoking status and baseline lung function. The ability to accurately predict this risk and the functional implications of RILD for an individual patient is lacking. Previous studies have typically used univariate analyses to predict lung function post-RT, with limited multivariate statistical analysis applied in this area. In this study, we apply statistical methods including principle component analysis (PCA) and multiple linear regression on a well-defined clinical dataset of patients with lung cancer before and after RT to develop a computational tool to improve RT planning and treatment in patients with lung cancer.

**Material and Methods**

Forty-four patients were selected from a Phase 1/2 trial of isotoxic dose-escalated RT and concurrent chemotherapy in patients with stage II/III non-small cell lung cancer, known as the IDEAL-CRT trial. All patients were treated with 63-73 Gy in 30 fractions over 6 weeks (daily). CT and pulmonary function data (FEV<sub>1</sub>, DLCO and FVC) were collected 12 months post-RT. We applied multivariate analysis, using PCA and multiple stepwise regression to develop a model to predict lung function post-RT. The dataset contained 14 variables, shown in Fig. 1. We used the PCAmix method which combines standard PCA for numerical data and multiple correspondence analysis for categorical data in the R software environment. PCAmix calculated the principal component scores (PCs) which were used as predictors to build a multiple linear regression model applying a stepwise method. Our results (PCAmix predicted) were compared with predictions using general multiple linear regression (MLR predicted) and measured values of lung function.

**Fig. 1:** Demonstration of the 14 variables used in our multivariate analysis.

**Results**

The r-squared value of the PCAmix regression model was 81%, compared to 55% when using the MLR model. The FEV<sub>1</sub> % predicted at 12 months post-RT measured/predicted were compared to assess how well

our model performed (Fig. 2). This method was also used to predict DLCO and FVC % predicted 12 months post-RT, with r-squared values of 71% and 74% respectively. A 10-fold cross-validation indicated that the model was over fitted using all 12 PCs, therefore 4 PCs with a p value greater than 0.05 were removed to resolve this issue.

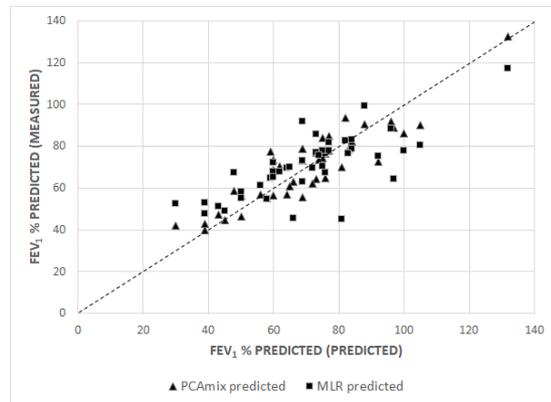

Fig. 2: Measured vs predicted FEV<sub>1</sub> % predicted 12 months post-RT. Predicted values were obtained using PCAmix regression (▲) and MLR regression (■) models.

#### Conclusion

The PCAmix regression method shows great potential in combining PFTs, dosimetry and demographic parameters for the prediction of lung function post-RT for lung cancer patients. This method must be validated with a larger sample size in the future.

#### PO-0949 Improved external validation performance of predictive radiomics models using statistical methods

A. Chatterjee<sup>1</sup>, M. Vallières<sup>1</sup>, A. Dohan<sup>2</sup>, I. Levesque<sup>1</sup>, Y. Ueno<sup>2</sup>, S. Saif<sup>2</sup>, C. Reinhold<sup>2</sup>, J. Seuntjens<sup>1</sup>

<sup>1</sup>McGill University, Medical Physics, Montreal, Canada ;  
<sup>2</sup>McGill University, Radiology, Montreal, Canada

#### Purpose or Objective

In radiomics, a predictive model may underperform on data from independent institutions. Region-of-interest contouring variability and image acquisition differences are two possible causes. While models can be made robust by inter-institutional data pooling, it is unlikely that the combined dataset reflects the global distribution of radiomic features. We aimed to create a statistical methodology to improve outcome prediction on external datasets of uterine adenocarcinoma patients with endpoints of (a) lymphovascular space invasion (LVSI), and (b) FIGO stage, grouped as early (IA) and advanced.

#### Material and Methods

The central idea, developed by us in earlier work, involves (a) creating balanced training and testing sets by under-sampling the majority class, and (b) standardizing training and testing sets separately. Standardization makes a feature distribution have zero mean and unit standard deviation. Standardizing features separately for each dataset reduces feature variability between datasets. Teaching set (used for training and validation) contained 94 samples (Hospital X) and testing set comprised 63 samples (Hospital Y). 6 different MRI sequences were available for each patient. Extracted features followed Image Biomarker Standardisation Initiative recommendations. They were divided into non-texture (e.g., morphological, histogram-based) and texture (e.g., matrix-based), to see if any benefit resulted from using texture features, which are harder to interpret. The 2 prediction approaches were: (i) using single features, and (ii) combining only three features, using basic machine learning tools (e.g., Naïve Bayes) to avoid over-training. Single feature selection focused on picking the strongest predictive features whereas combined feature selection

focused on predictors that were strong (but not necessarily the strongest) and did not have much redundancy. Feature selection was based on statistical stability of features in the teaching set. Corrections for multiple hypothesis testing were applied whenever appropriate.

#### Results

The table summarizes our findings. When including texture features in addition to non-texture features, the best AUC for a single feature improved in both the training set and the testing set. When combining three texture features into a model, the best AUC in the training set was better than for a single feature. However, this improvement was not seen in the testing set. The likely explanation is that while standardization reduces the differences between the two datasets, it cannot eliminate them.

Table: Summary of the best performing prediction models. First, we show a model with one feature (either non-texture or texture feature), and then a model with 3 features.

Outcome	Single non-texture feature	Training AUC (mean)	Testing AUC	Corrected p-value
FIGO	Least PCA axis length	0.78	0.78 [0.70,0.87]	0.004
LVSI	Area/Volume	0.75	0.75 [0.69,0.81]	0.016

Outcome	Single texture feature	Training AUC (mean)	Testing AUC	Corrected p-value
FIGO	NGLDM, dc_var	0.82	0.81 [0.72, 0.90]	0.01
LVSI	NGLDM, HDLGE	0.78	0.79 [0.73, 0.86]	0.01

FIGO (corrected p-value = 0.0017)	Training	Validation	Testing
Accuracy	0.79 [0.74,0.84]	0.78 [0.68,0.86]	0.78 [0.72,0.83]
Sensitivity	0.73 [0.62,0.83]	0.73 [0.64,0.86]	0.70 [0.63,0.77]
Specificity	0.85 [0.76,0.90]	0.82 [0.64,0.93]	0.87 [0.79,0.89]
AUC	0.88 [0.84,0.93]	0.87 [0.77,0.95]	0.79 [0.73,0.86]

LVSI (corrected p-value = 0.017)	Training	Validation	Testing
Accuracy	0.77 [0.69,0.82]	0.74 [0.60,0.87]	0.71 [0.65,0.76]
Sensitivity	0.74 [0.65,0.81]	0.72 [0.60,0.87]	0.69 [0.60,0.74]
Specificity	0.79 [0.71,0.84]	0.76 [0.60,0.93]	0.73 [0.65,0.82]
AUC	0.83 [0.78,0.89]	0.80 [0.69,0.92]	0.76 [0.68,0.85]

#### Conclusion

Our methodology yielded model performances that are statistically significant and match (FIGO stage) or surpass (LVSI) the performance of an expert radiologist. Due to the statistical nature of the approach, it can be applied to diverse scenarios. We are applying this technique when modeling the risk of distant metastasis in head and neck squamous cell carcinoma datasets collected from 6 different hospitals.

#### PO-0950 Determining the radiodensity range for data-driven quantification of radiation-induced lung fibrosis

L.M. Wang<sup>1</sup>, A. Chatterjee<sup>2</sup>, A. Semionov<sup>3</sup>, J. Tsui<sup>4</sup>, S. Lee<sup>5</sup>, I. Yang<sup>4</sup>, Y. Al Bulushi<sup>4</sup>, J. Seuntjens<sup>2</sup>, N. Ybarra<sup>6</sup>

<sup>1</sup>McGill University, Medical Physics Unit, Montreal, Canada ; <sup>2</sup>Cedar's Cancer Centre, Medical Physics Unit, Montreal, Canada ; <sup>3</sup>Royal Victoria Hospital, Radiology, Montreal, Canada ; <sup>4</sup>Cedar's Cancer Centre, Radiation Oncology, Montreal, Canada ; <sup>5</sup>Memorial Sloan Kettering Cancer Centre, Memorial Sloan Kettering Cancer Centre, New York, USA ; <sup>6</sup>Montreal University Healthcare Centre - Research Institute, Radiobiology, Montreal, Canada

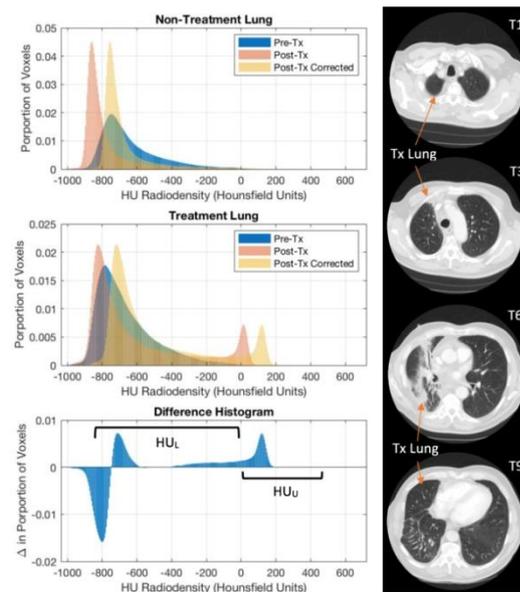

#### Purpose or Objective

Many data-driven strategies have been developed to quantify radiation-induced lung fibrosis (RILF) in patients after thoracic radiotherapy (RT). These methods make use of the unique distributions of voxel radio-densities, measured in Hounsfield Units (HU), in computed tomography (CT) images of the lung. These unique HU distributions can indicate the presence of certain interstitial diseases through measurable variations. However, to our knowledge, there is no empirical and quantitative evidence to support exact HU ranges that best characterize and delineate the radio-density

characteristics of RILF. This study aims to empirically test and propose an appropriate HU range which corresponds to RILF.

### Material and Methods

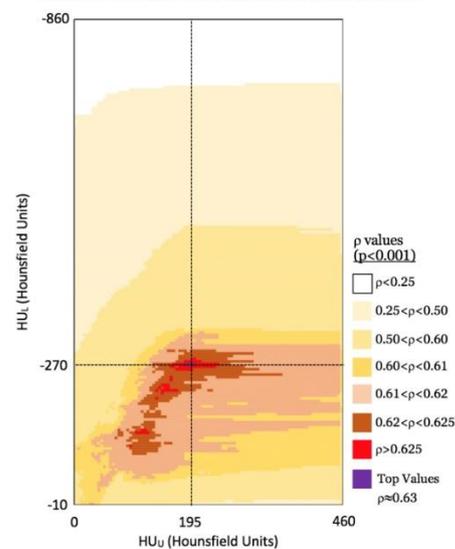

Voxel HU values were extracted from 68 patient lung CTs at pre-treatment (simulation CT) and 6-months post-treatment (diagnostic CT). A team of 2 radiation oncologists and 2 radiologists scored the patient population for RILF severity on a five-grade scale: 0 = no fibrosis, 1 = 1 pulmonary segment equivalent of fibrosis (PSEF), 2 = 2 PSEF, 3 = 3 PSEF, 4 = 4 PSEF, 5 = >5 PSEF. We defined PSEF as the volume of half the right middle lung lobe. Post-treatment images were deformably registered to pre-treatment CTs using an in-house algorithm developed in MevisLab™. The registered image was corrected using the non-irradiated lung to account for scanner differences between images acquired at baseline and follow-up. For the irradiated lung parenchyma (defined as total treated lung volume minus PTV) the voxel HU counts were binned as histograms. The difference between follow-up and baseline histograms was computed and its area normalized to unity. We then computed the integral ( $HU_{int}$ ) of the difference histogram between a lower ( $HU_L$ ) and upper ( $HU_U$ ) HU range.  $HU_L$  was varied between -860 HU (below which is health lung parenchyma) to -10 HU and  $HU_U$  was varied between 0 HU to 460 HU (above which is no longer soft tissues). Each combination of  $HU_L$  and  $HU_U$  yielded a unique  $HU_{int}$  for each patient. For the patient cohort, the Spearman correlation ( $\rho$ ) was calculated between these unique  $HU_{int}$  and the mode of the physician assigned scores. See Figure 1 for an illustration of the method.

### Results

As seen in Figure 2, for a fixed  $HU_U$  value of 200 HU, changes in the  $HU_L$  showed dramatic effects on  $\rho$ , with values of 0.07 ( $p < 0.001$ ) at -850 HU increasing to 0.63 ( $p < 0.001$ ) at -270 HU. With  $HU_L$  fixed at -270 HU, we observed no more than 20% variation in  $\rho$  when  $HU_U$  was varied. The best performance ( $\rho = 0.63$ ) was for  $HU_L = -270$  HU and  $HU_U = 195$  HU.

Heatmap of  $\rho$  between  $HU_{int}$  and Physician's Score

### Conclusion

For a quantitative analysis of RILF, we found a value of  $\approx -270$  HU to be appropriate for  $HU_L$ . We were unable to establish a  $HU_U$  recommendation given  $HU_U$  choice is less impactful on the predictive ability of  $HU_{int}$ . We suspect this is due to the reduced number of voxels that occupy the higher densities. These recommendations need to be externally validated on larger populations.

### PO-0951 How to build accurate prediction models without sharing patient data across hospitals?

I. Zhovannik<sup>1,2</sup>, Z. Shi<sup>1</sup>, F. Dankers<sup>1,2</sup>, T. Deist<sup>3</sup>, A. Traverso<sup>1</sup>, P. Kalendralis<sup>1</sup>, R. Monshouwer<sup>2</sup>, J. Bussink<sup>2</sup>, R. Fijten<sup>1</sup>, H. Aerts<sup>4,5,6</sup>, A. Dekker<sup>1</sup>, L. Wee<sup>1</sup>

<sup>1</sup>Maastricht University Medical Center +, Radiation Oncology - Maastricht, Maastricht, The Netherlands ; <sup>2</sup>Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands ; <sup>3</sup>Maastricht University, The D-Lab: Decision Support for Precision Medicine, Maastricht, The Netherlands ; <sup>4</sup>Harvard Medical School, Brigham and Women's Hospital, Boston, USA ; <sup>5</sup>Maastricht University Medical Center +, Radiology, Maastricht, The Netherlands ; <sup>6</sup>Dana-Farber Cancer Institute, Computational Imaging and Bioinformatics Laboratory, Boston, USA

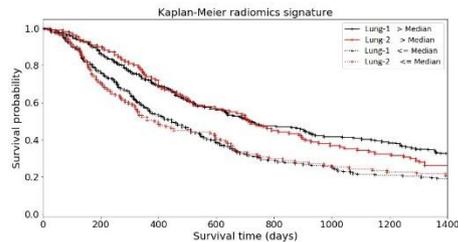

### Purpose or Objective

Imagine if you had an intelligent model that could select the most optimal treatment for a cancer patient, i.e. optimizing the tradeoff between tumor control and side effects. Are we close to having such a model? Patient data are unstructured and distributed in patient databases all over the world - that is the greatest challenge. In addition, there are bureaucratic and legal barriers to share (even anonymized) patient data. To avoid the difficulties of data-sharing we proposed to use a distributed learning approach where the privacy-sensitive data never leaves the hospital. In this approach, only a model is shared and optimized.

### Material and Methods

We used the pioneering approach of Aerts et al (2014) to build a model in a distributed fashion without data sharing between two hospitals. The developed Cox proportional hazards radiomic model splits a patient cohort into two groups by the median mortality risk. To train and validate the model we used two cohorts of non-small cell lung cancer patients of the two hospitals (441 and 221 patients respectively). We extracted radiomic image biomarkers from the Gross Tumor Volume (GTV) of both cohorts. Radiomics ontology (RO) and radiation oncology ontology

(ROO) were used to make radiomics and clinical data extracted in the hospitals intelligible for models. We validated the model distributedly using the Varian Learning Portal securing local patient data.

## Results

We found a significant split in both training (log-rank test  $p=0.009$ ) and validation cohorts (log-rank test  $p=0.03$ ).

## Conclusion

The original model was reproduced with the significant data split. This way we showed that imaging prediction models can be made in a distributed fashion without data-sharing.

## PO-0952 CT-based Radiomics Predicting HPV Status in Head and Neck Squamous Cell Carcinoma

Z. Shi<sup>1</sup>, C. Zhang<sup>2</sup>, M. Welch<sup>3</sup>, P. Kalendralis<sup>1</sup>, W. Leonard<sup>1</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>GROW - School for Oncology and Development Biology-Maastricht University Medical Centre, Department of Radiation Oncology Maastricht Clinic, Maastricht, The Netherlands ; <sup>2</sup>Maastricht University, Department of Data Science and Knowledge Engineering, Maastricht, The Netherlands ; <sup>3</sup>University of Toronto, Department of Medical Biophysics, Toronto, Canada

## Purpose or Objective

Human papillomavirus (HPV) testing is an important prognostic factor for oropharyngeal squamous cell carcinoma (OPSCC). HPV-related OPSCC is now considered to be a separate tumour type from non-HPV related tumours with differential cancer prognosis. Conventionally, HPV status is determined via a minimally invasive needle biopsy. The aim of this study was to investigate whether CT image-derived radiomics are able to predict HPV status of patients diagnosed with primary OPSCC in a non-invasive approach.

## Material and Methods

Six independent cohorts, 255 patients in total were collected in this study, in which patients were treated with radiation only or chemo-radiation therapy as part of their treatment. HPV positive was defined as expression of the p16 gene variant. CT scans with visible artifacts (e.g., metallic dental fillings) within the GTV were excluded from further analysis. The data was randomly split into training ( $n=142$ ), tuning ( $n=48$ ) and test ( $n=65$ ) sets. CT images were resampled to isotropic voxels of 2 mm via linear interpolation. A total of 1105 radiomic features, consisting of histogram statistics, shape, texture and features by Wavelet and Laplacian of Gaussian filtering, were extracted from the GTV via an open-source radiomics package O-RAW that is an extension wrapper of PyRadiomics. Feature selection was based on: (i) feature stability ranking, (ii) Kolmogorov-Smirnov test of each feature between HPV positive and negative, and (iii) correction between the remaining features. For the model, a parsimonious yet optimally predictive set of features from the remaining candidates after selection

were determined by recursive feature elimination. The radiomic features were not normalized on any data sets. Multivariable logistic regression, SVM, and random forest, were applied for training classifier. The classification performance of HPV status was assessed by the area under the receiver operator curve (AUC). The Wilcoxon test was used to assess significance between AUCs and random ( $AUC=0.5$ ).

## Results

Out of 255 patients, 174 (68.2%) patients were with HPV positive and the rest 81 (31.8%) patients were with negative. After feature selection, 3 radiomic features, (i) original\_shape\_Sphericity, (ii) original\_firstorder\_Entropy, and (iii) log-sigma-3-0-mm-3D\_glszm\_SizeZoneNonUniformityNormalized, were selected to develop models. The multivariable logistic regression classifier achieved the highest AUC on both training and test sets, yielding mean AUCs of 0.79 (95% CI: 0.78 - 0.79,  $p$ -value  $< 10^{-4}$  Wilcoxon test) and 0.72 (95% CI: 0.71 - 0.72,  $p$ -value  $< 10^{-4}$  Wilcoxon test), respectively. The AUCs are shown in Figure 1. The performance of HPV status prediction of the three classifiers are shown in Table 1.

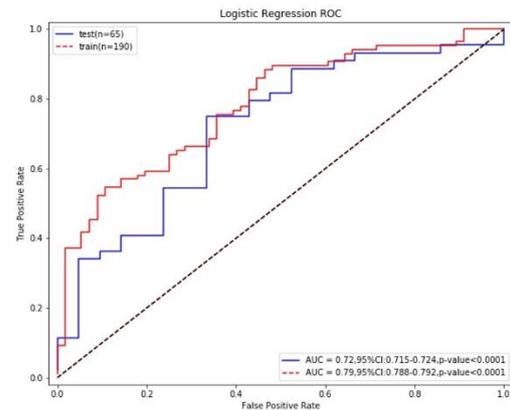

Figure 1: The receiver operator curve for HPV status classification using logistic regression.

Table 1: Classification of HPV status using three approaches.

	100 times 5-fold CV mean AUC on training set	1000 times bootstrapped AUC on test set
Logistic Regression	0.79, 95% CI: 0.78 - 0.79, $p$ -value $< 0.0001$ Wilcoxon test	0.72, 95% CI: 0.71 - 0.72, $p$ -value $< 0.0001$ Wilcoxon test
Linear SVM	0.76, 95% CI: 0.75 - 0.77, $p$ -value $< 0.0001$ Wilcoxon test	0.70, 95% CI: 0.70 - 0.71, $p$ -value $< 0.0001$ Wilcoxon test
Random Forest	0.68, 95% CI: 0.67 - 0.69, $p$ -value $< 0.0001$ Wilcoxon test	0.60, 95% CI: 0.59 - 0.61, $p$ -value $< 0.0001$ Wilcoxon test

\*CV: cross validation; CI: confidence interval

## Conclusion

It is possible to classify HPV status for HNSCC patients using CT image-derived features, which could lead to better precision treatment decision. However, the results should be further validated on larger and external datasets.

## PO-0953 Are quality assurance phantoms useful to assess radiomics reproducibility? A multi-center study

<sup>1</sup>Maastricht Radiation Oncology Maastricht Clinic, Radiotherapy, Maastricht, The Netherlands ; <sup>2</sup>Radboud University Medical Centre, Radiation Oncology, Nijmegen, The Netherlands ; <sup>3</sup>Radboud University Medical Center, Radiation Oncology, Nijmegen, The Netherlands ; <sup>4</sup>Erasmus Medical Center, Medical Physics, Rotterdam, The Netherlands ; <sup>5</sup>Erasmus Medical Centre, Medical Physics, Rotterdam, The Netherlands ; <sup>6</sup>University Medical Centre Groningen, Medical Physics, Groningen, The Netherlands ; <sup>7</sup>Maastricht Radiation

*Oncology Maastricht Clinic, Radiation Oncology, Maastricht, The Netherlands*

### Purpose or Objective

To guarantee the generalizability and validity of radiomics-based models, only reproducible features should be used. "Reproducible" features refer to features that show marginal differences when imaged with different settings. Only a few expensive phantoms specially designed for radiomics studies are available on the market. In this study, we exploited the feasibility of performing radiomics reproducibility studies with a quality assurance phantom, commonly used in the clinics.

### Material and Methods

The dataset (available at <https://xnat.bmia.nl/>) consists of CT scans of the COPD Gene Phantom II (Phantom Laboratory, Greenwich, NY, USA) acquired in three Dutch medical centers. Acquisition parameters like slice thickness, or convolutional kernel were varied from the standard thorax protocols.

Textural and statistical first order (FO) features were extracted using Pyrex (<https://github.com/zhenweishi/Py-rex>) from a spherical region in the insert cavities of the phantom. The relative difference (RD) between features values on different scanners with different settings was used to evaluate features reproducibility, with the following thresholds: a)  $0 < RD \leq 10\%$ : high reproducibility, b)  $10\% < RD \leq 30\%$ : medium reproducibility; c)  $RD > 30\%$ : poor reproducibility. Agreement between centers were evaluated using the Spearman rank correlation coefficients ( $\rho$ ).

### Results

73 radiomics features were extracted. Slice thickness: around 50% of the features in all the centers ( $\rho = 0.8$ ) showed poor reproducibility. Most of the GLSZM (Gray Level Size Zone Matrix) features were poorly reproducible compared to the other textural features. FO features were in general more stable than textural features. Reconstruction kernels: almost all the FO features presented high reproducibility in all the centers ( $\rho = 0.75$ ). Again, textural features were more impacted, with GLSZM features the least reproducible in all the centers. Only a small percentage of features (14% for center1, 14% for center2, and 30% for center3 presented high reproducibility) were robust for all the perturbations. There is only small subset (12%, 9/73) of common features with high reproducibility between the centers (Figure1). However, it is possible to isolate a larger common subset of features presenting poor reproducibility in all the three centers. Again, the majority of textural features had overall poor reproducibility compared to FO features.

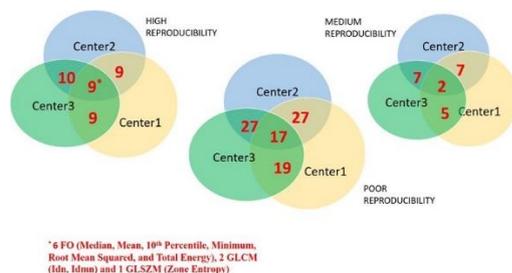

Figure1: results of the comparative analysis. A common subset of 19 features was found to be poor reproducible for all the centers. Only 9 features had high reproducibility

### Conclusion

Radiomics features are strongly affected by acquisition parameters. FO features were more robust than textural features. As Figure1 shows, the consensus is higher when using phantoms to identify features that present poor reproducibility. We showed that it is possible to use standard and common quality assurance phantoms to

investigate features reproducibility. In particular, as our results show, simple phantoms are mostly useful to define a list of "excluded" features due to their poor reproducibility even in the presence of inserts of simple shapes.

### PO-0954 A Prediction Model of Acute Esophageal Toxicity in Esophageal Squamous Cell Carcinoma Patients

L. Jiang<sup>1</sup>, S. Lu<sup>1</sup>, J. Lu<sup>1</sup>, W. Hu<sup>1</sup>, J. Wang<sup>1</sup>, Y. Chen<sup>1</sup>, K. Zhao<sup>1</sup>

<sup>1</sup>Fudan University Shanghai Cancer Center, Department of Radiation Oncology, Shanghai, China

### Purpose or Objective

This study sought to establish a multivariable normal tissue complication probability (NTCP) model for Grade  $\geq 2$  acute esophageal toxicity (AET) after definitive intensity-modulated radio(chemo)therapy in patients with esophageal squamous cell carcinoma (ESCC).

### Material and Methods

A cohort of 181 ESCC patients was enrolled in this study. The clinical and dosimetric parameters were analysed. Clinical parameters included age, gender, use of concurrent chemotherapy, T, N, M stage, and tumor location. Dosimetric parameters of the esophagus included the following: V5 to V65 with step of 5Gy, mean esophagus dose, maximum esophagus dose, GTV-L, PTVp-L. A Spearman's rank correlation coefficient matrix was calculated. A univariate logistic analysis was performed for each available predictor. The multivariate logistic regression model was achieved by least absolute shrinkage and selection operator (LASSO) logistic regression for predictor selection. The performance of the model was evaluated by the area under the curve (AUC) of the receiver operating characteristic (ROC) curve and calibration plot. The external validation of the model were carried out in a independent cohort.

### Results

A total of 42 patients (22.8%) developed Grade  $\geq 2$  AET. In the univariate logistic analysis, age  $> 65$  and length of planning target volume of primary esophageal cancer (PTVp-L) were significantly associated with risk of Grade  $\geq 2$  AET (Table 1). The final model (Table 2) enrolled age  $> 65$  (OR=0.59), PTVp-L (OR=1.03), and lower thoracic esophageal cancer (OR=0.53). The model parameters for the multivariable logistic regression model didn't correlate to each other. The AUC of the prediction model was 0.6837(95%CI: 0.5975-0.7699) (Figure 1), and the cross-validation optimism-corrected AUC was 0.64. The model showed moderate calibration (Figure 2). On validation in the external dataset, the prediction model showed moderate calibration and moderate discrimination (AUC 0.5901 (95%CI: 0.467-0.7132) for predicting Grade  $\geq 2$  AET.

**Table 1** Results from univariate logistic regression analysis for clinical and dosimetric parameters.

Clinical and dosimetric parameters	Coefficient	Standard error	Odds ratio (95%CI)	P-value
Age (years) (> 65 vs ≤ 65)	-1.141	0.413	0.32(0.14-0.72)	<b>0.006</b>
PTVp-L (per cm increase)	0.107	0.055	1.11(1.00-1.24)	<b>0.049</b>
No. of pack-years (>18 vs ≤ 18)	0.055	0.354	1.06(0.53-2.11)	0.877
Alcohol (yes vs no)	0.218	0.365	1.24(0.61-2.55)	0.550
Gender (female vs male)	0.249	0.386	1.28(0.60-2.73)	0.519

**Table 2** Predictive parameters from LASSO logistic regression analysis of the final model.

Predictor	Coefficient	Odds ratio
Age (> 65 vs ≤ 65)	-0.528	0.59
PTVp-L (per cm increase)	0.026	1.03
Lower thoracic ESCC constant	-1.254	

Figure 1

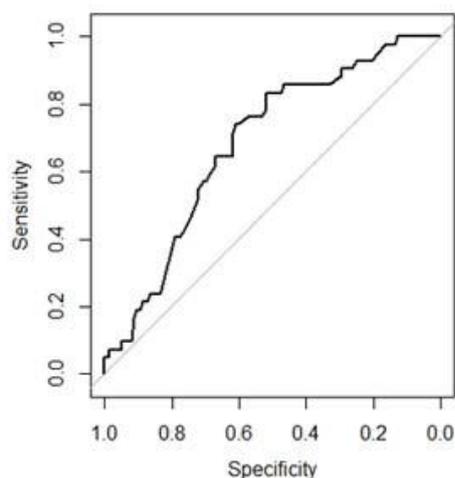

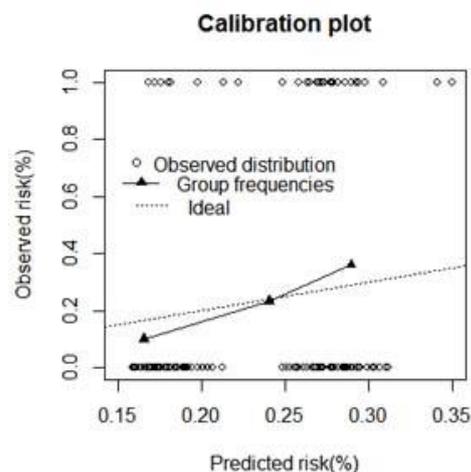

Figure 2

### Conclusion

A multivariate NTCP model including age, PTVp-L, and tumor location predicts Grade  $\geq 2$  AET after radio(chemo)therapy for ESCC. The results of this study suggest that the risk of Grade  $\geq 2$  AET decreased in elderly or lower thoracic esophageal cancer patients while increased in patients with longer PTVp-L.

### PO-0955 Radiomics signature as predictors of survival and local control after pancreatic carcinoma SBRT

Margarita<sup>3</sup>, A. Chiti<sup>6</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital and Humanitas University, Radiation Oncology Dept and Biomedical Science Dept, Milan-Rozzano, Italy; <sup>2</sup>Humanitas Research Hospital, Radiation Oncology Dept, Milan-Rozzano, Italy; <sup>3</sup>Humanitas Research Hospital, Radiology Dept, Milan-Rozzano, Italy; <sup>4</sup>Humanitas Research Hospital, Pancreatic Surgery Dept, Milan-Rozzano, Italy; <sup>5</sup>Humanitas Research Hospital, Nuclear Medicine Dept, Milan-Rozzano, Italy; <sup>6</sup>Humanitas Research Hospital and Humanitas University, Nuclear Medicine Dept and Biomedical Science Dept, Milan-Rozzano, Italy

### Purpose or Objective

Pancreatic adenocarcinoma has generally unfavorable prognosis. Combined chemio-radiotherapy is a frequently adopted treatment, especially for patients unfit to surgery, leading to possible overall survival at 2 years of about 30%. To better personalize the treatment, the ability of a radiomics signature to predict clinical outcome after stereotactic body radiation therapy has been explored.

### Material and Methods

One-hundred patients have been selected from the institutional database, presenting histologically proven, inoperable locally advanced pancreatic cancer and treated in our department with SBRT with a total dose of 45 Gy in 6 fractions. All patients underwent planning CT with no contrast agent, where the CTV was delineated and accurately cleaned from confounding regions. Radiomics texture features were extracted for these CTVs using the LifeX software tools. A total of 41 features were computed. The statistical analysis was conducted with dedicated routines on R scripts.

The cohort of 100 patients was separate in two groups of 60 and 40 patients, used for the training and validation processes, respectively. In the training phase, with the univariate Cox regression, the prognostic value of clinical and radiomic features was investigated to the predict

overall survival, OS, and the local control, LC. The quality of the models was appraised by means of the concordance index and the area under the curve, AUC. The significant predictors at univariate analysis were included in a multivariate Cox regression model including the uncorrelated significant features. The multivariate model was then verified on the validation group.

### Results

The analysis of clinical and textural data showed 9 predictors significant at univariate analysis for OS, and 4 predictors significant for LC. In the multivariate model, only two variables resulted significant predictors for OS: age and Homogeneity\_GLCM with  $p < 0.01$ , with AUC of 0.80 (95%CI: 0.66-0.94) and 0.73 (95%CI: 0.53-0.93) in the training and validation groups, respectively. Again in the multivariate model, two features were retained: short run low grey level emphasis and grey level non-uniformity, with AUC of 0.65 (95%CI: 0.52-0.81) and 0.61 (95%CI: 0.50-0.78) for the training and validation sets, respectively. In the low risk group, the median OS and LC in the validation group were 14.4 (95%CI: 12.2-21.2) and 28.6 (95%CI: 12.5-not reached) months, while in the high-risk group were 8.6 (95%CI: 7.0-18.0) and 17.5 (95%CI: 7.6-not reached) months, respectively.

### Conclusion

A CT based radiomic signature was identified which correlate with OS and LC after SBRT for pancreatic adenocarcinoma, and allowed to identify low and high-risk groups of patients.

### PO-0956 Non Invasive Grading of Non-Small Cell Lung Cancer Using Machine Learning Models Based on Radiomics

S. Aouadi<sup>1</sup>, R. Hammoud<sup>1</sup>, T. Torfeh<sup>1</sup>, N. Al-Hammadi<sup>1</sup>  
<sup>1</sup>National Center for Cancer Care & Research, Radiation Oncology, Doha, Qatar

#### Purpose or Objective

Grading of non-small cell lung cancer (NSCLC) is crucial for appropriate therapy decisions and prediction of prognosis. Traditionally, invasive histological methods are used. We propose non-invasive approaches for grading NSCLC by training machine learning models on radiomics.

#### Material and Methods

259 patients with NSCLC were collected from the dataset [NSCLC-Radiomics] in The Cancer Imaging Archive. For each patient, pretreatment CT scans, manual delineation of the GTV and histological classification (28 adenocarcinoma (AC), 85 squamous cell carcinoma (SCC), 93 large cell carcinoma (LCC), and 53 adenosquamous carcinoma (NOS) cases) were available. The dataset was randomized and divided into training and validation sets of 200 and 59 patients respectively.

CT scans were resampled to  $1 \times 1 \times 1 \text{ mm}^3$  voxels using three-dimensional Lagrangian polygon interpolation and intensities were divided into bins of 10HU from -1000 to 3000HU. 42 radiomic features were extracted from GTV's VOI, defined on each patient CT, using LIFEx software (v4.00). They were composed of 3 shape, 8 first order, and 31 texture features. Shape features describe the 3D geometric properties of the tumor. The first order features describe tumor intensity distribution. Texture features, which describe the intra-tumor heterogeneity, were extracted from the gray level co-occurrence (6), neighborhood grey-level different (3), grey-level run length (11), and grey-level zone length (11) matrices.

Machine learning models are composed of three blocs: preprocessing, selection and classification. Multiple configurations were benchmarked. Features preprocessing methods were QTRG (mapping data to have normal distribution), MINMAX\_SC (linear scaling to [0, 1]), or ROBUST\_SC (scaling to the interquartile range). The selection methods of the most representative features were based on elastic-net regularization (ELASTIC-NET), univariate statistical tests (Anova-F or mutual information

(MI)), or Support Vector Machine (SVM) model. The binary classifiers, trained to predict each histological class (AC, SCC, LCC, and NOS), were linear model or deep neural networks (DNN) (ReLU activation, dropout of 0.35, and 2 layers of 30 neurons each).

The performance of the machine learning models was assessed by the computation of the ROC curve, the area under the ROC curve (AUC; measure of separability between classes for any threshold) and the accuracy (the fraction of correct predictions) for each histological class.

### Results

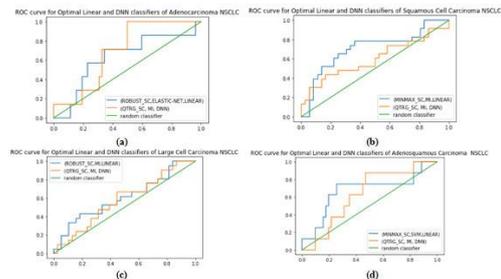

Table 1 displays the AUC and Accuracy on training and validation sets using the best machine learning methods having linear or DNN classifiers. Figure 2 shows the ROC curves obtained for tumor grade prediction on validation set. DNN gave superior modeling of the training set whereas linear models gave better prediction on the validation set.

### Conclusion

We demonstrated that machine learning models trained on CT's radiomic features could potentially predict histological categorization of NSCLC tumors. Further investigations will be done.

**Table1.** The AUC and Accuracy obtained for the training (auc<sub>t</sub>, acc<sub>t</sub>) and validation sets (auc<sub>v</sub>, acc<sub>v</sub>) using the superior machine learning method with linear or DNN classifiers.

Histology	Machine Learning Model	auc <sub>t</sub>	auc <sub>v</sub>	acc <sub>t</sub>	acc <sub>v</sub>
AC	(ROBUST_SC, ELASTIC-NET, LINEAR)	0.52	0.63	0.89	0.86
	(QTRG, MI, DNN)	0.81	0.58	0.89	0.88
LCC	(ROBUST_SC, MI, LINEAR)	0.60	0.60	0.60	0.70
	(QTRG, MI, DNN)	0.80	0.60	0.70	0.61
NOS	(MINMAX_SC, SVM, LINEAR)	0.60	0.70	0.80	0.90
	(QTRG, MI, DNN)	0.77	0.59	0.77	0.86
SCC	(MINMAX_SC, MI, LINEAR)	0.59	0.70	0.69	0.61
	(QTRG, MI, DNN)	0.70	0.60	0.74	0.63

### Purpose or Objective

Gliomics is a research project with the goal of extracting radiomics from multimodal imaging data of multicenter prospective phase III trial for newly diagnosed glioblastoma (NCT01507506) [1]. This study compares quantitative radiomics features extracted from the boost, ie. the high-dose volume (HDV) with the low-dose volume (LDV) on planning CT scan. The aim is to quantify increased aggressiveness of the tumor in area defined by MRI (the high dose).

### Material and Methods

Eighty Three patients included in the SPECTRO-GLIO trial presenting with and without local recurrence at the time of the radiomics analysis were analyzed in this study, Forty-one patients (49.4 %) were in Arm A, with Stupp protocol (3DCRT or IMRT 60 Gy/2Gy on contrast enhancement (GTV1)+ 2 cm margin with concomitant temozolomide (TMZ) and six months of TMZ maintenance); Forty-two patients (50.6 %) were in Arm B with the standard treatment with an additional simultaneous integrated boost of intensity-modulated radiotherapy (IMRT) of 72Gy/2.4Gy delivered on the MR spectroscopic imaging metabolic volumes of CHO/NAA>2 and contrast-enhancing lesions or resection cavity(GTV2)+ 1cm margin [2].

For each patient, the GTV1 and GTV2 were delineated in the participating centers following guidelines for arm A, delineated in the coordinating center for arm B and were all validated by central review. The CT and structure data in DICOM RT format were imported into IBEX (Imaging Biomarker Explorer software) [3] and automatically processed using in-house developed data analytics. As the majority of relapses were in the CTV, 116 features (GrayLevelCooccurrenceMatrix, GrayLevelRunLengthMatrix, Intensity, NeighborIntensityDifference, Shape) [3] were extracted from CTV1 and CTV2 volumes. The Wilcoxon signed-rank test was used for paired comparison and Bonferonni's correction was applied. Corrected p-value <0.05 was considered statistically significant. Statistical analyses were conducted using R version 3.5.1.

### Results

The statistics analysis showed that of the 116 features extracted, 39 of them proved to be significantly different between CTV1 and CTV2. As reported in table 1(below), 18 of significant features were RayLevelRunLengthMatrix, Intensity and NeighborIntensityDifference with a p value <0.0001.

**Table 1: The 18 most significant radiomics features between CTV1 and CTV2**

### Conclusion

There was a significant difference of features between the two doses volumes which may be a reflection of tumor heterogeneity. To consolidate the findings of this study we will extend the radiomics analysis to multimodal MR imaging data [4] that was acquired longitudinally during this trial and correlate the features of interest to survival. ### PO-0958 Mortality Risk Stratification Model based on Radiomics Only: Analysis of Public Open Access HNC Data

Z. Shi<sup>1</sup>, C. Zhang<sup>2</sup>, T. Zhai<sup>3</sup>, M. Welch<sup>4</sup>, L. Wee<sup>1</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>Maastricht University Medical Centre, Department of Radiation Oncology Maastricht Clinic- GROW - School for Oncology and Development Biology, Maastricht, The Netherlands ; <sup>2</sup>Maastricht University, Department of Data Science and Knowledge Engineering, Maastricht, The Netherlands ; <sup>3</sup>University of Groningen, Department of Radiation Oncology- University Medical Center Groningen, Groningen, The Netherlands ; <sup>4</sup>University of Toronto, Department of Medical Biophysics, Toronto, Canada

### Purpose or Objective

The primary aim of this study was to investigate whether CT image-derived radiomics are able to predict overall survival (OS) of patients diagnosed with primary Head and Neck Squamous Cell Carcinomas (HNSCC).

### Material and Methods

5 independent cohorts, 411 patients in total were collected in this study, in which patients were treated with radiation only or chemo-radiation therapy as part of their treatment. CT scans with visible artifacts (e.g., metallic dental fillings) within the GTV were excluded from further analysis. The dataset was split into training set (cohort 1, 2 and 3, n=308) and validation set (cohort 4 and 5, n=103) with the ratio of 3:1. CT images were resampled to isotropic voxels of 2 mm via linear interpolation. A total of 1105 features, consisting of

histogram statistics, shape, texture and features by Wavelet and Laplacian of Gaussian filtering, were extracted from the GTV via an open-source radiomics package O-RAW that is an extension wrapper of PyRadiomics. Radiomic features were pre-selected to reduce the probability of over-fitting. If the Spearman correlation between pairs of radiomic features was bigger than 0.85, then the feature with the lower univariable association with OS was eliminated from further analysis. All the pre-selected potential radiomic features were analysed for their prognostic power using the median value in the training set as the threshold value in the univariable analysis. The logrank test was used to assess whether the individual feature can stratify patients into high and low risk groups. The radiomic features were not normalized on any data sets. Multivariable Cox proportional hazards regression model was used to examine the association between survival and radiomic features. The concordance index (c-index) was determined to assess the models discrimination power. 100 times bootstrapping was performed to compute c-index and the Wilcoxon test was used to assess radiomics signature power, compared with random (c-index = 0.5).

### Results

After feature selection, 8 radiomic features were selected: (1) log-sigma-1-0-mm-3D\_glszm\_LowGrayLevelZoneEmphasis, (2) log-sigma-2-0-mm-3D\_gldm\_DependenceVariance, (3) log-sigma-2-0-mm-3D\_glszm\_SmallAreaLowGrayLevelEmphasis, (4) log-sigma-3-0-mm-3D\_gldm\_DependenceEntropy, (5) wavelet-LHH\_firstorder\_Median, (6) wavelet-LLH\_gldm\_DependenceVariance, (7) original\_firstorder\_Maximum, and (8) original\_glszm\_SmallAreaLowGrayLevelEmphasis. The Cox regression model resulted in a c-index of 0.70 (95%CI: 0.63-0.74) on the training set and a c-index of 0.65 (95%CI: 0.56-0.68) on the validation set. The Kaplan-Meier curves of training and validation sets are shown in Figure-1. The prognostic score demonstrated significant differences in OS between risk groups in both training ( $X^2$  17.0,  $p < 0.001$ ) and validation sets ( $X^2$  5.4,  $p = 0.02$ ).

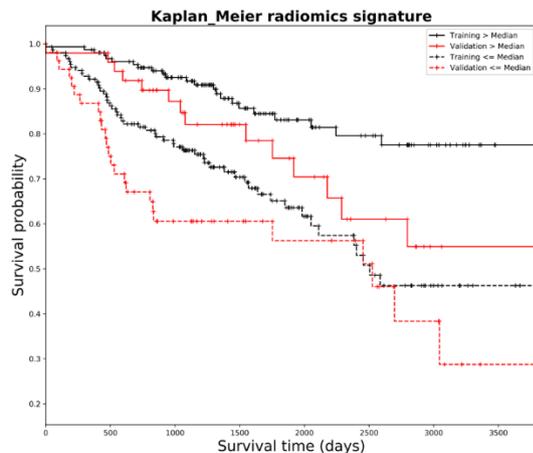

Figure 1: Kaplan-Meier curves for patients stratified by radiomics signature.

### Conclusion

The radiomics signature showed a promising performance to predict overall survival of HNSCC patient. The further study will investigate the prognostic performance models combining radiomics and clinical factors.

### PO-0959 Robust features selection in Apparent Diffusion Coefficient (ADC) maps of cervix cancer patients

<sup>1</sup>Maastricht Radiation Oncology Maastricht, Radiotherapy, Maastricht, The Netherlands ; <sup>2</sup>Princess Margaret Cancer Center, Department of Medical Physics, Toronto, Canada ; <sup>3</sup>Princess Margaret Cancer Center, Department of Biostatistics, Toronto, Canada ; <sup>4</sup>Princess Margaret Cancer Center, Radiation Medicine Program, Toronto, Canada ; <sup>5</sup>University Of Toronto, Department of Radiation Oncology, Toronto, Canada

### Purpose or Objective

Quantitative features (radiomics) extracted from computed tomography (CT) have shown promising prognostic and predictive power in radiation oncology. The extension of radiomics to Magnetic Resonance Imaging (MRI)/ Diffusion Weighted Imaging (DWI) is of interest to improve diagnostic performance and evaluate treatment response. However, several challenges apply: greater acquisition protocol differences compared to CT, presence of arbitrary units in the image (need for normalization), contouring inter-observer variability, and risk of redundant information (e.g. association of features with tumor volume). In this study, we investigated the aforementioned challenges, proposing a method for robust features extraction

### Material and Methods

This retrospective study was conducted using apparent diffusion coefficient (ADC) maps derived from DWI from 81 women with stage IB-IVA cervical cancer treated with definitive chemoradiation in 2009-2013. Two radiation oncologists independently delineated the gross tumour volume directly on the ADC maps with the aid of coregistered T2-weighted images (Median DICE 0.72±0.13). Radiomic features were computed with an open source software (PyRadiomics) for first-order intensity statistics (FO), shape metrics (SM) and textural analyses (TA) together with different imaging filters available (Table 1). To investigate the impact of normalization, five different normalizations were considered (Table1). Feature reproducibility with respect to inter-observer variability was assessed using concordance correlation coefficients (CCC). Association of features with tumor volume was investigated by using the Spearman Correlation Coefficient ( $\rho$ )

Table 1: Description of different normalizations and filters used in the analysis. The bin width corresponds to the width of the bins used to quantize the images values to create the histogram of their distributions. To avoid skewed distributions the bin counts should be between 60 and 300. The histogram is then used to compute statistical first order features used toward features. A filter is a pre-processing operation applied to the whole image before features extraction.

Normalization legend	Bin width / bin counts	Description
Raw	25 / 90	No normalization is applied. Only original values of the images are considered. The histogram of the image values is created with a bin width of 25 (e.g. 1 bin = 0.24 arbitrary units)
S1BW0.05	0.05 / 90	All the original values are centered creating a Gaussian distribution by centering the image values at the mean with standard deviation 1. A bin width of 0.05 is used
S333BW25	25 / 65	All the values are normalized between -1000 and +1 to make them similar to CT values. A bin width of 25 is used
S100BW5	5 / 85	Same as its normalization S1, but a scaling factor of 100 is applied to the values. This normalization was previously used by studies for ADC maps in prostate cancer. A bin width of 5 is used to create the histogram.
S100BW15	15 / 25	Same as S100BW5, but a bin width of 15 is used
S100BW20	20 / 25	Same as S100BW5, but a bin width of 20 is used
Filter Name	Description	
Exponential	Computes the exponential of the original image. The filter can enhance the present of signal in the ROI, compared to the background of other anatomical regions. However, in case of small ROIs the effect of noise can totally embed the importance of textural features	
Logarithm	Computes the logarithm of the absolute value of the original image + 1. Resulting values are rescaled on the range of the initial original image and negative intensities are made negative in resultant filtered image	
Square	Compute the square of the image intensities. Resulting values are rescaled on the range of the initial image, and negative values are kept negative	
Square Root	Computes the square root of the absolute value of the image intensities. Since the absolute values are computed, the importance of low intensity values (background) is reduced	
Gradient	Applies a gradient filter to the image before features extraction. The gradient filter is often used for edge detection. The goal of edge detection is to reveal particular patterns in the image. This filter can enhance the presence of particular textures in the ROI	

### Results

Figure 1C shows the Venn diagrams for the different normalizations applied to all 562 features. Overall, feature reproducibility was strongly affected by normalization; using a Gaussian distribution with no rescaling (S1) and a smaller bin width (BW005) resulted in best feature reproducibility (Figure 1A) Conversely, normalizing values to be as similar as in CT (S333BW25) led to the lowest reproducibility. The number of bin counts was too small for normalizations S100BW20 and BW15. There were no significant differences between filters except for the gradient filter, which increased both the number of reproducible features (Figure 1B) and

decreased the association with tumour volume. Finally, normalization and inter-observer variability had a larger impact on TA than SM and FO features.

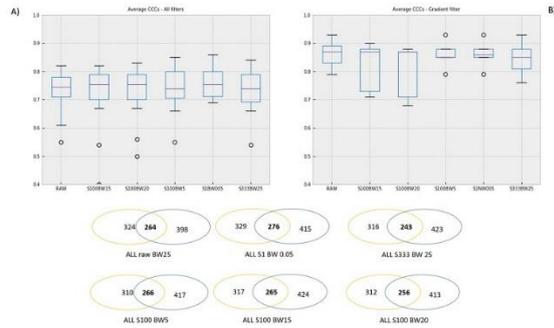

Figure 1: A) Average CCCs for all features for different normalizations. B) Average CCCs for gradient filtered features. C) Venn diagrams for features selection for the 562 features for different normalizations (see Table 1 for details on normalization). The orange circle contains all the features with CCC > 0.7 (reproducibility cut-off). The blue circle contains all the features with a Spearman correlation with volume < 0.0 (volume dependence cut-off). The intersection corresponds to both conditions verified. It is possible to see that the normalization S1 leads to more reproducible features, compared other normalizations and to non-normalized features.

## Conclusion

To reduce false discovery rates, only reproducible features with respect to inter-observer variability and acquisition settings should be used. Due to the presence of arbitrary units in MRI, normalization before feature extraction should be performed. A smaller bin width (0.05) together with Gaussian normalization is suggested when extracting radiomics features. Gradient filter reduces the dependence from volume and might provide additional valuable information to non-filtered features

## PO-0960 Automated sarcopenia assessment and its predictive power in lung cancer radiotherapy patients

A. Green<sup>1</sup>, C. Cipriano<sup>2</sup>, E. Vasquez Osorio<sup>1</sup>, J. Weaver<sup>2</sup>, M. Van Herk<sup>1</sup>, A. McWilliam<sup>1,3</sup>

<sup>1</sup>The University of Manchester, Department 58-Radiotherapy Related Research, Manchester, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom ; <sup>3</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom

### Purpose or Objective

Sarcopenia is a condition of progressive muscle wastage, and is typically assessed by measuring the properties of the skeletal muscle at the L3 vertebral level. Several studies have investigated the predictive power of sarcopenia assessment, particularly in conjunction with chemotherapy. In this work, we introduce an automated method to extract a slice from routine PET/CT close to the L3 vertebral level and segment the skeletal muscle. Several characteristics of the muscle were investigated for their predictive power in a large retrospective cohort of lung radiotherapy patients in a Cox survival model.

### Material and Methods

Skeletal muscle (SM), subcutaneous and visceral fat (SCF & VF) were manually delineated on 201 L3 slices from staging PET/CT images. A training (n=160) and validation (n=41) set was used to train an implementation of the well-known UNet convolutional neural network (CNN), configured to produce multi-label segmentation. This segmentation was followed by a dense conditional random field (CRF) to improve the results. The segmentation was validated using a 5-fold cross validation, with Distance To Agreement (DTA) calculated for each volume, see figure 1.

The L3 vertebrae were segmented in staging PET/CT for 95 lung cancer using ADMIRE v2.0 (10 atlases). Slices at the centre of the propagated structures were extracted and segmented using CNN+CRF. Areas and mean HU were extracted from the segmentations. These, along with log tumour volume, N stage, high/low performance status (PS), gender, and age were tested using an elastic net

regression, and those identified further analysed in a Cox model.

### Results

The mean DTA ranged between 0.7 and 1.6 mm for the SM segmentation, which was reduced to between 0.3 and 1.3 mm following the CRF. Elastic net regression selected log tumour volume, N stage, high/low PS and gender. Of the sarcopenia variables, only the mean HU in the SM was selected. These variables informed a multivariate Cox model, the result of which is shown in table 1. Mean HU in the skeletal muscle was found to be predictive (p=0.016), with a hazard ratio of 0.98 per HU: more sarcopenic patients would be predicted to have worse outcome. An optimum split value of 0 HU was found; those patients with mean HU greater than this value have median survival 13.5 months, whereas those in the low mean HU group have median survival of only 9 months. Survival curves, and the result of a Cox regression analysis for the two groups are shown in figure 2 and table 1 respectively.

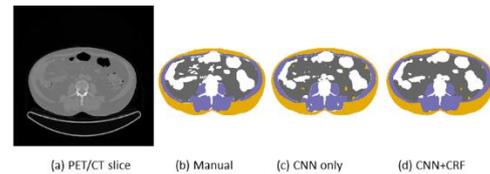

Figure 1: Example PET/CT slice (a) and manual segmentation (b) from the 201 images used to train the network. Automatic segmentations produced using the CNN alone (c) and with the additional CRF step (d) as part of the cross validation are also shown. Structures shown are the SCF in orange, SM in purple and VF in Grey. Characteristics extracted from these segmentations in the lung cohort include the area of all segmentations, and the mean HU of the SM.

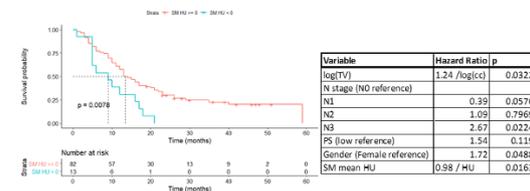

Figure 2: Kaplan-Meier curves for 95 patients split into high and low mean SM HU groups with a threshold value of 0 HU. Patients in the low group have median survival time of 9 months, while those with high mean HU have a median survival of 13.5 months. Low mean HU is indicative of fat infiltration in the SM, a sign of sarcopenia.

Table 1: Cox proportional hazard ratios for variables selected using elastic net regression on clinical variables and sarcopenia-related variables. Mean HU in the SM is identified as significant, with a HR < 1, indicating higher mean HU is protective.

### Conclusion

A fully automated sarcopenia assessment method has been developed and tested in a retrospective cohort of 95 lung cancer patients. This is the first analysis of the influence of sarcopenia on lung radiotherapy patient outcomes. In these patients, the mean HU of the SM has been found to be predictive, with an optimum cutoff of 0 HU. This can be explained as fat invasion in the SM is typical of sarcopenic patients, lowering the mean HU.

## PO-0961 MR-Δimage biomarkers to identify partial HNC responders that advance to complete responders

L.V. Van Dijk<sup>1</sup>, T. Zhai<sup>1</sup>, M. Van Dijk<sup>1</sup>, H.P. Bijl<sup>1</sup>, J.G.M. Vemer-van der Hoek<sup>1</sup>, M. Dieters<sup>1</sup>, N.M. Sijtsema<sup>1</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiation oncology, Groningen, The Netherlands

### Purpose or Objective

Many head and neck cancer (HNC) patients have radiological partial tumour response assessed 2 months after definitive (chemo-)radiotherapy. Most of these

partial responders eventually advance in to complete responders (approximately 70%). To support decision-making in additional diagnostic and therapeutic interventions, it is crucial to identify those who develop a complete response from those who have residue or recurrence, i.e. persistent disease. Therefore, this study aims to identify  $\Delta$ image biomarkers from MRI scans 2 months after radiotherapy that may identify patients that will advance into persistent disease, and for which a more aggressive approach may be needed.

#### Material and Methods

This is a retrospective analysis in a prospective cohort of consecutive HNC patients treated between 10-2012 and 11-2014 at our department. Included were those who had a partial tumour response 2 months after treatment, and in whom pre- and post T1-TSE contrast enhanced MRI (T1ce-MRI) scan was acquired. These MRI scans were standardized to fat tissue. Subsequently, image biomarkers, representing geometric, intensity and textural characteristics of the primary tumour were extracted from the standardized pre- and post T1ce-MRI scans. Univariable logistic regression was performed to identify significant  $\Delta$ image biomarkers, where the Area Under the ROC Curve (AUC) gives an indication of the discriminative power. Pearson correlation (<0.80) was used to select independent variables. Unpaired t-test was performed to test a significant difference between the  $\Delta$ image biomarkers in patients with and without persistent disease.

#### Results

Out of the 51 partial responders, 12 (24%) patients progressed into persistent disease, including 8 residues and 4 recurrences. The median follow-up time was 44 months (range: 4-63 months). Univariable analysis showed that 26 of the in total 84  $\Delta$ image biomarkers were significantly associated with persistent disease. After the correlation analysis, 6 independent significant variables were identified (Table 1). The t-test showed that 5 of 6  $\Delta$ image biomarkers were significantly different in the patient with and without persistent disease (Table 1). The best performing  $\Delta$ image biomarker, the information correlation 1 (texture feature) suggests that tumours that show a large reduction in heterogeneity are more likely to result in persistent disease than tumours that have increased heterogeneity (examples are shown in Figure 1).

#### Conclusion

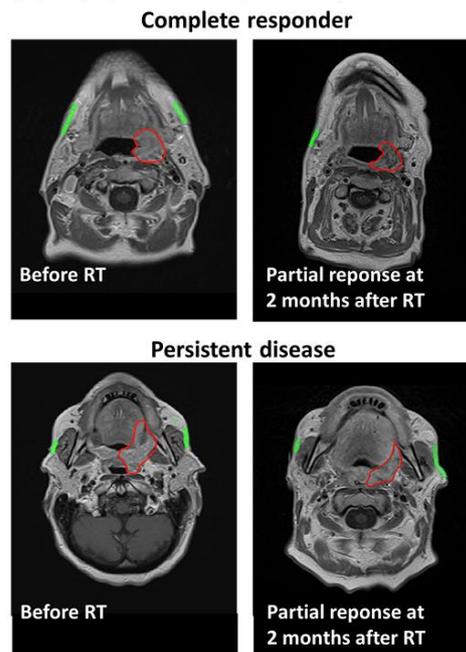

The results of this pilot study suggest that pre- and post-MRI information have potential to identify patients with radiological partial response at 2 months after radiotherapy will advance into complete responders or progress into persistent disease. This information may support clinical decision-making in cases with partial response at response evaluation using MRI.

PO-0962 Bladder changes during first week of RT for prostate cancer determine the risk of urinary toxicity  
O. Casares Magaz<sup>1</sup>, R. G. Raidou<sup>2</sup>, N. J. Petterson<sup>3</sup>, V. Moiseenko<sup>4</sup>, J. Einck<sup>4</sup>, A. Hopper<sup>4</sup>, R. Knopp<sup>4</sup>, L. P. Muren<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Medical Physics - Oncology, Aarhus, Denmark ; <sup>2</sup>TU Wien, Institute of Visual Computing & Human-Centered Technology, Wien, Austria ; <sup>3</sup>Sahlgrenska University Hospital, Medical Physics, Gothenburg, Sweden ; <sup>4</sup>University of California San Diego, Radiation Medicine and Applied Sciences, San Diego, USA

#### Purpose or Objective

Modern radiotherapy (RT) protocols for prostate cancer allow dose escalation to the prostate, however, the risk of late genitourinary (GU) toxicity is still dose-limiting. The associations between GU toxicity and dose/volume parameters in the bladder remain not fully understood. The weak associations may be due to considerable changes occurring in bladder volume, shape and position during the RT course. By using well-established methods for shape analysis and algorithms from machine learning for dimensionality reduction and clustering, we evaluated whether parameterized shape descriptors of the bladder from the first week of treatment better classify patients into exhibiting and not exhibiting late GU toxicity.

#### Material and Methods

A matched case-control study was performed within a cohort of 258 prostate cancer patients, where a previous analysis had not shown any differences in planned or actually delivered dose/volume endpoints between cases and controls. Patients were treated to prescription doses of 77.4-81.0 Gy using daily cone-beam CT (CBCT)-guidance. Twenty-seven patients (10.5%) presented late RTOG GU  $\geq$  Grade 2 toxicity and those without symptoms prior to treatment (N=8) were selected as cases. Each case was matched with three controls based on pre-treatment GU symptoms, age, Gleason score, follow-up time, and hormone therapy. CBCTs from the first week of treatment were rigidly registered to the planning CT using the recorded treatment shifts, and the bladder was manually contoured on each CBCT. Each bladder volume was described using seventeen shape descriptors. In order to

detect similarities across patients we performed dimensionality reduction using the t-distributed stochastic neighborhood embedding (t-SNE) followed by a Gaussian Mean Shift Clustering. ANOVA tests for each descriptor and each cluster were performed to find statistically significant differences. A repeated measurements model was fitted at each cluster to evaluate within-cluster trends for patients with and without toxicity (Fig. 1).

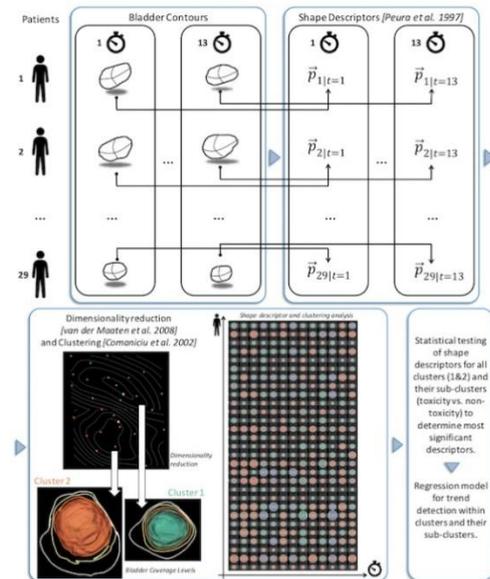

Figure 1. The workflow of our followed approach. Each patient bladder is described by 17 basic shape descriptors, and machine learning for dimensionality reduction and clustering is used to determine the two most important clusters (excl. outliers) in the data. Then, statistical testing and regression modelling is used to detect which of the 17 shape descriptors are more important.

## Results

Two clusters with distinct shape characteristics comprised 85% of the patients while a third cluster (15%) included outliers. Clusters remained similar when data from the entire RT course was pooled in the t-SNE classification. Significant differences between cases and controls were observed at each cluster in seven descriptors (convexity and elliptic variance along the three principal axes, and compactness). In cluster 1 (small bladder volumes) more convex and round bladder shapes were associated with higher toxicity risk, while in cluster 2 (large bladder volumes) more concave and elliptical shapes were associated with higher risk of toxicity (Fig. 2).

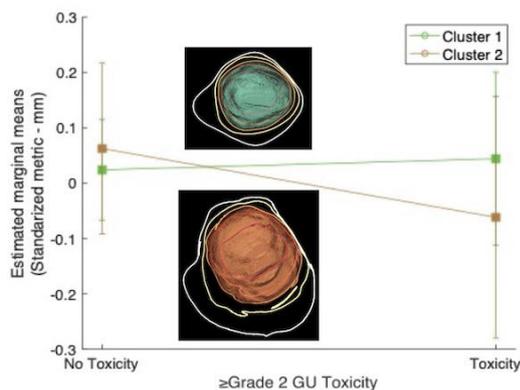

Figure 2. Fit to repeated measurements models using the data from each of the two clusters identified in the tSNE classification (only first week of treatment). The model for each cluster included the 7 shape descriptors not highly correlated (Pearson Coeff. < 0.6) and showing significant differences between patients presenting toxicity and those free from toxicity. For each cluster a sketch of the population average and quartiles bladder shape (at the central slice) are showed.

## Conclusion

Bladder shape changes occurring during the first week of treatment show potential to predict the risk of developing

late GU toxicity after RT for prostate cancer. Patient-specific changes in bladder shape might be related to the exposure of the most radiosensitive areas of the bladder to high doses.

## PO-0963 A novel normalisation technique for voxel size dependent radiomic features in oesophageal cancer

P. Whybra<sup>1</sup>, C. Parkinson<sup>1</sup>, K. Foley<sup>2</sup>, J. Staffurth<sup>2</sup>, E. Spezi<sup>1</sup>

<sup>1</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom ; <sup>2</sup>Cardiff University, School of Medicine, Cardiff, United Kingdom

### Purpose or Objective

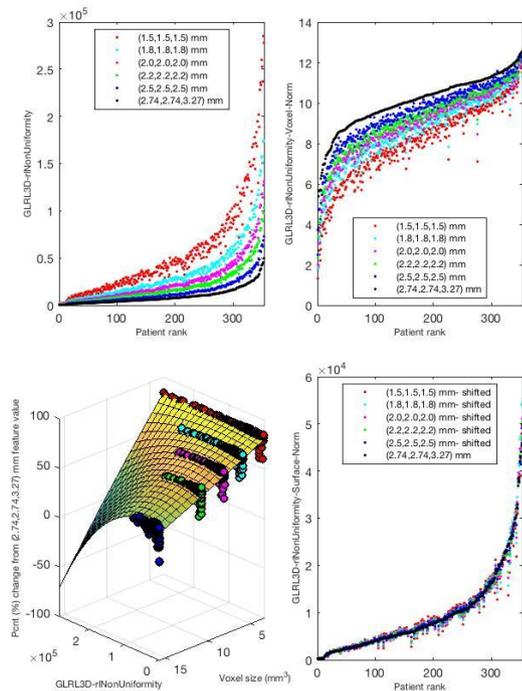

In oncology, radiomic studies hope to identify quantitative imaging features that predict survival and therapy response. To be clinically useful, features need to be robust. For 3D features that measure tumour heterogeneity, isotropic voxels are advised to ensure no directional bias [1]. Normally, PET/CT scans are not isotropic and require interpolation. The voxel size chosen is important; resampling a scan to smaller dimensions increases the number of voxels in a region of interest (ROI). An intrinsic dependency between common features and number of voxels in a ROI has been found [2]. This study evaluates methods to improve feature robustness and introduces a novel normalisation technique for voxel size dependent radiomic features in oesophageal cancer (OC).

### Material and Methods

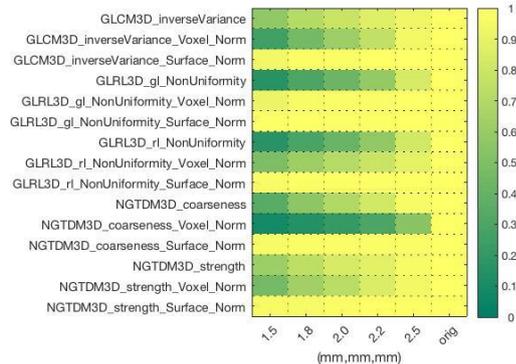

18F-FDG PET images (scanned and segmented with the same protocol) from 441 OC patients (training=353, validation=88) were included [3]. Standardised and validated [1] in-house feature extraction algorithms were used. Voxel intensities were discretised with a fixed bin width (0.5 SUV). Five selected features recommended for voxel normalisation [2] were extracted from the original scan dimension and 5 isotropic sizes. Patients were ranked based on the feature result of the original dimension. Surface models were generated on the training dataset to normalise each feature using the voxel size and feature value. A concordance correlation coefficient (CCC) was used to determine reproducibility between features extracted from the original dimension and a range of interpolated voxel sizes.

### Results

Fig.1 shows development of a surface model and results for a selected feature, run length non-uniformity (RLNU). Fig.2 is a feature heatmap of the CCC results for each voxel dimension for the validation dataset. There are 3 versions of each feature; standard (CCC 0.16-0.96), voxel number normalised (CCC 0.08-0.99), and surface model normalised (CCC 0.95-0.99). Features normalised with a surface model performed the best in each case.

**Fig. 1:** Results for RLNU (training). TOP: (left) feature calculated at each voxel dimension against patient rank. (right) Feature normalised by voxel number in ROI. BOTTOM: (left) Surface model to calculate feature change. (right) Surface model shifted result.

**Fig. 2:** CCC heatmap for each feature (validation dataset)

**Conclusion**

We developed, tested and validated a novel normalisation technique for voxel size dependent radiomic features. Ongoing work aims at validating the proposed approach on other imaging modalities.

Physics, Cardiff, United Kingdom ; <sup>3</sup>Velindre Cancer Centre, Department of Oncology, Cardiff, United Kingdom ; <sup>4</sup>Velindre Cancer Centre, Radiotherapy & Clinical Trials, Cardiff, United Kingdom ; <sup>5</sup>Cardiff University, School of Medicine, Cardiff, United Kingdom

**Purpose or Objective**

Radiomics aims at extracting quantitative features from medical images. Several studies focussed on the potential value of radiomic analysis in predicting tumour response for oesophageal cancer (OC) patients using contrast enhanced CT images. However, in clinical practice contrast agents are not always administrable, making the development of a new radiomic model necessary. In this work, we investigated the usefulness of radiomic features extracted from contrast and non-contrast enhanced CT scans in the development of a prognostic model in OC.

**Material and Methods**

CT images and radiotherapy volumes of 213 patients from a clinical trial in OC<sup>1</sup> were processed with the CERR package<sup>2</sup>. Patients were divided into 3 groups: mixed group (MG) with contrast and non-contrast enhanced CT images (n=213), contrast group (CG) with contrast enhanced CT scans (n=138) and non-contrast group (nCG) with non-contrast enhanced CT data (n=75). Radiomic features were automatically extracted in 2D and 3D in compliance with the IBSI<sup>3</sup>, using in-house developed data analytics software<sup>4</sup>. Stable features were selected as the ones with similar intra-groups distributions (Kruskal-Wallis test). Corresponding 2D and 3D stable features within each group were evaluated for differences (Wilcoxon signed rank test). Remaining filtered features and clinical characteristics were used to develop a prognostic model with the Cox regression method.

**Results**

A total of 119 2D and 3D features were computed from each group. The Kruskal-Wallis test excluded 82, 3 and 6 unstable features obtained from MG, from CG and from nCG, respectively (Fig. 1). Some stable features (6 for MG, 15 for CG and 17 for nCG) did not show a significant difference if extracted considering 1 tumour layer at a time or considering the whole tumour volume. Among stable features, 4 features showed no difference if obtained from 3D or 2D data and were stable in all the 3 groups. The Cox regression model, constructed with 8 clinical and radiomic variables, identified 1 feature (GLDZM zone distance variance) associated with survival (Table 1).

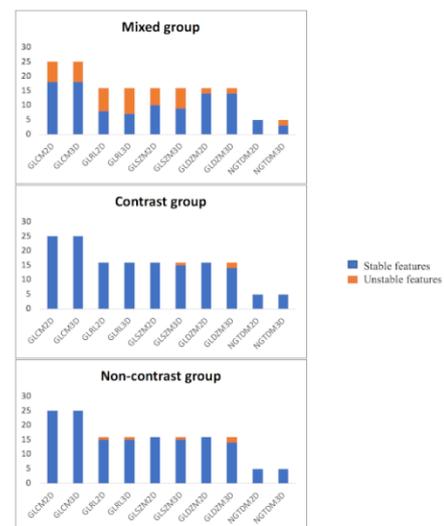

Figure 1. Stable and unstable features extracted from the different groups.

**Conclusion**

The prognostic model has identified 1 texture significantly and independently correlated with overall survival. This

feature can add value over and above currently known prognostic factors if computed in 2D or 3D and independently from administration of CT contrast agents.

Prognostic variable	p-value	Parameter estimate	Hazard Ratio	95% Confidence Intervals	
				Lower	Upper
GLDZM zone distance variance	0.005	0.274	1.315	1.085	1.593

**Purpose or Objective**

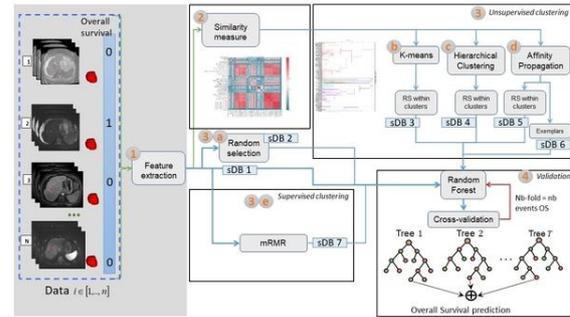

One of the major issues in radiomics is the very large amount of tested extracted features, compared to the often-reduced sample size and the low number of events. Reduction of dimensionality may be therefore an important preliminary step to improve the prediction capability of the predictive models. The aims of the study were:

- to propose methods for reducing redundancy by selecting the more informative features from -multimodal images;
- to evaluate and compare the prediction capability of the models when using these methods.

The considered example was MRI based radiomics to predict overall survival after SBRT for hepatocellular carcinoma (HCC).

**Material and Methods**

Eighty-one patients underwent SBRT for inoperable HCC. For each patient, 7 modalities of MR images were acquired. A total of 273 features were extracted from manually delineated tumours belonging to 4 radiomics categories (geometrical, first order, gradient-based and second order) in each modality. As we follow the workflow [Figure 1]

, a similarity measure based on Spearman correlation was computed across the features. Four methods for feature selection were then assessed namely three unsupervised (K-means, Hierarchical clustering (HC) and Affinity propagation (AP)) and a supervised (mRMR) clustering and compared random selection (RS) and no selection (using all the features). Affinity propagation clustering yields a set of exemplars which better represented each cluster. Finally, in order to assess the predictive capabilities of each one of the feature selection method, a random forest classifier was trained and tested via a stratified-K-fold (K=19 the occurrence of decease event) cross-validation. This process was repeated 1000 times. Feature importance as assessed by aggregation of the performance at each try. The performance is evaluated by computing the precision (True positive / True positive + True negative) of prediction.

**Results**

The table displays the selected predictive feature depending on the selection methods. Unsupervised clustering algorithms allowed to select a non-redundant set of features able to significantly better predict HCC overall survival [Exemplars from AP: Precision= 0.76 ± 0.01, (p-value < 0.001)], in comparison to the other methods [All features: Precision = 0.73 ± 0.001; RS from all features : Precision = 0.71 ± 0.3 ; RS from K-means clustering : Precision = 0.715 ± 0.1; RS from HC: Precision = 0.74 ± 0.02; RS from AP clustering: Precision = 0.735 ± 0.01 and exemplars from mRMR: Precision = 0.735 ± 0.01] . The most reproducible predictive features are related with the shape of the tumour [Figure 2]

All features		Random selection	Random Selection HC
1	T1_Tardif_Flatness	T1_Gado_Least_Axis_Length	T1_Gado_Least_Axis_Length
2	T1_Gado_Least_Axis_Length	T1_Tardif_Flatness	T1_Tardif_Flatness

7	T2_Sum_Average	T2_Sobel_mean	T2_Log_std
8	T1_Tardif_Elongation	T2_mean	T2_mean
9	Diffusion_DWI_1_Elongation	T2_max	T2_max
10	T2_Sphericity	T1_Gado_Sphericity	T1_Gado_Compactness1

**Conclusion**

A framework for feature selection in a radiomics workflow is presented. Unsupervised methods allow to cluster together groups of features increasing the prediction capabilities and reducing redundancy. AP outperforms the other features selection method suggesting the use of the exemplars as representative feature of each cluster.

**PO-0966 Prediction of Locoregional Control in Hepatocellular Carcinoma After SBRT with Deep Learning**

I. El Naqa<sup>1</sup>, R. Ten Haken<sup>1</sup>

<sup>1</sup>University of Michigan, Radiation Oncology, Ann Arbor, USA

### Purpose or Objective

Despite high local control in patients with hepatocellular carcinoma (HCC) who receive liver stereotactic body radiotherapy (SBRT), locoregional control (LRC) remains dismal and is associated with long-term failures and poor survival. The purpose of the current study is to evaluate deep learning models for predicting LRC and personalization of HCC treatment.

### Material and Methods

Data from 146 HCC patients who received SBRT from 2005-14 were analyzed retrospectively. Tumor doses (median prescribed = 49.8 Gy, delivered in 3 or 5 fractions) were bio-corrected to 2 Gy equivalents. Patient demographics (age, sex, stage, etc) dosimetric (dose-volume metrics of tumor and surrounding normal tissue), and toxicity information ((ALBI, Child-Pugh, enzymatic changes) were extracted from the patients' records. Despite local control of greater than 90%, the locoregional failure rate was 54.7% with a median follow-up of 11 months. Predictive models based on deep machine learning techniques for predicting LRC were developed using the open source neural network library (Keras). The deep learning network architectures included dense and dropout layers with ReLU activation functions. The loss function was defined in terms of cross-entropy and the weights for the network were estimated using an adaptive stochastic gradient algorithm (Adam). These models were compared with traditional statistical techniques based on variable shrinkage analysis with logistic regression (Lasso-logistic). The data were normalized using z-scoring (mean-centered) prior to modeling. To avoid overfitting pitfalls, 10-fold cross-validation resampling was used to evaluate prediction, and performance was assessed using the area under the receiver-operating characteristics curve (AUC).

### Results

When modeling with Lasso-logistic regression the predictive LRC achieved an AUC = 0.57 on cross-validation with functional toxicity (ALBI) as the highest contributor. When deep learning was applied, the prediction of LRC improved by 17.5%, and the prediction of the algorithm reached an AUC = 0.67 on cross-validation. The performance seemed to be affected by the dropout layer rates, which act as a regularization process to prevent neural network overfitting, with a dropout rate of 20% providing stable results.

### Conclusion

Machine learning methods based on deep learning can provide a robust framework for estimating locoregional failure risk in HCC patients post-SBRT. However, proper tuning of parameters is necessary to avoid overfitting and evaluation on independent data is needed to further assess generalizability. These new LRC models show promise for personalizing new regimens for combining local and systemic therapy in HCC patients.

### PO-0967 Prediction of treatment outcome for head and neck cancers using radiomics of PET/CT images

A. Rosvoll Groendahl<sup>1</sup>, A.D. Midtved<sup>1</sup>, G.S. Elvatun Rakh Langberg<sup>1</sup>, O. Tomic<sup>1</sup>, U.G. Indahl<sup>1</sup>, I. Skjei Knudtsen<sup>2</sup>, E. Malinen<sup>3</sup>, E. Dale<sup>4</sup>, C.M. Futsaether<sup>1</sup>

<sup>1</sup>Norwegian University of Life Sciences NMBU, Faculty of Science and Technology, Ås, Norway ; <sup>2</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway ; <sup>3</sup>University of Oslo / Oslo University Hospital, Department of Physics / Department of Medical Physics, Oslo, Norway ; <sup>4</sup>Oslo University Hospital, Department of Oncology, Oslo, Norway

### Purpose or Objective

The objective of this study was to evaluate the usefulness of radiomics for predicting locoregional relapse in head and neck cancer patients using PET/CT images.

### Material and Methods

This retrospective study includes 182 head and neck cancer patients, who underwent a combined 18F-FDG-PET/CT scan prior to radiotherapy. Patients were divided into two classes according to locoregional control; 47 with failures and 135 with control. The radiomics approach was used to extract features characterizing the primary tumour from both PET and CT images. First order statistical features such as median values and interquartile range, shape features including sphericity and tumour surface area as well as texture features describing intensity non-uniformity, busyness and coarseness were calculated. Features were also calculated from PET and CT images transformed using point and two-dimensional transformations to emphasize particular aspects of the tumour. Clinical factors (age, sex, ECOG status, Charlson comorbidity status, HPV-status, TNM stage, pack years of smoking, days on the hypoxic radiosensitizer nimorazole and number of weekly cisplatin doses) were also included as features. Seven feature selection methods were tested to select the most relevant features for classification among the more than 2 500 features. Classification of the patients according to outcome was performed using 14 different algorithms. The performance measure ROC-AUC (Receiver Operating Characteristics - Area Under the Curve) of the classification models was estimated using nested cross-validation and was used to assess and compare the models.

### Results

The classification models with the highest performance gave a mean AUC of  $0.66 \pm 0.10$ . The models were obtained using ReliefF for feature selection and either Partial Least Squares Regression (PLSR), logistic regression, Linear Discriminant Analysis (LDA) or AdaBoost as classifiers (Figure 1). These models were based on tumour shape and heterogeneity features such as busyness, which characterises rapid intensity changes between neighbouring voxels within the tumour. Interestingly, the feature selection methods consistently chose image features over clinical factors when these were included in the same classification. Classification models based solely on clinical factors gave poorer performance with a mean AUC of  $0.57 \pm 0.10$ .

### Conclusion

Characteristics of primary head and neck tumours extracted from PET and CT images were better predictors of treatment outcome than clinical factors alone. Particularly tumour shape and tumour heterogeneity were selected as relevant features for treatment outcome prediction. Future efforts should be directed at improving classification performance by exploring other feature engineering and feature selection approaches.

### Purpose or Objective

A phantom study to assess the repeatability, reproducibility and robustness of radiomic features in the presence of fiducial marker (FM) induced artefacts on multi-modality imaging.

### Material and Methods

An in-house developed pelvis water phantom containing boxes filled with gelatine and FMs (6 boxes) or without FMs (2 boxes), was used in this study. Three FMs were placed in each box in a spatial distribution similar to that for PCa patients. The boxes were placed at the centre of the water phantom and scanned using several imaging modalities typically used to image prostate cancer patients; MRI (2 scanners), CT (2 scanners), CBCT (3 different scanning protocols), Table 1. Four setup arrangements were used to place the 2 boxes of interest at the centre of the phantom for each scan. After contouring the boxes, and before features extraction, several image pre-processing settings (i.e. resampling and discretization) were tested. Radiomic features extracted were the first order gray-level (GL) statistics from intensity histograms, and features based on; GL co-occurrence matrix (GLCM), GL run length matrix (GLRLM), GL size zone matrix (GLSZM), GL distance zone matrix (GLDZM), neighbourhood gray tone difference matrix (NGTDM) and neighbouring GL dependence matrix (NGLDM). 1642 features were extracted from each box, including textural and statistical features after applying different image filtering methods. Intra-class correlation coefficient (ICC) was computed to provide an estimation of the test-retest reliability and consistency of the features extracted (ICC = 0 non-reproducible, ICC = 1 perfectly reproducible features). In this analysis, a threshold of ICC > 0.8 was considered to identify robust features.

Table1: Specifications of scanners, protocols and tests performed.

Modality	Model	Test-retest	Intra-scanner	Inter-scanner
CT1	GE Optima CT580	120 kV, 200 mA	120 kV, 200 mA	CT1 vs CT2
CT2	GE Discovery CT590 RT	120 kV, 200 mA	120 kV, 400 mA	120 kV, 200 mA
CBCT1	ver 2.5.16 on Varian TrueBeam	125 kV, 1080 mAs	CBCT1 vs CBCT2 vs CBCT3	
CBCT2		125 kV, 855 mAs		
CBCT3		140 kV, 1687.5 mAs		
MRI1	Siemens Magnetom Aera 1.5T	T1w T2w		T1w: MRI1 vs MRI2
MRI2	GE Optima MR450w 1.5T	T1w T2w		T2w: MRI1 vs MRI2

### Results

In the test-retest repeatability experiment (Figure 1 rows 1-9), a relatively high proportion of CT-based radiomic features were reliable (CT1= 78% and CT2= 86%). CBCT features showed the highest repeatability with (CBCT1=93%, CBCT2= 95%, CBCT3= 87%) of the features having ICC > 0.8 for different CBCT scanning protocols. Reduced reliability was observed for MRI-based features with MRI1 =53% and MRI2=74% reliable features for T1 scans and 73% and 85% T2 scans on MRI1 and MRI2, respectively.

The intra-scanner study of robustness of features against scanning parameters variation, table 1 showed that 72% and 89% of the features were robust, for CT1 and CT2, respectively. Using different CBCT scanning protocols 66% of the features were robust. Inter-scanner reproducibility was 48% for CT although only 2% and 4% of features were reproducible for T1 and T2 MRI scans, respectively, possibly due to different manufacturers.

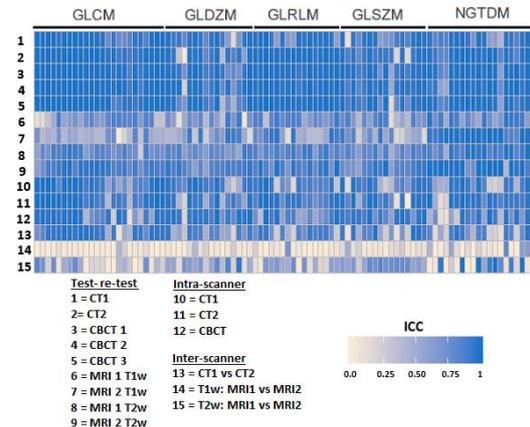

Figure1: a heat map showing a subset of the features' interclass correlation coefficients (ICC) for: test-retest (rows 1-9), intra-scanner (10-12) and inter-scanner (13-15) analysis. All scans were re-sampled to 2.5mm isotropic voxels before features extraction and grey level values discretised with 10 Hounsfield Units (HU) bin width.

### Conclusion

Despite significant FM artefacts on CT and CBCT, preliminary results from this study show that CT and CBCT features are more reliable and reproducible than MRI features. The very poor inter-scanner reproducibility of MRI-based features can have a drastic impact on the results of radiomics studies.

### PO-0969 Sensitivity analysis of an in silico model of prostate tumour growth and response to radiotherapy

C. Sosa marrero<sup>1</sup>, Ó. Acosta<sup>1</sup>, M. Castro<sup>1</sup>, A. Hernández<sup>1</sup>, N. Rioux-Leclercq<sup>1</sup>, R. Mathieu<sup>1</sup>, F. Paris<sup>2</sup>, R. De Crevoisier<sup>1</sup>

<sup>1</sup>Univ Rennes-CHU Rennes-CLCC Eugène Marquis-INSERM, Ltsi - UMR 1099- F-35000, Rennes, France ; <sup>2</sup>Université de Nantes, Crcina, Nantes, France

### Purpose or Objective

*In silico* models are appealing tools to understand and predict tumour growth and response to RT. A major issue of computational models is the large number of variables they may contain. The objective of this work was to perform a Morris sensitivity analysis on a prostate tumour growth and response to RT model, to identify the most relevant parameters and determine which ones can be negligible

### Material and Methods

Histopathological specimens from 7 patients with localized prostate cancer, treated with radical prostatectomy, were used to initialise 21 computational tissues with different tumour and vascular densities. Tumour foci were delineated by a pathologist on the HES axial slides (figure 1.a) and a CD31 staining (figure 1.b) was carried out to identify the blood vessels. A multi-scale *in silico* model was generated, considering the prostate computational tissues, where each voxel corresponded to a cell of the following 7 types: healthy glandular/endothelial, tumour glandular/neo-created endothelial and dead (by apoptosis, hypoxic necrosis or mitotic catastrophe). Figure 1.c shows the corresponding initial computational tissue. The model integrated 5 biological processes: oxygenation of the tissue (Oxy.) using a reaction-diffusion equation (Espinoza *et al.*, *Med Phys* 2013); proliferation of tumour cells, considering their life-cycle (Prolif.); angiogenesis based on the VEGF diffusion (Angio.) (Harting *et al.*, *Phys. Med. Bio* 2007); phase-and-oxygen-dependent response to irradiation, using the linear-quadratic model and considering cycle arrests and death by mitotic catastrophe (RespTolrr.) and resorption of dead cells (Resor). The table presents the 34 parameters of the model, indicating the process they intervene in. Every simulation considered a total dose of 80 Gy, administered every 24 h, from Monday to Friday.

Figure 1.d shows the computational prostate tissue after 80 Gy. The tumour density (number of tumour cells divided by the total number of cells) at the end of the treatment was used as output of the model. The Morris sensitivity method calculated, on the 21 computational tissues (73500 simulations in total), the mean and standard values ( $\mu_i^* \pm \sigma_i$ ) of 100 elementary effects for each parameter. The Euclidean distance of the point ( $\mu_i^*$ ,  $\sigma_i$ ) to the origin was the indicator of the impact of parameter  $i$ .

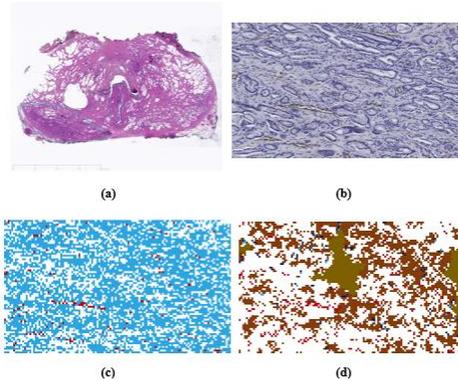

Figure 1. Example of an (a) histopathological cut; (b) CD31 staining; (c) initial computational tissue, where healthy cells are represented in white; tumour, in light blue and pre-existing endothelial in light red and (d) computational tissue after a 40 x 2 Gy RT treatment, where tumour cells with DNA damaged by irradiation are represented in dark blue; neo-created endothelial, in dark red and dead by hypoxic necrosis, in ochre and by mitotic catastrophe, in brown

## Results

The table shows a ranking of the 34 parameters of the model, according to their mean Euclidean distances over the 21 tissues.

Parameter of the model	Biological process	Mean Euclidean distance
Duration of cycle of tumour cells	Prolif.	41.68 ± 3.90
Dose per fraction	RespToIrr.	41.62 ± 4.47
Dose threshold of immediate death by apoptosis	RespToIrr.	21.51 ± 4.45
Duration of arrest at checkpoints G1/S and G2/M due to irradiation	RespToIrr.	11.23 ± 2.10
O <sub>2</sub> Michaelis constant	Oxy.	7.53 ± 4.36
O <sub>2</sub> Michaelis-Menten maximum rate	Oxy.	7.25 ± 3.75
pO <sub>2</sub> threshold of hypoxia	Oxy.	6.64 ± 3.14
α of tumour cells in phase G1	RespToIrr.	5.52 ± 4.87
α of tumour cells in phase G2	RespToIrr.	4.43 ± 2.98
α of tumour cells in phase M	RespToIrr.	3.56 ± 1.17
pO <sub>2</sub> of pre-existing endothelial cells	Oxy.	3.26 ± 1.96
O <sub>2</sub> diffusion coefficient	Oxy.	2.66 ± 2.04
α of tumour cells in phase S	RespToIrr.	2.13 ± 1.55
α of tumour cells in phase G0	RespToIrr.	1.77 ± 1.52
αβ of tumour cells in phase G0	RespToIrr.	1.74 ± 1.09
αβ of tumour cells in phase M	RespToIrr.	1.70 ± 0.53
αβ of tumour cells in phase G1	RespToIrr.	1.52 ± 0.82
αβ of tumour cells in phase G2	RespToIrr.	1.47 ± 0.94
Duration of cycle of healthy cells	Resor.	1.29 ± 0.87
α of healthy cells	RespToIrr.	1.29 ± 1.12
VEGF of hypoxic cells	Angio.	1.28 ± 1.20
pO <sub>2</sub> of neo-created endothelial cells	Oxy.	1.26 ± 1.03
αβ of healthy cells	RespToIrr.	1.25 ± 0.70
αβ of neo created endothelial cells	RespToIrr.	1.24 ± 1.25
αβ of pre-existing endothelial cells	RespToIrr.	1.21 ± 0.67
pO <sub>2</sub> threshold of hypoxic necrosis	Oxy.	1.18 ± 0.45
αβ of tumour cells in phase S	RespToIrr.	1.10 ± 0.22
α of neo-created endothelial cells	RespToIrr.	1.09 ± 0.35
Duration of cycle of neo-created endothelial cells	Angio.	1.06 ± 0.34
VEGF threshold to trigger angiogenesis	Angio.	1.04 ± 0.22
α of pre-existing endothelial cells	RespToIrr.	1.02 ± 0.17
VEGF Michaelis-Menten maximum rate	Angio.	0.99 ± 0.15
VEGF Michaelis constant	Angio.	0.99 ± 0.24
VEGF diffusion coefficient	Angio.	0.98 ± 0.21

**Table. Ranking of the 34 parameters of the model, according to their mean Euclidean distance to the origin**

**Conclusion**  
The Morris sensitivity analysis identified the duration of the cycle of tumour cells and the dose per fraction as the parameters having the greatest effect on the final tumour density after 80 Gy. The VEGF Michaelis-Menten maximum rate, the VEGF Michaelis constant and the VEGF diffusion coefficient had the lowest impact.

## Poster: Physics track: Intra-fraction motion management

### PO-0970 Advances in intra-fraction movement detection during stereotactic radiosurgery

O. Semeniuk<sup>1</sup>, P. Sadeghi<sup>1,2</sup>, J.D. Farah<sup>1</sup>, J. Robar<sup>1,2,3</sup>

<sup>1</sup>Nova Scotia Health Authority, Medical Physics, Halifax, Canada ; <sup>2</sup>Dalhousie University, Department of Physics & Atmospheric Science, Halifax, Canada ; <sup>3</sup>Dalhousie University, Department of Radiation Oncology, Halifax, Canada

#### Purpose or Objective

Detection of cranial position during stereotactic radiosurgery (SRS) is crucial for correcting for intrafractional motion. This abstract describes a novel technology that takes advantage of capacitive motion sensing (CMS) for real-time, 3D motion detection during SRS. The CMS system senses the capacitive signal from the cranium and provides advantages over systems that are based on x-ray imaging or use skin as the surrogate. Here, we report our progress on performance optimization for the CMS system with an emphasis on advances in sensitivity, detection precision and dynamic range.

#### Material and Methods

The performance of two capacitive-to-digital converters was evaluated to determine the most suitable candidate for practical applications. We compared the MPR121 (Adafruit Industries) converter performance (used in the proof-of-concept study [1]) against FDC1004 (Texas Instruments) - a device possessing an active shield technology. The active shield enables whole-system noise minimization, thus boosting sensitivity. Here, sensitivity was our primary performance metric, defined as capacitance change per unit of displacement; detection precision was defined as ratio of noise amplitude to sensitivity; and dynamic range was defined as the largest distance from the target at which we were able to detect a sub-millimeter displacement. CMS prototypes were tested with 5x5 cm<sup>2</sup> sensors in a parallel plate set-up and a head phantom made in-house. The phantom was 3D printed from a CT scan of a volunteer's thermoplastic mask, layered with a copper foil to provide a capacitive signal, and subsequently grounded. A micro-stage and 6D Hexapod were used to simulate subjects' motion with millimeter steps.

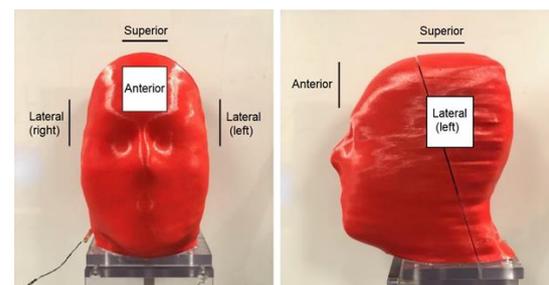

Figure 1. Diagram of CMS sensor positions with respect to the head phantom.

## Results

The sensitivity and detection precision of FDC1004-based CMS system were found to be at least an order of magnitude greater than the MPR121-based CMS system. A precision of 0.1 mm was reached with the FDC1004 sensors even at a large separation distance (34 mm) between the sensor and the ground plate, outperforming the MPR121 sensor which achieved precision of ~5 mm. When tested with the head phantom, the FDC1004 system also showed superior performance with submillimeter detection precision in all directions including anterior motion (reported to be most challenging orientation to detect

[1]). To provide the sensitivity of FDC1004, the MPR121-based system would necessitate sensors with areas larger by a factor of six. In addition, larger sensors would have to be two times closer to the target in order to provide similar performance [1].

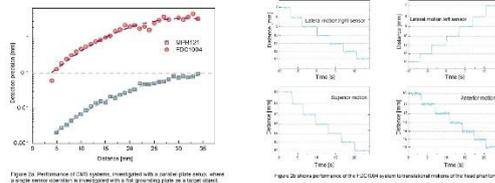

Figure 2a. Performance of 1200 capacitors investigated with a custom data logger. Average sensor capacitance is measured with a 100 pF generating plate at a larger depth. Figure 2b. Shows performance of the FDC1004 system for translational motions of the head phantom.

## Conclusion

These advances in CMS technology offer significant performance improvements in terms of sensitivity, detection precision, sensor size and the dynamic range relative to the system previously described [1], thus making it more attractive and practical for clinical use.

## PO-0971 Capacitive monitoring system for intrafraction rotation detection during frameless radiosurgery

P. Sadeghi<sup>1</sup>, O. Semeniuk<sup>1</sup>, R. James<sup>1,2</sup>

<sup>1</sup>Dalhousie University, Physics & Atmospheric Sciences, Halifax, Canada ; <sup>2</sup>Dalhousie University, Department of Radiation Oncology, Halifax, Canada

### Purpose or Objective

This work presents a novel, non-ionizing technique for continuous intra-fraction patient position monitoring during stereotactic radiosurgery. The system provides real-time cranial positioning information without relying on surrogates such as skin.

### Material and Methods

The system is comprised of an array of conductive sensors arranged around the cranium. Capacitance of the sensor array is monitored continuously. The system is unique in that it is not sensitive to the position of the thermoplastic mask but registers the motion of the cranium within. The system has been shown previously (Sadeghi, Lincoln *et al.* 2018) to demonstrate 0.1 mm sensitivity in detection of cranial translation, and in this work is assessed for rotation detection. A cranial phantom with a hollow space modelling the average human brain was 3D printed provided a signal for evaluation of the optimal sensor arrangement for rotation detection (figure 1). The brain cavity walls were covered with thin copper foil (0.025 mm thickness) to replicate the conductivity of human brain. The cranial phantom was attached to a hexapod stage capable of performing 6D motion with respect to any pre-defined origin in space. Three plates were arranged around the phantom at 1 cm distance in superior, left lateral, and right lateral directions. Each plate was comprised of three sensors, each made from 0.025 mm thick copper film on 3D printed PLA backing. The middle sensor was 2.7 cm in diameter, the anterior and posterior sensors (sensors 1 & 3) were half rims with inner and outer diameters of 9 cm and 12 cm, respectively (figure 1). Pitch and roll rotations were introduced as the phantom was rotated in 1 degree steps in both positive and negative directions. The axes and origin for head rotation were defined based on Fick convention (Kunin, Osaki *et al.* 2007). Sensitivity was defined as change in average signal per degree rotation. The range (noise band) was the difference between maximum and minimum data points under stationary conditions. When the sensitivity was higher than the noise band, the sensor was considered to be detecting the respective motion.

## Results

Our experiments show that posterior sensors on right and left lateral plates detect cranial roll (figure 2) with average sensitivity of 0.04 and 0.06 pF per degree, respectively. Posterior and anterior sensors on the superior plate detect cranial pitch (figure 2) with average sensitivity of 0.13 and 0.06 pF per degree, respectively.

## Conclusion

We had previously shown (Sadeghi, Lincoln *et al.* 2018) the capability of this system to detect translation motion. The current results show potential for rotation detection with this technology by monitoring the cranium without the need for ionizing radiation or the use of skin as a surrogate.

Figure 1. (a) The 3D printed phantom with copper layered brain cavity. (b) The array arrangement consisting of superior, left lateral, and right lateral plates. (c) Each plate is comprised of three sensors.

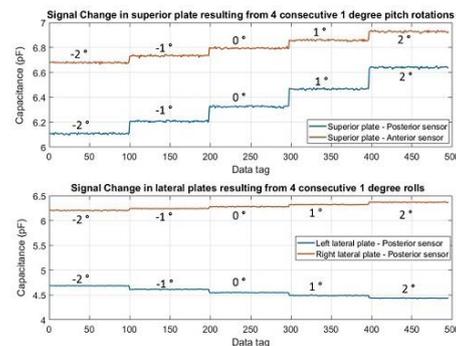

Figure 2. (Top) Detection of cranial pitch. Rotation ranging from -2 degrees (chin rotating away from the chest) to +2 degrees (chin rotating toward the chest) in 1 degree steps. (Bottom) Detection of cranial roll. Rotation ranging from -2 degrees (rotation toward the right) to +2 degrees (rotation toward the left) in 1 degree steps.

## PO-0972 Intrafraction prostate motion effects with or without ERB in highly hypofractionated proton therapy

<sup>1</sup>University of Groningen- University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>University of Twente, MIRA Institute for Biomedical Technology and Technical Medicine, Enschede, The Netherlands ; <sup>3</sup>Johns Hopkins University, Department of Radiation Oncology and Molecular Radiation Sciences, Baltimore, USA ; <sup>4</sup>University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA

### Purpose or Objective

Pencil beam scanning (PBS) technology allows the use of superior beam properties of protons to potentially improve outcomes with extreme hypofractionated radiotherapy for prostate cancer (PCa) patients. One of the technical challenges is the increased sensitivity to range uncertainties and intrafraction prostate motion. We have evaluated the robustness of extreme hypofractionated PBS proton plans to intrafraction prostate motion with (wERB) and without endorectal balloon (nERB) in PCa patients.

### Material and Methods

Intrafraction motion measurements were available from 59 patients treated in  $\geq 30$  fractions in the department of radiation oncology of the University of Pennsylvania. Motion was recorded in left, right, superior, inferior, anterior and posterior direction for up to 6 minutes using a real-time electromagnetic tracking system. Patients (five wERB and six nERB) with the largest magnitudes of

motion were selected. The time-weighted average motion for each direction was calculated for all fractions of each patient. Thereafter, the mean intrafraction motion for each direction was calculated for both wERB and nERB groups. Planning CTs (pCTs) of 4 representative PCa patients treated at our institution were used to create virtual proton plans, using an extreme hypofractionated regimen of 4 fractions of 9.5 Gy(RBE), applying robust optimization using 5 mm setup and 3% range uncertainty to fulfill V100>95% for the clinical target volume (CTV). The calculated mean intrafraction motion for both groups was applied to the pCTs of those 4 patients and 44 synthetic CTs (sCTs) were created using deformable image registration in RayStation 6.99 as a surrogate to real time 4D calculations. Differences in CTV coverage and max dose to the organs at risk between the sCTs and pCTs were compared.

### Results

Mean and standard deviation of intrafraction motion of both groups are listed in Table 1. The influence of intrafraction motion was negligible for CTV coverage which was maintained (V100>95%) in both groups. No detectable dose differences were found for the bladder. Posterior prostate motion resulted in a median max dose decrease to the anorectum of 61 cGy (wERB) and 65 cGy (nERB); inferior prostate motion resulted in a median max dose decrease of 53 cGy (wERB) and 57 cGy (nERB), respectively (Fig. 1A). A median max dose decrease to the anal canal of 0 cGy (wERB) and 158cGy (nERB) was found for posterior prostate motion and 92 cGy (wERB) and 184 cGy (nERB) for inferior prostate motion, respectively (Fig. 1B).

Table 1: Mean and standard deviation of intrafraction prostate motion with and without ERB in left, right, superior, inferior, anterior and posterior direction recorded using a real-time electromagnetic tracking system.

	Left (mm)	Right (mm)	Superior (mm)	Inferior (mm)	Anterior (mm)	Posterior (mm)
With ERB	0.31 ± 0.16	0.32 ± 0.12	0.67 ± 0.20	0.94 ± 0.22	0.77 ± 0.26	0.99 ± 0.20
Without ERB	0.57 ± 0.61	0.43 ± 0.22	1.09 ± 0.40	1.34 ± 0.47	1.40 ± 0.80	1.49 ± 0.45

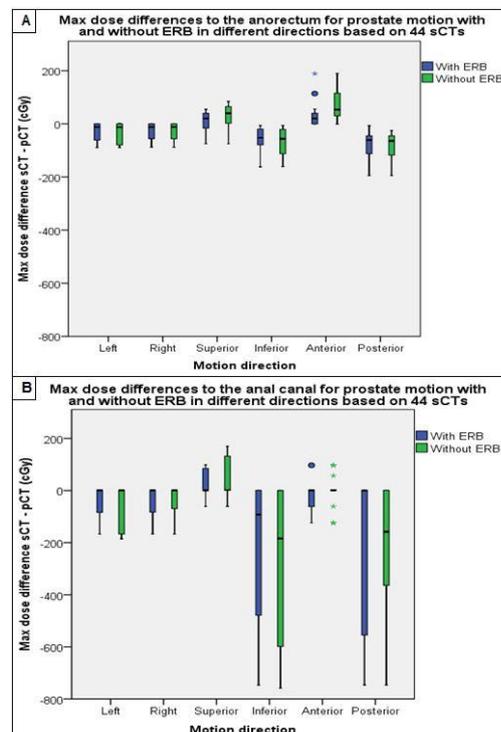

Figure 1: Max dose differences to the anorectum (A) and anal canal (B) for prostate motion with and without ERB in different directions based on 44 sCTs.

### Conclusion

Worst-case intrafraction prostate motion for both wERB and nERB groups did not negatively influence the

robustness of our extreme hypofractionated optimized proton plans, with negligible effect on target coverage and bladder dose. Doses to the anorectum and anal canal were most sensitive to posterior and inferior prostate motion. Our results suggest that ERB has no additive value on plan robustness. Further investigation with a larger patient cohort is needed to confirm our results.

### PO-0973 Residual intra-fraction error in non-immobilized patients treated with tracked robotic spinal SBRT

E. Rossi<sup>1</sup>, C. Fiorino<sup>1</sup>, A. Fodor<sup>2</sup>, G.M. Cattaneo<sup>1</sup>, C. Deantoni<sup>2</sup>, A. Sbalchiero<sup>2</sup>, A. Tavilla<sup>2</sup>, N.G. Di Muzio<sup>2</sup>, R. Calandrino<sup>1</sup>, S. Broggi<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute, Medical physics, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

### Purpose or Objective

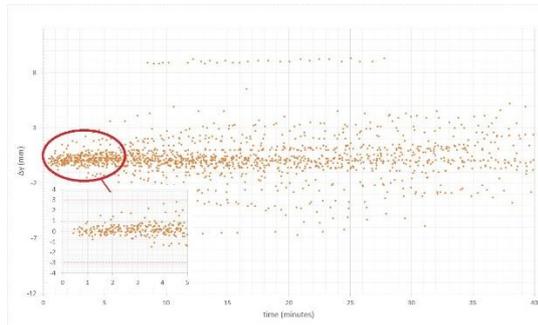

To assess residual intra-fraction patient motion in the delivery of spinal radiosurgery with CyberKnife (CK, Accuray, Inc.) using spine tracking in non-immobilized patients. Moreover, the intra-fraction motion with respect to the first alignment (i.e. tracking not available) is quantified and its relationship with time is assessed.

### Material and Methods

The Xsight Spine tracking technique with CK enables to track skeletal structures near the spine, avoiding the implantation of fiducial markers and, possibly, immobilization systems, allowing comfortable set-ups for, often, painful patients. X-ray images are taken to correctly align the patient on the treatment couch, then images are regularly acquired during treatment to correct for patient motion. Residual error during tracking deals with the shifts between consecutive images and may be safely quantified considering the registered shifts between them. We collected delivery data from 20 patients previously treated with tracking for spinal lesions without immobilization (51 fractions, 1615 images): 16-30 Gy (median 24Gy) in 1-5 fractions (10/20 with single fraction, 3/20 with multiple lesions) were delivered. The time between images for tracking varies between 30'' and 2' (median 1' ± 30''). Residual error is quantified for each image as the difference between measured translational and rotational corrections and the previous values. The error distribution for each fraction, patient and the whole population is assessed, including a possible relationship with time. Similarly, for intra-fraction motion in absence of tracking, we consider the shifts from the alignment coordinates (at time 0).

### Results

Residual intra-fraction error after tracking is limited: translational shifts >0.5mm are detected in only 2.5%, 6.8% and 4.8% of 1615 acquired images for cranio-caudal, left-right and anterior-posterior translations respectively; shifts >1mm in 0.8%, 2%, 1.4%; shifts >1.5mm in 0.2%, 0.5%, 0.3%; shifts >2mm in 0.2%, 0.2% and 0.1%. As for roll, 0.7% of shifts are >1°, 0.1% for pitch and yaw. No time dependence is found and the overall mean errors are close to 0 with SD (systematic error on the overall population) within 0.1 mm (table). About the "no-tracking" scenario, a time dependence is found (figure), especially for left-right ( $\Delta y$ ) translations. Up to 3' after starting the delivery no shifts larger than 2mm are observed, up to 5' they vary within a 3mm range. Then, major shifts appear mostly due to large (up to 9 mm) patient motion and time-related continuous shifts: after 10' and 20'  $\Delta y$  was > 3mm in respectively 4 and 10 fractions out of 51.

Without tracking		
	Mean	SD
$\Delta x$ (mm)	-0,19	0,81
$\Delta y$ (mm)	0,24	1,57
$\Delta z$ (mm)	0,15	0,62
$\Delta roll$ (°)	0,00	0,37
$\Delta pitch$ (°)	-0,03	0,29
$\Delta yaw$ (°)	-0,07	0,37
With tracking		
	Mean	SD
$\Delta x$ (mm)	-0,01	0,05
$\Delta y$ (mm)	0,02	0,06
$\Delta z$ (mm)	0,01	0,04
$\Delta roll$ (°)	0,00	0,02
$\Delta pitch$ (°)	0,01	0,02
$\Delta yaw$ (°)	0,00	0,02

### Conclusion

Spine tracking with CK is highly efficient also for non-immobilized patients: the residual error seems to be time independent and is close to 0. If tracking is not employed (i.e.: with other delivery modalities), shifts show a dependence on time. For delivery times exceeding 5' in the considered non-immobilized patient scenario, tracking seems to be highly recommendable.

**PO-0974 Intra-fractional stability of Deep Inspiration Breath Hold during RT for lung and lymphoma cancer**  
 D. Sloth Møller<sup>1</sup>, M.L. Schmidt<sup>1</sup>, T. Ravkilde<sup>1</sup>, P.R. Poulsen<sup>1</sup>, J. Hansen<sup>1</sup>, E.S. Worm<sup>1</sup>, H.H. Schmidt<sup>2</sup>, M.M. Knap<sup>2</sup>, A. Safwat<sup>2</sup>, H.K. Rose<sup>2</sup>, L. Hoffmann<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark ; <sup>2</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

### Purpose or Objective

Deep Inspiration Breath Hold (DIBH) during thoracic RT is attractive as it may reduce dose to the lungs and heart compared to free breathing RT. However, intra-fractional geometric instability during several breath holds may decrease the target coverage. We investigate intra-fractional uncertainties during planning, before/after each fraction delivery, and during actual field delivery.

### Material and Methods

Twenty-two patients (15 lung cancer (LC) and 7 sarcoma/lymphoma (SL)) were treated with DIBH-RT. The RPM system with an external marker (EM) placed caudally on the thoracic cage was used as a surrogate for the DIBH level. For all scans and treatments, the DIBH level measured by EM was < 2mm. Four DIBH planning-CT (pCT) scans were acquired: one for RT planning and three to

assess the inter-DIBH uncertainty (Fig1a). To assess inter-DIBH uncertainty during treatment, pre-treatment CBCT scans were acquired for daily setup (CBCT1) and post-treatment (CBCT2) at the first three fractions and once a week afterwards. For LC with tumour (T) and lymph node (N) involvement, T and N were analysed separately. SL targets were mostly mediastinal (M) and grouped with the mediastinal N targets. Systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors were calculated using the van Herk formalism. Intra-DIBH uncertainty was measured by intra-treatment 5Hz fluoroscopic kV imaging of gold markers implanted at N-site for LC (Fig1b) and motion trajectories were derived (Fig1c). The interquartile motion range (IQR) was determined for each treatment field.

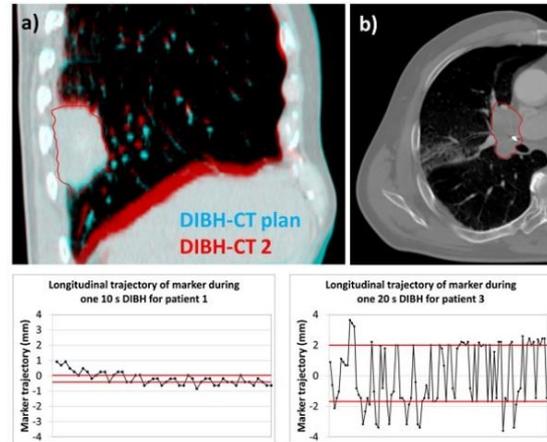

Figure 1 a) Inter-DIBH analysis. Comparison of two DIBH-CTs acquired for planning. Same comparison is made for CBCT acquired before and after treatment. b) DIBH-CT with gold marker implanted in lymph-node. c) Intra-DIBH analysis. Full motion trajectory of implanted gold marker for patient with intra-DIBH uncertainty below 2 mm and for patient with more than 4 mm intra-DIBH uncertainty. The red lines indicate the interquartile range for these two DIBHs.

### Results

The inter-DIBH uncertainty analysis (Fig 2) for LC T sites showed low stability in longitudinal position and poor correspondence between the uncertainties derived from DIBH pCTs and inter-DIBH CBCT1/2. In some patients, only minor overlap between motion ranges was seen and the mean value of the range was shifted from zero. For M sites the stability was higher and the correspondence better due to target location closer to EM, but the DIBH pCTs were still poor predictors of the actual inter-DIBH uncertainty during treatment. Errors in mm for the LC T sites were  $\Sigma_{LR}, \Sigma_{AP}, \Sigma_{CC}=0.7, 1.5, 2.3$ ,  $\sigma_{LR}, \sigma_{AP}, \sigma_{CC}=0.8, 1.5, 1.4$  (by CT) and  $\Sigma_{LR}, \Sigma_{AP}, \Sigma_{CC}=0.8, 1.1, 1.6$ ,  $\sigma_{LR}, \sigma_{AP}, \sigma_{CC}=1.2, 1.8, 2.9$  (by CBCT). For M sites  $\Sigma_{LR}, \Sigma_{AP}, \Sigma_{CC}=1.1, 1.1, 2.0$ ,  $\sigma_{LR}, \sigma_{AP}, \sigma_{CC}=0.9, 0.9, 1.7$  (CT) and  $\Sigma_{LR}, \Sigma_{AP}, \Sigma_{CC}=0.7, 1.2, 1.1$ ,  $\sigma_{LR}, \sigma_{AP}, \sigma_{CC}=0.9, 1.3, 1.6$  (CBCT). These errors do not reflect the difference between CT and CBCT observed for the individual patients (Fig 2).

Fig 1c shows examples of the intra-DIBH uncertainty. The mean IQR over all DIBH's for each patient ranged from 0.4mm to 1.9mm, in good agreement with the 2mm allowed EM window. The max IQR, however, ranged from 2.8mm to 16.4mm and 1%-23% of all DIBH's of each patient had IQR>2mm.

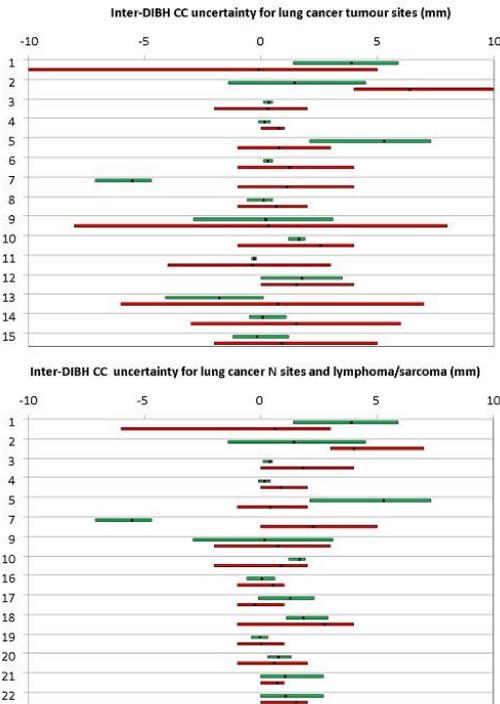

Figure 2: Upper panel: Inter-DIBH uncertainty for lung cancer primary tumour sites. Lower panel: Mediastinal targets (lymphoma/sarcoma patients (16-22) and lung cancer lymph node sites). For each patient the green bar indicates the range in uncertainty measured by DIBH-CTs, while the red bar indicates the range in uncertainty measured by comparison of CBCT1 and CBCT2. The black line in each bar indicates the mean value for the corresponding range.

### Conclusion

Inter-DIBH and intra-DIBH uncertainties varies greatly between patients. For some patients, the size of the uncertainties will undermine the advantages of DIBH. DIBH-CTs acquired before treatment do not predict the inter-DIBH uncertainty observed during treatment.

### PO-0975 Feasibility of single-camera intra-bore surface scanning in an O-ring linac

L. Delombaerde<sup>1</sup>, S. Petillion<sup>1</sup>, C. Weltens<sup>1,2</sup>, T. Depuydt<sup>1,2</sup>

<sup>1</sup>University Hospital Gasthuisberg, Department of Radiation Oncology, Leuven, Belgium ; <sup>2</sup>KU Leuven - University of Leuven, Department of Oncology, Leuven, Belgium

### Purpose or Objective

Patient surface scanning inside closed-bore linacs or imaging systems is difficult using ceiling-mounted projector/camera assemblies. A compact single camera surface scanning system (SCSS) for motion monitoring inside an O-ring linac is proposed and characterized.

### Material and Methods

A Microsoft Kinect depth camera is mounted on a movable rack placed at the back-end of the bore of a Halcyon (Varian Medical Systems, USA) (fig. 1). A transformation to the linac coordinate system retrieved from a cube detection calibration, is applied to the surface point cloud data acquired by the SCSS. The real-time surface data is registered using an Iterative Closest Point algorithm to a region-of-interest (a) of a 3D CAD-model or (b) of a reference surface acquisition from the first fraction. The positioning accuracy is investigated using anthropomorphic 3D printed phantoms with clinically relevant surface complexity: a head, hand and breast (fig. 2). Each phantom was placed 24 times to within 0 - 11 mm and 0 - 7.6° from the planned position to emulate clinically observed positioning errors. At every position a CBCT is acquired and a surface registration is performed. The surface registration result is compared to a CBCT-to-

planning-CT fiducial marker registration with 6 degrees of freedom. The performance of the SCSS for positioning accuracy for these specific phantoms was also benchmarked against a commercial surface scanning system (AlignRT, VisionRT Ltd., UK) on a C-arm system.

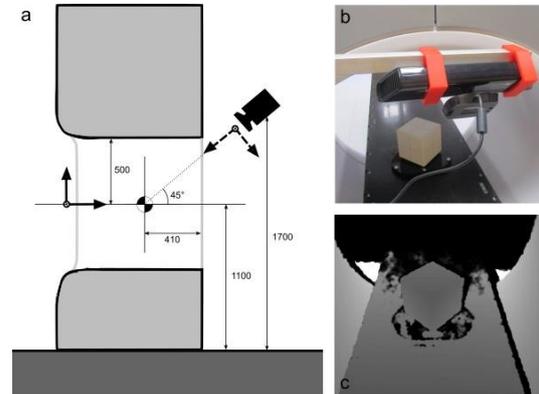

Figure 1: (a) Illustration of the depth camera's position relative to the linac isocenter. Distances (in mm) indicated as a reference. Sensor's dimensions not to scale. The camera's coordinate system is indicated with dashed arrows, the couch axes with solid arrows. (b) Photograph of the Kinect mounted on the movable rack. (c) View of the calibration cube from the sensor's position.

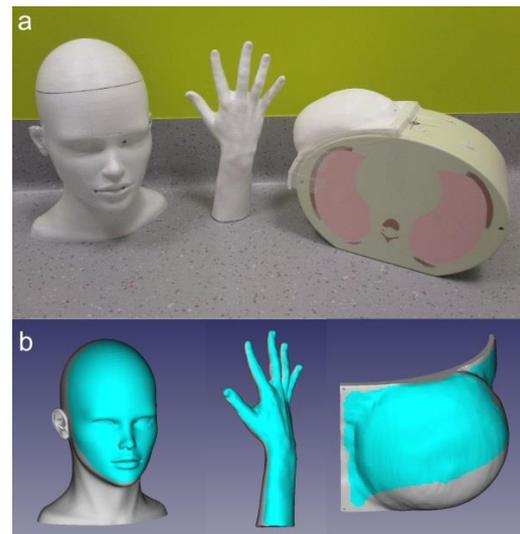

Figure 2: (a) Photograph of the 3 anthropomorphic phantoms used in the accuracy evaluation of the closed-bore surface scanning prototype. Head, hand and breast phantom were painted white and 10 lead markers inserted in evenly distributed cavities. The breast phantom is taped to the CIRS Thorax SBRT EZE phantom to simulate a realistic position. (b) The region-of-interest (cyan) selected on the 3D CAD-model.

### Results

The registration errors of the SCSS, compared to CBCT of the 3 phantoms combined were: Lat:  $0.30 \pm 0.76$  mm, Vert:  $-0.25 \pm 0.17$  mm, Long:  $0.31 \pm 0.48$  mm and Yaw:  $-0.31 \pm 0.83^\circ$ , Pitch:  $0.10 \pm 0.26^\circ$ , Roll:  $0.51 \pm 0.59^\circ$  for the CAD-model reference, and Lat:  $-0.65 \pm 0.74$  mm, Vert:  $0.32 \pm 0.15$  mm, Long:  $0.21 \pm 0.50$  mm and Yaw:  $-0.49 \pm 0.46^\circ$ , Pitch:  $0.13 \pm 0.25^\circ$ , Roll:  $-0.66 \pm 0.65^\circ$  for the surface acquisition reference. The AlignRT system had combined registration errors of: Lat:  $0.74 \pm 0.64$  mm, Vert:  $-0.57 \pm 1.40$  mm, Long:  $0.61 \pm 0.82$  mm and Yaw:  $-0.33 \pm 0.31^\circ$ , Pitch:  $-0.15 \pm 0.34^\circ$ , Roll:  $0.38 \pm 0.29^\circ$ . No correlation between displacement magnitude from the planned position and SCSS registration errors were found,  $p > 0.14$ .

### Conclusion

The prototype single camera intra-bore surface system is capable of accurately detecting displacements from the planned position of the phantoms. The compact system, proposed in this work, will allow surface guided radiotherapy and monitoring of intra-fraction motion inside the bore of O-ring gantries.

### PO-0976 Validation of respiratory motion modeling through repeated 4DMRI in the abdomen: preliminary results

G. Meschini<sup>1</sup>, C. Paganelli<sup>1</sup>, G. Fontana<sup>2</sup>, A. Pella<sup>2</sup>, A. Mancin<sup>3</sup>, A. Vai<sup>4</sup>, M. Riboldi<sup>5</sup>, F. Valvo<sup>6</sup>, G. Baroni<sup>1</sup>  
<sup>1</sup>Politecnico di Milano, Department of Electronics Information and Bioengineering, Milan, Italy ; <sup>2</sup>National Centre of Oncological Hadrontherapy, Bioengineering Unit, Pavia, Italy ; <sup>3</sup>National Centre of Oncological Hadrontherapy, Medical Radiology Technicians Unit, Pavia, Italy ; <sup>4</sup>National Centre of Oncological Hadrontherapy, Medical Physics Unit, Pavia, Italy ; <sup>5</sup>Ludwig-Maximilians-Universität, Chair of Experimental Physics - Medical Physics, Munich, Germany ; <sup>6</sup>National Centre of Oncological Hadrontherapy, Radiation Oncology Unit, Pavia, Italy

#### Purpose or Objective

Respiratory motion modeling in radiotherapy provides the estimation of anatomical changes induced by breathing, when continuous 3D imaging feedback is not available. However, the evaluation of the model performance in case of intra- and inter-fraction variability of the respiratory pattern is still a challenge. In this study, we exploited repeated 4DMRI acquisitions to create the training and testing datasets for respiratory motion model validation.

#### Material and Methods

Repeated 4DMRI of a pancreas (P\_pan) and a liver cancer patient (P\_liv) were acquired. Patients underwent two scans, one after the other, before irradiation and another scan after irradiation, in order to image intra- and inter-fraction variations, respectively (Table). Specifically, multi-slice acquisition of sagittal images (pixel size: 1.33mm×1.33mm, slice thickness: 5mm) during free breathing and retrospective 4DMRI reconstruction<sup>1</sup> were performed. The motion model<sup>2,3</sup> was trained on the first 4DMRI, thus establishing a correlation between a respiratory surrogate (here image-based) and motion information extracted through deformable image registration (DIR). The model was tested on the subsequent intra- and inter- 4DMRI, estimating the motion by means of the surrogate only. Inter-fraction baseline shifts were compensated<sup>3</sup> (Table). The estimated and the imaged ground truth (GT) motions were finally compared.

#### Results

The tumor center of mass (COM) distance between GT and model output had median values below 2.2mm both for P\_pan and P\_liv (Figure). Median errors below 2mm were observed consistently for the considered organs at risk (kidney and liver, respectively). For P\_liv, higher variability of tumor COM distances was quantified in the inter-fraction scenario, with errors up to 6.5mm for respiratory phases close to end-inhale. This is likely due to the baseline shift, the higher range of motion with respect to the training dataset (Table) and to DIR uncertainty.

Table.

	Tumor range of motion [mm]			Inter-fraction baseline shift [mm]
	Training 4DMRI	Intra-4DMRI	Inter-4DMRI	
P_liv	14.3	10.0	19.0	9.5
P_pan	10.5	9.2	10.9	2.7

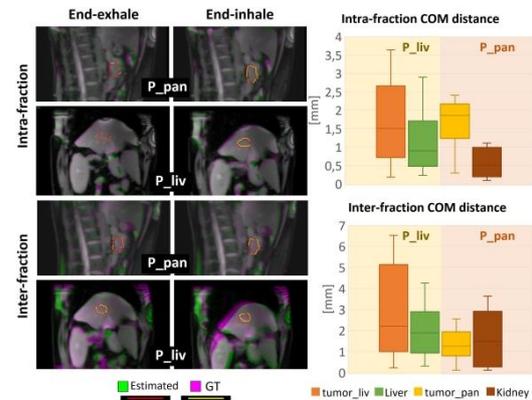

Figure. Left: sagittal slices showing the overlay between estimated and GT volumes, with the corresponding tumor contours. Right: boxplot of the COM distances between estimated and GT structures position.

#### Conclusion

A validation framework based on repeated 4DMRI is proposed for motion modeling in presence of intra- and inter-fraction changes. Preliminary results suggest the feasibility of motion modeling in the abdomen, with median residual errors comparable to the voxel size. The compensation of inter-fraction variations by re-training the model on a newly acquired dataset could improve its performance. Patient acquisitions is currently ongoing, aiming at extending the validation to a larger patient cohort and assessing the impact of DIR error.

### PO-0977 Improved 4D proton dosimetry via correlation with beam delivery details using log-files

N. Kostikhina<sup>1</sup>, H. Palmans<sup>2</sup>, S. Waid<sup>3</sup>, M. Stock<sup>2</sup>, D. Georg<sup>1</sup>, B. Knäusl<sup>1</sup>

<sup>1</sup>Medical University of Vienna / AKH Vienna, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria ; <sup>2</sup>EBG MedAustron GmbH, Medical Physics, Wiener Neustadt, Austria ; <sup>3</sup>EBG MedAustron GmbH, Therapy Accelerator- Commissioning and Development, Wiener Neustadt, Austria

#### Purpose or Objective

For implementing pencil beam scanning treatment in the presence of target motion, detailed insight in the treatment delivery sequence is essential. In this work, a 4D framework was implemented and applied for different scenarios, allowing to study the correlation between time-resolved dosimetry and beam delivery (BD) log files.

#### Material and Methods

A pulsed scanned proton beam with varying intensity was employed for the experiments. To represent target motion in a realistic human anatomy, an anthropomorphic breathing phantom, dedicated to proton dosimetry, was used. Two patient-specific parameters were varied: tumor volume (TV) and motion pattern. For TVs of 12cm<sup>3</sup> (TV1) and 97cm<sup>3</sup> (TV2) static and sinusoidal (0.6cm and 2.0cm amplitude) tumor motions were investigated. For both TVs a CT based treatment plan was created with the phantom in static position and delivered for all motion scenarios. The dose was determined in the target volume and the penumbral region with 0.5s time intervals using four (for TV1) and five (for TV2) pinpoint (PP) ionization chambers. The start of the phantom's motion was triggered by a pre-

defined beam extraction event enabling reproducible measurements. BD parameters, recorded with a time-resolution of 5.0 $\mu$ s, were retrospectively correlated time-wise with the dosimetric data (figure 1 (top)).

### Results

Comparing corresponding spills of the treatment deliveries, the intensity variation was up to 8% for TV1 and up to 24% for TV2 (see table 1). This resulted in accumulated treatment time differences of up to 11 and 39 sec, respectively. The total dose differences (DDs) between deliveries of the same plan were within 0.3% for individual PPs for static measurements for both TV sizes. 0.6cm target motion resulted in DDs of up to 1% for TV1 and up to 2% for TV2. Motion of 0.6cm did not introduce much larger contributions to the dose perturbations within tumor region than those coming from accelerator dependent intensity fluctuations. DDs were more pronounced for a target motion of 2 cm. The dose deviated more for the smaller volume, i.e. by 16, 7, 5 and 16 % for PP1-4 (figure 1 (bottom)), while for TV2 it remained below 9% for PPs within the tumor volume (PP1-4). Measurements in the penumbral region (PP5) for TV2 showed a high sensitivity to motion for both amplitudes (15% relative SD for 0.6cm motion and 42% for 2.0cm motion).

Table 1 - beam delivery parameters and resulting dose measurements for the considered tumor volumes and motion scenarios

Treatment plan specification:		Tumor volume 1 (12 cm <sup>3</sup> )	Tumor volume 2 (97 cm <sup>3</sup> )
Energy layers		34 (76.0 - 102.5 MeV)	46 (67.5 - 115.0 MeV)
Spot weight range		0.9-47.1 *10 <sup>6</sup> NP/fx	0.9-47.5 *10 <sup>6</sup> NP/fx
Number of spots		5643	7735
Beam intensity variation (relative SD), mean (min, max) [%]		3.7 (1.2, 8.4)	6.0 (2.0, 23.6)
Accumulated treatment time difference [sec]		11	39
Total dose differences between deliveries of the same plan for PP1-PP4(5) (relative SD) [%]	Phantom static	0.1, 0.0, 0.1, 0.0	0.0, 0.1, 0.1, 0.2, (0.3)
	Motion scenario - moving 0.6 cm	0.5, 0.3, 0.2, 1.2	2.3, 0.9, 1.5, 1.4, (15.4)
	Motion scenario - moving 2.0 cm	16.3, 6.8, 4.7, 15.7	4.7, 5.5, 8.5, 3.9, (41.9)

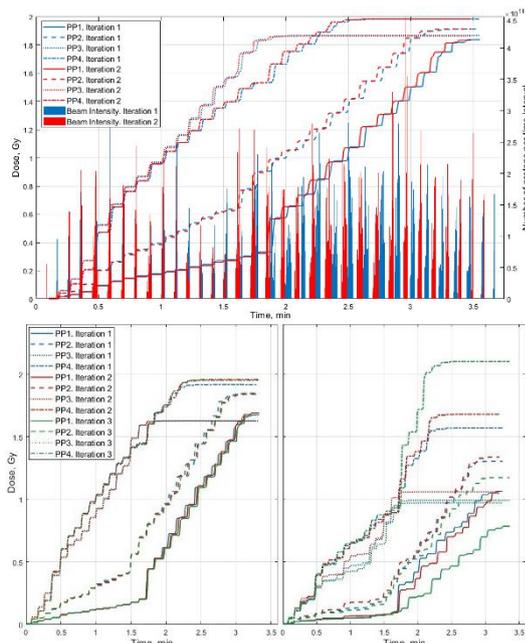

Figure 1 - (top) time-resolved dose measurements in the static phantom (2 iterations) for TV1 by means of four PPs, correlated in time with beam intensity. (bottom) time-resolved dose measurements for TV1 by means of four PPs in the presence of 0.6cm (right) and 2.0cm (left) target motion (3 iterations each).

### Conclusion

Time-resolved dose measurements and their correlation with the BD log files showed the relation of the BD time structure and the spill intensity, which is the basis for 4D

dose calculation. The application of 4D dosimetry in combination with the log file analysis underlined the dependence of the dosimetric accuracy of an individual plan delivery on beam delivery variations and patient-specific parameters.

### PO-0978 Accurate positioning with decreased treatment time using surface guided tomotherapy

A. Haraldsson<sup>1,2</sup>, S. Ceberg<sup>2</sup>, C. Crister<sup>2</sup>, S. Engelholm<sup>1</sup>, S.Å.J. Bäck<sup>1,2</sup>, P.E. Engström<sup>1</sup>

<sup>1</sup>Skåne University Hospital, Department of Hematology-Oncology and Radiation Physics, Lund, Sweden ; <sup>2</sup>Lund university, Medical Radiation Physics, Lund, Sweden

### Purpose or Objective

Accurate, reproducible, and fast setup of the patient is important for a successful radiotherapy treatment, especially for complex treatment techniques such as helical tomotherapy. Daily imaging with mega voltage computer tomography (MVCT) is accurate but increases the imaging dose and the total patient time on the treatment couch. Thereby additional intra-fraction position uncertainty caused by patient movements are introduced. In this study, we quantified the setup deviation and time gain when using surface scanning for daily setup with weekly MVCT imaging for reference as compared to daily MVCT. We analysed 16 835 treatment fractions from our TomoTherapy HD (Accuray Inc., Madison, USA) installed with a Sentinel optical surface scanning system (C-RAD Positioning AB, Uppsala, Sweden).

### Material and Methods

The surface of the patient was used to calculate the position using rigid registration against a reference surface. The patient setup was performed using in-room lasers, surface scanning and MVCT for the first three fractions. A new reference surface was acquired on the third fraction after a MVCT-based couch correction. On the following fractions, we used in-room lasers for setup, followed by daily surface scanning and weekly MVCT. The *MVCT image setup correction vector*, which was defined as the 3D translational correction as assessed by image registration, was used to evaluate the setup based on surface scanning. For each plan, the correction vector for one randomly selected fraction was used for the analysis. The *imaging time*, which was the time from imaging start to beam-on including any following procedures. The imaging time for one fraction was randomly selected per plan and imaging modality and multiplied with the number of fractions. Typical PTV margins at our clinic are 5 mm for head and neck patients and 10 mm for targets in the thorax and abdomen.

### Results

A total of 894 plans were analysed with a treatment date from 2012 to 2018. Of the setup correction vectors, 90 % were within 2.3 mm for CNS (N=284), 2.9 mm for H&N (N=254), 8.7 mm for thorax (N=144) and 10.9 for abdomen (N=134) patients. The setup deviations were divided in a random and a systematic component according to Yan et al. 1997 (Table 1). The difference in imaging time was assessed as total imaging time per treatment plan, modality, and treatment site (Figure 1). The difference in total imaging time per fraction was significant for all sites ( $p < 0.005$ ) as assessed by linear regression and the Mann-Whitney U test.

### Conclusion

The setup deviation was small compared to the standard PTV margins for all sites but the abdomen. In addition, daily surface scanning with weekly MVCT was significant faster than using daily MVCT. We therefore conclude that daily surface scanning with weekly MVCT is an accurate and fast alternative to daily MVCT for positioning of CNS, H&N and thorax patients receiving treatments on a TomoTherapy unit. For patients treated in the abdomen, daily surface scanning should proceed with caution.

Table 1: Mean systematic and mean random error (1SD) tabulated with the margin calculated for the PTV based on the deviations for surface scanning. Calculated from all MVCT setup correction vectors.

Site	Axis	Systematic error (mm)	Random error (mm)
H&N	Lateral	0.4	0.7
	Longitudinal	1.3	1.2
	Vertical	0.5	2.1
CNS	Lateral	0.2	0.5
	Longitudinal	0.3	0.6
Thorax	Lateral	0.8	1.4
	Longitudinal	1.2	4.0
	Vertical	1.0	2.5
Abdomen	Lateral	1.0	1.1
	Longitudinal	1.2	3.3
	Vertical	1.7	2.5

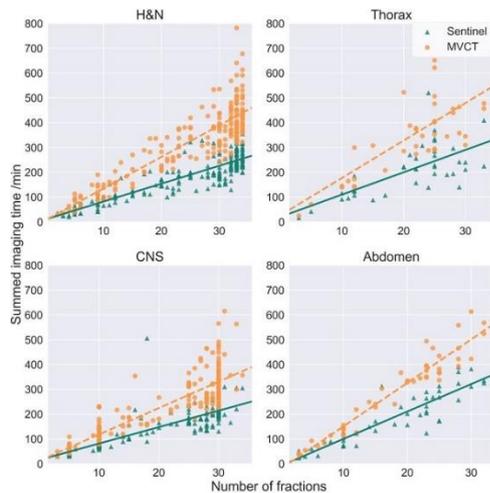

Figure 1: Summed imaging time against number of fractions per treatment plan, for imaging with Sentinel and with MVCT respectively. The imaging time for one fraction was randomly selected per plan and imaging modality and multiplied with the number of fractions.

### PO-0979 The Use of Triggered Imaging for Intrafraction Target Verification in Liver SBRT Breathhold

M. Walb<sup>1</sup>, K. Jethwa<sup>1</sup>, S. Park<sup>1</sup>, C. Hallemeier<sup>1</sup>, D. Pafundi<sup>1</sup>

<sup>1</sup>Mayo Clinic, Radiation Oncology, Rochester, USA

#### Purpose or Objective

Target localization in liver SBRT is challenging due to organ motion and target visualization difficulties using volumetric CBCT. To mitigate these concerns, respiratory gating techniques, such as breathhold (BH) with implanted fiducials, are used. The Varian TrueBeam RPM system uses external markers as a surrogate for internal motion to measure respiration amplitude. This assumes that a patient BH during treatment correlates with internal motion observed at simulation. A larger PTV expansion may address this uncertainty but at the cost of less normal tissue sparing.

To reduce uncertainty in target localization at treatment, we commissioned triggered imaging in the advanced imaging suite in TrueBeam 2.7. This allows for 2D kV images to be triggered at the beginning of each BH, before beam delivery, and verify that the internal fiducials are within an expanded contour overlay determined from simulation. A retrospective analysis was performed to determine the utility of triggered imaging for liver SBRT BH patients. **Material and Methods**

Target localization is initially performed with a 2D-2D kV match followed by 3D or 6D CBCT match to the fiducials. Then, prior to each beam delivery period, a 2D kV image acquisition is triggered when the patient holds their breath within the gating window. The acquired image

shows the overlay of a 5 mm radial expansion of each fiducial contour based on the planning CT coordinates to compare with the current location of the fiducials. The treatment team pauses the beam (1-2 s) for assessment of the contour overlay, and determines whether to resume beam delivery if the fiducials are inside the overlay or re-image if outside it. Re-imaging starts with repeating the triggered image and assessment, and re-evaluating if a full CBCT localization is warranted.

Retrospective analysis was performed on 129 fxs (30 pts) to quantify how frequently re-localization with CBCT was needed after commencing treatment, and how often the fiducials were not aligned in the initial BH attempt (false starts), but immediately repeating the triggered image with subsequent BH attempts (without shifting the patient) showed the fiducials within tolerance for treatment to proceed.

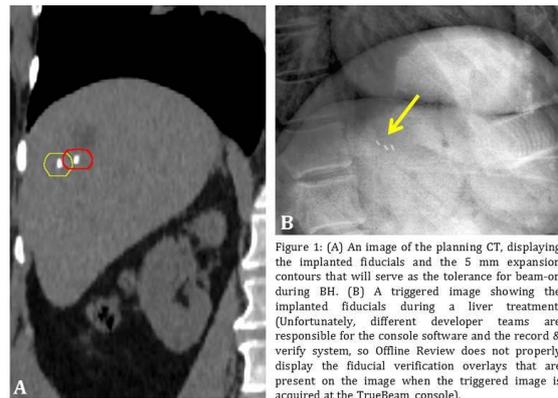

Figure 1: (A) An image of the planning CT, displaying the implanted fiducials and the 5 mm expansion contours that will serve as the tolerance for beam-on during BH. (B) A triggered image showing the implanted fiducials during a liver treatment. (Unfortunately, different developer teams are responsible for the console software and the record & verify system, so Offline Review does not properly display the fiducial verification overlays that are present on the image when the triggered image is acquired at the TrueBeam console).

#### Results

After initial localization, and treatment was either in progress or about to begin, 11.6% of fxs showed fiducials repeatedly outside of tolerance and required a new CBCT localization, requiring a mean vector ( $\pm$ SD) CBCT shift of  $5.8 \pm 2.7$  mm. In 27.1% of fxs, a false start was recorded, but re-imaging with another triggered image allowed treatment to proceed without a repeat CBCT.

Table 1: Frequency & Magnitude of Triggered Imaging-Guided Interventions

Total Fx with Triggered Imaging	Total Fx Re-CBCT	Total Fx False Starts		
129	15	35		
	11.63%	27.13%		
	Vertical	Longitudinal	Lateral	$\Delta r$
Mean Absolute Value of CBCT shifts $\pm$ SD	0.24 $\pm$ 0.21 cm	0.45 $\pm$ 0.27 cm	0.12 $\pm$ 0.13 cm	0.58 $\pm$ 0.27 cm

#### Conclusion

The results demonstrate a valuable role for intrafraction verification imaging for sites which rely on an external surrogate to gate the beam. Approximately 12% of patients required a second localization with a mean shift of 6 mm which can have a significant impact on a geographic miss. Plans include further analysis to guide liver margin expansions and assess the technology for additional SBRT sites, such as prostate.

### PO-0980 Dosimetric comparison of library of plans and online MRI-guided radiotherapy of cervical cancer

J. Visser<sup>1</sup>, P. De Boer<sup>1</sup>, K.F. Crama<sup>1</sup>, Z. Van Kesteren<sup>1</sup>, C.R.N. Rasch<sup>1</sup>, L.J.A. Stalpers<sup>1</sup>, A. Bel<sup>1</sup>

<sup>1</sup>Amsterdam UMC- location AMC, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Online MRI-guided radiotherapy of cervical cancer has the potential to further reduce dose to organs at risk (OAR) as

compared to a library of plans approach (LOP), which is currently the state of the art. However, intrafraction anatomical changes set a lower limit on the required PTV margin. The aim of this study is a dosimetric comparison of MRI-guided strategies with a LOP strategy taking intrafraction anatomical changes into account.

#### Material and Methods

The 14 patients included in this study were treated with chemoradiation at our institute and received weekly MRIs after informed consent. The weekly MRIs were considered to represent day-to-day anatomical changes that occur during the treatment. For the LOP strategy the plans were based on interpolations of the cervix-uterus on pretreatment full and empty bladder scans. The two MRI-guided strategies (MRI\_3mm and MRI\_5mm) consisted of treatment plans created on the weekly sagittal MRIs with 3 mm and 5 mm PTV margin around the cervix-uterus. All plans were VMAT dual arc plans with a prescribed dose of 45 Gy in 25 fractions. For the dosimetric evaluation of the different strategies targets and OARs were delineated on each weekly transversal MRI, which was acquired on average 10 minutes after the sagittal MRI. This way also the effect of intrafraction motion was taken into account. To enable comparison with DVH parameters for the whole treatment, for each weekly MRI the fraction dose was multiplied by 25, the total number of fractions. For the delineations on each transversal MRI the following DVH parameters were calculated: cervix-uterus CTV  $D_{98\%}$ , high-risk CTV  $D_{98\%}$ , bowel bag  $V_{40Gy}$  and  $V_{30Gy}$ , and bladder and rectum  $D_{mean}$  and  $V_{40Gy}$ .

#### Results

For the MRI\_5mm strategy  $D_{98\%}$  of the high-risk CTV was at least 95% for all weekly MRIs of all patients, while for the LOP and MRI\_3mm strategy this requirement was not satisfied for at least one weekly MRI for 1 and 3 patients, respectively. In Figure 1 an example is given where intrafraction anatomical changes resulted in insufficient coverage of the cervix-uterus CTV for the MRI\_3mm strategy. As compared to the LOP strategy the bowel bag  $V_{40Gy}$  was on average reduced by 148  $cm^3$  and 135  $cm^3$  for the MRI\_3mm and MRI\_5mm strategy, respectively, while for  $V_{30Gy}$  this was 136  $cm^3$  and 129  $cm^3$  (Figure 2). Bladder  $D_{mean}$  was reduced by 2.7 Gy and 1.8 Gy, for the MRI\_3mm and MRI\_5mm strategy, respectively, while bladder  $V_{40Gy}$  was reduced by 24% and 17% (percentage points). Rectum  $D_{mean}$  was reduced by 14.0 Gy and 11.9 Gy, while  $V_{40Gy}$  was reduced by 53% and 47% (percentage points). All differences were significant ( $p < 0.05$ ).

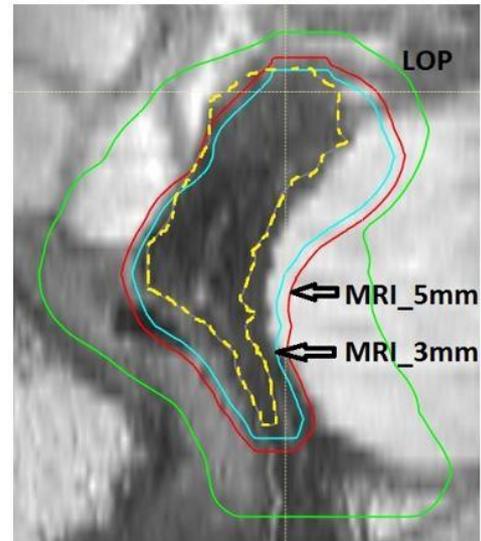

Figure 1: PTV of the selected plan in the LOP (green), and the PTVs of the MRI\_5mm (red) and the MRI\_3mm (blue) strategy overlaid on a transversal MRI. In this example, due to intrafraction bladder filling, the coverage of the cervix-uterus CTV (yellow dashed line) was insufficient for the MRI\_3mm strategy ( $D_{98\%} < 95\%$ ), while it was sufficient for the MRI\_5mm and LOP strategy

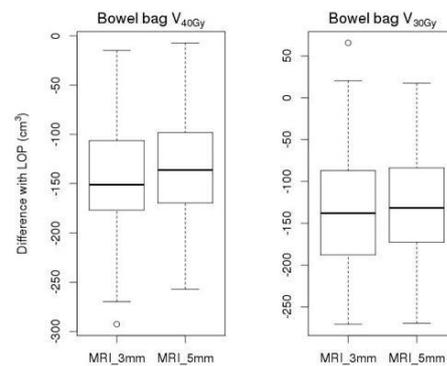

Figure 2: Bowel bag  $V_{40Gy}$  and  $V_{30Gy}$  for all weekly MRIs and all patients. The difference is shown between the MRI\_3mm and LOP strategy, and between the MRI\_5mm and LOP strategy. Negative values indicate more sparing for the MRI strategies.

#### Conclusion

With online MRI-guided radiotherapy of cervical cancer considerable sparing of OARs can be achieved. If a new treatment plan can be generated and delivered within 10 minutes, an online MRI-guided strategy with a 5 mm PTV margin for the CTV of the cervix-uterus is sufficient to account for intrafraction anatomical changes.

#### PO-0981 Role of on-table plan adaptation in MR-guided ablative radiation therapy for central lung tumors

T. Finazzi<sup>1</sup>, M. Palacios<sup>1</sup>, F. Spoelstra<sup>1</sup>, C. Haasbeek<sup>1</sup>, A. Bruynzeel<sup>1</sup>, B. Slotman<sup>1</sup>, F. Lagerwaard<sup>1</sup>, S. Senan<sup>1</sup>

<sup>1</sup>VU University Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

As patients with centrally located lung tumors are at increased risk of toxicity with SABR, we performed stereotactic MR-guided adaptive radiation therapy (or SMART) for such patients. We retrospectively analyzed the benefits of daily on-table plan adaptation.

#### Material and Methods

Twenty-four patients with central tumors underwent video-assisted, respiration-gated SMART on the MRIdian (ViewRay, Inc.). Tumors were sub-grouped as moderately central (PTV within 2 cm of proximal bronchial tree; n=18), ultracentral (PTV overlapping trachea / main stem

bronchi; n=1) or paracardial (PTV touching mediastinal or pericardial pleura; n=5). Risk-adapted fractionation was used to deliver 60Gy in 8 fx (n=19), 55Gy in 5 fx (n=4) or 60Gy in 12 fx using a GTV-PTV margin of either 3 mm (n=19) or 5 mm (n=5). For each fraction, daily MR-guided setup and on-table plan re-optimization based on PTV coverage and organ at risk (OAR) constraints was performed. Gated breath-hold delivery was performed under continuous MR-guidance. Of a total of 181 fractions, 167 were available for analysis. Benefits of daily plan re-optimization were studied by comparing 167 'predicted' plans, which are the calculated baseline plans on the anatomy-of-the-day, with the re-optimized treatment plans, using Wilcoxon signed-rank test after exclusion of normality.

#### Results

In baseline plans, median PTV was 30.5 cc (range 4.2-70.2), and 95% of PTV received a median dose of 60Gy (55.0-62.6) and a BED<sub>10</sub> of 105Gy (85.0-115.5 Gy). The mean interfractional volume change of clinician-contoured GTV and PTV were 0.4 cc (-3.2 - 6.8) and 0.7 cc (-3.3 - 11.7), respectively, with 75% of fractions showing a GTV/PTV variability  $\leq 1$ cc when compared to baseline. Clinicians had chosen re-optimized plans for treatment in 91% of fractions; reasons included better PTV coverage (62%), OAR sparing (5%), a combination of PTV coverage / OAR sparing (12%), or because institutional protocol for some other tumor sites routinely selected this option (12%). PTV coverage by the prescription dose improved in re-optimized plans (PTV V100% 87.7% vs. 92.2%; p<0.01), leading to an increase in fractions fulfilling the PTV V100%  $\geq 95\%$  objective from 24.6% to 85.6%. A benefit for adaptation persisted when the 40 fractions with a GTV/PTV change  $\geq 1$ cc from baseline were excluded from analysis (PTV V100% 87.7% vs. 91.6%; p<0.01). Median GTV and PTV doses, however, showed smaller improvements after re-optimization (GTV D50 69.0 vs. 69.3Gy, p<0.05; PTV D50 65.9 vs. 66.3Gy, p<0.01). Predefined OAR planning constraints were violated more often in predicted plans than in re-optimized plans (mean 0.73 vs. 0.53 violations per fx; p<0.05), and re-optimization allowed for better sparing of OARs in all cases when this was cited by the clinician as the reason for plan adaptation.

#### Conclusion

In central lung tumors treated using SMART, on-table plan adaptation improved PTV coverage, while avoiding excessive OAR doses.

#### PO-0982 The dosimetric impact of geometric image distortions in slice-based 4D-MRI on the MR-linac

M. Fast<sup>1</sup>, R. Keesman<sup>1</sup>, W. Van den Wollenberg<sup>1</sup>, C. Juan-Cruz<sup>1</sup>, T. Van de Lindt<sup>1</sup>, U. Van der Heide<sup>1</sup>, J. Sonke<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

4D-MRI is the modality of choice for guiding online plan adaptation of thoracic and abdominal lesions treated on the MR-linac. Like other MRI sequences, 4D-MRI is subject to scanner-specific geometric image distortions caused by gradient non-linearity and main magnetic field inhomogeneity. Specifically for research 4D sequences based on multi-slice 2D acquisitions, no 3D correction is currently available on the Elekta Unity MR-linac (Elekta AB, Stockholm, Sweden). Instead, only a 2D in-plane correction is applied leaving residual through-plane distortions unchanged. This study compares the dosimetric impact of (residual) geometric distortions on the online plan adaptation workflow of the MR-linac for liver SBRT.

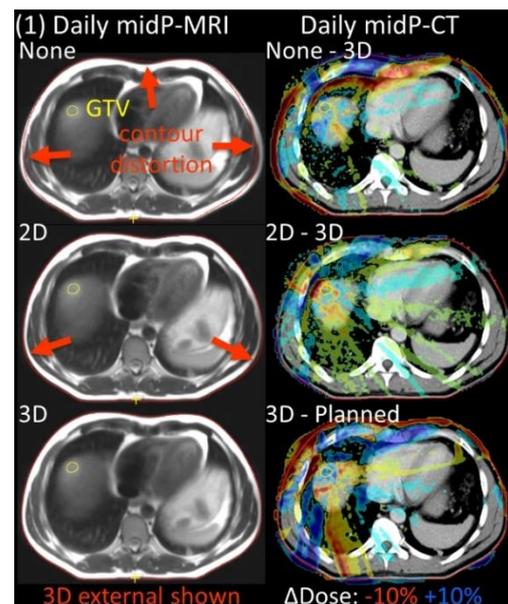

#### Material and Methods

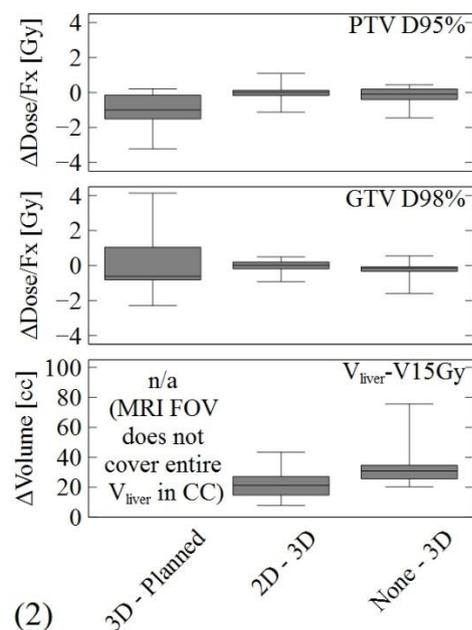

We investigated three different correction strategies for geometric image distortions on the Elekta Unity: A) None; B) 2D, in-plane distortion correction (current default); C) 3D, in-house developed full correction of the

retrospectively sorted 4D-MRI. The 3D-corrected images were considered as ground truth. All image corrections were derived from manufacturer-provided spherical harmonics coefficients. In this study, we included axial 4D-MRIs of three oligometastatic liver patients scanned on the MR-Linac (total: 10 imaging fractions). First, a step-and-shoot IMRT MR-linac plan (3x20 Gy, 10-13 beams) was created in Monaco 5.4 for each patient on the planning mid-position (midP)-CT. Next, each 4D-MRI was warped into a midP-MRI prior to applying the image corrections. The treatment plan was then adapted for each imaging fraction based on a rigid registration of the tumour mask in the planning midP-CT to the 3D-corrected midP-MRI ('adapt-to-position'). Last, the planning midP-CT was deformably registered to each version of the daily midP-MRIs. The adapted plan was then re-calculated and evaluated using these daily midP-CTs.

#### Results

Visual inspection of the daily midP-MRIs in the axial orientation revealed mostly consistent contours between 3D- and 2D-corrected images. Uncorrected images featured local distortions of the external patient contour of up to 2 cm (fig 1). For the tumours, which were always positioned within 10 cm of the machine isocentre, 3D distortions were below 1.5 mm and hardly visible. Dose on the daily midP-CT showed local differences of up to 4 Gy/Fx compared to the original plan. Importantly, the daily dose differences induced by anatomical variations (3D-Planned) were much larger than the dose differences of the correction strategies (2D-3D, None-3D) for the PTV D95% and GTV D98% (fig 2). For the liver, the median increase in volume receiving less than 15 Gy was 31 cc (None) and 21 cc (2D) compared to the 3D-corrected images.

## Conclusion

When evaluating delivered dose on the daily anatomy, the relatively simple 2D in-plane geometric distortion correction closely approximates the 3D correction for axial 4D-MRIs. Further research is needed to assess the impact of image distortions on contouring and plan re-optimisation ('adapt-to-shape').

## PO-0983 Accumulating delivered dose to the rectum using finite element analysis improves toxicity prediction

L. Shelley<sup>1,2</sup>, D. Noble<sup>3</sup>, M. Romanchikova<sup>4</sup>, K. Harrison<sup>5</sup>, A. Bates<sup>3</sup>, M. Sutcliffe<sup>1</sup>, S. Thomas<sup>2</sup>, N. Burnet<sup>6</sup>, R. Jena<sup>3</sup>  
<sup>1</sup>University of Cambridge, Department of Engineering, Cambridge, United Kingdom ; <sup>2</sup>Cambridge University Hospitals, Department of Medical Physics & Clinical Engineering, Cambridge, United Kingdom ; <sup>3</sup>Cambridge University Hospitals, Department of Oncology, Cambridge, United Kingdom ; <sup>4</sup>National Physical Laboratory, Data Science, Teddington, United Kingdom ; <sup>5</sup>University of Cambridge, Cavendish Laboratory, Cambridge, United Kingdom ; <sup>6</sup>University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

## Purpose or Objective

In prostate cancer radiotherapy (RT), the rectum is a dose-limiting organ. Existing NTCP models are based on planned DVH data from the static pre-treatment CT scan. However, delivered dose to the rectum differs from planned due to interfraction motion.

Here we present a system for accumulating motion-inclusive delivered dose to the rectal wall, using biomechanical modelling and finite element analysis (FEA) to build voxel-by-voxel dose histories, and use this data to construct NTCP models incorporating spatial features.

## Material and Methods

185 prostate cancer patients treated with helical IGRT were split into training (n = 139) and validation groups (n = 46). Dose prescriptions were 74 Gy/37# and 60 Gy/20#, combined by converting to EQD in 37 fractions. Rectal position during treatment was identified from daily MVCTs using a locally developed autosegmentation algorithm. The auto-contours were used to generate a simulated rectal model in the FEA environment, Abaqus (Dassault Systèmes®). For each patient, the model was biomechanically grown and deformed to the planned and daily contours. Daily dose to the rectal wall was calculated

using the independent dose calculation system, CheckTomo. Total delivered dose was determined by accumulating daily dose at each finite element (or, voxel). 3D voxel-wise statistical analysis was performed for dose differences between patients with and without rectal bleeding (RB)  $\geq$ Gr2 at 2 years (prospectively collected; CTCAEv4.03; n = 15 ,training; n = 6, validation), for planned and delivered dose. Subregions were identified where  $p < 0.05$  ( $SRR_{0.05}$ ) and  $p < 0.01$  ( $SRR_{0.01}$ ) (Figure 1), and the equivalent uniform dose (EUD) was calculated for each SRR, as well as the full rectal wall (RW).

Univariate analyses were performed to identify the dose metrics and clinical prognostic factors to be included in a multivariable logistic regression model. NTCP was calculated as:  $NTCP = 1/(1+exp(-S))$ , where S is dependent upon the outcome of the logistic regression (Schaake et al., 2017).

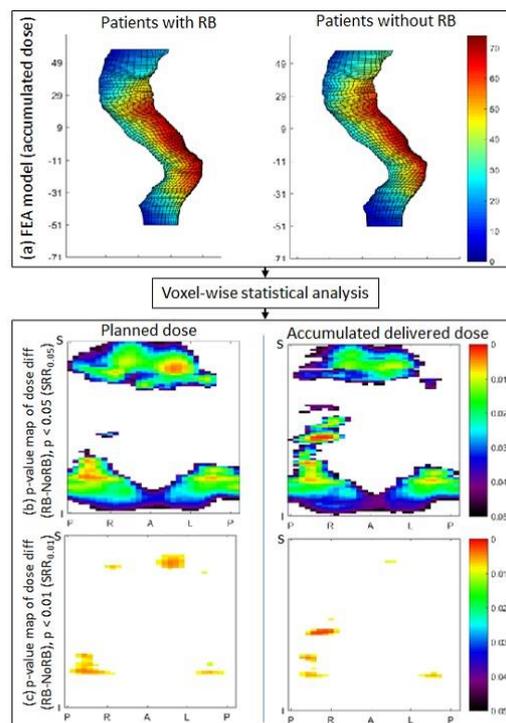

Figure 1 – (a) Delivered dose to rectum, accumulated using finite element analysis, split by patients with and without RB  $\geq$  G2. Voxel-wise statistical analysis was performed on dose differences (with/without RB) to generate p-value threshold maps (shown here virtually unfolded to 2D) to identify subregions where  $p < 0.05$  ( $SRR_{0.05}$ ), and  $p < 0.01$  ( $SRR_{0.01}$ ), for both planned and delivered dose. The EUD of each subregion was used to formulate a NTCP model.

## Results

Univariate analysis revealed that EUD of  $SRR_{0.01}$ ,  $SRR_{0.05}$ , and RW, from delivered dose, were discriminative of RB. No significant associations were observed for corresponding planned dose metrics. Pre-treatment status of hypertension (HTN) was associated with RB.

A NTCP model was generated for each dose metric. For the training set, all NTCP models were predictive of RB for both planned and delivered dose metrics (Figure 2), the strongest being  $SRR_{0.01}(\text{delivered})+\text{HTN}$ , with AUC 0.801 [95%CI: 0.697, 0.905]. The only model predictive of RB upon testing of the validation cohort was  $SRR_{0.01}(\text{delivered})+\text{HTN}$ , AUC 0.829 [0.693, 0.966].

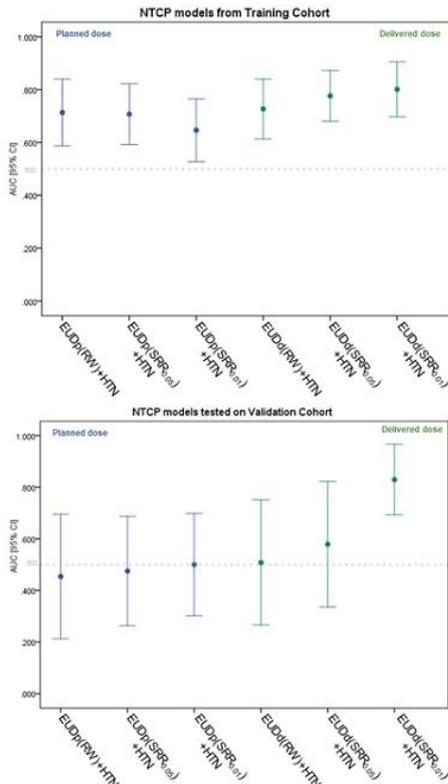

Figure 2 – Area Under the Receiver Operator Characteristic Curve (AUC) for NTCP models of RB ≥ G2. Results were considered significant if AUC > 0.6 and lower 95%CI > 0.5. Multivariable logistic regression models generated from the training cohort for dosimetric parameters (EUD of RW, SRR0.05, and SRR0.01) with HTN status, for planned and FEA-accumulated delivered dose, were all found to be good predictors. The only model predictive of RB upon testing with the validation cohort was based on delivered dose to SRR0.01+HTN, with AUC = 0.829 [95% CI: 0.693, 0.966].

**Conclusion**

A NTCP model based on delivered dose to SRR0.01 and HTN was generated and validated for RB. External validation would be desirable. FEA provides a more anatomically representative tool for dose accumulation than planar homogeneous expansion. Improved toxicity prediction based on delivered dose could be useful for decision making in adaptive RT.

**PO-0984 Univariate toxicity associations are stronger with delivered than planned dose in HNC patients.**

D. Noble<sup>1</sup>, K. Harrison<sup>2</sup>, A. Hoole<sup>3</sup>, M. Wilson<sup>4</sup>, S. Thomas<sup>3</sup>, A. Bates<sup>5</sup>, L. Shelley<sup>6</sup>, N. Burnet<sup>7</sup>, R. Jena<sup>1</sup>  
<sup>1</sup>University of Cambridge, Oncology, Cambridge, United Kingdom ; <sup>2</sup>University of Cambridge, Cavendish Laboratory, Cambridge, United Kingdom ; <sup>3</sup>Cambridge University Hospitals NHS Foundation Trust, Department of Medical Physics and Clinical Engineering, Cambridge, United Kingdom ; <sup>4</sup>University College London, Department of Medical Physics and Biomedical Engineering, London, United Kingdom ; <sup>5</sup>Cambridge University Hospitals NHS Foundation Trust, Cambridge Clinical Trials Unit- Box 401, Cambridge, United Kingdom ; <sup>6</sup>University of Cambridge, Engineering, Cambridge, United Kingdom ; <sup>7</sup>University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom

**Purpose or Objective**

Differences between planned (D<sub>P</sub>) and delivered (D<sub>A</sub>) dose to OARs in patients with HNC are well documented; adaptive strategies may reduce such differences, but lack an evidence base. To date, no data exists proving that patient toxicity associates more strongly with D<sub>A</sub>, compared to D<sub>P</sub>. This study aims to test that hypothesis.

**Material and Methods**

All HNC patients recruited to the VoxTox study (UK CRN ID 13716) were eligible. All were treated with standard radical protocols on TomoTherapy with daily IG. Swallowing OARs (ipsi & contralateral parotids - IPG & CPG, submandibular glands - ISMG & CSMG, superior & middle pharyngeal constrictors - SPC/MPC, oral cavity - OC and supraglottic larynx - SGL) were segmented on planning scans, according to published atlases. An open-source deformable image registration toolbox (Elastix), in-house dose calculation software (CheckTomo), planning kV and IG-MVCTs were used to compute D<sub>P</sub> and D<sub>A</sub> OAR DVHs. Mean dose was used for analysis. Toxicity was assessed with CTCAEv4.03 at baseline, and 1 year, using 3 endpoints: xerostomia (Xer), salivary duct inflammation (SDI), dysphagia (Dys). Baseline data on comorbidities, primary site (PDS), TNM staging, surgery, smoking, alcohol and systemic therapy (SACT) were collected. Univariate analysis was undertaken to examine relationships between baseline parameters, D<sub>P</sub>, D<sub>A</sub>, and Gr2+ toxicity. Odds ratios (ORs) were calculated for all variables. Dose differences between cases with and without Gr2+ toxicity were assessed with t-tests. AUC of ROC curves were calculated for dosimetric parameters.

**Results**

141 patients had full datasets available for analysis. PDS were: 90 oropharynx, 14 hypopharynx/larynx, 16 salivary gland/sinus/skin, 10 oral cavity, 5 nasopharynx, 6 CUP. Concomitant SACT: cisplatin 78, cetuximab 11, none 52. Mean dose differences (D<sub>A</sub> - D<sub>P</sub>, 95% CI) for each OAR were: IPG 1.58Gy (1.36-1.81), CPG 0.93Gy (0.71-1.15), ISMG 1.00Gy (0.84-1.15), CSMG 1.23Gy (1.07-1.39), SPC 0.92Gy (0.80-1.03), MPC 0.73Gy (0.55-0.92), OC 0.62Gy (0.46-0.79), SGL 0.95Gy (0.71-1.20) (Fig 1).

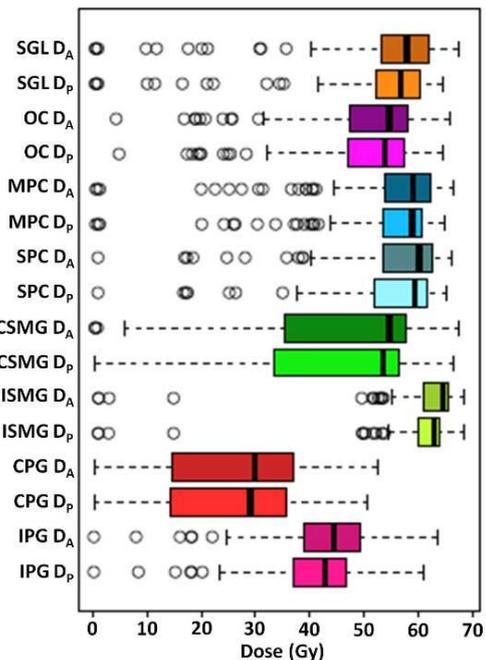

Figure 1: Planned (D<sub>P</sub>) and delivered (D<sub>A</sub>) mean dose to OARs. I = ipsilateral, C = contralateral. PG = parotid gland, SMG = submandibular gland, SPC/MPC = superior & middle pharyngeal constrictors, OC = oral cavity, SGL = supraglottic larynx. n = 141 patients.

Concomitant SACT increased the risk of all toxicity endpoints (ORs, 95% CIs); Xer 2.22 (1.10-4.52), SDI 3.16 (1.41-7.55), Dys 3.33 (1.04-14.1), as did baseline symptoms for Xer (2.10, 1.01-4.27) and SDI (5.06, 1.68-15.3), and higher N-stage (2+) for Xer (2.10, 1.04-4.27). Univariate relationships between dose to relevant OARs and toxicity are shown in Table 1.

Table 1: Univariate analysis of late toxicity (1 year point prevalence) as a function of planned ( $D_p$ ) and delivered ( $D_d$ ) dose parameters to OARs (ipsilateral - I and contralateral - C parotid glands - PG and submandibular glands - SMG, superior - S and middle - M pharyngeal constrictor muscles PC, oral cavity - OC and supraglottic larynx - SGL). ORs indicate % increase in odds of Gr2+ toxicity/Gy increase to OAR. No relationship found - cells clear. No relationship between dose to OAR and toxicity endpoint - cells clear. Relationship stronger - cells green ( $D_d$  stronger = 15). Relationship weaker - cells red ( $D_d$  weaker = 2). Relationship equivalent or equivocal - cells blue (7).

## Conclusion

Clear associations with concomitant SACT, pre-treatment symptoms and toxicity were seen.  $D_A$  was higher than  $D_p$  to all OARs. Differences were small in most patients. Despite this, a trend for marginally stronger univariate associations between  $D_A$  parameters, compared to  $D_p$ , and toxicity was seen. Results should be interpreted with caution due to multiple testing, and comparison with multivariate models is required as a next step. Nonetheless, this data is the first to compare relationships between both  $D_p$  &  $D_A$  and toxicity in HNC, and to suggest stronger links with the latter.

## PO-0985 Online-adaptive proton therapy: assessing accuracy of robust dose restoration in lung patients.

E. Borderias<sup>1</sup>, E. Sterpin<sup>1</sup>, X. Geets<sup>2</sup>, K. Bernatowicz<sup>1</sup>, K. Souris<sup>1</sup>

<sup>1</sup>Université Catholique de Louvain, Center of Molecular Imaging- Radiotherapy and Oncology, Brussels, Belgium ;

<sup>2</sup>Cliniques universitaires Saint-Luc, Department of Radiation Oncology, Brussels, Belgium

## Purpose or Objective

Intensity-modulated proton therapy (IMPT) offers excellent dose conformity and reduces the integral dose in the OAR compared to conventional radiotherapy. During the treatment, density changes may alter planned proton ranges in the patient and compromise the accuracy of the plan. To take into account this effect, isovolume dose restoration (iDR) uses isodose contours generated from the initial dose distribution and their associated weighted objectives (maximum and minimum) to reoptimize the plan and reproduce the initial dose in repeated CTs. The objective of this work was to test the performance of iDR in lung cancer patients.

## Material and Methods

The provided database included planned and two repeated 4D-CTs (every two weeks) for fourteen patients. Twelve of them present lymph nodes in addition to the primary tumour. iDR was performed in the first series of repeated 4D-CTs. The prescribed dose ( $D_p$ ) to target was 66 Gy (33 fractions of 2 Gy). Robust optimization was used for the targets, with setup errors of 5mm, range errors of 3%, and

three phases of the respiratory cycle (end-exhale, end-inhale, and midV). Plans were optimized based on CTV coverage criteria (worst-case  $D95% > 95%D_p$  and  $D5% < 105%D_p$ ) in RayStation (RaySearch Laboratories, Sweden). For the evaluation of the results, two different metrics were calculated: 1)  $D95%$  and  $D5%$  dose values for the CTV in the nominal case; 2) dose differences between restored/distorted and initial dose distributions reported by  $DE(vol=2\%)$  values in four different volumes (prescribed, high, medium and low dose regions).  $DE(vol=2\%)$  represents the absolute dose errors (evaluation-initial dose) in at most 2% of the analysed region.

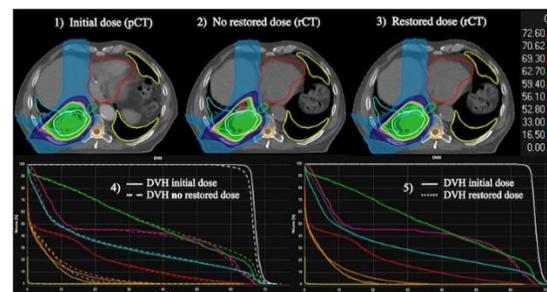

## Results

The evaluation of initial plans on repeated CTs showed large dose distortions, which were substantially reduced after restoration. No target underdosage was observed after restoration, whereas for 28% (4/14) of the patients, the CTV coverage criteria were not accomplished before restoration. In limit cases (21% or 3/14 patients), where  $D95%/D5%$  levels were reached (only  $\pm 1$ Gy), iDR improved considerably the DVH metrics (see Table 1). In the analysis of local dose differences, median  $DE(vol=2\%)$  decreased from 10.06 Gy in distorted plans to 3.23 Gy in the restored plans.

Patient	INITIAL		RESTORED		DISTORTED	
	D95% (Gy)	D5% (Gy)	D95% (Gy)	D5% (Gy)	D95% (Gy)	D5% (Gy)
1	65.74	67.99	65.85	67.91	65.55	68.60
2	65.26	70.02	65.42	70.08	63.10*	69.45*
3	65.24	68.79	65.35	68.85	64.52	69.73*
4	65.76	68.57	65.81	68.69	65.11	69.25*
5	65.74	68.14	65.03	67.83	65.41	67.62
6	65.48	68.62	65.45	68.94	62.26*	70.10*
7	65.36	68.04	65.57	68.10	60.68*	67.74
8	65.30	68.57	65.61	68.76	64.73	68.84
9	65.71	68.51	65.46	69.08	64.05	67.94
10	65.89	68.76	65.73	68.60	65.34	69.29
11	65.76	68.07	65.44	68.62	65.56	67.89
12	65.63	69.61	65.63	69.73	63.42*	68.84
13	65.79	68.30	65.63	68.52	65.67	68.55
14	65.58	68.97	65.57	69.18	64.54	68.78

## Conclusion

Restoring clinically-approved dose distribution on repeated CTs does not require new ROI segmentation and is compatible with an online adaptive workflow. With iDR, we are able to accurately reproduce the initial dose, despite density changes, maintaining stable the DVH-based parameters (see Figure.1). Hot spots and underdosage in the CTV can be corrected by implementing iDR in the clinical workflow.

## PO-0986 Inter-fraction anatomical changes in pediatric abdominal tumors during photon and proton therapy

F. Guerreiro<sup>1</sup>, E. Seravalli<sup>1</sup>, G.O. Janssens<sup>2</sup>, J.H. Maduro<sup>3</sup>, C.L. Brouwer<sup>3</sup>, E.W. Korevaar<sup>3</sup>, A.C. Knopf<sup>3</sup>, B.W. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands ; <sup>2</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands ; <sup>3</sup>UMC Groningen, Department of Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

During radiotherapy treatment (RT) of abdominal pediatric tumors, inter-fraction anatomical changes such as patient's diameter variations due to weight loss/gain and different gastrointestinal gas volumes might occur. The goal of this study was to investigate the dosimetric impact of daily anatomical changes based on cone-beam computed tomography (CBCT) information in robust optimized photon and proton RT dose distributions.

### Material and Methods

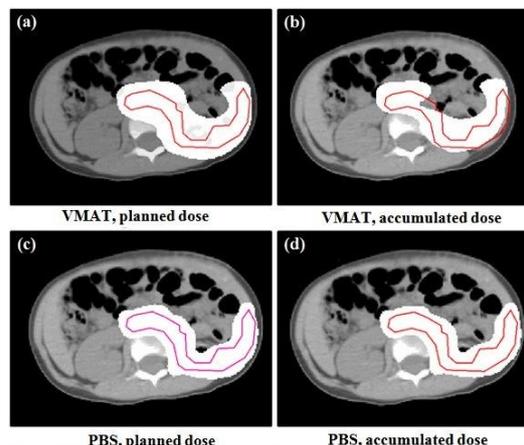

Volumetric modulated arc therapy (VMAT) and pencil beam scanning proton therapy (PBS) dose distributions were calculated using the original planning-CT scan for 20 pediatric patients (average 3, range 1-8 years) treated for neuroblastoma (n=11) and Wilms' tumor (n=9). VMAT plans were based on a 6 MV full-arc while PBS plans on 2-3 posterior-oblique fields with prescribed doses (PD) ranging between 14.4-36 Gy. Treatment plans were robust optimized on the patient-specific internal target volume (ITV) using a uniform 5 mm set-up uncertainty. Moreover, for the PBS plans a 3% proton range uncertainty was accounted for. The plan robustness was evaluated using multiple dose distributions associated with various error scenarios: set-up (with the magnitude of 5 mm in 26 directions per VMAT and PBS plans) and range errors ( $\pm 3\%$  density scaling, resulting in 52 scenarios per PBS plan). Plans were accepted if the V95% of the ITV > 98% in the voxel-wise minimum evaluation dose. Fractional dose re-calculations were performed using clinical CBCT images. For the estimation of Hounsfield units (HUs) from the daily CBCT data, the gas volumes on the planning-CT were filled with a water equivalent density and the planning-CT was deformably registered to each CBCT. Gas volumes were delineated on the CBCTs and copied rigidly to the deformed CTs (dCTs). Fractional doses were re-calculated on the dCTs and accumulated rigidly. To compare planned and accumulated doses, dose-volume histogram (DVH) parameters were calculated for the clinical ITV and organs at risk (OARs).

### Results

For both techniques, the ITV coverage was fulfilled for the original planned dose distributions. For the ITV, mean differences between planned and accumulated doses ranged between [-0.1% - 0.8%] and [-0.1% - 0.1%] for the VMAT and PBS plans (Table 1), respectively. On the accumulated doses, the ITV coverage was not reached (V95% < 99%) for 2 patients, for the VMAT plans (Figure 1). For the OARs, mean differences between planned and accumulated doses ranged between [-0.4% - 0.2%] and [-0.2% - 0.0%] for the VMAT and PBS plans (Table 1), respectively.

**Table 1.** Mean  $\pm$  standard deviation (SD) differences (%) between planned and accumulated doses for selected DVH parameters for VMAT and PBS dose distributions.

Structure	Parameter	Planned - Accumulated Dose (%)			
		VMAT		PBS	
		Mean $\pm$ SD	Range	Mean $\pm$ SD	Range
ITV	D <sub>95%</sub>	0.8 $\pm$ 1.7	[-1.9; 7.2]	0.1 $\pm$ 0.5	[-0.5; 1.9]
	D <sub>mean</sub>	0.2 $\pm$ 0.9	[-2.4; 2.2]	0.1 $\pm$ 0.1	[-0.1; 0.3]
	D <sub>2%</sub>	-0.1 $\pm$ 1.0	[-2.8; 2.3]	-0.1 $\pm$ 0.6	[-1.7; 0.5]
	V <sub>95%</sub>	0.4 $\pm$ 1.5	[0.0; 6.8]	0.1 $\pm$ 0.3	[0.0; 0.7]
Kidney R		-0.4 $\pm$ 2.3	[-5.4; 3.1]	-0.1 $\pm$ 0.4	[-1.0; 0.9]
Kidney L		-0.2 $\pm$ 1.7	[-5.2; 3.8]	0.0 $\pm$ 0.6	[-1.1; 1.6]
Liver	D <sub>mean</sub>	0.2 $\pm$ 0.7	[-0.9; 2.5]	-0.2 $\pm$ 0.7	[-2.3; 1.1]
Spleen		0.0 $\pm$ 1.7	[-5.6; 4.0]	0.0 $\pm$ 0.5	[-1.0; 1.5]

**Figure 1.** VMAT (a,b) and PBS (c,d) planned and accumulated dose distributions for one of the patients failing the ITV coverage (V<sub>95%</sub> < 99%) in the accumulated VMAT dose distribution (b). Dose distributions are overlaid on the planning-CT and the 95% isodose line is shown in white and the ITV in red.

### Conclusion

In this study, the need of performing re-planning during RT was evaluated for children treated for abdominal tumors. RT using PBS with posterior-oblique irradiation fields proved to be highly robust against anatomical inter-fraction changes. In photon therapy using a VMAT delivery, daily anatomical changes proved to affect the target coverage to a higher extent when compared to PBS.

### PO-0987 Rotational setup errors in breast cancer radiotherapy: the effect on treatment margins.

J. Seppala<sup>1</sup>, K. Vuolukka<sup>1</sup>, T. Viren<sup>1</sup>, J. Heikkilä<sup>1</sup>, J. Honkanen<sup>1</sup>, A. Pandey<sup>2</sup>, A. Al-Ghuri<sup>2</sup>, M. Shah<sup>2</sup>, S. Sefa<sup>2</sup>, T. Koivumäki<sup>3</sup>

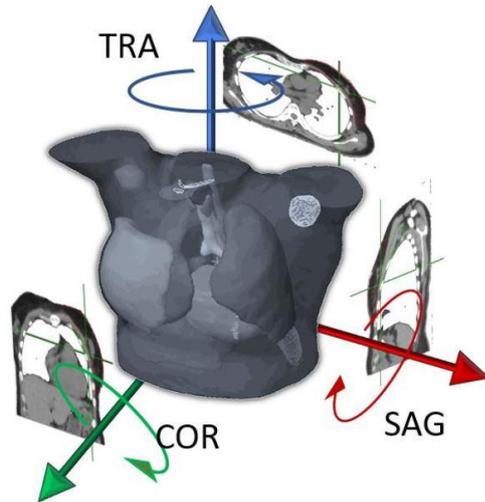

<sup>1</sup>Kuopio University Hospital, Center of Oncology, Kuopio, Finland ; <sup>2</sup>University of Eastern Finland, Department of Applied Physics, Kuopio, Finland ; <sup>3</sup>Central Finland Central Hospital, Department of Medical Physics, Jyväskylä, Finland

### Purpose or Objective

Rotational errors might have a significant effect on radiotherapy (RT) target coverage if not considered in PTV margins. In this work, we investigated the residual rotational errors in breast cancer RT.

### Material and Methods

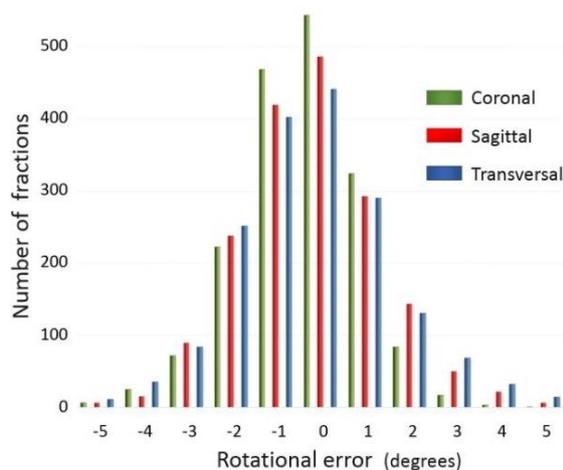

Daily low dose CBCT setup images of 93 breast cancer patients treated with RT were retrospectively investigated for rotational errors in patient setup. Patients were imaged with CT in supine position arms above the head on a breast board (C-Qual™ Breastboard, Civco, USA). 20 of the patients were imaged in deep inspiration breath hold (DIBH). With 50 patients, the treatment area included the whole breast and with 43 patients, the treatment area included also the axillary lymph nodes. A 3D image co-registration was conducted between 1731 CBCT images and the respective planning CT images (Mosaic system v2.62, Elekta AB) and image translation and rotations in coronal (COR), sagittal (SAG) and transversal (TRA) planes were recorded (Fig 1). Pearson correlation coefficient was used to determine the relation between the magnitude of rotational error and body mass index (BMI), age, side of a treatment, use of DIBH, chemotherapy, time between surgery and RT and the number of fractions (either 15 or 25).

**Fig 1.** The directions of the rotations investigated in this study.

#### Results

The mean absolute translational shifts from skin marker-based patient setup were  $4 \pm 3$  mm,  $3 \pm 3$  mm and  $4 \pm 4$  mm in anterior-posterior, left-right and cranio-caudal directions, respectively. The residual rotational errors were on average  $0.0 \pm 1.4^\circ$  for COR,  $0.2 \pm 1.6^\circ$  for SAG and  $0.2 \pm 1.9^\circ$  for TRA directions (Fig 2). The mean absolute rotations were  $1.0 \pm 0.9^\circ$  for COR,  $1.2 \pm 1.0^\circ$  for SAG and  $1.4 \pm 1.3^\circ$  for TRA directions, respectively. Overall, 35% of the residual rotational errors were larger than  $2^\circ$ . In 244 fractions (14%) the rotational error was over  $3^\circ$ . A three-degree rotational error would result in a translational shift of 4 mm at the edge of a typical breast cancer PTV (radius 8 cm), and for a PTV with axillary lymph nodes involved (radius up to 12 cm), the translational error would increase up to 6 mm. Modest but statistically significant correlations were found between patient age ( $r=0.27$ ,  $p=0.01$ , smaller errors with younger age) and the use of DIBH ( $r=0.23$ ,  $p=0.02$ , smaller errors with DIBH) and the rotational errors.

**Fig 2.** Histogram of the residual rotational errors in coronal, sagittal and transversal directions for all investigated setup images.

#### Conclusion

With online patient position correction methods, the translational setup deviations can be reduced to negligible values. However, the rotational residual setup errors should also be accounted when determine the PTV margins. Furthermore, the PTV margins taking into account the rotational errors should depend on the size

and shape of target volume. In whole breast RT with axillary lymph node involvement the clinical rotational setup errors can result in over 6 mm translational shifts at the edge of the PTV.

#### PO-0988 CBCT-based library of plans approach in gastric cancer radiotherapy: proof of concept

M. Bleecker<sup>1</sup>, K. Goudschaal<sup>1</sup>, A. Bel<sup>1</sup>, J. Sonke<sup>1,2</sup>, M.C.C.M. Hulshof<sup>1</sup>, A. Van der Horst<sup>1</sup>

<sup>1</sup>Amsterdam UMC- University of Amsterdam, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Current protocols for gastric radiotherapy (RT) use one treatment plan only. A library of plans for gastric cancer may ensure adequate irradiation by adapting the treatment to large day-to-day anatomical changes in size, shape and position. Here, we assess the feasibility of CBCT-guided gastric cancer adaptive RT (ART) with a library of plans based on the planning CT (pCT) and the daily CBCTs of the first week of RT.

#### Material and Methods

Three patients, who had received single-plan pre-operative RT within the CRITICS-II trial (NCT02931890; 45 Gy; 25 fractions; PTV margin = 10 mm) with daily CBCT-guidance, were included. For this retrospective study, all CBCTs were rigidly registered to the pCT based on bony anatomy and if needed corrected in longitudinal direction for diaphragm position (Velocity 4.0, Varian). One expert radiation oncologist manually delineated CTV (i.e. entire stomach and regional lymph nodes) according to trial protocol on pCT and the first 5 CBCTs (Fig 1A). For delineation on CBCT, the CTV\_pCT was copied and subsequently adjusted. From these 6 CTVs, we created 3 Plan Selection Volumes (PSVs) (Fig 1B): PSV\_large = union of all 6 CTVs + 3 mm, PSV\_medium = volume occupied by 4 of 6 CTVs (i.e. volume with at least 4 overlapping CTVs) + 3 mm, and PSV\_small = smallest delineated CTV + 3 mm; 3 mm was used to preserve a 7 mm PTV margin to account for remaining uncertainties. A specially trained RTT selected the most appropriate PSV for the remaining 20 fractions (i.e. fractions 6-25). The selected PSV must encompass the CTV as visible on the CBCT.

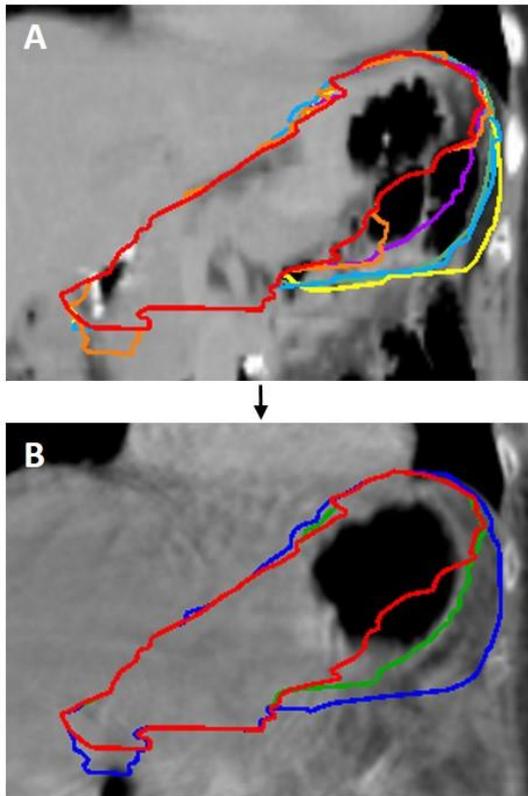

Fig 1: Example of ART approach in patient 3. A) Delineated CTV on pCT (red) and CBCTs; B) Generated PSVs for volume selection on CBCT.

## Results

For all patients, the CTV could be delineated on the first 5 CBCTs. However, often no adjustments with respect to CTV\_pCT were made in caudal, ventral and left-lateral direction because of poor visibility due to low image quality and changing volumes of gas in the stomach and colon (Fig 1A). All 15 CTV\_CBCTs were partially outside the pCT\_PTV, with on average 3.4% of the volume (range 0.0%-9.3%).

PSV selection showed no apparent pattern over time (Fig. 2A). Overall, PSV\_large was selected in 28 fractions (46.7%), PSV\_medium in 20 fractions (33.3%) and PSV\_small in 11 fractions (18.3%; Fig. 2B). For two patients, only PSV\_medium and PSV\_large were selected; for these patients, PSV\_small equaled CTV\_pCT. For only one fraction (1.7%), it was not possible to select a PSV.

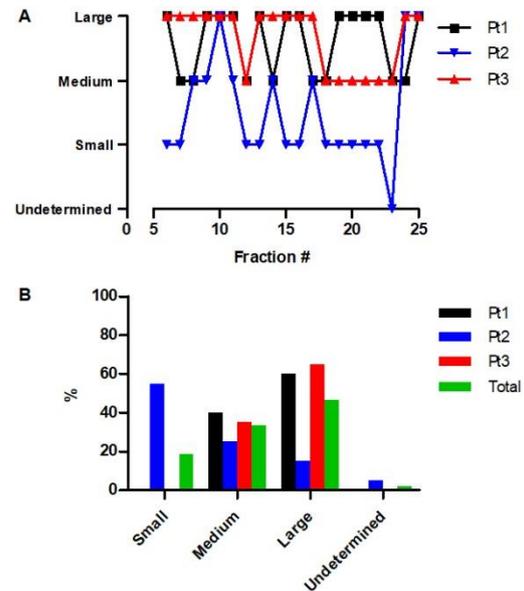

Fig 2: (A) Contour selection over time per patient. (B) Percentage of selected contours per patient and in total. For one fraction, no contour was selected.

## Conclusion

This study has demonstrated feasibility of CTV delineation and volume selection based on CBCT for certain anatomical regions of the stomach. The large variations in these regions showed the urgent need for improvement of the current clinical practice and these findings justify further research towards the development and implementation of gastric ART. However, for other regions of the stomach, CTV delineation and volume selection were unreliable due to poor visibility on CBCT. Consequently, the potential benefit of gastric fiducial markers will be explored in a follow-up study.

## PO-0989 Deep learning improves robustness of contour propagation for online adaptive IMPT of prostate cancer

M. Elmahdy<sup>1</sup>, T. Jagt<sup>2</sup>, R. Zinkstok<sup>3</sup>, C. Marijnen<sup>3</sup>, M. Hoogeman<sup>2</sup>, M. Staring<sup>1</sup>

<sup>1</sup>Leiden University Medical Center, Division of Image Processing- Department of Radiology, Leiden, The Netherlands ; <sup>2</sup>Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands ; <sup>3</sup>Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

## Purpose or Objective

Online-adaptive radiotherapy holds the promise to mitigate daily anatomical uncertainties thereby increasing treatment precision. One of the major challenges here is the development and validation of sufficiently fast, accurate, and robust segmentation algorithms for target volumes and organs at risk. The purpose of this study is to improve contour propagation in the pelvic region by combining deep-learning based auto-segmentation with image registration and to validate it geometrically and dosimetrically for online-adaptive Proton Therapy (PT) for prostate cancer.

## Material and Methods

The proposed registration pipeline registers the daily CT scan to the planning, based on a combination of image intensities and, moreover, by an automatic segmentation of the bladder from the daily CT scan using a novel 3D convolutional neural network. The bladder was chosen for its influence on prostate motion. Registration performance is further enhanced by a digital inpainting of gas pockets with realistic bowel content, using a state-of-the-art generative adversarial network. We further

perform data normalization and in relevant cases digitally remove contrast agent from the bladder. Evaluation was performed on CT data from 18 prostate cancer patients, each with 7 to 10 repeat CT scans. Manual delineations of the prostate, lymph nodes, seminal vesicles, bladder and rectum were available for evaluation. Geometric performance was quantified using the Mean Surface Distance (MSD). The pipeline was validated dosimetrically on 11 out of 18 patients by simulating an online-adaptive PT workflow based on the propagated contours. To this end, for each repeat CT, a treatment plan was generated based on the propagated contours and the plan was evaluated using the manual delineations. A dose of 74 Gy was assigned to the high-dose PTV (prostate) and 55 Gy to the low-dose PTV (lymph nodes and seminal vesicles). The generated treatment plans were considered clinically acceptable if dosimetric coverage constraints derived from the manual contours were met (PTV  $V_{95\%} \geq 98\%$  and  $V_{107\%} \leq 2\%$ ).

### Results

The proposed pipeline achieved a MSD of  $1.29 \pm 0.33$ ,  $1.44 \pm 0.68$ , and  $1.52 \pm 0.45$  mm for the prostate, seminal vesicles, and lymph nodes, respectively (Fig. 1). The propagated contours met the dose coverage constraints in 85%, 91%, and 99% of the cases for the prostate, seminal vesicles, and lymph nodes, respectively (Fig. 2). 78% of the cases met all constraints at the same time, compared to 65% when using a standard registration approach. The average runtime for the proposed pipeline is 98 seconds per registration.

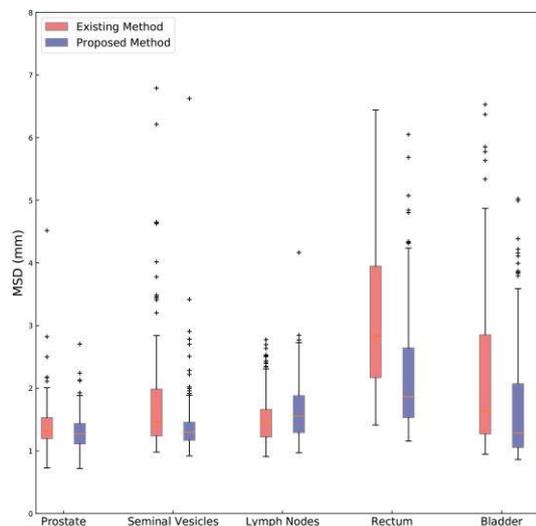

Figure 1. Boxplot comparison between an existing registrations method and the proposed method for image registration in terms of MSD for 161 registrations. Values closer to zero are better

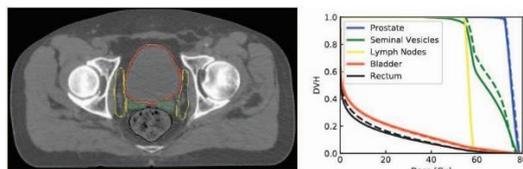

Figure 2. Example for the automatic contours propagation and the corresponding dose volume histograms. The solid line represents the manual contouring results while the dotted line is the automatically propagated one.

### Conclusion

The proposed registration pipeline obtained highly promising results for generating treatment plans adapted to the daily anatomy. With 78% of the automatically generated treatment plans directly usable without manual correction, a substantial improvement in system robustness was reached compared to an existing approach. The proposed method therefore facilitates more precise PT of prostate cancer.

### PO-0990 Positioning uncertainties for pediatric craniospinal irradiation and the impact of image guidance

D. Gasic<sup>1,2</sup>, A. Haraldsson<sup>3</sup>, N.P. Brodin<sup>4</sup>, K. Nysom<sup>5</sup>, T. Björk-Eriksson<sup>6,7</sup>, P. Munck af Rosenschöld<sup>3</sup>

<sup>1</sup>Rigshospitalet, Department of Oncology - Section of Radiotherapy, Nivå, Denmark ; <sup>2</sup>University of Copenhagen, Niels Bohr Institute, Copenhagen, Denmark ; <sup>3</sup>Skåne University Hospital, Department of Radiation Physics, Lund, Sweden ; <sup>4</sup>Albert Einstein College of Medicine, Institute for Onco-Physics, Bronx- NY, USA ; <sup>5</sup>Rigshospitalet - The Juliane Marie Center, Department of Pediatrics and Adolescent Medicine, Copenhagen, Denmark ; <sup>6</sup>Regional Cancer Centre, West, Gothenburg, Sweden ; <sup>7</sup>University of Gothenburg, Department of Oncology - Institute of Clinical Sciences - Sahlgrenska Academy, Gothenburg, Sweden

### Purpose or Objective

To investigate the setup errors for pediatric craniospinal irradiation (CSI) by following image guided correction protocols and explore how daily image-guided radiotherapy (IGRT) has impacted the positioning uncertainty. In particular, we wish to determine the use of six degree of freedom (DoF) couch corrections. Positioning uncertainty data may be used to estimate the uncertainty budget available for planning target volumes and organ-at-risk (OAR) margins, which is essential for the safe clinical implementation of hippocampal-sparing CSI for pediatric medulloblastoma. Patient alignment and setup errors become paramount when attempting to spare a critical organ such as the hippocampus during CSI.

### Material and Methods

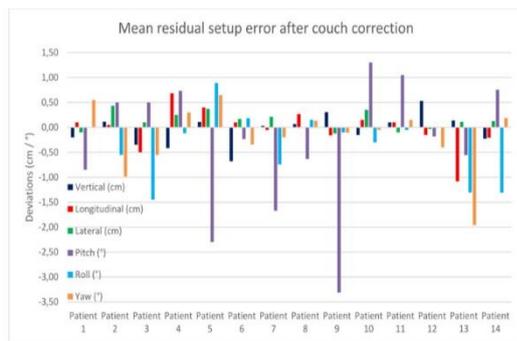

In this multicenter study, a total of 14 pediatric patients treated with CSI were identified for whom treatment records and setup images were available. The setup images were registered offline to the reference image (digitally reconstructed from their pre-treatment computed tomography scan) using the automated tool and matching on bony anatomy. A 3 and 6 DoF match was performed, respectively, using both translational (superior-inferior (SI), anteroposterior (AP) and medial-lateral (ML)) and rotational (yaw = rotation around the AP axis, pitch = rotation around the ML axis and roll = rotation around the SI axis) information, ignoring the rotational deviation since only the 3 DoF couch shift was used for positioning these patients during treatment.

### Results

The residual errors should only include rotational deviation since only translational movement on the couch is used. However, rotational errors can affect the translational deviation as well (Table 1). When correcting the shifts according to a simulated IGRT-protocol, where the average of the first two fractions are used to correct the coming fractions, the results show large inter-fractional deviations especially for rotational deviations (Figure 1). Translational and rotational random uncertainty (RU) and systematic uncertainty (SU) were derived as well. If using an IGRT-protocol, such as the above mentioned, the translational residual setup error can be as high as 2.2 cm for an individual patient during a single fraction, and the rotational error as high as  $5.4^\circ$ . If using daily IGRT the maximum setup error was reduced to 0.8 cm translational and  $5.4^\circ$  rotational as well as 0.8 cm translational and  $2.4^\circ$  rotational setup error for 3 and 6 DoF couch shifts, respectively. The RU and SU of ML and roll worsens when only correcting for the first two fractions which further strengthens the indications for daily IGRT.

**Table 1:** Mean translational (superior-inferior (SI), anteroposterior (AP) and medial-lateral (ML)) and rotational positioning errors with corresponding range and uncertainties assuming setup based entirely on skin marks for both 3 and 6 degrees of freedom (DoF) and all isocenters (Units: cm and °/degrees).

**Figure 1:** The mean residual setup error in 6 degrees of freedom for each patient after couch correction. Vertical describes the anteroposterior, longitudinal the superior-inferior and lateral the medial-lateral.

## Conclusion

Daily IGRT is the superior choice for pediatric CSI patients. However, following an IGRT-protocol is no insurance for a satisfactory alignment when only a 3 DoF couch is applied. There are still quite large residual errors some of which are the result of multiple isocenters and narrow field junctions even if a 6 DoF couch shift would be applied.

**PO-0991** A decision-support tool to select patients who may benefit from online adaptation in pancreatic SBRT  
 A. Magallón Baro<sup>1</sup>, P.V. Granton<sup>1</sup>, M.T.W. Milder<sup>1</sup>, M. Loi<sup>1</sup>, A.G. Zolnay<sup>1</sup>, J.J. Nuytens<sup>1</sup>, M.S. Hoogeman<sup>1</sup>  
<sup>1</sup>Erasmus MC Cancer Institute, Radiotherapy, Rotterdam, The Netherlands

## Purpose or Objective

At our institution, patients with Locally Advanced Pancreatic cancer (LAPC) responding to chemotherapy undergo SBRT on the Cyberknife using respiratory tracking via fiducial markers. SBRT plans exhibit conformal dose distributions with high dose gradients, sculpted to the anatomy of the planning CT scan (pCT) to protect the surrounding organs-at-risk (OAR). These OARs (stomach, duodenum and bowel) are also prone to receive additional dose due to daily anatomical variations that can result in dose-constraints violations. In our previous work, we developed a population-based motion model, which using principal component analysis, extracted common geometric variation patterns from a cohort of LAPC patients. Based on this model, we developed a tool to identify which LAPC patients may be at risk of exceeding the clinical dose-constraint of V35Gy<1ml due to daily anatomical changes, and hence, that may benefit from online adaptive strategies.

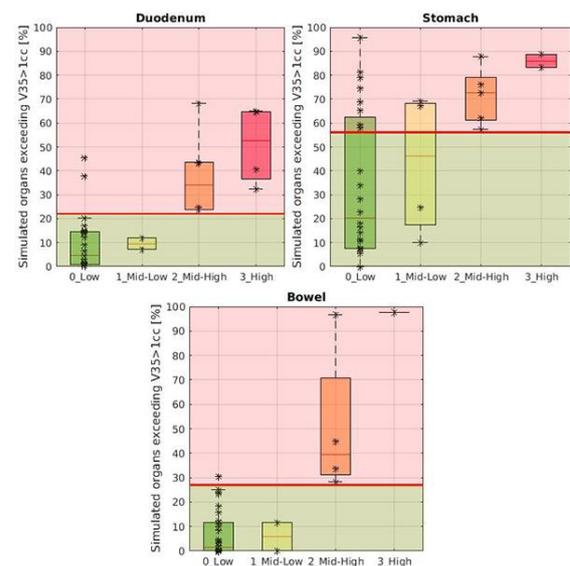

## Material and Methods

A total of 130 scans were collected for 35 LAPC patients, including the pCT scan and ideally 3 pre-fraction in-room CT scans (FxCT). The tool was validated by following a leave-one-out approach: each patient was tested on a model trained with the variations observed in the

remaining 34 subjects. For each case, the OAR pCT contours were registered non-rigidly to the model, which was used to sample N (~5000) random OAR deformations. The pCT dose volume was sampled inside each simulated organ yielding DVHs for each OAR. Next, we collected which percentage of simulated OAR had been detected to exceed the clinical dose-constraints on each patient. To validate the tool performance against real observed variations, simulated violation percentages were clustered in four risk groups (low risk-0/3Fx; mid-low risk-1/3Fx; mid-high risk-2/3Fx; high risk-3/3Fx) according to how many fractions exceeded the V35 when original plans were rigidly transferred to the FxCT. A threshold on each OAR was established by optimizing the discrimination of patients with higher risks.

## Results

Simulated violation percentages clustered per risk group are shown on Fig. 1. Pearson correlation coefficients of 0.5-0.8 were found between simulated risk and observed dosimetric changes, depending on the OAR. If all observed mid-high and high risk patient groups are combined into a high risk category, thresholds at 22, 57, 28% would maximally identify patients likely to violate OAR dose-constraints due to moving tissues for the simulated duodenums, stomachs and bowels; with a classification accuracy of 94, 71, 97%, respectively.

**Figure 1.** Percentage of simulated OARs exceeding the clinical dose-constraints (duodenum-upper left, stomach-upper right, bowel-bottom) clustered per risk group according to how many fractions resulted to exceed the dose-constraint in the clinic: 0/3 FxCT (low risk group), 1/3 FxCT (mid-low risk group), 2/3 FxCT (mid-high risk group), or 3/3 FxCT (high risk group). The thresholds established by the red horizontal line discriminate the patients (depicted in \*) who would be identified as mid-high or high risk (in the red region), and hence, that would be eligible for plan adaptation; against patients classified in the low or mid-low risk groups (in the green region), which would be discarded from applying this strategy.

## Conclusion

The positive relationship between the simulated probability of exceeding OAR dose tolerances and clinically observed dose-constraint violations is a promising tool to identify a high-risk patient suffering from the impact of daily variations. Established thresholds suggest patients can be stratified by making optimal use of available resources, and can prevent giving extra dose to low-risk patients not benefiting from plan adaptation.

**PO-0992** Investigating 4D Cone Beam CT reconstruction for moving targets at a scanned proton gantry system

L. Den Otter<sup>1</sup>, K. Chen<sup>2</sup>, G. Janssens<sup>3</sup>, A. Meijers<sup>1</sup>, S. Both<sup>1</sup>, J.A. Langendijk<sup>1</sup>, L.R. Rosen<sup>2</sup>, H.T. Wu<sup>2</sup>, A. Knopf<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiotherapy Oncology, Groningen, The Netherlands ;

<sup>2</sup>Willis-Knighton Cancer Center, Radiation Oncology, Shreveport, USA ; <sup>3</sup>Ion Beam Applications, Research and Development, Louvain-la-Neuve, Belgium

### Purpose or Objective

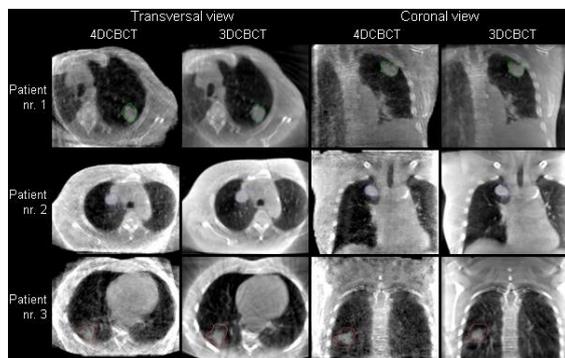

Scanned proton therapy is a highly conformal treatment technique and can provide increased healthy tissue sparing compared to photons or scattered protons. However, due to the time structure of the scanned beams this technique is highly sensitive to uncertainties and needs to be monitored when treating mobile tumors. Currently, only 3D Cone Beam CT (CBCT) acquisition is available on commercially available proton gantry systems. We investigate the possibility to use the same number of projections as for 3DCBCT acquisition to retrospectively reconstruct into 4D, with the goal to determine the inter-fraction tumor motion.

### Material and Methods

CBCT-projection data was acquired for eight patients at an IBA Proteus® ONE proton gantry system. Ten 4DCBCT images were reconstructed per patient. In order to compensate for the lower 4DCBCT quality due to the small amount of projections per phase, we applied a motion-aware temporal and spatial regularization method (MA-ROOSTER), by Mory *et al*<sup>1</sup>, to reconstruct with improved 4D-image quality. Corresponding 3DCBCT images were reconstructed using the conventional Feldkamp-Davis-Kress (FDK) algorithm. After importing the 4D-images into RayStation, the gross tumor volumes were deformably warped (ANACONDA algorithm) and centroid positions determined to calculate the 3D-vector motion[OLd(1)]. The contrast-to-noise ratio between tumor and lung tissue for the 4DCBCT images was calculated. Additionally, the structural similarity index (SSIM) between the 3DCBCT and 4DCBCT images were calculated to compare the quality of 3DCBCT vs. 4DCBCT images.

### Results

Figure 1 shows one phase of the reconstructed 4DCBCT images for three patients compared to 3DCBCTs. For the 4DCBCT images more noise is observed, and increased blurriness of anatomical features with more clearly present streak artefacts for some of the patients. Nevertheless, the tumor is visible and can be delineated to evaluate its motion. Table 1 shows the calculated 3D-vector centroid motion, the CNR, and SSIM for the 4DCBCT images. In all 8 patients motion variations could be tracked within all available ten scans. The CNR showed varying results for the different patients, confirming the observed variations in image quality when visually evaluating the reconstructed 4DCBCTs. The quality of the 4D-images according to the SSIM was around 30% of the 3DCBCT images (SSIM ~0.30).

**Figure 1.** Transversal and coronal views of the reconstructed images in 3D and 4D (one phase) and the visual differences in image quality. The colored region in each image represents the tumor.

**Table 1.** Measured centroid motion of reconstructed 4DCBCT images and quality measure results of the contrast between tumor and lung tissue and differences in quality between 3DCBCT images and 4DCBCT images.

	Centroid motion (mm)	CNR (↑ better ratio)	SSIM (0-1)
		Median (range)	
Patient nr. 1	2.30 (1.19 - 3.89)	2.42 (1.68 - 3.02)	0.30 (0.25 - 0.34)
Patient nr. 2	2.42 (1.93 - 2.91)	2.20 (2.00 - 2.49)	0.34 (0.30 - 0.43)
Patient nr. 3	3.52 (2.27 - 4.60)	1.30 (0.76 - 2.45)	0.30 (0.21 - 0.32)
Patient nr. 4	1.43 (0.75 - 2.66)	2.47 (0.51 - 3.28)	0.24 (0.22 - 0.30)
Patient nr. 5	2.66 (1.90 - 3.54)	1.93 (1.74 - 2.17)	0.29 (0.17 - 0.31)
Patient nr. 6	1.49 (0.91 - 4.43)	2.96 (2.32 - 4.40)	0.30 (0.21 - 0.32)
Patient nr. 7	0.44 (0.14 - 2.00)	4.14 (1.62 - 5.11)	0.38 (0.21 - 0.40)
Patient nr. 8	0.69 (0.60 - 1.28)	3.54 (2.92 - 5.19)	0.30 (0.24 - 0.32)

Abbreviations: CNR = contrast-to-noise ratio

SSIM = structural similarity index ('1' represents identical images).

### Conclusion

It is possible to reconstruct 4DCBCT images with sufficient quality for tumor motion evaluation using the MA-ROOSTER algorithm. This is an important step towards an image guided adaptive proton therapy workflow for treating moving targets, however further work is warranted to improve 4DCBCT image quality.

### PO-0993 Uncertainty estimation of dose accumulation with deformable image registration in head and neck region

T. Kanehira<sup>1</sup>, S. Kranen<sup>1</sup>, J. Sonke<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

The delivered dose distribution typically deviates from planned dose due to anatomical changes. Dose accumulation estimates the delivered dose over fractions using deformable image registration (DIR) to take anatomical changes into account. Registration errors, however, introduce an uncertainty in the dose mapping. This study estimates the uncertainty in the accumulated dose and compares it with differences between planned and accumulated dose for head & neck cancer (HNC) patients.

### Material and Methods

In this study, five HNC patients were included with a prescribed dose of 70 Gy in 35 fractions. Patients were positioned with daily CBCT guidance and received a repeat CT (rCT) mid-treatment for adaptive re-planning. CBCT-to-CT DIR was performed using an in-house implementation of bSpline deformations. To estimate the spatial uncertainty of the DIR, a modified version of the distance concordance metric (DDM) was implemented [1]. To that end, the deformable vector fields (DVF) deforming the plan CT (pCT) to the daily CBCT and the daily CBCT to the rCT were concatenated. Subsequently, the DDM for each voxel of the pCT was calculated as the standard deviation (SD) in all three directions over the typically 34 DVFs (we did not use the daily CBCT which was acquired on the same day as rCT) divided by the square root of 2. DDM was restricted to voxels within the patient external. To estimate accumulated dose, assuming the DIR uncertainty followed Gaussian distribution which had a SD of the DDM, we calculated the average dose over 35 samples from a 3D Gaussian distribution around each voxel. This was repeated 1000 times to calculate a confident interval of the accumulated dose. The dose uncertainty was calculated as a 95% confident interval (dose-CI) and any difference exceeding this dose-CI was considered as a true anatomical induced dose difference. For each patient, we calculated the accumulated dose, difference with planned dose ( $\Delta D$ , accumulated-planned), dose-CI, and the percentage of voxels with  $\Delta D$  exceeding the dose-CI.

### Results

DDM was larger in soft tissues and close to the field-of-view borders (Figure 1): median of 0.07 cm and 95<sup>th</sup> percentile of 0.37 cm within the external contour. These

registration uncertainties led to a median and 95<sup>th</sup> percentile dose-Cl of 0.0 Gy and 0.8 Gy, which were smaller than those of the difference between planned and accumulated dose: 1.1 Gy and 6.9 Gy respectively. The percentage of the voxels where the  $\Delta D$  was outside of the dose-Cl was 97.7 % (Figure 2).

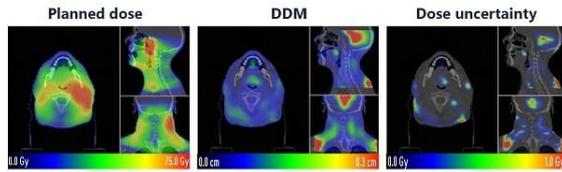

Figure 1. planned dose, DDM, and dose uncertainty for one of the patients. The left image shows the planned dose. The middle is the distribution of the norm of DDM. The right is the distribution of the width of the 95% confident interval of the dose uncertainty.

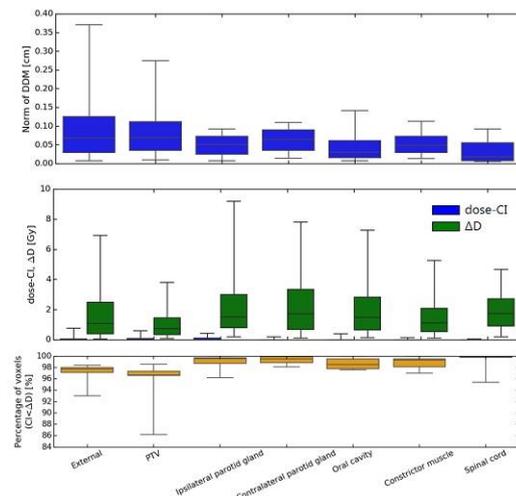

Figure 2. Boxplots of the norm of DDM and 95% confident interval of the dose uncertainty (dose-Cl), and differences between planned and accumulated dose ( $\Delta D$ ) and the percentage of the voxels with the  $\Delta D$  exceeding the dose-Cl for five patients. The box of the boxplots shows the interquartile, and the whisker shows 5/95 percentile for the top and middle boxplots and the minimum/maximum for the bottom.

## Conclusion

Small dose uncertainties were found. In the majority of voxels the uncertainties were smaller than the difference between planned and accumulated dose. This implies that DIR is sufficiently accurate to observe relevant changes in accumulated dose during treatments.

## PO-0994 Registration accuracy of 4D-MRI in lung acquired on the MR-linac

M. Rossi<sup>1</sup>, M. Fast<sup>1</sup>, T. Van de Lndt<sup>1</sup>, M. Nowee<sup>1</sup>, J. Belderbos<sup>1</sup>, F. Lalezari<sup>2</sup>, J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiotherapy Department, Amsterdam, The Netherlands ;

<sup>2</sup>Netherlands Cancer Institute, Radiology Department, Amsterdam, The Netherlands

## Purpose or Objective

Differential motion between the primary tumor and mediastinal lymph nodes requires considerable safety margins in locally advanced lung cancer patients. The Unity MR-linac (Elekta AB, Stockholm, Sweden) provides high soft-tissue contrast and thus the potential to adapt the treatment plan to account for such differential motion. We recently have developed a self-sorting 4D-MRI method for daily IGRT of liver patients. The aim of this study was to determine the registration accuracy in 4D-MRI scans of NSCLC lung patients acquired on the MR-Linac.

## Material and Methods

Six stage III NSCLC patients, receiving weekly 4D-MRI scans on the MR-linac were included in this study. Patients were treated on a conventional linac to a dose of 24x2.75 Gy.

To quantify local rigid registration accuracy, the first, third and last scans per patient were processed in a full circle method<sup>1</sup>. The 4D reconstructions of these scans were made with an in-house developed coronal 4D-MRI sequence. This is based on retrospective image sorting of 30 repetitions of a multi-slice turbo-spin echo acquisition with an image resolution of 2x2x5 mm<sup>3</sup>. The full circle either consisted of the mid-position planning CT(pCT) and two 4D-MRI scans or alternatively, the pCT was replaced by the mid-ventilation of the first 4D-MRI scan. A shaped region of interest of the primary tumour and of each individual lymph node was used for local rigid registration in both procedures. From the values obtained from the full circle method in each patient, the mean and SD were divided by  $\sqrt{3}$  to correct for the 3 registration steps in the circle. Patient characteristics were analyzed.

## Results

4D-MRI acquisition took about 4 minutes and showed adequate image quality (fig. 1) for 5 out of 6 patients. For the remaining 5 patients, all tumours were in the upper lobes and the average peak to peak amplitude of the primary tumour derived from the 4D-CT was 0.2, 0.4 and 0.2 cm in left/right, cranial/caudal and anterior/posterior respectively. The median GTV of the primary tumour was 88.3 cc and median GTV lymph nodes 49.9 cc. The corrected absolute mean of circle residuals was <0.11 cm for both primary tumor and lymph nodes in both methods. The corrected standard deviations are shown in table 1<sup>(1,2)</sup>.

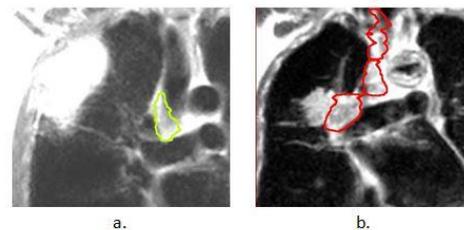

Fig. 1 a and b. a) 4D-MRI of lung showing primary tumour and lymph node 4R (in green) and b) 4D-MRI of lung showing lymph nodes 2R, 4R and 10R (in red)

Table 1. Registration inaccuracy in 4DMRI registration of MRI to pCT and MRI to MRI for primary tumour and lymph nodes calculated using the full circle method<sup>1,2</sup>

	Left/Right (cm)	Cranial/Caudal (cm)	Anterior/Posterior (cm)
Registration inaccuracy MRI to pCT			
Primary tumour	0.19	0.12	0.12
Lymph nodes	0.08	0.14	0.17
Registration inaccuracy MRI to MRI			
Primary tumour	0.08	0.15	0.10
Lymph nodes	0.12	0.17	0.10

## Conclusion

4D-MRI registration of primary tumor and lymph nodes seems feasible on the MR-Linac with local rigid registration inaccuracies <0.2 cm facilitating daily online IGRT for locally advanced lung cancer patients. Registration accuracy potentially increases following further optimization of 4D-MRI contrast and image resolution tailored to lung cancer patients.

<sup>1</sup>van Herk M et al. Med Phys 25:2054-2067, 1998

<sup>2</sup>Schaake et al. IJROBP 2014 Nov 15 90(4) 959-66

## PO-0995 An extension of van Herk's margin recipe to explicitly account for time trends in tumor set-up.

M. Giżyńska<sup>1,2</sup>, B. Heijmen<sup>3</sup>, P. Kukołowicz<sup>1</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics Department, Warsaw, Poland ; <sup>2</sup>University of Warsaw Faculty of Physics, Department of Biomedical Physics, Warsaw, Poland ; <sup>3</sup>Erasmus MC University Medical Center Rotterdam, Department of Oncology, Rotterdam, The Netherlands

## Purpose or Objective

The most applied CTV-PTV margin recipe is that proposed by van Herk et al.:  $M=2.5\sigma + 0.7\sigma$ , where  $\Sigma$  and  $\sigma$  describe

systematic and random setup errors [1]. This recipe does not explicitly account for interfraction time trends in tumor set-up, while such trends are observed for various tumor sites. In this work we propose 1) a novel characterization of set-up errors in a patient population with time trends, and 2) a margin recipe explicitly accounting for trends. The proposed formalism was evaluated for a large database of prostate cancer patients with time trends.

### Material and Methods

The database contains daily set-up errors of 839 prostate cancer patients, measured in their 39 treatment fractions using implanted gold fiducials.

Errors in a patient population with time trends are described by normal distributions characterized by  $\Sigma$ ,  $\alpha$  and  $\sigma'$ , with  $\alpha$  the standard deviation of observed time trend slopes (mm/fraction) in the population and  $\sigma'$  describing the true random errors, i.e. errors relative to the patient's trend line. Figure 1 shows the set-up errors for a single database patient with a time trend. For the analyzed database, population parameters were:  $\Sigma = [2.5, 3.4, 3.5]$  mm,  $\alpha = [-0.05, 0.07, 0.08]$  mm/fraction, and  $\sigma' = [1.9, 2.5, 2.6]$  mm for left-right, superior-inferior and anterior-posterior direction respectively.

Like in [1], the margin component for the random errors is given by  $0.7\sigma'$ . Similar to [1], we require for the margin component for the remaining errors (systematic and time trend errors) that 90% of the patients should be within the margin. The maximum set-up deviation during fractionated treatment,  $MD$ , of a patient with systematic set-up error,  $m$ , and time trend slope  $a$  is given by  $MD = |m| + 0.5(F-1)|a|$ , with  $F$  the total number of fractions (Fig. 1). To establish the required margin, the  $MD$  distribution is first determined by random sampling from the  $m$  and  $a$  distributions ( $10^7$  samples). The margin is then determined as the 90% cut-off point in the distribution. For validation of the novel margin recipe and for comparison with van Herk's recipe we established for both recipes the percentage of patients outside the margin. That was done with the ellipsoid test where we looked for patients not fulfilling  $\sum_i (MD_i/M_i)^2$  (with  $i$  denoting direction and  $M$  - margin size).

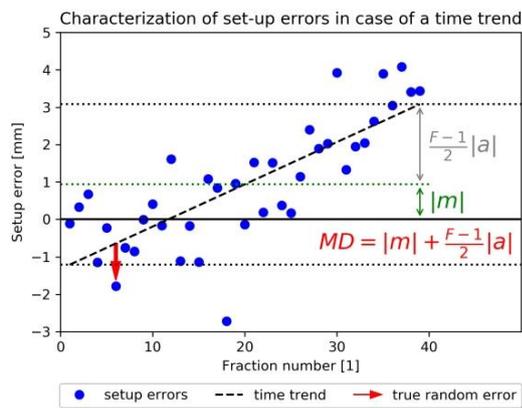

Figure 1. Maximum Deviation  $MD$  is derived from the middle position  $m$  and time trend slope  $a$  with the total number of fractions  $F$ .

### Results

For the prostate database, margins calculated with van Herk's recipe were 1-2mm smaller than those established with the novel recipe (Table 1). The percentage of patients outside the novel margin was 9.8% (compared to 10% expected), while for van Herk's margin this was almost 26%.

	Van Herk Approach	Time Trend Approach
Left-Right margin [mm]	6.3 (7.6)	7.6 (8.9)
Superior-Inferior margin [mm]	8.5 (10.2)	10.9 (12.7)
Anterior-Posterior margin [mm]	8.8 (10.6)	11.0 (12.9)
Percentage of patients outside	25.9%	9.8%

Table 1. Comparison of margins for three directions for the clinical database. Margins in brackets include the random error component given as  $0.7\sigma'$ . Percentage of patients outside the margin is calculated for the systematic margin component.

### Conclusion

Van Herk's CTV-PTV margin is not sufficient in case of time trends. We have proposed an extended recipe to fulfill the requirement that 90% of patients would indeed be irradiated with the prescribed dose when time trends are present. In case of no time trends, the modified recipe simplifies to van Herk's formula.

### PO-0996 A knowledge-based tool to estimate the gain of re-planning strategy for Head and Neck (HN) ART

E. Cagni<sup>1</sup>, A. Botti<sup>1</sup>, M. Orlandi<sup>1</sup>, R. Sghedoni<sup>1</sup>, E. Spezi<sup>2</sup>, M. Iori<sup>1</sup>

<sup>1</sup>Azienda USL-IRCCS di Reggio Emilia, Medical Physics Unit, Reggio Emilia, Italy; <sup>2</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

### Purpose or Objective

This study aimed to investigate if a commercial knowledge-based tool for radiotherapy planning, RapidPlan (RP) (Varian Medical System, Palo Alto, CA), can be used to estimate the potential organ at risks (OARs) sparing in re-planning strategy for HN ART.

### Material and Methods

A database of 45 HN VMAT plans, were used as training set for RP model. A second evaluation set, of 10 advanced oropharyngeal HN patients were randomly selected from the department database. All VMAT plans in the evaluation set were generated by means of RP module to treat 3 targets at dose levels of 69.96Gy/59.4Gy/54.12 Gy in 33 fractions using a SIB technique.

For each evaluation patient 2 CBCTs were extracted corresponded to 16th and the 26th fraction. In Velocity AI v.3.2 (Varian Medical System), the planning CT was registered with each CBCT using deformable registration algorithm, generating an Adaptive CT (ART-CT). For each ART-CT, the plan was re-calculated in Eclipse (delivered DVH) and RP predictions (RP DVH) were performed.

The gain of the re-planning was evaluated by comparing RP DVH with the delivered DVH for left and right parotid glands (PG), spinal cord and oral cavity. As a surrogate for the RP DVH we considered the line running in the middle of the predicted range. The restricted sum of the residuals (RSR) [Appenzoller et al. Med Phys. 2012] is used to measure the discrepancy between DVHs. To evaluate the feasibility of the method, the range of RP DVH estimations (RP uncertainties) were compared with the gain of the re-planning. The absolute sum of residual (ASR), considering both positive and negative difference in the sum, was used for this analysis. Wilcoxon signed rank were used as statistical test.

### Results

The RP model showed an average chi square of  $1.06 \pm 0.04$  and coefficient of determination of  $0.51 \pm 0.11$ . Numerical values of RSR, that quantified the gain of re-planning, were reported in Table 1. The overall RSR (mean $\pm$ 1std), for all patient and both fractions, resulted  $2.8 \pm 2.9$  Gy,  $2.6 \pm 2.7$  Gy,  $2.7 \pm 2.8$  Gy for spinal cord, left and right PG and oral cavity respectively. For 95% of the cases,

RP predicted a gain in the re-planning (RSR>0). No statistically difference resulted in RSR values between the 2 fractions (p=0.82).

	fraction #16 RSR (Gy)									
	patient number									
spinal cord	1.1	2.5	0.0	7.1	8.7	3.6	2.5	1.4	4.4	3.9
left PG	2.0	4.4	0.5	1.6	4.4	0.6	0.1	0.0	0.0	0.4
right PG	4.6	5.5	0.0	1.2	2.7	0.4	0.1	0.9	0.0	6.7
oral cavity	0.3	7.5	0.0	0.0	3.5	0.1	0.1	0.0	0.0	5.5

	fraction #26 RSR (Gy)									
	patient number									
spinal cord	0.9	1.1	0.0	7.2	8.1	3.1	2.2	1.3	0.0	3.6
left PG	4.0	2.6	0.5	3.2	1.7	0.7	2.0	0.0	0.7	4.6
right PG	5.8	1.1	0.1	1.7	1.0	0.9	1.8	0.6	0.0	7.8
oral cavity	1.3	5.7	0.0	0.4	3.3	0.1	0.2	0.0	0.0	5.3

Table 1 RSR values between delivered DVH and RP DVH that represent the gain of re-planning for spinal cord, left and right PG and oral cavity.

RP prediction uncertainties (RP bound ASR) resulted higher than the gain of re-planning (delivered- RP ASR), as is showed in Figure 1 by means of a correlation graph.. Statistical test confirmed this result (p<0.01)

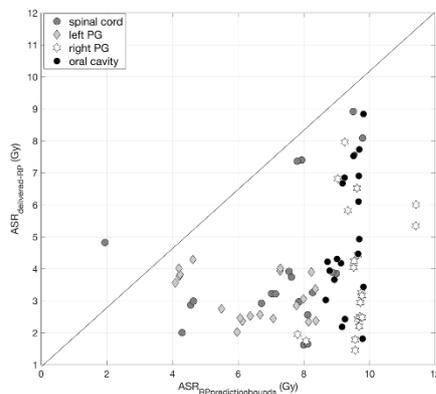

Figure 1 correlation graph, in term of ASR (Gy), between RP prediction uncertainties and the gain of re-planning (delivered - RP differences).

## Conclusion

In this study we have investigate the feasibility to use RP to estimate the potential gain of re-planning strategy for HN ART. Based on the analysis, DVHs predicted by RP can be used to estimate the potential OARs sparing when a new plan is performed. This information could be useful to assess the trigger point for a re-planning strategy. However, we found clinically relevant inaccuracies in RP predictions that limitate its application to HN ART. Therefore, further work is ongoing on RP model accuracy improvement.

## PO-0997 A Synthetic Generative Adversarial Network for Semantic Lung Tumor Segmentation

V. Kearney<sup>1</sup>, J.W. Chan<sup>1</sup>, S. Haaf<sup>1</sup>, S.S. Yom<sup>1</sup>, T. Solberg<sup>1</sup>  
<sup>1</sup>University of California UCSF, department of radiation oncology, San Francisco CA, USA

### Purpose or Objective

To demonstrate the feasibility of a novel generative adversarial network (GAN) for synthetic abnormal pulmonary CT generation and semantic lung tumor segmentation.

### Material and Methods

A 3D translational conditional GAN was implemented for synthetic image generation (label-to-CT) and segmentation (CT-to-label). Prior to synthetic image generation, a CT-to-label generator is given a CT image and trained to produce a binary mask of the left lung, right lung, heart, esophagus, spinal cord, and internal airways; a discriminator is trained to distinguish between “real” labels and synthetically generated “fake” labels. Once the network is conditioned, the label-to-CT synthetic image generator is trained by reversing the CT-to-label network and training the discriminator to perform the inverse task. The label-to-CT GAN is trained to generate arbitrary

abnormal pulmonary CTs with various tumor characteristics, which are used for synthetic data augmentation. A final CT-to-label GAN is trained to generate binary tumor masks from a 4 to 1 mixture of synthetic and real pulmonary CTs for 200 epochs, and fine-tuned for 20 epochs on real pulmonary CTs. Figure 1 shows the generator and discriminator components for all three GAN models. 208 stage I or stage II lung tumor patients previously treated with radiotherapy were used in this study. Patients with segmented hilar nodes were not included in this study. All algorithms were trained and hyperparameter tuned using 80% of the patients, and the remaining 20% were used to report final performance metrics. All models were distributed across two Nvidia V100 GPUs, and due to memory limitations, all images were resampled to 3x3x3 mm<sup>3</sup> and cropped to 128x128x64 voxels. To evaluate segmentation performance, all images were rescaled to their original dimensionality.

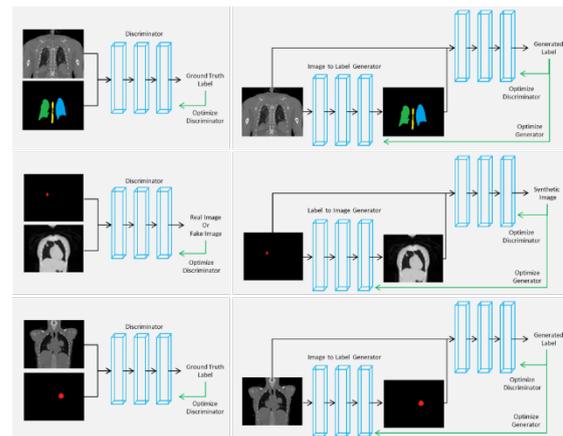

Figure 1. The preliminary GAN training workflow is shown for CT-to-label training of organs at risk (top). The label-to-CT workflow is shown which takes a binary tumor mask and generates arbitrary abnormal synthetic pulmonary CT variations (middle). The final CT-to-label GAN model is shown that generates realistic tumor masks given a CT image (bottom).

## Results

The synthetic GAN model (synthetic-GAN) was compared to a GAN model (real-GAN) and V-Net model (real-VNet) using only traditional data augmentation (rotation, random cropping, elastic deformation, and translation). Among the 20 patients analyzed, the average dice scores and standard deviations were  $0.82 \pm 0.15$ ,  $0.71 \pm 0.18$ , and  $0.69 \pm 0.16$  for synthetic-GAN, real-GAN, and real-VNet respectively.

## Conclusion

A synthetic conditional generative adversarial network was implemented that outperforms current state-of-the-art segmentation techniques for lung tumor segmentation. Furthermore, synthetically generated abnormal pulmonary images do not contain patient sensitive information and could be widely distributed to enhance cross institutional generalization.

## PO-0998 Setup and range robustness recipes for skull-base meningioma IMPT using Polynomial Chaos Expansion

C. Ter Haar<sup>1,2</sup>, S. Habraken<sup>2,3</sup>, D. Lathouwers<sup>1</sup>, R. Wiggenraad<sup>3,4</sup>, S. Krol<sup>3,5</sup>, Z. Perkó<sup>1</sup>, M. Hoogeman<sup>2,3</sup>  
<sup>1</sup>Delft University of Technology, Radiation Science & Technology, Delft, The Netherlands ; <sup>2</sup>Erasmus Medical Center Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands ; <sup>3</sup>Holland Proton Therapy Center, Radiation Oncology, Delft, The Netherlands ; <sup>4</sup>Haaglanden Medical Center, Radiation Oncology, Leidschendam, The Netherlands ; <sup>5</sup>Leiden University

Medical Center, Radiation Oncology, Leiden, The Netherlands

### Purpose or Objective

To determine setup and range robustness settings for IMPT planning required to achieve a D98%-CTV of 95% of the prescribed dose in fractionated treatments in 98% of skull-base meningioma patients, for given systematic and random setup errors and systematic relative stopping-power prediction (range) errors.

### Material and Methods

Robust treatment plans to 50.4 Gy in 28 fractions were made for 9 patients using in-house developed software for multi-criteria optimization of treatment plans. Setup robustness settings from 0 to 5mm and relative range robustness settings from 0 to 5% were used in minimax robust optimization with 9 error scenarios: the nominal scenario, 6 shifted setup scenarios and 2 scenarios with range errors.

Polynomial Chaos Expansion (PCE) was applied to model the impact of setup and range uncertainties on dose. PCE provides a computationally efficient metamodel of the voxel doses. Normal distributions were assumed, and setup and range uncertainties were modeled as rigid shifts and scaling of CT values respectively. PCE was validated for beam and couch angles used in clinical IMPT planning on an independent dataset for the same treatment site. Required range and setup robustness settings were determined in two steps. First, the range uncertainty leading to adequate target and population coverage was determined for various range robustness settings and no setup robustness. To this end, a PCE for range uncertainties was constructed to simulate and evaluate 100.000 complete fractionated treatments. Subsequently, random and systematic setup uncertainties for given setup and range robustness settings were determined in the same fashion. All plans were scaled such that, in the worst optimization scenario, the D98%-CTV was equal to 95% of the prescribed dose. Final results were based on the worst performing patient and validated on the others.

### Results

Scaling all plans to the same target dose in the worst optimization scenario reduced the population variation of the D98%-CTV due to inter-patient variability from 2% to 0.4%. We found a linear relationship between range robustness (RR) and the actual range uncertainty ( $\rho$ ), see Fig. 1. The relationship between random ( $\sigma$ ) and systematic ( $\Sigma$ ) setup errors that just can be dealt with for given setup robustness (SR, different colors) is shown in Fig. 2. Nearby points of the same color correspond to different range uncertainties (and the corresponding range robustness from Fig. 1). The dashed line and curves are fits to the data points.

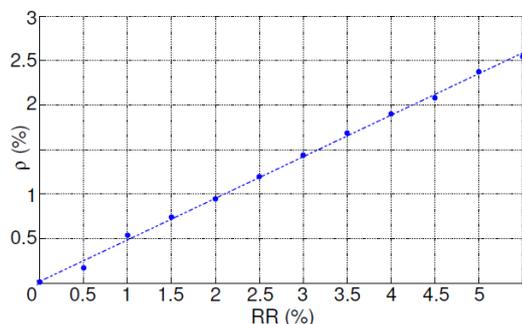

Figure 1: Required range robustness for varying range error.

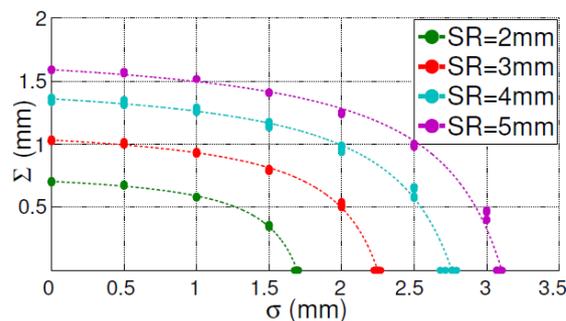

Figure 2: Random and systematic setup and range errors leading to adequate target and population coverage.

### Conclusion

With a population coverage of 98%, the required range robustness for range errors from 0 to 5mm is a factor 2 higher than the actual range error. Interference of setup and range error is negligible, and the required setup robustness does not depend on range robustness.

#### PO-0999 Functional Avoidance planning allows for lung dose reduction in radiotherapy of lung cancer

K. Farr<sup>1</sup>, K. West<sup>1</sup>, R. Yeghiaian-Alvandi<sup>1</sup>, D. Farlow<sup>2</sup>, R. Stensmyr<sup>3</sup>, A. Chicco<sup>2</sup>, E. Hau<sup>1,4,5</sup>

<sup>1</sup>Crown Princess Mary Cancer Centre- Westmead Hospital, Department of Radiation Oncology, Sydney West Radiation Oncology Network- Sydney, Australia ; <sup>2</sup>Westmead Hospital, Department of Nuclear Medicine-PET and Ultrasound, Sydney, Australia ; <sup>3</sup>Crown Princess Mary Cancer Centre- Westmead Hospital, Department of Medical Physics, Sydney West Radiation Oncology Network- Sydney, Australia ; <sup>4</sup>University of Sydney, Faculty of Medicine and Health, Sydney, Australia ; <sup>5</sup>Blacktown Hospital- Sydney West Radiation Oncology Network, Department of Radiation Oncology, Sydney, Australia

### Purpose or Objective

To evaluate the feasibility of functional avoidance radiotherapy planning for the definitive treatment of lung cancer. To characterize the achievable dosimetry of target and normal tissues of functional image-guided dose redistribution.

### Material and Methods

In all 15 consecutive patients with locally advanced non-small cell lung cancer (NSCLC) were included prospectively. Patients were planned to receive definitive (chemo)-radiation therapy (RT) of minimum 60 Gy. Perfusion SPECT/CT were performed prior to RT commencing. Functional lung, identified as 20-80% subvolumes of the maximum perfusion count (FL20-80), was segmented on SPECT/CT, and registered to planning CT. Two plans were optimized: 1) a reference CT-plan, blinded for functional structures, and 2) functional avoidance SPECT-plan, imposing higher priority on functional levels. The objective was to reduce dose to the highly perfused lung subvolumes without compromising PTV coverage, and respecting dose to other organs at risk (OAR) within the predefined constraints. Based on our previous study, dose constraint of 16 Gy to the FL40 sub volume, was used in functional dose planning to reduce the risk of radiation pneumonitis. For each patient a 3D-conformal, intensity modulated (IMRT) and volumetric arc (VMAT) plans were created for both reference and functional avoidance. In all six plans were produced per patient. Anatomical versus functional dose-volume parameters for functional lung subvolumes, and other OAR

were compared, as well as PTV coverage. All patients' treatment plans were delivered without the use of functional information.

### Results

Majority of patients had stage III disease (67%). Preliminary analysis of first eight patients showed the mean PTV volume of 375 cc, anatomical lung volume of 3595 cc. The mean volume for FL40 was 1144 cc. The ratio of functional lung to anatomical lung volume was 0.32. There was weak correlation between anatomical lung and FL volumes within patients (Pearson  $r=0.2$ ), due to perfusion defects variations (tumour, emphysema). The largest dose reduction was achieved with IMRT plans (Figure 1). Plans optimised to FL subvolumes resulted in a significant dose reduction by a mean of 2.1 Gy (20.2%) to the highest functional subvolume FL80 (CI 0.4-3.9  $p=0.02$ ). Dose reduction to FL40 and FL60 was 1.6 Gy (CI 0.6-2.7) and 1.5 Gy respectively (CI 0.3-2.8  $p=0.02$ ). Functional V20 improved by 5.4% (CI 1-10  $p=0.03$ ). Max dose to OAR (heart, oesophagus and spinal cord) and PTV coverage were not significantly different between plans. Detailed analysis of the whole patient cohort is underway.

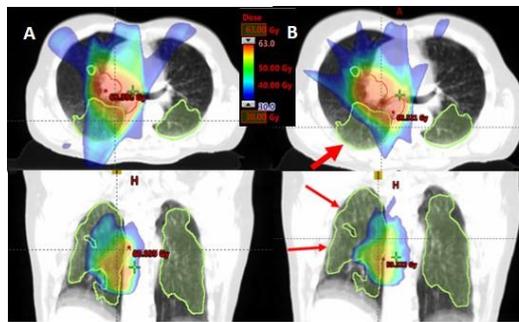

Figure 1. Differences in dose distribution with IMRT plan optimised to anatomical lung contour (A) and functional avoidance plan (B) optimised to FL40 sub volume, with FL40 volume spared for radiation dose as a result (arrows). CTV in red, FL40 in lime, dose in colour wash.

### Conclusion

Functional avoidance planning optimised to perfused lung volumes identified with SPECT resulted in improved dose volumetric outcomes for functional lung. This methodology may lead to potential reduction in radiation-induced lung toxicity in patients treated with definitive lung RT, and subsequently offers potential for target dose escalation.

### PO-1000 Vascular responses in normal brain tissue after combined immunotherapy and SRS to brain metastases

L. Nilsen<sup>1</sup>, E. Grøvik<sup>2</sup>, I. Digernes<sup>2</sup>, C. Saxhaug<sup>3</sup>, A. Latysheva<sup>4</sup>, O. Geier<sup>2</sup>, T.P. Hellebust<sup>5</sup>, D.O. Sætre<sup>6</sup>, B. Breivik<sup>7</sup>, K.D. Jacobsen<sup>8</sup>, Å. Helland<sup>8</sup>, K.E. Emblem<sup>2</sup>  
<sup>1</sup>Oslo University Hospital, Diagnostic Physics, Asker, Norway ; <sup>2</sup>Oslo University Hospital, Diagnostic Physics, Oslo, Norway ; <sup>3</sup>Oslo University Hospital, Radiology and Nuclear Medicine, Oslo, Norway ; <sup>4</sup>Oslo University Hospital, Radiology and Nuclear Medicine, Oslo, Norway ; <sup>5</sup>Oslo University Hospital, Medical Physics, Oslo, Norway ; <sup>6</sup>Østfold Hospital Trust, Radiology, Kalnes, Norway ; <sup>7</sup>Hospital of Southern Norway, Radiology, Kristiansand, Norway ; <sup>8</sup>Oslo University Hospital, Oncology, Oslo, Norway

### Purpose or Objective

Stereotactic radiosurgery (SRS) is a well-established treatment option for patients with brain metastases. Over the past few years, there has been a rapid increase in the additional use of immunotherapy. At present, there is limited understanding of the mechanisms behind the combined effects of immunotherapy and SRS. Our aim is to provide deeper insight into vascular responses of peri-

tumoral- and normal appearing brain tissue after combined immunotherapy and SRS.

### Material and Methods

Twenty-eight patients from our on-going prospective observational imaging study (*clinicaltrials.gov Identifier: NCT03458455*), with a total of 37 brain metastases from non-small cell lung cancer (N=14, n=17) or malignant melanoma (N=14, n=20), have so far been included. All patients received linear accelerator-based SRS (15-27Gy). The dose was prescribed to cover at least 99% of the PTV; contrast enhancing tumor on T1w post-contrast MRI+2 mm isotropic margin. The imaging protocol included pre-SRS MRIs and follow-up MRIs every third month for one year. Six patients (5 melanomas, 1 lung) received immunotherapy before and after SRS, and five patients (2 melanomas, 3 lung) started immunotherapy within 6 months post-SRS. Immunotherapy, pembrolizumab (2mg/kg) or ipilimumab (3mg/kg), or a combination, was given every third week. Relative cerebral vessel calibers (rVSI), and relative blood volume (rCBV) from micro- (spin echo) and macrovasculature (gradient echo), were calculated from perfusion MRI and Vessel Architectural Imaging. All values were normalized to normal appearing white matter receiving less than 2Gy. Normal brain tissue was defined as white- and gray-matter segmented from T1w pre-contrast images in SPM12 (Matlab), excluding tumor and edema which were drawn by experienced neuroradiologists. The normal appearing brain tissue was divided into five ROIs according to doses: >0-2Gy, 2->5Gy, 5->10Gy, 10->15Gy and >15Gy (peri-tumoral region) (Fig.1).

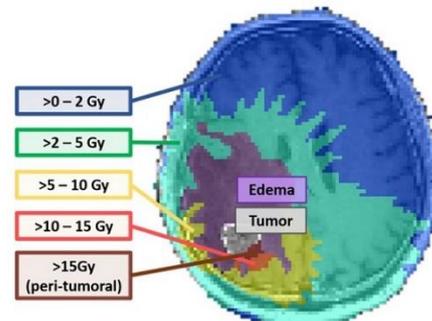

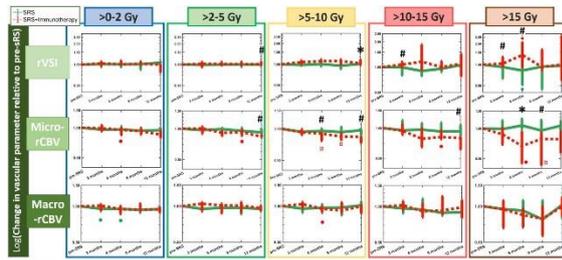

Fig. 1: The SRS dose distribution was divided into five distinct ROIs within normal appearing brain tissue (gray + white matter, excluding edema and tumor): >0-2Gy (blue overlay), >2-5Gy (green overlay), >5-10Gy (yellow overlay), >10-15Gy (orange overlay), and >15Gy; peri-tumoral region (brown overlay), excluding tumor and edema (purple overlay).

### Results

Before SRS, there were no significant differences in rVSI or micro- and macrovascular rCBV between the two treatment groups in any of the dose-level ROIs (Fig.2). However, six months post-SRS, patients treated with SRS and immunotherapy showed higher relative increase in rVSI (1.4;0.91-2.1 vs 0.82;0.51-0.97 ( $p<0.01$ )) together with greater reduction in micro-vascular rCBV (0.67;0.45-0.93 vs 1.1;0.98-1.3( $p<0.05$ )) in the peri-tumoral region. Median macro-vascular rCBV tended to decrease in both treatment groups, and there was no difference in the relative change (0.92;0.66-1.2 vs 0.85;0.68-0.96 ( $p=0.5$ )).

**Fig 2: Adding immunotherapy to SRS enhances treatment-induced effects in the peri-tumoral region (>15 Gy).** The three horizontal rows show log-transformed median change in rVSI (top), microvascular rCBV (middle) and macrovascular rCBV (bottom) relative to pre-SRS within the different dose ROIs at 3, 6, 9, and 12 months after SRS (error bars; interquartile range). No significant differences in any of the vascular parameters were present between the two treatment groups before SRS. Six months after SRS, peri-tumoral microvascular rCBV in patients treated with immunotherapy had increased relative to pre-SRS ( $p < 0.05$ ). In contrast, patients who had not received immunotherapy showed a decrease in rVSI ( $p < 0.05$ ), and at three- and six-months the relative change in peri-tumoral rVSI was different between the two treatment groups ( $p < 0.05$ ). While no significant changes in micro-vascular rCBV were present in patients treated with SRS only, patients on immunotherapy showed decrease in the microvascular blood volume 3-12 months after SRS in peri-tumoral regions as well as in regions receiving low doses (>2-5Gy) ( $p < 0.01-0.05$ ). Six and nine months post-SRS, the reduction on micro-rCBV was greater in the peri-tumoral region of patients treated with immunotherapy ( $p < 0.02/0.05$ ). Macrovascular rCBV tended to decrease in the high-dose regions for patients in both treatment groups, without any significant differences.

## Conclusion

Our preliminary data indicates that peri-tumoral regions are more susceptible to changes in vessel caliber and microvascular blood volume when immunotherapy is added to SRS. The relative decrease in microvascular rCBV, together with increase in rVSI in these patients, suggest that immunotherapy targets small and immature blood vessels in high dose regions.

### PO-1001 Combined image-based and biomechanical deformable image registration of extreme anatomical changes.

M. Nix<sup>1</sup>, S. Gregory<sup>1</sup>, M. Aldred<sup>1</sup>, L. Aspin<sup>1</sup>, B. Al-Qaisieh<sup>1</sup>, J. Lilley<sup>1</sup>, A. Appelt<sup>2</sup>, P. Dickinson<sup>3</sup>, L. Murray<sup>4</sup>  
<sup>1</sup>Leeds Cancer Centre, Radiotherapy Physics, Leeds, United Kingdom ; <sup>2</sup>Leeds Cancer Centre / University of Leeds, Radiotherapy Physics, Leeds, United Kingdom ; <sup>3</sup>Leeds Cancer Centre, Clinical Oncology, Leeds, United Kingdom ; <sup>4</sup>Leeds Cancer Centre / University of Leeds, Clinical Oncology, Leeds, United Kingdom

### Purpose or Objective

Deformable image registration (DIR) has long promised accurate fusion of radiotherapy (RT) images acquired with different geometry. However, with extreme tissue compression, e.g. reduced bladder/rectal filling, or post-surgical anatomy, where regularisation limits deformation, achieving acceptable accuracy has been challenging. The STRIDeR (Support Tool for Re-Irradiation Decisions guided by Radiobiology) project, required DIR of CTs, with bladder full at original RT and empty at reirradiation (reRT). In some cases, patient position changed from prone to supine and/or colorectal surgery had occurred in the interval. Accurate modelling of bladder filling is paramount for reRT as high original doses were typically delivered to the full bladder, not the bowel which moves into the previous RT field when the bladder is empty.

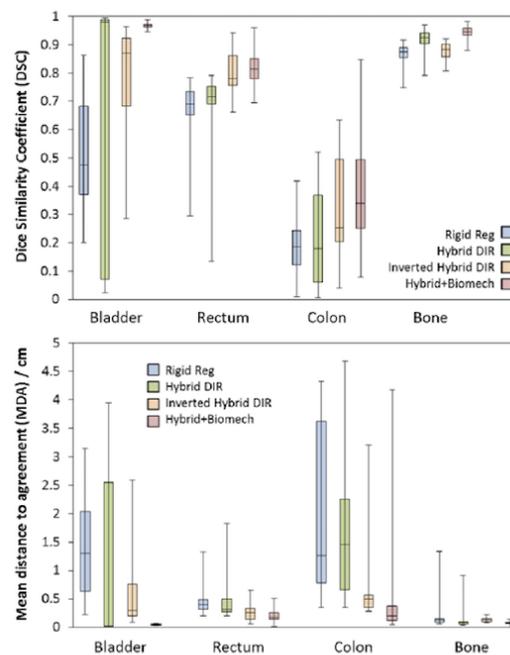

### Material and Methods

Commercially available tools (RayStation 7, RaySearch Laboratories, Stockholm, Sweden) were combined via scripting to develop an optimised automated method combining inverse hybrid<sup>1</sup> DIR, with biomechanical<sup>2</sup> DIR correction where necessary, which can accommodate large pelvic anatomical changes. Original and reRT CTs from 18 patients were registered using 1) Rigid registration, 2) Hybrid DIR, 3) Inverse hybrid DIR and 4) Optimised inverse hybrid + biomechanical DIR. Registration quality was assessed using Dice similarity (DSC) and mean distance to agreement (MDA).

Registration utility for reRT was also assessed by two expert oncologists using a 5-point Likert scale.

## Results

Optimised inverse hybrid + biomechanical DIR improved clinical utility for dose-summation in reRT considerably/moderately in 10/8 of 18 cases, with RIR never equivalent or preferred by clinician assessment. DSC was consistently improved (fig. 1) by optimised DIR, most notably for the critical bladder deformation (DSC >0.94 for all cases without compromising registration of other organs). Hybrid DIR alone completely failed in 7 cases, with bladder DSC <0.1, whilst achieving similar results to the optimised method for the remaining cases. MDAs were also smallest for the optimised method, achieving median MDA < 0.2 cm for bladder and bone. Colon, the most challenging organ to register due to sliding motion and interaction with bladder deformation, also showed improvement (median MDA = 0.3 cm (0.1-4.2 cm) relative to RIR and hybrid methods (median MDA > 1 cm).

**Figure 1: Dice similarity coefficient (upper panel) and mean distance to agreement (lower panel) for bladder, rectum, colon and bone contours registered by four methods including the optimised method developed for this work (pink) which shows significant gains in registration quality over standard hybrid DIR (green). Median, interquartile range and extrema are shown by boxes and whiskers respectively.**

## Conclusion

Combination of image-based hybrid and biomechanical CT to DIR allows accurate modelling of extreme changes in bladder filling and associated soft tissue deformation, where even advanced hybrid algorithms fail.

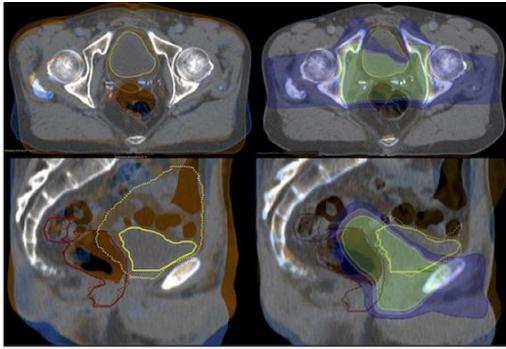

Figure 2: Example RIR (left) showing extreme bladder filling difference and DIR using the optimised method (right), showing final contour overlap and deformed dose. The dose originally delivered to the bladder is modelled correctly as having moved with the bladder. Bowel superior to the bladder at original RT is correctly modelled as having received minimal dose.

This accuracy is essential to realistically deform previously deposited dose (fig. 2), allowing accurate dose summation with radiobiological correction for planning of reRT. Combined image-based and biomechanical registration strategies may have application in dose-accumulation, adaptive re-planning, or summation of EBRT and brachytherapy doses.

#### PO-1002 Pseudo Computed Tomography generation using 3D deep learning - Application to brain radiotherapy

E. ALVAREZ ANDRES<sup>1,2</sup>, L. Fidon<sup>2,3</sup>, M. Vakalopoulou<sup>3</sup>, G. Noël<sup>4</sup>, S. Niyoteka<sup>1</sup>, N. Benzazon<sup>5,6</sup>, E. Deutsch<sup>1,5,7</sup>, N. Paragios<sup>2,3</sup>, C. Robert<sup>1,5,6</sup>

<sup>1</sup>U1030 Molecular Radiotherapy, Paris-Sud University - Gustave Roussy - Inserm - Paris-Saclay University, Villejuif, France ; <sup>2</sup>TheraPanacea, Radiotherapy, Paris, France ; <sup>3</sup>Centre for Visual Computing, Paris-Saclay University, Gif-sur-Yvette, France ; <sup>4</sup>Department of Radiotherapy, Paul Strauss Institute, Strasbourg, France ; <sup>5</sup>Paris-Sud University, Paris-Saclay University, Le Kremlin-Bicêtre, France ; <sup>6</sup>Department of Medical Physics, Gustave Roussy - Paris-Saclay University, Villejuif, France ; <sup>7</sup>Department of Radiotherapy, Gustave Roussy - Paris-Saclay University, Villejuif, France

#### Purpose or Objective

We used 3D convolutional neural networks designed for a high-resolution mapping of any T1-weighted Magnetic Resonance Imaging (MRI, with or without contrast agent) to a pseudo Computed Tomography (pCT). We conducted an evaluation using relevant metrics for radiotherapy based on the dose difference estimation from the Computed Tomography (CT) and the pCT. Our method achieves state of the art results and is robust to the potential use of a contrast agent.

#### Material and Methods

488 couples of brain 3D images including a CT and a T1-weighted or an enhanced T1-weighted MRI were used for training and validation of a 3D deep neural network architecture combined with a series of residual blocks containing dilated filter convolutions. All the network parameters were optimized based on the Mean Absolute Error (MAE) loss function (Figure 1).

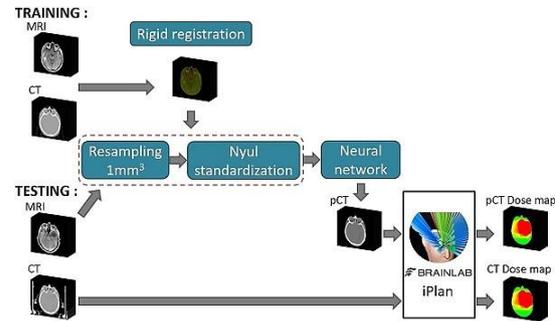

Figure 1: General workflow of the study.

For the evaluation step, we generated the pCTs of 10 grade 3 and 27 grade 4 new glioma patients (test cohort) who received either 3D conformational radiotherapy or Intensity Modulated Radiation Therapy. Prescribed doses ranged from 30Gy to 60Gy. The treatment plan based on the initial CT was transferred to the pCT. To evaluate the differences in the intensities between the initial CT and the pCT, the MAE was calculated. Global 1%/1mm, 2%/2mm and 3%/3mm gamma indexes and dose values extracted from the Dose Volume Histograms (DVHs) of the Planning Target Volume (PTV) were used to quantify the dose differences.

#### Results

Comparing the CT and pCT head regions of the 37 patients of the test dataset gave a MAE of 86 +/- 29 Hounsfield Units. Metrics based on the dose difference are more relevant for radiation therapy. Differences in DVHs were 0.13% +/- 0.08%, 0.14% +/- 0.10%, 0.15% +/- 0.17% for the doses corresponding to 50%, 95% and 98% of the PTV respectively. Global gamma indexes computed in the head region led to pass rates equal to 98.27% +/- 1.02%, 99.67% +/- 0.31% and 99.84% +/- 0.18% for the 1%/1mm, 2%/2mm and 3%/3mm criteria respectively (Figure 2).

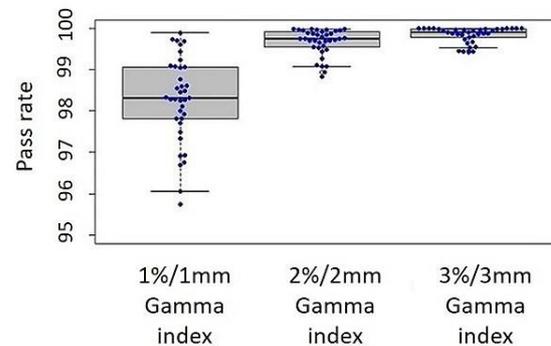

Figure 2: Gamma pass rates for the 1%/1mm, 2%/2mm and 3%/3mm global gamma index criteria.

#### Conclusion

To our knowledge, this is the first dosimetric study integrating 3D deep learning architectures. Promising pCT have been obtained with a high accuracy in terms of dose prediction. They outperform the state of the art dosimetric results (Dinkla et al., 2018), in which gamma pass rates of 91.1% +/- 3.0%, 95.8% +/- 2.1% and 99.3% +/- 0.4% for the 1%/1mm, 2%/2mm and 3%/3mm global gamma criteria were achieved and lead to a feasible application in clinics.

#### PO-1003 A deep learning based auto-segmentation for GTVs on NPC MR images

E. Xiangyu<sup>1</sup>, Y. Hongmei<sup>2</sup>, H. Weigang<sup>2</sup>, W. Jiazhou<sup>1</sup>  
<sup>1</sup>Shanghai Cancer Center- Fudan University, department of radiotherapy, Shanghai, China ; <sup>2</sup>Shanghai Cancer Center- Fudan University, department of radiotherapy, Shanghai, China

### Purpose or Objective

Segmentation of gross tumor volumes (GTVs) on nasopharyngeal carcinoma (NPC) MR images is an important basis for NPC radiotherapy planning. Manual segmentation of GTVs is a time-consuming and experience-dependent process in NPC radiotherapy. This study is aimed to develop a simple deep learning based auto-segmentation algorithm to segment GTVs on T1-weighted NPC MR images.

### Material and Methods

This study involved the analysis of 510 MR images from two datasets: (a) T1-weighted contrast-enhanced head and neck (H&N) MR images of 305 NPC patients and (b) T1-weighted H&N MR images of 205 patients without obviously abnormal regions in head. An FCN based on VGG16 was developed to perform automatic segmentation of GTVs. Data were randomly separated into training (90%) and validation (10%) datasets. Additionally, 15 patients were manually contoured by two oncologists for performance evaluation. Performance of the automated segmentation was evaluated the similarity of automated and manual segmentation on Hausdorff distance (HD), average surface distance (ASD), Dice index (DSC), and Jaccard index (JSC).

### Results

The HD, ASD, DSC, JSC (mean±std) were 16.18±7.93mm, 2.42±1.38mm, 0.71±0.12, 0.57±0.13 for validation dataset; and these indices were 14.21±4.73mm, 1.51±0.98mm, 0.83±0.08, 0.72±0.12 between two human radiation oncologists, respectively. The t-test indicated there was no statistically significant difference between automated segmentation and manual segmentation concerning HD(p=0.67), ASD(p=0.46), DSC(p=0.17), JSC(p=0.16).

### Conclusion

The results suggested that the performance of automated segmentation of GTV is close to manual segmentation's performance based on T1-weighted NPC MRIs. However, the manual segmentation performed better than automated segmentation. Thus, automated segmentation must be modified manually before being put into use.

### PO-1004 Simulation of tissue dependent magnetic field susceptibility effects in MRI guided radiotherapy

C. Kroll<sup>1</sup>, M. Opel<sup>2</sup>, C. Paganelli<sup>3</sup>, F. Kamp<sup>4</sup>, S. Nepl<sup>4</sup>, G. Baroni<sup>3</sup>, O. Dietrich<sup>3</sup>, C. Belka<sup>4</sup>, K. Parodi<sup>1</sup>, M. Riboldi<sup>1</sup>

<sup>1</sup>Ludwig-Maximilians-Universität Munich, Medical Physics, Garching, Germany; <sup>2</sup>Bayerische Akademie der Wissenschaften, Walther-Meißner-Institut, Garching, Germany; <sup>3</sup>Politecnico di Milano, Dipartimento di Elettronica- Informazione e Bioingegneria, Milano, Italy; <sup>4</sup>Ludwig-Maximilians-Universität Munich, Department of Radiation Oncology- University Hospital, Munich, Germany; <sup>5</sup>Ludwig-Maximilians-Universität Munich, Department of Radiology- University Hospital, Munich, Germany

### Purpose or Objective

The use of MRI for guidance in external beam radiotherapy needs to face the issue of spatial distortions, which may hinder accurate geometrical characterization. In this contribution, susceptibility values for different tissue types were measured, and tissue dependent effects simulated in a digital anthropomorphic CT/MRI phantom.

### Material and Methods

The simulation of the magnetic field distortion due to tissue dependent susceptibility effects relied on the iterative solution of Maxwell equations<sup>1,2</sup> in a multiple step procedure. The obtained magnetic field maps were then post-processed and values in parts per million (ppm) were converted into geometric distortion depending on the gradient strength. The simulation procedure was validated on test objects, for which an analytical solution can be

derived. For this purpose, a sphere and hollow shell were tested, varying the object susceptibilities from paramagnetic to diamagnetic and testing different convergence criteria. The digital anthropomorphic CT/MRI phantom CoBAT<sup>3</sup> was then used for simulation of tissue dependent effects. The input susceptibility values of liver, lung and muscle tissue were experimentally measured in porcine tissue samples, relying on SQUID (Superconducting Quantum Interference Device) magnetometry at normal pressure in the 0.35 - 3.0 T range (Figure A).

### Results

In the validation of the susceptibility algorithm, a RMS error between analytical and numerical solutions of 0.09 ppm for the sphere and of 0.35 ppm for the hollow shell was obtained, corresponding to a 10<sup>-12</sup> convergence tolerance. The tissue volume susceptibilities (expressed in SI units) remained constant in a physiological temperature range of 309.5 K - 313.5 K. The average ± standard deviation values over the temperature range were (-2.06 ± 0.02)·10<sup>-6</sup> for lung, (-9.91 ± 0.02)·10<sup>-6</sup> for liver and (-12.84 ± 0.08)·10<sup>-6</sup> for muscle tissue at 1.5 T (Figure A). Using the determined susceptibilities and values for bone, blood, fat, water and air as reported in the literature<sup>4,5</sup>, magnetic alterations stemming from susceptibility effects were simulated (Figure B). The ppm-differences ranged from -7.68 ppm to 4.36 ppm at 1.5 T, corresponding to 1.15 mm maximal distortion at a gradient strength of 10 mT/m.

### Conclusion

Different tissues create local magnetic changes, with enhanced effects at the boundaries (Figure B), which scale with the magnetic field strength. Through the determination of magnetic susceptibilities of different tissue types, a more realistic representation of susceptibility induced distortions is feasible. A phantom study, dealing with magnetic field alterations due to static field inhomogeneities and gradient non-linearities is currently ongoing, aiming at a comprehensive simulation of major effects in spatial distortion for MRI guidance.

**PO-1005 Evaluating different generator networks of a conditional generative adversarial network**

L. Fetty<sup>1</sup>, P. Kuess<sup>1</sup>, N. Nesvacil<sup>1</sup>, T. Nyholm<sup>2</sup>, D. Georg<sup>1</sup>, H. Furtado<sup>1</sup>

<sup>1</sup>Medical University of Vienna, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria ; <sup>2</sup>Umea University, Department of Radiation Sciences, Umea, Sweden

**Purpose or Objective**

The conversion of MR images to synthetic CTs (sCT) is of great importance for MR-only workflows. Deep learning has become a very popular and promising feature extraction technique which is used for many tasks in medicine. Image to image translations for MR-sCT conversions can be performed by classic convolutional neural networks and generative adversarial networks (GAN). For a better understanding of specific deep learning techniques and to identify the best suitable method on a quantitative basis, a systematic evaluation of different networks is of highest importance.

The aim of this study was to investigate the influence of different GAN generator structures on the image conversion and their impact on the mean absolute error (MAE). Further we transferred the learned features to different MRI scanners to identify whether the network-learned features can be applied globally. **Material and Methods**

4 different generator networks were implemented into an existing GAN structure (pix2pix). The generators were based on SE-ResNet (SN), DenseNet (DN), u-net (UN) and embedded net (EN). Pelvic T2-weighted MR (0.35T open MR) images of 40 patients (29 male and 11 female) were used, resulting in a training set of 1972 image pairs. The same settings for discriminator, loss function and learning cycles (epochs) were used for all tests. The test data set contained 12 patients. A gold atlas dataset (GA) was used to evaluate the impact of the trained networks on other MR scanners (1.5 and 3T). Finally, all networks were combined by calculating the median (ME) over all voxels of the converted images.

The performance of the networks was evaluated by the MAE in the outer patient contour and the bone region. **Results**

The best results for the training dataset were obtained using the SN and the DN. However, a divergence was observed between the training and test datasets with increasing epoch counts (Figure 1). EN and UN performed slightly worse, but training and test sets were always

within the standard deviation. The MAE at the 100<sup>th</sup> epoch count was about 47HU for DN and SN and 71HU for EN and UN for the whole body. During the testing phase the MAE of all 4 networks ranged between 61-70HU.

For the GA dataset, the EN performed worse with a MAE of 85-90HU. For both 3T systems the DN showed low ranges and a better performance than for the test data. ME produced the best results for bone regions in all datasets (Figure 2).

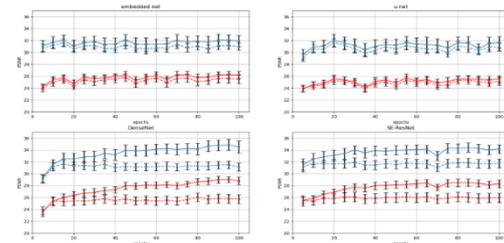

Figure 1: training and test loss of the GANs with the four different generator structures.

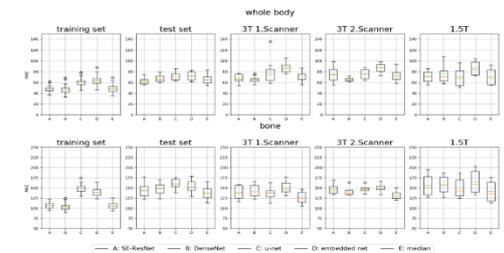

Figure 2: Metrical evaluation of the different datasets with the different network structures compared to the median calculated of all networks for the whole body and the bone

**Conclusion**

Differences between networks should be considered if applied to new data. Detailed information on the networks' performance should be reported in studies that utilize such methods. Our ME results suggest that a combination of multiple networks can increase overall performance. The results indicate that a comprehensive comparison between generator types is necessary when using deep learning methods on image post-processing with deep learning methods.

**Purpose or Objective**

Deep learning methods (DLM) have recently been developed to generate pseudo-CT (pCT) from MRI for radiotherapy dose calculation. The main advantage of these methods is the speed of pCT generation. The objective of this study was to compare a DLM to a patch-based method (PBM), an atlas-based method (ABM) and a

bulk density method (BDM) for prostate MRI-only radiotherapy.

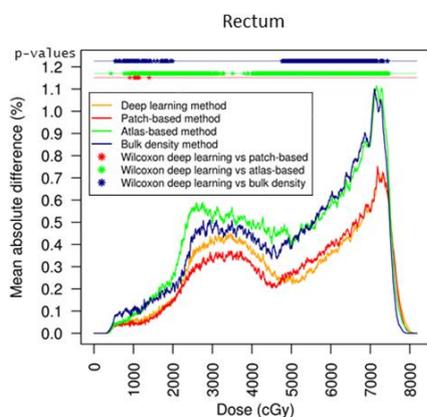

#### Material and Methods

Thirty-nine patients received VMAT for prostate cancer (78 Gy in 39 fractions). T2-weighted MR images were acquired in addition to the planning CT images. pCT were generated from MRI by four methods: a DLM, a PBM, an ABM and a BDM (water-air-bone density assignment). The DLM was a generative adversarial network (GAN) using a perceptual loss. The PBM was performed with feature extraction and approximate nearest neighbour search. DLM and PBM were trained with a cohort of 25 patients. The four methods were compared in a validation cohort of 14 patients. Imaging endpoints were mean absolute error (MAE) and mean error (ME) of Hounsfield units (HU) from voxel-wise comparisons between pCT and reference CT. Dose uncertainties of the methods were defined as the absolute mean differences between DVH parameters for the organs at risk and PTV calculated from the reference CT and from the pCTs for each method. 3D gamma index analyses (local, 1%/1mm) were also performed. The Wilcoxon test was used to compare the uncertainty of the DLM to those of the three other methods.

#### Results

In the whole pelvis, the DLM showed significantly lower MAE (mean value of 37 HU) compared to the PBM (41 HU), ABM (43 HU) and BDM (99 HU). The ME obtained from the PBM (-1 HU) was lower compared to those of the DLM (-9 HU), ABM (-8 HU) and BDM (-18 HU). The table shows the dose uncertainty of each pCT generation method for each volume-of-interest. The figure shows the dose uncertainty of each method along the whole DVH for the rectum. Significant differences are displayed with the use of the symbol \*. DVH differences were significantly lower when using the DLM and the PBM, than the ABM and BDM. All the mean gamma values were significantly lower with the DLM or the PBM, compared to the ABM and BDM.

Volumes of interest	Prostate CTV	Prostate PTV	Rectum	Bladder			
Dosimetric endpoints	D <sub>99%</sub> (cGy)	V <sub>95%</sub> (%)	V <sub>100%</sub> (%)	D <sub>max</sub> (cGy)	V <sub>50%</sub> (%)	D <sub>max</sub> (cGy)	
CT <sub>ref</sub> values	7150	96.4	5.9	7298	20.1	7770	
Absolute difference between the dose calculated on the reference CT and the pseudo-CT	Deep learning method	52	0.7	0.5	52	0.2	26
	Patch-based method	51	0.7	0.5	52	0.2	25
	Atlas-based method	79	1.3	0.8	81	0.5	61
	Bulk density method	79	1.3	0.8	80	0.5	67

#### Conclusion

In order to generate pCT from MRI for dose calculation, the four assessed methods provide clinically acceptable uncertainties (<1%). The DLM and PBM provide however

the lowest imaging and dosimetric uncertainties. The DLM appears particularly attractive due to its accuracy and the very fast calculation time (<1 min).

#### PO-1008 Image quality characterisation of a proton gantry-mounted cone-beam CT system

K. Andersson<sup>1</sup>, C. Vallhagen Dahlgren<sup>1</sup>, A. Dasu<sup>1</sup>

<sup>1</sup>The Skandion Clinic, Department of Medical Physics, Uppsala, Sweden

#### Purpose or Objective

Cone-beam computed tomography (CBCT) is an important tool for precise patient positioning and tracking of anatomical changes during the course of radiotherapy. For proton therapy, it is crucial to reduce such uncertainties due to the sharp distal dose fall-off. Proton gantry-mounted CBCT generally differ from linac systems, e.g., the source-to-isocenter distance (SID) may be larger and they may lack bowtie filters. Organ doses for a proton-gantry CBCT have recently been investigated by Ardenfors et al [1]. They concluded that posterior scans result in lower organ doses than anterior scans and should therefore be preferred if image quality could be preserved. The aim of the current project was to evaluate image quality for several scan protocols of the same proton gantry-mounted CBCT system.

#### Material and Methods

A Catphan® 600 phantom (The Phantom Laboratory, Salem, NY) was scanned with the CBCT system of a proton pencil-beam scanning gantry (Ion Beam Applications, Belgium) at the Skandion Clinic, Sweden. The system has SID=261.8 cm and no bowtie filter applied. Images were acquired for the head, thorax and pelvic protocols with rotations of 360°, 190° anterior or 190° posterior. Image quality was assessed several times over several months. Images were analyzed using ImageJ software (NIH, Bethesda, MD) using the image quality parameters recommended by the EFOMP-ESTRO-IAEA protocol [2]. The tolerance levels used for geometrical accuracy, CT number accuracy and uniformity were the same as during system acceptance. Contrast-to-noise ratios (CNR) and resolution were also evaluated.

#### Results

Geometrical accuracy was within tolerance for every protocol, while uniformity exceeded the tolerance for all series (see Table 1). CT number accuracy was generally within tolerance, but in some cases higher deviations were seen for a few contrast targets. CNR:s were considerably low for head scans, and were highest for pelvis protocols. Resolution was considered to be acceptable for all scans. Generally no relevant image quality differences between posterior and anterior scans were found.

Table 1. Summary of image quality parameters determined for the proton gantry-mounted cone-beam CT system.

Protocol	Tube voltage (kV)	Tube current (mAs)	Geometrical accuracy (Tolerance: 1%)	CT number accuracy (Tolerance: ΔHU < 40)	Uniformity (Tolerance: ΔHU < 40)	Low contrast (CNR)	Resolution (Line pair/cm)
Head, 190° A	100	569	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	0.6	7
Head, 190° P	100	569	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	0.7	7
Head, 360°	100	1082	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	0.9	7
Thorax, 190° A	110	910	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	1.2	8
Thorax, 190° P	110	910	✓	✓	X	1.4	8
Thorax, 360°	110	1732	✓	✓	X	1.9	8
Pelvis, 190° A	120	1820	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	1.9	8
Pelvis, 190° P	120	1820	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	2.2	8
Pelvis, 360°	120	3464	✓	ΔHU <sub>max,sk</sub> > 40 HU	X	2.8	8

A – anterior, P – posterior, HU – Hounsfield units, CNR – contrast-to-noise ratio

#### Conclusion

While geometrical accuracy was found to be acceptable, tests of CT number accuracy, uniformity and low resolution showed deviations. Therefore image quality based on these aspects needs to be further investigated. Posterior scans resulted in equal image quality as anterior scans, and could hence preferably be used since organ doses are reduced. The stability of the system will be assessed based on measurements repeated periodically for a longer time period.

### Purpose or Objective

The objective of this study was to assess methods based on PET thresholding, machine learning using a linear classifier, and deep learning for automatic tumour segmentation of head and neck cancers in PET/CT images.

### Material and Methods

This retrospective study examines 197 head and neck cancer patients who underwent a combined 18F-FDG-PET/CT scan prior to radiotherapy. Three tumour segmentation approaches with different levels of complexity were compared: (i) PET thresholding techniques, (ii) voxelwise classification using the machine learning algorithm Linear Discriminant Analysis (LDA), and (iii) deep learning using convolutional neural networks (CNNs). Manual gross tumour delineations made by an oncologist and a nuclear medicine specialist were considered as the ground truth. PET thresholding was conducted using either absolute thresholding or a percentage of maximum SUV, optimized using the Dice similarity coefficient (DSC) or the Receiver Operating Characteristics (ROC). The LDA approach used input features engineered using voxel intensities and voxel neighbourhood information extracted from the original PET/CT images and images transformed using CT windowing, as well as point and two-dimensional transformations to highlight different image characteristics. Training data was down-sampled to 50/50 class-balance prior to training the LDA model. The deep learning approach used a U-net architecture with a Dice loss function. Weights were initialised using the He initialisation scheme and optimised using Adam with a  $10^{-4}$  step size and default hyperparameters. Raw PET images and raw or windowed CT images without down-sampling were used for this approach.

The segmentation performance on validation data was assessed using the Dice similarity coefficient, sensitivity, specificity and the ROC-AUC (Receiver Operating Characteristics-Area Under the Curve).

### Results

For PET thresholding, optimizing the SUV threshold with respect to ROC rather than DSC resulted in somewhat better segmentation with higher and balanced sensitivity (0.83-0.87) and specificity (0.85-0.89) (Table 1). LDA segmentation based only on CT images performed poorly (DSC 0.17), whereas segmentation based on PET images gave high sensitivity, specificity, AUC and DSC (0.50). Thus, features engineered from CT images did not provide sufficient information for tumour segmentation using a linear classifier. CNN segmentation had the overall highest DSC (0.62) (Table 1, Figure 1). Interestingly, CNN

segmentation based only on CT images performed similarly to segmentation using PET images.

### Conclusion

All segmentation approaches based on PET images performed satisfactorily due to the high SUV of the tumour relative to other tissues. However, only the deep learning approach was able to discern the tumour in CT images, without the need of extensive feature engineering as required by the linear classifier.

**Table 1.** Mean performance measures for automatic tumour segmentation obtained using validation data for the methods PET thresholding, voxelwise classification using a linear classifier (LDA), and deep learning (CNN).

Method	Input images	DSC	Sensitivity	Specificity	AUC
Absolute threshold*	PET	0.58	0.62	0.98	NA

## PO-1010 Clinical evaluation of deep learning delineation of head and neck OARs.

W. Van Rooij<sup>1</sup>, H. Ribeiro Brandao<sup>1</sup>, A. Delaney<sup>1</sup>, B. Slotman<sup>1</sup>, W. Verbakel<sup>1</sup>, M. Dahele<sup>1</sup>

<sup>1</sup>VUMC, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

Target and organ-at-risk (OAR) delineation is a key step in radiotherapy treatment planning and adaptive radiotherapy, but it is often time consuming and resource intensive. Additionally, it is subject to interobserver variability and may require considerable anatomical knowledge. Most available automated methods for delineation do not, in general, perform as well as desired, and/or are slow. Deep learning for automated delineation is promising, but its evaluation has typically only been presented in terms of similarity coefficients or observer ratings for a limited number of OARs. Therefore, this retrospective study evaluates (1) the geometric accuracy, and (2) the dosimetric (clinical) impact of using deep learning delineation on many OARs for head and neck cancer (HNC).

### Material and Methods

142 anonymized clinical datasets, consisting of clinically contoured CT scans and structure sets, were used to train a convolutional neural network (U-Net) and 15 were used as a test set. The objective was to automate the delineation of the following OARs: left and right submandibular gland, left and right parotid gland, larynx, cricopharynx, pharyngeal constrictor muscle (PCM), upper esophageal sphincter (UES), brain stem, oral cavity and esophagus. Each OAR was delineated both manually (MD,

the clinical contour) and with deep learning (DLD). No manual editing was performed on the DLD contours. In order to avoid plan optimization bias, treatment plans were created using knowledge-based planning, based on MD and DLD structures (MD-plans, DLD-plans) and the mean dose to the manually delineated OAR structures was compared.

### Results

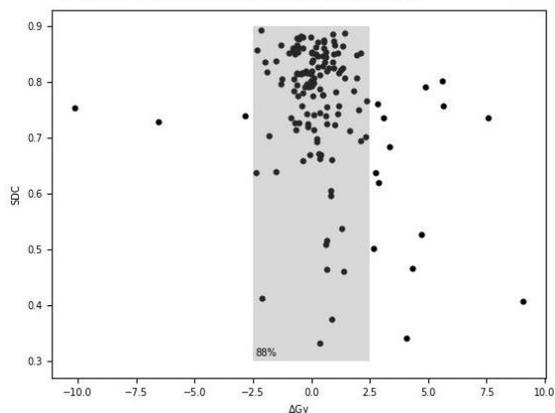

Generation of deep learning contours takes ~10 seconds for all OARs. The average dose was statistically significantly higher for DLD-plans for the lower larynx, the inferior PCM, and the esophagus (table 1). Average differences were not clinically significant, but differences in some individual cases could be. From the 209 OARs, 28 (13.4%) received an increase of more than 2Gy with the DLD-plans, and 7 (3.3%) a decrease of more than 2Gy. A full overview of the OARs' Sørensen-Dice coefficients (SDC) and their increase/decrease in Gy ( $\Delta$ Gy) for DLD-plans compared to MD-plans can be seen in figure 1. Low SDCs were generally the result of variability in the MD or the limited amount of training data.

Table 1. Averaged doses per OAR for MD-plans (MD-D) and DLD-plans (DLD-D) and the difference between them ( $\Delta$ Gy). \* implies statistical significance ( $p < 0.05$ ).

Structure	MD-D <sub>mean</sub> (Gy)	DLD-D <sub>mean</sub> (Gy)	$\Delta$ Gy
Brain stem	34.5 +/- 8.1	35.8 +/- 6.7	1.3 +/- 3.1
Spinal cord	42.0 +/- 1.2	41.7 +/- 1.4	-0.3 +/- 1.1
Oral cavity	31.1 +/- 8.7	31.6 +/- 8.5	0.4 +/- 1.2
Parotid (i)	31.1 +/- 11.1	31.0 +/- 11.4	-0.1 +/- 0.7
Parotid (c)	21.6 +/- 3.9	21.6 +/- 4.0	0.0 +/- 0.8
Submandibular (i)	50.9 +/- 11.5	51.8 +/- 11.1	0.9 +/- 3.4
Submandibular (c)	34.2 +/- 6.3	34.4 +/- 6.5	0.2 +/- 1.0
Cricopharynx	27.7 +/- 11.4	28.2 +/- 11.6	0.5 +/- 1.5
Lower larynx*	25.0 +/- 16.5	25.7 +/- 16.6	0.8 +/- 1.3
Upper larynx	42.4 +/- 15.8	42.2 +/- 15.8	-0.1 +/- 2.4
Inf PCM*	35.2 +/- 13.5	36.5 +/- 13.7	1.4 +/- 1.8
Med PCM	51.3 +/- 9.0	51.1 +/- 9.2	-0.1 +/- 0.9
Sup PCM	54.6 +/- 9.8	54.8 +/- 9.5	0.2 +/- 0.7
UES	21.5 +/- 11.3	22.0 +/- 11.7	0.5 +/- 2.1
Esophagus*	20.4 +/- 6.1	22.7 +/- 5.6	2.2 +/- 1.6

Figure 1. Scatterplot of the SDC (y-axis) and  $\Delta$ Gy (x-axis) of all OARs.

PCM and larynx are taken as composite structures here.

### Conclusion

Using a training set consisting of only a relatively limited number of OAR delineations without extensive curating, automated deep learning segmentation for head and neck OARs, is fast and for most organs it performs sufficiently

well for treatment planning purposes. Since some contours can deviate from the clinical contours, clinical inspection of automated contours is still required. The combination of automated DLD plus model-based automated planning has the potential to increase the efficiency of routine clinical care, and facilitate online adaptive radiotherapy.

### PO-1011 Calibration and validation of ion stopping power prediction with Philips IQon Spectral CT

F. Faller<sup>1</sup>, B. Ackermann<sup>2</sup>, G. Pahn<sup>3</sup>, M. Alber<sup>1</sup>, W. Stiller<sup>4</sup>, A. Mairani<sup>2</sup>

<sup>1</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany; <sup>2</sup>Heidelberg Ion-Beam Therapy Center HIT, Department of Radiation Oncology, Heidelberg, Germany; <sup>3</sup>Philips Healthcare, Clinical Scientist CT, Hamburg, Germany; <sup>4</sup>University Hospital Heidelberg, Diagnostic Radiology, Heidelberg, Germany

### Purpose or Objective

This study presents for the first time an experimental validation of stopping-power ratio (SPR) prediction from Philips IQon Spectral CT data, exploring its benefit for improving radiotherapy (RT) treatment planning, especially in view of the accuracy requirements imposed by proton and heavy ion therapy. For this purpose, we investigated the added value of derived quantitative image data, such as three-dimensional maps of effective atomic number ( $Z_{\text{eff}}$ ) and electron density relative to water (ED) covering the whole acquisition field-of-view. The ultimate purpose of this study was the derivation of an accurate three-dimensional map of  $\text{SPR}_w$  based on maps of  $Z_{\text{eff}}$  and ED acquired with spectral CT imaging technique.

### Material and Methods

The accuracy of ED and  $Z_{\text{eff}}$  by Philips IQon Spectral CT was verified in phantoms with various tissue-equivalent inserts (Gammex 467, CIRS 062M).  $\text{SPR}_w$  values were determined following the Bethe equation and applying different approaches available in literature aiming to convert  $Z_{\text{eff}}$  maps in ionization potential (I) maps. The impact of spectral CT scanning settings, regarding acquisition and reconstruction parameters, namely tube potential, acquisition dose, and gantry rotation time, on  $Z_{\text{eff}}$  and ED maps was assessed. The derived  $\text{SPR}_w$  maps values were validated against experimentally determined  $\text{SPR}_{\text{meas}}$  of the same insert. Comparisons against  $\text{SPR}_w$  derived using spectral CT were performed, evaluating the accuracy of the methodology.

### Results

We calibrated and validated three-dimensional maps of  $Z_{\text{eff}}$  and ED from spectral CT data with phantom measurements (deviation within a few per cent compared to reference data). Using  $Z_{\text{eff}}$  data from spectral CT, tissue surrogates can be characterized more accurately than using standard HU-calibration. For the tissue surrogates  $\text{SPR}_w$  predicted from spectral CT images was within a mean accuracy of <1 % compared to  $\text{SPR}_{\text{meas}}$  (Figure 1). The experimental validation in defined materials is a mandatory step to show absolute  $\text{SPR}_w$  errors from spectral CT prediction before considering biological tissue samples. Furthermore, a method for efficient integration of  $\text{SPR}_w$  in the Monte Carlo treatment planning framework available at the Heidelberg Ion Beam Therapy center was developed.

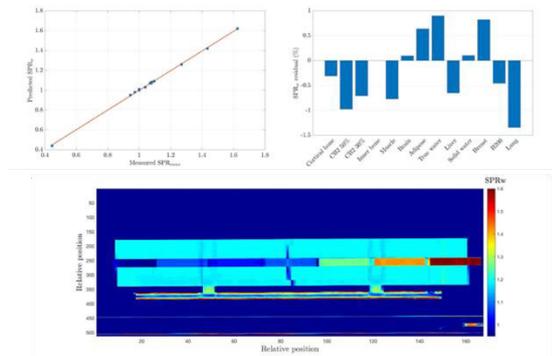

Figure 1: Upper left: Relation between predicted  $SPR_w$  and measured  $SPR_{meas}$ . Upper right:  $SPR_w$  residual for measured tissue surrogates. Bottom: Cross-section through a phantom with seven tissue-equivalent inserts showing predicted  $SPR_w$ .

### Conclusion

In this study we investigated the ability of Philips IQon Spectral CT imaging technique to predict the  $SPR_w$  for particle therapy more accurately using an image-based calculation of both ED and  $Z_{eff}$ . Further comparative studies of  $SPR_w$  maps derived from spectral CT to those determined by conventional CT imaging for RT planning and range measured in biological tissue samples will evaluate its potential in realistic tissue compositions. These results will be additionally presented at the conference.

### PO-1012 Dual-energy computed tomography for improved delineation in postoperative brain-tumor patients

P. Wohlfahrt<sup>1,2</sup>, L. Agolli<sup>3</sup>, M. Krause<sup>1,2,3,4,5</sup>, K. Pilz<sup>3</sup>, C. Richter<sup>1,2,3,4,6</sup>, E. G. C. Troost<sup>1,2,3,4,5,6</sup>

<sup>1</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus - Technische Universität Dresden - Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany; <sup>2</sup>Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiooncology - OncoRay, Dresden, Germany; <sup>3</sup>Department of Radiotherapy and Radiation Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus - Technische Universität Dresden, Dresden, Germany; <sup>4</sup>German Cancer Consortium DKTK, partner site Dresden and German Cancer Research Center DKFZ Heidelberg, Dresden, Germany; <sup>5</sup>National Center for Tumor Diseases NCT, partner site Dresden: German Cancer Research Center DKFZ Heidelberg - Faculty of Medicine and University Hospital Carl Gustav Carus at Technische Universität Dresden and Helmholtz Association / Helmholtz-Zentrum; <sup>6</sup>Both authors share last authorship, equal contribution, Dresden, Germany

### Purpose or Objective

The clinical use of dual-energy CT (DECT) contributes to an improved accuracy in proton treatment planning compared to single-energy CT (SECT) as demonstrated in recent studies. A precise delineation of tumor volumes and organs at risk (OARs) is essential in particular for emerging high-conformal treatment techniques. Since DECT provides additional tissue information and allows for the generation of various tissue contrasts, we assessed its influence on the intra- and inter-observer delineation variability.

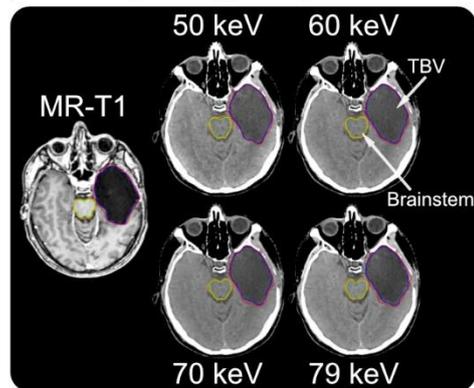

### Material and Methods

Two cohorts of 10 postoperative brain-tumor patients each, receiving either a 120kVp SECT or 80/140kVp DECT scan with identical total dose, were evaluated. Pseudo-monoenergetic CT (MonoCT) datasets of 50, 60, 70 and 79keV, representing several tissue contrasts, were derived

from DECT scans processed in syngo.via (Siemens Healthineers). Three radiation oncologists with different levels of experience in neuro-oncology delineated the postoperative tumor bed volume (TBV) and OARs (brainstem, parotid and lacrimal glands, eyes, lenses, optic nerves, and chiasm) on each dataset, at least two-weeks apart per patient. Relevant image information was blinded. The delineations on SECT datasets were repeated once to assess the intra-observer variability. Finally, the delineation was also performed on T1/T2 MR scans as clinical reference.

The contour conformity was quantified by the Jaccard index (JI) and Hausdorff distance (HD) between the intersection and union of the respective contours (Fig. 1).

### A Inter-observer variability - DECT (3 clinicians per energy & MR)

### B Intra-observer variability - DECT (4 different energies per clinician)

Fig.1: Assessment of inter- and intra-observer delineation variability for pseudo-monoenergetic CT (MonoCT) datasets derived from dual-energy CT (DECT). The tumor bed volume (TBV) and brainstem are exemplarily shown.

### Results

The median inter-observer TBV conformity (Fig. 2A) was almost independent from the CT dataset (HD=6-9mm, JI=61-66%) and comparable to MR scans (HD=6-7mm, JI = 66-67%). The consistency of brainstem contours (Fig. 2B) was best at the lowest energy of MonoCT datasets (median HD=2.8mm, JI=81%). In contrast, the contour conformity of the parotid glands (Fig. 2C) gained slightly from an increased energy (median HD reduction of 0.6mm, JI increase of 1%) and also led to better results as MR scans. For these OARs, using the most suitable MonoCT instead of SECT resulted in smaller inter-observer variations. No relevant differences between SECT and MonoCT were determined for the other OARs, potentially due to their small volume.

The intra-observer TBV variability obtained on SECT did not depend on clinical experience. However, the contouring of less experienced clinicians is more affected by different image contrasts introduced by MonoCT of different energies (Fig. 2D).

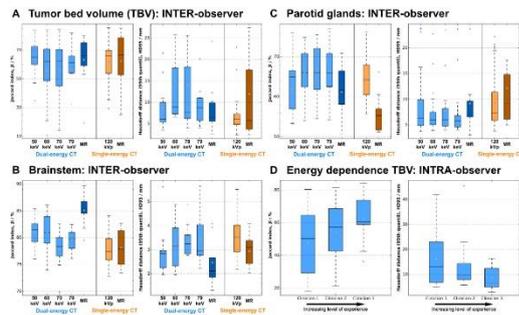

Fig.2: Inter-observer delineation variability of three radiation oncologists for TBV (A) and organs at risk such as brainstem (B) and parotid glands (C) as well as intra-observer variability of the TBV contour at different image contrasts (MonoCT of 50, 60, 70 and 79 keV).

### Conclusion

For postoperative brain-tumor patients, DECT-derived MonoCT datasets can improve the intra- and inter-observer delineation conformity compared to the currently used SECT. Moreover, they in part led to similar or better results as the gold standard MR. The most suitable image contrast to meet individual delineation requirements of anatomical structures can be chosen after CT acquisition. Future studies need to show whether the advantages can also be translated to other tumor entities and body regions.

Poster: Physics track: Implementation of new technology, techniques, clinical protocols or trials (including QA & audit)

### PO-1013 Unscheduled interruptions and total treatment time for VMAT prostate treatments

E.M. Ambroa Rey<sup>1</sup>, J. García-Miguel Quiroga<sup>1</sup>, A. Ramirez Muñoz<sup>1</sup>, D. Navarro Giménez<sup>1</sup>, R. Gómez Pardos<sup>1</sup>, M. Colomer Truyols<sup>1</sup>

<sup>1</sup>Consorci Sanitari de Terrassa, Medical Physics Unit-Radiation Oncology, Terrassa, Spain

#### Purpose or Objective

Treatment interruptions during radiotherapy may have a negative effect on patient outcome and uncompensated interruptions increase the risk of local recurrence. The causes of treatment interruptions may be preventive equipment maintenance, local and national public holidays, treatment toxicity, equipment breakdown, and also patient's private reasons.

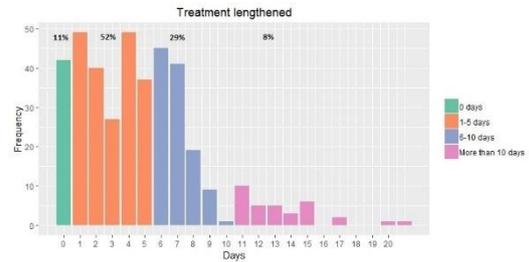

It is important to account for these interruptions and evaluate if the total treatment time (TTT) is within a reasonable margin.

#### Material and Methods

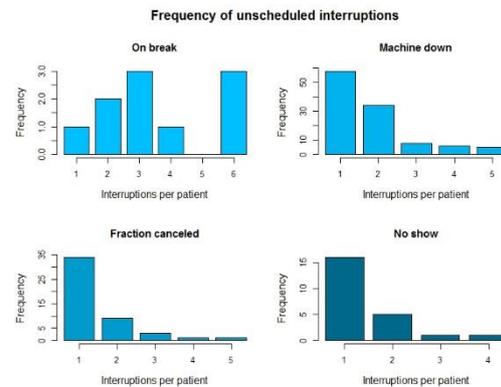

From April 2014 to July 2018, 392 patients with prostate cancer were analyzed for this study. VMAT plans were carried out using Monaco TPS (v5.10). There are 14 local/national holidays each year in our country. Although there is no consensus about what is the ideal treatment time for prostate cancer, most publications recommend not exceeding the TTT by more than 2 to 5 days. Some form of compensation should be introduced where the interruption results in a prolongation of overall treatment time of more than five days.

#### Results

Frequency of treatment lengthened is displayed in Figure I. If we consider scheduled treatment time plus 5 days at most, 63% of the treatments were completed on time (only 11% of them were completed with zero days of delay). Meanwhile, 29% had a delay between 6-10 days and approximately an 8% of the patients had a delay of more two weeks. That means that 37% of prostate patients must have treatment compensations.

Moreover, 73% of the patients started treatment on a Monday (38%) or Tuesday (35%); 16% started on a Wednesday, 10% on a Thursday and 1% on a Friday. Regarding the type of interruption (B= on break; M= machine down; X= canceled, N=no show), 37% of the patients suffered at least one type of unscheduled interruptions (one type 74%; combination of two types 23%; and combination of three types, 3%). Most frequent interruption is M, followed by X. Frequency of type of interruption is shown in Figure II. Also, 52% of the patients suffered scheduled interruptions like preventive machine maintenance or public holidays.

If we look the 'Machine down' histogram (Figure II), 58 patients had only one day of interruption because of a machine breakdown, meanwhile 34 patients had two days of interruption.

In the histogram 'Fraction cancelled' you can see that 34 patients suffered one day of interruption, meanwhile 8 patients suffered two days of interruption.

#### Conclusion

Unscheduled interruptions, like machine breakdown and patient illness, make difficult to complete the treatment in an ideal time. Although our institution has a protocol to deal with these interruptions, from the results we can conclude that this protocol should be reviewed. Also, due to the machine overload, it is difficult to compensate these unscheduled interruptions for every patient. Therefore the best option could be to open the facility to treat patients on weekend days and public holidays to cope with predictable and unpredictable interruptions to normal treatment.

### PO-1014 Novel independent dosimetry audit based on end-to-end testing in proton beam therapy.

A. Carlino<sup>1</sup>, H. Palmans<sup>1,2</sup>, C. Gouldstone<sup>2</sup>, P. Trnkova<sup>3,4</sup>, S. Vatnitsky<sup>1</sup>, M. Stock<sup>1</sup>

<sup>1</sup>MedAustron Ion Therapy Center, Medical Physics, Wiener Neustadt, Austria; <sup>2</sup>National Physical Laboratory, Medical Physics, Teddington, United Kingdom; <sup>3</sup>Erasmus MC, Medical Physics, Rotterdam, The Netherlands; <sup>4</sup>HollandPTC, Medical Physics, Delft, The Netherlands

#### Purpose or Objective

The purpose of end-to-end testing (EZE) is to confirm that the entire logistic chain of a radiation treatment starting from CT imaging, treatment planning, patient positioning and verification and beam delivery is adequately implemented resulting in sufficient accuracy of planned dose delivery. A novel methodology for dosimetric EZE based on customized anthropomorphic phantoms using alanine dosimetry, ionization chambers and radiochromic films was established at a scanned proton therapy facility (called A here). Based on this methodology an independent dosimetry audit was developed and applied, for the first time, to a starting proton therapy facility (called B here) equipped with a scanned beam delivery system. We present results of both proton facilities including overall 4 different beam lines.

#### Material and Methods

A homogeneous polystyrene phantom and two anthropomorphic phantoms (pelvis and head phantom) have been customized to allocate different detectors such as radiochromic films, Farmer chamber and alanine pellets. During testing, the phantoms were moving through the workflow as real patients to simulate the entire clinical procedure. The CT scans were acquired with pre-defined scan protocols used at the A and B proton therapy facility for cranial and pelvic treatments. All treatment planning steps were performed with RayStation (RS) v6.1 and v7.0 TPS available respectively at A and B institute. A physical dose of 10 Gy was planned to clinically shaped target volumes in order to achieve reproducibility better than 0.5% on the dose delivered to the alanine pellets. In the treatment rooms the plans were delivered to the phantoms loaded either with alanine pellets and radiochromic EBT3 films or a Farmer chamber (figure 1). The alanine pellets (5.0 mm diameter and 2.4 mm thickness) and their read-out were provided by NPL. Corrections for the alanine “quenching” were derived by a Monte Carlo dose calculation platform implemented in a non-clinical version of RayStation.

Figure 1: EZE audit procedures with the head phantom. Left: the phantom loaded with Farmer chamber at the B proton therapy facility. Right: the phantom loaded with 22 alanine pellets and EBT3 films at the A proton therapy facility.

#### Results

The measured absolute dose to water obtained with the Farmer chamber in all delivered plans was within 2% of the TPS calculated dose. A maximum lateral homogeneity index of 3.5% inside the treatment field was measured with EBT3 films. Doses derived with the alanine pellets after correction for the quenching effect showed a mean deviation within 2% and a maximum deviation below 5% in the homogeneous and anthropomorphic phantoms (figure 2). Several audits are planned to be performed in the near future and more results coming from other proton therapy facilities may be available at the time of the presentation.

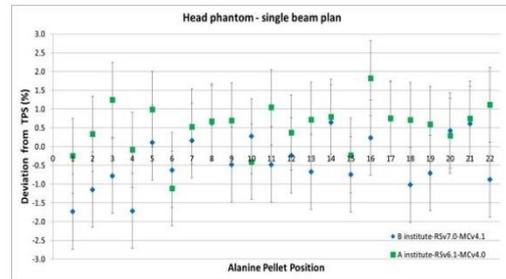

Figure 2: Relative differences between dose derived with alanine pellets and TPS planned dose for a single beam plan delivered to the head phantom. In blue symbols the comparison for the plan delivered at the B proton therapy center and in green symbols the comparison for the plan delivered at the A proton therapy center.

#### Conclusion

Our experience shows that alanine pellets are suitable detectors for dosimetric EZE test based audits and the developed procedures can be used to support implementation of upcoming new proton beam therapy facilities in Europe and may also serve as dosimetric credentialing for clinical trials in the future.

#### PO-1015 Design of 2.5 MeV electron beam applicator for < 5 mm thick superficial lesions

A. Valve<sup>1</sup>, H. Nurmi<sup>1</sup>, A. Kulmala<sup>1</sup>, S. Koskenmies<sup>2</sup>, M. Tenhunen<sup>1</sup>

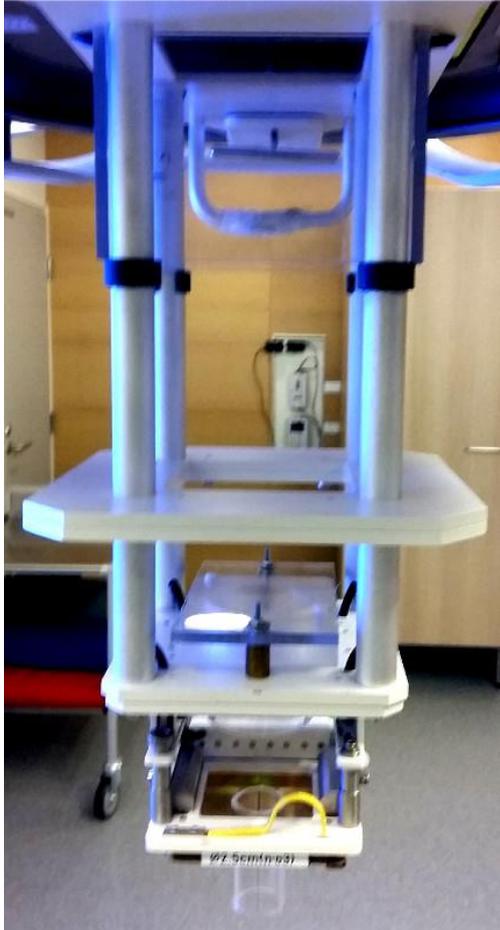

<sup>1</sup>Helsinki University Hospital, Cancer Center, Helsinki, Finland; <sup>2</sup>Helsinki University Hospital, Department of Dermatology, Helsinki, Finland

#### Purpose or Objective

Skin cancers are the most common of all malignant diseases. Many types of small cancerous skin lesions require only  $\leq 5$  mm treatment depth. Treating that kind of targets with any deeper penetration is unnecessary and may be harmful. We have modified a standard electron applicator to produce a set of well collimated circular fields, aiming nearly constant depth dose between 0 - 5 mm and a steep fall-off at depths  $> 6$  mm.

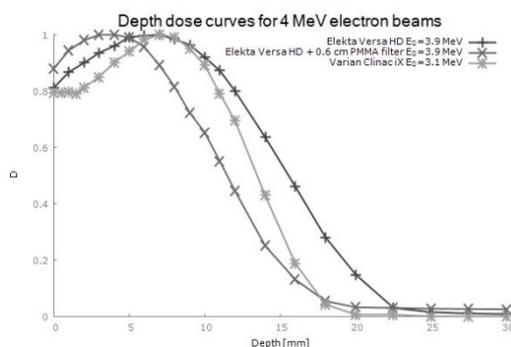

#### Material and Methods

The standard electron 6x6 cm square applicator of the Elekta Versa HD linear accelerator has been modified to reduce nominal 4 MeV electron beam suitable for the purpose. With a 6 mm thick polymethyl-metacrylate (plexiglas) filter slab bottom edge located 18.0 cm from the isocenter the energy was reduced from  $R50 = 1.8$  cm of the standard 4 MeV to  $R50 = 1.0$  cm. To achieve sharp edges the fields has been collimated with the plexiglas tubes from 2.5 to 5 cm inner diameters. In addition, lateral radiation through open sides of the applicator outside the field edges has been reduced with plexiglas plates. The final design of the applicator is presented in Fig 1.

## Results

With the modified applicator it is possible to achieve reasonably flat dose distribution in lateral and depth (< 6 mm) directions (Fig 2). After 6 mm depth there is a rapid dose fall-off with  $R50 = 1.0$  cm and  $R_p = 1.6$  cm. The penumbræ are sharp ( $\pm 6$  mm at depth of dose maximum). The energy filter plate reduces the dose output by a factor of 7.

## Conclusion

Our electron applicator has very favorable dose distribution characteristics for treating small superficial skin lesions, compared with either superficial x-ray devices or skin applicators of brachytherapy afterloaders. With x-rays < 100 kV tissues with higher density, like cartilage or bone, receive higher dose because of higher local absorption. Additionally, both x-rays and Ir-192 produce higher dose deeper than 5 mm in healthy tissue and higher dose inhomogeneity within the target depths  $\leq 5$  mm. Currently, we are initiating a clinical trial for testing the safety and efficacy of the new skin applicator.

## PO-1016 Segmentation of CT images with AI: compensating annotation uncertainties using contour augmentation

U. Javaid<sup>1</sup>, D. Dasnoy<sup>2</sup>, J. Lee<sup>1</sup>

<sup>1</sup>UCLouvain, IREC/MIRO, Brussels, Belgium ; <sup>2</sup>UCLouvain, ICTeam, Louvain-la-neuve, Belgium

### Purpose or Objective

Annotation of organs-at-risk (OARs) and target volumes (TVs) on CT scans is a key step in radiotherapy. Manual annotation is still in practice whereas to automate it, deep learning (DL) is currently being investigated. However, performance of DL networks (DLNs) depends highly on ground truth (GT) quality. For example, in radiotherapy, delineating TVs is of prime concern and proper care is taken while drawing them. OARs are not always a priority and sometimes roughly annotated. Rough annotation affects the predictive capabilities of DLNs in terms of organ localization. The network learning is thus sub-optimal, as it cannot improve over the given unique, possibly offset contour. Augmenting GT can address this issue. In this work, we propose **contour augmentation** to compensate the insufficient annotation quality by training a fully convolutional network (**dilated UNet**) with multiple GTs per image.

### Material and Methods

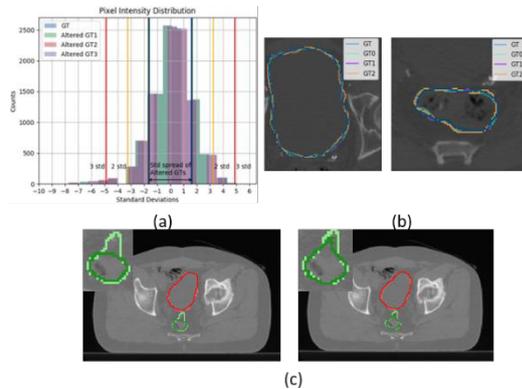

To address annotation uncertainties, we augment the input contours per image and produce multiple contours. Given a single GT, we apply random deformation within **4mm** to its x and y coordinates. A *Gaussian* smoothing is applied to smoothen the deformed contours to be qualitatively consistent with the original GT. Each deformed GT is considered as an additional GT. By incorporating multiple GT variations in the training phase, the model not only learns from a single ambiguous GT but from a sampled distribution of GTs, which can enhance its predictive capabilities, especially if some sampled GTs better correlate with features in the input image than the original GT. Our dataset consists of **pelvic** CT scans acquired from **67** patients (retrospective use). The CT images and their corresponding OAR annotations, in particular *bladder* and *rectum* were used for this study. We train our model on **1163** CT slices.

### Results

After training, our model is able to take into account the different variabilities in GT and thus is more robust to missing/wrong annotations as compared to a model trained with a single GT. In the example test case (Figure 1), we show that our model is able to correct the missing annotation. We report **Dice score**, **95th percentile Hausdorff distance** and **average symmetric surface distance** for bladder and rectum as  $0.91 \pm 0.12$  and  $0.89 \pm 0.09$ ,  $2.08 \pm 0.93$  and  $1.38 \pm 1.09$  mm,  $0.24 \pm 0.11$  and  $0.14 \pm 0.08$  mm respectively.

### Conclusion

We address insufficient annotation quality by augmenting the manual annotations in GT. We call it *contour augmentation*. The proposed framework enables the DLNs to capture variability in terms of localizing the organ boundaries, allowing to correct the missing annotations at inference time. Our framework offers good generalization ability as it can be trained on any semantic segmentation task. We believe that contour augmentation can lead to accurate organ localization as it can cope with the possible bias introduced by annotation uncertainty.

## PO-1017 Towards magnetically focused proton minibeam: investigating the limits of a clinical PBS nozzle

T. Schneider<sup>1</sup>, L. De Marzi<sup>2</sup>, A. Patriarca<sup>2</sup>, Y. Prezado<sup>1</sup>  
<sup>1</sup>Imagerie et Modélisation en Neurobiologie et Cancérologie IMNC, CNRS - Université Paris 11 - Université Paris 7, Orsay, France ; <sup>2</sup>Institut Curie - PSL Research University, Centre de Protonthérapie d'Orsay - Radiation Oncology Departmentn, Paris, France

### Purpose or Objective

Proton minibeam radiation therapy [1] is a novel and promising technique which already showed a remarkable widening of the therapeutic window for radioresistant tumours [2,3]. So far, this technique has been implemented at a clinical centre [4,5] by means of a multi-slit collimator. The goal of this work was to evaluate the feasibility of generating proton minibeam at a clinical beamline without the need of an external collimator. This would maximise the dose rate, reduce the neutron production and pave the way for 3D intensity-modulated treatment planning. The biological data obtained in recent experiments indicates that the tolerances of normal tissue can be increased when irradiated with narrower beams. In particular, in order to maximize the normal tissue sparing, beam widths narrower than 3 mm are preferred [2, 6]. However, in the current clinical configuration, the beam spot size at isocentre is 18 mm at 100 MeV and 10 mm at 200 MeV (values referring to the full width at half maximum [FWHM] of the lateral beam profile).

### Material and Methods

The Monte Carlo simulation toolkit TOPAS v.3.1.p02 [7] was used to model a complete pencil beam scanning nozzle (IBA Proteus PLUS) including the quadrupole and dipole magnets. The model was benchmarked against experimental data and the impact of different modifications of the beamline on the spot size and beam divergence was evaluated. Among others, the modifications included changing the magnetic field of the focusing elements, adding extra focusing magnets and reducing the distance between certain nozzle components.

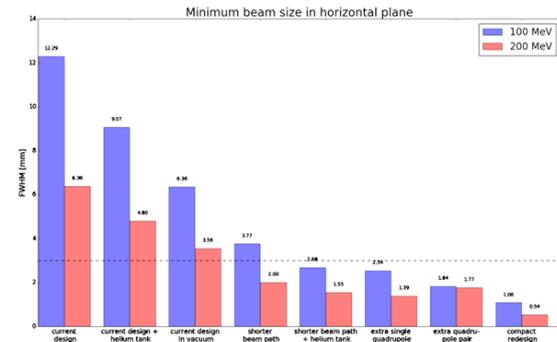

### Results

The limits of the current nozzle have been established: the beam widths cannot be made smaller than 12.3 mm at 100 MeV or 6.4 mm at 200 MeV by changing only the magnetic fields. The addition of extra focusing magnets at the exit of the nozzle allows to obtain widths as small as 1.8 mm at 100 MeV and 1.4 mm at 200 MeV. Furthermore, the reduction of nozzle dimensions, keeping only essential components allows to reach 1.1 mm at 100 MeV and 0.6 mm at 200 MeV.

### Conclusion

This is the first study evaluating a collimator-free generation of proton minibeam at a clinical centre. Our first results indicate that the implementation at current clinical beamlines will be challenging. However, we

propose different approaches that would enable the beam size reduction required to obtain proton minibeam.

## PO-1018 Current status of pediatric image-guided radiation therapy in Europe: An international survey

C. Windmeijer<sup>1</sup>, A. Bel<sup>1</sup>, R. De Jong<sup>1</sup>, B. Balgobind<sup>1</sup>, G. Collaboration<sup>2</sup>, C. Rasch<sup>1</sup>, I. Van Dijk<sup>1</sup>  
<sup>1</sup>Amsterdam UMC- location AMC, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>Participating institutions, Radiation Oncology, Various Europe, The Netherlands

### Purpose or Objective

Image-guided radiotherapy (IGRT) enables high precision tumor treatment while sparing healthy tissues. Particularly in pediatric radiotherapy the value of IGRT is widely acknowledged, but there is no consensus on the 'best practice'. With this survey we aim to evaluate clinical pediatric IGRT patterns in European radiotherapy institutes.

### Material and Methods

An eight-domain survey based on seven treatment sites was sent to members of the Pediatric Radiation Oncology Society and/or our IGRT project-based consortium in 70 European institutes. The domains include items on radiotherapy preparation, planning and delivery. Responses were collected from June-September 2018.

### Results

In total, 42/70 institutes (60%) responded; 33/42 (79%) treat children, one of which focuses exclusively on total body irradiation. The number of children treated annually varies between institutes and per site from 1 to 130 (Figure 1). Photon/electron therapy is used in 26/33 (79%) centers, and 3/33 (9%) use photon therapy only. Proton therapy (PT) is available in 5/33 (15%) institutes, whereas 7/28 (25%) of photon centers refer to proton centers; 2/33 (6%) use both photon and proton therapy. To immobilize patients, facial masks are used in 100% of brain, craniospinal axis (CSA) and head-and-neck (H&N) radiotherapy (all devices in Table 1). Most institutes (89% (thorax), 93% (abdomen), 96% (extremities) and 100% for other sites) use 3DCT scans to define the treatment target. Also MRI (range, 79% for thorax to 97% for brain), PET (range, 21% for CSA to 79% for H&N), and, for thorax and abdomen, 4DCT scans (by respectively 43% and 31% of institutes) are used. IMRT/VMAT is the most common treatment technique (range, 71% for CSA to 87% for brain), followed by 3DCRT (range, 36% for H&N to 69% for

extremities). Averaged over all sites, 3D conformal PT is used in 60% and IMPT in 80% of the proton centers. Averaged over all enquired indications, 70% of institutes follow (inter)national clinical treatment protocols, although varying protocols are used depending on indication and institute. Most institutes treat patients in supine position (range, 82% for CSA to 94% for brain). Regarding image guidance during treatment delivery, in-room 3D CBCT (kV) is used most frequently (range, 57% for CSA to 86% for thorax, Table 1). Daily online imaging is used by the majority (range, 85% for extremities to 90% for abdomen and pelvis), and offline imaging protocols (eNAL) are used by 14% (H&N) to 21% (thorax) of institutes.

Figure 1. Estimated number of patients treated annually across participating institutions, per treatment site.

Abbreviations: CSA, craniospinal axis; H&N, head and neck; 3DCT, 3D Computed Tomography; IMRT, Intensity Modulated Radiotherapy; VMAT, Volumetric Arc Therapy; IMPT, Intensity Modulated Proton Therapy; IGRT, Image-Guided Radiotherapy; EPID, Electronic Portal Imaging Device; CBCT, cone-beam CT; MR, Magnetic Resonance; NAL, non-action level; eNAL, extended non-action level; SAL, shrinking action level

## Conclusion

Our results show moderate agreement in clinical pediatric IGRT use in European institutes. The findings from this survey can help to define internationally acceptable standard quality criteria for 'best practice' guidelines for pediatric IGRT.

**PO-1019 The elephant plot: Differentiating between early recurrence and Benign Lung Injury after SABR**  
**I. Phillips<sup>1</sup>, H. Wang<sup>2</sup>, P. Evans<sup>2</sup>, V. Ezhil<sup>3</sup>, H. Saxby<sup>3</sup>, C. South<sup>3</sup>, M. Hussein<sup>4</sup>, A. Nisbet<sup>3</sup>, S. Alobaidli<sup>5</sup>, E. Chandry<sup>3</sup>**  
<sup>1</sup>Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom; <sup>2</sup>University of Surrey, Centre for Vision- Speech and Signal Processing, Guildford, United Kingdom; <sup>3</sup>Royal Surrey County Hospital, St Lukes Cancer Centre, Guildford, United Kingdom; <sup>4</sup>National Physical Laboratory, Medical Radiation Physics, Teddington, United Kingdom; <sup>5</sup>Kuwait Cancer Control Centre, Radiotherapy Physics, Kuwait City, Kuwait

## Purpose or Objective

SABR (Stereotactic Ablative Body Radiotherapy) is an effective radiotherapy treatment for early stage lung tumours. Differentiating between the morphology of early recurrent/residual tumour and radiation induced lung injury (RILI) after SABR is challenging using both CT and PET-CT imaging. In this study we investigated whether CT

textural analysis of the whole lung can help differentiate between tumour and RILI after SABR.

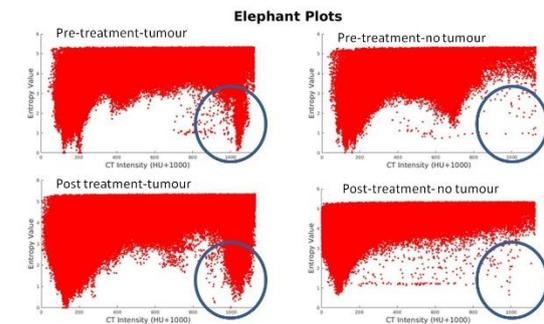

## Material and Methods

We compared the 6 month post SABR single phase CT scan of 25 patients (who had not recurred at 2 years), with 4 patients who had PET-CT proven recurrence 6 months after treatment.

The ipsilateral lung was segmented on the CT scan. A Grey Level Co-occurrence matrix (GLCM) for each lung containing tumour was created. Each voxel had a density and an entropy score assigned relative to the neighbouring 26 voxels. Previously we showed that a 2D data plot of each voxel (density vs entropy) showed an 'elephant plot' with the tumour corresponding to the elephant 'trunk' when comparing the lung ipsilateral to tumour with the contra-lateral lung. We performed a sub-region analysis on the elephant trunks, which included those voxels, which had a high density, but low entropy score. We performed 4 sub-analyses using different density and entropy thresholds, to include different parts of the elephant trunk.

## Results

The most statistically significant differences were found using an entropy score of 2 or less and density (HU) of 0-150. P values for Mann-Whitney test comparing recurrence vs non-recurrence was: number of voxels in sub-ROI (p=0.007) and Entropy Standard Deviation (p=0.048).

## Conclusion

CT texture analysis may be useful as a cost effective means of differentiating between tumour and RILI after SABR. This technique provides a promising model to track changes in lung parenchyma in malignant or benign lung disease. However, further validation in a prospective trial on a larger cohort of patients is required.

## Purpose or Objective

Multi-Institutional dosimetric projects allow to share knowledges and to ensure adequate quality of practice

and treatment delivery; the Sicily Dosimetric Project was born with this aim, using an approach very similar to external audits procedure.

#### Material and Methods

Thirteen centers from Sicily with a good experience in lung IMRT/VMAT treatments and with a great heterogeneity in terms of technologies, have participated to the project. In the first step, shared CT images (with CT calibration curve), with Target and OARs defined for a thorax anthropomorphic phantom, have been used to perform a treatment plan using 6MV energy beam with a prescription dose of 66 Gy in 33 fractions. Imposed planning constraints have been: at least 98% of the PTV received 95% of the prescribed dose and 2% of the PTV received 107% as maximum value; Heart,  $V_{25Gy} < 10\%$ ,  $D_{average} < 26Gy$ ; Lungs ((Dx+Sx)-GTV):  $V_{20Gy} \leq 30\%$ ;  $V_{5Gy} \leq 65\%$ ;  $D_{average} \leq 20Gy$ . Dosimetric analysis of treatment plans have been performed considering cumulative DVH curves for PTV and OARs. In the second step, OSL detectors, commissioned and analyzed from a pilot center, have been used. Preliminary measurements have been performed using RW3 slab phantom ( $30 \times 30 \times 10 \text{ cm}^3$ ) and reference conditions. One OSLD, allocated in apposite slab, situated at depth of 5 cm, has been irradiated at 2 Gy dose, with  $10 \times 10 \text{ cm}^2$  field and using SAD set up; the average over three measurements has been compared with expected dose. Verification plans have been generated and delivered in the same RW3 slab phantom using both ionization chamber and OSL dosimeters (repeating measurements three times). Finally, treatment plans have been delivered on the anthropomorphic phantom with end-to-end approach and OSLD allocated in the apposite inserts. Dose has been verified in three points: PTV, Heart and Mediastinum. To check the positioning of the phantom, CBCT, MV or kV, have been used. The anthropomorphic phantom without OSLDs inside has been resealed over the couch 5 times and the average positions for all directions, longitudinal, vertical and lateral, have been taken into account to obtain corrected dose values from TPS.

#### Results

Results related to the first step of the project satisfy imposed constraints by most of all centers; mean values for PTV:  $D_{98\%} = 63,50Gy$  (61,25-65,83),  $D_{2\%} = 69,18Gy$  (67,10-70,85); Heart:  $V_{25Gy} = 9,33\%$  (7,60%-11,65%),  $D_{average} = 9,87Gy$  (8,45-11,45); Lungs:  $V_{20Gy} = 22,74\%$  (18,50-27,90),  $V_{5Gy} = 51,39\%$  (39,48-58,28),  $D_{average} = 12,77Gy$  (10,71-14,80). Results related to the second step of the project are showed in Tab.1. Fig.1 shows the correlation between algorithms involved in the project and final results related to the anthropomorphic phantom; as it is expected Monte Carlo based algorithms give better results respect to CCC and AAA algorithms.

Center	RW3 Slab Phantom			Anthropomorphic Phantom		
	2Gy Ref. Cond. (OSLD)	IC	OSLD	Mediastinum (OSLD)	PTV (OSLD)	Heart (OSLD)
1	1,02	1,00	0,98	0,98	1,05	0,90

#### Purpose or Objective

Real-time soft-tissue image guidance is a desirable concept to improve the targeting precision of proton therapy. In 2017, the first prototype of an MR-integrated proton therapy setup was realised at our horizontal fixed research beamline. Moving towards a clinical application this *in-beam* MRI system shall be transferred to a pencil beam scanning (PBS) research beamline that provides volumetric dose spot delivery. A magnetic survey was performed to quantify the effects of beamline and scanning magnets on the environmental magnetic field.

#### Material and Methods

The magnetic fringe field at the PBS nozzle was measured by a tri-axial Hall-probe magnetometer (THM 1176-LF, Metrolab) at two positions: (P1) at a lateral position 700 mm from the center of the scanning magnets, and (P2) at the planned magnetic isocenter of the *in-beam* MR

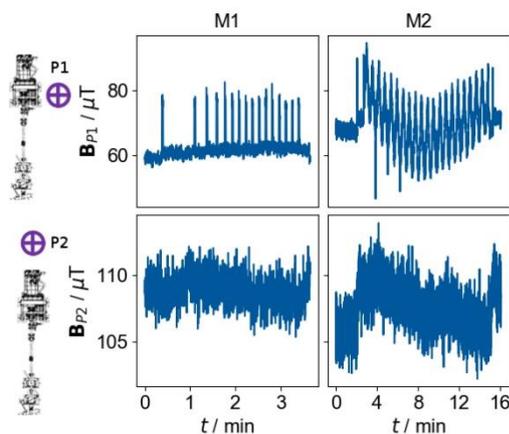

scanner, which is 2270 mm downstream from the last scanning magnet on the beam central axis. Measurement point P1 was chosen to be able to differentiate between magnetic field changes due to energizing the beamline (quadrupole) and the scanning (dipole) magnets. Two maps of PBS spots were delivered by the PBS nozzle: (M1) consisted of 16 energy layers ranging from 70 to 230 MeV (steps of 10 MeV) with a single central spot for each layer, and (M2) used a single energy of 200 MeV with a field size of (200 x 200) mm<sup>2</sup> and a step width of 5 mm, resulting in 41 x 41 spots. The magnets were energized to deliver maps M1 and M2 to study the magnetic field effects of changing beam energies and changing spot positions, respectively, but no beam was transported for radiation protection of the sensitive Hall-probe. All 3 magnetic field components were logged during spot map scanning by Labview-based software (THM1176 v4.0, Metrolab) at a sample frequency of 10 Hz.

### Results

For position P1, the magnetic field changes due to setting the beamline magnets to the 16 energy levels, as well as operating the scanning magnets to the 41 spot rows can be clearly observed (Fig. 1), with maximum amplitudes  $|\Delta B_{\max}|$  of up to 28.6  $\mu\text{T}$  and 55.3  $\mu\text{T}$ , for maps M1 and M2, respectively. For position P2, the  $|\Delta B_{\max}|$  was 9.0  $\mu\text{T}$  and 10.1  $\mu\text{T}$  for M1 and M2, respectively. This translates into an off-resonance frequency shift of 383.4 Hz and 430.3 Hz for <sup>1</sup>H-MR imaging, respectively.

### Conclusion

Significant changes in the environmental magnetic fringe field of a proton PBS beamline are measurable due to the operation of its beamline and scanning magnets. These changes translate into off-resonance frequency shifts that could cause significant MR image shifts in the frequency encoding direction. This needs to be confirmed by magnetic field mapping around the magnetic isocenter of the MRI scanner once it has been installed at the PBS nozzle. To counteract this effect, either the image shifts need to be compensated for or the PBS nozzle needs to be magnetically shielded from the MRI scanner.

**Figure 1:** Schematic representation of PBS beamline with measurement positions P1 and P2 (left). Amplitude of magnetic fringe field measured during delivery of maps M1 and M2 at positions P1 (top row) and P2 (bottom row).

### PO-1022 A study on the image registration accuracy of intrafraction cone beam computed tomography images

S. Arumugam<sup>1</sup>  
<sup>1</sup>Liverpool and Macarthur cancer therapy centres-  
 Liverpool Hospital, Department of Medical Physics,  
 Liverpool, Australia

#### Purpose or Objective

Intrafraction (IF) cone beam computed tomography (CBCT) image acquisition procedure allows the CBCT image acquisition during treatment delivery and has the

potential to improve the treatment efficiency. However the quality of IF-CBCT images may be degraded due to scatter from treatment beam. The purpose of this study is to investigate the change in image quality between CBCT and IF-CBCT images and its impact on image registration accuracy.

#### Material and Methods

An Elekta linear accelerator with XVI imaging system (Elekta Limited, Crawley, UK) was used for this study. The image quality that resulting from Head and Neck (H&N), Lung and Spine pre-treatment and IF CBCT presets were quantified by imaging a Catphan-503 phantom (The Phantom Laboratory Inc, NY, USA). The IF-CBCT images were acquired with the delivery of both 6MV and 10 MV FFF VMAT arc of hypofractionated treatment plans. The number of projection images acquired for both CBCT and IF-CBCT are maintained constant for respective treatment site specific presets. The image quality metrics such as uniformity, low contrast visibility, spatial resolution and image geometry in horizontal, vertical and longitudinal directions were studied to characterise the quality of CBCT image data. To study the accuracy of image registration, the CBCT and IF-CBCT image data of H&N, lung and lumbar spine region of an anthropomorphic phantom were acquired and registered with the respective reference planning CT data. The baseline registration error for each treatment site was quantified by registering pre-treatment CBCT with respective reference CT using grey value registration. The image registration error resulting from 6D position offsets, ranging from 3mm to 10mm in translation and 0° to 3° in rotation, of the IF-CBCT data was studied with both bone and grey value registration methods available in XVI system to study the registration accuracy with IF-CBCT images.

#### Results

Table 1 shows the Catphan image quality results for both CBCT and IF CBCT imaging. The image uniformity, low contrast visibility and spatial resolution of the IF-CBCT images are relatively degraded compared to pre-treatment CBCT images. The geometry of both CBCT and IF-CBCT images are within  $\pm 0.5$  mm of the expected values. The image registration results of IF-CBCT images agreed within  $\pm 0.5$ mm and  $\pm 0.5^\circ$  in translation and rotation directions compared to baseline error with both bone and grey value registration for studied treatment sites.

**Table 1:** Image quality metrics and CBCT and IF CBCT images if Catphan 503

Imaging mode	Uniformity (%)	Low contrast visibility (%)	Spatial resolution (lp/cm)	Geometry agreement (mm)
CBCT	1.9(0.5)	2.4(0.6)	3(1)	0.1(0.2)
IF-CBCT	4.0(0.7)	3.6(1.7)	3(0)	0.1(0.3)

#### Conclusion

The registration accuracy of IF-CBCT images are not affected by its degraded image quality and it deemed clinically useful for the studied anatomical sites and registration methods.

**PO-1023 Continuous Positive Airway Pressure for respiratory gating in lymphomas: a workflow analysis**  
 F. Giglioli<sup>1</sup>, E. Gallio<sup>1</sup>, M. Levis<sup>2</sup>, P. Solidoro<sup>3</sup>, C. Fiandra<sup>2</sup>, S. Bartoncini<sup>2</sup>, V. De Luca<sup>2</sup>, C. Cavallin<sup>2</sup>, G. Iorio<sup>2</sup>, R. Parise<sup>2</sup>, G. Furfaro<sup>2</sup>, U. Ricardi<sup>2</sup>  
<sup>1</sup>A.O.U. Città della Salute e della Scienza di Torino, Medical Physics, Torino, Italy; <sup>2</sup>University of Turin, Radiation Oncology- Department of Oncology-, torino, Italy; <sup>3</sup>A.O.U. Città della Salute e della Scienza di Torino, Division of Pulmonology, Torino, Italy

### Purpose or Objective

Continuous positive airway pressure (CPAP) is a form of positive airway pressure ventilator, which applies mild air pressure on a continuous basis and has long been safely used in patients with obstructive sleep apnea to maintain airway patency. The aim of this study is to determine the efficacy of CPAP on lung volume and respiratory management in patients treated for Hodgkin and primary mediastinal lymphoma.

### Material and Methods

The CPAP consists in a small air pump, tubing, and facemask, providing a constant stream of pressurized air to the lungs. Some effects expected during CPAP are hyperinflation of the lungs, stabilization and flattening of the diaphragm. The CPAP pressure used for each patient was selected as 18 cm H<sub>2</sub>O; two CT were performed: one in the free breathing condition (FB) and the other with the CPAP. The patients were trained for wearing the mask before the CT mainly to test the compliance with the system. 4DCT was accepted if the percent variation of the phase amplitude was < 0.25. Median prescription dose to the PTV was 30 Gy in 2-Gy fractions and Lungs, female breasts, heart and cardiac structures (coronary arteries, valves, atria and ventricles) were all contoured as organs at risk. Planning were performed with Monaco tps ver. 5.1; CPAP series were planned comparing a full arc (FA) plus an anterior non coplanar one in a sagittal plan with a butterfly geometry (BF). The best plan between the two solutions was selected and replanned in FB condition. The final plan was then chosen by the physician based on the OARs doses. The intersection between PTV and the Heart was evaluated as a measure of the "stretching" of the organs in case of CPAP. The treatment was performed with an Elekta Synergy and a Cone Beam CT (CBCT) was acquired before each session. To check the Lungs filling, the CBCT were analyzed in terms of measured volume displayed in the CT field of view of the fifteen days of treatment.

### Results

24 patients were recruited; 22/24 (92%) were treated with the CPAP system. The mean percent standard deviation of the amplitude was 0.19 (sd 0.08) compared to 0.21 (sd 0.11) of the 4DCT population. CPAP increased mean lungs volume (4.21 vs 2.71, p<0.001) and the mean volume difference was 1498 (sd 417) cc. The intersection between PTV and the hearts was 12 (sd 24) cc for CPAP and 27 (sd 29) for FB (p<0.01). The plans selected were 58% FA and 42% BF. The use of CPAP resulted in lower doses for all the cardiac structures (p<0.01). The variation of the volume of the lungs measured in all the CBCT was < 4,5%.

### Conclusion

CPAP has demonstrated to be a useful method for respiratory management; the analysis of the amplitude of the 4DCT revealed an equal or minor lungs movement respect to the 4DCT patients population. The analysis of CBCT demonstrated that CPAP is a constant and reproducible way to fill the lungs. Effort has to be made in finding some geometric parameters to prospectively select patients benefiting the use of CPAP by analyzing the CT.

### PO-1024 Solutions for MR-based RT planning with an open low field scanner using neural network tools

L. Fetty<sup>1</sup>, M. Buschmann<sup>1</sup>, G. Heilemann<sup>1</sup>, P. Kuess<sup>1</sup>, T. Nyholm<sup>2</sup>, H. Herrmann<sup>3</sup>, D. Georg<sup>1</sup>, N. Nesvacil<sup>1</sup>  
<sup>1</sup>Medical University of Vienna, Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria ; <sup>2</sup>Umeå University, Department of Radiation Sciences, Umeå, Sweden ; <sup>3</sup>Medical University of Vienna, Department of Radiotherapy, Vienna, Austria

### Purpose or Objective

In radiation oncology CT information is essential for TPS dose calculation whereas MRI is utilized to increase the delineation accuracy. In the past years multiple methods were developed to create synthetic CT (sCT) information from MR images directly, and are starting to be implemented in pilot studies on MRgRT. However, limited FOV can truncate the patient's body contour, which is required for calculating the dose deposition from the skin border to the target region. The use of small FOV scanners e.g. 0.35T open MR, thus are posing new challenges in the field of MR-only planning. The aim of this project was to develop (1) an MRI-acquisition and post-processing protocol to overcome scanner limitations, (2) an MR-only RT workflow for our department and (3) auxiliary software to implement conversion in this setting.

### Material and Methods

An MRI-only workflow for combining multiple laterally shifted MR scans and a conversion technique were designed and tested for the 0.35T MAGNETOM C! open-MR scanner (Siemens, Erlangen) with a maximum FOV of 400mm. The lateral table movement of the open-MR was used to position the patient twice off-isocenter to ensure the coverage of the complete body contour. A third sequence was acquired in the central position for delineation purposes. In a post processing step the two off-center images were stitched and further resampled to the single acquisition MRI to provide a full body contour. For sCT conversion a neural network was trained with about 2000 transversal 2D pelvis images. The workflow is illustrated in figure1.

The stitching protocol was tested for four prostate carcinoma patients treated with a VMAT technique. The sCT of the stitched volume was compared to the planning CT. Dose distribution comparisons was performed for the rigidly (rCT), deformed registered (dCT) corresponding CT and the sCT.

**Results**  
 Dice coefficient were 92% for left and right femoral bone and above 99% for the whole body between MR and sCT. The gamma analysis (2mm/2%) resulted in a 99.9% and 94.9% average pass rate for the dCT and rCT in the outer body contour, respectively. The dCT showed a dosimetric error below 1% in the target region where the rCT showed an increased error in the low dose region (D98%) of the target (as illustrated in table 1). The biggest uncertainty (D2% above 6%) was observed in the rectum for the rCT which was below 1.5% for the dCT.

Table 1: Dose comparison in percentage of PTV, femoral heads, bladder, rectum and the whole body.

		deformed CT		rigid CT	
		Mean [%]	SD [%]	Mean [%]	SD [%]
PTV	D2%	-0.9	0.4	-0.1	0.4
	D50%	-0.8	0.3	0.2	0.6
	D98%	0.2	0.9	4.4	4.0
femoral head right	D2%	-0.3	0.2	-0.3	0.4
	D50%	-0.4	0.2	-0.4	0.8
femoral head left	D2%	-0.5	0.3	-0.2	0.3
	D50%	-0.3	0.1	0.1	1.0
bladder	D2%	-2.0	0.4	-1.1	0.8
	D50%	-0.3	0.5	-0.1	0.2
	V70Gy	-0.7	0.7	-0.3	0.4
rectum	D2%	1.2	1.8	6.0	3.3
	D50%	-0.8	0.8	-1.6	1.0
	V70Gy	0.2	0.4	1.5	0.8
whole body	D10%	-0.3	0.1	-0.6	0.2
	D50%	-0.0	0.0	0.0	0.0
	D90%	0.0	0.0	0.0	0.0

### Conclusion

This study shows the potential of clinically implementing sCTs generated from a low-field open MR for patients with body contours larger than the single scan FOV. The lateral table movement is a benefit of the open-MR compared to most diagnostic scanners. The method could help overcome dosimetric uncertainties due to geometric distortions at the FOV borders. The dosimetric analysis showed comparable accuracy with published results of alternative methods for dose parameters and gamma analysis.

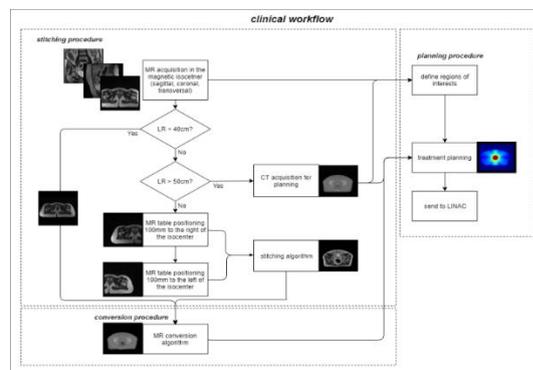

Figure 1: MR-only workflow description for the open 0.35T MR scanner

## PO-1025 The impact of dose to medium on the results of a national spine SBRT dosimetry audit

J. Lee<sup>1</sup>, R. Patel<sup>1</sup>, D. Eaton<sup>2</sup>, C. Clark<sup>3</sup>

<sup>1</sup>Mount Vernon Cancer Centre, National Radiotherapy Trials QA, Northwood, United Kingdom ; <sup>2</sup>Guy's Cancer Centre, Physics Department, London, United Kingdom ; <sup>3</sup>National Physical Laboratory, Teddington, London, United Kingdom

### Purpose or Objective

This national audit was carried out to verify the dosimetric and positional accuracy of spine SBRT treatment across a range of modalities and algorithm types. We investigated the impact of different algorithms for the calculation of dose in and around bone using film, Microdiamond (MD) and alanine dosimetry.

### Material and Methods

A modified CIRS E2E phantom was used; metal pins facilitated submillimetre registration between EBT3 GafChromic film and calculated dose grid. Bone and tissue equivalent alanine holders were used. The geometry of the detectors and target volumes is shown in figure 1. Centres were provided with a delineated CT dataset. Centres added their clinically used PTV and cord PRV margins. Planning constraints were prescription dose of 27Gy/3# to cover  $\geq 95\%$  of PTV, cord PRV  $D_{0.1cc} < 21.8\text{Gy}/3\#$  and cord  $D_{0.1cc} < 18\text{Gy}/3\#$ . Each centre scanned the phantom and re-calculated their optimised plan on their CT dataset with all locally available algorithm types; being of dose to medium (Dm,m), dose to water (Dw,w) and dose to water in a medium (Dw,m).

FilmQAPro software was used for analysis. Maximum distance-to-agreement (DTA) for the cord constraints and prescription isodoses were measured. The average dose to small areas-of-interest (AOIs)  $\sim 9\text{mm}^2$  at positions corresponding to the small volume dose detectors were also compared.

The Wilcoxon Signed Rank test was used to assess the difference between Dm,m and Dw,m algorithms.

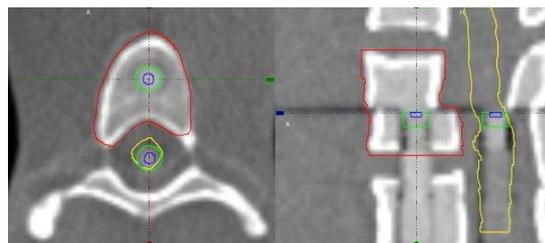

Figure 1. The geometry of the CTV (red), cord (yellow), alanine pellet (green), Microdiamond detector (blue). The film is inserted axially into the phantom 1mm superior of the alanine and MD detector. The small AOI film regions are at the same axial position as the MD detector and 1mm superior.

### Results

Measurements were made at 16 centres (1 Tomotherapy, 4 Cyberknife, 11 linac) which were treating SBRT spine routinely. Centres used PRV margins of 2mm and PTV margins of 2-3mm.

All centres achieved a DTA of  $\leq 2\text{mm}$  for the cord constraint isodose lines. The maximum distances between measured and calculated prescription isodoses was  $-2\text{mm}$  and  $+6\text{mm}$  (negative sign implying lower target coverage than planned). There was no significant correlation with algorithm type.

Small volume dose measurement results in the vertebra and cord for the different detectors and algorithms are shown in table 1. Particularly in the cord, differences between measured and calculated doses are higher than those normally reported in dosimetry audits, reflecting the contribution of the steep dose gradients in SBRT plans. For all plans, doses calculated in the vertebra with Dm,m were lower at all detector points than with Dw,m (average difference being 4.6% for MD, 4.0% for alanine, 3.4% for film,  $p=0.04$ ).

For all plans, Dm,m calculated cord doses were also lower than the Dw,m doses (average 0.9% for MD ( $p=0.08$ ), 0.7% for alanine ( $p=0.08$ ), 1.3% for film ( $p=0.04$ )).

	Dm,m (Acuros, MC), n=6	Dw,w (AAA, CC, Raytracing), n=14	Dw,m (Acuros, MC), n=5
Isodose DTA (mm)	average (min, max)	average (min, max)	average (min, max)
18Gy/3#	0.7 (-1.0, 2.0)	0.4 (-2.0, 1.5)	0.7 (-0.5, 2.0)
21.8Gy/3#	0.6 (-1.0, 1.5)	0.2 (-2.0, 1.5)	0.7 (-0.5, 1.5)
27Gy/3#	3.0 (1.5, 6.0)	1.5 (-2.0, 5.5)	2.6 (2.0, 3.0)
Film 9mm <sup>2</sup> area	average (min, max)	average (min, max)	average (min, max)
Vertebra (%)	5.0 (1.3, 9.6)	4.1 (-8.3, 10.3)	0.9 (-2.2, 6.1)
Cord VOI (%)	10.3 (4.8, 18.1)	4.6 (-19.9, 22.6)	7.8 (-5.6, 18.3)
Microdiamond	average (min, max)	average (min, max)	average (min, max)
Vertebra (%)	5.3 (1.1, 8.2)	3.9 (0.0, 9.0)	0.5 (-2.4, 3.4)
Cord VOI (%)	8.2 (0.1, 32.9)	-0.3 (-10.5, 12.5)	2.3 (-1.3, 8.5)
Alanine	average (min, max)	average (min, max)	average (min, max)
Vertebra (%)	4.2 (-1.0, 8.5)	2.4 (-1.4, 4.2)	1.3 (-2.1, 4.5)
Cord VOI (%)	9.7 (2.3, 35.1)	0.8 (-8.6, 8.2)	3.9 (-3.3, 8.7)

Table 1. Results of the isodose maximum distance-to-agreement, film small area-of-interest and MD and alanine dose comparisons. Positive values indicate measurements higher than calculated.

### Conclusion

The audit gathered evidence of safe implementation of spine SBRT; irrespective of algorithm type, all centres safely protected the cord and sufficiently covered the CTV with the prescription dose. Changing from Dm,m to Dw,m algorithms improved the agreement of point doses within vertebra and cord. This is assumed to be due to the water equivalence and calibration of the detectors.

## PO-1026 Evaluation of a microdiamond detector for a national spine SBRT end to end dosimetry audit

R. Patel<sup>1</sup>, J. Lee<sup>1</sup>, D. Eaton<sup>2</sup>, C. Clark<sup>3</sup>

<sup>1</sup>Mount Vernon Hospital, Radiotherapy RTTQA, Northwood Middlesex, United Kingdom ; <sup>2</sup>Guy's Cancer Centre, Radiotherapy, London, United Kingdom ; <sup>3</sup>Royal Surrey County Hospital, Radiotherapy, Guildford, United Kingdom

### Purpose or Objective

A national end to end audit of 16 centres (1 Tomotherapy, 4 Cyberknife, 7 Varian Linacs & 4 Elekta Linacs) was completed to assess the dosimetric accuracy of spinal SBRT. Spine SBRT plans are amongst the most complex currently delivered and the audit assessed the accuracy of treatment delivery by centres using a wide variety of equipment combinations. The audit utilised a microdiamond detector in addition to alanine and Gafchromic film. The results of the audit were analysed to determine the suitability of the microdiamond detector for future audits.

### Material and Methods

The audit required participating centres to deliver a clinically acceptable plan to an anthropomorphic spine phantom. Cyberknife centres had beam angles limited by  $40^\circ$  superiorly and  $20^\circ$  inferiorly from coplanar. Phantom alignment matched clinical practice for SBRT at each centre. Basic outputs were acquired in reference conditions using a PTW 0.125cc chamber and the microdiamond detector, with an additional output at the end of the audit to assess drift of the microdiamond detector. Delivered dose was measured at points in the

PTV vertebra and spinal cord, these measurements were compared with expected values from the TPS. Point doses were measured using alanine and the microdiamond detector. Detector output corrections were used for each centre based on measurements at standard output conditions. Centres also recalculated plans using all commissioned planning algorithms available on their TPS.

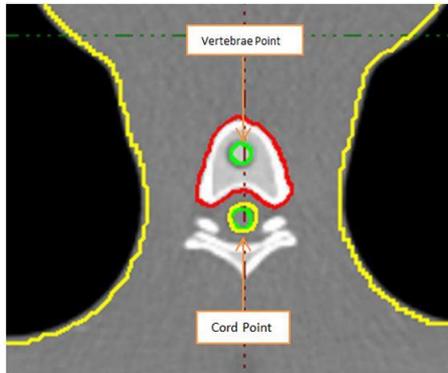

Figure 1 A CT image of the audit phantom with CTV (Red), Spinal Cord (yellow), Lungs (yellow) and measurement points (green) delineated

## Results

The output of the microdiamond detector had a mean deviation from the PTW 0.125cc chamber of 0.13% (S.D. 0.48%,  $P = 0.301$ ) at reference conditions for the 16 centres. The mean difference between outputs measured at the start and end of each audit visit was 0.07% (S.D. 0.32%,  $P = 0.929$ ).  $P$  values were calculated using a Wilcoxon sign rank test.

Results of the phantom measurement are given in Table 1. No significant difference was noted between the different detectors using a Wilcoxon sign rank test ( $P=0.926$ ). All linac treatments utilised coplanar VMAT delivery, while Cyberknife treatments utilised non-coplanar delivery.

Measurement Point	Delivery Equipment	No. Centres	Microdiamond Detector		Alanine	
			Mean Difference from TPS (%)	S.D. (%)	Mean Difference from TPS (%)	S.D. (%)
PTV Vertebra	Tomotherapy	1	5.8	-	1.8	-
	Cyberknife	4	3.2	1.5	0.7	1.7
	Varian	13	3.9	2.9	3.3	1.6
	Elekta	6	2.5	3.5	2.2	3.9
	All	24	3.5	2.8	2.6	2.5
Spinal Cord	Tomotherapy	1	-10.5	-	-8.6	-
	Cyberknife	4	-2.2	2.9	1.4	3.2
	Varian	13	2.3	5.9	2.2	5.1
	Elekta	6	8.6	12.2	11.3	12.3
	All	24	2.4	8.4	3.7	8.3

Table 1 Audit Results: The mean difference from TPS predicted values for the Microdiamond and Alanine phantom measurements, results are separated between the different delivery equipment.

## Conclusion

The results of the output measurements have shown that the microdiamond detector is consistent with the PTW 0.125cc chamber when measuring absolute dose. No drift was seen over the duration of any individual audits or the entire audit programme for the microdiamond detector. When measuring point doses during treatment delivery, the microdiamond detector was able to accurately measure dose independent of treatment equipment for both coplanar and non-coplanar delivery. The results were comparable with measurements with alanine, which has been widely used in national audit programmes. The results of this audit show that the microdiamond detector is suitable for future use in complex dosimetry audit, although further work is required to assess the long term stability of the detector and frequency of recalibration required.

## PO-1027 IMRT in breath hold for left breast cancer patients: surface tracking and clinical implementation

M. Cardoso<sup>1,2</sup>, S. Vieira<sup>1</sup>, A. Martins<sup>1</sup>, A. Soares<sup>1,2</sup>, M. Possanzini<sup>1,3</sup>, J. Morales<sup>1</sup>, C. Greco<sup>1</sup>  
<sup>1</sup>Champalimaud Foundation, Radiotherapy, Lisboa, Portugal ; <sup>2</sup>Mercurius Health, Radiotherapy, Lisboa,

Portugal ; <sup>3</sup>A.O. "G. Brotzu", Radiation Oncology, Cagliari, Italy

## Purpose or Objective

Deep inspiration breath hold (DIBH) for left breast cancer radiotherapy has shown beneficial dosimetric results on cardiac dose. Recently, DIBH was clinically implemented in our department for these cancer patients without lymph node (LN) involvement. This study reports on: a) validation of the optical surface tracking system used; b) aspects of treatment delivery with IMRT in DIBH.

## Material and Methods

We evaluated the static and dynamic performances of optical surface monitoring system (OSMS, Varian), which monitors patient surface, using a thorax phantom that can move periodically. To test system stability the phantom was continuously monitored during 90 minutes. Ten OSMS readings of the phantom position were done to test reproducibility. To evaluate the static accuracy, translational shifts from 1 to 20mm were manually applied to the couch and compared to OSMS shift readings. Dynamic tracking was analyzed, by comparing phantom surface markers position with pre-defined thresholds. Coincidence between linac beam hold signals, measured with an oscilloscope, marker positions and OSMS hold status, was analyzed.

Nineteen left breast patients were planned with IMRT (15 fractions, 2.7Gy to the whole breast with an integrated boost of 3.2Gy). CT scans were performed in free breathing (FB) and breath hold (BH) for each patient (fig1a) and contours were delineated in both by the radiation oncologist (RO). Similar plans were performed in Eclipse (Varian), with the same dose tolerances (fig1b). Doses to breast PTV, PTV and CTV boost, heart, left descending artery (LAD), right breast, right and left lung were analysed. The final delivery plan was chosen by RO. Before delivery a CBCT in FB was first acquired to verify patient position and a partial CBCT to evaluate BH. A beam hold threshold of 3mm was used for the OSMS (fig1c), given our CTV-PTV margin of 3mm. After delivery, a CBCT in BH was acquired.

Fig1. - Analysis of breath hold and imaging process for one patient.

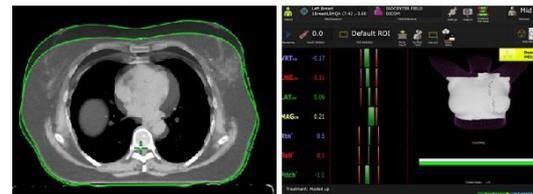

Fig1a. - Planning CT in free breathing (FB) and breath hold (BH).

Fig1c. - OSMS system during delivery. Red bars: beam hold threshold (3mm,<sup>39</sup>). Green bars: patient position within thresholds.

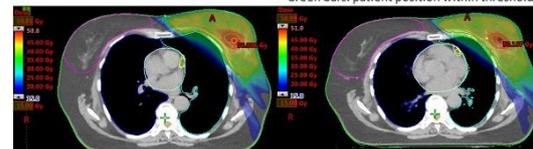

Fig1b. - Dose distribution: BH plan (left) and FB plan (right).

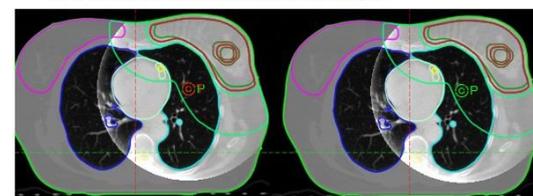

Fig1d. - Example of two CBCTs acquired in BH, during a treatment. Left: Initial CBCT before delivery (matching shifts: vrt=0.06cm, lng=0.00cm, lat=-0.08cm). Right: Final CBCT after delivery (matching shifts: vrt=0.01cm, lng=-0.08cm, lat=-0.06cm).

## Results

Concerning stability, a drift of 0.09mm was noted. The static reproducibility was found to be 0.04±0.01mm and

the agreement with 3D couch shifts was within 0.05 ±0.02mm. Beam hold can be achieved until threshold of 1mm and the gating coincidence between beam hold signals was estimated less than 1 second. Table 1 shows our planning data. In BH plans, as compared with FB, a decrease of 1.5±0.3Gy in mean heart dose and of 7.5±2.9Gy in maximum LAD dose was reported. Only for one patient the BH plan was not advantageous. On average, an extra CBCT in BH was acquired per session, due patient stability. On average, treatment delivery in BH was 26min, twice the FB value. Differences between BH CBCT before and after treatment delivery were well within the CTV-PTV margin (fig1d).

		FB Plan		BH Plan		Differences BH-FB		p value

**Table1** – Dose and volume differences calculated for the dosimetric plans in free breathing and breath hold for 19 patients. The statistical results, as calculated with the student t-test, are also shown (in green the values considered statistically significant, p<0.05).

## Conclusion

The OSMS system has been validated for continuous monitoring patient inspiration during treatment and is now being used clinically. DIBH with IMRT technique leads to better cardiac sparing as compared to FB. In the near future, we plan to extend DIBH to left breast patients with LN.

## PO-1028 Absolute validation of MR versus radiation iso-center on a high-field MR linac

U. Bernchou<sup>1</sup>, A. Bertelsen<sup>1</sup>, H.L. Riis<sup>1</sup>, H.R. Jensen<sup>1</sup>, C.R. Hansen<sup>1</sup>, F. Mahmood<sup>1</sup>, C. Brink<sup>1</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation physics, Odense, Denmark

### Purpose or Objective

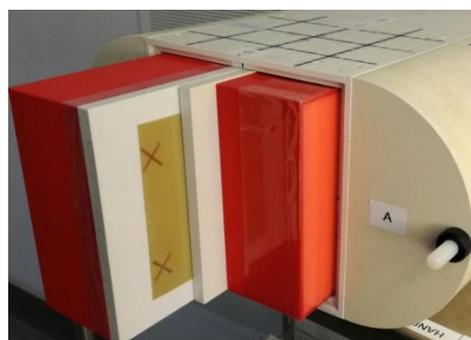

The superior soft-tissue contrast offered by the newly introduced MR linacs allows the localization of the tumour and surrounding normal tissue while the patient is on the treatment couch. However, in order to rely on the daily MR images for guidance of radiotherapy, there is a need to validate the positional accuracy between the planned and delivered dose distribution including all potential uncertainties of MR imaging and dose delivery. This abstract demonstrates a method to perform end-to-end validation of the dose delivery on a high-field MR linac based on an in-house 3D printed, MR visible phantom.

### Material and Methods

MR visible phantom inserts were created for the IMRT phantom (Scanditronix Wellhöfer). The MR visible parts were made of a bi-component silicone rubber (Eurosil 10 Orange) with added softener. The silicone is MR visible and the signal strength depends upon the amount of softener. Perspex rods were cast into silicone rubber with varying amounts of softener within 3D printed containers, creating an inhomogeneous MR visible phantom insert. Two such

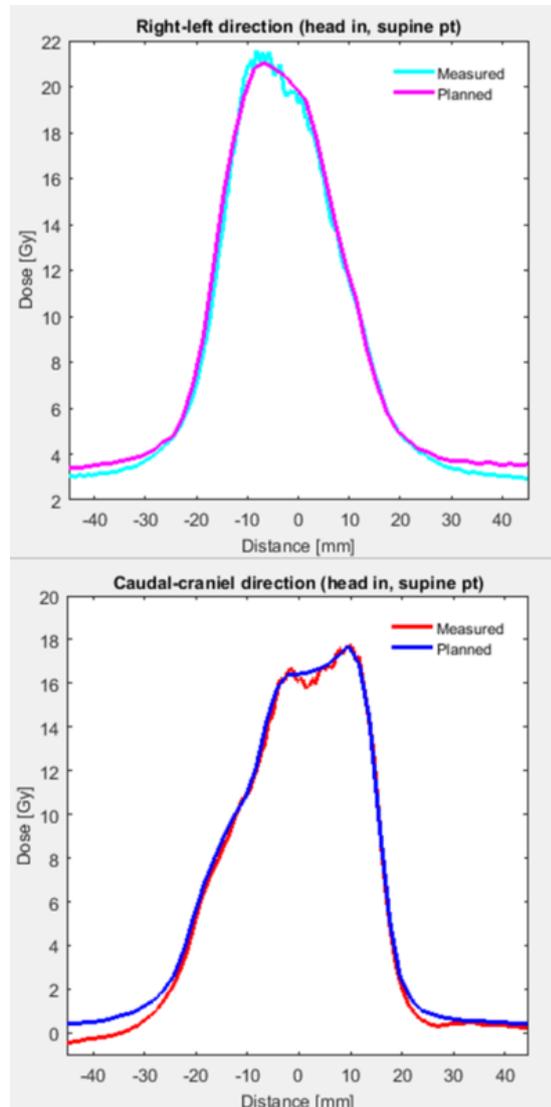

inserts were created and sandwiched around a radiochromic film supported by two solid water plates (see figure 1). The solid water plates contained copper crosses such that their positions were visible on the film after irradiation. The phantom supports both vertical and horizontal film alignment.

A seven beam stereotactic IMRT plan based on a CT scan of the entire phantom was created in the treatment planning system Monaco v 5.40 (Elekta AB, Sweden). At a high-field MR linac, T2 weighted 3D spin echo MR scans of the phantom were performed. Rigid registration of the MR position relative to the CT scan was performed in Online Monaco. The registration was used to calculate the current position of the treatment planning iso-center within the phantom as predicted by the entire treatment chain. After irradiation, the films were scanned in a flatbed scanner and gray levels were converted to dose (Lewis MedPhys 2012). The fixed copper crosses were visible on the film and were used to define the exact position of the film within the phantom.

## Results

An example of comparisons of relative profiles obtained from the film and the planned dose is shown in figure 2. The observable differences in dose are partly due to uncertainties in the conversion of optical density to dose. The high positional precision between the two dose profiles reflects the positional accuracy of the entire system. At our local MR linac, the end-to-end phantom measures a lateral offset of 0.4 mm, a longitudinal offset of 0.1-0.6 mm, and a vertical offset of 0.3 mm.

### Conclusion

Using 3D printed MR visible silicone inserts it was possible to create an end-to-end validation phantom for MR linacs. The phantom has been used in our department and the uncertainty of the dose positions is around half a millimeter, which is needed to make precise MR linac treatments.

### PO-1029 The use of Elekta Agility MLC Dynamic log files for VMAT QA

M. Picioli<sup>1</sup>, K. Torzsok<sup>1</sup>, A. Ruiz Plata<sup>1</sup>, F. Marangoni<sup>1</sup>, H. Broque<sup>1</sup>, J. Aponte<sup>1</sup>

<sup>1</sup>Fundacion Arturo Lopez Perez, Medical Physics, Santiago, Chile

### Purpose or Objective

The usage of massive dynamic parameters during VMAT treatments requires the implementation of new QA mechanisms. One major contributor potentially leading to mistreatments if not properly calibrated is the MLC. Following TG142 recommendations we have created a simple method in order to measure the constancy of leaf speed and positioning accuracy through Elekta Dynamic log files interpretation.

### Material and Methods

For MLC quality control a set of fields has been created using Elekta iComCAT V.13.0 software and loaded up in Linac Synergy console. In order to evaluate leaf speed

constancy a sweeping gap of 2cm x 24cm capable of sweeping 20 cm from X1 to X2 has been used. In order to calculate the theoretical MU value for this field, the following equation was applied:

$$UM = \frac{(\Delta UM / \Delta t)_{max}(x_f - x_i)}{(\Delta x / \Delta t)_{max}}$$

The MU above calculated took into consideration leaf banks at maximum nominal speed and maximum dose rate. Rising up the MU for this field in the software means that MLC should slow down. On the other hand, reducing this value means dose rate will slow down automatically. Once the desirable leaf speed has been calculated through a specific MU, it was compared against the logs from the machine. Regarding leaf positioning accuracy, a picket fence containing 3 segments of 6cm x 24cm was created and irradiated at 4 cardinal angles. For both field configurations, each leaf was analyzed individually and the actual values found in the logs were reported and compared against iComCAT theoretical values. Images for both field configurations were also acquired with IviewGT and compared against the logs providing a more reliable qualitative analysis than simple image visual inspection.

### Results

Figure 1 represents the real leaf speed constancy for both leaf banks obtained from the logs files. Leaf absolute positions were measured in 0,25 s time intervals and are represented by Y and X axis respectively. X1 bank starts moving at -10cm and bank X2 at -8cm (Elekta scale).

Figure 1 - MLC Speed Test

From Figure 1 we can see that both leaf banks have the same constant speed through the field. Any deceleration caused by lack of lubrication or issues with the motors could be easily recognized by deflections in the lines. The real leaf speed gathered from the graph differs less than 1% with respect to the calculated value in iComCAT. For the picket fence field, whilst irradiation of gantry 180 degrees, logs have shown maximum deviation of 0,4 mm for leaf 57 of X2 bank with respect of it nominal position. Leaf bank X2 also presented major differences in average for the same angle.

### Conclusion

Although the utilization of dynamic log files for Elekta linacs is not known in the clinical environment, this work shows it could be a very reliable and powerful tool for accuracy in positioning and speed constancy determination of the Agility MLC, also providing a quantitative complement of simple visual MLC Picket fence image inspection.

### PO-1030 Absolute validation of Multi Leaf Collimator (MLC) positions on a high-field MR linac.

A. Bertelsen<sup>1</sup>, U. Bernchou<sup>1</sup>, H.L. Riis<sup>1</sup>, C. Brink<sup>1</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

### Purpose or Objective

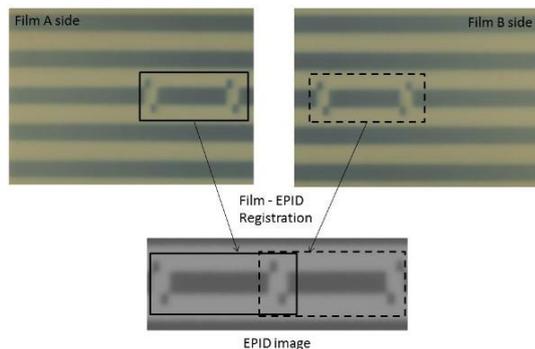

Use of MR guidance prior to each treatment delivery facilitates an improved target definition which has the potential to decrease the irradiated volume needed to ensure target dose coverage. In order to reduce the irradiated volume it is important that the MLC is well calibrated such that the dose is delivered as intended. On the high field MR linacs, that recently have started to treat patients, it is not possible to image all MLC positions on the EPID system (EPID cannot image all leaves and neither the full leaf range), which hinders full MLC validation using the EPID system. This abstract demonstrates a film-EPID combined method which can be used to make absolute validation of the full motion range of all MLC leaves.

### Material and Methods

Calibration of the Elekta Unity MLC was validated using film/EPID dosimetry. Two Gafchromic EBT3 films were placed with a ~7 cm overlap between two slabs of Perspex in the top of the bore so that the films covered the area of the largest possible area of a 56 cm wide field. MLC segments defined 2 cm wide fields offset by -9 cm, -4.5cm, 0cm, 4.5cm, and 9 cm from the isocentre, respectively. For the central segment three groups of adjacent pairs of MLC leaves, visible on the EPID, were deliberately offset to mark the position of these specific MLC leaves (Figure 1). While irradiating the films, the EPID system was used to measure the EPID-visible part of the field. The relation between the EPID system (positions and rotation) and the radiation isocentre is known from standard QA.

The films were scanned in a flatbed bed scanner and gray values converted to dose (Lewis et al MedPhys 2012). Data was evaluated using in-house developed MATLAB program. Based on the three groups of MLC offsets it was possible to perform an automated registration between the individual films and EPID image.

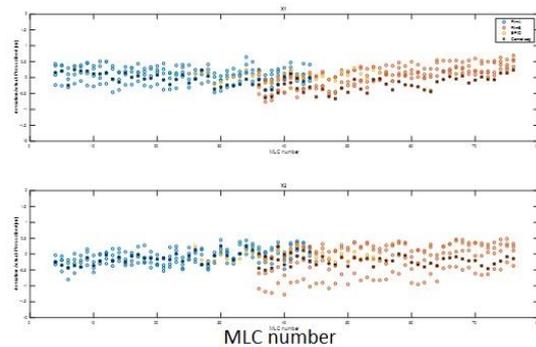

Based on the registration with the EPID it was possible to scale all detected film edges to actual positions. A linear fit per leaf between requested and observed leaf positions was made resulting in an amplitude/gain and offset correction need for an ideal calibration of the MLC.

### Results

The average amplitude/gain and offset for the two banks are (std. deviation): 0.995 (0.001), 0.994 (0.001), 0.133 mm (0.164mm), -0.017mm (0.189mm), respectively (deviations shown in figure 2). The average difference between actual and observed position for the individual leaves is 0.18 (0.39) mm and -0.07 (0.43) mm for the two banks, respectively. Except for offset of the second bank all the values do statistically significant deviate from

either one or zero with p values well below 0.001 (T-test).

### Conclusion

Validation of MLC positions of a high-field MR accelerator is possible by combining EPID and film. Small but likely clinically irrelevant systematic deviations are observed. The random error, standard deviation of the position errors, is below 0.5 mm which is needed in order to reduce irradiation volume based on MR imaging prior to each treatment fraction.

### PO-1031 Automated patient specific collision prevention: the future of noncoplanar SRS planning

T. Mann<sup>1</sup>, K. Thind<sup>2,3</sup>, N. Ploquin<sup>2,3</sup>

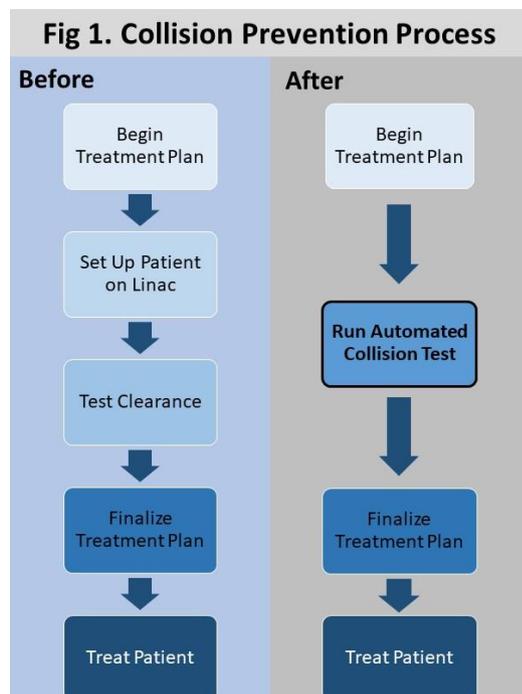

<sup>1</sup>University of Calgary, Physics and Astronomy, Calgary, Canada ; <sup>2</sup>University of Calgary, Oncology, Calgary, Canada ; <sup>3</sup>Tom Baker Cancer Centre, Medical Physics, Calgary, Canada

### Purpose or Objective

The use of noncoplanar treatment planning in Linac-based Stereotactic Radiosurgery (SRS) increases the likelihood of a collision between the gantry and the patient, immobilization device, or the couch. Treatment simulation is necessary prior to patient treatment which increases inefficiency due to implications on resource utilization. The goal of this project is the clinical implementation of an automated patient specific collision detection software during the treatment planning process, ultimately improving resource utilization and the process flow for SRS patients.

### Material and Methods

Eclipse Scripting Application Programming Interface (ESAPI) developed by Varian Medical Systems (Palo Alto, California, USA) was used to create patient specific collision detection software. This software uses patient contours, treatment plan parameters, and models of a Varian Edge Radiosurgery system to perform a clearance check. Previous validation with an anthropomorphic phantom demonstrated 100% collision detection accuracy of the software using a 5 cm expansion zone around the patient. During the planning process, the collision detection software was utilized for all frameless SRS patients planned over two months. In the implementation phase any potential collisions predicted by the software were further tested by treatment simulation on a Linac. The proposed change in treatment planning workflow post-implementation of the automated software is shown in figure 1.

## Results

A summary of the results for all fields tested can be seen in figure 2. The range of calculated minimum distances between the gantry and the patient or the treatment couch is shown for each couch angle. The average minimum distance was 16.6 cm and the median was 15.8 cm. One colliding field, using a 5 cm patient expansion zone, was detected by the software out of a total of 148 fields tested for 36 patients. This field was treatment simulated on a Linac and confirmed to be a collision risk. No undetected collisions occurred clinically during the implementation phase.

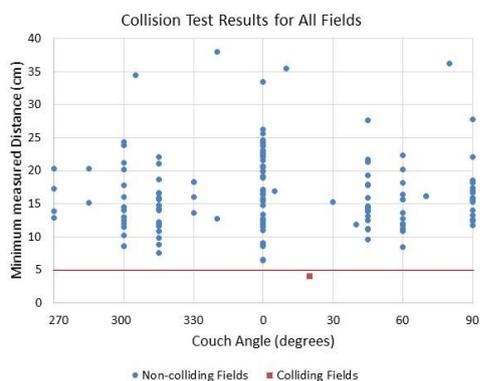

Fig 2. Minimum calculated distance between structures for each treatment field segmented by couch angle. Crossing the 5 cm safety margin outlined in red was defined as a collision.

## Conclusion

We successfully clinically implemented collision detection software for SRS. The software was capable of detecting all potential collision risks. Moving forward, using the automated software instead of performing treatment simulation on a Linac will result in clinical resources being utilized more effectively and help avoid any potential re-planning due to collision risk. While the current conservative gantry trajectory treatment planning approach is effective at avoiding most collisions, a planning approach that utilizes patient specific model based collision testing will allow for a larger number of control points to be used in treatment plan optimization.

The implications of this new method on SRS dosimetry are currently being explored.

## PO-1032 The potential of CBCT for setup and treatment verification in proton therapy for prostate cancer

E. Fura<sup>1</sup>, A. Dasu<sup>2</sup>, A. Ureba<sup>3</sup>, U. Isacson<sup>4</sup>, S. Johansson<sup>5</sup>  
<sup>1</sup>Stockholm University, Medical radiation physics, Stockholm, Sweden ; <sup>2</sup>Skandionkliniken, Medical radiation physics, Uppsala, Sweden ; <sup>3</sup>Karolinska University Hospital, Medical Radiation Physics, Stockholm, Sweden ; <sup>4</sup>Uppsala university hospital, Medical radiation physics, Uppsala, Sweden ; <sup>5</sup>Uppsala university hospital, Oncology, Uppsala, Sweden

### Purpose or Objective

Proton beam treatments (PBT) in the pelvic region can prove difficult due to the sensitivity of the particle tracks to changes in the medium and its implications on the dose distribution. Various registration approaches and stabilisation techniques are available for setup verification for pelvic treatments such as rigid registration to structures like bones and markers, but studies on the matter are scarce. Cone Beam Computer Tomography (CBCT) provides 3D information on the morphology of the patient and could be used daily in the clinic as an image-guided system to verify the patient positioning. However, CBCT images cannot generally be used directly to investigate the impact of inter-fractional changes on the dose distribution. Therefore, this study aimed at developing a method for assessing the impact of inter-fractional changes in proton therapy for prostate cancer by means of CT-to-CBCT deformable registration for various registration approaches.

### Material and Methods

Five prostate cancer patients with rectal rods, used as a stabilization technique, previously treated with photon therapy were included in this study. The patients were replanned with protons for a boost treatment aimed at delivering 4 fractions of 5 Gy, to a total of 20 Gy. The patients underwent a planning CT(pCT) before treatment and one CBCT before each fraction of the boost. The CBCTs were used to deform the pCT to four new deformed image sets representing each fraction. The newly deformed image sets were then rigidly registered to the pCT with two different registrations approaches, bones and markers. The robustness of these registrations was evaluated for two different plans on the pCT (a lateral field arrangement and an anterior oblique field arrangement). The plans were then copied and recalculated over to the bone or marker registered deformed CT sets. After deforming the dose distributions to the pCT, all fractions were then summed up, compared to the reference plan of the pCT and evaluated.

### Results

Bone and marker registrations for both plans resulted in close to 100% coverage of the CTV. The doses to nearby OAR on the summed plans were below the constraints. The coverage of the PTVs on the summed plans were up to 8% lower than for the reference plan. Interestingly, there was a trend for the PTVs where the registration to the bones for the lateral field arrangement had consistently higher coverage than the registration to the markers for all patients.

### Conclusion

The results show that it is possible to use deformable image registration of CBCTs to verify the coverage of the target with PBT. Registering the deformed CT to the bones of the pCT seems to be more robust than registration to the markers in the prostate when using a lateral field arrangement. However, both plans can be used clinically without compromising the coverage of the target.

**PO-1033 What is required to make logfile-based Monte Carlo a viable QA method for realtime plan adaptation?**  
 S. Klüter<sup>1,2,3</sup>, C.K. Spindelreier<sup>1,2,3</sup>, A. Fees<sup>1,2,3</sup>, G. Major<sup>1,2,3</sup>, J. Debus<sup>1,2,3,4,5,6</sup>, M. Alber<sup>1,2,3</sup>

<sup>1</sup>Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>National Center for Tumor Diseases NCT, Radiation Oncology, Heidelberg, Germany ; <sup>3</sup>Heidelberg Institute of Radiation Oncology HIRO, Radiation Oncology, Heidelberg, Germany ; <sup>4</sup>German Cancer Consortium DKTK, partner Site Heidelberg, Heidelberg, Germany ; <sup>5</sup>Heidelberg Ion-Beam Therapy Center HIT, Radiation Oncology, Heidelberg, Germany ; <sup>6</sup>German Cancer Research Center DKFZ, Clinical Cooperation Unit Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

Real-time plan adaptation renders common means of treatment delivery QA infeasible. To date, the only available method appears to be linac logfile recording and a high-accuracy secondary dose computation (LOG2DOSE). Here, we explore the level of detail and accuracy required for Monte Carlo (MC) simulation of the MRIdian Linac (ViewRay Inc, USA) as well as the necessary stability and precision of linac and MLC to afford a sufficient level of accuracy and sensitivity for daily QA of real-time adapted treatment plans.

#### Material and Methods

In order to detect dose delivery errors with LOG2DOSE with high sensitivity, two prerequisites must be met:

1. the logfile information needs to be precise in all parameters, which relates to MLC properties as well as linac characteristics,
2. the MC model needs to be accurate in every aspect of source and collimator simulation, i.e. it is not acceptable that errors cancel out.

From the combination of logfile precision and MC accuracy we estimate the maximum 3D dose errors that would go unnoticed with LOG2DOSE.

The data presented here were obtained with a prototype of an MR-compatible motorized water phantom, various MR-compatible ionization chambers (Standard Imaging, PTW), a micro-diamond detector (PTW), and two different ionization chamber (IC) arrays (Sun Nuclear, PTW). A set of specific measurements was designed to investigate the MC model of the ViewRay TPS with respect to photon spectrum, energy fluence distribution and MLC model. Logfile precision was evaluated with respect to mechanical stability of the MLC and its calibration, beam start-up behaviour and MU-linearity.

#### Results

The MC source model proved extremely accurate, confirmed by output factors and depth dose curves within 0.5%. Transmission/leakage through single stacks of the double-stack MLC was initially off by 50% (mean) and up to 350% (peak), reducing the leaf width by 0.075 mm fixed this issue.

Differences between actual and recorded linac behaviour originated from two sources: during beam start-up, the linac output can be between 1% and 6% less for the first 10 monitorunits (MU), with associated energy-dependent fluctuations of the cross-profile. Further, the leaves show a mean hysteresis of 0.4 mm. Leaf calibration remained stable during 6 months. The 2D array was reliable down to a 3%/3mm gamma (G33) criterion but showed spurious disagreements for more sensitive criteria, caused by coarse spacing and large volume averaging of the ICs in the array.

#### Conclusion

Issues with MC originated from an overly idealized linac model. Precise adjustment to reality including manufacturing and calibration tolerances is required. Logfiles contain residual errors that could be considered in MC simulations, but for practical reasons very narrow fields (leaf hysteresis) and less than 10 MU per segment

(beam start-up) should be avoided. Given these constraints, the sensitivity of LOG2DOSE is higher (up to G11) than that of a 2D array (G33). Thus, LOG2DOSE can be a viable QA method for the MRIdian Linac.

**PO-1034 Development of predictive daily machine quality assurance system to predict forthcoming failures**

T. Fuangrod<sup>1</sup>, W. Puyati<sup>2</sup>, A. Khawne<sup>2</sup>, M. Barnes<sup>3</sup>, P. Greer<sup>3</sup>

<sup>1</sup>Chulabhorn Royal Academy, Faculty of Medicine and Public Health- HRH Princess Chulabhorn College of Medical Science, Bangkok, Thailand ; <sup>2</sup>King Mongkut's Institute of Technology Ladkrabang, Department of Computer Engineering, Bangkok, Thailand ; <sup>3</sup>Calvary Mater Hospital Newcastle, Department of Radiation Oncology, Waratah, Australia

#### Purpose or Objective

A predictive daily machine quality assurance (QA) system based on machine performance check (MPC) tests was developed. This system can be used for a proactive prevention procedure for estimating forthcoming machine failures.

#### Material and Methods

An integration between statistical process control (SPC) and autoregressive integrated moving average (ARIMA) forecast model was applied. Total of 490 daily MPC outputs between 2/2015 - 3/2017 were acquired and each parameter of MPC were arranged, which ordered by testing dates, to be a time series. The time-series optimal ARIMA forecast model and the SPC-based warning level (2 sigma) were calculated from 85% of overall data. The system predicted the one-step ahead of MPC outputs then compared with the warning level. The accuracy of forecast model between predicted and measured MPC tests was evaluated using 15% of overall data.

#### Results

Most results of one-step ahead forecasting of each parameter of MPC were measured by mean absolute error (MAE) were less than 0.05, excepted jaw collimation, relative gantry, tangential of kV imager, beam output and uniformity change. Overall average MAE was 0.03 for all MPC tests. The accuracy of predicted MPC tests versus the warning level was 83.83%. The table 1 shows results of accuracy tests for the predictive daily QA system.

Table 1. Results of accuracy tests for ARIMA forecast model and accuracy rate of warning stage for each MPC test parameter.

Type	MPC tests	Mean absolute error (MAE)	Average accuracy
Isocenter	Size	0.01	97.80%
	MV imager projection offset	0.02	79.12%
	kV imager projection offset	0.03	61.54%
	Maximal offset leaves A	0.02	100.00%
Collimation	Maximal offset Leaves B	0.03	98.97%
	Mean Offset Leave A	0.02	98.97%
	Mean Offset B	0.02	98.97%
	Individual MLC leaf A	0.02	98.56%
	Individual MLC leaf B	0.02	98.13%
	Jaw X1	0.06	47.42%
	Jaw X2	0.05	95.88%
	Jaw Y1	0.07	64.21%
Gantry	Jaw Y2	0.05	79.17%
	Rotation offset	0.02	100.00%
	Absolute	0.01	92.86%
	Relative	0.06	100.00%
Couch	Lateral	0.04	100.00%
	Longitudinal	0.02	64.86%
	Pitch	0.01	98.63%
	Roll	0.00	95.38%
	Rotation	0.01	48.10%
	Vertical	0.04	91.78%
kV imager	Rotation induced couch shift	0.02	100.00%
	In plane rotation	0.00	100.00%
	Source Axial	0.03	95.60%
MV imager	Tangential	0.10	98.90%
	In plane rotation	0.00	100.00%
	Source Axial	0.01	60.44%
Beam	Tangential	0.01	100.00%
	Center shift	0.04	89.52%
	Beam output change	0.12	94.29%
Overall	Uniformity change	0.07	93.33%
	Overall	0.03	83.83%

## Conclusion

A novel concept of predictive daily machine QA system was proposed that applied the historical MPC test data to develop the ARIMA forecast model and SPC-based warning level for each parameter. The system could detect the forthcoming errors where predict MPC test exceeds the SPC-based warning level for each parameter. This represents the likelihood of machine failure in the near future and requires for further investigation and/or calibration.

## PO-1035 Linac commissioning methodology for the Elekta Unity MR Linac

I. Hanson<sup>1</sup>, S. Nill<sup>2</sup>, J. Chick<sup>1</sup>, U. Oelfke<sup>2</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust & The Institute of Cancer Research, Radiotherapy Physics, Sutton, United Kingdom ; <sup>2</sup>The Royal Marsden NHS Foundation Trust & The Institute of Cancer Research, Physics, Sutton, United Kingdom

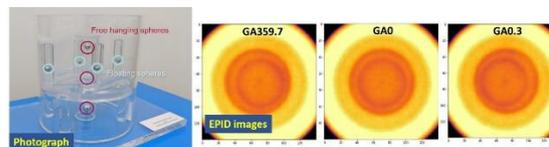

### Purpose or Objective

The Elekta Unity MR Linac (MRL) allows for daily adaptive radiotherapy based on high quality, real-time imaging. A commissioning program has been developed to ensure the safe and accurate operation of the MRL.

Measurements performed on the MRL have to overcome several challenges. Amongst these are the presence of the magnetic field and its influence and limitations on the measuring equipment that can be used, the lack of lasers and light field, the limited bore size and the lack of access to the linac head from the treatment room. We have developed novel methods and tools to address these issues. Consideration of the interdependencies of the MRL parameters was given when designing and ordering tests in order to eliminate any self-referencing loops.

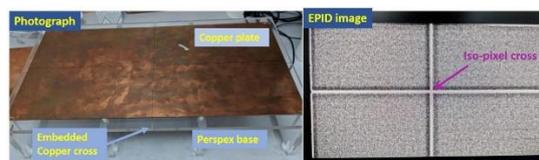

### Material and Methods

An in-house phantom was developed to provide a set of foundational measurements from which further dependent tests could be built upon (see figure 1). This phantom ensures the correct orientation of the radiation beam along the vertical and horizontal axis. The same phantom is used to measure the absolute position of the radiation beam with respect to the fixed EPID panel, and also the rotation of the EPID panel. Once this rotation had been determined the EPID panel could then be used to confirm the rotation of the collimating system.

The dose linearity & repeatability of the linac was confirmed using an ion chamber, with the same measurements used to assess the dosimetric characteristics of the EPID panel. This was necessary as the EPID will be used as a routine dosimeter for daily QA measurements.

Film was used to determine the absolute calibration of the MLCs and jaws using an in-house built copper jig. Copper is used to reduce the effect of the magnetic field on the secondary electron trajectories, such that the deposited dose more closely matches the photon fluence. The same jig was used to locate the films with respect to the absolute beam coordinate system defined by the EPID panel via a copper cross (see figure 2). Copper was also used in an in-house ring phantom used to measure the radiation isocentre radius of the MRL using a star-shot.

Finally, an end-to-end test was performed using the STEEV phantom. A reference plan was generated and adapted using a daily MRL. The difference between reference predicted dose and measured dose was recorded

### Results

The radiation beam was found to be within  $0.3^\circ$  in the horizontal and vertical plane. The EPID panel rotation was  $0.092^\circ$ . The collimator rotation averaged over all cardinal gantry angles was  $-0.01^\circ$ .

The average MLC positioning error was  $(-0.12 \pm 0.23)$ mm. The radiation isocentre radius was 0.32mm. Repeat 1MU exposures agreed dosimetrically to within 1.4%.

Finally, end-to-end testing of the adaptive workflow using the STEEV showed an excellent agreement of 0.018 %

### Conclusion

New methodologies and tools have been developed to commission the radiation delivery system of the Elekta Unity. Measurements showed that the MRL is operating within expectations.

## PO-1036 Deep Learning for automatic contouring of clinical target volumes in breast cancer patients.

P. Poortmans<sup>1</sup>, A. Henry Alexandre<sup>1</sup>, P. Aljabar<sup>2</sup>, R. Baggs<sup>2</sup>, M. Gooding<sup>2</sup>, M. Leclerc-Chalvet<sup>2</sup>, Y. Kirova<sup>1</sup>

<sup>1</sup>Institut Curie Ensemble Hospitalier, Department of Radiation Oncology, Paris cedex 05, France ; <sup>2</sup>Mirada Medical Ltd., Research & Development, Oxford, United Kingdom

### Purpose or Objective

To improve consistency and decrease workload, we introduced and evaluated a system for automated contouring of clinical target volumes (CTV) in breast cancer.

### Material and Methods

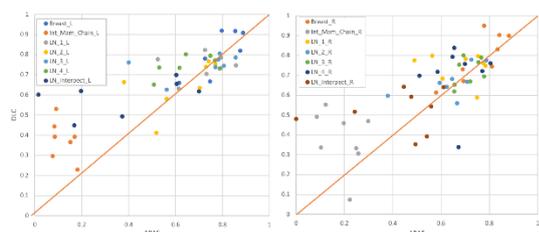

For 146 patients undergoing radiation therapy (RT) for breast cancer, CT-based images were acquired for treatment planning purposes. CTVs, including the breast, and the following lymph node regions: internal mammary chain, interpectoral and axilla levels one to four, were manually delineated on all slices following the ESTRO

guidelines. These delineations served as reference labels for evaluating the automated contours. The Deep Learning Contouring (DLC) model (DLCExpert™, WorkflowBox 2.0, Mirada Medical Ltd) was trained on 63 CTs for left-, and 52 for right-sided breast cancer. The remaining 15 and 16 CTs, respectively, served as a test set for evaluation. For the same test patients, atlas based automatic segmentation (ABAS) was also carried out using atlases formed by ten representative manually contoured pairs from each training set, i.e. two sets of auto-contours were generated for each patient: DLC and ABAS. The ABAS contours provide a benchmark for evaluating the DLC predictions. The accuracy of each method was assessed by quantitative measures against reference contours. Quantitative measures were obtained by comparing the automatic with the manual delineations, using the Dice similarity coefficient (DSC) and the median surface distance (SD).

### Results

The DSC for most CTV's, in both left and right patients, showed that DLC out-performed ABAS. The figure shows a scatter-plot comparing matched data and DSC. The surface distances for DLC were comparable or lower than for ABAS contours, again suggesting improved accuracy.

Figure: Scatter plots of Dice scores for ABAS and DLC.

### Conclusion

The tested deep learning contouring algorithm is a promising tool for improving clinical target volume delineation for breast cancer. To further validate this, we plan to assess the clinical acceptability of the automatic contours by using a modified version of the Turing Test to compare them against manually drawn contours ([www.autocontouring.com](http://www.autocontouring.com))

### PO-1037 In silico analysis of MR-only planning for simulation-free MR-guided spine SBRT

O. Green<sup>1</sup>, L. Henke<sup>1</sup>, S. Rudra<sup>1</sup>, A. Price<sup>1</sup>, S. Mutic<sup>1</sup>, C. Robinson<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Radiation Oncology- Physics Division, Saint Louis, USA

### Purpose or Objective

Spine SBRT is a proven treatment modality for primary and metastatic tumors. The proximity of the spinal cord necessitates the acquisition of either MR or CT myelography imaging. The time between diagnostic imaging, simulation, and treatment can stretch to upward of two weeks, potentially reducing the probability of favorable outcome. Application of an established online-adaptive radiotherapy workflow using a hybrid MR-linac system may allow for reduction in time to treatment. In this study, we sought to evaluate the dosimetric reliability of applying our current online adaptive radiotherapy method to enable a simulation-free workflow for spine SBRT patients, wherein the patient is imaged on the hybrid MR-linac unit, a pre-selected base plan is adapted, and treatment commences while the patient remains on-table, using a bulk density override MR-only planning approach.

### Material and Methods

Four patient datasets were chosen to be representative of typical patient habitus observed in the clinic (1 obese, 1 over-weight, 2 non-obese; 2 male, 2 female). For each, MRI datasets from previous MR-linac treatments as well as

simulation CT datasets were collected. For each dataset, six CTVs were contoured on MRI per International Spine Radiosurgery Consortium (ISRC) consensus guidelines. The bulk density override function of the integrated MR-linac treatment planning system was used to assign a tissue-equivalent density (1.02 g/cc) to all non-bony anatomy except lung-equivalent (0.25 g/cc) as appropriate. The spinal column and adjacent rib bones were assigned a standard bone density override value of 1.12 g/cc. Corresponding CT datasets were fused as secondary images to MRI datasets. For each PTV, three plans were created and compared by dose volume histogram analysis: (1) bulk density override plan, (2) bulk density override plan recalculated on the registered CT; (3) reoptimized plan using CT alone.

### Results

PTV coverage changed by an average of 2.5% when bulk density override plans were compared to plans using the real relative electron densities. The maximum dose to 0.035cc of the spinal cord changed by an average of 0.24 Gy (corresponding to 0.9% of the constraint dose of 28 Gy), with a maximum observed deviation of 0.83 Gy. All plans achieved maximum cord doses <28 Gy, with a maximum of 21.44 Gy). Similar differences were observed for 3, 5, 7, and 10 mm expansions around the cord and 100% and 50% conformity indices, indicating that bulk density overrides provided for robustness equivalent to CT-based plans (Figure 1).

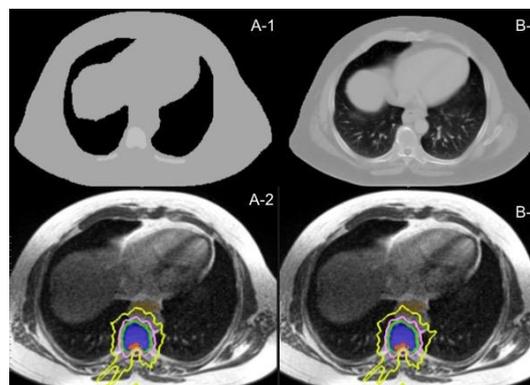

Figure 1. Bulk density (A-1) plan (A-2) compared to CT-based (B-1) plan (B-2), with 100%, 80%, and 50% isodoses (cyan, pink, and yellow) shown.

### Conclusion

Using a bulk density override for spine SBRT based on MR-linac images was found to have acceptable accuracy for a simulation-free, MR-only process. A Phase I clinical trial evaluating the feasibility and safety of simulation-free MR-guided spine SBRT is underway.

### PO-1038 MR-only Radiation Therapy: a silent patient-friendly workflow using a light-weight, flexible coil

C. Cozzini<sup>1</sup>, C. Bobb<sup>2</sup>, M. Engström<sup>3</sup>, S. Kaushik<sup>4</sup>, R. Molthen<sup>2</sup>, D. Rettman<sup>2</sup>, V. Goruganti<sup>5</sup>, W. Chiang<sup>5</sup>, F. Wiesinger<sup>1</sup>

<sup>1</sup>GE Healthcare, Applied Science Laboratory Europe, Garching bei München, Germany ; <sup>2</sup>GE Healthcare, Healthcare Imaging, Waukesha, USA ; <sup>3</sup>GE Healthcare, Healthcare Europe, Stockholm, Sweden ; <sup>4</sup>GEGlobal Research, GE Corporate, Bangalore, India ; <sup>5</sup>NeoCoil, MRcoil, Pewaukee, USA

### Purpose or Objective

The ability of using a single imaging system for tumor delineation and dose calculation for Radiation Therapy (RT) planning is highly appealing in terms of clinical workflow simplification and patient experience. MRI is known for its superior soft tissue contrast when compared to CT and silent Zero Echo Time (ZTE) MR imaging was

recently demonstrated suitable for both Attenuation Correction in PET/MR and for pseudo CT conversion for head and neck applications [1]. To achieve an optimized MR-only workflow however, dedicated RT coils are needed to allow patient positioning in the MRI including RT fixation devices. To reach the desired coverage and image quality, current clinical practice often results in a bulky and uncomfortable set-up typically in form of a composition of different coils. Here we present a novel RT coil based on GE lightweight Air technology [2] and demonstrate its performance for standard head and neck MR imaging and ZTE based pseudo CT conversion. This highly flexible Air coil greatly simplifies the RT workflow and well adapts to varying patient position and size.

#### Material and Methods

A 3-tesla GE SIGNA MR scanner (GE Healthcare, Chicago, IL) and a prototype coil were used for standard MRI and ZTE data acquisition in phantoms and healthy volunteers. The coil consists of 22 channels of which 15 located in the face, allowing for 3 different coil modes: head only, head and neck, and chest only. ZTE data were processed with a Deep Learning (DL) method where a 3D convolutional neural network of the U-net architecture with 8-layers, Adam optimizer and RMSE cost function was adapted to perform pseudo CT computation via image regression. This method was trained on N=50 patients using matched pairs of ZTE and CT patient data sets using standard product surface coils [3].

#### Results

Figure 1 shows the prototype coil and the coronal views of standard gradient echo (LAVA-Flex) and fast spin echo (FS) MR pulse sequences including Dixon type fat-water separation. The images clearly illustrate full head and neck coverage, including the shoulders, as required for RT planning.

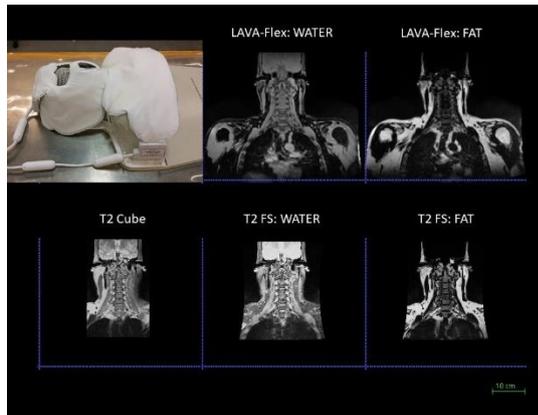

Figure 1 Top left: air coil prototype; Right: Water and Fat separation from LAVA-Flex for neck and shoulder coverage. Bottom: T2FS water; T2FS fat; T2cube acquisitions.

Figure 2 shows ZTE images acquired with 1.5 mm isotropic resolution with corresponding, DL computed pseudo CT at the bottom. The skull and the spine are correctly captured, while a few false positive bone voxels are present in the neck and in the sinus region. A proper training on data acquired with the prototype coil with matched resolution is expected to produce superior results

Figure 2: top ZTE images with 1.5 isotropic resolution. Bottom: DL derived pseudo CTs

#### Conclusion

A silent, patient-friendly MR-only RT workflow compatible with all types of fixation devices has been enabled by a new lightweight and flexible Air coil prototype. These first results show that the coil has appropriate coverage and image quality to achieve pseudo CT conversion paving the way for an efficient and patient friendly MR-only RT workflow

#### PO-1039 Spine SBRT with Halcyon™: Plan Quality, Delivery Accuracy, and Speed

H. Petrocchia<sup>1</sup>, I. Malajovich<sup>1</sup>, C. Wang<sup>2</sup>, K. Teo<sup>1</sup>, D. Lei<sup>1</sup>, T. Li<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA ; <sup>2</sup>Duke University, Radiation Oncology, Durham, USA

#### Purpose or Objective

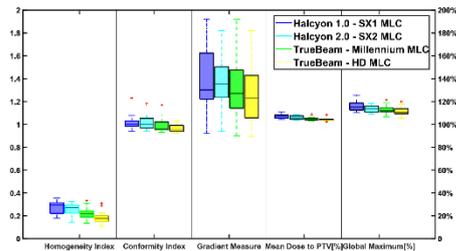

A new dual-layer staggered 1cm MLC in Halcyon™ treatment platform (Varian Medical, Palo Alto, CA) has improved speed, leakage, and DLG compared to 120-Millennium (0.5cm) and High Definition (0.25cm) MLCs in the TrueBeam platform. Halcyon 2.0 with SX2 MLC has the ability to modulate both upper and lower MLC banks; while previously in version 1.0 the SX1 MLC uses the lower MLCs to modulate the fluence and the upper MLCs function as a backup jaw by moving to the most distally extended lower leaf pair. It is not clear how these two newly designed MLCs perform for spine SBRT cases and when compared to TrueBeam MLCs. In this study, we investigate the effects of 4 different MLC designs on spine SBRT treatments.

#### Material and Methods

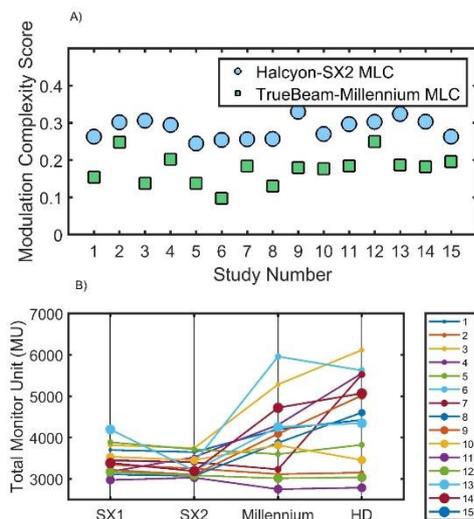

15 patients previously treated with spine SBRT were re-planned according to NRG-BR002 guidelines for all MLCs with a prescription of 3000cGy in 3 fractions, 6xFFF, 800 MU/min, and 3-arc VMAT technique. All plans were normalized to 90% of the target volume covered by prescription dose. Since the diameter of the spinal cord is comparable to the 1cm leaf width, this study evaluates the ability of the dual-layer staggered MLCs to modulate fluence using an 0.5cm effective leaf width by examining the percentage of shaping performed by the proximal MLC, the modulation complexity score (MCS), the total MU, and the gamma index passing rate based on delivery measurements using ArcCheck.

#### Results

Halcyon SX1 and SX2 plans are shown to have similar conformity and homogeneity index (SX2: CI 1.0±0.06, HI 0.27±0.05; SX1: CI 1.0±0.07, HI 0.29±0.05) as compared to the TrueBeam platform (HD: CI 0.95±0.03, HI 0.18±0.06; Millennium: CI 0.96±0.07, HI 0.21±0); however, the gradient measure as defined by Eclipse indicates the TrueBeam platform has steeper dose fall off than the Halcyon platform.

We investigate how much additional modulation is provided by the proximal MLC between SX2 and SX1 by analyzing the amount of leaf shaping for leading and trailing leaves. In Halcyon 2.0, the proximal MLC was found to shape the field on average by  $29.5 \pm 6.2\%$ . Despite the increase in modulation from SX1 to SX2, the MCS for the Millennium MLC is lower for all cases compared to SX2 plans. For delivery accuracy measurement, all TrueBeam plans were adjusted to be 1400 MU/min as compared to 800 MU/min available in the Halcyon platform to optimize delivery characteristics. The 2%/2mm gamma index passing rates for SX1 and SX2 are  $98.8 \pm 0.2\%$  and  $96.9 \pm 2.0\%$ , respectively. The delivery time for SX2 plans are  $4:19.0 \pm 25$  sec compared to  $3:59.46 \pm 24$  sec for the Millennium MLC.

### Conclusion

Halcyon SBRT plans are shown to have similar plan quality to plans generated with the Millennium MLC but inferior to HD MLC. Despite the increase in modulation between SX1 to SX2 and the theoretical modulation resolution of 0.5cm in the latter, the lower MCS implies SX2 is generating plans with less modulation than the 120-Millennium MLC with 0.5cm physical width. SX2 plans are superior in terms of heterogeneity and conformity than SX1.

#### PO-1040 Partial breast irradiation with interstitial multicatheter HDR BT for breast cancer.

N. Cihoric<sup>1</sup>, A. Tsikkinis<sup>1</sup>, D. Terribilini<sup>1</sup>, D. M. Aebersold<sup>1</sup>, K. Lössl<sup>1</sup>

<sup>1</sup>Inselspital- Bern University Hospital- University of Bern, Department of Radiation Oncology, Bern, Switzerland

### Purpose or Objective

To evaluate the efficacy, toxicity profile and dosimetric parameters of accelerated partial breast irradiation (APBI) delivered with interstitial multicatheter HDR brachytherapy (HDR-BT) after breast-conserving surgery (BCS).

### Material and Methods

We analyzed a series of patients (pts) treated from 2005 to 2017 with HDR-BT APBI using multicatheter interstitial brachytherapy after BCS. HDR-BT APBI was offered to pts fulfilling the ESTRO criteria for APBI and to selected pts with high-risk features but with metastatic disease and/or significant comorbidities and a limited life expectancy. In total 419 pts were treated. 279 (66.6%) pts fulfilled the ESTRO criteria for APBI and 140 (33.4%) pts did not. Catheters were implanted during or 4 - 8 weeks after BCS. Dose-volume parameters and quality indices were reported according to the ICRU 58 recommendations. We assessed the locoregional control and survival. Toxicity profiles were evaluated according to CTCAE v4.0.

### Results

The median age at time of therapy was 68 years (range: 31 - 93 years). A total dose of 32 Gy was delivered in 8 fractions of 4 Gy twice daily. 289 (69%) pts received hormonal therapy, 99 (24%) pts did not, for 31 (7%) unknown. Chemotherapy was administered in 45 (11%), omitted in 343 (82%) and unknown in 31 (7%) pts. HER2 oriented therapy was given in 6 (1%) pts. Median follow-up time was 25 months (range 3 - 131 months). 29 (6.9%) pts developed disease relapse. Seven (1.7%) pts developed in-breast tumor relapse, 10 (2.4%) relapsed in the regional nodal area and 22 (5.3%) developed systemic metastases. We did not record any relapse within the planning target volume. During follow-up 50 (11.9%) pts died. 384 (91.6%) pts did not experience any acute toxicities, 32 (7.6%) developed Gr. I toxicity, 1 (0.2%) Gr. II and 2 (0.5%) Gr. III toxicity. Late toxicity was not recorded in 263 (62.8%) pts, 145 (34.6%) pts presented Gr. I toxicity, 9 (2.1%) Gr. II and 2 (0.5%) pts developed late Gr. III toxicity. There were no cases of acute or late Gr. IV or higher toxicity. The mean volumetric doses were: MCD 5.3 (range 3.2 to 6.1), V PTV (ccm): 62.6 (8.7 - 332.6), V100 (ccm): 72.7 (range 13.1 - 960.2), V100(%) = CI - 91.0 (47.4 - 99.0), V150 (lmp ccm): 19.9 (5.4 - 90.9) V150 (%): 27.1 (range 15.1 - 51.1). The mean DNR was 0.3 (range 0.2 - 0.5), while the DHI was 0.7 (0.3 - 0.8). The mean COIN was 0.7 (0.4 - 0.8).

### Conclusion

HDR-BT APBI achieves excellent local control with a favorable toxicity profile. In selected pts with high-risk features, HDR-BT APBI provides a viable alternative to conventional radiotherapy.

#### PO-1041 Benefit of interstitial needles supplementing the ring applicator in cervical cancer brachytherapy

J. Ståhl Kornerup<sup>1</sup>, E. Thorstensen Andersen<sup>2</sup>, S. Danielsen<sup>1</sup>, A. Dybdahl Wanderås<sup>1</sup>, M. Sundset<sup>3</sup>, K. Fjellanger<sup>2</sup>, M. Eidem<sup>1</sup>, A.B. Langeland Marthinsen<sup>1</sup>

<sup>1</sup>St Olav's University Hospital, Department of Radiotherapy- the Cancer Clinic, Trondheim, Norway ;

<sup>2</sup>Norwegian University of Science and Technology,

Department of Physics, Trondheim, Norway ; <sup>3</sup>St Olav's

University Hospital, Department of Gynaecological Oncology, Trondheim, Norway

### Purpose or Objective

How well can dose prescription for target coverage and dose limits for organs at risk (OARs) be fulfilled in

brachytherapy (BT) of cervical cancer using ring applicator, if supplementary interstitial needles are used?  
**Material and Methods**

36 BT fractions from 9 patients were studied retrospectively. Target volumes (CTV<sub>HR</sub>) and OARs (bladder, rectum and sigmoid colon) were delineated in MR image sets acquired before each fraction. The BT dose was prescribed to provide a total CTV<sub>HR</sub> dose of 90-95Gy (EQD<sub>2</sub>,  $\alpha/\beta=10$ ) in terms of D<sub>90%</sub> when combined with external radiation of 1.8Gyx25. The maxdose (D<sub>2cc</sub>) to bladder, rectum and sigmoid colon was restricted to 80, 65 and 70Gy (EQD<sub>2</sub>,  $\alpha/\beta=3$ ), respectively. The Hybrid Inverse Planning Optimization (HIPO) algorithm (Oncentra Brachy, Elekta version 4.3) was used.

The 1<sup>st</sup> set of 36 plans was generated to fulfil CTV<sub>HR</sub> dose prescriptions without needles, whereas the OAR doses had secondary priority. These plans revealed the most challenging OARs regarding violating of dose limits. The 2<sup>nd</sup> set of 36 plans was generated with the primary goal to fulfill the OAR dose limits. These plans revealed which parts of the CTV<sub>HR</sub> that were difficult to cover with adequate dose without needles. The unsuccessful fractions of the 2<sup>nd</sup> set were re-optimized with use of interstitial needles for the 3<sup>rd</sup> set of plans. The needles were thoughtfully placed where possible, with appropriate distances to the OARs.

**Results**

In the 1<sup>st</sup> and 2<sup>nd</sup> set of plans, the dose constraints for OARs and CTV<sub>HR</sub> were fulfilled in 19 of 36 fractions (53%). The remaining 17 fractions (47%) were regarded as failed. The plans that failed in the 1<sup>st</sup> set of plans in terms of OAR dose constraints also failed in the 2<sup>nd</sup> set of plans in terms of not fulfilling CTV<sub>HR</sub> dose. The OAR most frequently exceeding the dose constraint in the 1<sup>st</sup> set of plans was sigmoid colon (11 fractions, mean excess dose (MED): 0.37Gy), followed by bladder (9 fractions, MED: 0.32Gy) and rectum (4 fractions, MED: 0.38Gy). For 10 of the 17 failed BT fractions, the dose constraints became fulfilled when interstitial needles were added (see table). The mean volume of CTV<sub>HR</sub> was 31.8±8.9cc for the primary successful plans, 38.2±7.7cc for the plans fulfilled using needles and 37.1±10.1cc for the not fulfilled plans.

Table: The BT fractions with all dose constraints for CTV<sub>HR</sub> (D<sub>90%</sub> within 7.7-8.3 Gy) and OARs (D<sub>2cc</sub> of 5, 4, 3, 9 and 4.5 Gy for bladder, rectum and sigmoid colon, respectively) fulfilled are indicated with "Success". The non-successful BT fractions are presented with the reason for failing.

7	1	Success	Success	Success	Success	N/A	N/A	N/A	Success
		Sigmoid = 5.0 Gy CTV <sub>HR</sub> = 6.9 Gy	Bladder = 5.5 Gy CTV <sub>HR</sub> = 7.6 Gy	Success	Success	Bladder = 5.6 Gy CTV <sub>HR</sub> = 7.2 Gy	Success	Success	N/A
8	1	Bladder = 5.7 Gy Sigmoid = 5.0 Gy CTV <sub>HR</sub> = 7.0 Gy	Sigmoid = 5.3 Gy CTV <sub>HR</sub> = 6.8 Gy	Bladder = 5.7 Gy CTV <sub>HR</sub> = 7.5 Gy	Bladder = 5.5 Gy CTV <sub>HR</sub> = 7.0 Gy	N/A	N/A	N/A	N/A
		Success	Success	Success	Success	N/A	N/A	Success	N/A
9	1	Bladder = 5.7 Gy Sigmoid = 5.0 Gy CTV <sub>HR</sub> = 7.0 Gy	Sigmoid = 5.3 Gy CTV <sub>HR</sub> = 6.8 Gy	Bladder = 5.7 Gy CTV <sub>HR</sub> = 7.5 Gy	Bladder = 5.5 Gy CTV <sub>HR</sub> = 7.0 Gy	N/A	N/A	Success	N/A
		Success	Success	Success	Success	N/A	N/A	Success	N/A

For each non-successful fraction (without needles):  
 The row above the dashed line indicates which OAR dose constraints that were exceeded, and by how much, when CTV<sub>HR</sub> was fulfilled (1<sup>st</sup> set of plans). The row below the dashed line indicates the best achievable CTV<sub>HR</sub> with all the OAR dose constraints fulfilled (2<sup>nd</sup> set of plans).  
 For each non-successful fraction (with needles):  
 The row above the dashed line indicates which OAR dose constraints that were exceeded, and by how much, when CTV<sub>HR</sub> was fulfilled (1<sup>st</sup> set of plans). The row below the dashed line indicates the best achievable CTV<sub>HR</sub> values with all the OAR dose constraints fulfilled.  
 N/A = not applicable.

**Conclusion**

When utilizing needles as supplement to ring applicators, the total number of BT fractions which fulfilled the prescribed CTV<sub>HR</sub> and OAR doses increased from 53% to 81%. Although not all plans became successful using needles, the CTV<sub>HR</sub> D<sub>90%</sub> was always improved. Sigmoid colon and bladder were most frequently surpassing the dose limits in the failed plans. For each patient, it was not possible to predict whether the dose plan would be successful or not for the consecutive fractions. The CTV<sub>HR</sub> tended to be smaller for the plans that were primary fulfilled. The result implies that interstitial needles are a helpful tool for optimizing the dose distribution; however, they do not ensure complete success for every BT fraction.

**PO-1042 Toxicity results after Electronic Brachytherapy treatment in endometrial cancer patients**

<sup>1</sup>Hospital Universitario Miguel Servet, Radiation Oncology, Zaragoza, Spain ; <sup>2</sup>Hospital Universitario Miguel Servet, Medical Physics and Radiation Protection, Zaragoza, Spain

**Purpose or Objective**

To analyse the toxicity outcomes after treatment with Electronic Brachytherapy (XB) in postsurgical endometrial cancer patients treated at our medical centre.

**Material and Methods**

Prospective study in which we selected 118 patients, between September/2015 and May/2018, that received treatment with XB (Axxent Xofter device) administered twice a week after endometrial cancer surgery, with IMRT planification. The patients were divided in two groups: Group 1 (73/118) considered high risk received external beam radiotherapy (46Gy) followed by XB (15Gy in 5Gy fractions) and group 2 (45/118) considered intermediate risk received exclusive XB (25Gy in 5Gy fractions). We analysed the median dose in bladder, rectum and sigmoid D2cc, V50, V35 with XB comparing the doses with Ir192. The vaginal mucosa, gastrointestinal (GI) and genitourinary (GU) toxicities were analysed with the Common Terminology Criteria for Adverse Events (CTCAE 4.0) scale.

Table: The BT fractions with all dose constraints for CTV<sub>HR</sub> (D<sub>90%</sub> within 7.7-8.3 Gy) and OARs (D<sub>2cc</sub> of 5, 4, 3, 9 and 4.5 Gy for bladder, rectum and sigmoid colon, respectively) fulfilled are indicated with "Success". The non-successful BT fractions are presented with the reason for failing.

 N/A = not applicable.

## Results

The median dose in bladder with XB vs. Ir192 was: 2cc 64.01 vs. 69.9%, V50 7.2 vs. 12.6Gy, V35 15.2 vs. 28.1. In rectum XB vs. Ir192 was: D 2cc 65.17% vs. 67.7%, V50 7.9 vs. 10.9Gy, V35 16.7 vs. 31.8Gy. In sigmoid XB vs. Ir192 was: D 50% vs. 58.0%, V50 8.6 vs. 16.2Gy, V35 21.1 vs. 37.5Gy.

The median follow-up was 21 months (range 5 - 36 months).

In group 1, acute vaginal mucositis (G1) was observed in 32.91% of the patients, GI toxicity (G1) in 5.41% and GU toxicity (G1) in 8.11%. In group 2, we observed acute vaginal mucositis G1 in 34.09% of the patients and G2 in 4.55%, GI toxicity (G1) occurred in 6.52% and GU toxicity (G1) was present in 13.04%. There was no grade 3 or greater toxicity in any of the groups. Late toxicity was observed in only 4 patients: Mucositis (G1) in 3 patients, GI (G1) in 2 and GU toxicity (G1) in 3 patients.

## Conclusion

The dose received by the organs at risk with the XB is less compared to Ir192, with a good coverage of the PTV. The greater toxicity was observed immediately after the treatment was finished with an important reduction of the symptoms after 6 months. This technique shows excellent results as for toxicity.

**PO-1043 Vaginal Cuff treatment with Electronic Brachytherapy in Gynaecologic Cancer: Our experience**  
A. Miranda Burgos<sup>1</sup>, A. Méndez Villamón<sup>1</sup>, R. Ibáñez Carreras<sup>1</sup>, M. Gascón Ferrer<sup>1</sup>, A. Campos Bonel<sup>1</sup>, E. Muñoz Sanz<sup>1</sup>, S. Lozares Cordero<sup>2</sup>, A. Gandía Martínez<sup>2</sup>, M. Tejedor Gutierrez<sup>1</sup>

<sup>1</sup>Hospital Universitario Miguel Servet, Radiation Oncology, Zaragoza, Spain ; <sup>2</sup>Hospital Universitario Miguel Servet, Medical Physics and Radiation Protection, Zaragoza, Spain

## Purpose or Objective

To analyse the outcomes in terms of toxicity and survival analysis after treatment with Xofigo Electronic Brachytherapy (XB) in postsurgical gynaecologic cancer patients treated at our medical centre.

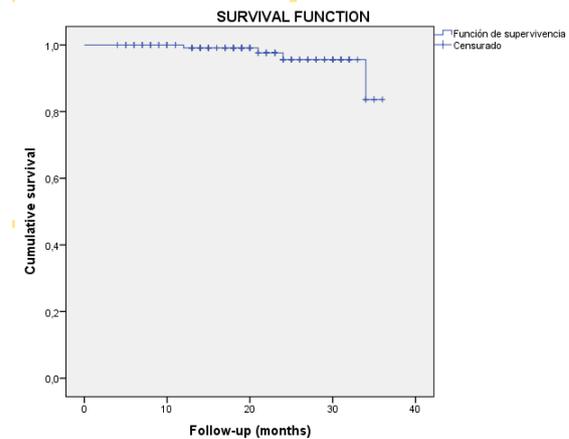

## Material and Methods

Prospective study in which we selected 140 patients that received treatment with Xofigo Electronic Brachytherapy administered twice a week after gynaecologic cancer surgery, with 3D planification. The patients were selected from September 2015 to July 2018. They were divided in two groups: Group 1 (91/140) considered high risk and group 2 (49/140) intermediate risk. Group 1 received external beam radiotherapy (46Gy) followed by XB (15Gy in 5Gy fractions) and group 2 received exclusive XB (25Gy in 5Gy fractions). We analyzed the median dose in bladder, rectum and sigmoid D2cc with XB. The vaginal mucosa, gastrointestinal (GI) and genitourinary (GU) toxicities were analyzed with the Common Terminology Criteria for Adverse Events (CTCAE 4.0) scale. We built a Kaplan-Meier curve to estimate the survival over time of follow-up.

## Results

The median follow-up was 20 months (range 3 - 36 months). Of all the patients treated, 87.14% were endometrial cancer patients, 7.86% cervical cancer, 2.86% vaginal cancer and 2.14% were vaginal recurrences. The median dose in bladder with XB was D2cc: 12,01Gy. In rectum median D2cc was 11,78Gy. In sigmoid median D2cc was 9,24Gy. In terms of toxicity, acute vaginal mucositis (G1) was observed in 21.29% of the patients and G2 in 1.43%, GI toxicity (G1) occurred in 4.28% and GU toxicity (G1) in 7.14%. There was no grade 3 or greater toxicity in any of the groups. At 6 months follow-up, all of the patients were asymptomatic. As for survival, 4 patients have died during the follow-up, 2 of them showed systemic progression and the other 2 had synchronous tumor. The

Kaplan Meier results, show that at 2 years follow-up, 95% of the patient are going to be alive. We have estimated that 97,1% of our patients are progression free and alive.

## Conclusion

The electronic brachytherapy is an alternative to high dose-rate brachytherapy. The XB obtains good coverage of PTV with lower doses in organs at risk. The greater toxicity was observed immediately after the treatment was finished with an important reduction of the symptoms after 6 months. It also shows an excellent rate of overall survival and progression free disease.

**PO-1044 Salvage brachytherapy for oral or oropharyngeal tumor in a previously irradiated volume**  
P. Pierre-Marie<sup>1</sup>, M. Mounie<sup>2</sup>, B. Fleury<sup>3</sup>, S. Racadot<sup>1</sup>, J. Suchaud<sup>1</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiotherapy, LYON, France ; <sup>2</sup>University Hospital of Toulouse, Inserm, Toulouse, France ; <sup>3</sup>Marie Curie Institute, Radiotherapy, Valence, France

## Purpose or Objective

To assess the outcome of salvage brachytherapy for oral and oropharyngeal squamous cell carcinoma in previously irradiated areas.

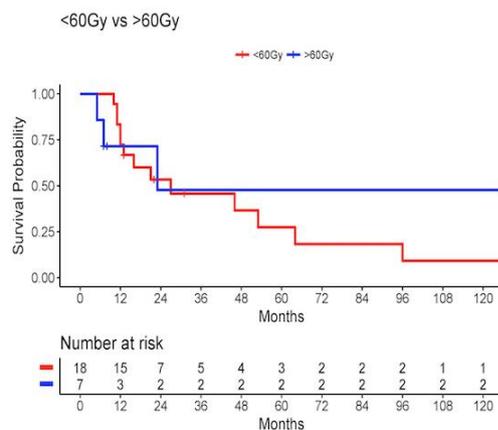

## Material and Methods

This is a retrospective study of 25 patients treated at the Centre Léon Bérard between 1997 and 2016 for primary (21) or recurrent (4) oral or oropharyngeal SCC in a previously irradiated area. Fifteen patients were treated with salvage brachytherapy alone, while 10 patients also received external radiotherapy. The median time between the first and the second irradiation was 56 months (range, 10-212 months). All but three patients had surgical resection and four patients received chemotherapy. The median brachytherapy dose was 45 Gy (range, 15-64 Gy) for a median total dose of 57 Gy (range, 40-70 Gy). Patient age, BMI, tumor stage, radiotherapy dose and time between the first treatment and recurrence were analyzed as prognostic factors.

## Results

The median overall survival was 16 months. Patients with less advanced (T1) tumors survived significantly longer (27 vs 14.5 months,  $p=0.046$ ). Five patients experienced a local recurrence, only one of which had been treated with a total dose greater than 60 Gy. In multivariate analysis, the risk of death was found to be 80% lower in patients who had received more than 60 Gy ( $p=0.072$ ). There was four grade 3 acute toxicities and no grade 3 or greater late toxicities.

Gemelli" IRCCS, Roma, Italy

### Purpose or Objective

To present the results of a patient therapeutic approach using a second course of Interventional Radiotherapy (Brachytherapy) in a setting of patients with local recurrence of uveal melanoma.

### Material and Methods

Patients who had already undergone ocular brachytherapy at IOC (Interventional Oncology Center) of the "Gemelli ART" (Advanced Radiation Therapy) of Rome were considered. In this group, five patients with a local recurrence that received a second course of treatment with a plaque were included in our analysis. The reirradiation was performed with a plaque of Ruthenium-106 (dose prescribed to the apex 100 Gy) or of Iodine-125 (dose prescribed to the apex 85Gy).

### Results

All patients were in the first time treated with Ruthenium 106 plaque; the reirradiation was performed with Ruthenium 106 plaque in three cases and with Iodine in the remaining two cases. The mean time between the first and the second plaque was 56.8 months (range 25-93 months). After a median follow-up of 44.2 months (range 26-65 months) from retreatment the local tumor control rate was 100% and there was no patient who underwent secondary enucleation due to retreatment failure. Distant metastasis occurred in one patient after 6 months from retreatment. All patients evolved a worsening of the visual acuity (median visual acuity was 0.42 at time of recurrence and declined to 0.24 at the most recent follow-up); cataract occurred in two cases, no patient developed scleral necrosis.

### Conclusion

In well selected cases a retreatment strategy with plaque may offer a high probability of tumor control and organ preservation with a worsening in the visual acuity.

#### PO-1046 Precision of source tracking in brachytherapy with scintillation detectors

J. Johansen<sup>1</sup>, H.M.L. Rosales<sup>2,3</sup>, M. Overgaard<sup>1</sup>, E.B. Jørgensen<sup>1</sup>, G. Kertzscher<sup>1</sup>, S. Beddar<sup>4</sup>, K. Tanderup<sup>1</sup>, L. Beaulieu<sup>2,3</sup>

<sup>1</sup>Aarhus University Hospital, Department of oncology, Aarhus C, Denmark ; <sup>2</sup>Université Laval, Département de physique- de génie physique et d'optique et Centre de recherche sur le cancer, Québec, Canada ; <sup>3</sup>CHU de Québec - Université Laval, Département de radio-oncologie et Axe Oncologie du CRCHU de Québec,

Québec, Canada ; <sup>4</sup>The University of Texas, MD Anderson Cancer Center, Houston, USA

### Purpose or Objective

The purpose of this study is to evaluate source tracking in brachytherapy using two state of the art detectors: 1) an inorganic scintillator detector (ISD) and a multipoint plastic scintillation detector (mPSD). The former is significantly energy dependent, while the latter is subject to the stem effect due to lower scintillation intensities. The hypothesis of this study is that source tracking with sub-millimeter precision can be obtained by accounting for these effects.

### Material and Methods

One ISD (Csl) and a mPSD composed by BCF-10, BCF-12, BCF-60 were placed in a 40x40x40cm<sup>3</sup> water phantom. The dosimeters were coupled to two independent data acquisition systems using optical fibers. The dose rates were read out at 40Hz (ISD) and 70kHz (mPSD). The dosimeters were surrounded by nine hollow plastic needles to provide a symmetric configuration for the two dosimeters, fig. 1. A treatment plan was used with ten source dwell positions in each needle and 5mm source steps. The dosimeters were placed in the center depth of the ten dwell positions. Irradiation was performed four times, two times with dwell times of 20s and two times with dwell times of 1s.

First, the distances between the individual source positions and the individual dosimeters were determined based on the relation between dose rate and distance (TG43 formalism). The distances were compared to the expected distances between dwell positions and dosimeters based on the phantom geometry.

For the ISD measurements, the distance offset was then separated in to a shift along the needle (z) and one radially away from the dosimeter (r). This was done by making a joint virtual shift of all the dwell positions in a single needle to best match the measured dose rates to TG43 as described in [1].

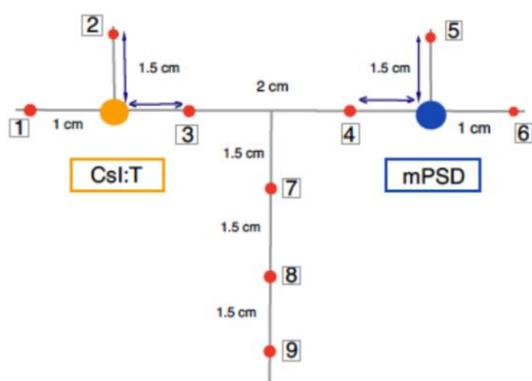

Fig. 1: Configuration of the phantom measurements.

### Results

The deviation between measured and expected distances for each dwell position were within 0.6mm (ISD) and 1mm (mPSD) at source-to-detector distances <40mm and within 1.1mm (ISD) and 1.8mm (mPSD) at larger distances (up to 58mm).

Table 1 shows the radial (r) and longitudinal (z) shifts determined for each needle individually using the ISD. The maximum offset was  $r=0.49\text{mm}$  and  $z=-0.79\text{mm}$ . The maximum differences between the four measurements for a single needle was  $r=0.29\text{mm}$  (Needle 6) and  $z=0.34\text{mm}$  (Needle 5). The mean $\pm$ SD offset across all needles and measurements were  $r=0.054\pm 0.21\text{mm}$ ,  $z=-0.22\pm 0.27\text{mm}$ . This precision corresponds to the precision of the source positioning of the afterloader.

Needle	Needle-to-ISD dist. (mm)	Run 1 (t=20s)		Run 2 (t=20s)		Run 3 (t=1s)		Run 4 (t=1s)	
		r (mm)	z (mm)	r (mm)	z (mm)	r (mm)	z (mm)	r (mm)	z (mm)

Mean (SD)		0.11 (0.27)	-0.21 (0.26)	0.061 (0.18)	-0.18 (0.28)	0.48 (0.20)	-0.19 (0.30)	0.0038 (0.19)	-0.32 (0.30)
Max		0.49	0.15	0.28	0.22	0.29	0.26	0.27	0.12

Table 1: The positional offset of each needle determined using the ISD and for each irradiation.

### Conclusion

Source tracking using state of the art scintillation dosimeters can be done with a precision comparable to the free space of the source and dosimeters inside the needles (-0.2mm). The tracking methodology can be transformed into a real-time approach.

### PO-1047 Evaluation of ACE dose calculation model on HDR treatments delivered with a multichannel applicator

M. Carrara<sup>1</sup>, P. Caricato<sup>1</sup>, T. Giandini<sup>1</sup>, C. Tenconi<sup>2,3</sup>, A. Cerrotta<sup>4</sup>, B. Papalardi<sup>4</sup>, F. Piccolo<sup>4</sup>, C. Fallai<sup>4</sup>, E. Pignoli<sup>1</sup>  
<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy ; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy ; <sup>3</sup>University of Milan, Oncology and Haemato-oncology, Milan, Italy ; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 2, Milan, Italy

### Purpose or Objective

To investigate the performance of the Advanced Calculation Engine (ACE) (Oncentra Brachy 4.5) in comparison to the AAPM-TG43 calculations for 24 HDR vaginal brachytherapy treatments delivered with a multichannel vaginal applicator (MVA), since patient's anatomy and heterogeneities are not considered with the latter algorithm.

### Material and Methods

After the commissioning of ACE according to the indications of the AAPM TG-186 recommendations, this dose calculation model was retrospectively applied on 24 vaginal HDR brachytherapy treatments delivered at our Institution with MVAs of two different diameters (i.e., 25 and 30 mm). The following volumes were all contoured: applicator, free air catheters, sigma, rectum, bladder, cortical bone, adipose tissue and remaining soft tissue, and their corresponding materials and priorities were assigned. Patient plans were then computed using both uniform and HU-based densities and compared with the TG-43 calculations in terms of relative differences between D0.1cc, D1cc and D2cc to rectum, sigmoid and bladder. D90%, D95%, D100%, V90%, V95%, V100% and V150% to the target were all compared, as well as the dose to a point P placed 5 mm above the applicator central tip.

### Results

The average relative differences between the calculated parameters for the 24 patients are shown in figure. All mean differences resulted within  $\pm 2\%$ , except the dose to the point P and the V150% to the target. In particular, the dose to P resulted higher if calculated with ACE, most probably due to the reduced attenuation by the air cavity of the central catheter. In some cases (i.e., sigmoid close over the applicator), this increased dose might result in a

higher dose to the sigmoid, as also demonstrated by the wider error bars of the sigmoid parameters plotted in figure. In the opposite, the V150% to the target resulted lower with ACE, probably in light of the higher attenuation of the applicator material if compared to water. Differences between uniform densities and HU-based calculations were all negligible, as well as dose distributions resulting with the use of MVAs of two different diameters.

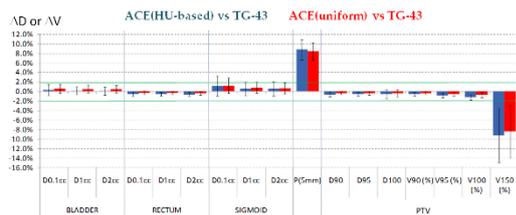

Figure 1: Mean relative differences between the dosimetric parameters evaluated for the target and the different organs at risk. In blue, comparison between HU-based ACE calculation and TG-43; in red, comparison between uniform density ACE calculation and TG-43. Error bars: one standard deviation.

### Conclusion

In general, on the 24 investigated treatments the ACE dose calculation model results in similar dose distributions as the commonly used AAPM-TG43 algorithm, both for targets and organs at risk, with the exception of the V150% to the target and the dose at 5 mm above the applicator tip.

### PO-1048 Variability in catheter reconstruction for multi-catheter interstitial brachytherapy

K. Kallis<sup>1</sup>, T. Kaltsas<sup>1</sup>, S. Kreppner<sup>1</sup>, M. Lotter<sup>1</sup>, V. Strnad<sup>1</sup>, R. Fietkau<sup>1</sup>, C. Bert<sup>1</sup>

<sup>1</sup>University Hospital Erlangen, Radiation Oncology, Erlangen, Germany

### Purpose or Objective

Accelerated partial breast irradiation of the tumor bed using interstitial brachytherapy is a common treatment option for selected breast cancer patients. Reconstruction of the source path is a time consuming manual procedure during treatment planning that influences the planned dose delivery. The aim of this study is to evaluate inter-observer variabilities for catheter reconstruction. Further, we explored the feasibility of an automated catheter reconstruction using an electromagnetic tracking (EMT) system, integrated into an afterloader prototype.

### Material and Methods

The catheter reconstructions of three physicists were compared for 26 patients, in total 426 catheters, see figure 1. Keeping constant the CT data, contours, dwell times, dwell positions (DPs), plan optimization and normalization settings, the geometrical deviations between the corresponding DPs of the repeated reconstruction and the reference plan were evaluated. Also, the effects on coverage index (CI), dose non-uniformity ratio (DNR), conformal index (COIN), and the dose to the organs at risk were analyzed. The clinical approved plan served as reference.

In addition, the catheter traces were reconstructed with the help of EMT data. The EMT measurement was conducted directly after CT imaging using a Flexitron prototype (Elekta, Veenendaal, The Netherlands) equipped with an EMT sensor. In combination with an Aurora EMT system (NDI, Waterloo, Canada) all catheters can be automatically digitized, which takes 6-9 minutes depending on the number of implanted catheters. Using an in-house routine, the measured catheter traces were rigidly registered to the catheter button centers defined on the CT image and automatically imported to the treatment planning system within one minute.

### Results

Over all patients and all manual catheter reconstructions a mean deviation between corresponding DPs of

0.58±0.49 mm was detected. Mean deviations to the reference plan of 0.48±0.31 mm and 0.58±0.35 mm were found for the first and second observer, respectively. The length of the catheter traces varied 0.45±0.39 mm on average. The mean deviation of CI varied by 0.25±0.29%, variations in DNR, COIN, mean heart dose and mean lung dose were all <0.01%. The skin dose changed in the maximum by 4.10%. Nevertheless, manual reconstruction of the catheter paths is a time consuming (3-5 minutes per catheter) procedure in treatment planning. Evaluation of magnitude and implication on the geometrical deviations and the dose distribution using the EMT measurements is still ongoing.

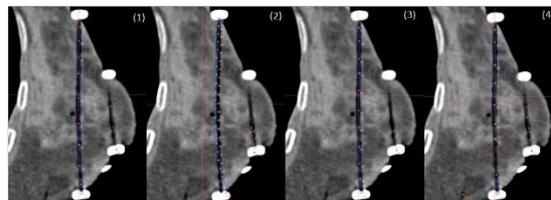

Figure 1 Comparison of different reconstruction techniques. Four different reconstruction techniques are presented. All images show the same slice of one patients CT image. In blue the projected catheter is visualized. The defined control points, defining the path are presented in red. Figure (1) shows the reconstruction of the approved clinical plan. Figure (2) shows the catheter reconstruction using the EMT measurement. Figure (3) presents the reconstruction of observer one and figure (4) the catheter path of observer two.

### Conclusion

The study proved that a repeated reconstruction of the catheter traces does not lead to a large change in dose exposure or large geometrical deviations. However, lack of ground truth poses a challenge to reliable quality assessment of the reconstruction. Using EMT measurements seems to be a feasible, dose free and quick option for catheter reconstruction.

### PO-1049 Assessing PTV margin adequacy in permanent breast seed implant for complex target geometries

A. Guebert<sup>1,2</sup>, A. Frederick<sup>1,2</sup>, M. Roumeliotis<sup>1,2,3</sup>, T. Meyer<sup>1,2,3</sup>, S. Quirk<sup>1,2,3</sup>

<sup>1</sup>University of Calgary, Department of Physics and Astronomy, Calgary, Canada; <sup>2</sup>Tom Baker Cancer Centre, Division of Medical Physics, Calgary, Canada; <sup>3</sup>University of Calgary, Department of Oncology, Calgary, Canada

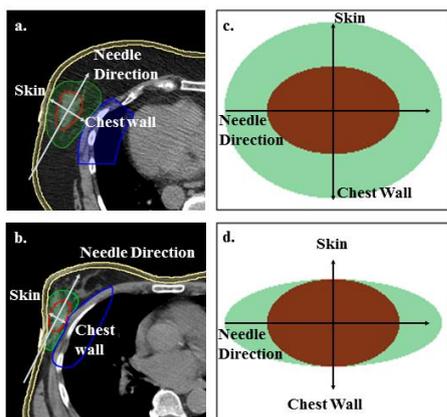

### Purpose or Objective

Permanent breast seed implant (PBSI) brachytherapy presents a convenient, single day alternative to standard whole breast radiotherapy. For widespread adoption, robust treatment planning recommendations are required. Clinical PBSI treatment plans recommend a 10-15 mm expansion of the clinical target volume (CTV) to the planning target volume (PTV). The PTV margin is cropped to the chest wall muscle and 5 mm from the skin surface as these structures present anatomic boundaries. For patients where the target is located in close proximity to the skin and chest wall, significant cropping of the PTV is required on both sides. For this subset of patients, accounting for approximately 25% of our cohort, poor coverage has been observed on the post-implant CT. This simulation study aims to investigate PTV cropping in the skin-chest wall direction and the impact on post-implant dosimetry.

### Material and Methods

Four typical CTV volumes (6.6, 10.1, 15.6, and 30.5 cm<sup>3</sup>) were modelled as ellipsoids. The PTV margin for each volume was modelled as isotropic expansions of 10 mm in the direction parallel to the needle, and the template left-right direction, and 0, 4, 7, or 10 mm in the skin-chest wall direction (Figure 1). Treatment plans were generated with 15 mm seed spacing for needles passing through the CTV, and 10 mm seed spacing for needles passing through only the PTV. The prescription dose was 90 Gy. For each margin combination, 1500 implants were simulated by application of a seed delivery error sampled from our reported clinical

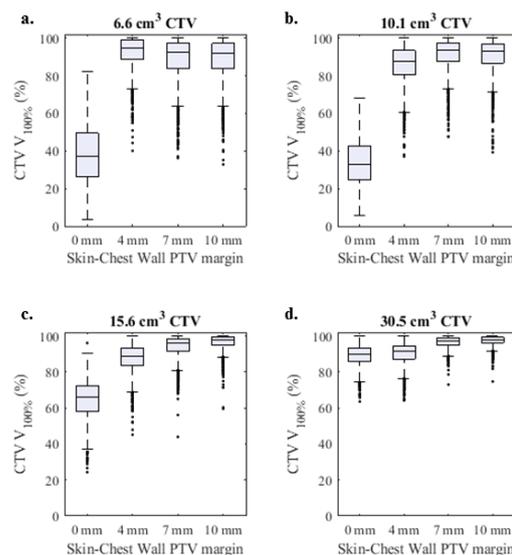

seed placement accuracy, treated as a normal distribution. In the three needle directions, the mean displacement ( $\pm$  standard deviation) was: 6.7 mm ( $\pm 7.8$  mm) in the shallow-deep direction, 0.75 mm ( $\pm 4.4$  mm) in the template left-right direction, and 0.10 ( $\pm 4.0$  mm) in the skin-chest wall direction. The skin and chest-wall were imposed as boundaries for seed placement in the simulation. Resultant CTV coverage was assessed using the  $V_{100\%}$ .

**Figure 1:** Axial patient CT scans (a. and b.) with contoured CTVs (red) and PTVs (green). The PTV in b. is cropped closely to the CTV due to proximity to the skin and chest wall. This is shown in ellipsoidal geometry in c. and d, where the CTV (red) is expanded isotropically to the PTV (green) in c., indicating no cropping, and anisotropically to the PTV in d, indicating cropping. The coordinate system is shown in all four panes, with left-right being the direction into and out of the page.

## Results

In general, PTV cropping has a larger effect on dosimetry for small volume CTVs. In this simulation, large decreases in  $V_{100\%}$  coverage are observed for the smallest PTV (0 mm skin-chest wall margin) on the three smallest CTVs, particularly in comparison to the largest CTV. For these CTV/PTV combinations, the mean  $V_{100\%}$  was 46%, as opposed to 89% for the largest CTV. For all CTVs, a cropping to a 7 mm skin-chest wall margin likely does not substantially affect coverage compared to the 10 mm uncropped PTV. Overall, the results show that the volume of the CTV is important when considering resultant  $V_{100\%}$  coverage when seed delivery error is taken into account, particularly when patient anatomy requires severe cropping to the skin and chest wall.

**Figure 2:** Resultant  $V_{100\%}$  for 1500 simulated implants for a. 6.6 cm<sup>3</sup>, b. 10.1 cm<sup>3</sup>, c. 15.6 cm<sup>3</sup>, and d. 30.5 cm<sup>3</sup> CTVs, for four skin-chest wall PTV margins. Boxes correspond to 25 and 75 percentiles of the data, with the line indicating median. Whiskers represent the 95% confidence interval. Outliers are indicated by dots.

## Conclusion

Simulations of an idealized target geometry reveal an interplay between CTV/PTV size and post-implant dosimetry when seed delivery error is accounted for. This motivates the necessity of considering CTV size and the extent of PTV cropping when assessing PBSI treatment plans.

### PO-1050 A gynecological multichannel applicator including a real-time treatment verification system

A. Romanyukha<sup>1</sup>, M. Carrara<sup>2</sup>, T. Giandini<sup>2</sup>, M. Petasecca<sup>1</sup>, T. Al-Salmami<sup>1</sup>, D. Cutajar<sup>1</sup>, A. Cerrotta<sup>3</sup>, B. Pappalardi<sup>3</sup>, F. Piccolo<sup>3</sup>, E. Pignoli<sup>2</sup>, A. Rosenfeld<sup>1</sup>  
<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics CMRP, Wollongong, Australia; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 2, Milan, Italy

### Purpose or Objective

To develop, calibrate, and test an innovative prototype of a vaginal multichannel applicator with an embedded system for real-time verification of source dwell position and time in HDR <sup>192</sup>Ir brachytherapy, to ensure that planned treatments are delivered in accordance to the original treatment plans.

### Material and Methods

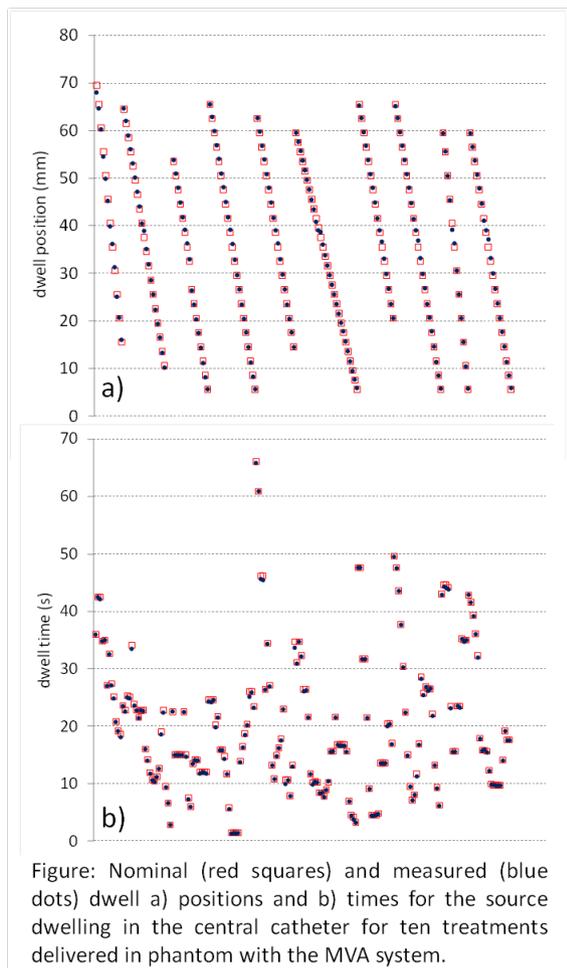

The applicator prototype is modeled based on a multichannel vaginal applicator (MVA) that is 30 mm in diameter and contains seven peripheral and one central catheter(s). Three p-type epi diodes are placed around the upper region of the MVA and were selected due to their efficiency in the measurement of high-energy photons associated with the <sup>192</sup>Ir source. The readout system is an AFE and FPGA system capable of 100  $\mu$ s online readout for up to four diodes at a time. The *ad hoc* detectors and electronics have been all developed and optimized according to the specific task.

In this study, a prototype of the MVA system was characterized, and an efficient method for real-time source localization and dwell time measurement was established. Once the method was defined and tested, the accuracy of the MVA system was then quantified in

phantom on ten vaginal treatments previously delivered at our Institution.

## Results

The characterization of the MVA system showed no significant dependence on radiation intensity for a range of Air Kerma Strengths between 34 and 13 mGy<sup>2</sup>h<sup>-1</sup>. After its characterization and calibration, the MVA system demonstrated the ability to resolve the HDR BT source position and dwelling time along the first 70 mm of the applicator, encompassing the most clinically relevant region for HDR BT vaginal treatments. 95% of measurements showed positional discrepancies between nominal and measured values within 0.8 mm and 1.5 mm for the source dwelling in the central and in the peripheral catheters, respectively. 95% of the measured dwell times for the central and peripheral catheters were within 0.4 s and 0.2s, respectively, if compared to the nominal values. Nominal and measured values for the source dwelling in the central catheter are shown in the figure.

## Conclusion

The proposed intracavitary MVA system has demonstrated the ability to simultaneously deliver and verify the HDR BT treatment with, in general, sub-mm and sub-second accuracy. Once improved, the system will provide essential information in real time to help ensure that the treatment is delivered in accordance with the planned treatment plan. Further studies may help to further increase spatial and time resolution.

## PO-1051 quality analysis automation of a prostate low dose rate seed implant using clustering methods

D. Rodríguez Latorre<sup>1</sup>

<sup>1</sup>Hospital Universitario Central de Asturias, Radiofísica, Oviedo, Spain

## Purpose or Objective

I-125 seed implants are a reference treatment for low risk prostate tumors. The quality of this treatment depends on the precision in the placement of these seeds in the planned points to achieve the proper dose distribution. Post-implant dosimetry is based on the need to evaluate the quality of the implant once the forces applied by needles and by the ultrasound probe have disappeared and once the edema caused in the implant process has gone. In many places post-implant dosimetry is not done because it is time-consuming and also because of the difficulty to have reliable image modality to simultaneously define the position of the seeds and volumes: prostate and OARs. We developed a fast and reliable method to identify strands and individual seeds that would give geometric quality index of the implant, which allows us to check the robustness of the implantation method and if any cold spot is to be expected.

## Material and Methods

The treatment planning system PSID™ 5.0 (Eckert & Ziegler BEBIG GmbH) is used, that allows us to extract the positions of the seeds of the planning in real time (online planning), as well as the positions after a month (postplanning).

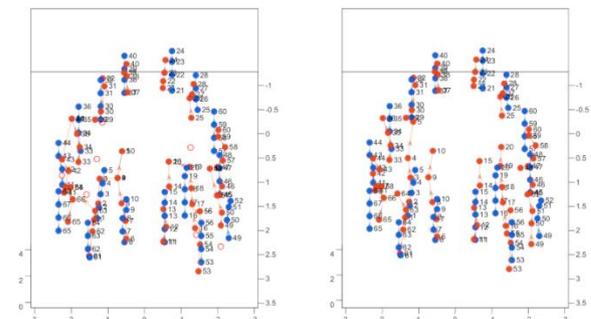

The MATLAB Statistics and Machine Learning Toolbox (MATLAB R2018a, MathWorks®) was used to write a code for seeds and strands identification using clustering techniques following the next steps:

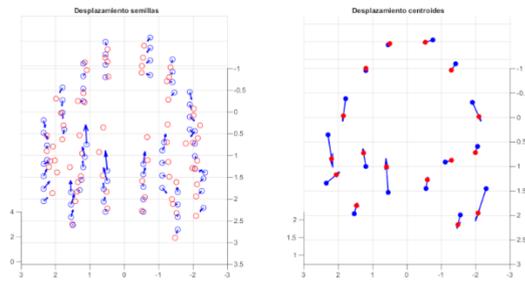

1. Rigid registration with Iterative Closest Point, which uses an affine transformation to get rid of the differences between imaging datasets (online and postplan) due to its different reference systems.
2. Hierarchical clustering with the dataset online using the MATLAB linkage function.
3. Assignment using KDTreeSearcher and knnsearch MATLAB functions, first to generate a binary tree and then the subsequent k nearest neighbor search.

## Results

The assignment is correct in most cases and it considerably reduces the time to obtain a visualization of the geometric differences between online and postplan datasets. Nevertheless the assignment is not completely when: there are seeds too far away from their original position in the XY plane, and when some strands appear bended in the Z direction.

Once the assignment problem was solved we calculated the displacement vector for each seed, the strand centroid displacement vector, and the separation between consecutive seeds in the same strand to see if the 1 cm metric remains, which is the theoretical separation between seeds. We saw that in average the postplan consecutive seed separation was 0.9 cm.

### Conclusion

We have developed a fast method to solve the assignment problem between two seed datasets which does not need any adjustable parameter to work. This allows us to calculate some metrics to assess the quality of the implant.

### PO-1052 Is there a clinically meaningful change in anatomy during planning of US HDR prostate brachytherapy?

A. David<sup>1</sup>, V. Brennan<sup>2</sup>, G. Cohen<sup>1</sup>, A. Damato<sup>1</sup>

<sup>1</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA ; <sup>2</sup>Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA

#### Purpose or Objective

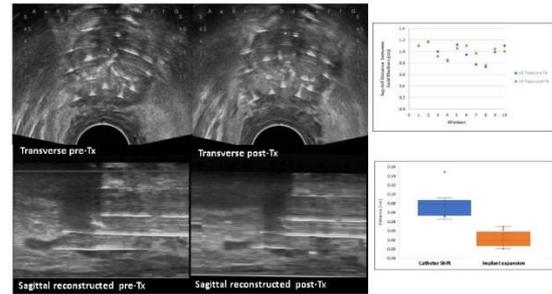

To investigate the role of anatomical and implant geometry changes during planning time in final delivered dose for US-based HDR prostate brachytherapy

#### Material and Methods

The record of 13 patients who received US-based HDR prostate brachytherapy at our institution was retrospectively reviewed. All patients receive a single dose fraction brachytherapy boost treatment, 2 weeks before external beam treatment. Gold fiducial markers were positioned at the apex and base of the prostate at the beginning of the procedure. A set of static US images were acquired using transverse transducer pre-treatment (pre-Tx) after needle insertion and used for contouring, final digitization, and dose optimization. Post-treatment (post-Tx) transverse images were acquired immediately after treatment delivery. Targets were re-contoured and the clinical plans (dwell pattern and times on the newly digitized catheters) was replicated on the post-Tx images. The DICOM plans were analyzed using MATLAB routines to assess **catheter shift** (average distances between reciprocal dwell source positions pre- and post- treatment after rigid registration between all dwell positions is performed) and **implant expansion** (average of the difference between the distances from each dwell source position to the center of mass of the dwell sources system). **Superior-inferior swelling** (difference between the post- and pre-Tx distance between fiducial markers) was assessed on 10 patients. Differences in target volumes are also reported.

#### Results

The number of needles (average  $\pm$  1 standard deviation) was  $13 \pm 2$  needles. No meaningful catheter shift ( $0.08 \pm 0.03$  cm), implant expansion ( $0.003 \pm 0.02$  cm) and sup-inf swelling ( $-0.01 \pm 0.09$ ) were observed. Changes in target volume, were  $0.26 \pm 3.41$  cm<sup>3</sup>.

### Conclusion

Geometric assessment of single catheter shift, implant expansion and superior-inferior swelling indicate that no clinical meaningful change occurred in the time between planning scan and treatment. Further analysis will be performed to assess the role of contouring uncertainty on the patient-by-patient results. More patients and dose distributions are being analyzed to validate these results, which suggest high fidelity between planned and delivered dose.

### Poster: Brachytherapy: Prostate

### PO-1053 Efficacy/toxicity after high dose rate brachytherapy as monotherapy for localized prostate cancer

S. Novikov<sup>1</sup>, S. Kanaev<sup>1</sup>, M. Gotovchikova<sup>1</sup>, R. Novikov<sup>1</sup>, D. Ilin<sup>1</sup>, M. Girshovitch<sup>1</sup>

<sup>1</sup>Prof. N.N. Petrov Research Institute of Oncology, Radiotherapy, St. Petersburg, Russian Federation

#### Purpose or Objective

to present toxicity profile and biochemical control rates of a prospective single center trial comparing 2 fractions of 13 Gy and three fractions of 11.5 Gy high dose rate brachytherapy as sole treatment for localized prostate cancer.

#### Material and Methods

Between 01.06.2013 and 01.06.2017, 198 men with clinically localized prostate cancer T1-T3aNOm0, Gleason score below 8 and PSA less than 20 ng/ml were included in the study. Sixty-seven patients received TRUS guided HDR brachytherapy in 2 fractions of 13 Gy, 131 men - in 3 fractions of 11.5 Gy. Qmax below 10 ml/sec and IPSS above 20 were excluding criteria. Biochemical failure was registered according to the Phoenix definition, and toxicity was scored according CTCAE-5.

#### Results

Median follow-up was 40.9 (range 15.1-71.1) months. The 36 month's biochemical control (BC) was 95.5% for 121 patients with follow-up of 36-56 months: 100% - in low-risk, 94.2% - in intermediate risk and 90.5% - in high risk groups. We found comparable BC rates for patients that received 2 fractions (BC-93.2%) and 3 fractions (BC-98.5%) HDR-BT.

Grade 2 late genitourinary toxicity manifested by urgency in 4 (2%) cases; grade 3 late toxicity was detected in 2 (1%) men with urethral stenosis and another 1 (0.5%) - with severe urgency. Median International Prostate Symptom Score raised from 8 [4; 12] (0-21) (before HDR-BT) to 12 [7;16] (1,0-28,0) 3 months after the treatment with subsequent decrease to 10 [9;16] (1-25) and 7 [7;8] (6-12) after 12 and 36 months of follow-up (p=0,001).

In the same manner median Q<sub>max</sub> decreased from 15,0 [12,7;18,0] (9,0-36,0) ml/sec to 14,3 [12,0; 17,0] (7,0-30,0) ml/sec 3 months after treatment (p=0,001) and subsequently reached 14,9 [13,1;17,0] (7,0-25,0) and 14,1 [13,0;16,0] (6,0-29,0) ml/sec 1 and 3 years after the end of HDR-BT.

Median International Index of Erectile Function score before treatment was 15 [10;20] (1-25) and decreased to 10 [4; 10] (1-21) 3 months after HDR-BT. Surprisingly it increased to 12 [4;16] (1-22) after 12 months of follow-up: at that time in 57.6% cases it was above 11 points. Grade I-II late gastrointestinal toxicity detected in 12 cases (6.1%), without any patient with grade III toxicity. Fractionation scheme has no significant impact on early and late toxicity.

#### Conclusion

this single center comparative study demonstrated that in patients with localized prostate cancer both fractionation regimes demonstrated high 36-months biochemical control with very limited early and late toxicity.

#### PO-1054 LDR versus HDR brachytherapy boost in prostate cancer patients - a retrospective analysis

S. Rodda<sup>1</sup>, L. Murray<sup>1</sup>, D. Bottomley<sup>1</sup>, P. Bownes<sup>2</sup>, C. Wilkinson<sup>3</sup>, E. Adiotomre<sup>4</sup>, B. Al-Qaisieh<sup>2</sup>, E. Dugdale<sup>1</sup>, O. Hulson<sup>4</sup>, J. Mason<sup>2</sup>, J. Smith<sup>4</sup>, A. M Henry<sup>1</sup>  
<sup>1</sup>St.James institute of Oncology, Clinical Oncology, Leeds, United Kingdom ; <sup>2</sup>St.James institute of Oncology, Brachytherapy Physics, Leeds, United Kingdom ; <sup>3</sup>St.James institute of Oncology, Brachytherapy, Leeds, United Kingdom ; <sup>4</sup>St.James institute of Oncology, Radiology, Leeds, United Kingdom

#### Purpose or Objective

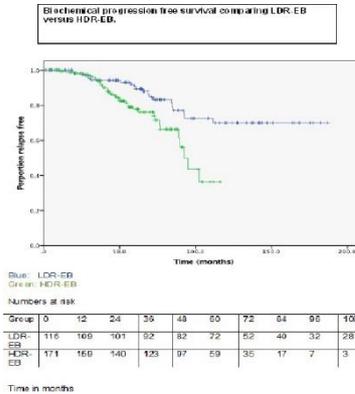

In the absence of randomised comparison, to report biochemical Progression Free Survival (bPFS) and morbidity outcomes in men with non-metastatic prostate cancer treated with LDR or HDR brachytherapy boost (BT) techniques combined with external beam radiotherapy(EBRT).

#### Material and Methods

347 men consecutively treated with combination of BT boost and EBRT from 1996 - 2012 from a single centre were included. All were staged using prostate MR and bone scan. Data was extracted from a prospectively maintained database and electronic case records. Patients with no record of post implant PSA were excluded from the analysis. 287 patients were evaluable. 116 had LDR (I-125) BT to a dose of 110 Gy in combination with EBRT 45Gy in 20 Fractions (LDR-EB) treated from 1996 to 2007. 171 had HDR BT (17 Gy in 2 fractions or 15 Gy in 1 fraction) in combination with EBRT 35.75Gy in 13 or 37.5Gy in 15 fractions respectively (HDR-EB) treated from 2007-2012. Duration of androgen deprivation was at clinician discretion. Nadir+2 definition was used to define bPFS and toxicity scored using RTOG.

#### Results

Median FU was 74.1 and 57.0 months for the LDR-EB and HDR-EB groups respectively. Both groups were relatively well balanced (Table 1). The LDR-EB group were slightly younger than HDR-EB group (63 vs 65 years: p=0.02) and had significantly larger proportion of high risk disease (p=0.02). At 5 years there was a significant improvement in bPFS in LDR-EB compared to HDR-EB groups (90.5% vs. 77.6%, p=0.003). On MVA Gleason grade  $\geq 8$  vs 6 (HR: 5.47) and treatment group LDR-EB vs HDR-EB (HR: 2.33) both predicted bPFS. The 5-year cumulative incidence of G3 and above GU and GI toxicity was higher in LDR -EB (8% and 5%) compared to HDR-EB groups (4% and 1%) but did not reach statistical significance.

	LDR N=128	-EB N=219	-EB N=219	P-Value
Evaluable patients	116	171		
Missing Data	12(9.5%)	48(22%)		
Median f/u(Range) months	74.1(1.0-187)	57.0(1.8-116)		
Median Age (Range) years	10.7(1.6-59)	10(1.4-131)		0.02
Median PSA ng/mL	10.7(1.6-59)	10(1.4-131)		ns
Gleason Score N (%)				
6	17 (15%)	20 (12%)		
7	76 (65%)	121 (71%)		ns
8-10	21 (18%)	29 (17%)		
Unknown	2 (2%)	1 (<1%)		
T category N (%)				
T1c-T2c	50 (43%)	69 (40%)		
T3a-T3b	56 (48%)	97 (57%)		ns
Unknown	10 (9%)	5 (3%)		
NCCN Risk group N (%)				
Low	2 (2%)	2 (1%)		
Intermediate	28 (24%)	68 (40%)		0.02
High	80 (69%)	94 (55%)		
Unknown	6 (5%)	7 (4%)		
Hormone Duration N (%)				
≤12 Months	74 (64%)	126 (74%)		0.06
>12 months	7 (6%)	27 (16%)		
Unknown	35 (30%)	18 (10%)		

#### Conclusion

The risk of biochemical failure was more than double in men treated with HDR-EB compared to LDR-EB. There was higher grade 3+ GU and GI toxicity in the LDR-EB group although this has not reached statistical significance. LDR-EB may provide the most effective PSA control at 5 years. The results of this study should be regarded as hypothesis generating in view of its retrospective design, lack of randomization and missing data.

#### PO-1055 High-dose rate brachytherapy boost for T3 prostate cancer patients: a single institution experience

M. XU<sup>1</sup>, D. Diao<sup>1</sup>, A. Lazar<sup>1</sup>, K. Shinohara<sup>2</sup>, A. Chang<sup>3</sup>, A. Cunha<sup>1</sup>, I. Hsu<sup>1</sup>

<sup>1</sup>University of California San Francisco, Radiation Oncology, San Francisco, USA ; <sup>2</sup>University of California San Francisco, Urology, San Francisco, USA ; <sup>3</sup>University of California Los Angeles, Radiation Oncology, Los Angeles, USA

#### Purpose or Objective

Treating prostate cancer with extraprostatic extension (stage T3a) or seminal vesicle invasion (stage T3b) using brachytherapy boost after external beam radiotherapy (EBRT) enables dose escalation and is technically challenging. Treatment outcomes associated with high-dose rate (HDR) brachytherapy boost for T3 disease have not been well described. This study sought to assess disease control rates among patients treated with HDR brachytherapy boost for T3 disease.

#### Material and Methods

Retrospective chart review was performed to identify patients with T3 prostate cancer treated with combination EBRT and HDR brachytherapy boost between July 1997 and September 2014. Biochemical recurrence (BCR), defined as prostate specific antigen (PSA) nadir + 2 ng/mL, locoregional recurrence (LRR), distant metastases (DM), and prostate-cancer specific mortality (PCSM) were estimated using cumulative incidence and subdistribution hazard ratio (SHR) competing risk analysis. Overall survival (OS) was estimated using Kaplan Meier product limit estimator, with Cox proportional hazards modeling used to analyze associations between pre-treatment characteristics and survival outcomes.

#### Results

Of 185 patients, 139 (75.1%) had T3a and 46 (24.9%) had T3b disease. Gleason 8-10 disease was present in 87 (47.3%) patients and the median PSA was 9.3 (interquartile range [IQR] from 25th to 75th percentile, 5.8-19.4). Nearly all patients received whole pelvis EBRT (178, 96.2%) and androgen deprivation therapy (95.7%, median duration 11 months).

The median follow-up time was 89 months (IQR 49-122). The 8-year BCR rate was 29%; 26.1% for T3a and 38.3% for T3b (SHR 1.5, 95% CI 0.9-2.7,  $p = 0.15$ ). The 8-year LRR rate was 7.9%, 5.2% for T3a and 16.8% for T3b (SHR 2.3 95% CI 0.9-6.1,  $p = 0.09$ ). The 8-year DM rate was 11.9%, 9.2% for T3a and 21.3% for T3b (SHR 3.0, 95% CI 1.5-6.2,  $p = 0.003$ ). The 8-year PCSM rate was 3.6%, 1.9% for T3a and 9.1% for T3b (SHR 6.1, 95% CI 1.6-23.7,  $p = 0.008$ ). The 8-year OS rate was 90.1%, 91.5% for T3a and 85.7% for T3b disease (Cox HR 2.1, 95% CI 0.9-4.7,  $p = 0.07$ ). Grade 3 or higher gastrointestinal and genitourinary (GU) toxicities were rare; only one patient had a grade 3 chronic GU toxicity (0.6%).

**Conclusion**  
HDR brachytherapy boost for T3 prostate cancer was well tolerated. Patients with T3b disease had higher rates of LRR and statistically significantly higher rates of DM and PCSM. This suggests HDR brachytherapy boost is safe and efficacious for T3 disease, but combination chemohormonal agents may be necessary to address the high metastatic risk in patients with locally advanced prostate cancer, particularly for T3b disease.

#### PO-1056 Ultra-Focal Salvage HDR-brachytherapy for recurrent prostate cancer: a single institution experience

C. Salembier<sup>1</sup>, A. Rijnders<sup>1</sup>, C. Assenmacher<sup>2</sup>, M. Debecker<sup>1</sup>, I. Tshiakatumba<sup>1</sup>, A. Gulyban<sup>1</sup>, O. Michel<sup>1</sup>  
<sup>1</sup>Europe Hospitals - Site St Elisabeth, Department of Radiation Oncology, Brussels, Belgium; <sup>2</sup>Europe Hospitals - Site St Elisabeth, Department of Urology, Brussels, Belgium

#### Purpose or Objective

To evaluate the clinical outcome of ultra-focal salvage brachytherapy (UFSBT) after primary external beam radiotherapy or LDR-brachytherapy in terms of toxicity and efficacy, based on a single institution experience.

#### Material and Methods

Between June 2016 and June 2018 twenty patients underwent UFSBT. Patients were initially treated for primary prostate cancer with external beam radiotherapy or LDR brachytherapy. Following the development of biochemical failures (based on the Phoenix criteria), the presence of exclusive local recurrences was confirmed using Ga-68-PSMA-PET/CT and multi-parameter MRI. Treatment procedure consisted of an ultrasound guided catheter placement followed by the definitive planning using dedicated CT with co-registered PET/CT and MRI datasets. Gross tumor volume (GTV) delineation was performed on these datasets, following cognitive co-registration focusing on the region of the treatment. A margin of 5 mm (constrained to the prostatic urethra and the anterior rectal wall) was added to generate the Clinical target volume (CTV). All patients were treated

using a MicroSelectron HDR (Elekta AB, Stockholm, Sweden). The prescription dose was a single fraction of 19 Gy to the CTV. The dose distribution was graphically optimized for maximal CTV coverage while respecting the pre-defined dose constraints for the organs at risk: Bladder\_D1cc  $\leq 12$  Gy, Rectum\_D1cc  $\leq 12$  Gy and Urethra\_D10  $\leq 17.7$  Gy. Patients were followed up every 3 months for Prostate Specific Antigen (PSA) and toxicity assessment using CTCAE version 4.0.

#### Results

Sixteen patients received external beam radiotherapy and four LDR-brachytherapy as primary treatment. The mean interval between the primary treatment and salvage brachytherapy was 9.2 years (range 4-16). At presentation for UFSBT, three patients received already a hormonal treatment for their biochemical recurrence. This treatment was stopped at the day of intervention. So none of the patients received concomitant or adjuvant hormonal treatment in association with the salvage brachytherapy procedure. The mean age at time of UFSBT was 72 years (range: 56-88). On average nine (range 6-12) needles were inserted. The mean CTV was 9.4 cc (range: 4.7-24.0). All relevant dose constraints were respected (average  $\pm$  standard deviation): CTV\_D95: 19 $\pm$ 2.1 Gy, Bladder\_D1cc: 5.5 $\pm$ 3 Gy, Rectum\_D1cc: 9.2 $\pm$ 2.2 Gy, Urethra\_D10: 10.8 $\pm$ 3.3 Gy.

Median follow-up after UFSBT was 12 months (range: 3.9-28.0), with two biochemical recurrences to date. One of these 2 recurrent patients refused additional investigation and was put under hormonal treatment, while the other one remained locally uncured (persistent and identical prostate lesion at 12 months follow-up). Toxicity was limited to GU and GI grades I in all treated patients.

#### Conclusion

Ultra-focal salvage brachytherapy using HDR with a single fraction of 19 Gy offers an effective treatment option with promising local control and limited toxicity.

#### PO-1057 Salvage high-dose-brachytherapy for recurrent prostate cancer patients: 10 years of experience.

P. Lelek<sup>1</sup>, M. Stankiewicz<sup>1</sup>, T. Krzysztofciak<sup>1</sup>, S. Kellas-Slecza<sup>1</sup>, M. Fijałkowski<sup>1</sup>, P. Wojcieszek<sup>1</sup>  
<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology Gliwice, Brachytherapy Department, Katowice, Poland

#### Purpose or Objective

The analysis of mature results of salvage high-dose-rate brachytherapy (sHDRBT) for recurrent prostate cancer.

#### Material and Methods

This retrospective study on sHDRBT analyses prostate cancer patients suffering local failure (biopsy confirmed) after primary irradiation. They were included in this research consecutively from the introduction of this method to achieve median follow-up >5 years. Planned treatment schedule was interstitial sHDRBT in three fractions of 10 Gy, every two weeks. Acute and late toxicity of the treatment was assessed using the RTOG/RTOG grading criteria. Biochemical relapse was defined according to the Phoenix consensus. 5-year biochemical failure-free survival was calculated.

#### Results

83 men were enrolled in our study, treated from 2008 to 2012. Median follow - up time was 61 months (11- 111 months). Median age was 70 years (55 - 80). Median relapse peak PSA was 3,1 ng/ml (0,065 - 19,9 ng/ml). Median PSA at last follow-up was 0,358 ng/ml (0,008-2470,74 ng/ml). 80 patients suffered from urinary toxicity grade 2 or below. 11 patients developed late urinary toxicity grade 3. 6 patients had late rectal toxicity grade 1. There were 34 biochemical relapses. 25 patients suffered from metastases. 5- year biochemical failure-free survival was 59%.

## Conclusion

There is a place for salvage HDRBT in the efficient treatment of localised prostate cancer relapse after prior radiotherapy due to its ability to deliver the significant radiation dose to the prostate while minimising normal tissue exposure. The toxicity rates of the procedure are acceptable although the selection of candidates for salvage HDRBT should be carried out carefully with the consideration of the individual risk of distant failures.

## PO-1058 Long-term outcomes of LDR compared to hypofractionated EBRT for intermediate-risk prostate cancer

N. Sanmamed Salgado<sup>1</sup>, L. Joseph<sup>1</sup>, J. Crook<sup>2</sup>, J. Borg<sup>1</sup>, P. Chung<sup>1</sup>, P. Warde<sup>1</sup>, A. Di Tomasso<sup>1</sup>, A. Berlin<sup>1</sup>, M. Patel<sup>1</sup>, A. Bayley<sup>1</sup>, C. Catton<sup>1</sup>, J. Helou<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Center, Radiation oncology, Toronto, Canada ; <sup>2</sup>BC Cancer Center for the Southern Interior, Radiation oncology, Kelowna, Canada

### Purpose or Objective

Low dose-rate brachytherapy (LDR) and hypofractionated external beam radiotherapy (EBRT) are accepted standard treatments in the setting of intermediate-risk (IR) prostate cancer. As yet, none of these options have been tested against one another in a randomized trial. We aim to compare the long-term oncologic outcomes of IR prostate cancer patients treated with LDR or EBRT at a single institution.

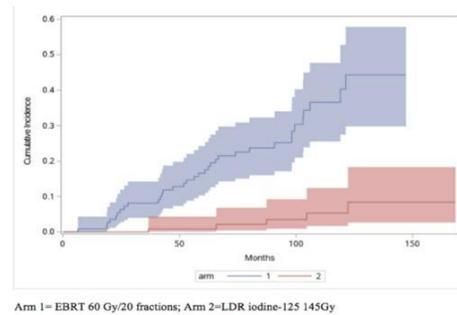

### Material and Methods

Between January 2005 and December 2013, 248 patients diagnosed with IR prostate cancer ( $\leq T2c$ , Gleason  $\leq 7$  and PSA  $\leq 20$  ng/mL) were treated with LDR or EBRT; 123 patients received a permanent implant of iodine-125 seeds prescribed to 145 Gy as a minimum peripheral dose and 125 patients were treated with EBRT to a total dose of 60 Gy in 20 fractions. The "nadir +2 ng/mL" PSA threshold (Phoenix definition) was used to define biochemical relapse (BR). To account for the competing risk of death, the cumulative incidence function (CIF) of BR and metastases for each group, and the 95% confidence intervals were reported. To test whether the difference between the groups is significant, Gray's method was applied. The Kaplan-Meier (KM) method was used to estimate overall survival (OS) and prostate cancer specific survival (PCSS), and log-rank test was used to compare treatment groups. A two-tailed p-value  $\leq 0.05$  was considered statistically significant.

### Results

Median follow-up was 95 [interquartile range (IQR): 79-118] and 96 (IQR: 63-123) months in the LDR and EBRT groups, respectively. In the LDR group, mean age was 65 ( $\pm 7$ ) with a median PSA at baseline of 6.8 ng/mL (IQR: 5.3-9.6); for the EBRT group, mean age was 71 ( $\pm 5$ ) years and median PSA at baseline was 7.4 ng/mL (IQR: 5.9-9.7). Neoadjuvant androgen deprivation therapy was used for cytoreduction in 4 patients treated with LDR and none with EBRT. BR was observed in 5 patients treated with LDR and 34 treated with EBRT. At 60 months and 90 months, the CIF of BR was 0.9% (0.1-4.4) and 3.5% (0.9-9.2) vs. 16.6% (95% CI: 10.3-24.2) and 23.7% (16.0-32.3) ( $p < 0.001$ ) in the LDR and EBRT groups (Figure 1). The median time to develop metastases was 99 months (IQR: 70-121) in the entire cohort with no statistical significant difference between groups. At 90 and 108 months, the CIF of metastases was 0% and 1.6% (95% CI: 0.1-7.5) compared to 3.4% (95% CI: 0.9-8.9) and 9.1% (95% CI: 3.5-18.2) in the LDR and EBRT groups ( $p = 0.003$ ), respectively. At the last follow-up, 24 patients were deceased in the cohort. Amongst those, 3 died from their cancer in the EBRT group [PCSS of 96.4% (95% CI: 89.3-98.8)] and none died in the LDR group ( $p = 0.09$ ).

Figure 1: Cumulative incidence function of biochemical recurrence with 95% CI

## Conclusion

Permanent iodine-125 seed implant was associated with higher biochemical and distant failure control in our cohort when compared to moderately hypofractionated EBRT. In the absence of a randomized trial, LDR when feasible should be offered to patients with a life expectancy of  $>7$  years.

## PO-1059 Separation and rectal dosimetry with a hydrogel spacer inserted during prostate HDR brachytherapy

R. DAVDA<sup>1</sup>, D. Pendsé<sup>2</sup>, A. Mitra<sup>1</sup>, M. Prentice<sup>1</sup>, L. Melcher<sup>3</sup>, N. Rosenfelder<sup>4</sup>, M. Singhera<sup>3</sup>, R. Patel<sup>5</sup>, M. Boutros<sup>5</sup>, C. Allen<sup>2</sup>, H. Payne<sup>1</sup>

<sup>1</sup>University College London Hospitals NHS Foundation Trust, Oncology, London, United Kingdom ; <sup>2</sup>University College London Hospitals NHS Foundation Trust, Radiology, London, United Kingdom ; <sup>3</sup>North Middlesex University Hospital NHS Trust, Oncology, London, United Kingdom ; <sup>4</sup>Royal Free London NHS Foundation Trust, Oncology, London, United Kingdom ; <sup>5</sup>University College London Hospitals NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

### Purpose or Objective

Pre-rectal spacers have been shown to reduce high dose radiation to the rectum and late patient reported toxicity for men treated with external beam radiation (EBRT). The ICEMAN trial is investigating the insertion of a pre-rectal spacer in men with high risk localised or locally advanced prostate cancer undergoing high dose rate (HDR) brachytherapy boost followed by EBRT to the pelvis. We report initial findings using a novel technique to insert hydrogel spacer (SpaceOAR) during the HDR procedure.

### Material and Methods

Trial participants underwent multi-parametric prostate MRI  $< 2$  weeks prior to the HDR brachytherapy and spacer insertion procedure, with a second MRI 5 days after the procedure. Brachytherapy procedures were via a transperineal approach under transrectal ultrasound guidance. Immediately prior to brachytherapy catheter implantation, a 15 cm Kellett needle was inserted in the midline between Denonvillier's fascia and the anterior rectal wall to the prostate midgland and the 5Fr Kellett sheath left in-situ. After HDR implant catheter placement hydrodissection of the pre-rectal space was achieved by injecting saline via this sheath with subsequent injection of 10 cc hydrogel spacer.

A CT planning scan was used to contour PTV, organs at risk and spacer. Brachytherapy plans were produced using graphical (GRO) and inverse planning by simulated annealing (IPSA). HDR prescription was 15 Gy to the prostate and seminal vesicles followed by 46 Gy in 23 fractions EBRT to the pelvis. Separation between posterior prostate and anterior rectal wall was measured by a Uro-radiologist on the MRI prior to, and MRI after the procedure on T2 axial 3 mm slices using sagittal planes for reference at the apex, mid-gland, base and seminal

vesicles. HDR rectal dosimetry in a cohort of men with hydrogel spacer inserted as described is reported, as well as for 10 patients contemporaneously treated without a spacer.

### Results

Complete 10cc hydrogel injection was successful in 6/7 patients and incomplete (<10 cc) in 1 case due to concerns of sheath placement. All men received 15 Gy HDR boost as planned. No complications have been observed. Initial results suggest separation between the prostate and anterior rectal wall was greater after the procedure compared with pre-procedure at all levels (Table 1).

Participant	separation prostate - anterior rectal wall pre-procedure (mm)					separation prostate - anterior rectal wall post-procedure (mm)				
	Apex	Mid-gland	Base	SV	Mean	Apex	Mid-gland	Base	SV	Mean
1	0	0	2	7	2.3	1	5	9	10	6.3
2	0	0	2	1	0.8	2	2	2	7	3.3
3	0	0	0	2	0.5	3	3	7	9	5.5
4	0	1	2	3	1.5	7	9	9	13	9.5
5	0	0	1	1	0.5	0	3	4	3	2.5
6	3	2	2	4	2.8	6	7	9	8	7.5
7	0	1	2	1	1	3	5	7	8	5.8

On comparison to contemporarily treated cohort without a hydrogel spacer, initial results suggest spacer reduces the volume of rectum receiving clinically significant moderate / high isodose levels  $\geq V30$  (4.5Gy) (Table 2).

Patient	PTV Volume (cc)	Absolute Rectum volume(cc) receiving dose (% of 150y)								
		V <sub>100</sub>	V <sub>95</sub>	V <sub>90</sub>	V <sub>85</sub>	V <sub>80</sub>	V <sub>75</sub>	V <sub>70</sub>	V <sub>65</sub>	V <sub>60</sub>
Participant1	32.7	26.6	12.4	4.9	1.8	0.6	<0.2	<0.2	<0.2	<0.2
Participant2	36.3	28.4	11	3.9	1.1	<0.2	<0.2	<0.2	<0.2	<0.2

Non Trial	38	31.8	12.9	5.1	2	0.7	0.1	<0.2	<0.2	<0.2
Non Trial	40.8	29.8	16.2	7.9	3.8	1.7	0.4	<0.2	<0.2	<0.2
Non Trial	42.5	28.6	14.8	7.2	3.2	1.3	0.3	<0.2	<0.2	<0.2
Non Trial	46.9	37.4	19.7	8.3	3.2	1	<0.2	<0.2	<0.2	<0.2
Non Trial	55.5	50.2	19.9	7.2	2.3	0.6	<0.2	<0.2	<0.2	<0.2
Non Trial	78.7	71.2	34.5	16.4	7.7	3.5	1.3	0.2	<0.2	<0.2

### Conclusion

Initial experience using an adapted, novel technique of hydrogel injection at the time of HDR brachytherapy suggests that this procedure is feasible and results in greater separation between the prostate and rectum, associated with improved rectal dosimetry. Further work will be reported in a larger cohort of study participants and clinical impact of any dosimetric improvement using patient reported outcome measures.

#### PO-1060 Role of intraluminal brachytherapy as palliative treatment in advanced esophageal cancer

V. Pareek<sup>1</sup>, R. Bhalavat<sup>2</sup>, M. Chandra<sup>2</sup>, C. Bakshi<sup>3</sup>, N. Bhambhani<sup>4</sup>

<sup>1</sup>Jupiter Hospital, Radiation Oncology, Mumbai, India ;

<sup>2</sup>Jupiter Hospital, Radiation Oncology, Thane, India ;

<sup>3</sup>Jupiter Hospital, Medical Oncology, Thane, India ;

<sup>4</sup>Jupiter Hospital, Surgical Oncology, Thane, India

#### Purpose or Objective

This study aims to assess the improvement in dysphagia, associated complications and overall and disease free survival with intraluminal brachytherapy (ILRT) as palliative care in advanced esophageal cancer

#### Material and Methods

Thirty-four patients were treated with high dose rate ILRT with or without external radiation therapy from 2009 to 2017 at our institute. Patients were assessed for various

parameters including disease stage, length of lesion, KPS and as per grade of dysphagia at presentation. The patients received median dose of 6Gy at 1 cm off axis for 2 fractions one week apart. Fourteen patients were treated radically and 20 patients post EBRT. Multivariate analysis was used to assess the predictors for dysphagia improvement. Remissions of dysphagia and other clinical and radiological factors were assessed in the first month post-treatment, and then in the third, sixth, and twelfth months. The survival rate was compared with some chosen clinical factors using a log-rank test and the Kaplan-Meier method.

### Results

Patients were followed up as per standard institute protocol. Median dysphagia free survival was 12 months. Stricture was seen in 3 patients and ulceration noted in another 2 patients. However, no tracheoesophageal fistula or procedure related complications were noted. Complications were seen with the post EBRT group. The overall survival in the cohort was 12 months and was better post EBRT as compared to radical ILRT ( $p < 0.001$ ). On multivariate analysis, stage of disease ( $p=0.02$ ), size of lesion ( $p=0.018$ ) and grade of dysphagia ( $p=0.023$ ) were found to be predictors for improved outcomes with use of ILRT in palliation.

### Conclusion

Brachytherapy in the form of ILRT in advanced esophageal cancer provides good palliation with minimal complications and improved survival and quality of life to patients.

#### PO-1061 Brachytherapy For Bladder Rhabdomyosarcoma In Children: Initial Single Institutional Experience

A. Slocker Escarpa<sup>1</sup>, E. Iraolagoitia Lasa<sup>2</sup>, J. Mases Rosines<sup>3</sup>, D. Najjari Jamal<sup>4</sup>, M. Vancells<sup>5</sup>, J. Mora<sup>6</sup>, F. Pino<sup>7</sup>, C. Gullón<sup>7</sup>, C. Gutierrez Miguez<sup>4</sup>

<sup>2</sup>Hospital Universitario Donostia, Radiation Oncology, Donostia - San Sebastián, Spain ;

<sup>3</sup>Institut Català d'Oncologia, Radiation Oncology, Barcelona, Spain ;

<sup>4</sup>Institut Català d'Oncologia, Brachytherapy, Barcelona, Spain ;

<sup>5</sup>Sant Joan de Déu - Esplugues, Paediatric Surgery, Barcelona, Spain ;

<sup>6</sup>Sant Joan de Déu - Esplugues, Medical Oncology, Barcelona, Spain ;

<sup>7</sup>Institut Català d'Oncologia, Medical physics, Barcelona, Spain

#### Purpose or Objective

As total cystectomy is mutilating, evidence has been published about the possibility of bladder conservation with macroscopic complete gross tumour resection followed by immediate High Dose Rate brachytherapy (HDR-BT). The aim of this abstract is to communicate our initial experience in multimodal approach of treating non-metastatic paediatric bladder rhabdomyosarcoma (RMS) with HDR-BT at Catalan Oncology Institute (ICO).

#### Material and Methods

3 children referred to our paediatric hospital have been treated until July 2018. In all cases, plastic tubes were placed during the surgery of tumour resection, following the HDR-BT technique described by Gustave Roussy Institute. They received 10 fractions (4Gy each, 2 times per day) with a total dose of 40Gy, completing it in the 15 days after surgery.

Patient 1: a 2 year-old boy diagnosed in 2009 of bladder neck botryoidal rhabdomyosarcoma classified at intermediate risk group was treated with induction chemotherapy. Protocol evaluation evidenced tumour persistence, and total tumour resection with HDR-BT was performed in December 2009. Afterwards, he received 6 cycles of adjuvant chemotherapy, finishing all the treatment in May 2010.

Patient 2: a 12 year-old girl initially treated with radical concomitant chemoradiotherapy (50Gy, standard fractionation) had tumour persistence. She was referred

to perform a salvage surgery of the tumour located at the limit of bladder trigone - output of the right ureter, followed by postoperative HDR-BT in November 2011.

Patient 3: a 11 months-old female affected with alveolar rhabdomyosarcoma at vesical neck classified at high risk group was initially treated induction chemotherapy in December 2017, resulting in partial tumour response after 2 different systemic lines. She underwent complete tumour resection and HDR-BT in July 2018.

#### Results

Patient 1 suffered from acute myeloblastic leukaemia in 2014; nevertheless, he currently is cured of both processes. Patient 2 relapsed locally after a year of treatment completion, so salvage total cystectomy needed to be done. Although the treatment of patient 3 has been very recent, she is free of disease at the first radiology control 3 months after treatment (follow-up is needed to see further results).

#### Conclusion

Multimodal approach in bladder conservative treatment with HDR - BT is a feasible alternative to total cystectomy in children. Although our experience is limited, the results could be comparable to those reported by the series of cases published in literature.

#### PO-1062 brachytherapy in patients with bowen disease

J.L. Munoz Garcia<sup>1</sup>, M.A. Gonzalez Ruiz<sup>2</sup>, J. Quiros Rivero<sup>1</sup>

<sup>1</sup>Badajoz University Hospital, Radiation Oncology, Badajoz, Spain ; <sup>2</sup>Punta de Europa Hospital, Radiation Oncology, Algeciras, Spain

#### Purpose or Objective

**Purpose/Objective:** High-dose-rate (HDR) brachytherapy, plesiotherapy modality, is a treatment option for Bowen disease (BD) patients with good oncologic outcomes. The objective of our study was to evaluate the initial results of BD patient treated in our centre in terms of local and cosmetic control.

#### Material and Methods

**Material/methods:** Observational, retrospective study of 12 BD lesions (12 patient) treated in our hospital from May 2015 to October 2017 with HDR brachytherapy using Valencia applicators, flaps and hand-made custom moulds (plesiotherapy). The treatment for all patients was delivered in 6 Gy fractions over seven sessions, two times a week, to a total dose the 42 Gy (EQD2 56 Gy; a/b10).

#### Results

**Results:** With a median follow-up of 32 months (range 19-48), all patients had complete response and are alive (LC 100%). Only one patient presented a new lesion in a different area from the first location treated (DFS 90%). Most of the patients (67%) did not have acute toxicity; 4 patients (33%) developed erythema grade 2 and one patient (8.33%) developed conjunctivitis. One patient presented Ectropion as a late adverse event with regular cosmetic result (8.33%). 91% of patients had good or excellent cosmetic result with high level of satisfaction.

#### Conclusion

**Conclusion:** Our initial results in Bowen disease patient treated with High-dose-rate brachytherapy, plesiotherapy modality, shown and excellent local control, and disease free survival and cosmetic results. Brachytherapy hypofractionated regimen is a simple and cost-effective non-surgical attractive treatment option for the treatment of BD patients.

#### PO-1063 Single-fraction low-energy electronic brachytherapy for conjunctival lymphoma

G. Sarria<sup>1</sup>, C. Cabrera<sup>2</sup>, G.J. Sarria<sup>2</sup>, M. Buitrago<sup>3</sup>, P. Fuentes Rivera<sup>2</sup>, S. Serpa<sup>3</sup>, F. Giordano<sup>1</sup>

<sup>1</sup>Universitätsklinikum Mannheim, Strahlentherapie, Mannheim, Germany ; <sup>2</sup>Instituto Nacional de Enfermedades Neoplásicas, Radiotherapy, Lima, Peru ;

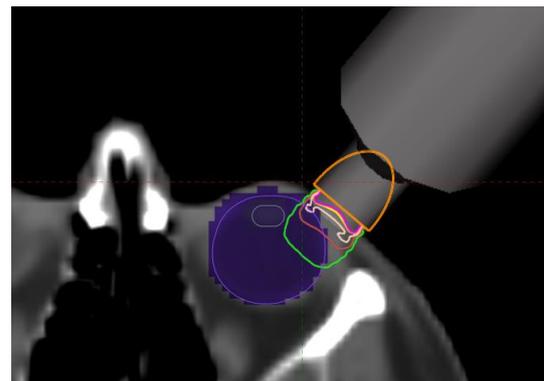

<sup>3</sup>Instituto Nacional de Enfermedades Neoplásicas, Ophthalmic Oncology, Lima, Peru

#### Purpose or Objective

Conjunctival lymphoma represents an uncommon tumor accounting for 5-10% of total extranodal lymphomas. Although radiotherapy is a frequent treatment option, limited capacities and lack of specialized centers are common problems in Peru, forcing radiation oncologists to apply short courses of radiotherapy. We here report a case series of patients treated with a novel single-shot scheme and also reviewed the literature for current short-course irradiation strategies.

#### Material and Methods

Three cases of conjunctival marginal zone (B-cell) lymphoma (MZL/MALT) of the fornix are presented. Following biopsy and sonographic assessment of the lesion thickness the application procedure was then carried out under topical anesthesia, blocking of the ocular musculature and fixing of the eyelids with a blepharostat. The head was then fixed in a thermoplastic mask, which was fenestrated over the affected eye. For brachytherapy, a low-energy X-ray device (50 kV maximum energy; Intrabeam, Carl Zeiss Meditec AG) equipped with a flat applicator was placed on the lesion, with light pressure to flatten the tumor. A focused single dose of 14 Gy kilovoltage brachytherapy, prescribed to the maximum thickness of the lesion was applied. This dose was chosen after calculating the equivalent dose of a 2 Gy fraction scheme ( $EQD2 = BED/[1 + \{2/\alpha/\beta\}]$ ) which, taking into account an approximate relative biological effectiveness (RBE) of 1.3 and a tumor  $\alpha/\beta$  ratio of 10 Gy, resulted in an EQD2 of 36.4 Gy. Follow-up was scheduled in quarterly intervals.

#### Results

Due to the absorption properties of low-energy x rays, the dose to the lens was less than 4 Gy in the worst case scenario. After 16, 19 and 28 months of follow-up, none of the three patients treated exhibited acute or chronic toxicities and remained local or distant disease-free.

#### Conclusion

Single-dose kilovoltage brachytherapy was effective and safe in this small collective. Based on the literature, there

is evidence that local treatment in short-course radiotherapy is effective and should be considered amongst the therapeutic options for these patients; however this should be evaluated prospectively in a larger patients cohort.

**PO-1064 Reducing dysphagia with palliative 2D HDR brachytherapy improves survival in esophageal cancer**

W. Burchardt<sup>1</sup>, A. Chyrek<sup>1</sup>, J. Skowronek<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Department of Brachytherapy, Poznan, Poland

**Purpose or Objective**

The goal of this study was to assess the effectiveness of dysphagia relief and overall survival in patients with advanced esophageal cancer treated with palliative high-dose-rate (HDR) 2D brachytherapy (BT).

**Material and Methods**

The study was conducted using data from medical reports of Cancer Center from January 2010 to December 2016. 133 patients with advanced or incurable esophageal cancer were treated with palliative purpose with 2D HDR BT. Median dose was 22,5 Gy in 3 fractions as primary treatment. The dysphagia was assessed in 93 patients and these patients were further analyzed. Median age was 65 years (45-88). 17,2 % of patients were female and 82,8 % male. Squamous cell carcinoma was diagnosed in 59,4 %, adenocarcinoma in 22,6% and other tumors in 6,7% cases. In 11,3 % of patients, the histopathological report was unknown. 19 patients were treated with chemotherapy and 4 with external beam radiotherapy after BT.

**Results**

Median follow up was 2,8 months (range 0,2-42,7). Median tumor length was 7,5 cm. Patients before treatment present following grades of dysphagia: I - 57 %, II - 33,3 %, III - 6,5 %, IV - 3,2 %; grades dysphagia after BT were significantly lower: 0- 38,7 %, I - 31,2 %, II - 20,4 %, IV - 1,1 % (p<0,001, Wilcoxon test). Mean time of dysphagia relief was 4,6 months and was achieved in 55 %, stabilization occurred in 31 %, and worsening of symptom was reported in 14% of cases. The patients with dysphagia relief (4,2 vs 2,2 months, p<0,01) or age <= 65 lived longer (3,7 vs 2,0 months p<0,01). The length of the tumor, primary localization, and primary grade of the dysphagia weren't factors which influenced the survival of patients. The logistic regression model didn't find any predictors for treatment response.

**Conclusion**

HDR 2D BT reduces dysphagia and prolongs survival especially in younger patients who response the treatment. HDR 2D BT meets the assumption of palliative treatment for advanced esophageal cancer.

**PO-1065 Multiparametric radiobiological parameters implementation to predict radiation-induced side effects**

M. Ben Kacem<sup>1</sup>, M. Benadjaoud<sup>2</sup>, F. Soysouvanh<sup>1</sup>, M. Dos Santos<sup>3</sup>, G. Tarlet<sup>1</sup>, V. Buard<sup>1</sup>, A. François<sup>1</sup>, O. Guipaud<sup>1</sup>, F. Milliat<sup>1</sup>, V. Paget<sup>1</sup>

<sup>1</sup>National Insitute for Radiobiological Protection and Nuclear Safety IRSN, Radiobiology of Medical Exposure Laboratory LRMed, Fontenay aux Roses, France ;

<sup>2</sup>National Insitute for Radiobiological Protection and Nuclear Safety IRSN, Radiobiology and Regenerative Medicine Research Service SERAMED, Fontenay aux Roses, France ; <sup>3</sup>National Insitute for Radiobiological Protection and Nuclear Safety IRSN, Radiobiology of Accidental Exposure Laboratory LRAcc, Fontenay aux Roses, France

**Purpose or Objective**

Radiotherapy (RT) is used to treat more than half of cancers. Despite the development of practices and devices that precisely deliver radiation dose to tumor with high dose rate, the biological effects on healthy tissue remain poorly studied.

To predict radiation-induced biological effects, radiobiologists use the Relative Biological Effectiveness (RBE) concept to compare doses between two ionizing radiations given the same biological effect. RBE is essentially based on clonogenic assay to determine the impact of a defined ionizing radiation. Survival clonogenic curves are modelled by the linear quadratic model, and, according to several studies, this assay is insufficient to predict effects on healthy tissues after radiation. Based on the various effects known after irradiation, it is necessary to develop multiparametric RBE measures to predict the biological effects of emerging radiation therapy protocols.

**Material and Methods**

Human Umbilical Vein Endothelial Cells (HUVECs) were irradiated with a linear accelerator using two different dose rates (0.63 and 2.5 Gy/min). Endothelial cells (EC) were chosen for their involvement in radiation induced damages on healthy tissue. To predict accurately the adverse effects on healthy tissues, we have measured multiple *in vitro* biological readouts (clonogenic assay, viability, cell cycle, senescence and gene expression) at 3, 7, 14 and 21 days post-irradiation. The biological measures are already modelled on Matlab for each assay and will be integrated all together in a unique predictive model. Finally, total body irradiations and localized irradiations were conducted on preclinical mice models (C57BL/6J) to validate the *in vitro* data.

**Results**

Our *in vitro* results show a significant dose rate effect on cellular morphology of HUVECs. After irradiation at the lowest dose rate, clonogenic survival (RBE = 0.8) and cell viability (RBE < 1) are higher. Furthermore, we have measured less B-galactosidase activity (related to radio-induced senescence) after irradiation at 0.63 Gy/min compared to 2.5 Gy/min (RBE = 0.5). Moreover, the proportions of cells in the cell cycle phases and a 44 genes expression involved in senescence process were found modified according to the dose rate. *In vivo*, after the irradiation of an exteriorized segment of small intestine (19 Gy) on mice, a significant higher loss of weight was measured at the higher dose rate.

**Conclusion**

These data show a deleterious effect of the highest dose rate. The mathematical model will be consolidated by supplemental *in vitro* measures on Human Lung Microvascular Endothelial Cells (HMVEC-L) to validate the impact of the dose rate.

To complete this study, we also focus our work on biological effects of different fractionated irradiation protocols both *in vitro* (on HUVECs) and *in vivo* (whole thorax irradiations on a preclinical mice model). These biological measures will be modelled and integrated within the predictive model in the future.

**PO-1066 The unique DDR mechanisms of human induced pluripotent stem cells (hiPSC)-derived chondrocytes**

E. Stelcer<sup>1,2,3</sup>, K. Katarzyna<sup>1,2</sup>, S. Wiktoria M.<sup>1,2</sup>

<sup>1</sup>Poznan University of Medical Sciences, Department of Electroradiology, Poznan, Poland ; <sup>2</sup>Greater Poland Cancer Centre, Radiobiology Lab, Poznan, Poland ;

<sup>3</sup>Medical University of Warsaw, Postgraduate School of Molecular Medicine, Warsaw, Poland

### Purpose or Objective

Human induced pluripotent stem cells (hiPSCs) constitute a real breakthrough in regenerative medicine. We differentiated hiPSCs towards chondrocytes (hiPSC-derived chondrocytes, hiPSC-DCHs) as a real hope for patients diagnosed with osteoarthritis. However, it is still a research area that must be more precisely investigated to ensure safety of patients. Thus, we investigate the DDR mechanisms of these cells exposed to IR. Previously, we demonstrated results concerning  $\gamma$ H2AX, DNA repair, apoptosis and senescence. In this study, we aim to show the analyses of cell cycle, ROS level and changes in mitochondrial membrane potential of irradiated cells.

### Material and Methods

We differentiated of hiPSCs into chondrocyte-like cells. The hiPSC-derived chondrocytes were treated with IR (0; 1; 2 and 5 [Gy]). Then, we performed analysis of cell cycle using propidium iodide (9h after IR as a most sensitive time point that we previously selected). Immediately after IR, we investigated level of generated ROS taking advantage of CellROX Green Flow Cytometry Assay Kit (TBHP served as a positive control). Finally, the analysis of mitochondrial membrane potential was based on JC-1 staining (CCCP served as a positive control).

### Results

The irradiated hiPSCs demonstrated accumulation of cells in S phase. On the contrary, both mature chondrocytes and hiPSC-DCHs revealed arrest of cell cycle in G2 phase. Furthermore, chondrocyte-like cells obtained from hiPSCs revealed characterization of cell cycle similar to fully differentiated cells (hiPSC-DCHs vs chondrocytes). In that case the majority of cells were noticeable in G1 phase. In contrast, non-irradiated hiPSCs as highly proliferative type of cells demonstrate the highest percentage of S phase. The IR did not cause a dramatic differences in the ROS level in all investigated types of cells (hiPSCs, hiPSC-DCHs and mature chondrocytes). However, there was a significant dissimilarity between overall profile of hiPSCs and differentiated cells (both hiPSC-DCHs and chondrocytes). The non- and irradiated hiPSCs showed the relatively high level of ROS- that was shifted to the positive control- in contrast to differentiated cells. In turn, the most notable changes of mitochondrial membrane potential was observed as hiPSC-DCHs (above 30% of stained cells) revealing - in this aspect - their high radiosensitivity.

### Conclusion

We provided a new knowledge concerning hiPSC-derived cells. We can observe that radioresistance of hiPSC-DCHs significantly differ from both "parental" hiPSC and mature chondrocytes generating a unique, individual and specific DDR of these cells. It may have an influence on their genetic stability. In further part of research we plan to focus on testing hiPSC-DCHs in *in vivo* model.

### PO-1067 High expression of CCND2 in glioblastoma is associated with an increased risk of early mortality.

C. Bouchart<sup>1</sup>, A. Trépant<sup>2</sup>, M. Hein<sup>3</sup>, D. Van Gestel<sup>1</sup>, P. Demetter<sup>4</sup>

<sup>1</sup>Institut Jules Bordet - Université Libre de Bruxelles, Department of Radiation-Oncology, Brussels, Belgium ;

<sup>2</sup>Erasme University Hospital - Université Libre de Bruxelles, Department of Pathology and DIAPATH-Center of Microscopy and Molecular Imaging CMMI, Brussels, Belgium ; <sup>3</sup>Erasme University Hospital - Université Libre de Bruxelles, Department of Psychiatry and Sleep Laboratory, Brussels, Belgium ; <sup>4</sup>Institut Jules Bordet - Université Libre de Bruxelles, Department of Pathology, Brussels, Belgium

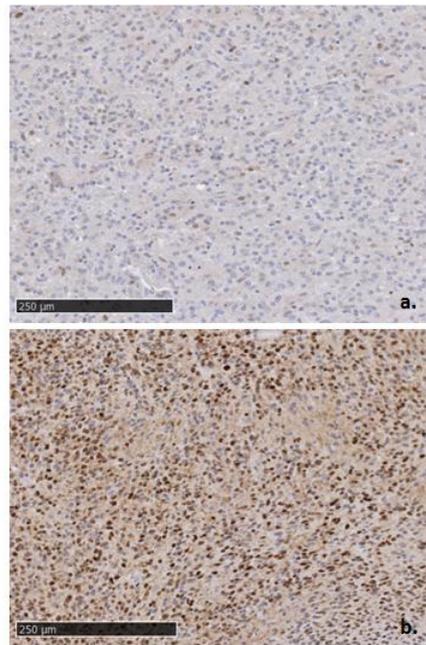

### Purpose or Objective

Glioblastomas (GBM) are highly radio- and chemoresistant tumors associated with poor outcome. Cyclin D2 (CCND2) is known to play a critical role in cell cycle progression, tumorigenicity and radioresistance in GBM, particularly in the subpopulation of glioma stem cells. The aim of our study is to better understand the evolution of CCND2 expression during treatments and to investigate its clinical significance in GBM.

### Material and Methods

Immunohistochemical expression analysis of CCND2 was carried out on paired GBM samples of 72 patients, comparing initial resections with recurrent tumors after radiation therapy alone (RT) (n=36) or radio-chemotherapy with temozolomide according to the Stupp regimen (RT-TMZ) (n=36). Semi-quantitative analysis of CCND2 nuclear staining was performed by two independent observers. Every tumor was scored according to the number of stained cells (low nuclear expression < 30% and high nuclear expression  $\geq$  30%). (Figure 1) Multivariate logistic regression analysis was conducted to investigate clinical and demographic risk factors of early mortality in GBM patients.

Figure 1. CCND2 expression profile in glioblastoma.

CCND2 presents a nuclear and a cytoplasmic expression in glioblastoma. a. Low nuclear expression of CCND2 (<30% of tumour cells nuclei stained). b. High nuclear expression of CCND2 ( $\geq$ 30% of tumour cells nuclei stained).

### Results

Compared to the primary tumor, CCND2 expression was decreased in GBM recurrences after treatment with RT ( $32.00 \pm 19.00$  vs  $20.00 \pm 19.00\%$ ,  $p = 0.013$ ) or RT-TMZ ( $31.00 \pm 20.00$  vs  $19.00 \pm 18.00\%$ ,  $p = 0.001$ ). The decrease in CCND2 expression did not differ significantly according to the treatment used ( $p = 0.731$ ). Multivariate logistic regression analysis revealed that significant risk factors predicting early mortality (<12 months) in GBM patients are: time to recurrence  $\leq$  6 months [OR 23.88 (CI 95% 4.36 to 130.68)], subtotal surgery at recurrence [OR 10.58 (CI 95% 1.81 to 62.01)] and high nuclear expression of CCND2 ( $\geq$  30%) at initial surgery [OR 7.97 (CI 95% 1.35 to 46.98)]. The following variables were not included in the model because they were not significant: gender, age, preoperative use of corticosteroids, type of initial surgery,

type of adjuvant treatment, and nuclear expression of CCND2 at recurrence. (Table 1)

**Table 1: Summary of logistic regression for screening variables predicting early mortality in glioblastoma patients (n=72).**

Variables	Adjusted OR (CI 95%)	P-value
Time to recurrence (months)		<0.001
>6 (n=42)	1	
≤6 (n=30)	23.88 (4.36 to 130.68)	
Type of surgery at recurrence		0.009
Total (n=31)	1	
Subtotal (n=41)	10.58 (1.81 to 62.01)	
CCND2 nuclear expression (%)		0.022
At initial surgery	1	
<30 (n=30)		
≥30 (n=42)	7.97 (1.35 to 46.96)	

Not included in the model because not significant: gender, age, preoperative corticosteroids, type of initial surgery, type of adjuvant treatment, and nuclear expression of CCND2 at recurrence.  
Adequacy of model: Hosmer-Lemeshow chi2 (p=0.927)  
Specificity of model: Linktest (linear component p<0.001 and nonlinear component p=0.260)  
OR = Odds Ratio, CI = Confidence Interval

## Conclusion

Adjuvant treatments globally reduce expression of CCND2. To our knowledge, we are the first to demonstrate that high nuclear CCND2 expression at initial surgery is associated with higher risk of early mortality for GBM patients. These results confirm preclinical data observed in immunocompromised mice suggesting that targeting CCND2 could be promising for GBM therapy.

### PO-1068 Very high yield of double strand breaks found at the distal end of the proton Bragg peak

N.F.J. Edin<sup>1</sup>, A.M. Rykkelid<sup>1</sup>, A. Görgen<sup>1</sup>, A. Baker<sup>1</sup>, S. Siem<sup>1</sup>, K. Ytre-Hauge<sup>2</sup>, E. Malinen<sup>1</sup>

<sup>1</sup>University of Oslo, Physics, Oslo, Norway ; <sup>2</sup>University of Bergen, Department of Physics, Bergen, Norway

#### Purpose or Objective

While protons can be delivered more precisely with less radiation to the normal tissue than X-rays, emerging reports indicate that X-rays and protons affect cellular response pathways in different ways. The involved mechanisms include DNA repair, epigenetic modulation, immunogenicity, and regulation of cytokines and protein phosphorylation. It is therefore not possible to predict biological effects of proton irradiation from dose-response data from X-ray irradiation. In this study, we use low energy protons of 16 MeV with a high dose-averaged linear energy transfer (LET) to measure differential cellular responses at different positions in the proton Bragg Peak (BP) with varying LET. We compare measured clonogenic survival to H2AX-phosphorylation at 3 different time points after proton irradiation using an experimental setup ensuring accurate dosimetric depth positioning of T98G glioblastoma cells.

#### Material and Methods

A horizontal 16 MeV proton beam line for in vitro cell irradiation was constructed. The beam line consisted of a single scattering foil, a monitor chamber type 7862 (PTW, Freiburg, Germany) and an Advanced Markus ionization chamber (PTW) with a 30 micron entrance window for absolute dosimetry. T98G glioblastoma cells plated on dishes were irradiated with protons in a cylindrical heater at different depths, corresponding to different position before and in the BP. Clonogenic survival was measured and the number of DNA double strand breaks was assessed by an H2AX-phosphorylation-antibody using flow cytometry at 3 different time points to measure initial damage as well as repair. LETs varied from 7.5 to 44 keV/um and 220 kV X-rays were used as reference radiation.

## Results

Clonogenic survival of T98G cells followed a linear-quadratic response for X-irradiation and irradiation at the front of the BP. At the distal end of the BP, cell survival per dose was much lower and a log-linear response function was found to be a better fit. Comparing with X-ray response at 37 % survival, RBE values at frontal and distal end of the BP were  $1.7 \pm 0.1$  and  $4.9 \pm 0.4$ , respectively. The initial H2AX phosphorylation was found to be up to 4 times higher at the distal end of the BP compared to the front as measured 0.5 h after 5 Gy irradiation using the same dose-rate and proton fluence in both positions. When the cells were irradiated at the top of the BP with the same proton fluence, the dose was 22 Gy and induced similar amounts of H2AX-phosphorylation as in the distal end of the BP with 5 Gy (figure 1). While most damage was repaired for cells irradiated in the front of the BP, high amounts of residual damage were seen after 5 Gy in the distal end and for 22 Gy at the top of the BP.

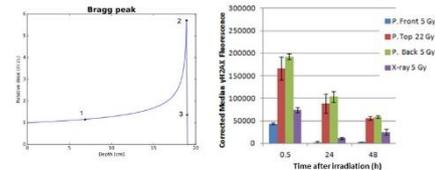

Figure 1. Left panel: T98G cells were irradiated at 3 different positions in the Bragg peak: 1: Front of the BP; 2: Top of the BP; 3: Back or distal end of the BP. Right panel: The amount of DNA double strand breaks was measured using flow cytometry and +H2AX antibody at 3 time points after proton irradiation in 3 different positions in the BP as well as X-ray irradiation. The proton fluence, as measured by a monitor chamber, was kept constant for the 3 positions in the BP.

## Conclusion

A higher amount of more complex DNA double strand breaks is induced by high LET relative to low LET protons. This is consistent with a change in shape of the survival curves with the presence of a “shoulder” for the lower LET, which is strongly reduced for the higher LET.

### PO-1069 RBE calculation for hadrontherapy by the BIANCA biophysical model

M.P. Carante<sup>1</sup>, F. Ballarini<sup>2</sup>

<sup>1</sup>Istituto Nazionale di Fisica Nucleare INFN, Physics Department, Pavia, Italy ; <sup>2</sup>University of Pavia, Physics Department, Pavia, Italy

#### Purpose or Objective

The main purpose of the present work consists of comparing RBE values calculated by the BIANCA model for V79 cells (often used for hadrontherapy beam characterization) and AG01522 cells (considered as representative of normal tissues) exposed to different charged particles (protons, C-ions and He-ions) with the corresponding experimental values, and showing examples of applications to hadrontherapy beams.

#### Material and Methods

BIANCA (Biophysical Analysis of Cell death and chromosome Aberrations) is a two-parameter biophysical model that calculates the probability of radiation-induced cell death as well as chromosome aberrations, which can be regarded as indicators of normal tissue damage. The model is based on the idea that some DNA damage types (“Cluster Lesions”, where by definition each CL produces two independent chromosome fragments) lead to chromosome aberrations following distance-dependent (mis-)rejoining, or un-rejoining, of chromosome fragments, and that some aberrations lead to (clonogenic) cell death. The yield of CLs, which depends on radiation

quality (i.e. particle type and energy), is an adjustable parameter; the probability that a chromosome fragment remains unrejoined, which depends on cell type but is independent of radiation quality and thus can be adjusted basing on photon data, is the second parameter.

#### Results

Up to now, the model has been tested against experimental data on V79 cells and AG01522 cells exposed to protons, C-ions and He-ions of different energy, as well as photons for comparison. The good agreement between simulations and data allowed validating the model; furthermore, a database of CL yields was produced that allows predicting cell survival curves for different ions, in principle for any LET value. By fitting these curves, tables of alpha and beta coefficients were produced for different ion types and energies for both considered cell types, and the corresponding RBE were calculated. The RBE values predicted this way were in good agreement with experimental data taken from the literature. Since these tables can be read by a radiation transport codes, an interface was developed between BIANCA and FLUKA, which allows producing "biological" profiles for hadrontherapy beams.

#### Conclusion

These results show that BIANCA can produce RBE values to be used in hadrontherapy.

#### PO-1070 Identification of biologically active factors in ionizing radiation regulated secretome

M. Pruschy<sup>1</sup>

<sup>1</sup>University of Zurich, Applied Radiobiology, Zurich, Switzerland

#### Purpose or Objective

Ionizing radiation (IR) leads to DNA damage and genome instability. In addition, IR also leads to stress responses in tumor cells by activating signal transduction pathways and inducing secretion of numerous auto- and paracrine factors. As part of an exhaustive IR-dependent secretome analysis, which was previously performed in our laboratory, placental growth factor (PLGF) was identified to be secreted in response to IR. It is a homodimeric protein, belongs to vascular endothelial growth factor (VEGF)-family and binds to VEGFR1. PLGF expression is low to undetectable in most tissues in healthy subjects, but becomes significantly upregulated in disease.

#### Material and Methods

PLGF expression and secretion were analyzed across multiple cancer cell lines and at different time points after irradiation with increasing doses of IR (0, 5 and 10Gy) by qRT-PCR and ELISA, respectively. Two medulloblastoma cell lines (p53 wildtype vs. p53-mutated) were chosen for further experiments with siRNA and the HIF1-alpha inhibitor BAY 87-2243 under normoxic and hypoxic (1% O<sub>2</sub>) conditions to investigate the downstream targets of BAY 87-2243.

#### Results

PLGF expression and secretion was already upregulated at 4h and 24h, respectively, in p53 wild-type cancer cells. Interestingly, only minimal or delayed PLGF expression could be detected in p53-mutated cell lines. PLGF is also upregulated under hypoxic condition. Therefore, cells were treated with the HIF1-alpha inhibitor BAY 87-2243 under normoxic and hypoxic condition (1% O<sub>2</sub>). Interestingly, BAY 87-2243 attenuated PLGF-secretion only in p53-mutated cells. These results suggest that PLGF is differentially regulated by either p53 or HIF1-alpha. To further link p53 and PLGF, p53 wildtype cells were treated with p53 inhibitor Pifithrin-α or MDM-2 inhibitor MI-773. PLGF secretion was decreased after Pifithrin treatment

and increased in MI-773 treated cells further linking p53 and PLGF.

In order to investigate the paracrine effect of PLGF, we have developed PLGF knock out cells using a CRISPR-Cas9 approach. These cells will be used for *in vitro* and *in vivo* experiments to study the paracrine effect of IR-induced PLGF secretion on tumor and endothelial cells and for tumor radiosensitivity.

#### Conclusion

In conclusion, PLGF, which has so far not been investigated in response to IR, might play a relevant role for the radiation response on the level of tumor angiogenesis.

#### PO-1071 RIBE alters biological properties of the wound fluids

K. Kulcenty<sup>1</sup>, I. Piotrowski<sup>2</sup>, D. Murawa<sup>3</sup>, W. Suchorska<sup>2</sup>

<sup>1</sup>Poznan University of Medical Sciences- Greater Poland Cancer Centre, Department of Electroradiology- Radiobiology Lab, Poznan, Poland ; <sup>2</sup>University of Medical Sciences- Greater Poland Cancer Centre, Department of Electroradiology- Radiobiology Laboratory, Poznań, Poland ; <sup>3</sup>Poland Baptism Monument Hospital, Department of General and Minimally Invasive Surgery, Gniezno, Poland

#### Purpose or Objective

After breast cancer surgery, more than 90% of local recurrences occur in the same quadrant as the primary cancer. Wound fluids (WF) are believed to play a role in this process by inducing an inflammatory process in the scar tissue area. Given that most local relapse occur within the scar tissue area, researchers have investigated whether localized radiotherapy, such as intraoperative radiotherapy (IORT), could be more effective than postoperative RT in inhibiting local tumor recurrence. Despite the availability of strong clinical data demonstrating the benefits of IORT, the biological basis underlying this process is still not well- understood. It is known that ionizing radiation (IR) directly affects the cells by damaging DNA and consequently changing the phenotype of the cell. In addition to a direct action, the effect of IR may also be observed in cells that were not irradiated, but were in a close proximity to irradiated cells - a phenomenon called radiation induced bystander effect (RIBE). It was also showed that RIBE significantly modifies the tumor microenvironment. Given this background we assume that postoperative fluid from patients after intraoperative radiation therapy acts through bystander effect (RIBE, radiation induced bystander effect) that induces the radiobiological response in unirradiated cells and modify their phenotype.

#### Material and Methods

To confirm this hypothesis, WF collected from patients after breast conserving surgery (BCS) alone (WF) (i.e., without IORT), after BCS followed by IORT treatment (RT-WF) or WF from BCS patients together with conditioned medium from irradiated cells (WF+RIBE) were incubated with MDA-MB-468 cells. Using microarray analysis we compared cells incubated with collected fluids. The GSEA analysis was performed to demonstrate biological processes characteristic for treated cells. RT-qPCR and flow cytometry analysis were used to confirm obtained results.

#### Results

The microarray analysis of wound fluids stimulated MDA-MB-468 cells indicated common biological processes for RT-WF and WF+RIBE group. Overrepresentation of processes involved in cell cycle regulation, DNA repair and oxidative phosphorylation was observed in RT-WF and WF+RIBE group while WF group was characterized by overrepresentation of pathways involved in INF-α response, INF-γ response, inflammatory response and IL6 JAK/STAT3 signaling pathway.

### Conclusion

In the present study we indicated a common biological processes activated in MDA-MB-468 cell line stimulated with WF collected from patients after IORT treatment and cells treated with WF collected from BCS patients together with RIBE medium. Therefor we confirmed the role of the radiation-induced bystander effect in altering the biological properties of the wound fluids.

#### PO-1072 INTRABEAM: precision hypo-fractionated radiotherapy with a systemic immune response.

I. Linares<sup>1</sup>, M.Á. Berenguer<sup>1</sup>, E. Martínez<sup>1</sup>, M. Laplana<sup>1</sup>, R. Cañas<sup>2</sup>, S. Comas<sup>3</sup>, H. Pérez-Montero<sup>1</sup>, M. Ventura<sup>1</sup>, F. Guedea<sup>1</sup>

<sup>1</sup>Institut Català d'Oncologia, Radiation Oncology, Barcelona, Spain ; <sup>2</sup>Institut Català d'Oncologia., ONCOBELL Program-IDIBELL., Barcelona, Spain ; <sup>3</sup>Institut Català d'Oncologia, Radiation Oncology, Badalona, Spain

#### Purpose or Objective

To evaluate the changes in immune-cell phenotype in peripheral blood following intraoperative radiotherapy (IORT) in breast cancer patients.

#### Material and Methods

45 patients were classified in three groups of treatment as follows: Group A (Lumpectomy and Intrabeam exclusive), Group B (Lumpectomy and Intrabeam followed by EBRT 40.05 Gy in 15 fractions of 2.67 Gy) and Group C (Lumpectomy and EBRT 40.05 Gy in 15 fractions of 2.67 Gy +/- EBRT boost 9 Gy in 3 fractions). For each group, peripheral blood mononuclear cells (PBMCs) were isolated from heparinized venous blood samples collected before treatment and during different time points after treatment: before lumpectomy, 48 hours after IORT or EBRT, and 3 and 10 weeks after radiation treatment was completed. Peripheral blood populations of cytotoxic T-cells (CTL), helper T-cells, Natural Killer cells (NK), regulatory T-cells (Treg) and Myeloid Derived Suppressor cells (MDSC) were measured using flow cytometry. Cell phenotypes were evaluated using the FACS Navios system (BeckmanCoulter). Data were analyzed using FlowJo software (Tree Star Inc., Ashland, OR, USA).

#### Results

30 patients were included: 11, 15 and 4 patients for Group A, B and C respectively. For group A and B, the number of CTL increased three weeks after IORT (60.20% basal vs 67.10%) and EBRT (66.50% basal vs 71.30%) respectively. In contrast, for the control group (group C), a decrease in CTL was seen (64.35% vs 61.50%). In group A the number of NK cells increased after treatment (46.20% basal vs 59.20%), while in group B (42.90% basal vs 36.35%) and group C (56.80% basal vs 38.40%), we observed a NK decrease. For Treg we had mixed results which were hard to interpret. For Group A we saw a decrease during treatment (1.54% basal vs 1.44%) while for Group B we observed an increase of these cells (2.0% basal vs 2.75%). After 3 weeks, this tendency was reverted. For Group C, we observed an increase during treatment (1.45% basal vs 2.87%). For the MDSC panel, for granulocytes we observed a decrease in group A (6.44% basal vs 5.78%) and an increase in both group B (7.90% basal vs 10.31%) and group C (7.65% basal vs 10.20%) after 10 weeks. For Monocytes, in group A we observed the number of activated monocytes stable (8.95% basal 9.13%), whereas in group B and C we saw an increase after EBRT.

#### Conclusion

These results suggest that high doses per fraction would play an important role in CT, NK cells but not on the Treg and monocytes immunosuppression cells. Deciphering immune responses to treatment in breast cancer patients

might introduce new useful biomarkers for treatment choices in the future.

#### PO-1073 Biomathematical modeling of fractionated irradiation on immunogenic cell death induction in vitro

F. Eckert<sup>1</sup>, L. Bardoscia<sup>1,2</sup>, P. Hausmann<sup>1</sup>, Z. Daniel<sup>1</sup>, D. Thorwarth<sup>3</sup>, S.M. Huber<sup>4</sup>

<sup>1</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany ; <sup>2</sup>University of Brescia, Radiation Oncology, Brescia, Italy ; <sup>3</sup>University Hospital Tübingen, Section for Biomedical Physics- Department of Radiation Oncology, Tübingen, Germany ; <sup>4</sup>University Hospital Tübingen, Experimental Radiation Oncology, Tübingen, Germany

#### Purpose or Objective

Immunogenic cell death (ICD) is counted among the crucial steps of eliciting effective anti-tumor immune responses after irradiation. Most publications argue in favor of hypofractionated regimens. However, systematic analyses of radiobiological parameters such as fractionation sensitivity are scarce for ICD induction. Several clinical settings such as the treatment of glioblastoma including large volumes of normal brain tissue rely on normofractionated radiotherapy regimens. Thus, we aimed to evaluate ICD induction systematically after different radiation regimens and modeled the data with biomathematical methods.

#### Material and Methods

A standard glioblastoma cell line (U87MG) and two patient-derived, stem cell enriched glioblastoma cell lines (LKVII and LKXVII) were analyzed for their membrane exposure of Calreticulin (CRT) 24h after irradiation (determined as a suitable time point in an initial experiment for the kinetics of CRT exposure after irradiation with 15 Gy) with single doses (2-24 Gy) and daily fractionated treatment (5 x 2 Gy, 3 Gy and 4 Gy, respectively). Percentage of cells with irradiation-induced CRT exposure after single dose irradiation was fitted with a non-linear least square fit to a Hill function. Equivalent single fraction irradiation doses were calculated for membranous CRT after fractionated irradiation using the equation derived from the data fit. Immunogenic cell death induction was confirmed by HMGB1 release (ELISA), normalized to number of viable cells 48h after single dose irradiation for U87MG and LKVII.

#### Results

The three cell lines showed a vast difference in basal CRT positivity in unirradiated controls of 6.9±0.24%, 9.5±0.09% and 15.3±0.18% for U87MG, LKVII and LKXVII, respectively. All cell lines showed significant ICD induction after irradiation with ≥8Gy single dose and 5 x 3 Gy and 4 Gy. The data were well fitted by a Hill function (R<sup>2</sup>>0.98). For both patient-derived cell lines, normofractionated irradiation of 10 Gy significantly increased membrane exposure of CRT. Corresponding single doses for fractionated regimens were higher for LKVII and LKXVII compared to U87MG. Significant HMGB1 release into the medium was observed for 8 Gy irradiation for LKVII and for 16 Gy for both tested cell lines (8.9±0.9 pg/10<sup>6</sup> cells vs. 21.1±1.5 pg/10<sup>6</sup> cells, 4.0±0.7 pg/10<sup>6</sup> cells vs. 47.4±9.35 pg/10<sup>6</sup> cells for LKVII and U87MG, respectively).

#### Conclusion

Glioblastoma cells, a highly radioresistant tumor entity, shows ICD after single dose of 8 Gy or higher and fractionated irradiation. Daily fractionated irradiation seems to lead to accumulation of cellular damage leading to immunogenic cell death. Even a clinically low dose of 5 x 2 Gy induces ICD in patient-derived, stem cell enriched cultures. Thus, at least concerning the initial step of effective anti-tumor immune response, normofractionated radiotherapy might be a possible partner for immunotherapy strategies in the clinic.

**PO-1074 Radiotherapy and immuno-check point inhibitors for brain metastases. A mono-institutional analysis.**

C. Di Carlo<sup>1</sup>, F. Patani<sup>1</sup>, D. Fasciolo<sup>1</sup>, S. Di Biase<sup>1</sup>, C. Rosa<sup>1</sup>, A. Allajbeji<sup>1</sup>, L. Gasparrini<sup>1</sup>, P. Di Marino<sup>2</sup>, M. De Tursi<sup>2</sup>, L. Caravatta<sup>1</sup>, M. Trignani<sup>1</sup>, D. Genovesi<sup>1</sup>  
<sup>1</sup>Department of Radiation Oncology- SS Annunziata Hospital, G. D'Annunzio University, Chieti, Italy ;  
<sup>2</sup>Medical Oncology Unit- SS Annunziata Hospital- Chieti, Department of Medical- Oral and Biotechnological Sciences- University G. D'Annunzio, Chieti-Pescara, Italy

**Purpose or Objective**

As suggested by the literature, immunotherapy (IT) combined with radiotherapy (RT) could be a promising strategy to enhance treatment efficacy, but the safety and timing of their association remains unclear. The aim of our analysis is to assess the safety of IT concomitant or close to RT in patients with brain metastases.

**Material and Methods**

From November 2016 to September 2018, 13 patients with brain metastases from renal cells carcinoma (2 patients), non-small cell lung cancer (6 patients) and melanoma (5 patients) were treated in our Institute and retrospectively analyzed. The radiation treatment was defined concomitant when it was performed after the beginning of IT course. Acute and late toxicities were evaluated according to CTCAE v 4.0 scale. After RT, patients were reevaluated with total body CT scan. MRI was also performed in case of FSRT after 3 months from RT.

**Results**

Median age was 71 years (range: 54-78 years). All patients reported a performance status  $\geq 70\%$  according to Karnofsky scale, except one with 60%. Median follow up was 12 weeks (range: 2-60 weeks). Patients received IT with anti-PDL1 (12 patients) or anti-CTLA4 (1 patients) that was concomitant in 10 cases, while 2 patients started immunotherapy within two months from RT. Whole brain radiotherapy (WBRT) with a total dose of 20 Gy (4 Gy/fraction) was administered in 11 patients, while the remaining 2 patients underwent fractionated stereotactic radiotherapy (FSRT) with a total dose of 24 Gy (8Gy/fraction). Median number of IT cycles was 9 and it is still ongoing in 3 cases. All patients received concomitant corticosteroids therapy (dexamethasone, at ranging dose between 2 mg/die and 12 mg/die).

Combination IT-RT was well tolerated without unexpected toxicities. The 92% of patients had G0 acute toxicities according to CTCAE scale. Only in one case, radiotherapy was interrupted for poor clinical condition. Late toxicities were collected in 7/13 patients and it was G0 in the 70%. The remaining 30% of patients, showed G1-G2 neurological toxicity. No case of radionecrosis was detected. At the time of analysis, 5 patients were died for disease complications, non-related to the treatment.

**Conclusion**

From our data, IT resulted to be safe in patients treated with concomitant RT for brain metastases without G3-G4 acute toxicities and radionecrosis. Longer follow-up and a higher number of patients are necessary to confirm these data.

**Poster: Radiobiology track: Radiation and tumour metabolism**

**PO-1075 CBX4 contributes to radioresistance of esophageal squamous cell carcinoma by targeting autophagy**

H. Zhu<sup>1</sup>, L. Chu<sup>1</sup>, Q. Liu<sup>1</sup>, H. Zhu<sup>1</sup>, S. Lai<sup>1</sup>, K. Zhao<sup>1</sup>  
<sup>1</sup>Fudan University Shanghai Cancer Center, Radiation Oncology, Shanghai, China

**Purpose or Objective**

We investigated the effects of Chromobox 4 (CBX4) in esophageal squamous cell carcinoma (ESCC) and its role in radiosensitivity.

**Material and Methods**

We used quantitative real-time polymerase chain reaction and immunohistochemistry analyses to compare expression of CBX4 between radioresistant and radiosensitive ESCC samples. Lentivirus was used to knockdown of CBX4 gene and stable transmitted cell line of KYSE150 and TE13 were made. In vitro cell counting kit 8 and clone formation assay were used to detect cell viability and proliferation. Radioresponse was primary examined by clone formation assay after exposure of 0, 2, 4, 6, 8 Gy X-ray by a medical accelerator of different stable cell lines. Then autophagy as well as apoptosis, cell-cycle arrest, and  $\gamma$ -H2AX expression were examined in 0 Gy and 8 Gy by flow cytometer and immunofluorescence. Gene-chips and western blot were used to investigate molecular mechanism. In vivo experiments of xenografts were used to confirm the results.

**Results**

Levels of eEF2K were increased in radioresistant ESCC samples compared with radiosensitive tissues, as well as ESCC cell lines. Increased levels of CBX4 were associated with ESCC survival times of patients ( $P < 0.05$ ). CBX4 promotes ESCC proliferation and tumorigenicity in vitro and in vivo. An improved radioresponse was detected in CBX4 knockdown cells. Affymetrix GeneChip was used in CBX4 knockdown TE13 and control cells in normal conditions and 8 Gy of irradiation and autophagy pathways were detected by bioinformatic analysis. Improved protein expression of Atg5, mTOR, LC3, and TP53 were confirmed by western blot. In xenograft radiosensitivity experiments, improved radioresponse with a reduction of tumor doubling time was observed. Immunohistochemistry and immunofluorescence of tumor tissue confirmed the molecular mechanism of autophagy pathway.

**Conclusion**

CBX4 is overexpressed in ESCC and associated with progression and shorter survival times of patients. Decreased expression of CBX4 correlated with a reduction of malignancy in biological behavior and an improvement of radioresistance in ESCC, which may be mediated by autophagy signaling pathway. Targeting CBX4 may be a potential therapeutic approach of ESCC in the future.

**PO-1076 Concomitant association of T-DM1 and radiation: An in vitro study on HER2 breast cancer cells**  
M. Fabien<sup>1</sup>, Y. Kirova<sup>1</sup>, P. Verrelle<sup>1</sup>, M. Teulade-Fichou<sup>2</sup>, F. Mègnin-Chanet<sup>2</sup>

<sup>1</sup>Institut Curie, Radiotherapy, Paris, France ; <sup>2</sup>Institut Curie-Recherche, inserm U1196/CNRS UMR 9187 - CMIB, Orsay, France

**Purpose or Objective**

The better understanding of the EGFR receptors involved in the oncogenesis of HER2 positive breast cancers has led to the emergence of new therapeutic classes: the Antibodies Drug-Conjugate (ADC). T-DM1 is an ADC combining the anti-HER2 monoclonal antibody trastuzumab with molecules of DM1, a powerful mitotic spindle inhibitor. In HER2 positive breast cancer, T-DM1 is a validated treatment but the effects of concomitant association with radiation are not known. The objective of this study is to determine *in vitro* the effects of concomitant irradiation with T-DM1 on five different HER2 positive breast cancer cell lines.

**Material and Methods**

Five cell lines of human breast cancer with different levels of HER2 expression (HCC-1954, BT-474, SKBR-3, MDA-MB-453, ZR-75). T-DM1 was provided by Roche®/Genetech upon MTA. Expression levels were determined by western blot. T-DM1 toxicity was assessed using the CellTiter-Glo®

assay. Cell cycle analysis was performed by flow cytometry after incorporation of BrdU. HER2 cells were irradiated (GSR  $^{137}\text{Cs}$  662 keV) at different dose levels (from 1 to 8 Gy) after exposure to T-DM1. Survival fractions were determined based on clonogenic assays or on cell survival after 5 doubling times. Radiosensitivity parameter ( $D_{10}$  and  $D_{37}$ ) were calculated using the mean values of a and b determined from the curves drawn for best fit to the experimental data.

### Results

The action of T-DM1 on HER2 cells showed significant lethality by deprivation of the HER2 signaling pathway and intracellular DM1 action on the cell cycle with significant G2/M phase blocking. After 72h treatment with T-DM1 alone, the median effective dose ( $ED_{50}$ ) determined for the six cell lines used is function of the expression of the receptor HER2 except for one cell line (BT474). Using sub-toxic doses of T-DM1 and short-term drug exposure (6 or 12h), the cell viability still decreases dramatically after several days. After irradiation alone,  $D_{37}$  and  $D_{10}$  were significantly higher for the three high-HER2 expressing cells lines (HCC1954, BT474 and SKBr3) compared to the low-HER2 expressing cells (MDA-453 and ZR-75-1), with a linear increasing relationship between the radioresistance and the level of HER2 expression ( $D_{37}$ :  $r^2=0.9$ ;  $p<0.0001$  and  $D_{10}$ :  $r^2=0.7$ ;  $p<0.0001$ ).

In combination with radiation, T-DM1 elicited strictly additive interaction. There was no significant difference on  $D_{10}$  compared to control for all cell lines. HCC1954 :  $D_{10}$  T-DM1 =  $6.15\pm 0.64$  vs  $6.0\pm 0.24$  for control; BT-474:  $D_{10}$  T-DM1 =  $7.86\pm 0.22$  vs  $7.6.0\pm 0.43$  for control; SKBr3 :  $D_{10}$  T-DM1 =  $5.68\pm 0.29$  vs  $5.43\pm 0.14$  for control; MDA-MB-453 :  $D_{10}$  T-DM1 =  $4.82\pm 0.07$  vs  $4.02\pm 0.17$  for control and ZR-75-1 =  $D_{10}$  T-DM1 =  $3.3\pm 0.3$  vs  $3.02\pm 0.3$  for control.

### Conclusion

Although HER2 expression is a radioresistant factor, T-DM1 did not have any radiosensitizing impact on HER2 positive breast cancer cells in this *in vitro* study. The major toxicity of T-DM1 alone could explain this phenomenon but further explorations are needed.

### PO-1077 The heterogeneous metabolic and mutational landscape of non-small cell lung carcinomas

T. Van Zon - Meijer<sup>1</sup>, W. Peeters<sup>1</sup>, M. Looijen-Salamon<sup>2</sup>, R. Biemans<sup>3</sup>, L. Dubois<sup>3</sup>, P. Span<sup>1</sup>, J. Bussink<sup>1</sup>

<sup>1</sup>Radboud university medical center, Radiotherapy and Oncology Laboratory- Department of Radiation Oncology, Nijmegen, The Netherlands ; <sup>2</sup>Radboud university medical center, Pathology, Nijmegen, The Netherlands ; <sup>3</sup>Maastricht Comprehensive Cancer Centre- Maastricht University Medical Centre, Department of Precision Medicine- The M-Lab- GROW - School for Oncology and Developmental Biology, Maastricht, The Netherlands

### Purpose or Objective

Both hypoxia and oncogenic mutations rewire tumor metabolism causing treatment resistance. Metabolic inhibition might therefore sensitize tumors to radiation. We explored glucose and glutamine metabolism-related markers and mutation status in stage I-IIIa NSCLC in relation to histology and tumor aggressiveness characteristics. Furthermore, we examined the effect of lonidamine (hexokinase inhibitor) and/or 968 (glutaminase inhibitor) on metabolism, cell growth, cytotoxicity and radiosensitivity in NSCLC cell lines *in vitro*.

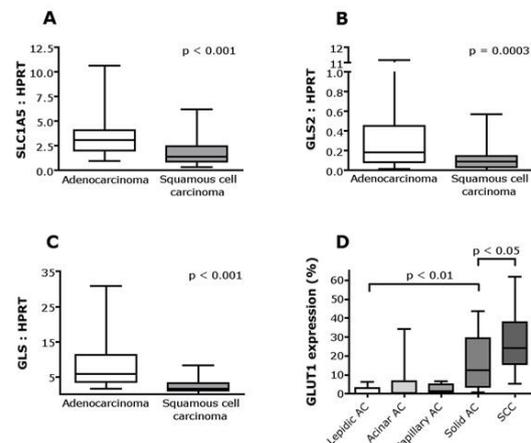

### Material and Methods

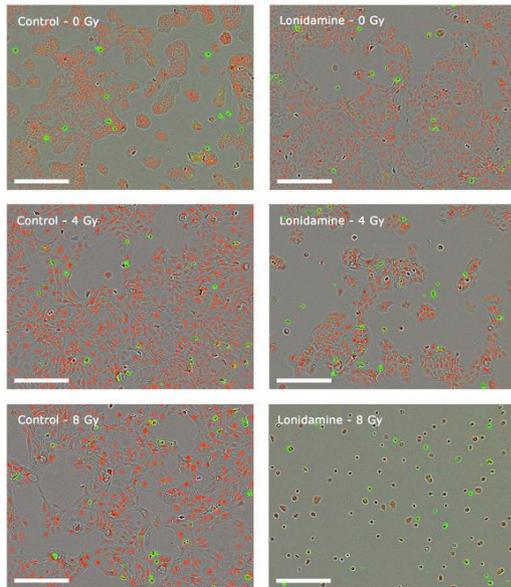

Mutation analysis was performed for 97 tumors. Metabolic marker expression was measured by immunofluorescent staining (protein) and qPCR (mRNA) (n=81). Adeno- (H23, HCC827, H1975) (AC) and squamous cell carcinoma (H520, H292, SW900) (SCC) NSCLC cells were treated with lonidamine and/or 968 for 72 hours under physiological levels of glucose (1.5 mM). Cells were irradiated with 0, 4

or 8 Gy. Cell growth of H2B-mCherry transduced cells and cytotoxicity (CellTox™ Green Cytotoxicity Assay) were measured using live cell imaging (IncuCyte). Inhibitory effects on metabolic profiles were determined using Seahorse XF96 extracellular Flux analyzer.

### Results

Glutamine metabolism-related markers were significantly higher in AC than SCC (Figure 1A-C). Glucose transporter 1 (GLUT1) protein was higher in solid than lepidic AC ( $p<0.01$ ), but was highest in SCC ( $p<0.05$ ) (Figure 1D). In AC, GLUT1 protein correlated with poor differentiation grade ( $p<0.001$ ), lymph node metastases ( $p=0.003$ ) and worse disease-free survival ( $p=0.008$ ). Glutamine transporter (SLC1A5) protein was higher in AC with worse pTNM stage ( $r(s)=0.39$ ,  $p=0.009$ ). *TP53* and *PIK3CA* mutations were more often found in SCC than AC (97.4% versus 71.2%,  $p=0.001$ ; 10.5% versus 0%,  $p=0.011$  respectively), while *EGFR* and *KRAS* mutations were more frequently observed in AC (10.2% versus 0%,  $p=0.042$ ; 35.6% versus 5.3%,  $p=0.001$  respectively). NSCLC cell lines responded differently to lonidamine and/or 968, largely corresponding with changes in glycolytic and mitochondrial metabolism upon treatment. 968 was cytotoxic in cell lines with high glutaminase C expression (H1975 and H520), whereas combination treatment was cytotoxic in *KRAS* mutated cell lines (SW900 and H23). H292 and HCC827 were resistant to combination treatment. Treatment with 968 and especially lonidamine resulted in radiosensitization of H292 and HCC827 in terms of decreased relative cell growth and increased cytotoxicity (Figure 2).

### Conclusion

NSCLC is a heterogeneous disease, with differences in mutational status, expression of metabolism-related markers between AC and SCC but also within AC subtypes, and response to metabolic inhibition. GLUT1 and SLC1A5 expression correlated with aggressive tumor behavior only in AC. So, these markers could select a group of AC patients that require intensification of treatment. Only a part of NSCLC patients may benefit from the combination of radiation therapy and metabolic inhibition, making stratification necessary.

### PO-1078 Superparamagnetic Iron Oxide Nanoparticle Mediated Radiosensitization at Megavoltage Radiation

E. Korkmaz Kıraklı<sup>1</sup>, G. Takan<sup>2</sup>, S. Hoca<sup>3</sup>, F.Z. Biber Müftüleri<sup>2</sup>, A. Yurt Kılçar<sup>2</sup>, S. Arun Kamer<sup>3</sup>, Y. Anacak<sup>3</sup>  
<sup>1</sup>DR. Suat Seren Chest Diseases and Surgery Research and Educational Hospital, Radiation Oncology, Izmir, Turkey; <sup>2</sup>Ege University Institute of Nuclear Sciences, Department of Nuclear Applications, Izmir, Turkey ; <sup>3</sup>Ege University, Radiation Oncology, Izmir, Turkey

### Purpose or Objective

Superparamagnetic Iron Oxide Nanoparticles (SPIONs) in combination with radiotherapy have been representing themselves as novel radiosensitizers in recent years. The purpose of this study was to assess SPION's *in vitro* radiosensitizer effect at clinically utilized 6MV energies which remains relatively as an unexplored issue and to calculate Nanoparticle Enhancement Ratio (NER) of SPIONs.

### Material and Methods

Human breast adenocarcinoma (estrogen receptor positive) (MCF-7), human breast adenocarcinoma (triple negative) (MDAMB-231) and human ovarian carcinoma (MDAH-2774) cell lines were used. Citrate coated-SPION's were synthesized.

Morphology and size analysis of *cit*-SPIONs were performed by transmission electron microscopy (TEM). The size distribution of nanoparticles was determined by dynamic light scattering (DLS).

The effect of the *cit*-SPIONs on cell viability was evaluated using trypan blue exclusion test. MTT assay was applied to determine the safe SPION dose to perform radiation treatment experiments.

To achieve full scatter conditions, a special type of solid water phantom was designed which 96 well-plates can be placed in, at 5cm depth along the central axis. Cells were then irradiated with various doses (2,4,6,8Gy). Cells were

left to grow to form clones. At 14<sup>th</sup> day of colonization, colonies containing  $\geq 50$  cells were scored. The whole procedure was repeated three times independently. Clonogenic survival curves were plotted as the log of the surviving fraction as a function of the dose. Dose Modifying Factor (DMF) which can be called as Nanoparticle-mediated Enhancement Ratio (NER- very similar to well-known oxygen enhancement ratio) based on clonogenic assays for each single radiation dose, was derived from cell survival curves.

### Results

By TEM images, dimensions of *cit*-SPION's were measured between 6-25nm and they were spherical in shape.

Cell viability (trypan blue) and MTT assay were carried out and it was proven that *cit*-SPION's at 0.1mg/mL concentration and after 24 hours of incubation did not exhibit cytotoxic effect on all three cell lines .

NER values were cell line specific and depended on radiation dose.

The highest radiosensitization effects were seen in MCF-7 and MDAH 2447 cells at 2Gy (NER: 1.49 and 1.39 respectively), in MDA-MB-231 cells at 4Gy (NER:1.20). Cell survival fraction was also significantly lower in MDAH 2447 cells at 4Gy (p=0.019). While at 6Gy there was radiosensitization effect only in MCF-7 cells (NER:1.10), at 8Gy there wasn't any radiosensitization in any cell line (NER:1.03-1.08)

### Conclusion

These results raise the possibility that synergistic effects of SPIONs may cause dose dependent and cell line specific radiosensitization at 6MV X-ray energies. Since there has been scarce data inquiring information on the "Z" and the X-ray energy dependence and *in vitro* radiosensitizer effect of SPIONs at high MV energy levels relevant in clinic, our study might be accepted as important.

### PO-1079 Metabolic changes with the administration of radiotherapy in lung, head and neck cancer patients

E. Rodríguez-Tomás<sup>1</sup>, M. Murcia<sup>2</sup>, M. Arguís<sup>2</sup>, I. Dolz<sup>2</sup>, M. De Abreu<sup>2</sup>, G. Baiges-Gaya<sup>1</sup>, N. Cabré<sup>1</sup>, F. Luciano-Mateo<sup>1</sup>, L. Torres-Royo<sup>2</sup>, M. Arquez<sup>2</sup>, J. Gómez<sup>2</sup>, J. Acosta<sup>2</sup>, D. Gómez<sup>2</sup>, C. Jordi<sup>1</sup>, J. Jorge<sup>1</sup>, S. Sabater<sup>2</sup>, M. Arenas Prat<sup>2</sup>

<sup>1</sup>Hospital Universitari Sant Joan de Reus, Unitat de Recerca Biomèdica, Reus, Spain ; <sup>2</sup>Hospital Universitari Sant Joan de Reus, Radiation Oncology, Reus, Spain

### Purpose or Objective

Radiotherapy treatment can produce metabolic changes in cancer patients. The application of metabolomics to the study of energy metabolism in cancer is an underdeveloped issue, and only a few studies have investigated this in lung (LC) and head and neck cancer (HNC) patients exposed to radiotherapy (RT), despite its potential relevance in clinical practice. The aims of our study were to analyze the changes produced by RT on the activity and concentration of serum PON1 and the variations in the lipoprotein profile and metabolites of low molecular weight in LC and HNC patients and to correlate these changes with the clinical and pathological characteristics of patients and tumors, and their response to treatment.

### Material and Methods

The study included LC patients (n=33) and HNC patients (n=28) treated with RT. Control group (n= 50) was formed by Mediterranean health people. Blood samples for analyses were obtained before and after 8one month later) the irradiationtreatment. Lipoprotein profile and the metabolites of low molecular weight carried out by nuclear magnetic resonance. Statistical analysis was performed with SPSS 22.0 statistical package.

### Results

Mean ages were 72 (65.50-79.0) and 65 (56.25-73.0) years old in LC and HNC patients, respectively. The most prevalent histologic type was squamous carcinoma in both groups. Even though, the frequency of tumor relapse was

similar in both groups (LC 14%; HNC 9%), the deaths were higher in LC patients (19%). The schedule of RT treatment was 45-60 Gy (2-2.6 Gy/day, 5 days/week). Relative to control, both groups had significantly lower serum PON1 concentration, and arylesterase activity ( $p < 0.001$ ). We observed that after RT not only increased PON1 concentration in cancer patients but also arylesterase activity decreased. Intermediate density lipoprotein (IDL), triglycerides linked with different lipoprotein profiles and the VLDL particles size were significantly higher in cancer groups in comparison to control group. Whereas leucine, isoleucine, tyrosine, acetate, glutamine and formate metabolites were significantly lower in cancer groups, alanine, glucose and glutamate were significantly higher in the same groups. Only in HNC group showed significantly differences in glutamine and glutamate metabolites between before and after RT treatment.

**Conclusion**

Our study demonstrates that RT treatment can modulate anti-oxidant defense mechanisms and metabolites in cancer patients. These results could be useful as a biomarker to predict RT response and the prognosis of patients.

**Poster: Radiobiology track: DNA damage response**

**PO-1080 Does hyperthermia clinically alter the  $\alpha/\beta$ ? Insights from thermoradiotherapy vs. radiotherapy trials**

N.R. Datta<sup>1</sup>, S. Bodis<sup>1</sup>

<sup>1</sup>Kantonsspital Aarau, Radio-Onkologie, Aarau, Switzerland

**Purpose or Objective**

Hyperthermia at 39-43°C is a known potent radiosensitizer, primarily due to its ability to radiosensitize hypoxic tumor cells and inhibit post radiation repair of the potentially lethal DNA damage. This should be expected to alter the  $\alpha/\beta$  values of the linear-quadratic (L-Q) model. The present study has been carried out to clinically estimate the  $\alpha/\beta$  from randomized studies of thermoradiotherapy (HTRT) vs. radiotherapy (RT) in recurrent breast (RBRT), head and neck (stages III/IV) (LAHNC) and cervix cancers (stages IIB-IVA) (LACC).

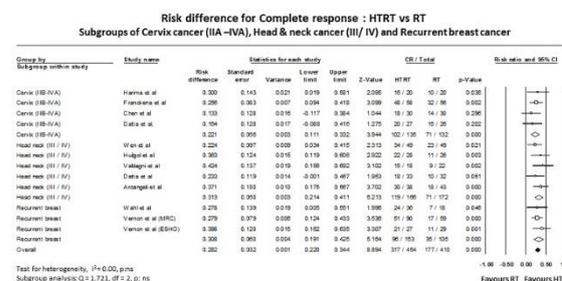

**Material and Methods**

Three recently published meta-analyses (2016) for HTRT vs. RT in RBRT, LAHNC and LACC, totaling 20 studies with 1,505 patients were evaluated for their complete response (CR). Only those studies with a specified RT dose (D), dose per fraction (d) and corresponding CRs in both groups were selected. Effect measures - odds ratio, risk ratio, risk difference (RD), tests for heterogeneity ( $I^2$ ) and subgroup analysis were carried out for the included trials. The biological effective dose with RT ( $BED_{RT}$ ) in these studies were individually computed using the L-Q equation without any time factor correction and assuming an  $\alpha/\beta_{RT}$  of 10 Gy for all sites. Since all trials had a positive outcome with HTRT over RT, the resultant enhanced thermoradiobiological BED for HTRT ( $BED_{HTRT}$ ) was correspondingly computed as a product of the  $BED_{RT}$  and %difference in CR between HTRT and RT. With the "D" and "d" of both HTRT and RT arms in each trial being similar, the  $\alpha/\beta$  following HTRT ( $\alpha/\beta_{HTRT}$ ) was estimated as,  $\alpha/\beta_{HTRT} = Dd / (BED_{HTRT} - D)$ , derived from the L-Q model.

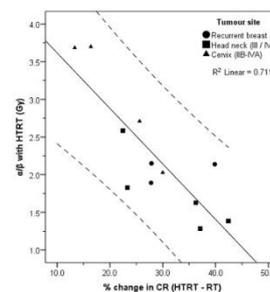

**Results**

12 studies with 864 patients were shortlisted - RBRT (3 studies, n=259), LAHNC (5 studies, n=267) and LACC (4 studies, n=338). Mean RT dose was 53.4 Gy (SD:  $\pm 14.3$ ) delivered in 2.2 Gy/fraction (SD:  $\pm 0.74$ ). Mean temperature was 42.4°C (SD:  $\pm 0.9$ ) and most patients received 2 sessions of HT per week for an average duration of 50 minutes, delivered mostly following RT. The overall risk difference of 0.28 was in favour of HTRT ( $p < 0.001$ ).

There was no significant difference in outcomes for the three sites on subgroup analysis (Fig.1).

Mean  $BED_{RT}$  was 64.7 Gy (SD:  $\pm 15.5$ ) while the mean  $BED_{HTRT}$  was estimated as 109.5 Gy (SD:  $\pm 32.1$ ). The overall computed  $\alpha/\beta_{HTRT}$  was 2.25 Gy (SD:  $\pm 0.79$ ) and it revealed an inverse relation with the %improvement in CR with HTRT ( $r^2: 0.71, p=0.001$ ) (Fig.2).

The  $\alpha/\beta_{HTRT}$  for RBRT, LAHNC and LACC were 2.05 Gy, 1.74 Gy and 3.03 Gy ( $p=0.027$ ), reflecting a reduction in  $\alpha/\beta$  by HTRT (range: 69.7% - 82%). On regression analysis, none of the treatment variables except %improvement in CR predicted for  $\alpha/\beta_{HTRT}$  (coeff: -0.74,  $p=0.001$ ).

**Conclusion**

The reduction in the clinically estimated  $\alpha/\beta_{HTRT}$  corroborates with the *in vitro* studies. HT inhibits repair of RT induced DNA double strand breaks resulting in enhancing the  $\beta$  component of cell kill, consequently leading to a fall in  $\alpha/\beta$ . This should be of practical use in optimizing RT time-dose-fractionation schedules with HT in the clinics.

**PO-1081 Biological interaction of a static magnetic field (SMF) with ionizing irradiation**

T. Schmid<sup>1,2</sup>, F. Hellmund<sup>2</sup>, S. Lemmer<sup>2</sup>, K. Illicic<sup>1</sup>, M. Melzner<sup>2</sup>, S. Bartzsch<sup>1</sup>, J.J. Wilkens<sup>2</sup>, S.E. Combs<sup>1,2</sup>

<sup>1</sup>Helmholtz Zentrum München, Institute of innovative Radiotherapy, Neuherberg, Germany ; <sup>2</sup>Klinikum rechts der Isar - Technical University of Munich, Radiooncology, Muenchen, Germany

**Purpose or Objective**

During the last decade there have been several technical developments in radiotherapy, like the development of integrated magnetic resonance imaging (MRI) in a linear accelerator. However, in literature the interaction of a static magnetic fields (SMFs) with radiation as part is still controversially discussed. Interactions could lead either to

aneugenic damages, induced by alteration in the mitotic spindle, as well as clastogenic damages produced by chromosome breaks. In this study, a clonogenic cell survival assay was performed to measure the interaction of a static magnetic field with radiation. Additionally, the mechanism of a possible biological interaction was analyzed using multicolor fluorescence in situ hybridization (mFISH).

#### Material and Methods

Human glioblastoma cells (LN-18) as well as human peripheral blood T-cell lymphocytes were seeded in petri dishes, which were placed inside a phantom. The irradiation for cell survival test was performed with a 6 MV linac with doses of 0, 1, 2, 4, 6, and 8 Gy in the presence and absence of a SMF of 1 Tesla produced by a permanent magnet. For the chromosome aberration test, irradiations with 2 and 4 Gy in the presence and absence of a SMF of 1 Tesla were performed. Chromosome aberrations were analyzed in at least 300 metaphases per treatment group using Metafer4 software. For both experiments three technical as well as three biological replicates were performed.

#### Results

The survival curves were fitted using the linear quadratic model. The survival fractions in absence of an SMF exceed the ones in presence of an SMF for all dose points between 1 and 8 Gy by 12% to 31%. The statistical analysis showed a significant decline ( $p \leq 0.05$ , ANOVA test) of the overall cell survival when irradiation was combined with a static magnetic field. However, the chromosome aberration test did not show an induction of chromosome aberrations in general or a shift in the complexity or completeness of damages. The number of all chromosome aberrations was  $0.71 \pm 0.05$  without and  $0.73 \pm 0.05$  with a SMF during the 2 Gy irradiation.

#### Conclusion

Up to now, there are only very few studies that have investigated the combinational effect of a static magnetic field and radiation. Most of these studies were in line with our results showing that a static magnetic field increases the efficiency of the radiotherapy. Additionally, our study showed evidence that the altered cell survival is not caused by clastogenic DNA damages, which leads us to the hypothesis that aneugenic effects may cause the change in cell survival. Further experiments, including a micronucleus assay with centromere FISH and staining of the mitotic spindles by immunohistochemistry are proposed.

#### PO-1082 Dihydroouabain is a novel radiosensitizer identified by high throughput screening.

Z. Li<sup>1</sup>, K. Tamari<sup>1</sup>, Y. Seo<sup>1</sup>, K. Minami<sup>1</sup>, Y. Takahashi<sup>1</sup>, K. Otani<sup>1</sup>, O. Suzuki<sup>1</sup>, F. Isohashi<sup>1</sup>, K. Ogawa<sup>1</sup>

<sup>1</sup>Osaka University Graduate School of Medicine, Radiation Oncology, Suita-Osaka, Japan

#### Purpose or Objective

Radiosensitizers have had only limited success in clinic. High throughput screening (HTS) is a popular method to identify candidate compounds from a large number of compounds for drug discovery, however it has not been used to establish a method to identify new radiosensitizers so far. The aims of this study were identifying potential radiosensitizers by HTS and clarifying the specific mechanisms of new radiosensitizers in combination with radiotherapy (RT).

#### Material and Methods

We performed HTS by using 1280 compounds. The parental HeLa human cervical cancer cells were pre-treated with compounds and exposed to gamma-irradiation under normoxic and hypoxic conditions. After incubating the cells for 4 days, cellular viabilities were measured by using MTS assay. Then, the radiosensitizing effect of candidate compounds was validated by clonogenic survival assays. The radioresistant cell line (HeLa-RT) was established

from HeLa cell line. Apoptosis assay and western blot analysis were examined in 0Gy and 8Gy with or without a candidate compound in HeLa and HeLa-RT cell lines. Sphere formation assay was utilized to detect tumor sphere forming capacity.

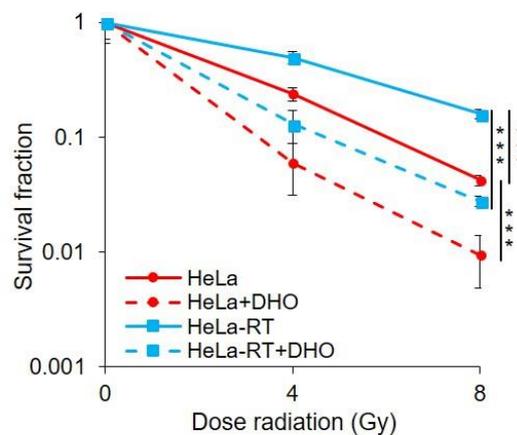

Figure 1: Clonogenic survival assays of HeLa and HeLa-RT cells treated with DHO, n=3 wells per group. \*\*\*P-value < 0.001.

#### Results

HTS identified 22 compounds as candidates for radiosensitizers. Among them, we selected Dihydroouabain (DHO) which was known as an inhibitor of  $\text{Na}^+/\text{K}^+$  ATPase and was not reported as a radiosensitizer. Clonogenic survival assays showed significant radiosensitizing effect of DHO in HeLa cells and in HeLa-RT cells (Figure 1). The combination of DHO and RT enhanced radiation-induced apoptosis. Western blot showed that  $\gamma\text{-H2AX}$  and pS345-Chk1 significantly increased and prolonged in combination treatment with DHO and RT compared with RT alone or DHO alone group. In addition, DHO treatment inhibited the capability of tumor spheres forming in HeLa and HeLa-RT cells. Taken together, DHO enhanced radiosensitivity through inhibition of DNA repair pathway, and induction of cancer cell apoptosis.

#### Conclusion

HTS is an efficient method for identifying new radiosensitizers. We identified DHO as a novel radiosensitizer by HTS.  $\text{Na}^+/\text{K}^+$  ATPase might be a novel target for radiosensitization.

#### PO-1083 The dual inhibitor BEZ235 radiosensitizes HNSCC cells due to impairment of the DSB repair

A. Arenz<sup>1</sup>, V. Balzer<sup>1</sup>, K. Dreffke<sup>1</sup>, T. Rieckmann<sup>2</sup>, S. Köcher<sup>3</sup>, E. Dikomey<sup>1,3</sup>, R. Engenhart-Cabillic<sup>1</sup>, A. Wittig<sup>4</sup>, U. Schötz<sup>1</sup>

<sup>1</sup>Philipps-University Marburg, Department of Radiotherapy and Radiooncology, Marburg, Germany ;

<sup>2</sup>University Medical Center Hamburg Eppendorf, Laboratory for Radiobiology & Experimental Radiooncology and Department of Otolaryngology and Head and Neck Surgery, Hamburg, Germany ; <sup>3</sup>University Medical Center Hamburg Eppendorf, Laboratory for Radiobiology & Experimental Radiooncology, Hamburg, Germany ; <sup>4</sup>Friedrich-Schiller-University Jena, Department of Radiation Oncology, Jena, Germany

#### Purpose or Objective

The Phosphatidylinositol-3-kinase (PI3K) pathway is the sixth most frequent mutated oncogenic pathway in head and neck squamous cell carcinoma (HNSCC) presenting in 60% of HPV-positive (HPV pos) and 31% of HPV-negative (HPV neg) tumors. The following study examines the

impact of PI3K pathway inhibition by the dual inhibitor BEZ235 on radiation sensitization of HPV pos and HPV neg HNSCC cell lines.

#### Material and Methods

The effect of BEZ235 in combination with radiation was determined for five HPV pos and five HPV neg HNSCC cell lines. Therefore, assays were used to identify alterations in the PI3K pathway and the DNA damage response (DDR), specifically ATM and DNA PKcs by Western Blot. Flow cytometric analysis was used to examine the cell cycle by Nicoletti staining and apoptosis by AnnexinV-staining. Repair of DNA double strand breaks (DSB) was visualised by gamma-H2AX foci formation and repair efficiency of homologous recombination (HR) and non-homologous end joining (NHEJ) was examined with repair plasmids. Survival after treatment was determined by colony formation assay.

#### Results

Treatment of cells with BEZ235 (50 nM) suppressed activation of Akt via Ser473 phosphorylation. Single use of BEZ235 does not interfere with cell cycle progression. In combination with irradiation, BEZ235 induces a significant increase in G1 arrest with a similar effect for both HPV pos and neg cell lines. Radiation-induced apoptosis was unaffected after the dual treatment. However, for all HNSCC cell lines DNA DSB repair was notably impaired in a way which is independently from HPV- or Akt- status but restricted to G1 cells, while clearly less effects were seen for S or G2 phase cells. These results suggest an inhibition of NHEJ, but not HR, which could be validated using repair-specific plasmids. The reduction of NHEJ could be attributed to a strong inhibition of DNA PKcs at S2056. In accordance with these data, colony formation assay revealed a significant increase of cellular radiosensitivity, which was especially pronounced for G1-phase cells.

#### Conclusion

The dual PI3K-inhibitor BEZ235 can be used to increase the radiation response of HNSCC independently from HPV- and Akt-status.

#### PO-1084 Poly ADP-ribose polymerase-1 inhibitors enhance soft tissue sarcoma radiosensitivity: in vivo study.

<sup>2</sup>Istituto Toscano Tumori, Itt, Florence, Italy ;

<sup>3</sup>University of Florence, Medical Physics Unit, Firenze, Italy ;

<sup>4</sup>University of Florence, Orthopedic Oncology Unit, Firenze, Italy

#### Purpose or Objective

Soft-tissue sarcomas (STS) are aggressive tumors with a poor prognosis and limited effective therapeutic options, thus there is a major clinical need for novel strategies. Poly-ADP ribose polymerase (PARP)-1 promotes base excision repair and DNA strand break repair. Inhibitors of PARP (PARPi) have shown to enhance the cytotoxic effect of irradiation, and evidences suggest that PARPi could be used to selectively kill cancers defective in DNA repair. Tumorigenesis in sarcomas is linked to aberrant biological pathways and some STS have defect in DNA repair systems, so there is a rationale for using PARPi in STS.

We previously demonstrated that PARPi are potent radiosensitizers on human STS in vitro models: they reduced cell survival, inhibited DNA damage repair and pro-survival ERK signaling when used in combination with irradiation.

The aim of the present study was to investigate the effect of PARP inhibition and irradiation on tumorigenesis of irradiated tumor cells in a xenograft model of rhabdomyosarcoma in mice.

#### Material and Methods

Rhabdomyosarcoma cells were irradiated with 3 Gy, with or without a 24 hours olaparib (1 µM) pre-treatment. Non-irradiated cells were used as controls. Four group of mice were compared: 1) control; 2)olaparib; 3)irradiation; 4)irradiation+olaparib.

Rhabdomyosarcoma xenograft was obtained by s.c. injection of 6×10<sup>6</sup>cells in the flank of CD1 nude mice. Tumor volume was measured twice a week for 30 days by the formula  $[\text{lenght} \times (\text{width} \times \text{width})]/2$ . Immunofluorescence and western blotting analysis have been performed.

#### Results

Olaparib alone reduced tumor growth compared to control, but without reaching a statistical significance. Irradiation alone showed an effect on tumorigenesis with a significant reduction of tumor volume compared to control. The association of olaparib and irradiation showed an even higher decrease in tumor volume compared to irradiation alone, reaching the statistical significance vs. irradiation or olaparib alone after 8 days. The mean immunofluorescence of gamma H2AX on rhabdomyosarcoma cells was significantly increased after treatment with olaparib and with radiation alone; a significantly higher intensity of fluorescence was obtained with combined treatment. Tumor growth was inversely proportional to the mean immunofluorescence of gamma H2AX. Further biomolecular analysis are ongoing.

#### Conclusion

In this study we confirmed previous in vitro data and showed that olaparib enhances the therapeutic effect of radiation on rhabdomyosarcoma xenograft, with significant reduction of tumorigenesis. These preliminary data encourage to further study association of PARPi with IR as a promising treatment for STS.

#### PO-1085 Prolonged trifluridine/tipiracil treatment radiosensitises colorectal cancer cells

<sup>6</sup>University Medical Center Hamburg - Eppendorf UKE, Department of

Radiotherapy and Radio-Oncology, Hamburg, Germany

#### Purpose or Objective

Trifluridine/ Tipiracil (TFTD) has shown clinically relevant activity in colorectal cancer after fluoropyrimidine failure and may be of increased efficacy in combination with radiotherapy (RT) compared to current standard capecitabine chemoradiotherapy (RChT). As the underlying molecular mechanisms are still poorly understood, we aimed to determine the response of four colorectal cancer cell lines to TFTD alone and in combination with RT in order to provide a preclinical rationale for TFTD-based RChT treatment of rectal cancer.

#### Material and Methods

HT29 (MSS, CIN+, Ras wt, BRAF mut (V600E), p53 mut), HCT116 (MSI, CIN-, Ras mut, BRAF wt, p53 wt), SW48 (MSI,

CIN-, Ras wt, BRAF wt, p53 wt) and CaCo2 (MSS, CIN+, Ras wt, BRAF wt, p53 mut) colorectal cancer cells were analysed for cell viability (beta-hexosaminidase assay), trifluridine incorporation (anti-BrdU immunofluorescence), DNA damage induction (H2AX phosphorylation), cell cycle dynamics (5-ethynyl-2'-deoxyuridine pulse labelling & flow cytometry) and colony formation following treatment with TFTD and/or X-rays.

#### Results

While treatment with 1-10 µM TFTD for three days only moderately affected cellular metabolic activity, 5-day treatments showed significant effects at all concentrations in all cell lines except CaCo2. All cell lines incorporated similar amounts of trifluridine during S phase, irrespective of TFTD concentration and duration of treatment. Cells arrested in S phase and appeared to undergo endoreplication, resulting in polyploidy. TFTD treatment for 2, 6 and 24 h induced gamma-H2AX mainly in S/G2, while G1 phase cells remained mostly unaffected. Interestingly, levels subsided close to controls at 6 h in TFTD-resistant CaCo2 cells. Colony assays performed for 4 µM TFTD and X-rays alone as well as in four different treatment combination schedules demonstrated purely additive effects when cells were treated with X-rays and TFTD within 6 hours of each other. However, 24 h TFTD treatment prior to irradiation caused marked radiosensitisation in all cell lines analysed so far, with dose enhancement factors of 1.5-3. Corresponding xenograft studies using the same cell lines are underway.

#### Conclusion

Cell cycle arrest and endoreplication resulting in polyploidy may contribute to the cytotoxicity of TFTD. The observation of a strong radiosensitising effect after prolonged treatment with TFTD provides a robust argument for a daily fractionated combined regime of TFTD and RT in rectal cancer treatment.

#### Purpose or Objective

Objective of the research was to study the anti-tumor activity of gene therapeutic constructs (GTC) used in combination with radiotherapy.

#### Material and Methods

*Gene therapeutic constructs*: bicistronic constructs of HSVtk-hGM-CSF plasmid DNA with HSVtk (thymidine kinase of herpes simple virus) and human hGM-CSF (granulocyte-macrophage colony stimulating factor) genes and HSVtk-mGM-CSF plasmid DNA with HSVtk and murine mGM-CSF genes. Every construct is included into a non-viral vector of PPT (Polyethylene glycol-Polyethylenimine-TAT peptide) block-copolymer. *Prodrug*: ganciclovir (GCV) (Cymeven, Roche Products

Ltd, Switzerland). *Animals*: mice BALB/c and nude mice. *Lines of the human* (KB oral mucosa carcinoma) *and murine* (C26 colon carcinoma) *tumor cells*. *Irradiation* of the animals was performed once in a single focal dose (RPM) of 5 Gy for every mouse using Elekta Precise linear accelerator (nude mice, KB tumor) or Theratron Equinox gamma-therapeutic apparatus (60Co, γ-radiation, BALB / c mice, C26 tumor) after its intratumoral injection GTC. *The efficacy of the combined gene and radiotherapy* was evaluated by the grade of tumor growth inhibition (T/C, u), and the treatment was considered to be efficient (synergistic effect) at T/C[combined therapy] < T/C[GENE THERAPY] x T/C[RADIOTHERAPY]. *Statistical analysis* was performed using Statistica ver. 10.0 programme.

#### Results

The combined treatment using GTC and the local irradiation in a single dose of 5 Gy on the model of subcutaneous KB xenograft or on the transplanted C26 murine tumor demonstrated a pronounced antitumor effect. The indices of efficiency of the combined therapy demonstrated the synergism of GTC/GCV and radiation impacts. The obtained synergism of the experimental therapeutic effects of the suicide gene therapy and radiotherapy opens up good prospects of further study of the combined therapy with the inclusion of these components of treatment.

#### Conclusion

The revealed spectrum of the anti-tumor activity of GTC/GCV systems may be used as the basis for choice of cancer diseases in early clinical trials. The synergy between suicidal gene therapy and radiation therapy proves to be prospective for further study of the combined therapy with an inclusion of these components of treatment. The reported study was funded by RFBR according to the research project No. 16-34-60185.

#### PO-1087 The interaction between miR-221 overexpression and radiosensitivity in mamma carcinoma cell lines

E. Hirmer<sup>1,2,3</sup>, R. Kell<sup>3</sup>, S. Winkler<sup>3</sup>, K. Winkler<sup>3</sup>, L. Mutschelknaus<sup>3</sup>, S. Mörtl<sup>3</sup>, M. Atkinson<sup>1,2,3</sup>, S. Combs<sup>1,2</sup>, T. Schmid<sup>1,2</sup>, N. Anastasov<sup>3</sup>  
<sup>1</sup>Klinikum rechts der Isar, Radiooncology, München, Germany ; <sup>2</sup>Helmholtz Zentrum München, Institute of innovative Radiotherapy, Neuherberg, Germany ; <sup>3</sup>Helmholtz Zentrum München, Department of Radiation Sciences, Neuherberg, Germany

#### Purpose or Objective

Despite the steady improvement of breast cancer therapy, the prognosis for certain subgroups like triple negative breast cancer (TNBC) remains poor. In order to identify new therapeutic targets, it is important to analyze the pathogenesis of TNBC on a molecular level. TNBC shows significant overexpression of miR-221, which is associated with poor prognosis. By regulating cellular processes like proliferation, migration and cell survival, miR-221 is heavily involved in tumor pathogenesis. The interaction of miR-221 overexpression with radiation and its influence on migration, proliferation and colony formation were further investigated.

#### Material and Methods

The mammary carcinoma cell lines SKBR3 and MDA-MB-231 were transduced with lentiviral vectors to ensure miR-221 overexpression in SKBR3 cells or miR-221 knock-down in MDA-MB-231, naturally overexpressing miR-221. In order to analyze the interaction between radiation and miR-221 expression, the miR-221 or anti-miR-221 cells were compared to the empty vector controls (EV co-expressing

GFP), whose miR-221 expression levels equal the non-transduced cells. The cells were irradiated at doses of 0 to 8 Gy using a Cs<sup>137</sup> gamma irradiation source. Clonogenic cell survival with respect to radiation and miR-221 overexpression was examined using colony formation assays. Effects of miR-221 expression combined with irradiation on proliferation (cell counting) and migration (wound scratch assays) were analyzed. qRT-PCR was performed to determine miR-221 expression changes upon irradiation.

#### Results

miR-221 overexpressing cells showed significantly higher migration capacity in both cell lines. Remarkably, the migration capacity remained constant even upon 8 Gy ionizing radiation treatment. In parallel, miR-221 overexpressing cells showed elevated proliferation in both cell lines 72 hours after radiation. The reduction of cell numbers upon radiation was more pronounced in MDA-MB-231 than in SKBR3. The clonogenic survival assays confirmed that miR-221 overexpressing SKBR3 cells were more radioresistant than the control. In MDA-MB-231, no significant effect of miR-221 knock-down on clonogenic survival was observed. Additionally, irradiation did not alter the miR-221 expression levels significantly.

#### Conclusion

The results of our experiments show reproducibly increased migration and proliferation of mammary carcinoma cell lines SKBR3 and MDA-MB-231 upon miR-221 overexpression. The effect of miR-221 on migration remains constant upon irradiation whereas proliferation decreases after radiation treatment. Additionally, the proliferation assays show a drastic reduction of viable cells upon irradiation, whereas no strong reduction of migration upon radiation can be observed. This leads to the assumption that irradiation might increase migration levels. Regarding the consequences for a personalized radiotherapy in the future, miR-221 overexpression in TNBC patients indicates a higher risk of metastasis development.

#### PO-1088 DNA repair genes polymorphisms as biomarkers of tumor control in LDR BT prostate cancer patients

#### Purpose or Objective

To evaluate the association of inherited germline variations in DNA repair associated genes with tumor control in patients treated with permanent implant prostate brachytherapy (PIPB).

#### Material and Methods

The cohort consists of 478 I-125 PIPB patients with a median follow-up of 51 months after seeds implantation. Upon consent of patients, DNA was prepared from mononuclear cells and genotyped for 215 haplotype tagging single nucleotide variations (htSNPs) in genes of DNA damage response and repair pathways. Their

association with biochemical recurrence (BCR) was assessed using Cox regression models and Kaplan-Meier survival curves with log-rank tests.

#### Results

After adjustment for the established risk factors including age, PSA at diagnostic, Gleason score and androgen-deprivation therapy use; 17 htSNPs in ACVRL1, ERCC1 and 3, MGMT, MSH6, RAD51A, TP53BP1 and XRCC6, were initially found to be associated with an altered risk of BCR, with adjusted hazard ratios (HR<sub>adj.</sub>) ranged between 0.27 - 12.39 ( $P \leq 0.05$ ). Upon adjustment for multiple testing, one marker remained significant ( $q < 0.001$ ). Compared to carriers of the ERCC3 rs4150499 T allele, patients homozygous for C allele ( $n = 23$ ) had a significant higher risk of BCR with a HR of 12.39 (IC<sub>95%</sub> 4.22-36.39;  $p < 0.0001$ ;  $q < 0.001$ ). The Kaplan-Meier survival curve revealed a median BCR-free survival time reduced from  $213 \pm 7$  to  $99 \pm 12$  months (log-rank  $P < 0.00001$ ) for homozygous carriers of the ERCC3 rs4150499 C allele compare to non-carriers.

#### Conclusion

This study suggests an association of the rare intronic variant (Frequency=0.05 in the study) of the ERCC3 with an elevated risk of BCR after PIPB. An independent validation is required whereas the underlying biological mechanism remained to be assessed.

#### PO-1089 Improvement and optimization of $\gamma$ H2AX foci assay as a predictive tool for radiation sensitivity

T. Rassamegevanon<sup>1</sup>, S. Löck<sup>1,2</sup>, M. Baumann<sup>1,2,3,4,5</sup>, M. Krause<sup>1,2,3,4,5</sup>, C. Von Neubeck<sup>1,4</sup>

#### Purpose or Objective

Prediction of tumor radiation response using molecular biomarkers has been considered as a promising approach for treatment individualization to improve therapeutic outcome. Phosphorylation of histone H2AX ( $\gamma$ H2AX) is one of the earliest response to DNA double strand break induction. Detection of  $\gamma$ H2AX focus formation on *ex vivo* irradiated solid tumor biopsies demonstrated a high potential as a predictive assay for intrinsic radiosensitivity [1]. We aim to further optimize and develop the *ex vivo*  $\gamma$ H2AX foci assay to increase clinical relevance.

#### Material and Methods

Tumor xenograft models of human head and neck squamous cell carcinoma were used in this study. Tumor-bearing mice (*in vivo*) and xenograft-derived biopsies (*ex vivo*) were irradiated with 0 - 8Gy; fixed and paraffin embedded 24 h post irradiation. The  $\gamma$ H2AX foci were visualized by immunostaining. Manual quantification of  $\gamma$ H2AX foci was performed solely in perfused regions determined by pimonidazole (hypoxic marker) and BrdU (proliferation marker) staining.

#### Results

This study is focused on two aspects: a) Tumor heterogeneity: To study the effect of tumor heterogeneity in the *ex vivo*  $\gamma$ H2AX foci assay, we analyzed multiple equally treated xenograft tumor specimens (sham- and 4 Gy irradiated). The outcome

suggested a strong intratumoral heterogeneity with a slight intertumoral heterogeneity [2]. We studied degree of heterogeneity in  $\gamma$ H2AX foci between experimental set-ups (*in vivo* and *ex vivo*) by subjecting two published *in vivo* and *ex vivo* datasets to a statistical model. A lesser degree of heterogeneity was found in the *in vivo* dataset relative to *ex vivo* dataset [3]. These results confirmed the necessity of multiple biopsies, regions of interest, and nuclei to obtain an accurate prediction. We currently characterize  $\gamma$ H2AX foci in different chromatin distributions to gain deeper insight into the heterogeneity of foci in both set-ups.

b) Reflectiveness of *ex vivo* biopsies to *in vivo* tumors: We investigated whether *ex vivo* tumor biopsies can reflect radiation response of the corresponding *in vivo* tumors. Dose response curves of  $\gamma$ H2AX foci showed a comparable radiation response between biopsies and tumors in most of evaluated tumor lines. The slopes of dose response curves could classify tumors according to intrinsic radiosensitivity.

#### Conclusion

Overall, our results support the clinical applicability of the *ex vivo*  $\gamma$ H2AX foci assay as a predictive method for radiation sensitivity. To minimize inter-observer variations, a semi-automated foci-counting algorithm is under development.

This work was supported by a grant of the Federal Ministry of Education and Research (BMBF 02NUK035C).

#### PO-1090 A second (third, fourth...) look at the In Vitro Clonogenic Assay

R. KOCH<sup>1</sup>, C. Harmel<sup>2</sup>, I. Dokic<sup>2</sup>, A. Abdollahi<sup>2</sup>, M. Alber<sup>1</sup>, E. Bahn<sup>1,3</sup>

<sup>1</sup>Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg, Germany ;

<sup>2</sup>Translational Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg, Germany ; <sup>3</sup>Clinical Cooperation Unit Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg, Germany

#### Purpose or Objective

The *in vitro* clonogenic assay (IVCA) presents the standard *in vitro* experimental method in radiobiology: the cell survival curve lays the foundation for most biological models in radiotherapy. Since its introduction in 1956, the IVCA has remained basically unchanged: irradiated cells are incubated to form colonies, which are subsequently scored as either doomed or vital, based on their size. Here, we suggest to record the colony growth and show by temporally resolved statistical analysis of colony formation that the underlying basic assumptions of the *in vitro* IVCA are often not fulfilled, which may lead to systematic errors in cell radiation response parameters  $\alpha$  and  $\beta$ .

#### Material and Methods

Cells of different strains were seeded onto 96 well plates, irradiated with single doses of 0-7 Gy X-Rays and immediately placed into an incubator with automated acquisition of phase-contrast images in 3 h intervals for up to 9 days (IncuCyte® Live-Cell Analysis System). Image-treatment and automated colony scoring were performed in R/ImageJ with the use of self-developed routines. Colonies were scored and tracked over time based on combined position and shape parameters. Cell survival curves were calculated from the acquired database for different combinations of scoring parameters. A biomathematical colony growth model was developed that numerically simulates the entire experimental procedure:

stochastic radiation damage, colony growth via proliferation, size-dependent colony scoring.

#### Results

We analysed the effects of time-of-scoring and of scoring threshold on cell survival curves and on extracted parameters. These thresholds should have no influence on the outcome within a reasonable range. However, we made contrary observations: cell survival curves undergo an apparent shift when scored at subsequent time points, with (logarithmic) slope decreasing and curvature increasing over time (Fig. 1a). As a result, cell survival parameters and shift considerably when a linear/quadratic formula is fitted to the cell survival curves, the derived  $\alpha/\beta$  ratio varies over a large range (Fig. 1b). Analysis of colony growth curves suggests that this effect is connected to a dose-dependent proliferation rate.

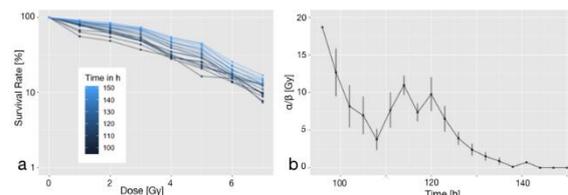

Fig. 1: Effect of time-of-scoring in the clonogenic assay of H3221 cells. a) Cell survival curves when scored at different time points. b)  $\alpha/\beta$  ratio at each time-of-scoring.

#### Conclusion

The clonogenic assay rests on the working hypothesis that irradiated cells will either perish after few mitoses, or proliferate constantly to form vital colonies. We observe that, since this condition is not generally fulfilled, systematic errors arise. We propose a temporally and statistically resolved analysis of colony size distributions. This removes the scoring bias by separating cell survival from the effects of colony growth. Additionally, a biomathematical model can be employed for in-depth analysis of the underlying colony formation.

#### Poster: RTT track: Patient preparation, positioning and immobilisation

#### PO-1091 Multimedia assisted information to patients with prostate cancer undergoing curative radiotherapy.

S. Rahbek<sup>1</sup>, I. Nordentoft<sup>1</sup>

<sup>1</sup>Herlev Hospital, Radiotherapy, Herlev, Denmark

#### Purpose or Objective

To reduce side effects, it is important for patients with prostate cancer, treated with curative radiotherapy, to have an empty rectum and a moderately filled bladder. To ensure that, they need to follow a bladder/bowel protocol.

The purpose of this study is:

- To use multimedia assisted information in preparing of the patient before radiotherapy treatment to increase the patient awareness of how to follow the instructions of the bladder/bowel protocol.
- To improve patient understanding of organs anatomical placement in the treatment area.

#### Material and Methods

Semi-structured individual interviews of a sample of 10 men undergoing radiotherapy were conducted. Each interview covered 5 topics: Information, understanding, experience, knowledge and improvement. At the end of each interview we showed two images: an animated image, and an x-ray image of the pelvic organs. Additionally, three of the patients were also shown an animated movie.

The data was taped, transcribed and analyzed within the 5 topics.

### Results

Through the analysis of the interviews it was clear that most of the patients, despite the information provided, had a misconception about how the organs are placed inside the small pelvic - including the prostate. The patients claimed that they understood the protocol presented to them, but most of them were not able to explain why it was important to follow. Some patients had formed their own alternative understanding of why the protocol was important to make sense of it. Almost all patients pointed out that beside side effects from the treatment itself, external factors such as finding a parking lot and different time of treatment appointments, had a negative impact on their ability to follow the protocol. All the patients, who were shown the two images, pointed out that the animated image helped them to a better understanding of the bowel/bladder protocol. The three patients who were shown the animated movie all preferred the movie and the animated image as a combination. All the patients felt that the use of multimedia as an information tool had a great impact on their understanding of the protocol and why it is important to comply.

### Conclusion

The use of multimedia assisted information to patients undergoing curatively intended radiotherapy treatment for prostate cancer can support and improve the understanding of the importance of complying with the bladder/bowel protocol - as well as the understanding of organs anatomical placement in the treatment area. The results of this study are going to be used for further investigation of patient ability, and an animated movie is created as well as animated images are implemented in the department.

Even though this study only focuses on patients with prostate cancer, we presume that data can be applied to similar diagnostic groups, that also need to follow a bowel/bladder protocol.

### PO-1092 The influence of a 6D couch and an individual head support on positioning in head-and-neck cancer

M. Rodrigue<sup>1</sup>, S. Veen<sup>1</sup>, J. Van Egmond<sup>2</sup>, M. Van Hameren<sup>1</sup>, T. Van Oorschot<sup>1</sup>, S. De Vet<sup>1</sup>, J. Van Santvoort<sup>2</sup>, R. Wiggenraad<sup>1</sup>, M. Mast<sup>1</sup>  
<sup>1</sup>Haaglanden Medical Center, Radiation Oncology, Leidschendam, The Netherlands ; <sup>2</sup>Haaglanden Medical Center, Medical Physics, Leidschendam, The Netherlands

#### Purpose or Objective

Accurate patient positioning in head and neck radiotherapy is of utmost importance because of the enhanced risk of overdosage to radiation-sensitive tissues. A six degrees of freedom couch permits optimization of set-up by enabling correction of rotational errors. Improved patient immobilization can be achieved by adding an individual head support to the immobilization system. No previous study has compared different treatment couches and head supports in combination with online cone-beam CT-based position verification in head and neck radiotherapy. Therefore, the aim of this comparative study was to evaluate the benefit of a six degrees of freedom couch and an individual head support using online cone-beam CT position verification and correction in head-and-neck cancer patients.

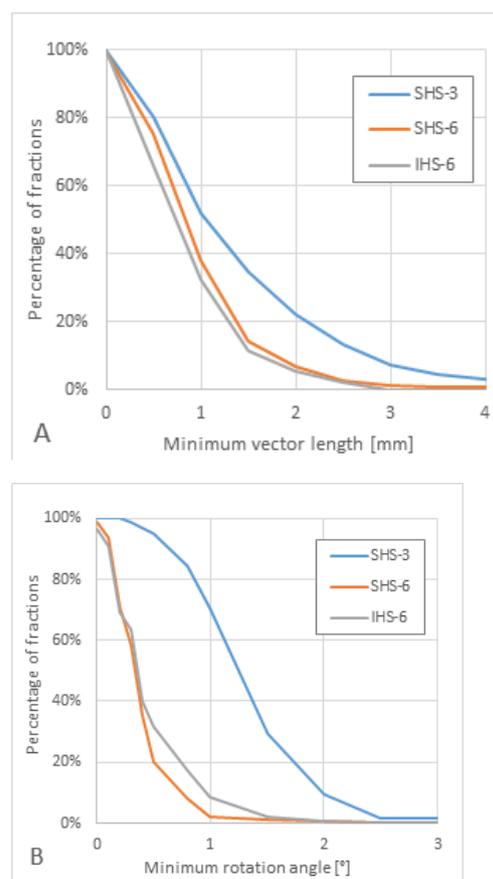

#### Material and Methods

This prospective study analysed 30 patients in three cohorts. Patients were either treated with a standard head support and conventional three degrees of freedom couch (SHS-3), a standard head support and six degrees of freedom couch (SHS-6), or an individual head support and six degrees of freedom couch (IHS-6). All set-up errors

were corrected online using cone-beam CT. Interfraction and intrafraction clipbox translations and rotations were assessed. Linear mixed models were used to calculate differences between cohorts.

### Results

A total of 1,605 matches were performed derived from 827 cone-beam CT's in 413 fractions. Interfraction mean translation vectors of the clipbox were <1.5 mm for all cohorts. These vectors were significantly lower for IHS-6 compared to SHS-3 ( $0.8 \pm 0.3$  vs.  $1.4 \pm 0.7$  mm,  $P=0.001$ ). Interfraction translation vectors of  $\geq 2$  mm were seen in 22%, 7%, and 5% of fractions for SHS-3, SHS-6 and IHS-6, respectively (Figure A). Interfraction rotation angles of  $\geq 1$  degree were seen in 71% of all fractions for SHS-3, as opposed to <8% of all fractions in the other cohorts (Figure B). Intrafraction clipbox translations and rotations did not differ between cohorts.

### Conclusion

A six degrees of freedom couch and an individual head support in head and neck radiotherapy yields less interfraction clipbox translations and rotations. The use of these tools could be of importance in reducing radiation-related toxicity of organs at risk in head-and-neck cancer patients.

### PO-1093 Comparison of conventional dark tattoo ink versus invisible tattoo ink for breast radiotherapy

L.H. Lim<sup>1</sup>, P.P.E. Pang<sup>1</sup>, F.Y. Wong<sup>1</sup>  
<sup>1</sup>National Cancer Centre Singapore, Division of Radiation Oncology, Singapore, Singapore

#### Purpose or Objective

Reproducibility is critical in radiotherapy (RT). In addition to immobilization, patients are usually tattooed. Occasionally, female breast cancer patients have refused permanent tattoos due to cosmetic reasons and a wish not to be reminded of their disease. Henna was used as a non-permanent alternative. Sometimes, these markings are

lost, ensuing repeated CT simulations and planning, incurring treatment delays, increased costs and impact on logistics and manpower.

An invisible ultraviolet (UV) tattoo ink has been used as an alternative to tattoos. Landeg et al. [1] previously reported no significant inter-fraction setup reproducibility deviation and improved patients' personal body image. However, the acceptability and reproducibility of UV tattoo ink on Asians who differ in skin pigmentation and cultural sensitivity as compared to Caucasians is unknown. We conducted a pilot study to assess the feasibility of replacing Indian ink with UV ink in our female breast cancer patients undergoing RT.

#### Material and Methods

5 patients were enrolled in this prospective study. Each patient was given 2 conventional dark ink and 2 invisible UV ink tattoos. During treatment, the given tattoos were used to align to setup treatment field borders. Routine X-ray verification was used to confirm RT position. The visibility of UV tattoos were assessed during each RT fraction. A body image survey [2] was used to assess patients' acceptance of each ink type. This was administered at 3 time points (CT simulation, last week of RT and 6 weeks post-RT). An in-house staff satisfaction survey was administered once to the Radiation Therapists (RTTs) to assess their perception of the UV tattoos and their use in RT positioning.

#### Results

At 'CT simulation', 3 out of 5 (60%) patients were apprehensive about the impact of the tattoos on their body image and felt conscious about their appearance. However, post-RT, 100% of the patients were satisfied with the appearance of the UV tattoos and did not feel less attractive physically/sexually or less feminine. At post-RT, 4 out of 5 (80%) patients were satisfied with their body with respect to the UV tattoo and did not feel conscious about their appearance, found no difficulties looking at their naked self and did not intentionally avoid people. The UV tattoo ink posed minimal risk of infection or allergy as none of these events were observed. 12 RTTs responded to the staff satisfaction survey. All of them found it easy to locate the UV tattoos and recommended its use in future breast cancer patients. Although 92% of RTTs felt that UV tattoos did not affect the total time taken for patient setup, 42% indicated more time is needed to locate them. Nonetheless, most commented that invisible ink is aesthetically acceptable and can improve patients' confidence. In addition, some felt that it would be valuable for patients with darker skin pigmentation.

#### Conclusion

From this feasibility study, we conclude that the invisible ink is well accepted by the breast cancer patients and RTTs.

#### PO-1094 Use of an individual abdominal corset in patients with upper-GI tumors treated with proton therapy

Universität Dresden- Dresden- Germany, OncoRay - National Center for Radiation Research in Oncology- Dresden- Germany- Helmholtz-Zentrum Dresden - Rossendorf- Institute of Radio, ; <sup>5</sup>University Hospital and Faculty of Medicine Carl Gustav Carus- Technische Universität Dresden- Dresden- Germany, Department of Radiotherapy and Radiation Oncology- OncoRay - National Center for Radiation Research in Oncology- Dresden- Germany- Helmholtz, ; <sup>6</sup>University Hospital and Faculty of Medicine Carl Gustav Carus- Technische Universität Dresden- Dresden- Germany, Department of Radiotherapy and Radiation Oncology- OncoRay - National Center for Radiation Research in Oncology- Dresden- Germany- Helmholtz,

#### Purpose or Objective

The irradiation of tumors, which are subject to respiration-induced motion is challenging for pencil beam scanning (PBS) based proton therapy due to the interplay effect and the temporally varying tissue densities along the beam path. Here, we report on the feasibility, tolerability and setup reproducibility of an individualized immobilization device for patients with tumors in the upper abdomen, who are treated with PBS.

#### Material and Methods

Since January 2018, nine patients with tumors in the upper abdomen (pancreas, liver and gall bladder) have been treated with PBS at our department. All patients eligible for this study underwent the following procedure within 10-days: (1) intra-tumoral implantation of three fiducial markers for target localization, (2) design of an individualized abdominal corset for motion reduction by abdominal compression, (3) abdominal MRI scan with intravenous contrast agent (c.a.) for target volume definition and tumor motion quantification, and (4) 4D-CT scan with c.a. for treatment planning. CT simulation and irradiation was performed with a vacuum mattress (Fig.1). Before each treatment fraction, the position of the target volume was verified with orthogonal X-ray imaging. First, a 2D/2D match with the DRRs was performed and then the position of the fiducial markers was verified (tolerance level: 3-5mm). In case this tolerance level was exceeded, a CT scan was performed in-room and the dose distribution was recalculated for plan comparison; in case of clinically relevant changes in the dose distribution, a new plan was calculated.

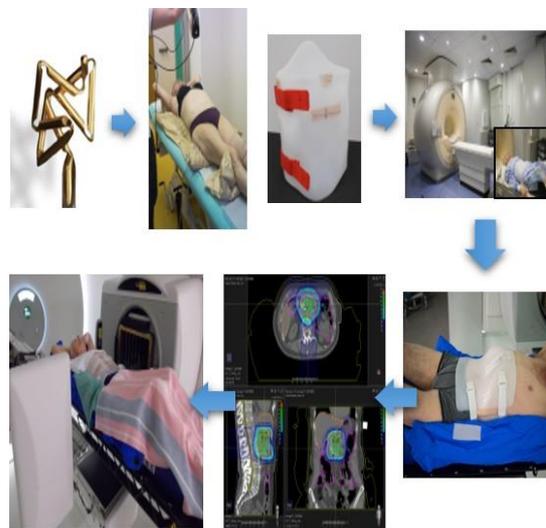

Fig.1 Workflow: fiducial marker (GoldAnchor®) implantation, individual abdominal corset, diagnostic MRI in treatment position; planning dual-energy CT; treatment volume delineation and planning; delivery of PBS.

## Results

All patients tolerated the marker implantation, the abdominal corset and the treatment well with no treatment interruptions. In 4 out of the 300 applied fractions (1,3%) the tolerance level of the fiducial markers was exceeded. For these fractions, the recalculated dose distribution nevertheless showed sufficient target coverage (Fig. 2). The entire treatment fraction (including patient positioning, setup verification and dose delivery) did not exceed the standard time slot of 30 minutes.

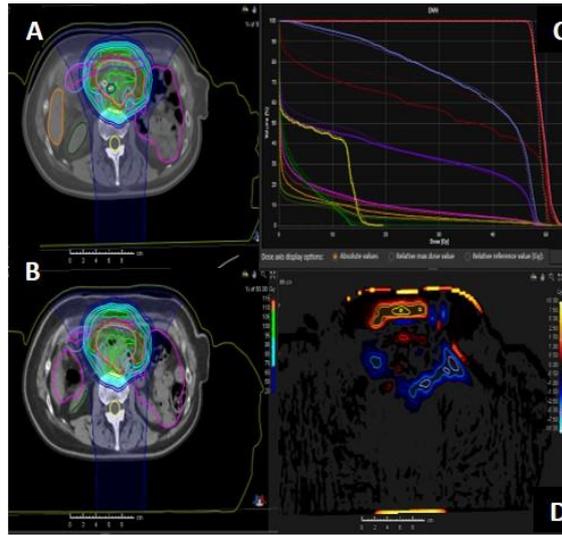

Fig. 2 Plan comparison during treatment. A: original dose distribution on treatment planning dual energy CT; B: dose distribution recalculated during treatment; C: the DVH highlighting the differences between the two plans (solid line: planning CT, dotted line: repeated CT); D: difference in dose distribution.

## Conclusion

This study demonstrates that PBS-based proton therapy with an abdominal corset to reduce breathing motion of GI-tumors is feasible, well-tolerated by patients and provides a reproducible setup without prolonging the daily treatment time.

### PO-1095 Time management and hands-on experience with ELEKTA Unity 1.5T MRI-Linac

C. Marks<sup>1</sup>, A. Stolte<sup>1</sup>, D. Thorwarth<sup>2</sup>, L.H. Braun<sup>1</sup>, S. Boeke<sup>1</sup>, D. Wegener<sup>1</sup>, J. Boldt<sup>1</sup>, C. Ortinau<sup>1</sup>, M. Kammler<sup>1</sup>, B. Holl-Henkel<sup>1</sup>, C. Gani<sup>1</sup>, D. Zips<sup>3</sup>, M. Nachbar<sup>4</sup>, O. Dohm<sup>4</sup>, D. Mönnich<sup>4</sup>

<sup>1</sup>University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany; <sup>2</sup>Section for Biomedical Physics Tübingen- Eberhard Karls University Tübingen, Department of Radiation Oncology, Tübingen, Germany; <sup>3</sup>University Hospital Tübingen- Eberhard Karls University Tübingen, Department of Radiation Oncology, Tübingen, Germany; <sup>4</sup>Section for Biomedical Physics Tübingen, Department of Radiation Oncology, Tübingen, Germany

### Purpose or Objective

MR-Linac (MRL) hybrid devices are a new development in radiation oncology. Workflow and time management represent a challenge for all involved professions. Herein we present our initial experience with the ELEKTA Unity. Despite longer treatment times at MRL, patients may benefit from MRL and could be treated more accurately with hypofractionated radiotherapy. MRI allows better soft tissue contrast of the tumor and adjacent OARs. The mobility of the tumor and the patient movement can be detected online and adaptive response may be considered. In addition, the MRI, unlike a CBCT, does not generate additional radiation exposure to the patient.

## Material and Methods

The first patient treated with MRL had oligometastatic prostate cancer and was treated for a pararectal lymph node metastasis.

The workflow consisted of: CT planning with MRL table top and acquisition of an MRI at the MRL. An 8 beam step-and-shoot IMRT plan was created. The staff consisted of RTTs, Radiation Oncologists and Medical Physicists.

The daily MRL workflow included a pretreatment MRI. Based on this, plans were optimized with the "adapt to position" algorithm in order to adjust the plan of the daily anatomy. The patient received real time MRI (4D) during plan optimization and beam-on to confirm sufficient target volume coverage. Post-treatment MRI was performed for in-silico studies after treatment. Time required for individual steps (CT planning, patient positioning, MRI, plan optimization and daily treatment) of the treatment process were recorded.

## Results

At Unity the total duration for planning was 395 minutes on average, for IMRT at a conventional linac it was 330 minutes for CT (no additional MRI). An average of 46 minutes was required for daily treatment on MRL, 16 minutes for the linac. The radiation delivery time is comparable on both devices with approximately 2-3 minutes.

The total time required for planning, radiation and post-MRI and offline verification of the adapted and treated plan was 503 minutes at MRL and 357 minutes at linac (CBCT, no MRI).

The daily pre-treatment scans took 3-7 minutes at MRL and 2-3 minutes for linac with CBCT.

## Conclusion

Due to the new workflow and the involvement of all professional groups for daily radiation, each individual step took more time than with conventional linac treatment (IMRT). With each additional patient, we expect significantly reduced treatment times. With increasing experience, the planning and treatment times can be further reduced to enhance efficiency.

<sup>1</sup>Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

Following the RTOG0933 contouring atlas [1], the hippocampus is visualized with a T1-weighted 3D gradient TFE sequence. Unfortunately, this can have a Water Fat Shift (WFS) in the order of 2mm. When matching the fatty skull bone tissue to the planning-CT, this may result in a 2mm mismatch of the hippocampus (fig.1a). For Radiotherapy (RT), scanning in an immobilization mask is debated as the benefit to obtain the scan in RT position and minimize motion artifacts comes at the cost of a reduced Signal to Noise Ratio (SNR). Patients can be scanned with flexible coils at either side of the mask combined with Anterior and Posterior (A&P) coil arrays to regain SNR.

Purpose of this study is to obtain a geometrically correct MR sequence with sufficient image quality to use for delineation of the hippocampus, in head coil or in RT position.

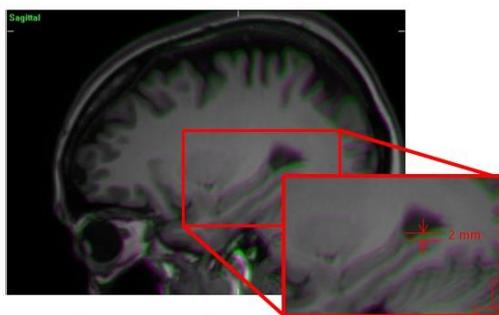

Fig 1a. Hippocampus displacement due to WFS

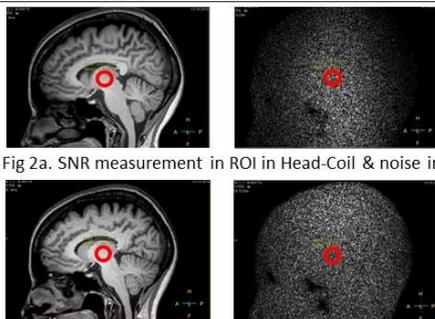

Fig 2a. SNR measurement in ROI in Head-Coil & noise image

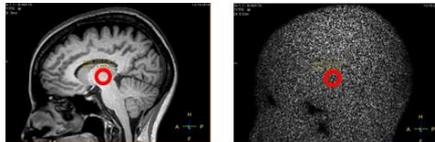

Fig 2b. SNR measurement in ROI in Flex-Coil & noise image

#### Material and Methods

A volunteer was scanned on a 3T Philips Ingenia MRI scanner. The 3D T1-TFE sequence had a field of view of 270x253x204mm, 1.1x1.1x1.2mm voxels (FHxAPxRL), TR/TE 6.8/3.1ms, Flip Angle 9°, Sense 1.8 (RL). A diagnostic sequence was scanned in head-coil with WFS 1.8 pixel, the optimal RT sequence with flexible and A&P and WFS of 1.0 pixel. Both coil set-up and WFS were varied separately.

A separate noise scan without RF was obtained with the same setting and scaling as the 3D T1-TFE. The SNR was obtained by taking the ratio of the mean signal and noise measured in a Region Of Interest (ROI) of 235mm<sup>2</sup> in two locations: a homogeneous part of the ventricle near the hippocampus and the right part of the brain (fig.2). Two trained observers were asked to give the scans a [1-4] score if the scan was suitable for hippocampus delineation (table 1).

#### Results

The SNR measurements are reported in table 1. Changing the WFS from 1.8 to 1.0 pixel results in a 25.9-30.8% decrease in SNR (head coil) and 26.0-26.1% (flex+A&P coils). The use of flex+A&P coils resulted in a reduction in SNR compared to the head coil of 23.1-42.2% depending on location and WFS. The flex+A&P coils give a homogeneous SNR over the image. When scanning in head coil a SNR increase by a factor 1.2-1.3 is seen from center to the right side of the brain. The SNR reduction from the diagnostic to the optimal RT sequence was 46.8% near the hippocampus and 57.1% in the right part of the brain. The observers gave all scans a sufficient score ( $\geq 3$ ) for delineation of the hippocampus, irrespectively which type of coils or WFS setting were used.

SNR = Signal/Noise				
Location	Headcoil WFS 1.8 pixel		Flexcoil WFS 1.0 pixel	
	HP*	RB**	HP	RB
Signal (mean)	1509.1	1309.5	1452.3	1277.4
Noise (mean)	40.4	28.5	56.2	37.5
SNR	37.4	45.9	25.8	34.1
			26.9	26.6
			19.9	19.7
Observer score [1 = not usable, 2 = recognisable anatomy, not sufficient, 3 = good/sufficient, 4 = excellent]				
	Headcoil WFS 1.8 pixel	Headcoil WFS 1.0 pixel	Flexcoil WFS 1.8 pixel	Flexcoil WFS 1.0 pixel
observer 1	3	3	3	3
observer 2	4	3	3	3

\*HP = near the hippocampus

\*\*RB = part of the right side of the brain

Table 1: measured SNR and observer score

#### Conclusion

Scans with a large WFS setting should not be used for RT delineation of the hippocampus, since shifts of 2mm can be found. Changing from head coil to flex+A&P coils, has more effect on SNR loss than changing to a smaller WFS. Scanning in RT position with flex+A&P coils and low WFS, the 3D TFE scan was considered suitable for delineation.

#### PO-1097 Interobserver variability in tumor bed contouring for breast cancer: comparison between RTO and RTT

E. La Rocca<sup>1,2</sup>, M. Dispinzieri<sup>1,2</sup>, T. Giandini<sup>3</sup>, V. Lici<sup>2</sup>, S. Frasca<sup>2</sup>, F. Bonfantini<sup>3</sup>, R. Valdagni<sup>1,4</sup>, L. Lozza<sup>2</sup>, E. Pignoli<sup>3</sup>, M.C. De Santis<sup>2</sup>

<sup>1</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milano, Italy; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiotherapy Unit 1, Milano, Italy; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milano, Italy; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Director- Radiation Oncology 1 and Prostate Cancer Program, Milano, Italy

#### Purpose or Objective

To evaluate the interoperator variability between radiation oncologist (RTO) and radiation therapist (RTT) in tumor bed (TB) contouring for patients (pts) with early breast cancer.

#### Material and Methods

We retrospectively analyzed pts undergoing breast conservative surgery who received a boost on the TB. The RTT contoured the TB independently of the RTO after a training course. In the group 1 CTV boost was the surgical bed, defined by adding 1 cm to the surgical clips placed in the lumpectomy cavity during surgery. In the group 2 the boost CTV was defined on the evaluation of preoperative mammography, medical history, intraoperative data and ultimate histological description. Moreover in this group the seroma cavity or a metallic find on the scar were used to identify the CTV boost. The CTVs were three dimension expanded of 0.5 cm creating a planning target volume. We compared the contours in terms of volume, number of slices, and DICE similarity coefficient (DSC).

#### Results

Forty pts were evaluated. Twenty pts had surgical clips (group 1), the other twenty had no clips (group 2). For each pts of group 1, no difference in the number of contoured slice was found between the two operators, but a statistically significant difference was found in terms of volumes, being RTT TB on average ~ 45% smaller than RTO TB (9.5±5.5 cm<sup>3</sup> vs. 17.4±10.5 cm<sup>3</sup>). For group 2, random variations between the two operators were found in terms of contour location, number of contoured slices, and volumes, with mean values of 24.7±16.3 cm<sup>3</sup> and 26.7±17.1 cm<sup>3</sup> for RTT TB and RTO TB, respectively. The TB delineated for this group were significantly bigger (p<0.05) than those delineated by the RTT for group 1. A difference was obtained by comparing the TB volumes delineated by both the operators in each group: 13.4±9.2 cm<sup>3</sup> in group1 vs. 25.7±16.5 cm<sup>3</sup> in group 2. The mean

DICE value between RTO TB and RTT TB was  $0.69 \pm 0.07$  (range 0.53-0.81) in group1 and  $0.37 \pm 0.18$  (range 0-0.58) in group2 ( $p < 0.05$ ).

### Conclusion

This study showed a decrease of the interoperator variability in the TB contouring with the use of surgical clips. The reduction of the volumes in the group with clips is closely related to the possibility of decrease side effects like fibrosis. The RTT following an appropriate training may become an important figure in the radiotherapy multidisciplinary team, able to support the RTO also in the contouring phase of the radiotherapy treatment.

### PO-1098 GTV definition agreement in brain metastasis radiosurgery using 1.5T MRI-sim: a multi-observer study

J. Yuan<sup>1</sup>, G.G. Lo<sup>2</sup>, Y. Zhou<sup>1</sup>, O.L. Wong<sup>1</sup>, W.W.K. Fung<sup>3</sup>, K.F. Cheng<sup>3</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China ; <sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Diagnostic and Interventional Radiology, Happy Valley, Hong Kong SAR China ; <sup>3</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China

### Purpose or Objective

We aim to assess the gross target volume (GTV) definition agreement in the treatment planning of frameless radiosurgery for brain metastasis by using 1.5T MRI-simulation data via a multi-observer study of MRI/CT registration and lesion delineation variability.

### Material and Methods

10 patients (brain metastases  $n=33$ ) received CT-simulation (no contrast,  $0.78 \times 0.78 \times 1 \text{mm}^3$ ) and 1.5T MR-simulation (3D-T1w-FSE with Gd contrast:  $1 \times 1 \times 1 \text{mm}^3$ ) scans in the identical thermoplastic mask fixed treatment position on the same day prior to their Cyberknife radiosurgery. Three observers were asked to blindly conduct rigid MRI/CT registration and then GTV contouring on the MRI fused CT images. Registration transformation matrix and the center position, volume, dice similarity coefficient (DSC) of the delineated lesions between the observers (obs) were compared using one-way ANOVA and intraclass correlation coefficient (ICC).

### Results

The inter-observer registration translational variability (RMS of the registration shift SD between 3 observers) was 0.07, 0.07, 0.1 and 0.08mm in LR, AP, SI and 3D, respectively. The GTV center position variability (RMS of GTV coordinate SD of 3 observers) was 0.18, 0.21, 0.18 and 0.23mm in LR, AP, SI and 3D. All individual rigid registration shifts relative to the mean registration shifts of all observers were well within 0.3mm in all translations (Fig. 1 upper row). All GTV center positions relative to their mean delineated position by all observers were all within 0.5mm (Fig. 1 lower row). The volumes of the delineated GTVs between three observers (obs1:  $1.23 \pm 1.51 \text{cc}$ , obs2:  $1.35 \pm 1.67 \text{cc}$ , obs3:  $1.30 \pm 1.59 \text{cc}$ ) showed insignificant difference (one-way ANOVA:  $p=0.955$ ); and excellent ( $\text{ICC} > 0.75$ ) agreement ( $\text{ICC}=0.9986$ , 95% CI = [0.9975, 0.9993]). The DSC between the observers were  $0.87 \pm 0.06$  (obs1vs2),  $0.85 \pm 0.07$  (obs1vs3) and  $0.85 \pm 0.12$  (obs2vs3). The inter-observer agreement was excellent ( $\text{ICC}=0.9546$ , 95% CI = [0.9076, 0.9797]) for the tumors with volume  $\geq 0.2 \text{cc}$ . However, large inter-observer variability in terms of DSC ( $\text{ICC}=0.2505$ , poor) was observed for the small targets with volume  $< 0.2 \text{cc}$  (Fig.2).

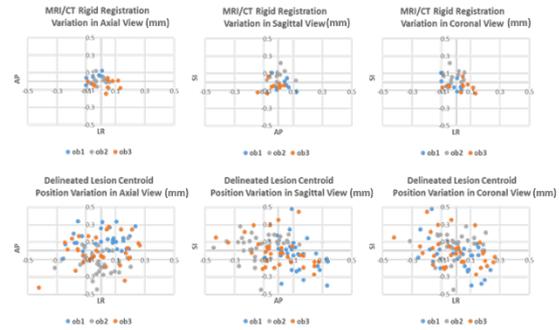

Fig. 1. The scatter plot of the rigid registration variability relative to the mean lesion volume of the whole cohort and the contoured lesion centroid position variability relative to each lesion's mean centroid position

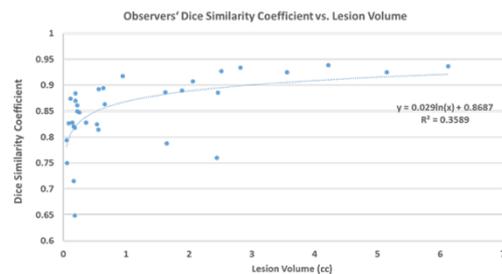

Fig. 2. The scatter plot of the observer's Dice Similarity Coefficient vs. mean tumor size. Excellent inter-observer agreement was found when the tumor size is larger than 0.25cc.

### Conclusion

Excellent inter-observer GTV definition agreement could be achieved in the frameless brain metastasis radiosurgery planning using 1.5T MR-sim data.

### PO-1099 A multi-center contouring study of spinal cord comparing myelo-CT and MRI fusion.

H. Tanaka<sup>1</sup>, H. Shimizu<sup>1</sup>, T. Aoyama<sup>1</sup>, H. Tachibana<sup>1</sup>, Y. Koide<sup>1</sup>, D. Katou<sup>1</sup>, S. Adachi<sup>1</sup>, R. Miyauchi<sup>1</sup>, Y. Ooshima<sup>2</sup>, T. Koidaira<sup>1</sup>

<sup>1</sup>Aichi Cancer Center, Radiation Oncology, Nagoya, Japan ; <sup>2</sup>Aichi Medical University, Radiation Oncology, 1-1 Yazakokarimata- Nagakute-Aichi, Japan

### Purpose or Objective

Spine stereotactic body radiotherapy (SBRT) is an emerging treatment for patients with spinal metastases and is rapidly being adopted in the clinic. Spinal cord is one of the most important organs at risk in Spine SBRT. To contour spinal cord, Myelo-CT or MRI fusion are used. To date, inter modality validation between Myelo-CT and MRI fusion in contouring spinal cord has not been evaluated. A multi-center contouring study was performed to evaluate inter modality variations between Myelo-CT and MRI fusion.

### Material and Methods

Six matured radiation oncologists from 2 centers joined this study. Plain CT, myelo-CT and MRI scans were performed on 12<sup>th</sup> thoracic to 5<sup>th</sup> lumbar vertebra of a patient who had bone metastases in 4<sup>th</sup> lumbar vertebra. The myelo-CT and MRI were registered to a plain CT by a radiation oncologist. Six radiation oncologists contoured lumbar 1<sup>st</sup> to 2<sup>nd</sup> spinal cord without metastases in vertebra on registered myelo-CT and MRI independently for this study. To avoid inter Radiation Treatment Planning system variations, all registration and contouring were performed on RayStation. Inter modality validation between myelo-CT and MRI fusion, inter observer variations in myelo-CT, and inter observer variations in MRI were evaluated with Dice similarity coefficient.

### Results

Inter modality Dice similarity coefficient between myelo-CT and MRI was  $0.801 \pm 0.026$ . (Average  $\pm$  SD) Inter observer Dice similarity coefficient in myelo-CT was  $0.873 \pm 0.030$ . (Average  $\pm$  SD) Inter observer Dice similarity coefficient in MRI was  $0.836 \pm 0.092$ . (Average  $\pm$  SD) Average volume spinal cord with MRI was  $1.874\text{ml} \pm 0.408$ . (Average  $\pm$  SD) Average volume spinal cord with Myelo-CT was  $1.682\text{ ml} \pm 0.221$ . (Average  $\pm$  SD). All contours were showed in Figure.

#### Conclusion

Inter modality variations between myelo-CT and MRI fusion, inter observer variations in myelo-CT and inter observer variations in MRI were evaluated and were larger than 0.7. The difference between myelo-CT and MRI fusion is small in contouring Spinal cord.

#### PO-1100 Validation of Atlas Based Segmentation for OAR in the brain.

A. Van Nunen<sup>1</sup>, A. De Graaf<sup>1</sup>, T. Budiharto<sup>1</sup>, D. Schuring<sup>1</sup>  
<sup>1</sup>Catharina hospital, Radiotherapy, Eindhoven, The Netherlands

#### Purpose or Objective

Manual delineation of organs at risk (OAR) is time consuming and possibly variable between observers. Atlas Based Segmentation (ABS) enables automatization of OAR delineation and can reduce workload and variability. Aim of this study was to investigate the accuracy of OAR delineation in the brain when using ABS.

#### Material and Methods

Delineations of OAR (brainstem, chiasm, cochlea, optic nerves, pituitary gland, retina, lacrimal glands, lenses and eyes) were generated using the ABS module in RayStation (Raysearch Laboratories, Stockholm, Sweden). OAR were segmented in 15 patients using four different atlases containing 10 CT scans, 25 CT scans, 10 MRI scans and 25 MRI scans. These were compared to the manual delineations. All OAR were reviewed by a radiation oncologist (RO) to determine whether they were clinically acceptable. Different parameters (volumes, specificity, sensitivity and Dice Similarity Coefficient (DSC)) were analysed and a Receiver Operating Characteristic (ROC) analysis was performed. A pairwise statistical analysis was performed to determine whether larger atlases could increase the accuracy of the automatic delineation and whether MRI atlases improve the delineation of the brainstem and chiasm.

#### Results

Highest median DSC (>0.8) was found for eyes and brainstem (figure 1). The median DSC was 0.5-0.7 for the cochlea, pituitary gland and optic nerves, and 0.4-0.5 for lenses, retina and chiasm (MRI). Lowest DSC was found for the chiasm based on the CT-atlas (figure 1). No statistically significant improvement was observed for atlases with 25 scans compared to atlases with 10 scans. The delineation of the brainstem and chiasm improved significantly by using an MRI atlas.

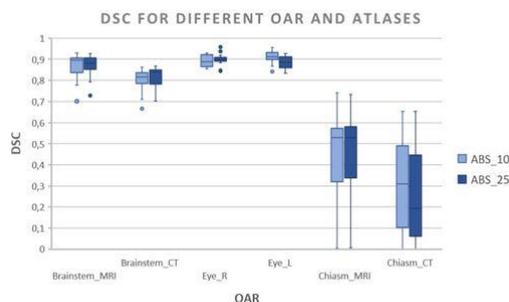

Figure 1: DSC for the evaluated atlases and OAR.

The ROC analysis shows that all points for the eyes and 14/15 points for the brainstem are plotted in the

“acceptable” quadrant (figure 2). This was confirmed by the RO who considered the delineations clinically acceptable. Most of the plotted points for the cochlea are in quadrant “acceptable” and some points were plotted in the “poor” quadrant, however the qualitative analysis shows that most ABS delineations were acceptable (13/15). Unacceptable results for pituitary gland, optic nerves, retina, lacrimal glands and lenses were found, which is in accordance with the DSC results. Despite the low DSC and the ROC analysis for the chiasm, the RO concluded that 11/15 ABS delineations were clinically acceptable.

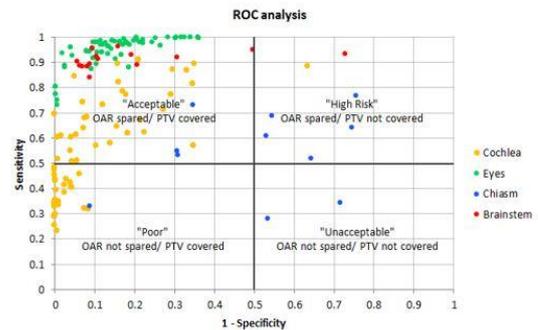

Figure 2: ROC analysis for different OAR.

#### Conclusion

Accurate delineation of the brainstem, cochlea and eyes was obtained by using ABS. Automatic delineations of optic nerves, retina, lacrimal glands, lenses and pituitary gland were not clinically acceptable. Automatic delineation of the chiasm with a MRI atlas is a good starting point, however manual corrections are needed for an accurate delineation. Increasing the number of scans in the atlas did not significantly improve the results, but caused an increase in computation time. Using an MRI atlas improved the accuracy of automatic delineations of the brainstem and chiasm.

#### PO-1101 Feasibility of PSMA PET/CT for evaluation of radiotherapy toxicity in salivary glands

N. Bruin<sup>1</sup>, V. Mohan<sup>2</sup>, J. Van de Kamer<sup>2</sup>, A. Al-Mamgani<sup>2</sup>, J. Sonke<sup>2</sup>, W. Vogel<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Departments of Radiation Oncology and Nuclear Medicine, Amsterdam, The Netherlands ; <sup>2</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Patients treated with high dose radiotherapy for head and neck cancer may suffer from a severe dry mouth (xerostomia) due to salivary gland damage. This toxicity has been difficult to evaluate with quantitative and gland-specific measurements. Functional imaging with prostate specific membrane antigen (PSMA) PET/CT is thought to indicate viable gland cells in salivary glands, and can theoretically be used to evaluate cell loss after radiotherapy. Our purpose is to investigate the technical and logistical feasibility of repeated PSMA PET/CT to evaluate salivary gland toxicity after radiotherapy.

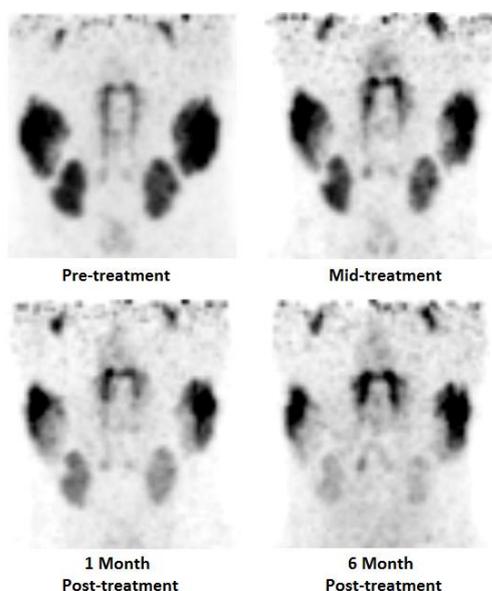

#### Material and Methods

Seven patients have been included in an ongoing prospective study, that will include 20 head-neck cancer patients who are treated with 35 fractions of 2 Gy. Four PSMA PET/CT scans of the head-neck area were made at baseline, during treatment, and at 1 and at 6 months post treatment. Patients were scanned in treatment position using a flat table top, base, personalized mask and knee support, using a Philips Gemini TOF PET/CT scanner. A low dose of 50 MBq PSMA was administered, and the scan was acquired after an incubation period of 45 min. The field of view was from orbit to clavicles, in 2 bed positions of 6

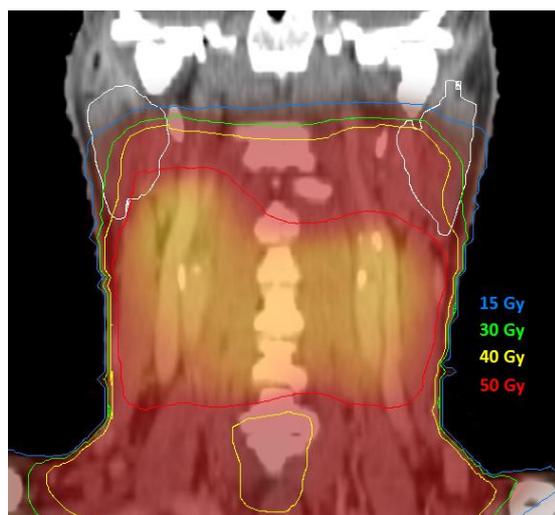

minutes each. PET images were reconstructed to voxels of  $2 \times 2 \times 2 \text{ mm}^3$ . Low dose CT parameters included 2 mm slices and 40 mAs with dose optimization. PSMA PET images were co-registered to the original planning CT using rigid registration, based on the accompanying low dose CT. The image quality and image registration, along with the change in uptake were assessed visually.

### Results

At the time of this evaluation, all included patients had completed their scheduled scans successfully. 7 had received a baseline and mid-treatment scan, 5 had received a 1 month post-treatment scan and 3 had received a 6 month post-treatment scan. The radiation dose per scan was estimated at 3 mSv (1 mSv for PET, 2 mSv for CT). The image quality of the PSMA PET and low dose CT were visually good and without artefacts (figure 1). Image registration between the PSMA PET and the planning CT was visually good for the baseline scan, but was increasingly challenging during and after treatment due to anatomical changes caused by weight loss and gland regression. Areas of signal loss corresponded to the dose distribution (figure 2).

**Figure 1.** PET imaging results of patient 1. Coronal projections of four PSMA PET scans at progressive time points.

**Figure 2.** Dose distribution for patient 1, overlaid on planning CT with isodose lines. Parotid gland outlines visible in white.

PSMA PET/CT for monitoring of salivary gland cell loss is feasible, with acceptable patient burden, low radiation burden, and sufficient image quality for quantitative gland-based and voxel-based evaluations. Anatomical changes after treatment can complicate image registration.

### PO-1102 Multi-atlas vs. single-atlas auto-segmentation for Head and Neck OARs: time efficiency and accuracy

D. Gugyeras<sup>1</sup>, A. Farkas<sup>2</sup>, M. Csima<sup>3</sup>, Z. Cselik<sup>4</sup>, J.

Hadjiev<sup>2</sup>, A. Gulyban<sup>5</sup>, F. Lakosi<sup>2</sup>

<sup>1</sup>Kaposi Somogy County Teaching Hospital, Dr. József Baka Diagnostic- Radiation Oncology- Research and Teaching Center, Kaposvár, Hungary ; <sup>2</sup>Somogy County Kaposi Mor Hospital, Dr. József Baka Diagnostic- Oncoradiology and Research Center, Kaposvar, Hungary ; <sup>3</sup>Kaposvar University, Faculty of Pedagogy, Kaposvar, Hungary ; <sup>4</sup>Csolnoky Ferenc Hospital, Radiation Oncology, Veszprem, Hungary ; <sup>5</sup>Europa Hospitals, Radiation Oncology, Bruxelles, Belgium

### Purpose or Objective

to test and compare time efficiency and accuracy between single-atlas (SingleA) and multi-atlas (MultiA) based auto-segmentation in Head and Neck (H&N) organs at risk (OAR) delineation.

### Material and Methods

60 patients with hypopharynx/larynx cancer were selected and divided into two groups: ideal population (T1-T2/N0-1, n=30 pts) and clinical scenario ( $\geq T3/ \geq N2a$ , n=30 pts). All manual delineation was performed by an expert RTT, including semi-automated options (Ref). The baseline single- and multi-atlas for both groups consisted of 10 reference delineated cases with 20 OARs (Brain, Brainstem, Oral cavity, Mandible, Oesophagus, PharynxConstr, PituitaryGland, Spinal Cord, ThyroidGland, Trachea, L/R Submandgland, L/R Eye, L/R Lens, L/R OpticNerve and L/R Parotis). For the next 10 patients (11-20th) atlas contours were generated with both MultiA and SingleA, followed by manual corrections (MultiCor, SingleCor). For the remaining patients (21-30th) the extended atlas (consisting of 1-20th cases with "Ref" contour) was used to generate the same set of OARs. Time required for Ref, Multi, MultiCor ( $T_{MultiCor}$ ), Single, SingleCor ( $T_{SingleCor}$ ) were measured and compared using t-test. Delineations (Ref vs. Multi, MultiCor and Single, SingleCor) were compared using relative Dice Similarity Coefficient (DSC), Jaccard index (JI), commonly contoured volumes (CCV) and 95% of the Hausdorff distance (HD95%). Baseline vs. extended atlas performance was compared using two sided t-test with  $p < 0.05$  significance level.

### Results

MultiA outperformed in 57.5 % of the volumetric parameters the SingleA with significantly lower  $T_{Cor}$  as well (11min:19sec vs. 15:20,  $p < 0.001$ ) (Table1-2). By increasing the number of atlas cases a >7 min gain per patient (8:37 vs. 15:57,  $p < 0.001$ ) was achieved. Time saving ( $T_{MultiCor} - T_{SingleCor}$ ) did not differ between ideal and clinical population ( $p = 0.66$ ) and became more pronounced with advanced atlases (4:00 vs. 7:20,  $p < 0.001$ ). The extended atlas did not improve delineation performance compared to baseline atlas.

AtlasSet	Significant difference (No of metrics, %)		No significant difference (No of metrics, %)	
	MultiA better	SingleA better	MultiA better	SingleA better
MultiA vs. SingleA	92/160 (57.5)	1/160 (0.5)	30/160 (19)	37/160 (22)

### Purpose or Objective

Stereotactic radiosurgery (SRS) of intracranial lesions is based on the accurate delivery of very high doses of radiation in one or a few fractions to a well-defined volume, thus effectively sparing adjacent organs at risk (OARs). Milestone of this technique is therefore the acquisition of appropriate imaging for a really optimised treatment planning. Conventional magnetic resonance imaging (MRI) may not be able to differentiate tumor / non-tumor enhancing tissues. In this study we introduce treatment response assessment maps (TRAMs) [Zach et al. Neuro Oncol. 2015], based on the concept of delayed contrast extravasation MRI, into a radiosurgery treatment planning system (TPS) for target identification purposes.

### Material and Methods

Five patients presenting with disease progression of glioblastoma multiforme (GBM), previously treated according to our clinical practice, were enrolled in this study. For all patients an irradiation theoretical target volume was defined by contouring the enhancement area on a 3D T1-weighted MRI sequence (1-mm slice thickness, contiguous slices) acquired after contrast agent intravenous injection.

TRAMs were obtained subtracting the post-contrast 3D T1-weighted images from the same MRI sequence acquired about 75 minutes after. Tumor burden was then also identified and outlined on TRAMs images, specifically processed to be imported in the TPS (Figure 1). Maintaining the target coverage maximization as primary objective (prescription dose to 95% of the target) for comparison purposes, plan optimization tests were performed in two ways for each patient: considering only the conventionally delineated target or considering only the TRAMs delineated target. The plans obtained for each patient were compared in terms of target volume and dose volume histogram (DVH) data.

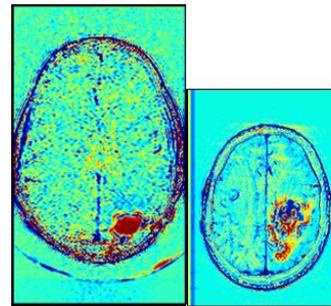

Figure 1.

Example showing one of the TRAMs used for radio-surgical planning. Difference values are colour code segmented. Blue pixels correspond to negative differences, i.e. complete contrast clearance (tumor areas), while red pixels represent the ones in which difference is positive, i.e. contrast medium accumulation during time (treatment-effect areas).

## Results

For all patients the target volume contoured on the TRAMs images was smaller than the one contoured on conventional MRI, with a fraction of approximately 1/2 in one case. Non-overlapping areas were also identified. Consequently, the percentage of healthy brain volume receiving 12 Gy was always in favour of the TRAM target case, with a reduction from 1.5 to 5%. Doses to other OARs adjacent to the target were also reduced.

## Conclusion

The addition of delayed contrast extravasation MRI information in the identification of the radiosurgery treatment target can affect the planning optimisation process in the re-irradiation scenario of relapsing glioblastoma multiforme. Further investigations on the actual clinical impact of this imaging modality seems appropriate.

## PO-1104 Implementing an automated target delineation service in multi-institutional environment in Finland

J. Heikkilä<sup>1</sup>, H. Virsunen<sup>1</sup>, L. Voutilainen<sup>1</sup>, K. Vuolukka<sup>1</sup>, A. Nevantaus<sup>2</sup>, M. Haatanen<sup>2</sup>, L. Sailas<sup>3</sup>, J. Seppälä<sup>1</sup>  
<sup>1</sup>Kuopio University Hospital, Centre of Oncology, Kuopio, Finland ; <sup>2</sup>Central Finland Central Hospital, Department of Radiotherapy, Jyväskylä, Finland ; <sup>3</sup>North Karelia Central Hospital, Department of Radiotherapy, Joensuu, Finland

### Purpose or Objective

According to many publications there are remarkable variations in radiotherapy (RT) target delineation. These publications conclude that interobserver variability in target delineation is the biggest source of uncertainty in RT process, potentially inducing systematic errors in radiation dose delivery. In some cases, this uncertainty could have an impact on clinical outcome of individual patients. [1]

Different tools to reduce variability in target volume delineation has been studied, such as training, guidelines, and autosegmentation methods. In this study we implemented fully automated target delineation service into multi-institutional environment, which should decrease the interobserver variability.

### Material and Methods

The developed delineation service consists of the following components (Fig 1): pseudonymization gateway in a hospital network, Ensemble integration platform between the hospital and delineation service,

interobserver variation in RTQA feedback and allow meaningful interpretation of RTQA results with associated outcomes. RTQA should implement prospective TVD review to identify deviations that require modification prior to treatment delivery.

**PO-1106 Comparison of hybrid IMRT techniques for breast SIB irradiation**

C. Van den Beemd<sup>1</sup>, J. Penninkhof<sup>1</sup>, N. Holtzer<sup>1</sup>, M. Baaijens<sup>1</sup>, B. Heijmen<sup>1</sup>  
<sup>1</sup>Erasmus MC, Radiotherapy, Rotterdam, The Netherlands

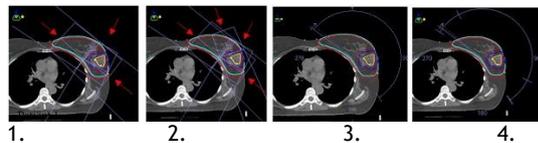

**Purpose or Objective**

Intensity modulated radiotherapy (IMRT) significantly reduces target dose heterogeneity in curative breast treatments. However, it is associated with an increase in whole body exposure to low doses from scattered and leakage radiation, and the reproducibility of the planned dose distributions during delivery (robustness) may become more challenging. To mitigate these problems, hybrid IMRT has been proposed, combining open fields with an overall low dose contribution of IMRT. This study compares four different techniques for hybrid planning of simultaneous integrated boost (SIB) treatment, using either a static-gantry Dynamic Multi-Leaf Collimation (DMLC) or VMAT beams in combination with two open beams.

**Material and Methods**

Plans were created for a dose prescription of 45.57 Gy to the whole breast and 55.86 Gy to the tumor bed volume in 21 fractions. All hybrid techniques employed two open tangential beams encompassing the whole breast, together contributing at least 70-80% of the prescribed dose. This dose was used as bias dose in optimization of the full dose while adding 1) three DMLC beams (hDMLC3), 2) four DMLC beams (hDMLC4), 3) one partial arc of 200 degrees (hVMAT1), or 4) three partial arcs (hVMAT3: 30, 200, 30 degrees). See Figure 1 for graphical presentations of the four treatment approaches.

Figure 1: Beam arrangements of the DMLC/VMAT beams in the four investigated hybrid techniques.

Five patients were included with scans both in breath hold and in free breathing. Target coverage, dosimetric parameters for organs at risk, conformity indexes and delivered Monitor Units are evaluated. All plans were created using Monaco version 5.11.01 (Elekta AB, Stockholm). **Results**

Relative rankings of the hybrid approaches were similar for free breathing and breath hold planning CT-scans. For all patients, target coverage and homogeneity in the 4 hybrid approaches were clinically acceptable and comparable. The best conformality was always observed with VMAT. For the organs at risk hybrid plans with DMLC fields were superior to VMAT. Particularly the mean dose to the contralateral lung and contralateral breast was higher for VMAT plans with average differences of 0.6 Gy and 0.5 Gy, respectively. Differences between three or four DMLC beams were clinically insignificant. The hybrid DMLC technique with three beams (hDMLC3) resulted in the lowest amount of MU (374 MU), compared to 408 MU for hDMLC4, 426 MU for hVMAT1 and 593 MU for hVMAT3, respectively.

**Conclusion**

Because of lower doses in the organs at risk, hybrid DMLC plans are preferred over hybrid VMAT plans. The differences between three or four DMLC beams were small in this study. During the clinical implementation we found that in some individual cases the use of four DMLC beams resulted in a better plan quality, in particular the conformality. Therefore, the use of four DMLC beams is preferred and currently used in our clinic.

**PO-1107 Institutional experience of adaptation from IMRT to VMAT in post-operative cases of carcinoma tongue**

K. Jain<sup>1</sup>, P. Patel<sup>2</sup>  
<sup>1</sup>GCRI- civil hospital - Ahmedabad, Radiotherapy, Ahme, India ; <sup>2</sup>GCRI, Radiotherapy, Ahmedabad, India

**Purpose or Objective**

Intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) are being used for treatment of head and neck cancers with discrepancy regarding superiority of one technique over the other. Our aim was to analyse various dosimetric parameters of IMRT and VMAT plans, to compare between the two techniques for treatment of operated cases of Ca. Tongue

**Material and Methods**

The study included 50 patients of IMRT and 50 patients of VMAT with patients matched with respect to the pathological stage and volume of PTV to minimise selection bias. Following parameters were assessed for comparison: Target coverage Dose to Organ at Risk (OAR), conformity index (CI) Homogeneity index (HI) Monitor Unit (MU) delivered Treatment time

**Results**

There was no significant difference regarding PTV coverage, HI and CI in both plans ( $p > 0.05$ ). Significantly more MUs were delivered in IMRT with average difference of about 30% more MUs as compared to VMAT ( $p < 0.001$ ). Treatment delivery time was reduced by around 8.5 +/- 4 minute for VMAT. No significant difference was found in dose to OAR like larynx, Parotid, brain stem and pharyngeal constrictor muscles. Spinal cord maximum dose was about 1 +/- 0.4 Gy less in VMAT plans.

**Conclusion**

VMAT is emerging as mainstream treatment option for various sites like pelvis, lung and head and neck. No sufficient data is available for a specific sub site in head and neck cancers. In our study, we found that both VMAT and IMRT plans had comparable coverage of PTV. Sparing of OAR was marginally better with VMAT. But there was marked reduction in treatment delivery time with VMAT. Risk of intrafraction motion was reduced with VMAT with improved patient compliance. VMAT has become an institutional policy for patients of Ca. Tongue receiving adjuvant radiotherapy at our centre. We are exploring role of VMAT in other sub sites too.

**PO-1108 Comparison of VMAT plans for spine SABR according to optimization algorithm PRO and PO**

S. Son<sup>1</sup>  
<sup>1</sup>Seoul national university hospital, Radiation Oncology, Seoul, Korea Republic of

**Purpose or Objective**

To evaluate the quality of volumetric modulated arc therapy (VMAT) plans for stereotactic ablative radiotherapy (SABR) by optimization algorithm of progressive Resolution Optimizer (ver.13. 7.16, PRO) and Photon Optimizer (ver.13.7.16, PO).

**Material and Methods**

20 cases of VMAT plans for spine SABR were retrospectively selected for this study. For each case, 2 kinds of VMAT plans with coplanar 2 full arcs were generated using Eclipse (Ver.13.7) and optimized with 2 different optimization algorithms the PRO and PO

respectively. Every condition was applied identically to both plans except optimization algorithms for fair comparison. The dose distributions were calculated using the AcurosXB (ver.13.7) with the calculation grid of 0.2 cm. All VMAT plans were normalized that the target volume irradiated by 18Gy the prescription dose ( $V_{100\%}$ ) would be 80%. For organs at risk (OARs),  $D_{10\%}$ , of spinal cord, dose received at 0.03 cc of spinal cord ( $D_{0.03cc}$ ) and mean dose to the spinal cord were calculated. The homogeneity indices (HIs) of target volumes and total monitor units (MUs) for each VMAT plan were calculated. High-definition MLC<sup>TM</sup> (HD MLC) and 10 MV flattening filter free (FFF) photon beams of TrueBeam STx<sup>TM</sup> were used for VMAT plans.

#### Results

The average values of  $D_{10\%}$ ,  $D_{0.03cc}$  and mean dose to spinal cord of PRO plans were  $896.62 \pm 59.66$  cGy,  $1004.67 \pm 65.70$  cGy,  $619.83 \pm 67.23$  cGy and PO were  $981.2 \pm 76.89$  cGy,  $1116.3 \pm 80.94$  cGy,  $655.01 \pm 64.87$  cGy, respectively. ( $p < .001$ ) The average value of HIs of PRO plans were  $1.13 \pm 0.09$  while that was  $1.17 \pm 0.1$  for PO plans, showing better homogeneity of target volumes. ( $p < .001$ ) The average values of total MU of PRO and PO plans were  $6146 \pm 576.79$  and  $5156 \pm 627.29$ , respectively. ( $p < .001$ )

#### Conclusion

Using PRO with higher MU for spine SABR VMAT plans are showing better results for the spinal cord doses while maintaining better target volume coverage as PO.

#### PO-1109 Plan quality and treatment time comparison between DCA and VMAT for cranial SRT

Y. Kato<sup>1</sup>, D. Watanabe<sup>1</sup>, R. Wakabayashi<sup>1</sup>, M. Inohira<sup>1</sup>, S. Itoya<sup>1</sup>, J. Okubo<sup>1</sup>, K. Miyamoto<sup>1</sup>, S. Shimizu<sup>2</sup>, Y. Oshiro<sup>2</sup>  
<sup>1</sup>Tsukuba Medical Center Hospital, Radiological Technology, Tsukuba, Japan ; <sup>2</sup>Tsukuba Medical Center Hospital, Radiation Oncology, Tsukuba, Japan

#### Purpose or Objective

Dynamic conformal arc therapy (DCA) and intensity modulated radiotherapy (IMRT) are major techniques of cranial stereotactic radiotherapy (SRT). Some reports have suggested that IMRT using step and shoot and dynamic techniques improved dose concentration and homogeneity, but increases low dose area and treatment time compared to DCA. In this study, we compare DCA and volumetric modulated arc therapy (VMAT) techniques for cranial IMRT, and compare dosimetry parameters and treatment time.

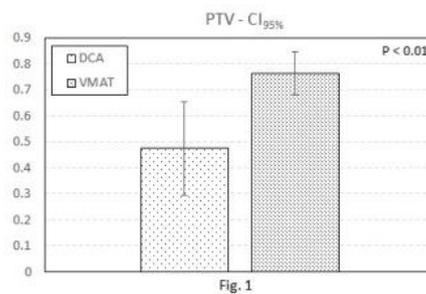

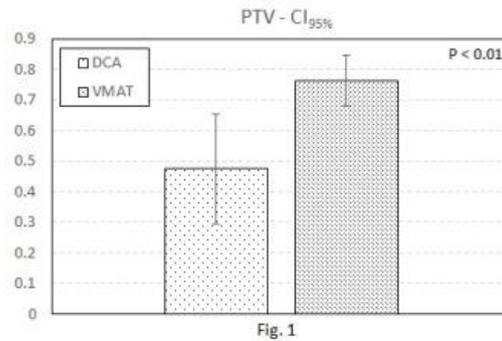

#### Material and Methods

Each 10 clinically-used treatment plans with DCA and VMAT for a single brain metastatic lesion were randomly selected for this study. The DCA treatment was re-planned with VMAT techniques, therefore total of 30 treatment plans were evaluated. In the DCA plans, 6 non-coplanar arcs with couch rotations ranged from  $285^\circ$  to  $75^\circ$  generally spaced at  $30^\circ$  interval were used. In the VMAT plans, 4-arcs with couch rotation ranged from  $270^\circ$  to  $45^\circ$  spaced at  $45^\circ$  interval were used. Conformity index (CI) and homogeneity indexes (HI) were calculated to compare dosimetry for target lesion, and V10 was calculated to evaluate low dose extent. The objective for each plan was to mean dose of the PTV covered by 100% of prescribed dose while minimizing the dose to the normal brain. All plans were generated using a single isocenter. A dose of 42 Gy in 7 fraction was prescribed and normalized to the isocenter. CI and HI were compared between clinically used DCA and VMAT. Also between clinically used and re-planned plan for each patient, CI, HI, and V10 were compared. Actual value was evaluated for treatment time.

#### Results

In comparison of the clinically-used plans, the mean CI was  $0.479 \pm 0.177$  and  $0.773 \pm 0.095$  for DCA and VMAT, respectively ( $p < 0.01$ ), and the mean HI was  $1.585 \pm 0.321$  and  $1.172 \pm 0.046$  for DCA and VMAT, respectively ( $p <$

$0.01$ ) (Fig.1). Also in the comparison of the plans of each patients, better CI and HI were observed in VMAT plans (CI:  $0.582 \pm 0.193$  vs.  $0.810 \pm 0.087$ ,  $p < 0.01$ , HI:  $1.237 \pm 0.150$  vs  $1.121 \pm 0.045$   $p < 0.05$ ). V10 was  $14.57\% \pm 8.02\%$  and  $17.24\% \pm 9.32$  respectively ( $p = 0.35$ ) for DCA and VMAT, respectively. The mean treatment time was 4 minutes 53 seconds ( $\pm 1.4$  seconds) and 3 minutes 56 seconds ( $\pm 2.8$  seconds) for DCA and VMAT, respectively ( $p < 0.01$ ) (Fig.2).

#### Conclusion

VMAT significantly improved dose concentration and homogeneity to the target compared to DCA and reduced treatment time. Also, there was no significant difference in low dose spreading.

#### PO-1110 CT-based HDR brachytherapy for salvage prostate cancer: the way to avoid or delay hormonal treatment

N. Dunnewold<sup>1</sup>, E. Kouwenhoven<sup>1</sup>, P. Koper<sup>1</sup>, S. Van den Berg<sup>1</sup>, J. Van der Klein<sup>1</sup>, J. Noordermeer<sup>1</sup>, N. Tak-Nobel<sup>1</sup>, K. Van Wingerden<sup>1</sup>, M. Mast<sup>1</sup>, H. De Jager<sup>1</sup>  
<sup>1</sup>Haaglanden Medical Center, Radiotherapy, The Hague, The Netherlands

#### Purpose or Objective

Despite ongoing technical improvements, about 40% of the patients will experience a PSA relapse after external radiotherapy [1]. Many recurrences are confined to the prostate and burdensome androgen deprivation therapy is prescribed frequently. In the era of mpMRI and PSMA-PET, early local recurrences can be diagnosed and treated locally using HDR salvage brachytherapy. This treatment has been described using MRI in the operating room (OR) [2]. However, many departments do not have access to such imaging equipment, making it challenging to adopt this procedure. We describe an adapted CT-based workflow in our department.

#### Material and Methods

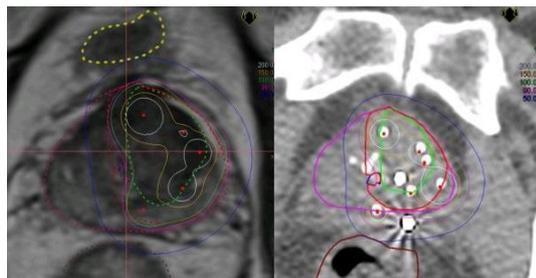

Up until now we treated eight patients, 4 - 11 years after their primary radiotherapy treatment, with mpMRI and PSMA-PET proven local recurrence. Mean PSA by diagnosis of recurrence was 3.3 ug/l (range 1.5-5.8). For GTV delineation the PSMA-PET, T2 weighted SPACE MR and T2W TSE MR were co-registered. The CTV was obtained from the GTV, applying a margin of 5mm, avoiding the urethra and removing the parts outside the prostate. Defining the

needle configuration was one of the pre-plan goals. A single dose of 19 Gy was prescribed. Sparing of critical organs (OARs) is a prerequisite, with specific focus on the urethra constraint (max. 17.7 Gy in 10% volume). A slight underdosage of the target was accepted when necessary. When the primary goal of target coverage (100% dose in 95% volume) could not be met, a second requirement (17 Gy in 90% volume) was used. The implantation of needles in the OR was performed using TRUS imaging co-registered with mpMRI / PSMA-PET. In the radiotherapy department a CT scan was obtained for catheter reconstruction and contouring of OARs. The final treatment plan was calculated. Prior to treatment the position of the needles was verified against gold fiducials or seeds from the primary treatment using fluoroscopy.

### Results

The defined workflow has proven to be feasible. The primary coverage goal for the pre-plan was met in 3 out of 8 cases. The secondary coverage requirement for the pre-plan was met in all cases. For the treatment plan these numbers are the same, except for two cases:

1. Primary goal was met at treatment, not for pre-plan;
2. Primary goal was not met; secondary requirement was met for the pre-plan but failed for treatment (13.1 Gy for 90% volume).

Example of MR-based pre-plan and CT-based treatment plan. Shown are CTV (red), GTV (green), urethra (blue), rectum (brown), bladder (yellow). Coverage was 87% and 86%, respectively.

Mean urethra dose was 16.8 Gy in 10% volume; mean rectal dose 7.9 Gy in 1 cc. Acute toxicity was limited so far with only one patient needing a catheter for 2 weeks (calculated risk: initial IPSS score 18; Qmax 6ml/s).

### Conclusion

This single fraction treatment of prostate recurrences is feasible using CT only for treatment planning. Dose constraints can be met, tumour coverage is in general adequate and acute toxicity limited. This seems to be a way to delay or even avoid androgen ablation. The treatment effect needs to be evaluated after sufficient follow-up.

2. Maenhout et al. Technol Cancer Res Treat. 2017;16:1194

### PO-1111 Knowledge-Based Planning as a Real Time Review QA Feedback Tool in the TROG 1501 SPARK trial

O. Cook<sup>1</sup>, A. Moore<sup>1</sup>, R. Kaderka<sup>2</sup>, K. Moore<sup>2</sup>, P. Keall<sup>3</sup>, J. Martin<sup>4</sup>

<sup>1</sup>TROG Cancer Research, Radiation Therapy Quality Assurance, Newcastle, Australia ; <sup>2</sup>University of California- San Diego, Radiation Medicine and Applied Sciences, California, USA ; <sup>3</sup>University of Sydney, Faculty of Medicine and Health, Sydney, Australia ; <sup>4</sup>Calvary Mater Newcastle, Radiation Oncology, Newcastle, Australia

### Purpose or Objective

Quality assurance (QA) in radiotherapy (RT) clinical trials is essential to ensure protocol compliance, patient safety and trial quality. However, protocol compliance does not necessarily ensure optimal plan generation. This study aimed to demonstrate the feasibility and impact of

Knowledge-Based Planning (KBP) feedback as part of the Real Time Review (RTR) process for the Stereotactic Prostate Adaptive RT Utilising Kilovoltage Intrafraction Monitoring (SPARK) trial.

### Material and Methods

A knowledge based dose-volume histogram (DVH) estimation model and automated planning routine were created using 34 SPARK RT plans that had previously been submitted as part of the clinical trial QA program. The KBP routine was applied to 6 subsequent patients pre-treatment. A feedback report comparing the KBP generated DVH versus the initial plan was collated using a customised script and sent to the site within 24 hours. Centres were asked to review the report and decide whether they would amend their clinical plan. A patient specific questionnaire (PSQ) was also supplied to each centre to gauge implementation and interpretation of the KBP information.

### Results

Of the 6 patients, 5 were protocol compliant and 1 case was replanned due to a major protocol deviation. As a result of KBP feedback 2/5 (40%) cases which were originally protocol compliant, were nevertheless replanned (Figure 1). Protocol dose constraints for all 6 cases were calculated and an average for each metric was generated. The mean dose-volume metrics were then compared between the initial submission, resubmission and KBP generated plans. Overall, the rectum, bladder, penile bulb and urethra planning risk volume (PRV) demonstrated that an improved dose-volume relationship could be achieved compared to the initial submission and was implemented in practice for the 3 resubmitted cases. Variable results were observed for the femoral heads, demonstrating a potential dose trade off (Table 1).

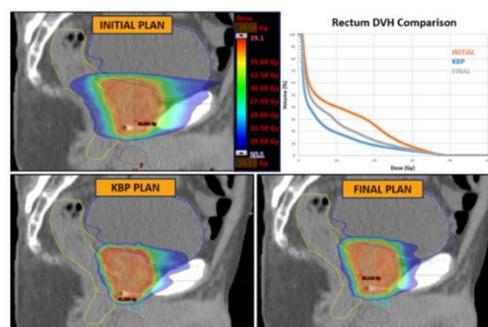

Figure 1. Case Study: Sagittal slice and DVH comparison of initial, KBP and final plans

Table 1

Organ at Risk (OAR)	Trial Constraint	Initial D (Gy)	KBP D (Gy)	Initial (Resubmitted) D (Gy)	Resubmitted D (Gy)
Rectum	V18.13Gy ≤50%	21.7 (15.5 - 29.3)	13.7 (8.8 - 20.9)	23.1 (15.5 - 29.3)	15.0 (10.8 - 19.2)
	V32.63Gy ≤5%	2.6 (0.4 - 4.9)	1.7 (0.0 - 3.9)	2.0 (0.4 - 4.8)	1.4 (0.1 - 3.1)
Bladder	V18.13Gy ≤50%	16.1 (3.5 - 29.6)	14.9 (4.4 - 32.2)	21.1 (16.1 - 29.6)	19.5 (9.4 - 32.4)
	V32.63Gy ≤10%	4.5 (0.9 - 8.5)	4.57 (1.0 - 10.4)	5.8 (3.6 - 8.5)	5.4 (2.0 - 9.1)
Urethra PRV	D0.1cc ≤38.78Gy	37.6 (37.1 - 37.9)	37.0 (36.6 - 37.7)	37.4 (37.1 - 37.5)	37.2 (37.0 - 37.5)
Penile Bulb	D0.1cc ≤36.25Gy	14.8 (3.7 - 25.3)	12.9 (3.5 - 21.5)	14.4 (4.9 - 25.3)	12.1 (6.3 - 20.1)
Lt FemHead	D0.1cc ≤30Gy	16.4 (12.1 - 20.8)	16.6 (13.6 - 21.9)	14.8 (12.1 - 16.5)	16.7 (14.3 - 20.0)
Rt FemHead	D0.1cc ≤30Gy	17.1 (14.3 - 21.9)	17.7 (14.4 - 22.0)	16.2 (14.3 - 18.1)	18.4 (13.5 - 21.5)

The PSQ was completed for 3 patients and open ended email response was received for the remaining 3 cases. All centres indicated that the KBP feedback process was a valuable tool for quality improvement in clinical trials and that the KBP feedback report provided enough information to make meaningful changes to their plans. In 2 cases the centres felt the turn-around time and resources were not sufficient if they were to make the suggested changes.

### Conclusion

KBP feedback was successfully incorporated into the RTR process for the SPARK trial and demonstrated that both improvements to and validation of plan quality for OAR dosimetry could be achieved. KBP feedback was received well with centres seeing value of this novel QA tool. There is potential to continue to build and improve on the model for future SBRT prostate trials, whether it be used as a QA

feedback tool or utilised at a site level during initial planning. Further prospective investigation of the role of KBP in radiotherapy clinical trials is planned.

**PO-1112 Real-time online matching in high dose treatments: Do RTTs perform as well as physicians?**

D. Levin<sup>1</sup>, G. Grinfeld<sup>1</sup>, V. Greenberg<sup>1</sup>, Y. Lipsky<sup>1</sup>, S. Zalmanov-Faermann<sup>1</sup>, Y. Tova<sup>1</sup>, R. Pfeffer<sup>1</sup>

<sup>1</sup>Assuta Medical Centers, Radiation Therapy, Tel Aviv, Israel

**Purpose or Objective**

For high dose per fraction treatments such as stereotactic body radiotherapy (SBRT) we require a physician to perform the pre-treatment on board imaging (OBI) match. The purpose of this study was to determine if patient matching positioning performed by radiation therapists (RTTs) is as accurate as physician matching.

**Material and Methods**

Sixteen RTTs and five physicians participated in this study. Data were collected from 113 patients totaling 324 measurements. 60 patients were treated for bone lesions, 53 for soft tissue lesions such as lung and liver. Matching was performed using kV-kV imaging for bones, and cone beam CT (CBCT) for soft tissue. All treatments were delivered on Varian linear accelerators (Palo Alto, CA). The initial match was performed by the RTTs and the shifts noted. The match was then reset, and the physician performed an independent match without prior knowledge of the RTT match. Physician couch shifts were applied for treatment. We used the Mann-Whitney rank sum test to determine statistical significance.

**Results**

The differences in patient shifts between physicians and RTTs were calculated in three translational and one rotational axis. The average vector shift was  $0.88 \pm 0.57$  cm vs.  $0.91 \pm 0.57$  cm for RTTs vs. physicians respectively. Neither the average vector nor the individual axis shifts were statistically significantly different ( $p > 0.2$ ). There was no significant difference when testing for bony or soft lesion matches separately.

**Conclusion**

RTT OBI matching is as accurate as physician matching for both bone and soft tissue lesions. Based on these results, RTTs are as qualified as physicians to perform a pre-treatment match. Thus, it may be feasible for the RTTs to perform the match, and the physician to review it off-line, without being present at the machine during treatment. When the RTT team is well-trained this does not compromise patient safety.

**PO-1113 Evaluation of CBCT and Orthogonal X-ray for Position verification in Radiotherapy of Prostate Cancer**

S.Y. Ng<sup>1</sup>, V.W.C. Wu<sup>2</sup>, G. Chiu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China ; <sup>2</sup>The Hong Kong Polytechnic University, Department of Health Technology and Informatics, Hong Kong, Hong Kong SAR China

**Purpose or Objective**

In routine practice of modern radiotherapy, cancer patients are scanned with a computer tomography (CT) scanner to obtain a set of CT images (planning CT) for treatment planning. Before treatment delivery, the patient position is verified by using Cone Beam Computed Tomography (CBCT) or conventional orthogonal planar image (OPI), for matching with the planning CT or the digitally reconstructed radiographs (DRR) generated from

the planning CT respectively. This study aims at evaluating the dosimetric impact and the matching time of using CBCT and OPI in position verification in radiotherapy of prostate cancer.

**Material and Methods**

Fifteen prostate cancer patients positioned with CBCT during radiotherapy were recruited retrospectively. OPI were simulated by generating DRR using CBCT in Eclipse™ treatment planning system (Varian Medical Systems, Palo Alto, CA). 3D-3D matching on CBCT/planning CT and 2D-2D matching on simulated OPI/DRR were performed in MIM Maestro™ (MIMSoftware, inc., Cleveland, OH, USA). Time spent on matching was recorded. Treatment plans were created on CBCT and the matching results were applied for dose calculation in Eclipse™. The two position verification methods were compared in terms of Iso-displacement vector (IDV), conformity index and homogeneity index of targets, dose-volume parameters of bladder and rectum in the resultant dose distributions, and matching time consumption. The results were tested using two-tailed Wilcoxon matched pairs signed rank test with a significance level of 0.005.

**Results**

Largest differences in IDV of CBCT-based and OPI-based position verification were found in antero-posterior direction (average 1.6 mm) and were statistically significant. The conformity index and homogeneity index of targets, the dose-volume parameters of bladder and rectum of the two position verification methods are summarized in Table 1. The use of CBCT resulted in a better conformity and homogeneity of the targets. Dosimetrically, CBCT was superior than OPI in terms of bladder dose but slightly inferior than OPI in terms of rectum dose for position verification. The scatter plot for matching time consumption in CBCT-based and OPI-based position verification in each fractions are shown in Figure 1. The time spent on performing 3D-3D matching and 2D-2D matching were  $4.2 \pm 0.5$  minutes and  $1.7 \pm 0.3$  minutes respectively and the differences were statistically significant.

	CBCT-based positional verification		OPI-based positional verification		Difference is statistically significant? (p<0.005)
	Mean	SD	Mean	SD	
Conformity Index (PTV)	0.654	0.088	0.628	0.100	Yes
Homogeneity Index (Prostate bed)	0.053	0.033	0.062	0.043	Yes
D <sub>max</sub> (bladder) [Gy]	71.724	1.274	71.941	1.251	Yes
V <sub>max</sub> (bladder) [cc]	20.416	13.936	21.824	14.699	Yes
D <sub>max</sub> (rectum) [Gy]	70.573	1.477	70.079	1.883	No
D <sub>0</sub> (rectum) [Gy]	22.924	16.829	22.216	16.018	No

Table 1: Summary of the conformity and homogeneity of the targets and the dose-volume parameters of bladder and rectum in the resulted dose distributions of the CBCT-based and OPI-based positional verifications

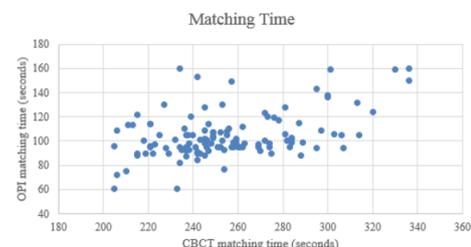

Figure 1: Scatter plot for matching time consumptions in CBCT-based and OPI-based positional verifications.

**Conclusion**

CBCT-based position verification yields a significant different IDV and is dosimetrically beneficial comparing with OPI-based position verification in radiotherapy treatment of prostate cancer. However, in addition to CBCT acquisition time, CBCT-based position verification requires a longer matching time than OPI-based position verification. Therefore, the choice of position verification

methods should depend on the availability of resources in the radiotherapy department and the tolerance on the treatment accuracy.

**PO-1114 Organ motion characterization by a novel fiducial marker in esophageal cancer radiotherapy**

H. Gripsgård<sup>1</sup>, K.C.D. Pham<sup>2</sup>, N.I. Glenjen<sup>1</sup>, G.M. Engeseth<sup>1</sup>, B.K. Abelseth<sup>1</sup>, T.H. Sulen<sup>1</sup>, U.Ø. Sølsvik<sup>3</sup>, L.B. Hysing<sup>4</sup>

<sup>1</sup>Haukeland University Hospital, Cancer Treatment and Medical Physics, Bergen, Norway ; <sup>2</sup>Haukeland University Hospital, Department of Medicine, Bergen, Norway ; <sup>3</sup>University of Bergen, Department of Global Public Health and Primary Care- Faculty of medicine, Bergen, Norway ; <sup>4</sup>Haukeland University Hospital/University of Bergen, Cancer Treatment and Medical Physics/ Department of Physics and Technology, Bergen, Norway

**Purpose or Objective**

A novel fiducial marker was explored for use in image-guided radiotherapy (IGRT) of esophageal cancer patients by characterizing inter- and intra-fractional organ motion.

**Material and Methods**

Twelve esophageal cancer patients proposed for radiotherapy participated in this pilot-study. Markers (1-6 per patient) were implanted EUS- guided prior to radiotherapy planning CT (CT<sub>p</sub>) with additional 4DCT, and the patients received IGRT (23-33 fractions, 41.4-66.0 Gy) with daily cone beam computed tomography (CBCT, n=302) and/or orthogonal planar images (2D/2D, n=61) and a repeated CT- and 4DCT the last treatment week. Marker presence, planning target volume (PTV) coverage, centroid position and extreme positions on CBCT were recorded per patient and -treatment fraction. Inter- and intra-fractional motion were characterized, in all patients and grouped according to marker location.

**Results**

At treatment end, 92% of markers visible at CT<sub>p</sub> were still present. The PTV accounted for marker variation in >95% of treatment fractions for 92% of the patients. Overall 3D inter-fractional variation was >1cm in 23% and >0.5cm in 58% of the markers. Median (IQR) intra-fractional motion of all markers was 1.2 cm (0.4 cm) in the longitudinal, 0.11 cm (0.51 cm) in the ventral and 0.0 cm (0.13 cm) in the lateral direction.

**Conclusion**

The use of the investigated fiducial marker may be beneficial for IGRT in esophageal cancer as the marker loss during radiotherapy was limited. Inter- and intra-fractional variation was substantial with largest motion in the longitudinal direction and more pronounced in the caudal part of esophagus.

**PO-1115 The UK lung SABR survey on behalf of the Advanced Radiotherapy Technologies Network**

S. Brown<sup>1</sup>, M. Beasley<sup>2</sup>, H. McNair<sup>3</sup>, C. Faivre-Finn<sup>4</sup>, K. Franks<sup>2</sup>, L. Murray<sup>5</sup>, M. Van Herk<sup>4</sup>, A. Henry<sup>5</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom ; <sup>2</sup>Leeds Cancer Centre, Radiotherapy Research Group, Leeds, United Kingdom ; <sup>3</sup>The Institute of Cancer Research and Royal Marsden Hospital, Division of Radiotherapy and Imaging, Sutton, United Kingdom ; <sup>4</sup>University of Manchester and The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom ; <sup>5</sup>University of Leeds- Leeds Institute of Cancer and Pathology and Leeds Cancer Centre, Radiotherapy Research Group, Leeds, United Kingdom

**Purpose or Objective**

SABR has become the standard of care for patients with medically inoperable early stage non-small cell lung cancer or for patients who decline surgical resection. In the UK a limited number of centres are commissioned by the NHS to provide this treatment. The delivery of large

doses of radiotherapy is potentially associated with serious toxicity. Therefore strict image guidance protocols are required to ensure its safe delivery.

To build a comprehensive national picture of SABR provision, and the barriers faced by centres attempting to implement SABR, a survey was conducted on behalf of the UK Advanced Radiotherapy Technologies Network (ART-NET). In particular this focused on image guidance and the management of anatomical changes.

The aim was to identify any variation in current practice and areas where guidance may require updating. This work will inform the development of adaptive protocols for novel treatment platforms.

**Material and Methods**

An online survey was created and piloted amongst ART-NET member centres. This was then disseminated electronically to radiotherapy service managers in all UK NHS centres.

**Results**

100% of NHS centres responded to the survey. 36/62 UK centres deliver lung SABR. Of these, 6 English centres provide SABR despite not being commissioned to do so. 56% of SABR centres treat 20-100 patients per year, and 19% treat fewer than 20 patients per year. Lack of national commissioning was cited as the most common barrier to implementation by non-SABR centres (86%). These centres will refer appropriate patients to a SABR centre, although 62% also provide conventionally fractionated radiotherapy as a local alternative.

Most variation was seen in the frequency of cone-beam computed-tomography (CBCT); 8 different CBCT workflows were reported. Only 52% of centres have a protocol for addressing the impact of anatomical changes. Overall, 67% of centres planning to develop a service in the next year believe image guidance protocols require updating. The most commonly suggested topic was the frequency of image guidance including the necessity of pre or post-treatment scans.

**Conclusion**

Eligible patients may face difficulty accessing SABR due to a lack of commissioning in some centres. This issue should be investigated further to ensure there is equitable access to lung SABR in the UK. There is a need to update existing guidelines, as evidenced by the heterogeneity in image guidance practice across the UK. These should also incorporate advice on the management of anatomical changes and will inform future adaptive IGRT protocols on novel radiotherapy platforms such as the MR-linac.

**PO-1116 Set-up in locoregional breast irradiation: reduced margins for subclavicular and axillar lymph nodes.**

M. Admiraal<sup>1</sup>, S. Hoek<sup>1</sup>

<sup>1</sup>VU University Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

**Purpose or Objective**

For locoregional irradiation of the breast, tangential fields to the breast were combined with VMAT to achieve steep dose falloff around the lymph node levels I-IV. After introduction of this new planning technique, setup instructions were adapted with additional focus on these lymph node regions. This allowed for reduction of the CTV-PTV margin in the lymph nodes, from 8mm to 5mm in all directions.

**Material and Methods**

21 breast cancer patients with 47 sessions were included in this study. Treatment plans consisted of tangential, ventrally open fields which delivered most of the dose to the breast and VMAT which delivered most of the dose to the nodal area.

Setup was performed based on 2 orthogonal 2D kV images. Instructions for this setup defined a maximum misalignment of 5mm in the bony anatomy in the lymph node regions, and 8mm in the humeral head and the

ventral bony anatomy. Online, CBCT's and tangential MV images were acquired for verification of adequate positioning of the lymph node region and breast tissue. Offline, the CBCT's and MV portal images were used to evaluate the misalignment in lymph node regions, thoracic wall, breast and humeral head after the online match. Accurate quantification of these misalignments was obtained by performing separate CBCT matches offline, focusing on each of these structures individually.

#### Results

For lymph nodes level I-II, 2D-2D kV setup lead to adequately positioning in all sessions. Levels III-IV were adequately positioned in 46 out of 47 sessions. In only one session setup lead to a 6mm misalignment in vertical direction which was larger than the CTV-PTV margin. Average misalignments were 0.2, 0.19 and 0.13 in vertical, longitudinal and lateral directions respectively (fig.1) Verification with CBCT and tangential MV images shows that misalignment of the thoracic wall was less than 8mm in all sessions. The breast contour deviated more than 8mm in 5 out of 47 sessions. This was related to seroma change. With the tangential field approach, breast contour deviations had a minimal effect on the breast dose coverage. Misalignment of the humeral head exceeded the limit of 8mm in 5 of the 47 sessions, but none resulted misalignment of the lymph nodes larger than 5mm.

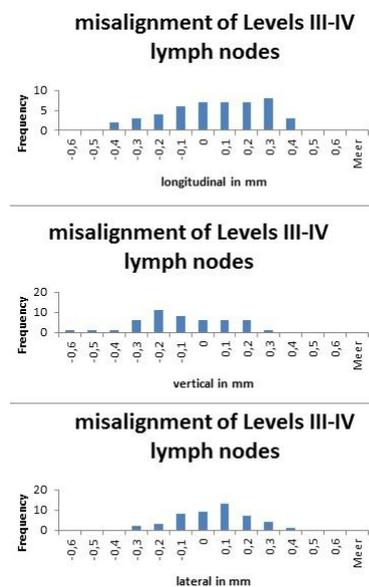

Fig 1. Misalignment of lymphnodes level III-IV after 2D/2D kV setup with additional setup instructions.

#### Conclusion

For locoregional breast irradiation, this study has shown that 2D-2D kV setup with additional setup instructions results in adequate positioning of the lymph nodes having a 5 mm CTV-PTV margin. Accurate positioning of bony anatomy in the lymph node region and the humeral head remains important, and misalignments of more than 5mm resp 8mm should result in repositioning or CBCT verification of the lymph nodes.

#### PO-1117 Dosimetric effect of parotid glands geometric modifications during the IMRT for NPC

W. Mnejja<sup>1</sup>, H. Daoud<sup>1</sup>, L. Farhat<sup>1</sup>, N. Fourati<sup>1</sup>, T. Sahnoun<sup>1</sup>, W. Siala<sup>1</sup>, J. Daoud<sup>1</sup>

<sup>1</sup>Hbib Bourguiba Hospital, radiotherapy, sfax, Tunisia

#### Purpose or Objective

During the treatment of nasopharyngeal carcinoma (NPC), the use of intensity modulated radiotherapy (IMRT) showed positive therapeutic effects on irradiated patients by reducing xerostomia. We proposed in this work to evaluate the dosimetric impact of parotids anatomic variation during the IMRT for the NPC.

#### Material and Methods

Patients with NPC receiving IMRT treatment were included. For each patient, a second dosimetric CT was performed at a dose of 38 Gy, which was fused with the initial planning dosimetric CT. Manual contouring of the parotids was performed on the second scanner. We recorded the volume and the isocenter position in the three planes of space (X, Y, Z), and the average dose at parotids (right and left) on both scanners. We calculated the volume percent change. Statistical mean differences were calculated using Wilcoxon signed-rank' test and SPSS 20 software was used for data analysis.

#### Results

Twenty consecutive patients were enrolled in this study. We observed a significant decrease of right parotid volume of 28 % [5%-48%] with  $p = 10^{-3}$ , and a decrease of 27.9% for the left parotid [0-54%] with  $p = 10^{-3}$ . Parotid migration averages in the medial direction (X) were of 2.1 mm [-2,3\_15](right) and 2,2 mm [-60\_2,8] (left). Moreover, It was only 0.9 mm (right) and 0.2 mm (left) in the postero-anterior direction (Y) , also in cranio-caudal direction with 0.9 mm (right) and 0.4 mm (left). Regarding dosimetry results, we observed an increase in the mean dose. This increase was significant for the left parotid with an average value of 3.23 Gy more ( $p = 0.02$ ), and no significant for the right parotid with an average value of 0.82 Gy more ( $p = 0.35$ ).

#### Conclusion

The moving of the parotid after nodal tumor falling, and also the decrease of its volume cause the migration of parotid to the higher dose areas. This can explain the dose increase noted on the scanner during treatment. It seems that a careful adaptation of the treatment plan should be considered during therapy.

#### PO-1118 Verification of new respiratory gating device for clinical use in proton therapy wobbler method

I. Maeshima<sup>1</sup>

<sup>1</sup>Suwa Red Cross Hospital, Radiation Therapy Center, Fujimi, Japan

#### Purpose or Objective

In recent years, a new respiratory synchronizer (AbchesET) has been developed that allows the patient's own respiratory control to be more easily performed. By using AbchesET, respiratory control by the patient himself can be easily and accurately reproduced by directly seeing indication of rotation angle of pointer displayed on a small monitor. In this study, we compared the conventional respiration synchronizer (ANZAI) as a comparative subject and made various investigations on the usefulness of respiratory synchronous irradiation of proton beam wobbler method using a new respiratory synchronizer (AbchesET).

#### Material and Methods

Verification of proton beam characteristics and delay time at respiratory synchronized irradiation was performed for each of ANZAI and AbchesET. With regard to verification of beam characteristics, verification of synchronism with no synchronization (stopped state) (Gate width: 12%, 25% when maximum expiration is 0%) is performed using a moving body phantom and a two dimensional detector for a rectangular radiation field. We evaluated each beam characteristics (Flatness, Symmetry, Penumbra, Field size and Dose) of the irradiation field. We also evaluated the dose distribution by gamma analysis. The breathing waveform of the moving body phantom was evaluated with respect to three types of respiration rates (Breath per

Minute, BPM), two kinds of amplitudes ( $\pm 1$  cm,  $\pm 2$  cm) with reference to the sinusoidal wave, and the breathing waveform of the respiratory synchronizer. The delay time from the gating signal until the proton beam is generated and cut off was measured by our own measurement system.

#### Results

Flatness and Symmetry were confirmed to be within  $\pm 2\%$  in all conditions, within the range of  $\pm 3\%$  with respect to the field size and Dose, and clinically no problem. On the other hand, with regard to Penumbra, BPM tends to increase as BPM gets bigger, especially with amplitude of  $\pm 2$  cm, it was necessary to consider both AbchesET and ANZAI for clinical use. Regarding the evaluation of the dose distribution, the gamma pass rate tends to decrease as the Gate width increases and as BPM increases, particularly when the amplitude is  $\pm 2$  cm, it shows a remarkable drop in the pass rate. Regarding measurement of delay time, the delay time of AbchesET is  $36.7 \pm 27.2$  msec,  $46.8 \pm 28.7$  msec with beam ON and OFF, the delay time of ANZAI is  $48.6 \pm 24.8$  msec,  $57.2 \pm 25.2$  msec with beam ON and OFF respectively there were. In beam ON and OFF, the delay time tends to be less for AbchesET, and clinical use is considered to be no problem.

#### Conclusion

Although respiratory synchronous irradiation of proton beam wobbler method using AbchesET has some use restrictions, it was confirmed that it can be sufficiently used clinically. We conclude that respiration synchronized irradiation of proton beam wobbler method with higher accuracy is achieved by using AbchesET.

#### PO-1119 Strategies to maintain bladder and rectum volumes do not reduce the GTV movement for rectal cancer rt

N. Espinosa<sup>1</sup>, A. Coral<sup>1</sup>, M. Lizondo<sup>2</sup>, J. Balart<sup>3</sup>, S. Bermejo<sup>3</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain ; <sup>2</sup>Institut de Recerca Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain ; <sup>3</sup>Hospital de la Santa Creu i Sant Pau, Servei d'Oncologia Radioteràpica, Barcelona, Spain

#### Purpose or Objective

The aim of our study is to determine whether the variability of rectal volume diminishes when bladder and rectum filling preparation instructions are followed by patients who undertake preoperative rectal IMRT.

#### Material and Methods

Thirty patients that received preoperative IMRT (45 Gy in 5 weeks, 1.8 Gy/day) for a rectal cancer between May 2016 and May 2017 were evaluated. Patients were treated in supine position. Fifteen patients without (group A) and 15 with bladder and rectum filling preparation instructions (group B) were evaluated. Group B patients were required to urinate and drink 330 mL of water 1 hour before planning CT and each fractional treatment. In addition, they were required to empty the rectum just before planning and treatment with probiotics help. Radiation was delivered using a 2100CD Clinac linear accelerator equipped with on-board Imager System (Varian). A no-action level offline setup protocol was employed by taking and averaging first 5r images and at least a cone beam CT (CBCT) was weekly undertaken. Two staff members delineated the GTV on each slice of CBCT (weekly\_GTV). As well, CBCTs were co-registered (Eclipse, Varian) with its respective planning CT to determine whether any weekly\_GTV was 1.5 cm or more beyond the planningGTV according to the Figure 1. The results were reported as percentages (%), and the chi-square test (SPSS) was used to examine differences between groups.

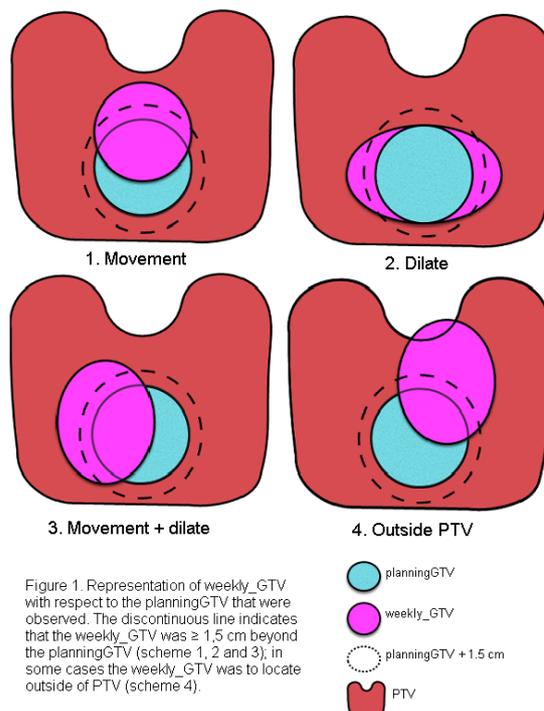

Figure 1. Representation of weekly\_GTV with respect to the planningGTV that were observed. The discontinuous line indicates that the weekly\_GTV was  $\geq 1.5$  cm beyond the planningGTV (scheme 1, 2 and 3); in some cases the weekly\_GTV was to locate outside of PTV (scheme 4).

#### Results

In total, 72 CBCT per group were analyzed. It was found that the weekly\_GTVs meet the criteria of the Figure 1 in 23 CBCTs (31.9%) of the patients in the group A and in 19 CBCTs (26.4%) of the group B; p-value = 0,58. Per each patient, weekly\_GTVs were found  $\geq 1.5$  cm beyond planningGTV in 28% times in the group A and 22.7% in the B; p-value = 0.39 (Figure 2). However, variations in the group B were lower than group A in which there were patients that every weekly\_GTV were  $\geq 1.5$  cm beyond, whereas this scenery was not found in group B (Figure 2). Weekly\_GTVs meet the criteria 4 of the Figure 1, in which GTV bring outside PTV, in 9 CBCTs (12.5%) in the group A and in 6 (8.3%) in B.

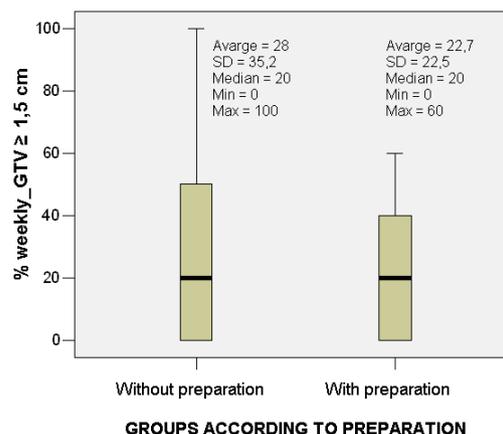

Figure 2. Percentage of the weekly\_GTV that was  $\geq 1.5$  cm of the planningGTV for each patient in particular according to the preparation. The differences are not significant (p=0,39)

### Conclusion

These findings suggest that the strategies used to keep bladder and rectum volumes constant in these cohort of patients were useless to prevent GTV movement, sometimes beyond the PTV. This conclusion could be translated to the CTV. We highly recommended complementing these strategies with daily image guided IMRT. Our results support the notion of having plan libraries for preoperative rectal IMRT to adapt anatomic variations.

### PO-1120 Deformable-image-registration-based Adaptive Radiotherapy on Halcyon's MV CBCT system

Y. Huang<sup>1</sup>, H. Qiaoqiao<sup>1</sup>, W. Hao<sup>1</sup>, Z. Yibao<sup>1</sup>

<sup>1</sup>Peking University Cancer Hospital & Institute, Department of Radiation Oncology, Beijing, China

### Purpose or Objective

Imaging dose integration as enabled by the MV CBCT system of Varian's new Linac Halcyon can avoid extra dose in image guidance as encountered by routine adaptive therapy(ART). To investigate benefits of ART on the new system, this work performed deformable image registration algorithm to reconstruct daily dose, validated the dosimetric accuracy and indicated appropriate time of replanning.

### Material and Methods

A historical Nasopharyngeal Cancer patient treated by 33 fractions of one full-arc VMAT on Halcyon was studied. CT rescanning and replanning was conducted after 18<sup>th</sup> fraction due to macroscopic tumor shrinkage. Planning CT(pCT) and replanning CT(rCT) along with pre-treatment MV CBCT images were retrieved from Varian's ARIA system. Reconstructed dose of second plan (Ddir) based on pCT deformed to MV CBCT at 21<sup>st</sup> fraction was compared with original dose of second plan(Dgold) through a 3mm/3%/10%threshold global gamma analysis. With the DIR algorithm provided by Velocity AI, pCT was registered to MV CBCT at each fraction and produced a series of reconstructed dose of initial plan (rDp), which were further accumulated and compared with original dose of initial plan (Dp) scaled with fraction number. Taking replanning into account, reconstructed dose(rDr) of second plan based on rCT deformed to MV CBCT was used in place of rDp in the last 13 fractions and further accumulated with rDp in the first 20 fractions, which was compared with accumulation of second plan's original dose (Dr) in the last 13 fractions with Dp in the first 20 fractions. The accumulated dose comparison was restricted within the FOV of MV CBCT.

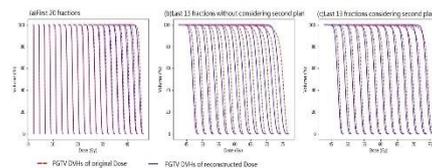

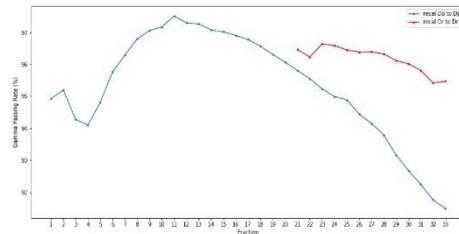

### Results

91.01% of the dose grid points fall within 3mm/3% criteria of 10% threshold global gamma analysis with Ddir as evaluation and Dgold as reference, with over half of the dose grid points having a gamma index below 0.2. Using accumulated Dp as reference and accumulated rDp as evaluated dose distribution, gamma passing rates gradually increase from 95% to 97% due to averaging of random dose deviation, but decrease continuously after one third of the course, down to less than 92% in the end, indicating when anatomical variation began to take the major effect (Fig 1). In comparison, using Dr accumulated with Dp as reference and rDr accumulated with rDp as evaluated dose distribution, gamma passing rates maintain steadily above 95% (Fig1). In accordance, planned and recalculated DVHs of PGTV are largely overlapped in the first 20 fractions(Fig2(a)) but the disparity between DVHs gradually increase without replanning in the last 13 fractions (Fig2(b)), while high DVHs similarity is maintained when considering replanning in the last 13 fractions (Fig2(c)).

### Conclusion

This study validates the dosimetric feasibility of dose reconstruction based on CT-to-MV CBCT deformable

registration as conducted on the MV CBCT imaging modality provided by Halcyon that enforces image guidance at each fraction and takes imaging dose into account, providing guidance on time to replan.

### PO-1121 Characterizing Dosimetric Uncertainties to Tumour Volume and Organs at Risk in Rectal Cancer

O. Babatunde<sup>1</sup>, S. O'Cathail<sup>1</sup>, R. Cooke<sup>1</sup>, B. George<sup>1</sup>, M. Robinson<sup>1</sup>, F. Van den Heuvel<sup>1</sup>, M. Hawkins<sup>1</sup>

<sup>1</sup>University of Oxford, Department of Oncology, Oxford, United Kingdom

### Purpose or Objective

Avoiding adverse toxicities in rectal cancer is dependent on a high degree of accuracy and precision in treatment. However, the daily uncertainty with position and volume of the Organs at Risk (OAR) can result in an increased dose to these organs. In this study, we sought to characterize the inter-fractional uncertainties in target volume and OAR, and identify factors that might predict patients most likely to benefit from online plan adaptation.

### Material and Methods

10 patients treated with neoadjuvant intensity modulating radiation therapy (IMRT) for locally advanced rectal cancer were retrospectively analysed. All patients received 45 Gy/25 fractions with simultaneous integrated boost (SIB) to GTV of 52 Gy total five times a week. The presence or absence of rectal gas was subjectively assessed in each patient's planning computed tomography (CT) and treatment cone beam CT (CBCT) images. Bladder volumes were re-contoured for all patients and mean bladder dose was calculated. Increased small bowel dose was assessed by a Yes/No criteria: Increased small bowel volume in the greater than 5Gy isodose region than was planned and/or increased dose to the small bowel of greater than 5Gy.

### Results

30% of patients had rectal gas changes in greater than 50% of their CBCT images. Rectal gas changes were as common in the first week of treatment as during the remaining treatment course and no clear time trend was seen (36% versus 32.43%). Relative change in bladder volume varied extensively between and within patients. Average planning bladder volume was 399.51 ml (SD ± 273.93) versus 254.95 (SD ± 112.49) for the treatment CBCT bladder volume. No significant difference was seen in bladder volumes over the course of treatment (t statistic: -0.382; DF: 85; p value: 0.410), but 74% of treatment volumes were smaller overall for the duration of treatment in comparison to the initial planning bladder volumes. The mean bladder dose was correlated with the relative change in bladder volume (Regression coefficient: -0.68; Pearson coefficient: -0.67; p value < 0.0001). 64% of treatment scans met criteria for increased bowel

dose. A relative decrease in bladder volume was predictive of meeting criteria for increased dose to the small bowel ( $\beta$  estimate: -4.7; Odds Ratio: 0.0091;  $p$  value < 0.0001).

#### Conclusion

Volume variability in the bladder suggests that the planned dose is not equivalent to the dose delivered to the OAR for the majority of rectal cancer patients. Early changes in bladder and rectal gas volume do not predict for late changes. Large decreases in bladder volume result in a dose increase to the bladder and small bowel dose metrics, which are in the clinically significant range.

#### PO-1122 Assessment of bladder volume and urinary symptoms for patients undergoing prostate radiotherapy.

E.P.P. Pang<sup>1</sup>, M. Lian Chek Wang<sup>1,2</sup>, J.K.L. Tuan<sup>1,2</sup>, T.W.K. Tan<sup>1,2</sup>, M.L.K. Chua<sup>1,2</sup>, E.T. Chua<sup>1,2</sup>, W.S. Looi<sup>1</sup>, W.L. Nei<sup>1</sup>, A. Hussain<sup>1</sup>

<sup>1</sup>National Cancer Centre Singapore, Division of Radiation Oncology, Singapore, Singapore; <sup>2</sup>Duke-NUS, Graduate Medical School, Singapore, Singapore

#### Purpose or Objective

Patients undergoing prostate radiotherapy have been routinely instructed to obtain a full bladder. However, the achieved bladder volumes during treatment were often sub-optimal due to persistent issues of incontinence, frequency and side effects of treatment. Some of these patients undergoing radiotherapy to the prostate alone would have limited radiation dose to the bowels by default. This study investigated the achieved mean bladder volume in relations to pre-existing urinary functions and side effects after prostate (+/- seminal vesicles) volumetric modulated arc therapy (VMAT).

#### Material and Methods

20 patients undergoing prostate (+/- seminal vesicles) VMAT (74Gy, 37# over 7.5 weeks) were recruited in a prospective observational study to evaluate the impact of their urinary functions on bladder volume. 736 cone-beam computed tomography (CBCT) scans were used to analyse the overall bladder consistency. All the patients were routinely instructed to obtain a full bladder (150cm<sup>3</sup> as threshold) by voiding, followed by drinking 400-600ml of water and wait 30-60 minutes before CT simulation and daily treatment. No specific rectal preparations were given but all the patients were encouraged to empty their bowels before each procedure. Treatment planning constraints to the bladder ( $V_{70}$ ,  $V_{65}$ ,  $V_{60}$ ) were routinely evaluated based on the Quantitative Analyses of Normal Tissue Effects in the Clinic (QUANTEC) guidelines and approved for treatment. Spearman correlation test was conducted to analyse the mean bladder volume of each patient in relations to their respective urinary functions that were assessed using the Common Terminology Criteria for Adverse Events (CTCAE, version 3) and International Prostate Symptom Score (IPSS) at three timepoints (pre-treatment, mid-treatment and post-treatment). A further Mann-Whitney U test was performed to analyse pre-treatment urinary functions between the patients with mean bladder volume <150cm<sup>3</sup> versus  $\geq$ 150cm<sup>3</sup>.

#### Results

The mean (range) population bladder volume was 152.2cm<sup>3</sup> (79.6cm<sup>3</sup>-336.2cm<sup>3</sup>). There was a moderate positive correlation between mean bladder volume with incomplete bladder emptying symptoms during mid-treatment ( $r_s=0.498$ ,  $p=0.025$ ) and post-treatment urinary straining ( $r_s=0.491$ ,  $p=0.028$ ) respectively for the IPSS sub-scores. Patients with pre-treatment incontinence tend to

achieve mean bladder volume <150cm<sup>3</sup> (n=11) versus those without  $\geq$ 150cm<sup>3</sup> (n=9) ( $p=0.023$ ). However, none of the CTCAE-assessed radiation-induced urinary side effects had showed significant correlation with the mean bladder volume.

#### Conclusion

This study suggests a further review on patient selection to be instructed with full bladder protocol as those with pre-existing urinary incontinence tend to sustain a smaller mean bladder volume during treatment. In addition, patients with larger bladder volumes sustained throughout the treatment may experience post-treatment urinary straining compared to those with smaller bladder volumes.

#### PO-1123 Could patient-related outcome measures help us in radiotherapy review clinics?

M. Sivanandan<sup>1</sup>, C. Sharma<sup>1</sup>, J. Christian<sup>1</sup>

<sup>1</sup>Nottingham University Hospitals NHS Trust, Oncology and Radiotherapy, Nottingham, United Kingdom

#### Purpose or Objective

Common Terminology Criteria for Adverse Events (CTCAE) are widely used in radiotherapy (RT) review clinics to assess severity of acute toxicities. No clinical intervention is generally indicated in those with no toxicity (grade 0) or mild toxicity (grade 1) in contrast to those with higher grades of toxicity.

Toxicity symptom monitoring is an area in which patient self-reporting could be used to inform clinical interventions: If those with no or mild toxicity from RT could be identified through appropriate patient-related outcome measures (PROMs), this cohort could potentially be spared a face-to-face review in a RT clinic whereas those with greater toxicity could be identified for clinical review.

The aim of our retrospective analysis was to ascertain the frequency of different acute toxicity grades for patients on RT for breast and prostate cancer, which represent the highest volume tumour sites in our tertiary centre, to inform the usefulness of PROM collection.

#### Material and Methods

The trust's RT database was used to identify adjuvant breast RT and radical prostate RT patients between April and May 2018 inclusive. The RT clinic annotations for those patients were analysed and appropriate CTCAE toxicity grades were extracted for appropriate adverse events relevant for tumour site.

#### Results

116 breast and 91 prostate RT patients were identified. In the breast cohort, 89 patients suffered grade 0/1 toxicity at worst, representing 76.7% of the cohort. In the prostate cohort, 52 patients suffered grade 0/1 toxicity at worst, representing 57.1% of the cohort. No grade 3/4 toxicity was seen in either group. The most common grade 1 toxicity in the breast patients was skin toxicity (44.7%) and in prostate patients was urinary frequency (45.6%). Grade 2 toxicity in the breast cohort was largely skin toxicity (76.7%) and in the prostate group was principally urinary frequency (44.4%). In the prostate cohort, grade 2 toxicity was more commonly seen in those that received nodal RT versus those that did not (76.9% vs.37.2%), reaching statistical significance ( $p = 0.01$ ); in the breast cohort, grade 2 toxicity was more common in those that received a boost versus no boost (35.3% vs. 21.2%) but not reaching statistical significance ( $p=0.20$ ). Both the prostate nodal and breast boost RT groups represented a small proportion of their overall tumour-site groups (14.3% and 14.7% respectively).

#### Conclusion

A large proportion of patients on adjuvant breast and radical prostate RT suffer minimal acute toxicity with potential subgroups more likely to suffer toxicity. If appropriate PROM tools were developed to reliably identify these groups, both those who could safely avoid attending a clinic appointment in person and those who

require a face-to-face review could be identified. This serves as a proof of concept for the work of the digital technology team in our department and we are developing a pilot programme incorporating electronic PROM measures in RT review clinics to explore this in further detail.

**PO-1124 A pilot study: Utilization of PROMs in hypofractionated radiotherapy for localized prostate cancer**  
K. Crowther<sup>1</sup>, P. Shiels<sup>1</sup>, A. Cole<sup>1,2</sup>, P. Shepherd<sup>3</sup>, S. Jain<sup>1,2</sup>, D. Mitchell<sup>1</sup>

<sup>1</sup>Belfast Health and Social Care Trust, Cancer Centre-Radiotherapy, Belfast, United Kingdom ; <sup>2</sup>Queen's University, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom ; <sup>3</sup>Ulster University, School of Health Sciences, Belfast, United Kingdom

**Purpose or Objective**

Patient Reported Outcome Measures (PROMS) are a useful metric in evidence-based clinical care and translational research. Recording treatment toxicities and Quality of Life (QoL) scores can provide useful information in counseling future patients to aid decision-making and inform consent. Real time PROMS have the ability to improve patient care and guide changes to therapy. Curative treatment options for prostate cancer (PCa) include prostatectomy, brachytherapy, external beam radiotherapy (EBRT) and combination therapy utilizing EBRT followed by High Dose Rate Brachytherapy (HDR-BT). There is limited published evidence comparing PROMS for modern day radiotherapy techniques. This prospective study tested the feasibility of collecting multiple PROMS from PCa patients comparing HDR-BT combined with hypofractionated EBRT (hEBRT) (Combination Group) and hEBRT alone (Monotherapy Group).

**Material and Methods**

Between June and August 2017, 20 men with localised PCa with confirmed treatment regimen, consented to participate. Ten patients received combination therapy (37.5Gy/15f + 15Gy HDR implant) and ten received hEBRT (60Gy/20f). Urinary, bowel, sexual, hormone problems and QoL were examined before, during and after treatment, using validated PROMS questionnaire methods and analysed as specified by developers. The results presented using descriptive statistics including the Mann-Whitney U test to exam statistical significance.

**Results**

All participants completed treatment without interruption with 100% response rate to PROMS. SF-12 assessed QoL and results are summarized in Figure 1.

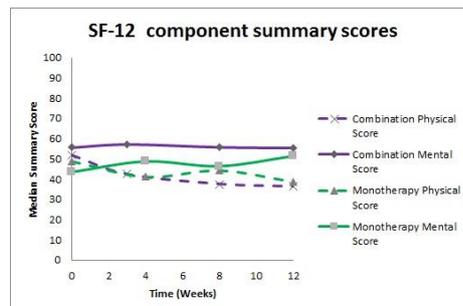

Figure 1: Summary of SF-12 results for Physical and Mental Component Summary Scores

International Index of Erectile Function (IIEF-5), International Prostate Symptom Score (IPSS) and Expanded Prostate Index Composite-26 (EPIC-26) assessed treatment-related symptoms. IIEF-5 demonstrated severe erectile dysfunction (ED) occurrence at baseline at 20% this increased to 80% at Week 12 within both groups. All men reported some ED symptoms at Week 12. IPSS results

showed a significant difference at the end of hEBRT; Combination (M=12, SD=4.58) and Monotherapy (M=20.5, SD=9.97); p=0.041. EPIC-26 results are presented in Table 1.

Time point/ Measure		Urinary Summary Score				Bowel Summary Score			
		MP	SD	MID**	P	MP	SD	MID**	P
Baseline	Combination Group	90.28	8.08	4.04	0.43	100	7.45	3.72	0.97
	Monotherapy Group	90.28	18.83	9.32		100	6.05	3.03

	Monotherapy Group	2.09	9.29			75.00	24.55		
12 weeks	Combination Group	17.34	13.82		1.0	85.00	22.81		0.79
	Monotherapy Group	15.28	11.7			80.00	18.33		

\*Median; \*\* minimum important difference (MID) = 0.5 SD

Table 1: Summary of EPIC-26 results for Combination and Monotherapy groups

Final fraction of hEBRT bowel summary demonstrated a clinically relevant difference and statistically significant difference; Combination (M=85.42, SD=18.01) and Monotherapy (M=64.59, SD=25.89); p=0.03 this remained at Week 12 (p=0.005).

**Conclusion**

This small study showed excellent patient compliance with completion of PROMS. Both treatment groups tolerated treatment well and there was minimal impact on QoL. In relation to treatment-related symptoms, the monotherapy group reported a higher incidence of bowel toxicity compared to the combination group. The feasibility of collecting multiple PROMS is evidenced in this study, streamlining of these tools into integrated technology applications and real time PROMS measurement has the ability to benefit patients and guide clinicians in adapting therapies based on individual need.

**PO-1125 Helical Tomotherapy for patients with pectus excavatum treated for early stage breast cancer.**

A. Alexandre<sup>1</sup>, P. Dominique<sup>1</sup>, F. Alain<sup>1</sup>, K. Youlia M.<sup>1</sup>

<sup>1</sup>Institut Curie Ensemble Hospitalier, Radiothérapie, Paris cedex 05, France

**Purpose or Objective**

To evaluate our experience with Helical Tomotherapy (HT) for patients with pectus excavatum (PE) who received adjuvant radiotherapy (RT) for early stage breast cancer (BC).

**Material and Methods**

A retrospective study of all patients with PE treated by intensity modulated radiation therapy (IMRT) using HT between 2009 and 2015 was done. All patients received breast +/- boost or chest wall irradiation and most of them received lymph nodes (LN) irradiation. Dose constraints for organs at risk (OAR) were defined using optimization scale developed in our Department. Evaluation of early and late toxicity was done using Common Terminology Criteria for Adverse Events v.4.0 (CTCAE).

**Results**

Between 2009 and 2015, 179 patients were treated with adjuvant HT when conventional radiation therapy techniques cannot ensure an optimal dose distribution. Among them, 40 patients (7.8%) were presented with PE and were included in this study. Median age was 53 years (range 30-75). Twenty-nine patients (72.5%) received

adjuvant or neoadjuvant anthracycline and taxans based chemotherapy and 28 (70%) received adjuvant hormonal treatment. Thirty-six patients were treated with breast conserving surgery and 4 by mastectomy. All patients were treated with normofractionated radiotherapy with a dose of 50Gy to breast or chest wall and LN if indicated, and a dose of 63Gy to the boost volume in case of indication. There were 15 (45%) left side and 22 (55%) right side breast cancers. Median follow-up was 47 months. Among them, 27 patients (67.5%) received irradiation to regional LN including internal mammary chain (IMC). Every patient received optimal CTV and PTV coverage of 96-98%. The mean heart dose was: 8Gy (3.5-10.8). The mean lung V20Gy was 20.8% (7.2-29.2) to ipsilateral lung. The contralateral breast received mean dose of 4.7Gy (2.5-6.1). The HT was well tolerated with grade 1 (67.5%) and 2 (30%) acute skin reactions and only 1 (2.5%) grade 1 acute esophagitis. Concerning late toxicities, we observed only 4 cases (10%) with grade 1 fibrosis. No cardiac toxicity was observed. At last follow-up, there was only 1 local recurrence, no regional LN recurrence and 3 (7.5%) metastatic progressions.

#### Conclusion

HT is useful for this very much selected group of PE breast cancer patients for whom the conventional radiation therapy techniques cannot ensure an optimal homogeneous dose distribution or cannot respect the constraints to the OAR. Longer follow-up is necessary to confirm and validate these results in this population of patients.

#### PO-1126 Caring for Patients with Dementia Undergoing Radiation Therapy - A National Audit

A. O'Donovan<sup>1</sup>, J. Flood<sup>1</sup>

<sup>1</sup>Applied Radiation Therapy ARTT research group, Discipline of Radiation Therapy- Trinity College Dublin, Dublin, Ireland

#### Purpose or Objective

The number of people with dementia is increasing in conjunction with the rapid growth of the older aged population in many countries worldwide. More people with dementia will also be diagnosed with cancer and may require radiotherapy at some stage of their disease trajectory.

It is therefore necessary that care is taken to ensure that the Radiation Therapy (RT) department practice environment meets criteria for good practice in dealing with patients with dementia, in order to limit distress whenever practically possible.

The primary aim of this national audit was to investigate Irish radiation therapy departments, with regard to dementia care in the areas of the department environment, clinical practice and staff training.

#### Material and Methods

The audit was conducted according to recommendations for best practice and universal design, particularly those of the Society and College of Radiographers (UK), the dementia friendly environment/dwelling guidelines and the King's Fund. The audit took place between September and November 2017.

The environmental assessment consisted of six standards encompassing orientation, mobility, security, continence, wellbeing, and meaningful interaction. Clinical practice consisted of four standards encompassed by patient rights, informed consent, holistic care, and patient autonomy. Staff education and training was divided into the standards of training and support.

#### Results

Nine RT departments were assessed during the course of this audit, representing a 75% response rate. The national mean level of compliance with current best practice was 67%, with overall compliance to the recommendations for environmental layout (65%), clinical practice (67%) and staff training (75%). Only the latter achieved the target level of compliance.

#### Conclusion

Improvement of areas such as environmental layouts, dementia-focused protocols and education, as well as establishing links with other healthcare professionals and departments, will enable centres to meet all current standards of best practice in the future.

#### PO-1127 The development and initial evaluation of a simulated clinical radiotherapy training centre.

S. Ketterer<sup>1</sup>, P. Bridge<sup>1</sup>

<sup>1</sup>University of Liverpool, Department of Radiotherapy-School of Health Sciences, Liverpool, United Kingdom

#### Purpose or Objective

While the radiotherapy clinical environment is a source of rich learning for therapeutic radiography students, workload pressure on clinical departments can impact on implementation and support of placements as well as restrict learning opportunities. Although evidence supports use of simulation for health profession training, much of this is based on students' self-assessment of enjoyment and perceived learning. Simulation activities are also generally restricted to specific aspects of the role and rarely provide a realistic representation of the daily workload. This study aimed to determine the feasibility of developing and evaluating an integrated simulation placement capable of simulating a real radiotherapy department. The project also aimed to scope the potential to reduce the clinical training burden by directly replacing some clinical weeks with simulation.

#### Material and Methods

The project commenced with a scoping exercise that identified the range of activities, tasks and skills development expected from a first year student on their clinical placement. This was then mapped to existing and potential simulation equipment and activities. Realism was provided by "branding" of the facility as a virtual department, while actors and service users provided a range of patients for students to engage with. Students were randomised to simulation or clinical placement and then their assessment scores following placement were compared.

#### Results

A two-week integrated simulation placement was successfully developed and implemented within an academic department. The core simulation workspaces comprised a couch with alignment lasers, mould room water-bath, computed tomography scanner, virtual linear accelerator, radiotherapy planning consoles and virtual reality headsets. The placement was populated with academic and clinical staff, with actors and service users providing "patient" contact. Initial evaluation indicated that students valued the structured approach of the placement and the opportunity to gain familiarity with techniques in a safe unpressured environment. The ability to learn from mistakes was perceived to be particularly valuable. Comparison of assessment scores demonstrated equivalence of learning for the simulated placement. The integrated and prospectively designed learning experience of the simulation placement is targeted to the specific learning outcomes of the placement and in some cases led to improved learning compared to clinical placement.

#### Conclusion

Results from this study indicate that an integrated radiotherapy simulation placement can be undertaken successfully in a dedicated academic facility. The placement can be used to prepare students for more

efficient clinical placement and reduce overall clinical placement time. In turn, this can increase student throughput and capacity.

#### PO-1128 Clinical implementation of deformable image registration (DIR)

C. Callie<sup>1</sup>, G. Dinsdale<sup>1</sup>, S. Deshpande<sup>1</sup>, M. Jameson<sup>2</sup>  
<sup>1</sup>SWSLHD Radiation Oncology, Liverpool and Macarthur Cancer Therapy Centres, Liverpool BC, Australia ;  
<sup>2</sup>Ingham Institute for Applied Medical Research, Ingham Institute, Liverpool, Australia

##### Purpose or Objective

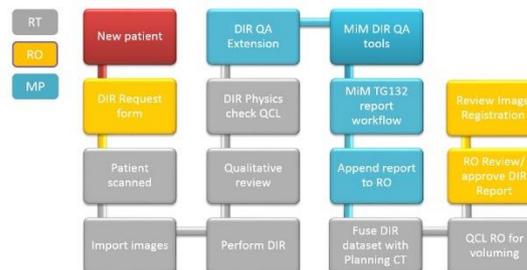

Deformable Image Registration (DIR) is increasingly used worldwide in adaptive radiotherapy scenarios, although local knowledge and experience within Australia is limited. DIR is a complex technique and clinical use of it brings many uncertainties, potential risks and workflow considerations. A recent publication by AAPM Task Group 132 (TG-132) addresses this and has outlined recommendations for mitigating potential risks associated with image registration. DIR involves significant collaboration between the multidisciplinary team, therefore governance around responsibilities and communication is essential. Training and education amongst all staff groups is also important. The purpose of this presentation is to discuss our departments' experience in the clinical implementation of DIR for pre-planning head and neck PET fusions. This will cover workflow, quality assurance procedures, education and incorporation of TG-132 recommendations.

##### Material and Methods

MiM Maestro software V6.8.5 was used as the platform to perform DIR before the data was transferred to either Tomotherapy or Pinnacle for planning. Multidisciplinary stakeholder meetings were held between radiation oncologists, radiation therapists and medical physicists to determine the clinical workflow and governance of data management. An in-house quality assurance tool was developed to provide quantitative information on the results of the deformation in user defined regions of interest. The TG-132 report was reviewed, and processes were developed to incorporate the recommendations into clinical practice. A comprehensive multidisciplinary competency package was developed to address training and education requirements. Radiation oncologists, radiation therapists and medical physicists were trained using our competency based system. The requirements to be deemed competent were tailored for each group. This involved: watching training videos, completing quizzes, performing practice cases and attending DIR registrations.

##### Results

A DIR request was developed and added to our existing booking process in Mosaic Oncology Information System. Quality Checklist items (QCLs) were created in Mosaic to manage workflow and facilitate communication between the multidisciplinary team (figure 1). Processes were established to combine the report generated from the in-house QA tool with a modified MiM report to meet TG-132 recommendations. DIR training cases were loaded into a training database. Radiation therapists performing DIR completed three cases of varying difficulty as part of their competency requirements. Radiation oncologists were required to attend three DIR registrations to understand the process before being able to freely request the technique for their patients. Medical physicists received training and performed initial cases under close supervision by lead physicist.

##### Conclusion

DIR was successfully implemented for head and neck pre-planning PET and PETCT within our department.

#### PO-1129 An analytical approach to aggregate patient workflows for system dynamics modelling of radiotherapy

J. Lindberg<sup>1</sup>, P. Holmström<sup>1</sup>, S. Hallberg<sup>2</sup>, T. Björk-Eriksson<sup>3</sup>, C. Olsson<sup>1</sup>  
<sup>1</sup>Clinical Sciences, Radiation Physics, Gothenburg, Sweden ; <sup>2</sup>Templog, Gothenburg, Sweden ; <sup>3</sup>Clinical Sciences, Oncology, Gothenburg, Sweden

##### Purpose or Objective

Radiotherapy (RT) is one of the most technology-intense and complex disciplines of health care and understanding departmental responses to various changes are challenging. Simulation models, as suggested by system dynamics (SD) methodology, can help to increase this understanding by allowing scenarios to be tested *in-silico* before implementation. To this end, patient inflows to RT departments constitutes the first step of the RT process and must be thoroughly understood to create the initial parts of the model. Patients are treated with different intents for numerous diagnoses, typically leading to over 100 possible workflows for a large RT department. In this work, we investigate to what extent individual workflows can be reduced (aggregated) based on similarity in resource use to meet requirements of an SD-model where the aim is to keep the data input format small.

##### Material and Methods

We used real data for patients treated with curative and palliative intent at a seven-linac RT department in Sweden during 2015-2016. Workflow similarity was investigated by Mann-Whitney U tests and pair-wise correlations ( $r$ ) between all possible combinations of workflows, with and without consideration of treatment intent. Similarity was quantified by averaged absolute pair-wise utility rate differences (%) and correlation analysis ( $r$ ). Grouping of workflows was decided using two customized algorithms: 1. All elements correlate with one main element; 2. All elements correlate with each other. Both algorithms were applied to five correlation coefficient cutoffs ( $r=0.75/0.80/0.85/0.90/0.95$ ) to identify the smallest number of workflow groups.

##### Results

During the studied period, 128 workflows could be distinguished for 3209 patients (72 workflows for 2094 patients with curative intent/56 workflows for 1115 patients with palliative intent). Workflow dissimilarity was indicated for <1%; correlations were generally  $\geq 0.87$  (median). For grouping algorithm 1, median number of groups (maximum within-group differences) for workflows with curative intent only were in the range 10-33 (107-279%), for palliative intent only 5-14 (37-63%), and without consideration of treatment intent 11-39 (30-123%). For grouping algorithm 2, corresponding numbers were 10-45 (41-279%), 5-39 (32-92%), and 11-87 (60-252%). Detailed results in Table 1.

TABLE 2. Results of the self-perceived didactic value of the e-learning program for experienced radiation therapists (RTT) working only with treatment delivery. The results are presented in the table below. The results are presented in the table below. The results are presented in the table below.

Grouping	Learner's self-perceived didactic value				Learner's self-perceived didactic value				Learner's self-perceived didactic value

41	80	10	10	10	80	10	10	10	80	10	10	10
42	80	10	10	10	80	10	10	10	80	10	10	10
43	80	10	10	10	80	10	10	10	80	10	10	10
44	80	10	10	10	80	10	10	10	80	10	10	10
45	80	10	10	10	80	10	10	10	80	10	10	10
46	80	10	10	10	80	10	10	10	80	10	10	10
47	80	10	10	10	80	10	10	10	80	10	10	10

**Conclusion**

Regardless of grouping approach, number of patient workflows could be aggregated into a tenth of initial number of individual workflows for the least conservative correlation coefficient. Even fewer groups could be identified when treatment intent was disregarded, but only for a reduced criteria of group similarity. It seems feasible to create an SD-model over the RT-process with a manageable number of aggregated workflows of high similarity without having to compromise on treatment intent. Having such reduced number of workflows at hand may also be of assistance when scheduling RT.

**PO-1130 Development of an e-learning program to enhance and maintain the knowledge of experienced RTT's**

J. Gornitzka<sup>1</sup>, L. Aksebo<sup>1</sup>, M. Torp<sup>2</sup>, V. Matthäi<sup>2</sup>, T. Bjørn<sup>3</sup>, K.L. Gottlieb<sup>3</sup>

<sup>1</sup>Odense University Hospital, Department of Oncology, Odense, Denmark ; <sup>2</sup>Unit for E-learning, Region of Southern Denmark, Vejle, Denmark ; <sup>3</sup>Laboratory of Radiation Physics, Odense University Hospital, Odense, Denmark

**Purpose or Objective**

Radiotherapy Planning (dosimetry) is a highly specialized area of radiotherapy and clinical oncology ensuring accurate radiation treatment to cancer patients. In the radiotherapy clinic it is difficult to find time and space to enhance and maintain knowledge about dosimetry among the experienced radiation therapist (RTT) working only with treatment delivery. The lack of daily experience with dosimetry can potentially impact their confidence and clinical skills. The aim of this project was to develop an e-learning program for experienced RTT's and evaluate the impact on the program on their clinical work.

**Material and Methods**

An e-learning program was developed in collaboration between department physicists, RTT's and the regional unit for e-Learning. The e-learning program consists of four main topics: Patient simulation, image modalities (CT, MR, PET), dose planning and plan control (see example in Figure 1). The four topics explain the pre-treatment-workflow.

The self-perceived didactic value of the program was evaluated using a face validated (5 persons) questionnaire with a 4-point Likert scale, which was sent immediately after completion of the e-learning. The questionnaire referred to the applicability of the course within the four topics, as well as their degree of understanding the workflow among the different professions in the pre-treatment. The evaluation questionnaire was repeated three months after to measure whether the RTT's used their knowledge from the course in their clinical work.

Figure 1: Example from the e-learning program

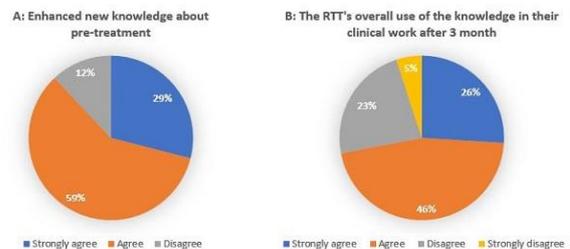

**Results**

The response rate among the 47 RTT's in the first questionnaire was 87 %, and 83 % at follow up questionnaire 3 month after.

88 % of the responders strongly agreed or agreed in having enhanced new knowledge about pre-treatment (Figure 2 A). In the group of RTT's with 0-10 years of experience (n=10) 50 % strongly agreed that the e-learning had given them new knowledge, while 22 % of the group with more than 10 years of experience (n=31) strongly agreed in this question.

The RTT's responded that the two chapters about image modalities and dosimetry had the highest applicability to their clinical work. 98 % strongly agreed or agreed to this. All responders (100 %) strongly agreed or agreed that the e-learning gave them an understanding of the pre-treatment workflow. After three months 79 % had used this knowledge about workflow in their clinical work. After three month 72 % of the responders used their overall enhanced knowledge about pre-treatment in their clinical work (Figure 2 B). In the group with 0-10 years of experience 70 % had used this knowledge, compared to 78 % in the group of the more experienced RTT's .

Figure 2: The responders evaluation of the e-learning program

**Conclusion**

The use of an e-learning program for experienced RTT's in the treatment site is an effective method to enhance and maintain knowledge about dosimetry and the pre-treatment workflow.

Petrov Research Institute of Oncology, Nuclear Medicine, St Petersburg, Russian Federation ; <sup>3</sup>Prof. N.N. Petrov Research Institute of Oncology, Head and Neck Surgery, St Petersburg, Russian Federation ; <sup>4</sup>Prof. N.N. Petrov Research Institute of Oncology, Radiotherapy, St Petersburg, Russian Federation

#### Purpose or Objective

to determine topography of sentinel and second echelon lymph nodes (LNs) in patients with tongue cancer and to analyze how this information can be used for radiotherapy planning.

#### Material and Methods

SPECT-CT visualization of lymph-flow patterns was performed in 26 primary patients with tongue cancer. Data acquisition was started 60-90 min after 4 peritumoral injections of 99mTc-nannocolloids (100-150MBq in 0.3-0.4ml). On SPECT-CT images we determined topography of all sentinel and second echelon LNs according to standard LN levels and the type (mono- or bilateral) of lymph-flow from the primary tumour. All patients underwent MRI and US examinations of regional LNs and in 17 cases LNs status was verified by histological examination.

#### Results

In 14 of 26 (54%) patients SPECT-CT determined bilateral pattern of lymph flow from tongue cancer. In most of these patients (10 cases, 71%) distance from medial border of the primary lesions to medial sulcus of the tongue was less than 5 mm. On the contrary, in 10 of 12 patients with lateralized lesions (distance to medial sulcus 5 and more mm) we detected monolateral lymph-flow pattern.

In 5 of 26 patients (19%) LNs with 99mTc-nannocolloids uptake were localized only on Ib-IIa levels. In another 16 cases (62%) sentinel and second echelon LNs were visualized on level Ib-IIa-III. Wide distribution (Level Ia-IIa-III-IV-VI) of LNs with tracer uptake was mentioned in 5 (19%) cases.

One of 13 cT1-2N0M0 operated patients had non-signal LN metastasis on the same level with signal LN. None of the 2 non-operated cT1-2N0M0 patients demonstrated signs of LN recurrence. On the contrary, at least 2 of 9 patients with cT1-3N1M0 disease had metastatic LNs distally from LNs with uptake of radiocolloids.

In 12 patients with monolateral lymph flow we didn't find cases with contralateral LN involvement. According to proposed strategy of lymph flow guided radiotherapy we plan radiotherapy to regional LNs that localized on the same levels as visualized sentinel and second echelon LNs. Finally we compared standard treatment plans with radiation portals that were designed according to topography of sentinel and second echelon LNs. Preliminary data indicated that lymph flow guided strategy can significantly (1.6-3.3 times) reduce clinical treatment volume and absorbed dose in contralateral parotid gland (1.1-3.3 times).

#### Conclusion

In patients with tongue cancer and clinically negative regional lymph nodes SPECT-CT visualization of lymph flow from the primary tumour can significantly influence the

# E-POSTERS

decision about optimal clinical treatment volume. Lymph flow guided strategy can significantly reduce radiation exposure to normal tissues.

#### EP-1134 Head and neck cancer management in Chinese hospitals: a multicentre questionnaire-based survey

C. Wu<sup>1</sup>, G. Li<sup>2</sup>

<sup>1</sup>The 4th Affiliated Hospital of China Medical University, Radiotherapy, Shenyang, China ; <sup>2</sup>1st hospital of China Medical University, Radiotherapy, Shenyang, China

##### Purpose or Objective

The treatment modalities for head and neck cancer (HNC) may vary in different departments of tertiary care hospitals. This survey was conducted to demonstrate the diagnosis and management practices for HNC in radiotherapy (RT) and other departments (OTH) in various tertiary care hospitals across China.

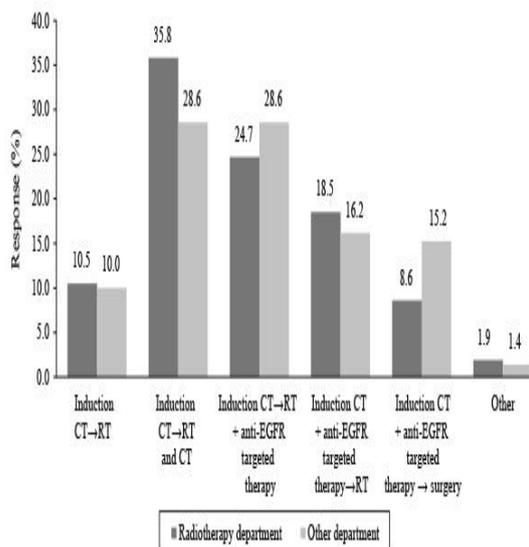

##### Material and Methods

This study was a real-world, multicentre, questionnaire-based survey, conducted between October, 2017 and January, 2018. The survey included oncologists working in RT and OTH from 100 randomly selected tertiary care hospitals in 21 cities of China. A questionnaire developed after consulting 9 HNC experts and pre-tested by 40 oncologists was used for formal investigation with oncologists. The evaluated outcomes consisted of the most prevalent stage and type of HNC treated, treatment strategies used and effect of human papilloma virus (HPV) test and age on HNC prognosis. The results were presented as percentages.

##### Results

Of the 272 oncologists included, 120 (44.1%) and 152 (55.9%) were from RT and OTH, respectively. Of the 120 oncologists from RT, 91 (75.8%) oncologists reported presence of HNC multidisciplinary team for HNC management in their institution. Locally advanced (LA) non-resectable HNC and LA HNC was the mostly reported tumour type and stage of HNC on the 1<sup>st</sup> visit of the HNC patients across both the departments as shown in Table 1. A greater percentage of oncologists reported metastatic/recurrent stage of HNC at the 1<sup>st</sup> visit in OTH compared to RT, Table 1. The most commonly treated type of HNC in both RT and OTH was reported to be nasopharyngeal carcinoma followed by laryngeal cancer, oropharyngeal and nasal cancers, as indicated in Table 1. Almost all the oncologists in RT and >93% in OTH, considered induction therapy for large tumours requiring shrinkage in HNC management. Induction chemotherapy (ICT) with radiotherapy and radiotherapy + anti EGFR were the preferred algorithms in both RT and OTH, as shown in Figure 1. In RT, 36.7% and 35.8% oncologists considered adding anti-EGFR to combined radical radiotherapy + chemotherapy during induction and post induction respectively, with a similar trend observed in OTH (40.8% and 27.6%). HPV testing was performed via polymerase chain, fluorescence in situ hybridization and P16 immunochemistry reaction as responded by 49.1%, 28.3% and 22.5% oncologists, respectively in the RT. Compared with OTH, higher proportion of oncologists in RT (64.5% Vs 81.7%) agreed that HPV testing could guide HNC prognosis. According to 75.8% and 71% oncologists in RT and OTH, age >70 years affected treatment decision for HNC. Additionally, >70% and 60% oncologists in RT and OTH agreed that patients aged >75 years had poorer prognosis for HNC than patients aged <65 years.

Figure 1. Treatment modalities followed by oncologists in radiotherapy and other departments

→ Followed by; + Combined with; CT Chemotherapy; RT Radiotherapy

Table 1. Type of tumour and stage of HNC on the first visit in Radiotherapy and other departments

Characteristics	Oncologists Response (%)	
	Radiotherapy	Other
<b>Type of tumour for HNC</b>		
Early stage and surgery allowed	15.0	17.8
Locally advanced (resectable)	15.8	19.7
Locally advanced (Non-resectable)	63.3	44.1
Metastatic/recurrent	5.8	18.4
<b>Stage of HNC</b>		
Early Stage	6.7	12.5
Locally advanced stage	90.0	69.1
Metastatic/recurrent	3.3	18.4
<b>Type of HNC</b>		
Nasopharyngeal carcinoma	70.8	60.5
Laryngeal cancer/hypopharyngeal carcinoma	18.3	25.0
Oropharyngeal cancer/oral cancer	6.7	9.9
Nasal tumour/ethmoid sinus tumour/ maxillary sinus tumour	4.2	4.6

##### Conclusion

The findings revealed that most Chinese oncologists in RT recommend induction therapy primarily with induction chemotherapy and radiotherapy which was in accordance with NCCN guidelines for HNC management.

#### EP-1135 Effect of Primary Treatment on Neck Dissection Choice in Nasopharyngeal Carcinoma Regional Failure

R. SIM<sup>1</sup>, S. Mueller<sup>2</sup>, G. Iyer<sup>3</sup>, N.C. Tan<sup>3</sup>, K.C. Soo<sup>3</sup>, R.S. Mahalakshmi<sup>3</sup>, H.K. Tan<sup>4</sup>

<sup>1</sup>Yong Loo Lin School of Medicine- National University of Singapore, Medicine, Singapore, Singapore ; <sup>2</sup>National Cancer Centre Singapore, Department of Surgical Oncology, Singapore, Singapore ; <sup>3</sup>SingHealth Duke-NUS Head and Neck Centre, Surgical Oncology, Singapore,

Singapore ; <sup>4</sup>Singapore General Hospital, Division of Surgery, Singapore, Singapore

### Purpose or Objective

Regional failure in nasopharyngeal carcinoma (NPC) is managed by salvage treatment in the form of neck dissection. Radical neck dissection (RND) is preferred over modified radical neck dissection (MRND), since it is traditionally believed to offer better long term disease control. However, with the advent of more advanced imaging modalities like high-resolution Magnetic Resonance Imaging, Computed Tomography and Positron Emission Tomography-CT scans, earlier detection is achieved. Additionally, concurrent chemotherapy also contributes to reduced tumour burden. Hence, there may be a lesser need for a RND and a greater role for MRND. With this retrospective study, the primary aim is to ascertain whether MRND, as opposed to RND, has similar outcomes and hence, whether there would be more grounds to offer a less aggressive procedure to achieve lower patient morbidity.

### Material and Methods

This is a retrospective study of 66 NPC patients treated at Singapore General Hospital between 1994 to 2016 for histologically proven regional recurrence, of which 41 patients underwent RND and 25 who underwent MRND, based on surgeon preference. The type of ND performed, primary treatment mode, adjuvant treatment and pattern of recurrence was reviewed. Overall survival (OS) was calculated using Kaplan-Meier estimate and compared.

### Results

Overall, the disease parameters such as nodal involvement and extranodal extension were comparable between the two groups. Comparing MRND and RND, the median (IQR) OS is 1.76 (0.58 to 3.49) and 2.41 (0.78 to 4.11) respectively. However, the p-value found is 0.5301 and hence not statistically significant.

### Conclusion

RND is more aggressive and has been associated with greater morbidity. Hence, with similar outcomes, MRND could be an alternative salvage procedure for regional failure in selected NPC patients, allowing similar salvage rates with lesser mortality and morbidity.

### EP-1136 Management SCC unknown primary with contemporary diagnostic and radiotherapy techniques

C. Paterson<sup>1</sup>, R. Crosbie<sup>2</sup>, P. McLoone<sup>3</sup>, D. Grose<sup>1</sup>, A. James<sup>1</sup>, C. Lamb<sup>1</sup>, M. Rizwanullah<sup>1</sup>, S. Schipani<sup>1</sup>, C. Wilson<sup>1</sup>, F. Campbell<sup>4</sup>, F. Easton<sup>4</sup>, M. Thomson<sup>5</sup>

<sup>1</sup>Beatson WoSCC, Clinical Oncology, Glasgow, United Kingdom ; <sup>2</sup>NHS Greater Glasgow & Clyde, Ear Nose & Throat, Glasgow, United Kingdom ; <sup>3</sup>Beatson WoSCC, Radiotherapy, Glasgow, United Kingdom ; <sup>4</sup>Beatson WoSCC, Nursing, Glasgow, United Kingdom ; <sup>5</sup>Beatson WoSCC, Therapeutic Radiography, Glasgow, United Kingdom

### Purpose or Objective

No randomised evidence exists to guide treatment of squamous cell carcinoma of unknown primary (SCCUP) of the head and neck. Two main approaches with RT exist - treating involved neck only (INO) or the addition of an elective dose to potential primary sites and contralateral neck (MUC). The rationale for this is to reduce the likelihood of the primary tumour emerging in the future but results in increased toxicity. If the frequency of mucosal primary emergence remains low without elective irradiation, we may be able to spare our patients toxicity. As SCCUP in the head and neck has a much better prognosis than unknown primary cancers presenting below the clavicles, the avoidance of late and permanent toxicity is highly relevant.

The purpose of our study was to evaluate disease related outcomes and doses to organs at risk in a contemporary

cohort of patients investigated, diagnosed and treated for SCCUP.

### Material and Methods

This was a retrospective cohort study; patients with histologically confirmed SCCUP with unilateral neck disease staged with FDG PET-CT scan were eligible. Patients were identified from the radiotherapy database and electronic case records reviewed.

### Results

26 patients with unilateral neck disease from SCCUP were treated between August 2012 and April 2016. All patients underwent investigation with FDG PET-CT and EUA.

All patients underwent radiotherapy with volumetric modulated arc therapy (VMAT). Patients receiving radiotherapy as primary treatment received 65Gy/30# to areas of gross disease and entirety of that involved nodal level and 54Gy/30# to areas considered at risk of harbouring microscopic disease. Patients who received adjuvant RT following neck dissection received either 65Gy/30# (if ECS) or 60Gy/30# to involved nodal levels (if no ECS) and 54Gy/30# to areas at risk of microscopic disease.

16 patients received INO RT, 10 patients received MUC RT. 37.5% patients receiving INO RT had HPV/p16 positive disease. 50% patients receiving MUC RT had HPV/p16 positive disease. 56.3% patients in INO group received concurrent cisplatin, 50% in the MUC cohort.

Median follow up is 35 months (range 30-46mths). No mucosal primaries in either group have emerged. 1 patient in the MUC group relapsed in contralateral neck in the elective dose volume. 2 year OS is 81.3% in INO group, 80% in MUC group.

Dose to organs at risk are shown in table below.

	INO RT (n=16)	MUC RT (n=10)	
Mean dose contralateral parotid	1217cGy	3336cGy	p<0.01
Maximum dose brain stem	3270cGy	4191cGy	p<0.01
Maximum dose spinal cord (	3686cGy	4023cGy	p=0.056
Mean dose midline mucosa (thyroid-cricoid)	4040cGy	5068cGy	p<0.01
Mean dose midline mucosa (cricoid - sternum)	2658cGy	3324cGy	p=0.07

### Conclusion

This is the only contemporary series of SCCUP head and neck where all patients have undergone a PET-CT as part of their diagnostic work up and the first series to compare outcomes from unilateral neck radiotherapy with VMAT to irradiating potential mucosal primary sites with VMAT.

RT to INO does not result in more frequent emergence of mucosal primary or contralateral recurrence in SCCUP. The observed reduction in dose to OARs with INO approach may represent an opportunity to spare patients toxicity and would support further research to confirm the benefits of RT to INO.

### EP-1137 DW MRI as biomarker of response during RT for intermed/high risk SCC oropharynx: a feasibility study

C. Paterson<sup>1</sup>, I. McCrea<sup>2</sup>, L. Hay<sup>3</sup>, S. Allwood-Speirs<sup>4</sup>, L. Devlin<sup>3</sup>, M. Sankaralingam<sup>4</sup>, P. McLoone<sup>1</sup>, C. Wilson<sup>1</sup>, D. Grose<sup>1</sup>, A. James<sup>1</sup>, C. Lamb<sup>1</sup>, M. Rizwanullah<sup>1</sup>, S. Schipani<sup>1</sup>, I. Nixon<sup>1</sup>, M. Thomson<sup>3</sup>, M. McJury<sup>4</sup>, J. Foster<sup>4</sup>, A. Duffton<sup>3</sup>

<sup>1</sup>Beatson WoSCC, Clinical Oncology, Glasgow, United Kingdom ; <sup>2</sup>NHS Greater Glasgow & Clyde, Radiology, Glasgow, United Kingdom ; <sup>3</sup>Beatson WoSCC, Therapeutic Radiography, Glasgow, United Kingdom ; <sup>4</sup>NHS Greater Glasgow & Clyde, Medical Physics, Glasgow, United Kingdom

### Purpose or Objective

Despite radical chemo-radiotherapy (CRT), many patients with intermediate and high risk SCC oropharynx (OPSCC) relapse. Treatment related toxicity limits further uniform

intensification across the patient group. If a predictive biomarker for outcomes from CRT can be identified during treatment, individualised and adaptive treatment strategies may be employed for the non-responders. This is the 1<sup>st</sup> study to use DW MRI for early response assessment in a specific H&N sub-site with sub-type of similar biological behaviour. The primary aim of this study was to determine the feasibility of:

- Recruiting patients
- Carrying out DW MRI at baseline (MRI 1) and week 3 (MRI 2) of RT
- Measuring apparent diffusion coefficient (ADC) on each scan for each target lesion, as per study protocol (Paterson et al, Clinical and translational radiation oncology, Feb 2017, Vol 2, p 13-18)

#### Material and Methods

Patients with intermediate and high risk, locally advanced OPSCC receiving radical RT/CRT were recruited to this prospective observational imaging study with national REC approval (15/WS/0159);
