Delivery error sensitivity was then tested by modifying the initial plans to introduce errors on dose (+1%, 2% and 3%), leaf bank shifts (1 mm and 2 mm), 10 mm central leaf shift, central leaf blockage, gantry rotation (+5° and +15°) as well as collimator rotation (+5° and 15°). For each energy, these errors were introduced for the largest and smallest PTV. Gamma agreement indices (GAI) were calculated with 2% local dose difference, 2 mm distance-to agreement and 10% threshold.

##### Results

EPIbeam gave gamma index passing rates similar to those with 3D phantom : for 6 MV FFF, the GAI were (98.79±0.61)% for EPIbeam and (99.86±0.26)% for 3D phantom and for 10 MV FFF, the GAI were (98.55±0.47)% and (99.55±0.86)% respectively.

Delivery error sensitivity varied with PTV size but not with energy. For small lesions (6-59 cm<sup>3</sup>), EPIbeam is more sensitive to dose errors compared with 3D phantom, spotting errors from 1% difference whereas for the largest lesion (327 cm<sup>3</sup>), a 3% difference was necessary. Leaf bank errors had to be at least 2 mm to fail the test with EPIBEAM whereas the 3D phantom test spotted a 1 mm error for small lesions. Central leaf 10 mm shift was spotted for the small lesions but not for the large lesion with both techniques. Leaf blockage was identified as error with both detectors. As expected, EPIbeam was completely insensitive to gantry rotation errors, unlike 3D phantom. EPIbeam is also less sensitive to collimator errors, compared to 3D phantom.

##### Conclusion

Once the treatment planning system has been validated with 3D phantom measurements, EPID based pre-treatment quality insurance can be achieved with EPIbeam for fluence verification, provided that independent QA of collimator and gantry rotations is performed on a regular basis on the machine.

#### EP-1725 Two years' experience with Esteya QA

M. Van het Loo<sup>1</sup>, W. Jansen<sup>1</sup>, A. Loopstra<sup>1</sup>

<sup>1</sup>Radiotherapiegroep, Department of Radiation Physics, Arnhem, The Netherlands

##### Purpose or Objective

Esteya® (Elekta AB, Sweden) is used to treat non-melanoma skin cancer. The QA results, since the installation in March 2016, have been reviewed to check the stability of the system.

##### Material and Methods

Esteya® is an electronic brachytherapy device with a 69.5 kV X-ray source enabling treatments up to 4 mm depth. In general the applied dose rate is 3.3 Gy/min and the maximum aperture is 30 mm. Esteya® QA consists of two parts: mandatory daily tests on radiation days carried out with the QA tool provided by Elekta and periodic QA tests. During the monthly tests reference dosimetry, energy, symmetry, flatness and penumbra size are checked for the 30 mm applicator. Annually the other applicator diameters are checked as well.

The reference dosimetry in air is performed with an ionization chamber (34013, PTW-Freiburg GmbH, Germany). Three fractions of 6 Gy prescribed at 0 mm depth are delivered for verification.

The energy consistency is determined by measuring at three depths. A Plastic Water Low Range (PWLRL, Cirs inc., USA) slab with a cavity for the ionization chamber is placed on top of 60 mm of PWRL backscatter material. As a reference a measurement without an additional slab is used. Besides we perform measurements with additional slabs of 5 and 10 mm PWLRL.

Flatness, symmetry and penumbra size are determined using Gafchomic EBT3 film (Ashland inc., USA) irradiated with a 5 Gy fraction. The film is placed on top of 60 mm PWLRL and covered with PWLRL slabs with a total thickness of 3 mm. The film is scanned with an Epson Perfection V750 Pro transmission scanner (Seiko Epson Corp., Japan) and analyzed using FilmQA Pro software (Ashland inc., USA). The penumbra size is determined as the distance between points representing 20% and 80% of the central axis dose.

#### Results

During acceptance measurements, the characteristics of Esteya® have been determined. Since acceptance neither the X-ray source, nor other major items have been replaced.

The results presented here are based on the monthly checks. The mean value of the reference dosimetry is 5.96 Gy (SD 0.03 Gy). All measurements are in tolerance of  $\pm 0.12$  Gy ( $\pm 2\%$ ). The mean value for the percentage depth dose at 5 mm is 72.8% (SD 0.7%) and at 10 mm 53.7% (SD 0.3%). This is well within  $\pm 2\%$  compared to the reference values of 73.1% and 53.9% at respectively 5 and 10 mm depth. The larger SD found at 5 mm depth is due to a difference in thickness of the slabs. All measurements of the symmetry and flatness are within the tolerance of  $\pm 3\%$ . The mean penumbra size is 0.3 mm (SD 0.1 mm).

#### Conclusion

All measurements are within the set tolerance limits. The physics characteristics of Esteya® have proven very stable and consistent. Hence, in combination with the sharp penumbra (mean size 0.3 mm) and steep dose fall off in depth, Esteya® enables a reliable and precise treatment of non-melanoma skin cancer.

#### EP-1726 Utilization of bolus in post-mastectomy radiation therapy

R. Chakarova<sup>1</sup>, D. Lundstedt<sup>2</sup>, H. Svensson<sup>1</sup>, M. Gustafsson<sup>1</sup>, M. Hällje<sup>1</sup>, P. Karlsson<sup>2</sup>

<sup>1</sup>Sahlgrenska University Hospital, Medical Physics and Biomedical Engineering, Göteborg, Sweden ;

<sup>2</sup>Sahlgrenska Academy, Dept. of Oncology- Institute of Clinical Sciences, Göteborg, Sweden

#### Purpose or Objective

Women receiving radiotherapy to the chest wall after mastectomy due to breast cancer usually have a bolus over the scar. The aim of this work is to evaluate the bolus effect on target coverage and in particular to determine if bolus recommendation should be related to the chest wall thickness and if different dose calculation algorithms estimate target coverage differently.

#### Material and Methods

The smallest thickness of the thoracic wall in the CTVT region was estimated for 160 consecutive patients

receiving radiation therapy after mastectomy. CT images were taken with bolus. CTVT and PVT were delineated according to national (SBRG) guidelines. 3DCRT plans were generated in Eclipse TPS using AAA and re-calculated with the same MU by Acuros XB and a Monte Carlo (MC) system based on EGSnrc. Calculations were performed on original CT scans and modified scans with bolus excluded. Dose distributions were obtained for three groups, (10 patients in each group), with selected chest wall thicknesses; below 15 mm (group 1), between 20 - 25 mm (group 2) and between 30 - 35 mm (group 3). Target coverage was evaluated in terms of DVH parameters; CTVT mean dose, CTVT\_V95%, PTV\_D98%, PTV\_V95% and PTV\_V105%.

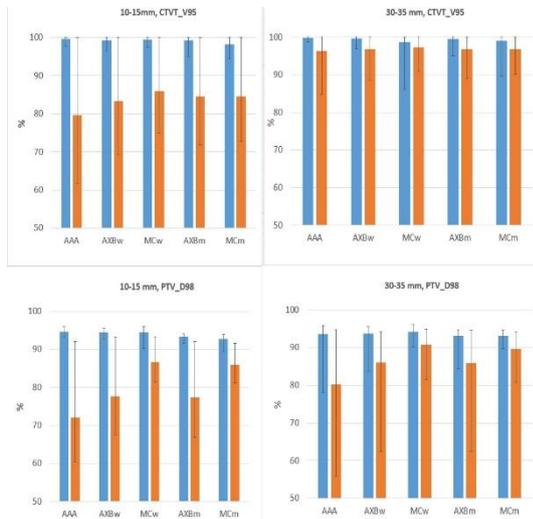

#### Results

The distribution of chest wall thickness for the 160 patients is shown in the Table. The bolus effect was most pronounced for patients in group 1. About 10-15% higher CTVT\_V95 and 10-20% higher PTV\_D98 values were obtained in case of bolus (Figure). For the patients in group 3, CTVT\_V95 differed by 4% and PTV\_D98 by 5-15% (Figure). CTVT mean dose for group 1 was 2% higher as estimated by Acuros XB and MC (4.5% for AAA) and 1% lower for groups 2 and 3 (negative bolus vs no-bolus difference). The increase of PTV\_V95% in absolute volume due to presence of bolus was comparable for the three groups: about 20 cm<sup>3</sup>; 15 cm<sup>3</sup> and 10 cm<sup>3</sup> as estimated by AAA; Acuros XB and MC, respectively. PTV\_V105% decreased in case of bolus by 5 - 10 cm<sup>3</sup> (group 1) and 20 - 40 cm<sup>3</sup> (group 3). The presence of bolus enhanced the agreement between the different algorithms and reduced the variation of the estimation within the group (max-min intervals in the figure).

**Table.** Chest wall thickness near CTVT for 160 patients undergoing post-mastectomy radiation therapy

Chest wall thickness, mm	Frequency, %
up to 15 mm	14
15 to 20	19
20 to 25	20
25 to 30	20
30 to 35	15
35 to 40	6
40 to 45	6
more than 45	6

**Figure.** CTVT\_V95% and PTV\_D98% for group 1 and 3 estimated by: AAA, Acuros XB dose to water and medium (AXBw, AXBm), Monte Carlo (MCw, MCm). Blue bars: bolus; red bars - no-bolus. Error bars indicate min-max interval.

### Conclusion

Bolus considerably improves the dose distribution in thin chest wall target. It is advisable also for other chest wall thicknesses to achieve better target coverage and decrease the overdose volume. Dose estimation in presence of bolus is more robust and less sensitive to the calculation algorithm. If the improved dose distribution with bolus translates into fewer chest wall recurrences needs to be verified in clinical trials.

### EP-1727 Validation of the Raystation Monte Carlo Code using dedicated ionization chambers

G. Pittomvils<sup>1</sup>, E. Bogaert<sup>1</sup>, P. Thysebaert<sup>2</sup>, C. De Wagter<sup>1</sup>, Y. Lievens<sup>1</sup>

<sup>1</sup>Ghent University Hospital, Dienst Radiotherapie, Gent, Belgium ; <sup>2</sup>Odisee Hogeschool-Universiteit, Campus Terranova, Brussels, Belgium

### Purpose or Objective

Electron Monte Carlo dose calculation algorithms are capable of predicting dose distributions within tolerances defined by international and national organizations for standard and non-standard setups, such as extended SSD treatments, oblique incidences and heterogeneous tissues. At Ghent University Hospital the Raystation planning system was introduced in 2016 and the electron Monte Carlo was also commissioned, allowing the dose prediction of electron dose deliveries for all treatment modalities.

### Material and Methods

Raystation Monte Carlo Code is verified using plane parallel chambers; Roos Chamber and a linear array using liquid filled plane parallel chambers (PTW, Freiburg, Germany) and an PTW Electron Diode type 6012. The clinical calculation grid size of 2mm<sup>3</sup> was selected using 250000 histories resulting in a statistical dose accuracy of 1.5%. The NCS15 protocol (Nederlandse Commissie Stralingsdosimetrie)[1] is used to validate the results. The dose output versus SSD (95.5-115cm) is evaluated for all applicators at Zref using the Roos chamber. The output of 19 different inserts is verified using de Electron Diode at SSD=100 cm. The dose reduction at the standard R50 value for a 14x14cm<sup>2</sup> applicator was verified for beam incidence angles ranging from 0° to 30°. The calculated dose is verified with a linear array for lung and air inserts of different dimensions with and without 1 cm build up material behind the 3D plus shaped cavity. The same linear array is used to verify the dose behind a cylindrical insert with three different bone density inserts.

### Results

Dose calculation and dose measurements remain within tolerances of NCS15 confirming the accuracy of the Monte Carlo Algorithm for different SSD's and all investigated inserts. Large fields remain in output very close to 1/(SSD)<sup>2</sup> and steeper measured dose fall off for small fields is predicted within tolerance with the Raystation Monte Carlo algorithm. The Distance To Agreement for the R50 values with increasing incidence angle remains 2 mm or smaller, again within NCS15 tolerances. The best fit for the line profiles behind the air, lung and bone cavities was obtained within 3 mm for the δ2 region (high dose gradient) and within 4% in dose for the δ4 region (photon tail), both within the tolerance of NCS15.

### Conclusion

According to NCS15 for non-standard treatment setups a dose agreement of 3 % in the d1 region of 4 % in de d4 region and for the d2 region a distance to agreement of 3 mm has to be obtained between measurements and calculations. This is investigated using different air filled and liquid field ionization chambers and diodes in several setups. This confirms the accuracy of the Monte Carlo code of Raystation for prediction of dose distribution within acceptable timeframes (<1000000 histories) for standard clinical treatment planning.

### EP-1728 1-year experience with automated transit in vivo dosimetry in a busy multicenter department

E. Bossuyt<sup>1</sup>, R. Weytjens<sup>1</sup>, S. De Vos<sup>1</sup>, R. Gysemans<sup>1</sup>, D. Verellen<sup>1</sup>

<sup>1</sup>Iridium Kankernetwerk Antwerpen, Physics department radiotherapy, Wilrijk, Belgium

### Purpose or Objective

Being a busy department with 5600 new patients/year and several satellite centers, efficiency, standardization and automation are key for a QC program. A web-based system was installed in our center early 2017, for pre-treatment and in-vivo QA based on phantomless EPID and/or log files (Sun Nuclear Corporation). DICOM data is pushed to the server. Images and log files are actively retrieved. Calculation and analysis occur automatically in the background. A clinical validation of the system's performance on detection of errors and reducing workload will be reported. Special attention was given to identify and mitigate false positive (FP) results.

### Material and Methods

In this study results are reported from an analysis for all patients treated between October 2017 and August 2018. During treatment every field or arc was controlled by means of logfiles for all patients receiving photon treatment. In addition, the first 3 days and then weekly, transit EPID images were generated. These were compared using relative 2D analysis. Recently absolute verification was introduced comparing the images to calculated data, further enhancing detectable errors. Appropriate actions were undertaken based on a decision tree derived from an initiating training period.

### Results

No relevant patient errors were detected with analysis of the logfiles, 15% of integrated images failed. One third were FP, due to incomplete dose accumulation (beam stop, 6%) or dispositioning of the imager (27%). Creating a report in Aria helps detecting these FP's. The remainder concerned patient related issues. Most common causes were patient positioning and anatomy changes such as weight loss (41%) and deviations in bladder or rectal filling (6%). Rare observations were shrinkage of tumor, hematoma, pneumonia, air cavity in the tumor and accidental translation of the table between fields. Actions to mitigate the most dominant causes of errors were

introduced such as adapting the imaging protocol, recalculating treatment plans on CBCT or a new CT, weekly weight control of patients at risk, adjusting rectal and bladder filling protocol. In 17% of cases no actions were taken. Due to the high resolution of transit images, most of the conventional portal images in non VMAT could be omitted. A learning curve was observed during feedback moments with staff, which resulted into a wide acceptance by repeated training using practical examples.

### Conclusion

A standardized transit dosimetry program using a decision tree was introduced in a busy department. Some treatment and imaging protocols were adjusted based on this experience and pre-treatment imaging could be omitted for some treatments. After 6 months half of the observed deviations could be reduced, contributing to a wide acceptance level in our department. A detailed report of further experience using an adapted workflow on the first years' experience will be presented as well as the preparatory work needed to establish a standardized QC program.

### EP-1729 Evaluation of beam modeling parameter variations among radiotherapy institutions using common TPS

M. Glenn<sup>1</sup>, D. Followill<sup>1</sup>, R. Howell<sup>1</sup>, J. Pollard-Larkin<sup>1</sup>, S. Zhou<sup>2</sup>, S. Kry<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA ; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Biostatistics, Houston, USA

### Purpose or Objective

Previous studies indicate that a major contributor to erroneous radiotherapy treatments is the inaccuracy of the dose calculation itself. This study evaluates the variation of several treatment planning system (TPS) beam modeling parameters to determine the degree to which the radiotherapy community shows consensus in how clinical beam models are established. Simultaneously, this study provides reference values for TPS parameters that can assist clinical physicists in the TPS commissioning process.

### Material and Methods

Beginning January 2018, TPS beam modeling parameter surveys were distributed to users of IROC services through online facility questionnaires. These surveys, designed for Eclipse, Pinnacle, and RayStation users, instructed physicists to report parameter values used to model the radiation source and multileaf collimator (MLC) for each treatment machine and beam energy used clinically for IMRT. Parameters collected included the effective source/spot size, MLC transmission, dosimetric leaf gap, tongue and groove effect, as well as other nondosimetric parameters specific to each TPS. To facilitate survey participation, instructions were provided on how to identify requested beam modeling parameters within each TPS environment. Survey results were then isolated according to calculation algorithm, beam energy, machine class, and MLC type, and then examined for trends.

### Results

To date, parameters for 2171 beam models from 533 radiotherapy institutions have been aggregated via online questionnaires. 76% of reported beam models were commissioned using Eclipse, 18% of responses were for Pinnacle, and 6% of responses reported values for RayStation beam models. Some parameters, such as the effective target spot size (Eclipse AAA and AcurosXB), exhibited very good uniformity (>75% reported the same value for a given machine class). Other variables presented broad distributions of values, especially for factors that are physically measured for the characterization of the MLC (e.g. MLC transmission and dosimetric leaf gap). These parameters that showed

remarkable variations tended to remain without strong consensus across different energies and machine classes.

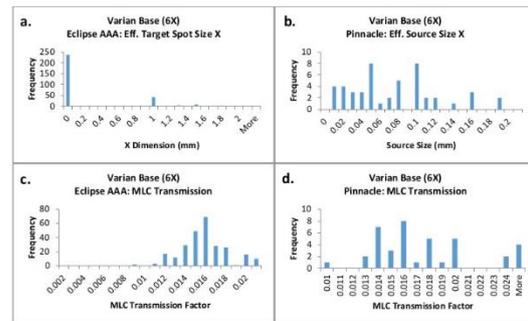

Figure 1. Histograms of several Eclipse and Pinnacle beam modeling parameter responses for 6 MV Varian Base Class models submitted: a) effective target spot size (Eclipse AAA), b) effective source size (Pinnacle), c) MLC transmission factor (Eclipse AAA), d) MLC transmission factor (Pinnacle).

### Conclusion

This study demonstrates that high variation exists in several TPS beam modeling parameters, thus highlighting the need for further exploration to determine what effects these discrepancies may have on dose calculations. These results can be employed by the radiotherapy community to compare parameter values obtained during commissioning to better inform what are considered reasonable values for model creation.

### EP-1730 Systematic Monte Carlo dose verification of VMAT treatment plans for TrueBeam linac using PRIMO

A. Sottiaux<sup>1</sup>, V. Baltier<sup>1</sup>, A. Monseux<sup>1</sup>, C. Leclercq<sup>1</sup>, D. Vanache<sup>1</sup>, M. Tomsej<sup>1</sup>

<sup>1</sup>CHU Charleroi, Radiotherapy, Montigny-leTilleul, Belgium

### Purpose or Objective

Complex techniques like VMAT require appropriate QA to check if the predicted dose is delivered to patient, including TPS dose verification. Regarding dose verification, Monte Carlo methods are often considered as gold standard. PRIMO is a Monte Carlo software self-containing (geometry included), publically available and able to handle VMAT plan for TrueBeam linacs.

The purpose of this study is to check if PRIMO is suitable for systematic VMAT plans dose verification.

### Material and Methods

PRIMO v0.3.1 combines linacs geometry, Graphical User Interface and 2 Monte Carlo engines: PENELOPE/PenEasy and DPM (Dose Planning Method, optimized for radiotherapy). DPM is faster but less accurate in low density materials. Download, Installation and PRIMO setup is very easy.

We used a PRIMO beta-version v0.3.1.1625 that provides 2 additional features: Macro mode and start from command line. Macro mode allows required task to simulate VMAT plan (load DICOM, set parameters, start simulation and perform Gamma Index (GI) analysis) to be executed with simple commands, without user action nor risk of error. We developed scripts to automate the process. After DICOM export from TPS, appropriate Macro file is generated, and simulation is launched (including GI) without any user action.

As TrueBeam head's geometry (beam production) is not implemented in PRIMO, Phase Space Files provided by Varian are used. They are designed to match TrueBeam standard tuning. We compared PRIMO simulation against PDD measurements for 3x3 cm<sup>2</sup> and 10x10 cm<sup>2</sup> beams, on 2 different TrueBeam.

50 VMAT plans (calculated with Eclipse/Acuros 13.7, dose to medium) have been compared for various cases and PTV size. All plans were calculated with DPM, and 8 recalculated with PENELOPE because they failed our criteria with DPM. We performed GI (3%/3mm and 2%/2mm, 95% passing

criteria), including noise reduction (integrated to PRIMO) in order to reduce underestimation of GI due to statistical noise in reference dose.

### Results

For all 4 PDD comparisons (2 beam sizes, 2 linacs), GI 1%/1mm is 99.7%-100%. With 3%/3mm criteria, all plans pass GI. 1 plan fails with DPM, but passes with PENELOPE. With GI 2%/2mm, 42/50 plans pass with DPM (6/8 failing plans are lung cases). Combining with PENELOPE recalculation, 45/50 plans pass GI. For 8 recalculated plans, mean GI is 90.5% and 95.2% for DPM and PENELOPE respectively. Average PTV median dose difference is +0.95% between PRIMO (DPM) and Acuros.

Calculation time varies from 19 min to 2 h 17 min (DPM), with an observed correlation with both PTV volume and Acuros calculation time. Calculation time with PENELOPE is -6-8 times longer.

### Conclusion

PRIMO can perform systematic VMAT plan dose verification for TrueBeam, using Varian Phase Space files. This requires low setup effort.

With enhancement regarding automation (PRIMO side and in-house developments), user time required is reduced to a few seconds.

### EP-1731 Using plane-parallel ionization chamber PPC40 to measure Dose Area Product Ratio

D. Mateus<sup>1,2</sup>, G. Mora<sup>3</sup>, M.J. Cardoso<sup>1,2</sup>, A. Martins<sup>1</sup>, A. Rocha<sup>1,2</sup>, C. Greco<sup>1</sup>

<sup>1</sup>Fundação Champalimaud, Radiotherapy, Lisboa, Portugal; <sup>2</sup>Mercurius Heath, Radiotherapy, Lisboa, Portugal; <sup>3</sup>Faculty of Sciences- University of Lisbon, Institute of Biophysics and Biomedical Engineering, Lisboa, Portugal

### Purpose or Objective

The introduction of Dose Area Product Ratio ( $DAPR_{20,10}$ ) as a new beam quality parameter for small field dosimetry to replace the traditional  $TPR_{20,10}$  have been suggested by several authors. These studies have been investigated the characteristics of  $DAPR_{20,10}$  for FF photon beam energies using large-area plane-parallel ionization chambers (IC), such as LACs, with diameter between 96.5 and 39.6mm. But LACs are not commonly used in the radiotherapy clinical centers and there is a lack of research about  $DAPR_{20,10}$  for FFF photon beam energies. In the present work, it was investigated the feasibility of using the common plane-parallel ionization chamber PPC40 (diameter of 16mm) instead of LACs for the  $DAPR_{20,10}$  measurements. In addition, it was studied the variation of  $DAPR_{20,10}$  with field size, beam energy and the diameter of the active area of IC. Finally, it was calculated correction factors to compensate the observed dependence of  $DAPR_{20,10}$  on the beam diameter of the IC (see Fig. 1).

### Material and Methods

Measurements of  $DAPR_{20,10}$  and  $TPR_{20,10}$  for photon beams emerging from the linear accelerator *Edge*, Varian, were performed using the PPC40 and PTW60019 microDiamond detector, respectively. Beam collimation included: 1) cones of different diameter (7.5mm, 10mm, 12.5mm, 15mm and 17.5mm) with jaws opening of 5x5 cm<sup>2</sup>; and 2) square field size of 1x1 cm<sup>2</sup>. Several energies were studied: 6MV (FF and FFF) and 10MV (FFF).

### Results

Our preliminar results indicate 1) using the PPC40, it is possible to properly measure DAP for the circular fields with diameter up to 12.5 mm and also the square field of 1x1cm<sup>2</sup> defined by the jaws; 2) differences between  $DAPR_{20,10}$  and  $TPR_{20,10}$  are around 2% (see Table 1); 3)  $DAPR_{20,10}$  does not depend practically on field size (maximum difference of 0.5%); 4)  $DAPR_{20,10}$  and  $TPR_{20,10}$  have similar variation with energy (difference around 7% between the energies 6MV-FFF and 10MV-FFF).

Table 1. -  $DAPR_{20,10}$  and  $TPR_{20,10}$  measurements acquired with PPC40 and microDiamond, respectively, for the cones of 7.5mm, 10mm, 12.5mm of diameter and the square field size of 1x1 cm<sup>2</sup>, for the energies 6MV, 6MV-FFF and 10MV-FFF.

Field Sizes	$DAPR_{20,10}$			$TPR_{20,10}$		
	6MV	6MV-FFF	10MV-FFF	6MV	6MV-FFF	10MV-FFF
Cone 7.5mm	0.627	0.593	0.668	0.614	0.581	0.647
Cone 10mm	0.622	0.591	0.665	0.617	0.585	0.653
Cone 12.5mm	0.622	0.590	0.665	0.621	0.589	0.658
1x1 cm <sup>2</sup>	0.626	0.592	0.666	0.622	0.590	0.658

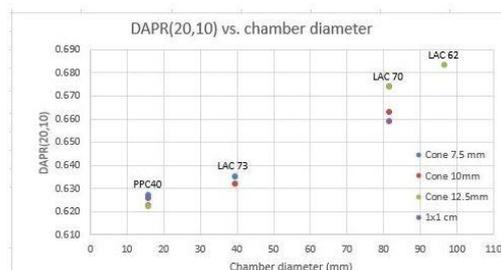

Fig. 1 – Variation of the  $DAPR_{20,10}$  with the diameter of the PPC40, LAC 70 (J. Niemela, 2017), LAC 73 (J. Niemela, 2017), M. Pimpelino, 2017; T. Kupfer, 2014) and LAC 62 (M. Pimpelino, 2017) for 6MV energy.

### Conclusion

The characteristics of  $DAPR_{20,10}$  determined for the circular fields up to 12.5 mm and square field of 1x1 cm<sup>2</sup> using the common clinical PPC40 are similar to those reported by previous studies which used LACs. We are conducting more research to validate our calculated correction factors by Monte Carlo method.

### EP-1732 The effect of different table top models on patient-specific QA

L. Paelinck<sup>1</sup>, E. Wuyts<sup>1</sup>, B. Vanderstraeten<sup>1</sup>, C. De Wagter<sup>1</sup>, Y. Lievens<sup>1</sup>

<sup>1</sup>University Hospital Ghent, Radiotherapy, Ghent, Belgium

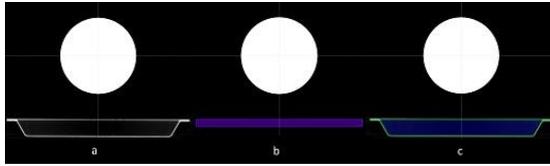

### Purpose or Objective

The purpose of this study was to investigate the effect of different table top models on the agreement between calculations and measurements on the Delta4 phantom (Scandidos) for different beam configurations. Also, 8 full arc prostate plans were measured and compared with calculations without the table model and with the three different table models included.

### Material and Methods

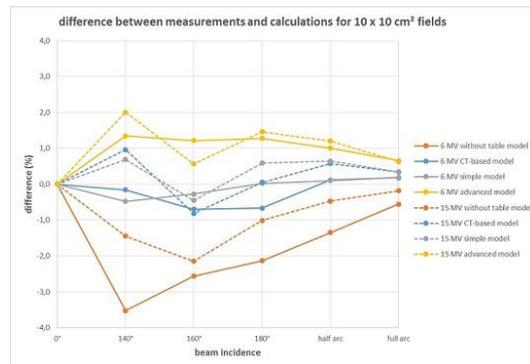

Our Elekta linear accelerators are equipped with the iBeam evo carbon fiber table top. Three different models for this table were considered in our TPS RayStation 6 (RaySearch): a CT-based, a simple and an advanced geometric model. For the CT-based model the treatment table was removed from the linear accelerator and scanned with a Toshiba Aquilion LB CT simulator. Thereafter, the part of the CT-images where the table-pixels are located, were extracted and injected in the artificial CT-images of the Delta4 phantom with a home-made java program. The result of this operation is seen in fig 1a. The simple geometric model is represented by a slab with a density of 0.25 g/cm<sup>3</sup> (fig 1b). The advanced geometric model is represented by a thin outer surface layer mimicking the table contour composed of carbon fiber (1.18 g/cm<sup>3</sup>) and an inner core composed of foam (0.055 g/cm<sup>3</sup>) (fig 1c).

Different beam configurations of 3x3 cm<sup>2</sup>, 5x5 cm<sup>2</sup> and 10x10 cm<sup>2</sup> at angles of 0°, 140°, 160° and 180° as well as a half arc of 180° crossing the table and a full arc of 360° for 6 and 15 MV were measured and calculated on the Delta4 phantom without and with the three table models included. The same was done for the 8 full arc prostate plans. All measurements were performed on the same day and a proper daily correction factor was applied. For the analysis of the prostate plans, a gamma criterion of 3%/3mm was used.

## Results

The percentage difference between measurements and calculations in the centre (at isocentre) of the Delta4 phantom is shown in fig 2 for 10 x 10 cm<sup>2</sup> field configurations both for 6 MV and 15 MV. Graphs for the other investigated field sizes are similar. The percentage differences for the CT-based and simple model are fluctuating around zero, whereas the percentage differences without table and with the advanced table model are all either negative or positive and have a larger range. This means that the CT-based and simple table model are equivalent to each other and superior to the others. Gamma analysis of the prostate plans shows little variances between the different models. This can be declared by the observation in fig 2 that the differences between measurements and calculations are below 1% for full arcs.

## Conclusion

The quality of the simple model and the CT-based model are equivalent. It is surprising that the quality of the advanced model is not satisfying. We prefer to use the simple model in routine clinical practice since it is more user-friendly than the CT-based model.

## EP-1733 CFR-PEEK vs titanium spinal stabilization implants in photon and proton therapy: A phantom study

R. Poel<sup>1</sup>, F. Belosi<sup>1</sup>, N. Klippel<sup>2</sup>, F. Albertini<sup>1</sup>, M. Walser<sup>1</sup>, A. Gisep<sup>3</sup>, D. Terribilini<sup>2</sup>, A. Joosten<sup>2</sup>, H. Hemmatzad<sup>2</sup>, K. Zaugg<sup>4</sup>, D. Aebersold<sup>2</sup>, P. Manser<sup>2</sup>, D. Weber<sup>1</sup>

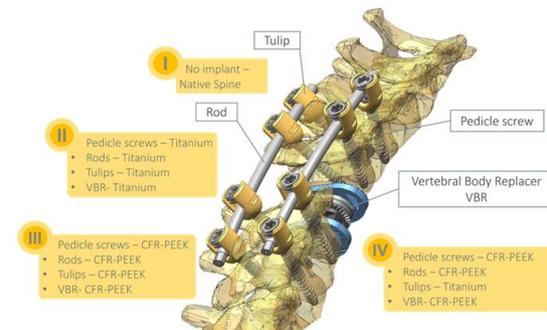

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland ; <sup>2</sup>Inselspital University Hospital, Medical Radiation Physics and Radiation Oncology, Bern, Switzerland ; <sup>3</sup>Cotec AG, Clinical Research, Altstätten, Switzerland ; <sup>4</sup>Stadtspital Triemli, Radiation Oncology, Zurich, Switzerland

## Purpose or Objective

High density implants cause artefacts in CT and MRI which is problematic for the delineation process and dose calculation. The high density titanium implants are not properly accounted for in the dose calculation algorithms of the treatment planning system (TPS). This can result in an incorrect computation of the dose on TPS. Implants made from carbon fiber reinforced polyetheretherketone (CFR-PEEK) are radiolucent, non-magnetic and have a low density. Therefore, they do not produce artefacts and should be more compatible with the TPS algorithms. This study aims to assess the advantages of CFR PEEK vs. titanium implants in both photon and pencil beam scanning proton therapy (PT) for spinal treatment.

## Material and Methods

A unique phantom was developed with 4 interchangeable inserts at spine level Th 7-11: one reference case with a native spine and three with a spinal stabilization implant consisting of: titanium, CFR-PEEK and a hybrid composition of both materials. These 4 scenarios were irradiated with both proton and photon plans with a fraction dose of 2 Gy. A single field and a clinical scenario with 3 fields Intensity Modulated PT (IMPT) plan with spinal cord sparing were applied with protons. Static field plans and VMAT plans were created with the Varian Eclipse planning system and applied with a Varian linac with 6 MV photons. The severity of the artefacts was measured by size, contouring time and overlap with other structures. The delivered dose was measured with GafChromic films.

**Figure 1:** Design schematic of the interchangeable insert of the phantom. The 4 different inserts exist of: A native spine (case I), a full titanium implant (case II), an implant completely out of CFR-PEEK (case III) and a hybrid implant where the tulips are made of titanium (case IV).

## Results

The total volume of artefacts on CT was 390.6 cc, 174.2 cc and 33.9 cc for the titanium, hybrid and CFR-PEEK case respectively; with 7.5% of the spinal cord and 58.2% of the GTV affected by artefacts for the titanium while these structures were not affected in the CFR-PEEK cases. This resulted in a delineation time 4 times shorter for CFR-PEEK case (43.7 ± 36.5 min) compared to the titanium case (172.0 ± 111.6 min). The single field proton plans showed a large deviation of measured dose in the titanium containing cases. In the clinical plans this improved slightly, but cold spots still exceeded clinical acceptance levels of >5%. Photon plans showed the same effect for a single dorsal static field. The disturbance by titanium results in hot and cold spots with dose deviations up to 25% of the prescribed dose. The applied VMAT plans showed no detectable dose deviations compared to the reference case. The CFR-PEEK showed in all plans a result comparable to reference. The maximum deviation measured by GafChromic films with respect to the prescribed dose for all cases an both planning techniques are presented in Table I.

	Protons		Photons	
	Single field	3 field SC sparing	single field	VMAT SC sparing
Reference	4.4%	4.6%	5.5%	10.0%
Titanium	14%	10.8%	25.0%	10.0%
CFR-PEEK	4.0%	4.7%	7.0%	10.0%
Hybrid	17.5%	13.5%	11%	10.0%

**Table 1:** Represented is the maximum relative deviation of the prescribed dose as measured with the GafChromic films for the different plans. The single field plans and the 3 field and VMAT plan with spinal cord (SC) sparing for proton and photons respectively. Results of all the 4 phantom cases implant are presented.

## Conclusion

Whereas titanium leads to severe artefacts, prolonged planning time and incorrect dose calculations, use of CFR-PEEK implants solved all these issues. As such, CFR-PEEK implants should be used during the surgical procedure if adjuvant PT is considered for a patient.

### EP-1734 Dosimetric effects due to uncertainties in tissue segmentation for prostate cancer treatments

M. Krantz<sup>1</sup>, A. Lund<sup>1</sup>, R. Chakarova<sup>1,2</sup>

<sup>1</sup>Sahlgrenska University hospital, Department of Medical Physics and Biomedical Engineering- Sahlgrenska University Hospital- Gothenburg- Sweden, Gothenburg, Sweden ; <sup>2</sup>Sahlgrenska University hospital, Department of Radiation Physics- Sahlgrenska Academy at the University of Gothenburg- Sweden, Gothenburg, Sweden

#### Purpose or Objective

In a previous work, presence of gold markers, contrast in the bladder and rectum interpretation were identified as potential factors influencing tissue segmentation and causing discrepancies between dose distributions from the TPS and a Monte Carlo (MC) system [Phys Med 51 (2018) 32]. Thus, the objective of this work is to quantify dosimetric effects on the target dose determination due to uncertainties in tissue segmentation for prostate cancer treatments.

#### Material and Methods

CT scans of more than 200 consecutive VMAT plans for prostate cancer were reviewed. Three groups of plans were selected: (i) 18 plans with enhanced CT artifacts in the PTV due to presence of gold markers but no contrast in the bladder or visible air in the rectum as a part of the PTV; (ii) 15 plans with contrast in the bladder as a part of the PTV but no marker artifacts or air in the rectum in the PTV; (iii) 15 plans with air in the rectum as a part of the PTV but no contrast in the bladder in the PTV. Calculations were carried out by Eclipse™ TPS algorithms, AAA and Acuros XB (dose to medium ( $AXB_m$ )) and by an MC system (dose to water/medium ( $MC_w$ )/( $MC_m$ )) based on the EGSnrc. Dose distributions were obtained on the original CT scans as well as on the modified scans by setting HU to zero in the PTV, the bladder and the rectum for groups (i), (ii) and (iii), correspondingly. DVH estimates such as the mean dose to the CTV, PTV,  $D_{98\%}$  PTV and  $D_{2\%}$  PTV were compared to evaluate the effect of the various factors.

#### Results

The parameter  $D_{98\%}$  PTV was most sensitive to uncertainties in tissue segmentation, notably gold markers and air in the rectum. The maximum difference between AAA and  $MC_w$  was 2.8% (i) and 5.4% (ii) and between  $AXB_m$  and  $MC_m$  1.1% (i) and 4.5% (ii) (Figure 1). The variations were reduced to  $\pm 2.1\%$  when  $D_{98\%}$  PTV was determined on modified scans with HU=0 in the PTV or the rectum. A more detailed investigation showed that the TPS dose domination may be distributed in larger parts of the PTV volume with markers and visible CT artefacts (Figure 2). For group (ii), AAA may dominate locally, in the air part of the PTV, whereas the dose to the rest of the PTV may be lower compared to  $MC_w$ . In the case of contrast in the bladder, all DVH parameters showed similar results for calculations on original and modified CT scans. The median difference between AAA,  $AXB_m$ ,  $MC_w$  and  $MC_m$  estimations of the mean dose to the CTV and the PTV was within 0.5% for all cases. Mean dose deviations up to 2.4% were observed for individual plans.

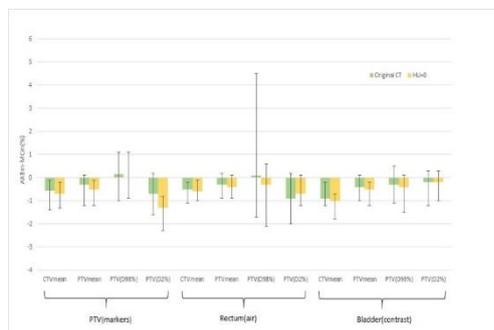

Figure 1. The median difference between DVH parameters estimated by  $AXB_m$  and  $MC_m$  for the three groups. Green bars - original scans, yellow bars - modified scans. Error bars; min-max variation of the difference.

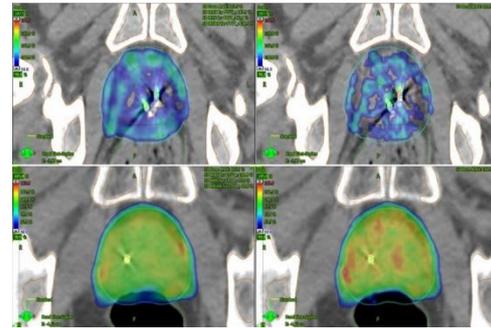

Figure 2. Dose distributions for selected plans from (i) and (ii). Color scale starts with 98%.

#### Conclusion

The presence of gold markers and inclusion of rectum air in the PTV may increase the variations in the  $D_{98\%}$  PTV estimation. However, no clinically relevant dosimetric effects were detected.

### EP-1735 Dosimetric verification of single isocenter VMAT for multiple brain metastases

E. Decabooter<sup>1</sup>, A. Swinnen<sup>1</sup>, R. Canters<sup>1</sup>

<sup>1</sup>Maastricht Radiation Oncology Maastrro, Physics Innovation, Maastricht, The Netherlands

#### Purpose or Objective

To verify the dose delivered by a single isocenter volumetric modulated arc therapy (VMAT) for stereotactic radiosurgery (SRS) of multiple brain metastases.

#### Material and Methods

Verification measurements were performed on single isocenter SRS plans of patients with 4-10 brain metastases treated on a Varian TrueBeamSTx. The 3x8Gy plans, calculated with Varian Eclipse treatment planning system (TPS) (Acuros version 15.5.11, 1mm grid size), consisted of 2 coplanar arcs and were normalized to deliver 100% of the prescription dose to all lesions.

Firstly, the dosimetric agreement between radiochromic EBT-XD film and the calculation by the TPS was investigated. Films were placed in an Alderson radiation therapy head phantom (ART-200) in 2 transverse planes both intersecting high dose regions. The phantom was positioned using a CBCT and 6 degrees of freedom (6D) couch. The film dosimetry measurement was analysed by Film QA pro software (Ashland) using the one-scan method with a dose threshold of 50% and a local gamma criterion of 2%, 2mm[1].

Secondly, to check the consistency of the film measurement, portal dose measurements were done by acquiring MV pre-treatment greyscale value images per field using a Varian aS1000 flat panel and converting them to full-scatter portal dose images using the dosimetric calibration model described in [2]. These measured portal dose images were converted to fluence and reconstructed to a 3D dose distribution in the CT data set. The evaluation was performed using a gamma criterion of 3%, 3mm.

#### Results

Comparison between film and calculation show a mean agreement of 96.3% for both measurement planes for all plans with 4-10 brain lesions. The gamma analysis of the reconstructed 3D dose distribution resulting from the portal dose measurements shows a mean agreement score of 99.7%.

#### Conclusion

We have found that both film as well as portal dose based dosimetry show comparable agreements with TPS

calculations. This study indicates that electronic portal imaging is suitable as a routine quality assurance tool for VMAT SRS for 4-10 brain metastasis using a single isocenter in combination with 6D couch.

#### EP-1736 Study VMAT modulation to predict DQA results and have an efficient DQA workflow

S. Chiavassa<sup>1</sup>, A. Moignier<sup>1</sup>, A. Batista Camejo<sup>1</sup>, M. Wahl<sup>1</sup>, G. Delpon<sup>1</sup>

<sup>1</sup>Institut de cancerologie de L'Ouest, physic department, Saint-Herblain, France

#### Purpose or Objective

For complex treatment such as VMAT, a patient-specific DQA (PS-DQA) is usually systematically performed. Debate is set up around the efficiency of controlling all plans. The goal of this study is to improve the efficiency and the workload of DQA for VMAT treatment using modulation indexes.

#### Material and Methods

Nine indexes have been studied considering 303 VMAT plans splitted in four groups (prostate, prostatic bed, female and male pelvis with lymph nodes). Each plan had DQA results based on  $\gamma$ -analysis (3%/3mm criteria and  $\gamma$  passing rate  $\gamma_{PR} \geq 95\%$ , PTW 2Darray and Octavius). First, correlation test between indexes and  $\gamma_{PR}$  (R from Spearman Test), ROC analysis (AUC) and sensitivity score with 100% specificity were performed. Simultaneously, a study aimed to identify the machine parameters (leaves gap (DLG), gantry angle, dose rate and leaves offset) impacting the delivery accuracy. Finally, the use of automated planning optimization was investigated to adapt the degree of modulation to the clinical requirements.

#### Results

Only two modulation indexes out of 9 (MCSv<sup>1</sup> and LOIC<sup>2</sup>) provide good results: the thresholds of MCSv=0.38 and LOIC=1.03% give R=0.44, AUC=0.73, sensitivity=36% and R=-0.52, AUC=0.79, sensitivity=33% respectively. Moreover, these indexes reflect the clinical plan complexity: mean values of MCSv/LOIC were 0.50±0.11/0.97±0.53%, 0.35±0.07/1.37±0.44%, 0.28±0.07/1.41±0.50% and 0.28±0.05/1.80±0.39% for prostate, prostatic bed, female and male pelvis with lymph nodes respectively. Therefore, DQA could be skipped for plans with indexes below the thresholds. For plans with indexes beyond the thresholds,  $\gamma_{PR}$  are scattered and not correlated with indexes. LOIC reflects the plan sensitivity to DLG. The machine parameter study happens to show that the dosimetric impact is maximal with DLG whereas negligible for other parameters within the machine tolerance. For plans with a high LOIC, results of single day PS-DQA would depend on the DLG, which parameter varies over time. Therefore, a systematic DQA for these plans could be efficiently replaced by a daily DLG QA.

Our TPS (RaystationV7) allows to create automated optimization standardizing processes and dosimetric objectives. Such a protocol was created for prostatic bed to limit optimization on femoral heads. Testing it on 10 plans, mean values of MCSv were increased from 0.33±0.05 to 0.47±0.04 and corresponding PS-DQA results were improved from 94.8±2.9% to 99.2±1.3%. Moreover, a TPS script calculates MCSv and LOIC during and after optimization process to manage the degree of modulation.

#### Conclusion

This study shows that systematic PS-DQA for VMAT is not useful for low-modulated plans and not efficient for high-modulated plans. A daily DLG QA should ensure the

dosimetric accuracy for the most sensitive plans. Moreover, the workflow can be improved by adapting the degree of modulation to the clinical requirements.

#### EP-1737 "End-to-end test" for setting up multiple brain metastases SRS

E. Graulieres<sup>1</sup>, S. Ken<sup>1</sup>, S. Kubler<sup>1</sup>, R. Ferrand<sup>1</sup>

<sup>1</sup>Institut Universitaire du Cancer de Toulouse - Oncopôle - Institut Claudius Regaud, Department of Engineering and Medical Physics, Toulouse, France

#### Purpose or Objective

Multiple brain metastases Stereotactic Radiosurgery (SRS) has proven its benefits over Whole Brain Radiotherapy for treating patients with a better prognosis<sup>1</sup>. SRS has become routine practice in a large number of centers thanks to advances in linear accelerators technology and dedicated software can now be used to treat Multiple Brain Metastases with one isocenter and several dynamic arcs. However, there are two major issues before setting up SRS for multiple brain metastases:

- How can we control the positioning for metastases that are at a certain distance from the isocenter?
- How can we realize dose quality assurance as targets are spread all over the brain?

We performed an "end-to-end test" at our center using an anthropomorphic brain phantom filled with polymer-based gel in order to realize a complete control with 3D dosimetry.

#### Material and Methods

An anthropomorphic brain phantom was 3D-printed and irradiated with the same treatment plan as the patient it was originated from. The phantom was scanned and images were exported into the treatment planning system Elements Multiple Brain Mets SRS (Brainlab). Six non-coplanar dynamic arc beams were placed to generate the single isocenter SRS plan to treat 5 metastases with the prescription dose of 9 Gy. Dose calculation was realized with a 1 mm resolution. This phantom was positioned on a linear accelerator TrueBeam (Varian) via the Brainlab ExacTrac imaging system and the six arc beams were delivered (Fig 1). After the treatment, 1 mm resolution multi-echo magnetic resonance images of this anthropomorphic phantom were acquired on a 1.5T system. MR images were remotely analyzed by RTsafe in order to provide profiles, 2D, 3D gamma index and Dose Volume Histogram (DVH) comparisons between measured and calculated dose distributions.

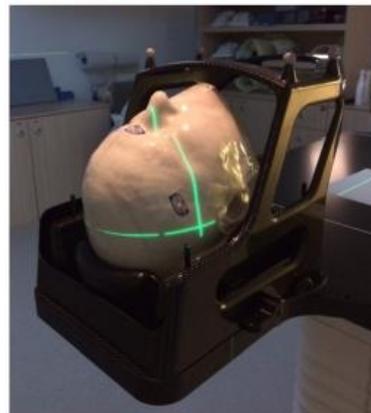

Figure 1: Anthropomorphic phantom positioned on the TrueBeam couch

#### Results

Plans comparison showed slightly narrower profiles of 1 mm at half maximum for measured dose (Fig 2). 2D gamma index calculations also showed a shift on the edge of the target when looking at the cartographies. The 3D gamma

index for 2 mm - 3% was over 97% for all the targets except for one which was at 94.7%. Measured DVHs showed a loss of dose coverage of 10% for targets when looking at 95% of volume.

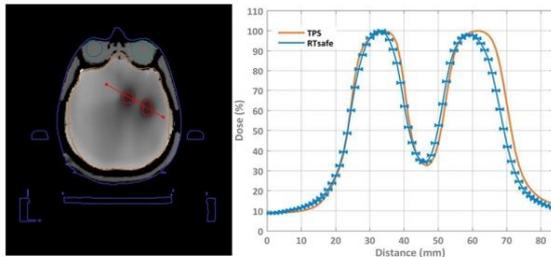

Figure 2: Profile of two targets (left). Superposition of calculated (TPS, in orange) and measured (RTSafe, in blue) profiles (right).

### Conclusion

The 3D gamma index passed the acceptance criteria. However, other data showed a slight underdosage and a slight dose distribution shift of all targets. Tests are still undergoing to understand the origin of these discrepancies. This study demonstrates the need to perform “end-to-end tests” before setting up complex treatments such as multiple brain metastases SRS.

### EP-1738 Validation of the electron Monte Carlo (eMC) algorithm in Eclipse 13.6

D. Kelly<sup>1</sup>, S. Meara<sup>2</sup>, K. Fogarty<sup>1</sup>, L. Gately<sup>1</sup>

<sup>1</sup>The Clatterbridge Cancer Centre NHS Foundation Trust, Medical Physics, Wirral, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Medical Physics, Manchester, United Kingdom

### Purpose or Objective

To commission and evaluate the eMC 13.6.23 algorithm in Eclipse. To replace the manual calculation of MU for electron treatments for a TrueBeam linac.

### Material and Methods

Beam models at 6, 9, 12 and 16 MeV were built using the Varian representative data for TrueBeam linacs, with calibration points on the PDDs derived from measured values. A block of water was simulated in Eclipse and used to compare to measurements taken in a water tank or phantom. Profiles, PDDs, absolute dosimetry, applicator factors, cut-out factors and stand-off factors were compared using this method.

20 patients, previously treated with manually calculated MU, were re-planned using eMC and the calculated monitor units compared.

End-to-end tests were performed at 12 and 16 MeV. This was to test the accuracy of the beam model in conditions where the previously treated patients had large differences in the number of MUs between eMC and manual calculation. A wax dome was used to test curvature (figure 1) whereas stacked sheets of different density material (plastic, wood, cork and solid water) tested inhomogeneity.

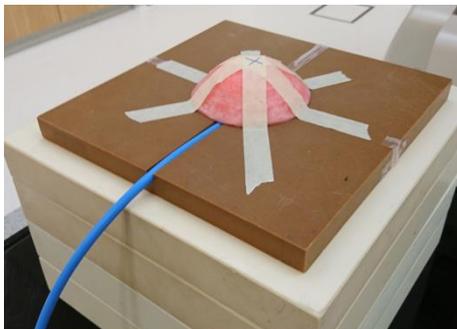

Figure 1 - Wax dome setup with Roos chamber for end-to-end test of curvature.

In-vivo skin surface measurements are performed at first fraction of treatment using TLDs according to local standard protocol. A retrospective audit of these measurements was performed to compare agreement to the predicted dose between manually and eMC calculated plans.

### Results

The profiles and PDDs were compared using the Venselaar criteria [1]. All were acceptable but approach tolerance close to surface, where Eclipse systematically overestimates the dose in the first 1-5 mm by up to 3%. The doses to a point in reference conditions matched to  $\pm 0.8\%$ . Applicator factors agreed to  $\pm 1.2\%$ . Cut-out factors agreed to  $\pm 1.9\%$ . Stand-off factors agreed to  $\pm 1.4\%$ .

The average difference between eMC and the manually calculated MU for the previously treated patients was 6.2% with a maximum difference of 14.7%. Patients with large differences had significant curvature and/or inhomogeneity, hence the need for the end-to-end tests. Eclipse calculated doses matched Roos measurements underneath the wax dome to  $\pm 2.0\%$  and TLD measurements at various points underneath the dome to  $\pm 0.7\%$ . The inhomogeneity measurements agreed to  $\pm 3.3\%$  with the plastic sheet and to  $\pm 0.9\%$  in all combinations without the plastic sheet. A CT artefact in the plastic contributed to the poorer result when the plastic sheet was included.

The results of the TLD audit are shown in figure 2. All measurements so far are within the local tolerance level of  $\pm 5\%$ .

Figure 2 - TLD audit results showing the difference between measured and predicted doses.

### Conclusion

All tests performed to validate the eMC beam model had satisfactory results, including in non-standard conditions. For some patients the eMC calculated MUs are significantly different to previous manual calculation. Patients planned using eMC in Eclipse have shown good agreement with skin dose TLD measurements.

### EP-1739 Indicators evaluation for robust dose prescription in SBRT of peripheral non-small cell lung cancer

G. Beldjoudi<sup>1</sup>, V. Bernard<sup>2</sup>, R. Tanguy<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiotherapy, LYON, France ;

<sup>2</sup>ORLAM, Radiothérapie, Lyon, France

### Purpose or Objective

Lung SBRT is a well-established alternative to surgery for inoperable early stage lung cancers. In our center, small peripheral lesions are mainly treated on a Cyberknife (CK) device at a dose of 3x18Gy (RTOG0236 study) usually prescribed on the isodose 80% with a type A algorithm (RayTracing [RT]). However, ESTRO ACROP recommendations are to use type B or type C algorithms when calculating doses in situations of small lesions surrounded by low density tissues and to prescribe 3x15Gy to D<sub>95-99%</sub>PTV. Nevertheless, these recommendations do not

question the usefulness of changing the volume of interest (PTV or GTV) for dose prescription as suggested by Lacornerie et al. (2004). The purpose of our study is to define a method that ensures robustness when prescribing dose using a MonteCarlo [MC] algorithm.

#### Material and Methods

Treatment plans of 30 patients were recalculated from RT algorithm to MC algorithm and three different indicators to prescribe dose were studied:  $D_{95\%PTV}$  (ESTRO ACROP),  $D_{50\%GTV}$  (Lacornerie et al.) and  $D_{98\%GTV}$  ( $D_{near-minGTV}$ ). On these indicators, overall doses prescription deviations were analyzed in function of tumor volume. Dose ratios to the indicator between MC and RT were calculated as it reflects the dose degradation. In a second part, using the same data, a prescription of  $3 \times 15\text{Gy}$  to  $D_{95\%PTV}$ , as recommended by ESTRO ACROP, with MC algorithm is calculated and the doses to the three indicators are compared to the ones determined in the first part.

#### Results

When prescribing  $D_{95\%PTV}=54\text{Gy}$  with a type A algorithm, doses to  $D_{95\%PTV}$ ,  $D_{50\%GTV}$  and  $D_{98\%GTV}$  with a MC algorithms are respectively, for  $GTV \leq 10\text{cm}^3$  (21 patients)  $41.3 \pm 3.2\text{Gy}$ ,  $53.8 \pm 3.5\text{Gy}$  and  $49.1 \pm 3.0\text{Gy}$  and when  $GTV > 10\text{cm}^3$  (9 patients)  $43.7 \pm 3.5\text{Gy}$ ,  $56.2 \pm 1.5\text{Gy}$  and  $50.2 \pm 1.7\text{Gy}$ .

Mean dose ratio between MC and RT algorithms are respectively  $77.4 \pm 6.1\%$ ,  $86.8 \pm 4.2\%$  and  $84.6 \pm 4.1\%$ . Prescribing doses of  $3 \times 15\text{Gy}$  to  $D_{95\%PTV}$  with a MC algorithm results, for  $GTV \leq 10\text{cm}^3$ , in doses to  $D_{95\%PTV}$ ,  $D_{50\%GTV}$  and  $D_{98\%GTV}$  of respectively  $45\text{Gy}$ ,  $58.7 \pm 2.6\text{Gy}$  and  $53.6 \pm 2.0\text{Gy}$  and for  $GTV > 10\text{cm}^3$  to  $45\text{Gy}$ ,  $58.2 \pm 4.0\text{Gy}$  and  $51.9 \pm 3.1\text{Gy}$ . Thus, following ESTRO ACROP prescription results in a dose increase to each indicator, for  $GTV \leq 10\text{cm}^3$  of respectively  $8.2$ ,  $8.3$  and  $8.4\%$  and for  $GTV > 10\text{cm}^3$  of  $2.9$ ,  $3.4$  and  $3.3\%$ .

#### Conclusion

Despite ESTRO ACROP recommendation, it has been shown in this study that  $D_{95\%PTV}$  is not a robust indicator to prescribe dose as, for a unique dose prescription, large doses fluctuations received by the tumors are observed depending on their volume: doses of  $3 \times 18\text{Gy}$  ( $GTV \leq 10\text{cm}^3$ ) and of  $3 \times 17\text{Gy}$  ( $10\text{cm}^3 < GTV < 20\text{cm}^3$ ) are obtained to  $D_{98\%GTV}$  when prescribing a unique dose of  $3 \times 15\text{Gy}$  to  $D_{95\%PTV}$ .  $D_{50\%GTV}$  indicator appears as the most robust indicator with the tumor volume, but it is not relevant to visually evaluate a treatment plan by looking at this criteria.  $D_{98\%GTV}$  indicator represents a good tradeoff between prescription robustness and clinical meaning as it represents the near-minimum dose the target.

**EP-1740 GLAaS absolute dose calibration for EPID on Halcyon: from algorithm validation to multi-center QA**  
G. Nicolini<sup>1</sup>, D. Nguyen<sup>2</sup>, C. Marais<sup>3</sup>, D. Lojko<sup>4</sup>, E. Vanetti<sup>1</sup>  
<sup>1</sup>Radiqa Developments, Medical Physics Team, Bellinzona, Switzerland ; <sup>2</sup>Groupe ORLAM, Service de Radiothérapie, Mâcon, France ; <sup>3</sup>Busamed Hillcrest Oncology Centre, Yenzakahle Consulting, Durban, South Africa ; <sup>4</sup>Nemocnica Komárno, Radiotherapy Department, Komárno, Slovakia

#### Purpose or Objective

The introduction of very recent technologies in clinical practice could require a more demanding QA program to guarantee safe treatments. In case of IMRT/VMAT treatments, a robust pre-treatment patient specific verification is a key-point. Amorphous silicon EPID technologies are particularly interesting since a very efficient timing solution is combined with high spatial resolution, large area, stability, dynamic range, and real-time acquisition capabilities.

Limited to standard C-arm linacs, the GLAaS algorithm (MedPhys 2006) has proved capable to meet a variety of applications with a simple direct calibration process to convert EPID raw readings into absorbed-dose-to-water. The purpose of this study was to verify the applicability of

the GLAaS principles to a new delivery system, Varian Halcyon, a 6FFF linac mounted on an O-ring gantry, equipped with a dual-layer stacked MLC with an effective shaping capability of 5mm at isocenter.

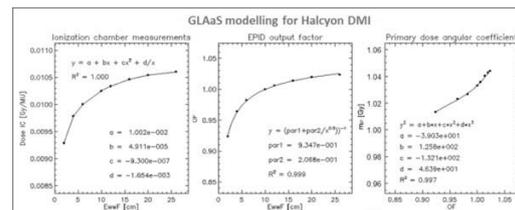

#### Material and Methods

Dosimetric data from 3 institutes were collected at dmax for primary and transmitted radiation to be correlated with Halcyon digital megavoltage imager (DMI) signal: pixel-by-pixel response changes were modelled on time basis, differentiating on segment sizes and beam quality, i.e. primary or below MLC radiation. The satisfactory GLAaS algorithm configuration allowed pre-treatment QA verifications in all the centers. For 3 different sites (prostate, head-and-neck and breast), each center pooled 5 patients from its own database to be acquired with DMI and other QA devices locally available (ArcCHECK, MapCHECK, Octavius, ion chamber point dose). For all centers, DMI images were analysed versus TPS dose water matrices with GLAaS algorithm and predicted fluences with Varian Portal Dosimetry (VPD).

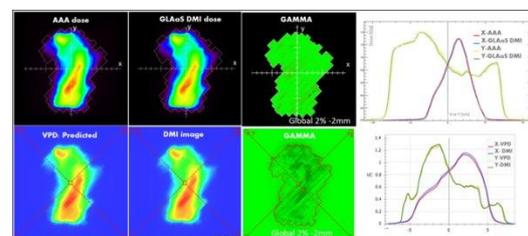

Among the previous 45 plans, a sub-set of 6 was shared among all to investigate the single machine delivery behavior respect to calculation based on the same pre-configured and not customizable beam modelling (Varian AAA dose algorithm).

#### Results

Adapting the GLAaS principles to Halcyon technology, it was possible to conveniently model the DMI dose response. Although in the CIAO area the global result is mainly affected by primary radiation modelling (ima1) due to the low MLC transmission (0.5% per layer), a dedicate model for transmission guarantees a more robust and accurate evaluation of the measured dose.

Overall, pre-treatment QA was fully satisfactory, with differences in terms of specific results depending on the devices; in case of DMI images, the gamma agreement index (GAI) was greater in comparison versus predicted /VPD than versus calculated /GLAaS doses (e.g GAI for 3%-3mm: global VPD>99% vs GLAaS>97%, local VPD>98% vs GLAaS>92%).

#### Conclusion

The extension of GLAaS to Halcyon offers the opportunity to easily set-up flexible and reliable verification, allowing a straight but independent comparison between EPID measurements and TPS water dose maps.

#### EP-1741 Evaluation of the application of NIPAM gel dosimeter to quantify dynamic dose effects

J.C. Sun<sup>1,2</sup>, Y.W. Tsang<sup>1</sup>, B.T. Hsieh<sup>2</sup>, K.Y. Cheng<sup>2</sup>  
<sup>1</sup>Department of Radiation Oncology, Chia-Yi Christian hospital, Chiayi City, Taiwan ; <sup>2</sup>Department of Medical

*Imaging and Radiological Sciences, Central Taiwan University of Science and Technology, Taichung, Taiwan*

#### Purpose or Objective

To evaluate the feasibility of N-isopropylacrylamide (NIPAM) polymer gel dosimeter in combination with MRI (magnetic resonance imaging) on dynamic dose distribution.

#### Material and Methods

The gel preparation was prepared with a composition of 5% NIPAM monomer, 5% gelatin and 3% BIS. 5 mM THPC was added to the solution to reduce the oxygen content and to improve sensitivity and reproducibility. The test treatment plan was a 4x5 cm<sup>2</sup> single-field treatment plan created using the Eclipse treatment planning system with an exposure angle of 180. A cylindrical acrylic model and a dynamic phantom were then selected to simulate the moving target with a motion period of 4 seconds and a range of 2 cm. The gel was irradiated with 0, 1, 2, 5, 8 and 10 Gy absorbed doses using a Varian iX linac with 6 MV X-rays. After the polymerization was completed, a slice image of the gel was extracted using a GE 1.5 Tesla MRI scanner. The slice images were analyzed using MATLAB and the results of the gamma test ( $\gamma$ -test) were performed on the treatment planning system and the NIPAM gel dosimeter. Since the estimated dynamic dose distribution is reduced, 4x4 and 4x3 cm<sup>2</sup> treatment plan are made to perform the gamma test together and the passing rate is evaluated.

#### Results

The gel results were compared to the 4x5, 4x4, and 4x3 cm<sup>2</sup> treatment plans. To verify the dose, the gamma-test was performed according to the gamma standards of 3% and 3 mm. The comparison results showed that the passing rates in the coronal section images were 60.76%, 95.07%, and 50.02%, respectively. Further analysis found that the dynamic dose distribution was the closest to the 4x4 cm<sup>2</sup> result and the highest passing rate. Shows that the dynamic dose distribution range is reduced, and the reduction range is 50% of the motion range.

#### Conclusion

The results demonstrate that it is feasible to validate the dynamic dose distribution using NIPAM gel and MRI scanners, and the dynamic dose range can be quantified by evaluating dynamic effects. In this study, the gel dosage and dynamic phantom simulate the breathing state of the human body, and the real situation is more complicated. It is recommended that future research can evaluate more types of treatment plans and design more impact parameters, such as: motion period and range, and get more careful assessment of dynamic effects, which can provide a more precise definition of treatment margin.

#### EP-1742 In vivo EPID dosimetry for prostate cancer treatments with an endorectal balloon

M. Wendling<sup>1</sup>, B. Sterckx<sup>1</sup>, I. Steinseifer<sup>1</sup>

<sup>1</sup>Radboud university medical center, Radiotherapy, Nijmegen, The Netherlands

#### Purpose or Objective

*In vivo* dose verification is an ideal QA method, because the dose distribution is verified during the actual treatment and no additional time for a pre-treatment measurement is needed. The commercial solution iViewDose (Elekta, Crawley, UK) offers EPID-based *in vivo* dose verification and has been proven for various treatment sites. Because large tissue inhomogeneities are not accurately handled by the algorithm, *in vivo* dose verification of lung cancer treatments is done “*in aqua*”, i.e. before dose reconstruction the images are first converted to a situation as if the patient consisted entirely of water [“*In aqua vivo* EPID dosimetry,” Med. Phys. 39, 367-377, 2012]. In this study we demonstrate that the *in aqua* method also leads to improvements in the verification of prostate cancer treatments, in case an air-

filled endorectal balloon is used to spare part of the rectal wall.

#### Material and Methods

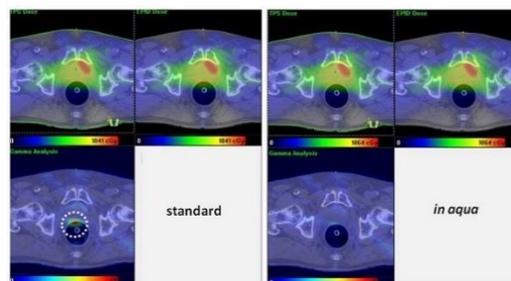

Six clinical hypo-fractionated prostate cancer treatments (5 x 7 Gy to the prostate with/without seminal vesicles, 5 x 10 Gy to the dominant intraprostatic lesion) were investigated. Treatment planning was done in Pinnacle (version 9.10, Philips, Fitchburg, WI, USA) using auto-planning with 2 VMAT arcs of 10 MV photons. Before treatment, the plans were verified with a pre-treatment measurement on a Delta4 phantom; all plans fulfilled our clinical gamma-criterion, i.e. 95% of the measured points within the 50% isodose surface were within 3%/3mm.

After position verification with cone-beam CT and correction for translational errors, the patients were treated and EPID dose measurements were done *in vivo* (3 to 4 fractions per patient were measured). The measured dose distributions were compared “as such” to the clinical plan and also *in aqua* to the *in aqua* plan, i.e. with a density override equal to 1 on the whole CT dataset.

#### Results

In the figure the TPS dose, the EPID-reconstructed dose and the gamma analysis are shown for both the standard EPID-based dose reconstruction and for the *in aqua* method. With the standard reconstruction and comparison, the disagreement in the region of the endorectal balloon can clearly be seen in the gamma analysis (white dotted circle). This is due to the large density inhomogeneity caused by the endorectal balloon. The agreement improves considerably, when the *in aqua* method is used.

On average (over fractions and patients) the percentage of points in agreement within the 50% isodose surface improves from 91%±2% (1SD) to 98%±2% for the clinical plan and the *in aqua* plan, respectively. The mean gamma improves from 0.46±0.05 to 0.36±0.05, respectively.

#### Conclusion

Although originally developed for lung cancer treatments, the *in aqua* method for EPID dosimetry also works as a correction for other large density inhomogeneities. EPID-based dose verification with iViewDose can therefore be used for *in vivo* dose verification of prostate cancer treatments with an endorectal balloon.

#### EP-1743 Dosimeter selection for small field percentage depth dose and tissue maximum ratio measurements

S. Crowe<sup>1,2</sup>, E. Whittle<sup>2</sup>, C. Jones<sup>3</sup>, K. Tanya<sup>1,2</sup>

<sup>1</sup>Royal Brisbane and Women's Hospital, Cancer Care Services, Herston, Australia ; <sup>2</sup>Queensland University of Technology, Science and Engineering Faculty, Brisbane, Australia ; <sup>3</sup>Princess Alexandra Hospital, Radiation Oncology, Brisbane, Australia

#### Purpose or Objective

The measurement of small field tissue-maximum ratio (TMR) and percentage depth dose (PDD) data is necessary for the calculation of dose for stereotactic radiotherapy treatments. The measurement of beam configuration data, including TMRs and PDDs, is complicated by a loss of lateral charged particle equilibrium in small fields and

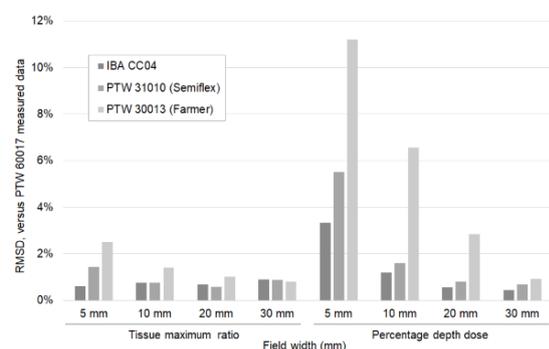

volume averaging effects. For this reason, various small-field-suitable dosimeters (e.g. diodes, scintillators) are recommended in the literature in place of the large ionisation chambers typically used for beam configuration data measurements in larger fields. The objective of this study was to evaluate whether relatively large volume ionisation chambers, that are unsuitable for other small field applications, might be used for accurate TMR or PDD measurements.

#### Material and Methods

PDD and TMR measurements were performed in an IBA BluePhantom 3D water tank with 100 cm source-to-surface distance and 100 cm source-to-detector distance, respectively; using four dosimeters: PTW 60017 (Diode E), IBA CC04, PTW 31010 (Semiflex) and PTW 30013 (Farmer); with active volumes of 0.00003, 0.04, 0.125 and 0.6 cc. Data was acquired for four field sizes (0.5×0.5, 1×1, 2×2 and 3×3 cm<sup>2</sup>) produced using an Elekta linear accelerator. Lateral scans were repeated for each field size to verify the positioning of the dosimeter in the centre of the field. Dose was measured to depths of 25 cm. Measurement data was resampled to a resolution of 0.5 mm, where necessary, and smoothed with a mean filter with a 2 mm window. Root-mean-square deviations (RMSD) were calculated between diode measurements (the "gold standard" data) and measurements acquired using the other dosimeters.

#### Results

PDD and TPR measurement data varied with detector volume (see figure). The largest disagreement in PDD profiles existed between the PTW 60017 diode and PTW 30013 chamber measurements at the smallest field size, with an RMSD of 11.2%. The corresponding RMSD for TMR data was 2.5%. The impact of a larger active volume is reduced when measuring TMRs, where the field size varies minimally with depth.

#### Conclusion

The results indicate that accurate TPR measurements may be obtained using dosimeters otherwise considered unsuitable for small field applications. While the PTW 30013 is not suitable for small field dosimetry, it provides a useful example of how TMR measurements are less sensitive to the active volume of the dosimeter than PDD measurements. If small-field-suitable dosimeters are unavailable, TMR measurements may provide more accurate beam characterisation data than PDD measurements.

#### EP-1744 Enhancing the accuracy in VMAT dose verification by the use of EPID-based commercial software

Y. Md Radzi<sup>1</sup>, R.S. Windle<sup>2</sup>, G.D. Lewis<sup>2</sup>, E. Spezi<sup>3</sup>  
<sup>1</sup>Universiti Sains Malaysia, School of Physics, Penang, Malaysia ; <sup>2</sup>Velindre Cancer Centre, Department of Medical Physics, Cardiff, United Kingdom ; <sup>3</sup>Cardiff University, School of Physics, Cardiff, United Kingdom

#### Purpose or Objective

Advanced radiotherapy dose verification using an EPID-based method such as a commercial software, Dosimetry Check (DC) has been extensively highlighted in recent years and its validity in verifying dose has become the major topic of interest in avoiding dosimetric errors [1-4]. In this work, we emphasised on the implementation of the commercial available DC [5-6] dose reconstruction system to address the significant of nonuniform backscatter effect from the Varian aS1000 EPID arm [4-5] to clinical VMAT pretreatment Head-and-Neck.

#### Material and Methods

The feasibility of applying the developed backscatter correction method [7] to a clinical VMAT Head-and-Neck case was investigated. A phantom was used with an optimised VMAT irradiation beams and all plans were calculated in local TPS. The assessment included, i) improvement of the beam profiles along in-line direction for dose reconstructed by DC, ii) pass-rate of the gamma criteria of 3%/5mm and 3%/3mm and iii) pass rate for gamma volume index.

#### Results

By using the correction method, an average percentage difference for DC dose relative to TPS dose improved from 4.2% to 1.7% in the in-line profiles (Fig.1). For gamma evaluation of 3%/5mm calculated in DC, about 95% and 97% of points passing gamma at coronal and sagittal planes respectively whereas more than 85% of points passing gamma for 3%/3mm gamma criterion at both planes. Gamma volume index calculated by DC for a ROI outlined within the Head-and-Neck phantom also improved from 73% before correction to 87% after correction and from 89% to 95% for a 3%/3mm and 3%/5mm gamma criterion respectively (Table1).

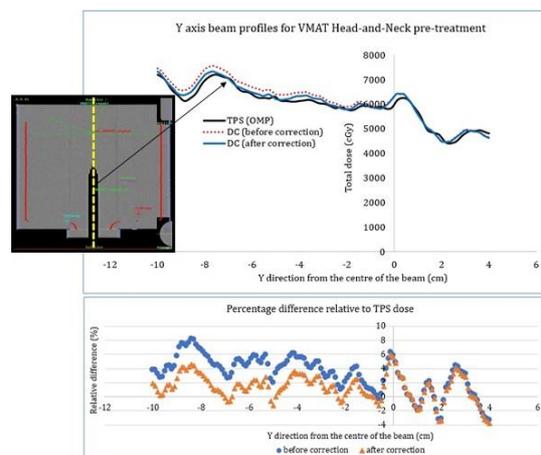

Fig. 1

VMAT Head-and-Neck pre-treatment plane	Gamma criteria pass rate (%)			
	3%/3mm		3%/5mm	
	Before	After	Before	After
Coronal	69.63	86.47	84.33	95.25
Sagittal	75.16	90.02	87.84	97.12
Average	72.40	<b>88.36</b>	86.09	<b>96.19</b>
Gamma criteria	Cumulative Gamma Volume index on ROI			
	Before correction		After correction	
	3%3mm	72.62%	3%5mm	87.03%
	88.52%		95.42%	

Table 1

#### Conclusion

This 'proof-of-concept' of the novel correction shown to give benefit to pretreatment VMAT verification techniques especially to critical plan such as Head-and-Neck using DC as a dosimetric verification tool. Ultimately, the software

effectively reduces verification inaccuracy caused by backscatter from the affected Varian EPID arm.

#### EP-1745 Performance of ArcCHECK based quality assurance in helical tomotherapy with TomoEdge technology

B. Yang<sup>1</sup>, H. Geng<sup>1</sup>, W.W. Lam<sup>1</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>  
<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China

#### Purpose or Objective

As a useful 3D quality assurance (QA) tool, ArcCHECK has gained wide application in helical tomotherapy (HT), but most of the studies were based on old models. This study is to report our experience in ArcCHECK based QA for HT with TomoEdge technique including the establishment of the action level.

#### Material and Methods

A total number of 303 clinical plans in different treatment regions in our hospital were retrospectively studied. The tomotherapy plan verification was conducted using the ArcCHECK diode array with an acrylic insert for placing an A1SL ionization chamber. DQA plans were created by situating the target at the center of ArcCHECK for point dose measurement and meanwhile, making sure the electronic part of the device was not under the main beam. Gamma analysis method was then used to quantitatively compare the dose measured by ArcCHECK and that calculated from the treatment planning system (TPS). The criteria of 3mm distance to agreement (DTA), 3% dose difference, 10% threshold and absolute dose comparison were chosen. According to AAPM TG 119, the recommended action level of gamma passing rate was calculated as  $AL = Gm - 1.96\sigma$ , where  $Gm$  was the mean of the gamma passing rate and  $\sigma$  was the standard deviation (SD).

#### Results

Details of our data are shown in table 1. A value pitch of 0.287 was used for almost all cases except for some brain treatments with values of 0.143 and 0.215. Jaw width of 2.5cm and 5cm with dynamic technique took up 95.7% of total cases and only fixed setting was used for 1cm jaw width. Good point dose agreements between measurements and TPS data were obtained with a mean deviation of 0.75%. Absolute gamma comparison gave an averaged passing rate of 96.6% with the SD of 4.7%, which resulted in an action level of 87.4%. Cases with lower gamma passing rate appeared to be in thorax and abdomen regions, which were suspected to be related to high MF and off-axis induced diode over-response. Our limited data showed that the gamma passing rate could be larger than 92% after a new DQA plan was created by locating the ArcCHECK close to the isocenter.

Table 1. Plan parameters for different treatment regions including planned actual MF, couch speed, proportion of different jaw widths, pitch value, measured point dose deviation and gamma passing rate.

Ta Region	No. of cases	Planned MF	Actual MF	Couch Speed (mm/s)	Proportion of Jaw Width (cm)			Pitch	Point Dose Deviation (%)	Gamma Passing Rate (%)
					103	2.5/5/0	5/0			
Abdomen	40	2.8128.51	2.96120.37	0.42710.213	2.5%	79.0%	22.3%	0.287	0.8720.08	96.1(67.5-100)
Breast/Chest Wall	47	3.5710.56	2.96350.29	0.60610.186	0.0%	42.4%	57.4%	0.287	1.0000.00	96.8(85.1-100)
Proba	52	2.7610.51	2.1770.39	0.60710.143	2.0%	86.3%	11.8%	0.287	0.9811.03	97.2(88.1-100)
Head/Neck	62	3.320.47	2.29120.30	0.99710.217	6.5%	93.3%	0.0%	0.287	0.7612.27	97.5(85.9-100)

Brain	27	2.7620.80	2.13220.67	0.84120.215	22.2%	74.1%	3.7%	0.287(0.875)	0.4751.16	97.6(84.6-100)
Abdomen-Proba	9	2.8510.44	2.16910.33	0.51810.106	0.0%	77.8%	22.2%	0.287	1.1211.24	97.0(80.1-99.9)
Thoran-Abdomen	11	2.8710.50	2.80310.29	0.53110.190	0.0%	63.6%	36.4%	0.287	0.6110.78	96.9(86.8-100)
Spine	3	2.2201.18	1.8810.87	1.04710.008	0.0%	0.0%	100.0%	0.287	0.8810.37	94.8(89.4-99.5)
Overall	303	3.010.59	2.15310.38	0.67710.300	4.3%	77.9%	17.8%	0.287(0.875)	0.7311.08	96.6(4.7)

#### Conclusion

The clinical action level of treatment plan verification using absolute gamma comparison can be established at 87.4% with 95% confidence level. High MF values and large off-axis setup might be the possible reason for low absolute gamma passing rate in some cases.

#### EP-1746 GLAaS absolute dose calibration for iViewGT EPID with flat and FFF beams: multicenter experience

E. Vanetti de Palma<sup>1</sup>, J.M. Perez<sup>2</sup>, S. Ren Kaiser<sup>3</sup>, G. Nicolini<sup>1</sup>

<sup>1</sup>Radiqa Developments, Medical Physics Team, Bellinzona, Switzerland; <sup>2</sup>Hospital Universitario HM Puerta del Sur, Servicio de Radiofísica, Móstoles - Madrid, Spain; <sup>3</sup>Fondazione Poliambulanza Istituto Ospedaliero, Servizio di Fisica Sanitaria, Brescia, Italy

#### Purpose or Objective

Intensity modulation radiotherapy requires the implementation of adequate pre-treatment QA programs to guarantee safe treatments. Amorphous silicon EPIDs are particularly suitable for this task, due to their main characteristics: high spatial resolution, large area, stability, dynamic range and real-time acquisition. The GLAaS algorithm showed to adapt to a variety of applications with a simple direct calibration process to convert raw detector readings into absorbed-dose-to-water; nevertheless, up to now GLAaS validations were limited to Varian EPIDs technology. To test its feasibility out of single manufacturer environment, in this study GLAaS algorithm was applied to Elekta iViewGT images, using both flat and FFF beams.

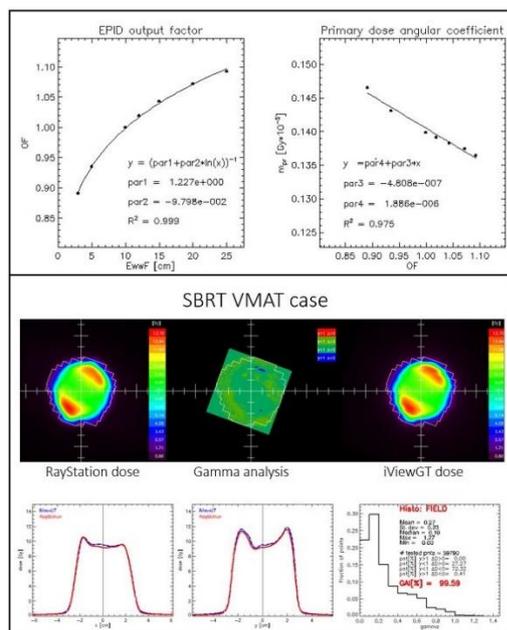

#### Material and Methods

Dosimetric data for 6MV, 10MV, 6FFF and 10FFF beams, delivered from 2 Elekta linacs both equipped with FFF (Synergy and Versa HD) belonging to 2 different institutes, were collected at maximum dose depth. Primary and transmitted radiation were correlated with iViewGT pixel reading and GLAaS algorithm was configured for both flattened and unflattened beams. For open and modulated fields, comparison respect to TPS dose maps (Monaco-MonteCarlo, RayStation-Collapsed Cone) was assessed through profiles and gamma analysis (local and global dose normalization criteria). Concerning modulated fields, 15 IMRT/VMAT plans were pooled from the clinical database of each institute, according to the following stratification: 5 breast, 5 H&N and 5 SBRT cases.

#### Results

As already observed for Varian EPIDs, the response of iViewGT was confirmed linear. Similarly, pixel-by-pixel response changes in time differentiating on field and/or segment sizes and beam quality basis, i.e. primary or transmitted through MLC radiation component, were properly modelled. FFF beams operated at high dose-rates showed saturation effect of the detector: in order to overcome such behaviour, attenuators were placed on the detector front cover during irradiation.

The satisfactory GLAaS algorithm configuration for both the linac models allowed pre-treatment QA in a variety of cases, IMRT and VMAT, flat and FFF beams, small and large fields. Analysis performed in field area showed an average gamma agreement index > 95% (global 3%-3mm) and > 90% (local 3% - 3mm).

### Conclusion

GLAaS algorithm application to iViewGT EPID is a smart tool to easily set-up flexible and reliable pre-treatment verification QA. Moreover, the high resolution of the EPID is of interest in highly demanding conditions such as in SRS/SBRT treatments and/or complicate fluence patterns. Indeed, the GLAaS approach allows a straight comparison between EPID measurements and TPS water dose maps (calculated with the same algorithm used clinically for the patient). The GLAaS compatibility with the two main EPID manufacturers could offer a valid measurement tool in multicentric studies dealing with treatment delivery and dose calculation aspects.

### EP-1747 In vivo dosimetry with electronic portal imaging device in VMAT for prostate cancer

S. Inui<sup>1</sup>, Y. Ueda<sup>1</sup>, S. Ono<sup>1</sup>, S. Ohira<sup>1</sup>, M. Isono<sup>1</sup>, Y. Nitta<sup>1</sup>, S. Murata<sup>1</sup>, M. Miyazaki<sup>1</sup>, T. Teshima<sup>1</sup>  
<sup>1</sup>Osaka International Cancer Institute, Radiation Oncology, Osaka, Japan

#### Purpose or Objective

This study aimed to identify inhomogeneity regions such as those with rectal gas during volumetric modulated arc therapy (VMAT) by using electronic portal imaging device (EPID)-based *in vivo* dosimetry (IVD).

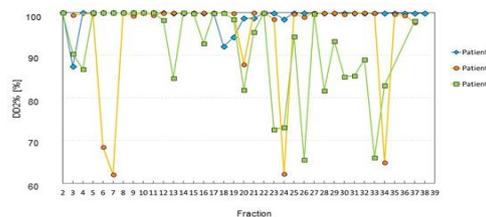

#### Material and Methods

All measurements were performed using TrueBeam STx system (Varian Medical Systems) by determining the radiation fluence using an EPID and analysed using PerFRACTION (version 1.7.3, SunNuclear) commercial software. Two phantom studies were performed to assess EPID-based IVD in prostate cancer patients. The anthropomorphic phantom was correct setup and irradiated while radiation fluence data were captured using EPID images. Systematic setup errors were simulated by moving this phantom 1, 3, and 5 mm in each translational direction. In the cube phantom attached to the Quasar phantom (Modus Medical), single-arc VMAT plan was used for baseline measurements after correct setup. An air cavity of 12 (2 × 2 × 3) cm<sup>3</sup> and 48 (4 × 4 × 3) cm<sup>3</sup> was created 1 cm below the center of the cube phantom. The presence of small and large air cavities was controlled by moving the Quasar phantom after single-arc VMAT quarter (T<sub>25%</sub>), half (T<sub>50%</sub>), and three quarter times (T<sub>75%</sub>). A complete air cavity (T<sub>0%</sub>) was also measured. From April 2017 to May 2018, 30 prostate cancer patients [median age: 76 (64-81)] received EPID-based IVD during

single-arc VMAT in our institute. X-ray images after the treatment of 16 patients were acquired to confirm the presence of rectal gas via offline reviews (Varian Medical Systems).

### Results

In the phantom study, no systematic setup error was detected. The 2% dose difference (DD2%) in small and large air cavities were 75.62% and 58.11%, 92.79% and 62.63%, 93.19% and 72.64%, and 99.40% and 80.71%, respectively, in the appearance of the air cavity after T<sub>0%</sub>, T<sub>25%</sub>, T<sub>50%</sub>, and T<sub>75%</sub>. The mean rectal diameter was 3 cm, which was between the sizes of the large and small air cavities in the phantom studies. We decided to assess the occurrence of rectal gas for DD2% < 90% in the clinical study by calculating the mean values of T<sub>75%</sub> in the large and small air cavities. In the clinical study, some fractions caused a sharp decline in the DD2% pass rate (Figure 1). The amount of DD2% < 90% was almost as same as that of the fraction confirmed with a rectum full of rectal gas (Table 1). The average DD2% values of the fractions with an empty rectum and a rectum full of rectal gas after irradiation were 96.12% and 86.13%, respectively.

	Fraction (%)
All patients (n=30, 1102 fractions)	
DD2% ≥ 90%	961 (87.21)
DD2% < 90%	141 (12.79)
Patients confirmed rectal gas after VMAT (n=16, 589 fractions)	
Empty rectum	524 (88.96)
Rectum full of rectal gas	65 (11.04)

### Conclusion

This study suggests that EPID-based IVD is better for the identifying of inhomogeneity regions such as those with rectal gas than for detecting systematic setup errors in VMAT for prostate cancer patients. There is a high possibility that rectal gas may occur in ~13% of the fractions in the clinical study.

### EP-1748 Adaptive solution for an improved treatment verification using Dosimetry Check system

Y. Md Radzi<sup>1</sup>, R.S. Windle<sup>2</sup>, D.G. Lewis<sup>2</sup>, E. Spezi<sup>3</sup>  
<sup>1</sup>Universiti Sains Malaysia, School of Physics, Penang, Malaysia ; <sup>2</sup>Velindre Cancer Centre, Department of Medical Physics, Cardiff, United Kingdom ; <sup>3</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

#### Purpose or Objective

Advanced radiotherapy such as IMRT and VMAT require an accurate and precise QA dose verification to avoid dosimetric errors [1-2]. In recent years, the use of one of the commercially available EPID-based method such as Dosimetry Check (DC) has been growing and demanded for an accuracy in treatment validation [3]. In this work, an Adaptive Arm Backscatter Solution (AdABS) [4-5] to accommodate the future application of DC allied with the widespread use of Varian aSi EPID was investigated.

#### Material and Methods

An existing feature in DC facility was investigated for a practical and more convenient way of routinely applying

the developed backscatter correction matrix (Fig.1 (a)). This provide an easy-to-apply method to correct for backscatter from the linac arm that may be applied to all clinical images before dose reconstruction (Fig. 1 (b)). Dose profiles of some static fields were then being assessed for the effectiveness of AdABS application against the Matlab-based scripted system externally to DC. TPS profiles were compared with (i) DC profiles without backscatter correction, (ii) DC profiles corrected with the Matlab script and (iii) DC profiles corrected with AdABS.

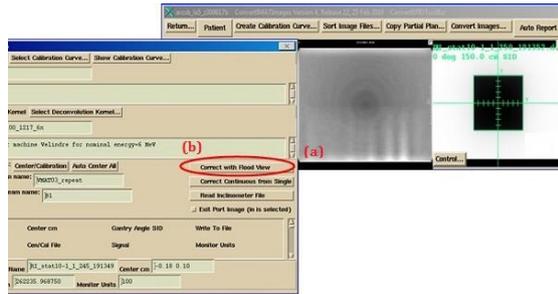

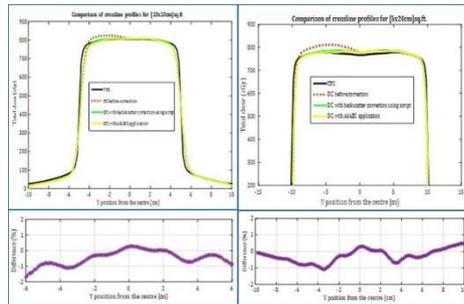

Fig. 1 (a) and (b)

**Results**

Profiles corrected for backscatter with the scripted method and with AdABS showed excellent agreement, with percentage differences of less than 1.5% relative to each other suggesting that AdABS is a feasible correction method that may be applied in the clinic for more accurate treatment verification (Fig. 2).

**Conclusion**

This technique provided a feasible way of applying the correction within DC without the need to generate corrected images using external software (Matlab) scripts for every plan. Ultimately, this will benefit clinical advanced radiotherapy treatment plan verification by providing a ready solution that will help in implementing a quick and efficient workflow in Dosimetry Check.

**EP-1749 Relation between depth dose and HVL for electronic brachytherapy systems: a Monte Carlo study**

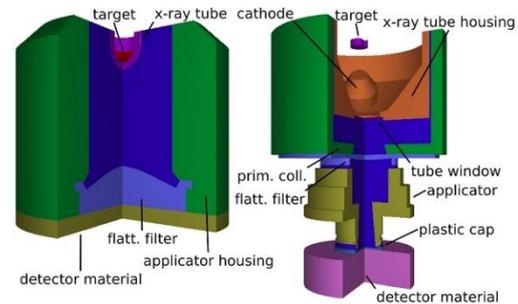

C. Valdés<sup>1,2</sup>, F. Ballester<sup>1</sup>, J. Vijande<sup>1</sup>, J. Perez-Calatayud<sup>1,3</sup>  
<sup>1</sup>Universitat de Valencia, Departamento de Física Atómica- Molecular y Nuclear, Valencia, Spain ; <sup>2</sup>Centro Oncológico de Antofagasta, Radioterapia, Antofagasta, Chile ; <sup>3</sup>La Fe Hospital, Radiofísica, Valencia, Spain

**Purpose or Objective**

There is a consensus on the use of the HVL (mm of Al) as an indicator of the beam quality for electronic brachytherapy equipments (eBT). Usually, the manufacturer supplies dosimetric data as percent depth dose (PDD) and HVL among others, being the responsibility of the final user to verify this information. HVL is obtained through a cumbersome procedure, which requires absorbent layers of high purity with very accurate thickness. The aim of this work is to investigate the relation between PDD and HVL for two eBT systems widely used in surface skin treatments, to evaluate the plausibility of verifying the PDD and the HVL supplied with a single measurement in water (or water-equivalent material).

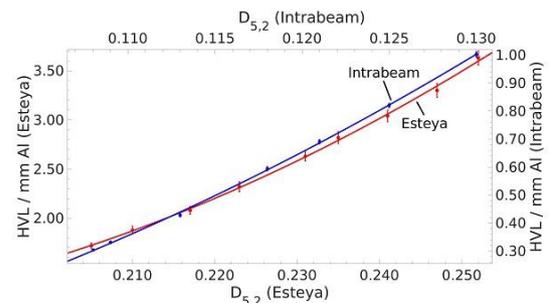

**Material and Methods**

The simulations of the Intrabeam® (Carl Zeiss Meditec AG, Oberkochen, Germany) and the Esteya® (Elekta Brachytherapy, Veenendaal, The Netherlands) systems; which emit flattened bremsstrahlung beams of 50 kVp and 69.5 kVp, respectively; were performed with penEasy for PENELOPE2014. In both cases, surface applicators of 10 mm in diameter were used. To obtain beams with different HVLs, the original beams were filtered (filtered beams) with different amounts of Al, calculating the new HVL and the ratio of the absorbed doses at 5 cm and 2 cm depth (D<sub>5,2</sub>), for both the original and the filtered beams.

**Results**

HVLs of the original beams were 0.304 ± 0.004 mm and 1.72 ± 0.04 mm for the Intrabeam and the Esteya systems, respectively. The D<sub>5,2</sub> of the original beams were 0.108 ± 0.002 and 0.205 ± 0.005 for the Intrabeam and the Esteya systems, respectively. We found that a change of 5% in D<sub>5,2</sub> deviates the HVL by approximately 40% and 20% in the Intrabeam and Esteya systems, respectively.

**Conclusion**

The present work has proven that small deviations detected in a PDD measurement can predict noticeable changes in the HVL for the eBT investigated. The finding

of optimum depth dose indexes, the effects of the depth dose measurement uncertainties on the HVL determination and the sensitivity of this method to safely predict changes in the dose calibration factors are some of the areas that require more investigation. These topics will be studied in a second step in this project.

#### EP-1750 Evaluation of Acuros XB in the presence of metallic elements

R. Chipana<sup>1</sup>, T. Younes<sup>1,2</sup>, L. Vieilleigne<sup>1,2</sup>

<sup>1</sup>Institut Claudius Regaud- Institut Universitaire du Cancer de Toulouse, Department of Medical Physics, Toulouse, France ; <sup>2</sup>Centre de Recherche en Cancérologie de Toulouse- UMR 1037 INSERM- Université Toulouse 3- ERL5294 CNRS- Oncopole, Department of Medical Physics, Toulouse, France

#### Purpose or Objective

The aim of this work was to evaluate Acuros XB (AXB) in presence of metallic elements, such as hip prosthesis and dental implants. Comparisons against Monte Carlo (MC), Anisotropic Analytical Algorithm (AAA) calculations and measurements were undertaken.

#### Material and Methods

In order to challenge AXB algorithm, radiation photon beams were selected to transit through metallic elements. Firstly, AXB calculations were performed in simple virtual phantoms constituted of water, Titanium and stainless steel and were compared with AAA and with GATE (Geant4 Application for Tomography Emission) platform based Monte Carlo as the benchmark. Secondly, measurements were undertaken in water tank phantom containing hip prosthesis (in Titanium, and in stainless steel) and dental implants (in stainless steel alloy). The PTW PinPoint 3D T31016 ion chamber was used to measure profiles and absolute doses at different depths beyond the metallic implants. The measured doses were then compared to the predicted ones by AXB and AAA. AXB and MC dose calculations were reported to dose-to-medium.

#### Results

In the virtual phantoms, AXB calculations were in good agreement with GATE. AAA failed predicting the backscatter in front of water/Titanium or water/stainless steel and exhibited differences up to 11%. Beyond 2 mm after the metallic heterogeneity, AXB differed by 1% and 4% for Titanium and stainless steel respectively, whereas AAA differed by 3% and 12%. The absolute dose measurements (around 2 cm after the metallic implants) for 6 and 10 MV photons beams indicated maximum differences of 1.5% and 5.8% for AXB and AAA, respectively. The PinPoint 3D dose profiles presented good agreement (<1% on average) compared with AXB calculations, in contrary to AAA calculations, as shown in the figure 1.

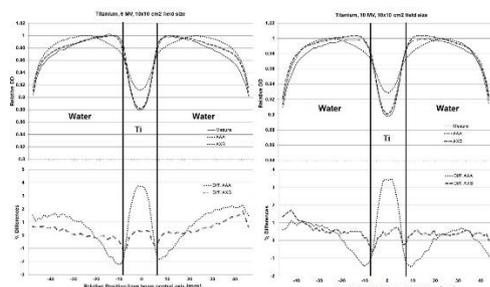

Fig. 1: Comparison of dose profiles: measurements with the PinPoint 3D and calculations with AXB and AAA at around 2 cm beyond the titanium hip prosthesis for 6 MV and 10 MV photon beams.

#### Conclusion

Even when the beams transited through the metallic implants, AXB has been shown to handle perturbations as

well as Monte Carlo calculations. AXB calculations were in good agreement with profile and absolute dose measurements, highly better than AAA calculations.

#### EP-1751 Topical skin agent application-thickness

influence on surface dose in external radiation therapy

K. Miko<sup>1</sup>, J. Kobayashi<sup>1</sup>, Y. Ono<sup>1</sup>, T. Tanino<sup>2</sup>, N. Uchida<sup>2</sup>

<sup>1</sup>Tottori University Hospital, Radiology, Yonago, Japan ;

<sup>2</sup>Tottori University Hospital, Radiology- Department of Pathophysiological Therapeutic Science, Yonago, Japan

#### Purpose or Objective

Radiation dermatitis during radiotherapy sometimes affects patients' quality of life or continuity of treatment. Topical skin agents such as ointments, lotions or creams may be prescribed. However, there remain concerns of a bolus effect due to the applied thickness or of beam scattering due to trace-metal components, possibly increasing irradiating surface doses. The purpose of this study was to investigate the effects of varied application thicknesses of topical agents, and their base ingredients or trace-metals on the surface dose, experimentally.

#### Material and Methods

The calibration curves in the range of 0 cGy to 500 cGy of 6, 10 MV-X-ray were acquired using Gafchromic dosimetry Film (EBT 3). Next, the films were placed on the surface of a water-equivalent phantom, then polyethylene wrap sheet. Various topical agents were applied on the sheet in varying thickness ranging from 0 mm to 5.00 mm. 100 MU of 6 MV or 10 MV X-ray was exposed to the film with SSD 100 cm, 10 × 10 cm<sup>2</sup> field size. The topical agents were simple creams or ointments, with ingredients such as silver, zinc, sodium and iodine. Each entrance surface dose was calculated by conventional Gafchromic dosimetry film method.

#### Results

The surface-absorbed dose increased with increasing thicknesses of simple cream. Simple regression analysis revealed a strong correlation between thickness of topical agent and surface dose ( $y = -0.088x^2 + 0.868x + 1.000$ ,  $R^2 = 0.996$ ). The surface dose with cream containing trace-metal was greater than that with simple cream ( $p < 0.05$ ). The difference between the dose with simple cream and the dose with trace-metal cream became greater with a decrease of application thickness. The surface dose difference between simple cream and trace-metal cream was greater in cases of 6 MV-X ray than that in 10 MV-X ray, especially when the application thickness was thin. Even at a thickness of 0.27 mm, which is similar to clinical use, elevations of surface dose were observed.

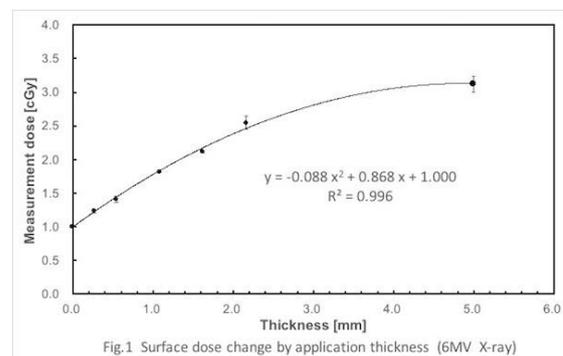

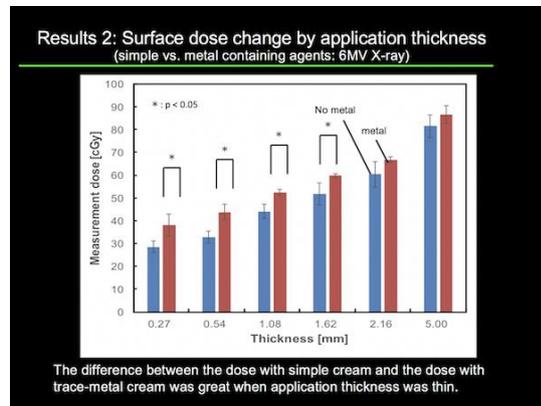

Fig.1 Surface dose change by application thickness (6MV X-ray)

### Conclusion

Thickness of the topical agent influenced surface dose, regardless of metallic composition or the base ingredient, even when applied in a very thin layer. It is necessary to consider appropriate application and timing in cases where topical agents are applied to the radiation treatment site.

### EP-1752 Impact of Leaf Spread Function on Fluence Reconstruction from Exit Detector Signals in TomoTherapy

H.H.F. Choi<sup>1</sup>, T.Y. Lee<sup>1</sup>, Y.W. Ho<sup>1</sup>, W.K.R. Wong<sup>1</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China

### Purpose or Objective

The onboard exit detector of TomoTherapy has been proposed as a tool to detect errors in fluence delivery during treatment. Many fluence reconstruction methods require a deconvolution of the collected signal with a leaf spread function (LSF). Measuring the LSF for all leaves and all jaw openings will yield the most accurate results, but may be time-consuming and unnecessarily complicated. Conversely, relying on a single LSF for the deconvolution of all data may be an oversimplification. This study aims to investigate the impact of the leaf spread function as measured with different jaw widths and different multileaf collimator (MLC) opening.

### Material and Methods

During the projections 6000-6599 in the TomoTherapy Quality Assurance (TQA) DailyQA module, blocks of eight neighbouring leaves were opened successively with a narrow jaw opening (J7, corresponding to a width of 1 cm at isocentre). The LSF was then taken to be the signals received in the exit detector channels corresponding to the fifteen unopened leaves next to the block of opened leaves. The central and edge LSFs were measured when the block of opened leaves was located at the centre and the edge of the beam, respectively. This was repeated for a similar MLC opening pattern with a wider jaw opening (J20, corresponding to a width of 2.5 cm at isocentre) in projections 7000-7599. Finally, a third "average LSF" was constructed by averaging the J7 and J20 LSFs. This was to observe the effects of jaw opening on LSF profiles. Next, the exit detector signals were collected for three standard plans (TomoPhant) supplied by the manufacturer, with the couch retracted from the bore. Fluence was then reconstructed using the J7, J20 and average LSFs for the TomoPhant plans. The deconvolution and fluence reconstructions were done with MATLAB.

### Results

The central and edge LSFs were found to be very similar (see Figure 1). The J20 LSF exhibited a slower drop-off than that measured with J7. The leaf opening times calculated from deconvolving with a J7 LSF were

consistently higher than that with a J20 LSF (see Table 1). The average LSF yielded reconstructed leaf opening times that lay between J7 and J20 LSFs for all jaw openings.

Figure 1: Leaf spread function profiles for different opened leaves and different jaw openings

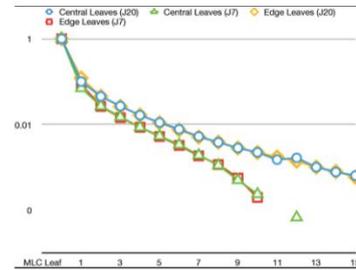

Table 1: Leaf opening errors (%) compared with the planned leaf opening patterns as calculated with different leaf spread functions for TomoPhant plans with different jaw openings

	Leaf opening errors (%)		
	Plan_01	Plan_03	Plan_05
Jaw opening at isocenter	5.0 cm	2.5 cm	1.0 cm
Reconstructed with average LSF	0.16 ± 1.47	-4.26 ± 1.94	-6.03 ± 2.39
Reconstructed with J7 LSF	1.77 ± 1.22	-2.52 ± 1.49	-4.25 ± 1.87
Reconstructed with J20 LSF	-1.97 ± 1.91	-6.06 ± 2.47	-7.88 ± 2.97

### Conclusion

The position of the opened leaf was not found to affect the measured LSF profile; however, different jaw openings were found to influence the fluence reconstruction. Measuring LSF for all clinically applicable jaw widths may yield a more accurate reconstruction.

### EP-1753 A dual detector system for in-vivo dosimetry: transit dose verification and error identification

O. Brace<sup>1</sup>, S. Alhujali<sup>1</sup>, S. Deshpande<sup>2</sup>, P. Vial<sup>2</sup>, P. Metcalfe<sup>1</sup>, M.L.F. Lerch<sup>1</sup>, M. Petasecca<sup>1</sup>, A.B. Rosenfeld<sup>1</sup>  
<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia ; <sup>2</sup>Liverpool and Macarthur Cancer Therapy Centres, Department of Medical Physics, Sydney, Australia

### Purpose or Objective

This work tests the ability to perform real time transit dosimetry and MV imaging with a dual detector system for radiotherapy. The system's ability to accurately measure water equivalent dose, predicted by the TPS for a heterogeneous phantom will be validated. Further the dual detector will be used for the identification of dose errors though co-registration of dose and imaging profiles.

### Material and Methods

The dual detector comprises of a silicon diode array detector (MP) and standard a-Si EPID. The MP is between two sheets of 5 mm thick water equivalent material and mounted directly above the EPID. The dual detector was placed at 150 cm SSD and aligned beneath the LINAC couch. The lung phantom has at its centre a 2 cm diameter water equivalent sphere to represent a tumour volume, surrounded by lower density lung equivalent material. With the target positioned at isocentre an ELEKTA LINAC was used to deliver 250 MU with a 6MV beam for a 5x5 cm<sup>2</sup> field. Transit dose was compared to both TPS calculations and measurements taken with the EBT3 film substituted for the MP in the dual detector system. Two deliberate dose errors were also introduced. Firstly a 5.2% increase of monitor units (263 MU) was delivered. Additionally, with the nominal 250 MU delivery the target was laterally shifted 7 mm from isocentre. EPID images taken were co-registered to MP profiles through physical markers present in the EPID images. Prior to transit measurements the MP

response was calibrated to dose at the machines reference condition.

### Results

Transit dose profiles of the MP, film and TPS are displayed in Fig. 1a) with the dose difference calculated in respect to the MP (Fig. 1b)). The MP measured dose agrees within error to both TPS and film across the inter-umbra region. A drop in dose at the centre of the field, in correspondence with the position of the target is present in all three profiles. The deliberate overdose delivery of 5.2% resulted in an increase in dose measured by the MP at the centre of the field of ( $5.4 \pm 1.8$ )%. Fig. 2 displays normalised profiles of the EPID and the MP when the target was at isocentre and laterally shifted. In Fig. 2a) the decrease in dose at the centre of the MP profile is aligned with the position of the target observed in the EPID image. The registration of the profiles in Fig. 2b) confirms deviation in the transit dose profile for the misalignment error delivery is due to a shift in the target position.

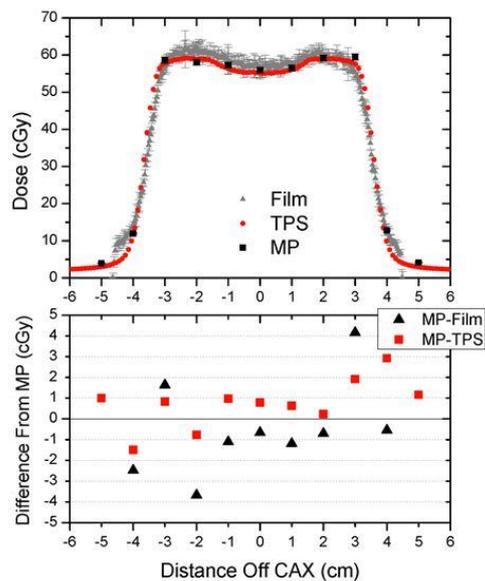

Figure 1. a) Profile of central axis transit dose for heterogeneous phantom for MP, film and TPS. b) Dose difference between film and TPS profiles in respect to the MP measured dose.

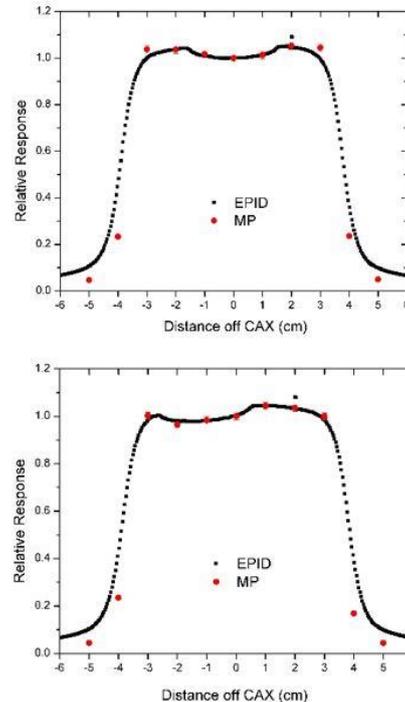

Figure 2. a) Normalised profiles for MP and EPID with target correctly aligned at isocentre. b) Profiles when target is shifted laterally 7 mm from isocentre.

### Conclusion

The dual detector system is capable of verifying the transit dose in water, predicted by the TPS for a heterogeneous phantom in real time. The mechanical mounting of an array detector above the EPID would create an easy to implement and low cost in-vivo dosimeter. Development of an array detector with improved spatial resolution would further effectiveness of the system. The dual detector system has been shown to be able to identify potential in-vivo dose errors of incorrect MU delivery and target misalignment with the aid of imaging and dose co-registration.

### EP-1754 High-resolution assessment of dose calculations in small MV photon beams on and off central axis

G. Biasi<sup>1</sup>, N. Hardcastle<sup>2</sup>, M. Petasecca<sup>1</sup>, S. Guatelli<sup>1</sup>, V.L. Perevertaylo<sup>3</sup>, A.B. Rosenfeld<sup>1</sup>, T. Kron<sup>2,4</sup>

<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia ; <sup>2</sup>Peter MacCallum Cancer Centre, Department of Physical Sciences, Melbourne, Australia ; <sup>3</sup>SPA-BIT, n/a, Kiev, Ukraine ; <sup>4</sup>University of Melbourne, Sir Peter MacCallum Cancer Institute, Melbourne, Australia

### Purpose or Objective

There is an increasing use of standard treatment planning systems (TPSs) for stereotactic radiosurgery (SRS), as opposed to dedicated SRS TPSs. In the literature, investigations have assessed their accuracy, and that of dose calculation algorithms, in clinical stereotactic situations with multiple fields combined, but not in small static fields. Small static fields are also not considered for beam modelling in TPS commissioning, since measurement accuracy cannot be guaranteed owing to a mix of uncertainties in effective field size, detector positioning and field-size dependent correction factor. The present work aimed at investigating the accuracy of calculations

by the Eclipse™ TPS in small static fields in homogeneous medium.

**Material and Methods**

We considered square fields in the range from 5 mm to 30 mm side produced by a multi-leaf collimator (MLC). Fields were centred on machine central axis (CAX) or off-CAX by 100 mm; collimators set to 0° or 90°. All fields were produced by a 6 MV flattening filter free beam delivered by a Varian TrueBeam STx® linear accelerator equipped with an HD-MLC. TPS plans were generated by Eclipse 15.5, independently commissioned and optimized for IMRT/VMAT deliveries. Calculations were performed, using the same beam model as input, a single isocentre and 1.0 mm grid, by the analytic anisotropic algorithm (AAA) and the Acuros-XB algorithm (AXB). Calculations were compared in terms of output factors (OFs) and off-axis ratios (OARs) (FWHM and penumbral width at 20%-80%) against measurements with a prototype 2D solid-state dosimeter 'Octa' and Gafchromic™ EBT3 films.

**Results**

In a 10 mm field on CAX, calculated and measured OFs (Table 1) were in agreement within 1.4% (AAA) and 1.5% (AXB) with collimators at 90°, and within 1.7% (AAA) and 1.8% (AXB) with collimators at 0°. In this same field off-CAX, agreement was within 5.1% (AAA) and 8.9% (AXB). In-line FWHMs (Fig. 1) were overestimated by calculations, with largest differences in 5 mm and 10 mm fields. In the latter field, overestimations were of comparable magnitude regardless of collimators rotation and position with respect to CAX. In-line penumbral widths (Fig. 1) were overestimated by calculations, with largest differences in off-CAX fields.

Square field	OF		
	AAA	AXB	Octa
5 mm 0° on-CAX	54.2	53.3	52.2
10 mm 0° on-CAX	71.0	71.1	69.8
10 mm 90° on-CAX	71.0	71.1	70.1
10 mm 0° off-CAX	54.0	55.9	51.4
20 mm 0° off-CAX	60.9	62.1	58.5
30 mm 0° off-CAX	63.8	64.5	61.8

Table 1. Output factors, normalized to the 100 mm side square field defined by the jaws, calculated by AAA and AXB algorithms and measured with the Octa.

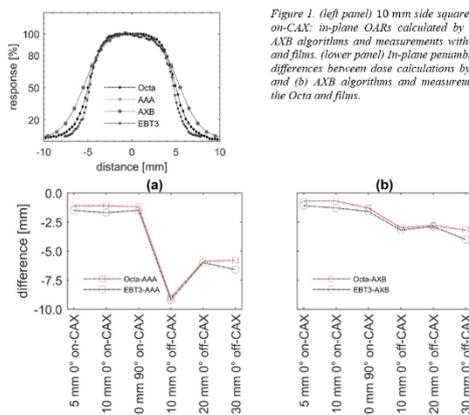

Figure 1. (left panel) 10 mm side square field 90° on-CAX: in-plane OARs calculated by AAA and AXB algorithms and measurements with the Octa and films (lower panel) In-plane penumbral width: differences between dose calculations by (a) AAA and (b) AXB algorithms and measurements with the Octa and films.

**Conclusion**

Calculation errors, which may be enhanced in small static fields, are expected to be smoothed out in dynamic multi-field clinical planning. In the present study, differences between calculations and measurements were affected by field size, position with respect to CAX and collimators rotation. Wider calculated FWHMs and penumbral widths were likely the result of a beam modelling aimed at ensuring modulated fields were accurately delivered, at the potential expense of inaccuracies in static fields. Our results emphasized the necessity of a thorough verification of a TPS in small static fields. The study had the limitation of not investigating the influence of parameters such as different back-up jaws settings, beam energy and depths in water.

**EP-1755 Implementation of EPID in vivo dosimetry for SBRT: setting tolerance levels for routine clinical use**

M. Esposito<sup>1</sup>, A. Ghirelli<sup>1</sup>, S. Pini<sup>1</sup>, S. Russo<sup>1</sup>, G. Zatelli<sup>1</sup>, P. Alpi<sup>2</sup>, R. Barca<sup>2</sup>, B. Grilli Leonulli<sup>2</sup>, L. Paoletti<sup>1</sup>, F. Rossi<sup>1</sup>, P. Bastiani<sup>2</sup>

<sup>1</sup>Azienda USL Toscana Centro, S.C. Fisica Sanitaria, Bagno a Ripoli, Italy ; <sup>2</sup>Azienda USL Toscana Centro, S.C. Radioterapia, Bagno a Ripoli, Italy

**Purpose or Objective**

Electronic portal imaging device (EPID) transit in vivo dosimetry is a powerful tool for patient specific quality assurance (QA), however there is a lack of consensus about which dose difference metric should be used for alert and action level. The aim of this work is to analyze results of transit EPID dosimetry of stereotactic treatment in the abdominal and pelvic sites, and establish tolerance levels for clinical routine use that are sensitive enough to find relevant errors but have also high specificity.

**Material and Methods**

64 stereotactic VMAT treatments (113 fractions) with target in the abdomen or pelvis were analyzed (15 liver, 10 adrenal gland, 7 spine, 32 lymph nodes). In vivo 3d doses were reconstructed with the back-projection EPID commercial algorithm Dosimetry Check 4.10. The differences between planned and in vivo doses were evaluated using Gamma Agreement Index (GAI) 3%/3mm (20% Dose threshold), and dose volume histogram (DVH) differences in prescription target volume (PTV) and clinical target volume (CTV). Initial tolerance levels were set to GAI<85% in PTV. Fractions exceeding tolerance levels (OTL) were checked by experienced Medical Physicists and were classified as due to set-up errors, incorrect use of immobilization devices, 4d errors, transit EPID algorithmic error, and unknown/unidentified errors.

**Results**

44% of total fractions were out of tolerance levels and were classified as: set-up errors (5%), incorrect immobilization device (3%), 4d errors (3%). 50% of OTL were due to transit EPID algorithm failure. In the remaining 28% the OTL causes were not identified. Average difference of PTV and CTV mean dose (± standard deviation) were -3.4%±3.4% and -2.4%±3.2% Average GAI (81.8±20.6) % in PTV and (72.8±31.2) % in CTV. Setting the tolerance level to ΔCTV mean dose > 5.5% the percentage of OTL decrease to 15% and only in one case (6%) EPID algorithmic error occurred.

	85% GAI PTV	3.5% ΔPTV <sub>mean</sub>	5.5% ΔCTV <sub>mean</sub>
Out of tolerance	50 (44%)	58 (51%)	17 (15%)
Residual set-up	5 (10%)	5 (9%)	5 (29%)
4d-intrafraction	3 (6%)	3 (5%)	3 (18%)
Immobilization devices	3 (6%)	3 (5%)	3 (18%)
Algorithm failure	24 (49%)	32 (56%)	1 (6%)
Unknown/unidentified	14 (29%)	14 (25%)	5 (29%)

Table1 In this table, results of the application of three different alert criteria are shown.

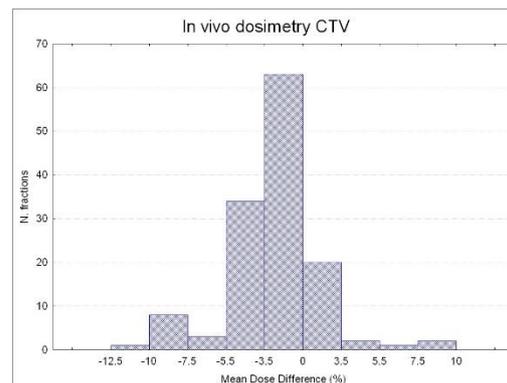

Figure1 Histogram of  $\Delta$  CTV  $D_{mean}$  for 113 fractions is shown in this figure.

#### Conclusion

Results of in vivo transit dosimetry using a commercial system are reported in this paper. A new tolerance level for abdominal and pelvic SBRT was established in this work.

#### EP-1756 Ion recombination and polarity correction for a plane-parallel ionization chamber in hadrontherapy

D. Maestri<sup>1</sup>, A. Mirandola<sup>1</sup>, G. Magro<sup>1</sup>, A. Mairani<sup>1</sup>, E. Mastella<sup>1</sup>, S. Molinelli<sup>1</sup>, S. Russo<sup>1</sup>, A. Vai<sup>1</sup>, M. Ciocca<sup>1</sup>  
<sup>1</sup>Fondazione CNAO, Medical Physics, PAVIA, Italy

#### Purpose or Objective

In order to physically characterize the particle beams clinically used in hadrontherapy, the integrated depth-dose-distributions (IDDs) are measured and implemented as basic input data for commissioning of commercial TPSS, usually compared against Monte Carlo (MC) simulations. The IDD curves are typically acquired as a ratio of readings of two large parallel-plate ionization chambers mounted on a variable depth water column detector. The purpose of this work is the evaluation, in terms of ion recombination and polarity effect, of the dosimetric correction for both proton and carbon ion curves as a function of depth in water, hence of LET variation.

#### Material and Methods

Dose-averaged LET values were calculated with a MC code for some selected IDD. Several points were investigated: the beam entrance, the initial slope, the Bragg peak position, the distal falloff and the practical range position. The charge produced was measured with the plane-parallel Bragg ionization chamber mounted on the PTW Peakfinder by delivering a fixed number of particles, with the maximum current level available. For each measurement, the field chamber was alternatively supplied with +400, +200, +100, -400 Volt. Ion recombination and polarity correction factors were then punctually calculated. Three different beam energies, representative of the clinical commissioned range, were investigated for this study, for both protons and carbon ions. The IDD's, corrected for the aforementioned factors, were then compared against MC simulations, for the same experimental setup.

#### Results

Ion recombination correction factors were both LET and energy dependent, ranging from 1.000 to 1.035 with uncertainties  $\leq 0.5\%$  for carbon ions, while they were found to be nearly negligible for protons. Moreover, no corrections need to be applied due to polarity effect, being  $< 0.5\%$  along all the measured IDD for both particle types. Corrected IDD's (IDD<sup>b</sup>) showed a better agreement than uncorrected curves when compared to MC simulations.

#### Conclusion

In this study, correction factors due the ion recombination and polarity effect were estimated and applied along the pristine IDD for protons and carbon ions. The IDD's were then compared against MC simulations showing a very good agreement. All results confirmed that corrections cannot be completely neglected.

#### EP-1757 Comparison of geometrical accuracy of different SRS delivery systems with end-to-end tests

G. Stelczer<sup>1,2</sup>, D. Szegedi<sup>1</sup>, T. Major<sup>1,3</sup>, C. Polgár<sup>1,3</sup>, C. Pesznyák<sup>1,2</sup>

<sup>1</sup>National Institute of Oncology, Center of Radiotherapy, Budapest, Hungary ; <sup>2</sup>Budapest University of Technology and Economics, Institute of Nuclear Techniques, Budapest, Hungary ; <sup>3</sup>Semmelweis University, Department of Oncology, Budapest, Hungary

#### Purpose or Objective

Purpose: at our institution in the last decades stereotactic radio surgery (SRS) treatments have been performed with frame-based targeting methods on linear accelerators. Recently a CyberKnife M6 (CK) with InCise2 MLC collimator has been installed in our department. Simultaneously the transition from frame-based to frameless SRS treatments was started on a TrueBeam v2.5 (TB) linear accelerator. The aim was to implement a unified method for quantification of spatial accuracy for these delivery systems.

#### Material and Methods

Materials and methods: on the CK the end-to-end tests were implemented according to the AAPM TG135 report with an antropomorphic phantom and Ball-cube insert. The concept of the method is to plan and deliver 4,2 Gy (70% isodose line) as conformal and symmetrically centered on the ball inside the phantom as possible, then calculate the distance between the mass center of the irradiated circle on EBT3 films and the center of the ball. For measurements pre-cut Gafchromic EBT3 Ball Cube II films were orthogonally placed inside the phantom and Accuray developed Matlab software was used for analysis. This way vertical, longitudinal and lateral targeting errors can be measured. The total targeting error is the vectorial sum of these three values. 7 deliveries were performed with both CK and TB. MLC collimator and 6DSkull tracking were used on CK. Rapid Arc delivery with KV-CBCT verification and 6DoF couch were used on TB. 3 of 7 TB deliveries were coplanar arcs without couch movement, while the others had 4 different couch angles, to evaluate the possible errors originating from couch movement during treatment.

#### Results

Results: the end-to-end test method dedicated to CK system was implemented also on the TB system successfully. Both systems' spatial accuracy was far below the tolerances. The average targeting errors in vertical, longitudinal and lateral directions for CK and TB in mm were 0,14±0,22; 0,13±0,18; -0,07±0,18 and -0,15±0,22; -0,24±0,14; -0,29±0,18, respectively. The average total targeting errors in mm for CK and TB were 0,36±0,09 and 0,48±0,13. Average total targeting errors with TB regarding coplanar and non-coplanar techniques were similar, with the values of 0,43±0,14 mm and 0,53±0,13 mm respectively.

		Vertical [mm]	Longitudinal [mm]	Lateral [mm]	Total targeting error [mm]	
CyberKnife	Average	0,14	0,13	-0,07	0,36	
	SD	0,22	0,18	0,18	0,09	
TrueBeam	Average	-0,15	-0,24	-0,29	0,48	
	SD	0,22	0,14	0,18	0,13	
TrueBeam	Non-coplanar	Average	-0,25	-0,15	-0,37	0,53
		SD	0,24	0,09	0,16	0,13
	Coplanar	Average	-0,01	-0,36	-0,19	0,43
		SD	0,05	0,09	0,15	0,14

#### Conclusion

Conclusion: the AAPM TG135 report recommended end-to-end test with the head phantom of CK is also feasible on

other SRS delivery systems such as TB. The test results are reproducible and consistent. The spatial accuracy of the CK's 6DSkull tracking with MLC is better than TB's kV-CBCT verification and 6DoF couch, but the difference is small. These results confirm that both systems are appropriate for safe SRS deliveries.

**EP-1758 A validation and criticality assessment of imaging dose calculation discrepancies of Halcyon MVCBCT**

Y. Zhang<sup>1</sup>, Y. Huang<sup>1</sup>, M. Wang<sup>1</sup>, R. Wang<sup>1</sup>, W. Wang<sup>1</sup>, H. Wu<sup>1</sup>

<sup>1</sup>Key Laboratory of Carcinogenesis and Translational Research Ministry of Education/Beijing- Department of Radiation Oncology- Peking University Cancer Hospital & Institute, Department of Radiotherapy, Beijing, China

**Purpose or Objective**

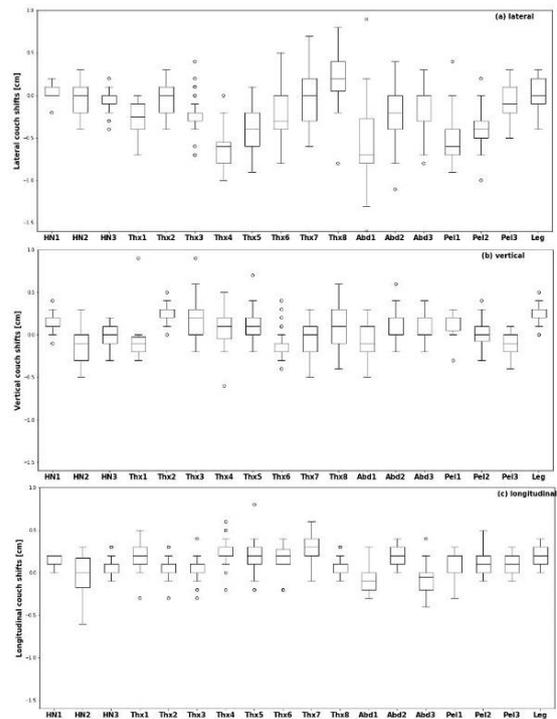

By using identical 6MV flattening-filter-free photons for both imaging and treatment on Varian Halcyon system, the total dose of the two can be incorporated automatically in Eclipse Treatment Planning system, which, however, uses treatment isocenter to calculate the imaging dose. This work aims to assess the criticality of the calculation deviations induced by fractional image-guided-couch-shifts for Halcyon MV cone beam CT (CBCT) imaging dose, based on real patient data.

**Material and Methods**

Eclipse-calculated imaging dose was first validated using a calibrated A1SL chamber in the 'Cheese Phantom' by measurement. Then, the actual imaging dose ( $D_{act}$ ) for 18 historical patients of various sites were recalculated based on 513 MV CBCT-guided-couch-shift data, and compared with the reference computations based on treatment isocentre ( $D_{ref}$ ). 'High Quality' and 'Low Dose' MV CBCT modes were applied in 382 and 131 fractions, delivering 10 MU and 5 MU per scan respectively. Patient- and plan-specific dose from treatment fields was integrated with  $D_{act}$  and  $D_{ref}$  respectively for comparison (Total Dose). More efficient computation was achieved by the automation using Eclipse Scripting Application Programming Interface.

**Results**

The average unsigned relative disagreements between the measured and Eclipse-calculated dose in Cheese phantom were less than 1.23%, hence the following studies were based on Eclipse simulations. Figure 1 displays the couch shifts on the lateral (a), vertical (b) and longitudinal (c) directions of 18 patients as guided by 513 MV CBCT scans. The bottom and top of the boxes indicate the first and third quartiles. The bands inside the boxes show the second quartile (the median). The whiskers display the lowest/highest datum still within 1.5 interquartile ranges of the lower/upper quartiles. The circles indicate the outliers.

As shown in table 1, the Gamma passing rates of the accumulated imaging dose were all better than 95.08% based on 3mm/3%/global/10% threshold criteria, and the mean±1SD was 97.54%±1.42%. The accumulated errors of minimum imaging dose to PTV were no larger than -14.38 cGy, which were reduced to -0.82 cGy after the heterogeneous treatment dose was overlaid. The mean relative discrepancies of PTV minimum dose were -0.61 cGy (-0.71%) and -0.00 (0.00%), before and after incorporating the treatment dose respectively.

**Table 1** Imaging dose deviations accumulated from the whole treatment course: comparisons between the calculations based on the treatment isocentre ( $D_{act}$ ) and the actual dose with fractional couch shifts included ( $D_{ref}$ ). The negative sign (-) indicates lower  $D_{act}$  than  $D_{ref}$ . Total dose (integration of imaging and treatment dose) were also compared.

Mean	97.54	-0.61 (-0.71)	-0.19 (-0.08)	-0.00 (0.00)	-0.17 (-0.00)
SD	1.42	3.67 (5.34)	0.38 (0.20)	1.08 (0.02)	0.37 (0.00)

\*The criteria used for the Gamma passing rate calculations were 3mm/3%/global/10% threshold. The relative errors (data in the brackets) were normalized to the reference dose as calculated on the treatment isocentre.

**Conclusion**

The Eclipse-calculated Halcyon MV CBCT dose was validated by measurement. Although the isocentre displacement-induced imaging dose calculation discrepancies for Halcyon MV CBCT were partially cancelled out by couch shifts of various directions and distances, especially after the incorporation of

heterogeneous treatment dose, it is still advisable to minimize unnecessary and avoidable uncertainties by recalculating the imaging dose using the fractional couch shifts.

#### EP-1759 Patient plan QA using EBT3 GafChromic film for the Unity MRI-Linac system

J. Wolthaus<sup>1</sup>, S. Hackett<sup>1</sup>, B. Asselen- van<sup>1</sup>, W. Vries- de<sup>1</sup>, S. Woodings<sup>1</sup>, J. Kok<sup>1</sup>, P. Kroon<sup>1</sup>, B. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

##### Purpose or Objective

In our department an Elekta Unity MRI-Linac was installed, accepted and commissioned prior to start clinical patient treatments in August 2018. Individual treatment plan QA on the Unity is performed for both pre-treatment and online adapted plans. The presented work describes our patient plan QA procedure of absolute film dosimetry using EBT3 film obtaining high resolution, high accuracy dose measurements to compare to TPS dose calculations.

##### Material and Methods

Plan QA measurements using EBT3 film were performed for more than 30 7-field IMRT plans (optimized to deliver 800 cGy in a single pelvic lymph node). An associate OD-to-Dose model has been determined in advance for the conversion of the pixel values of the film (optical density) to absorbed dose. For each box of films, an additional dose calibration was performed by cutting four small pieces of film (5x10 cm<sup>2</sup>, film orientation specified) and irradiating three of the films with defined doses (650, 800 and 1100 cGy) on the Unity system. The OD-to-Dose model is updated with the results of this measurement.

On the Monaco TPS, the patient plan is calculated (2mm grid, MCVar 1%) on a 19x30x30 cm<sup>3</sup> RW3 slab phantom. Subsequently, the point location of the maximum dose is determined and the height defines the coronal film measurement plane. The 3D dose file is exported for TPS to film comparison. The RW3 phantom is positioned isocentrically on the couch. The film is placed at the determined height using slabs of various thicknesses (1-10mm). A few droplets of water are spread below and above the film to prevent any (small) airgaps. The plan is delivered.

Films are digitized the next day (Epson10000XL), to reduce the effect of post-exposure OD growth. Film images are corrected for scanner distortions and converted to absolute dose with the updated OD-to-Dose model, using in-house developed software. The same software is used for image registration of the 3D TPS dose file to the 2D film dose. Profiles can be extracted in both data sets to evaluate the similarity. A 2D local Gamma analysis (5%/2mm, stereotactic clinical criteria) in the film plane is performed.

##### Results

Currently, 34 patient plans have been analysed with this method: 12 prior to clinical introduction with varying tumour size and location and 22 clinical plans from 4 LN patients. The figure shows an example of the dose images, profiles and gamma distribution. All plans fulfilled the clinical criteria for an acceptable treatment plan and measured and calculated plans agreed well, the average pass rate was 99.7% using a 60% target dose threshold (mean gamma 0.3±0.2).

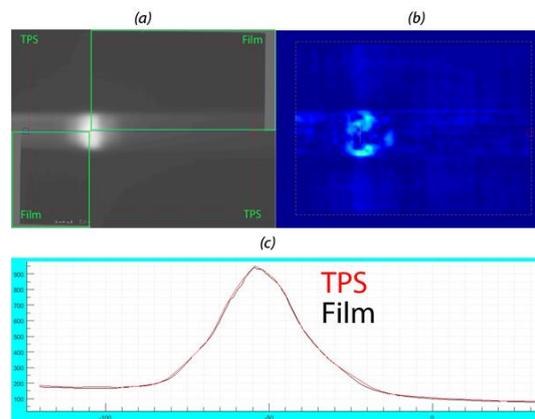

Figure. Example of a patient QA result: a) TPS and Film dose, b) Gamma distribution 5%/2mm (green = 0.9) and c) Absolute dose profiles

##### Conclusion

A patient plan QA procedure using film was developed for the MRI-linac. No additional ion chamber measurements are required to normalise the film dose. The methodology can readily be extended to conventional linacs or ViewRay systems. The results showed excellent agreement between planned and delivered doses for the Elekta Unity system.

#### EP-1760 Impact of cranial implants on proton dose distributions

A. Sjögren<sup>1</sup>, K. Andersson<sup>2</sup>, L. Stolarczyk<sup>2</sup>, U. Granlund<sup>1</sup>, C. Vallhagen Dahlgren<sup>2</sup>

<sup>1</sup>Örebro University, Department of Medical Physics-Faculty of Medicine and Health, Örebro, Sweden ; <sup>2</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden

##### Purpose or Objective

The presence of metallic implants in patients can cause considerable uncertainties in proton therapy treatment planning. The purpose of this study was to investigate the impact of cranial implants on proton dose distributions calculated with Eclipse v13.7 (Varian) using pencil beam scanning technique. Experiments were focused on verification of range calculations for plans based on CT series with and without metal artefact reduction.

##### Material and Methods

The four implants were investigated; a 0.3 mm and a 0.4 mm Ti mesh, a 0.5 mm burr-hole cover and a craniofix implant with a diameter of 16 mm. Each implant was attached to a bone equivalent plate (CIRS) and scanned on a solid water phantom with a Siemens SOMATOM Definition AS Open CT. The images were reconstructed with and without the metal artefact reduction algorithm iMAR. In addition, reference images without implants were acquired. A treatment plan with 35 mm WET range shifter, field size 8 x 8 cm, range 10 cm and modulation 8 cm was created in Eclipse 13.7 using PCS beam model and a calculation grid size of 1 mm. Measurements of depth dose distributions were performed in a water phantom (BluePhantom2, IBA) using Roos IC (PTW) to verify the calculations. In addition, a theoretical value for the proton range shift introduced by a titanium plate was calculated using the equation proposed by Moskvina et al:

$$\Delta(t_m, Z) = t_m [\rho_m (1.192 - 0.158 \ln(Z) - 1)]. \quad [1]$$

Where  $t_m$  is the thickness of the titanium plate,  $\rho_m$  is the plate density and  $Z$  the atomic number of titanium.

Due to the structure of the craniofix implant, film measurements were performed instead. For this purpose Gafchromic EBT3 film, calibrated in a proton beam with the red channel method, was used to determine the dose at several different depths within a solid phantom setup.

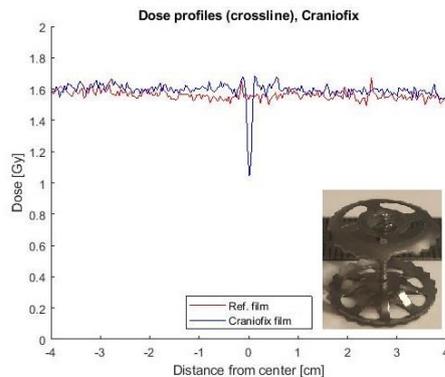

## Results

Table 1 shows the measured and theoretical range shifts, and also the range shifts calculated in Eclipse for CT series with and without iMAR. The calculations based on both the uncorrected and the iMAR images showed higher  $\Delta R_{50}$  values compared to the measured deviations. Also the theoretical  $\Delta R_{50}$  using equation (1) were higher the the measured values.

**Table 1:** Results from the measurements of the range shifts ( $\Delta R_{50}$ ) for three cranial implants.

Implant	$\Delta R_{50}$ measured [mm]	$\Delta R_{50}$ theoretical [mm]	$\Delta R_{50}$ Eclipse [mm]	$\Delta R_{50}$ Eclipse iMAR [mm]
Ti mesh (0.3 mm)	0.2	0.7	0.5	1.5
Ti mesh (0.4 mm)	0.5	0.9	1.4	2.0
Burr-hole cover	0.9	1.1	3.8	3.1

In Fig. 1 the result of the film measurement for the solid water setup with and without the craniofix can be seen. It can clearly be seen that the center of the craniofix caused a reduction in dose in the area where the titanium rod connects the two plates of the implant.

**Figure 1:** Crossline dose profiles for film measurements with and without the craniofix implant (inserted image) at a depth of 1.6 cm

## Conclusion

The cranial implants investigated were shown to reduce proton ranges by up to 0.9 mm. Calculated ranges in treatment plans showed an overestimation of the deviations due to metal artifacts.

## EP-1761 Single isocenter multiple brain mets SRS with Elekta VersaHD and Monaco: end-to-end accuracy study

A. Nevelsky<sup>1</sup>, E. Borzov<sup>1</sup>, S. Daniel<sup>1</sup>, R. Bar Deroma<sup>1</sup>  
<sup>1</sup>Rambam Health Care Campus, Oncology, Haifa, Israel

## Purpose or Objective

The advantages of stereotactic radiosurgery (SRS) to multiple intracranial targets with a single isocenter have been well described. However, the efficiency of this approach strongly depends on the dosimetric and geometric accuracy at all steps of the workflow. In this work we report on the results of the end-to-end accuracy study of SRS treatment of multiple brain mets using Elekta VersaHD linac and Monaco TPS.

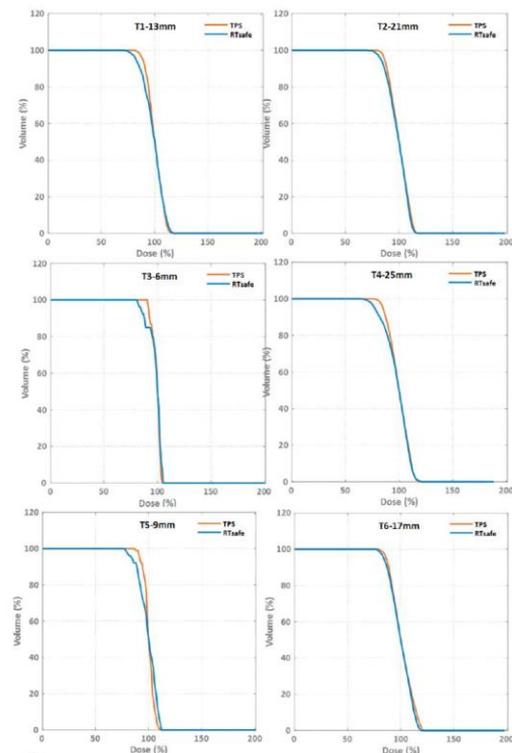

## Material and Methods

A CT simulation scan from a previously treated patient was used as the data set for definition of six clinical targets (ranging in diameter from 6mm to 25 mm) and one QA target in the brain. Based on this set, pseudo-patient phantom filled with dosimetric gel was constructed by

RTSafe company (RTsafe P.C, Athens, Greece). In addition, two phantoms of same size and shape as above but with ionization chamber and film inserts at location of QA target were created. A VMAT treatment plan with 5 non-coplanar VMAT arcs (lateral, vertex and 45°) was devised using Monaco. Using this plan, all three phantoms were irradiated at VersaHD linac. Forty-eight hours after the irradiation, the gel phantom was scanned on a 1.5 T MRI unit in order to obtain 3D dose distribution. In addition, absolute point dose was measured with PTW PinPoint ion chamber and 2D dose distribution at the QA target was measured with film dosimetry.

## Results

The difference between absolute point dose measured with ion chamber and the corresponding dose calculated with Monaco was 0.9%. The gamma passing rate in the film plane using 3D global gamma analysis was 98.2% (3%/2mm). For all clinical targets, the 3D gamma passing rate measured with gel dosimetry was more than 94.5%, with passing rate 97.1% averaged for all targets (3%/2mm). Comparison between planned and measured relative dose distributions in terms of DVHs for all clinical targets is presented in Figure 1 (all dose distributions were normalized to the corresponding D50% metric of each target).

## Conclusion

The end-to-end accuracy of SRS to multiple intracranial targets with a single isocenter at our center has been successfully validated using patient-like phantoms and 3D gel dosimetry.

## EP-1762 in vivo skin dosimetry correction factors for IMRT

P. Carrasco de Fez<sup>1</sup>, M.A. Duch<sup>2</sup>, N. Jornet<sup>1</sup>, P. Delgado-Tapia<sup>1</sup>, M. Lizondo<sup>1</sup>, C. Cases<sup>1</sup>, A. Latorre-Musoll<sup>1</sup>, A. Ruiz<sup>1</sup>, M. Ribas<sup>1</sup>

<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain ;

<sup>2</sup>Universitat Politècnica de Catalunya, Institut de Tècniques Energètiques, Barcelona, Spain

### Purpose or Objective

In IMRT any point at the patient's skin can be at the same time the entrance for some beam angles and the exit for others. Pure entrance correction factors ( $CF_{\text{entrance}}$ ) for skin *in vivo* dosimetry do not apply if some beams exit through the detector surface or in case of a mixed entrance-exit scenario. This study was aimed to establish a method to perform reliable skin *in vivo* dosimetry for IMRT techniques.

### Material and Methods

Ultra-thin TLDs with an effective point of measurement (EPOM) at a depth  $< 5 \text{ mg/cm}^2$  and EBT3 radiochromic films (RCF) with EPOM-120  $\text{mg/cm}^2$  were compared against the results of a PTW23392 Extrapolation Chamber (EC) with an entrance window  $\sim 0.7 \text{ mg/cm}^2$  TLD and RCF were enclosed inside sleeves of LowDensityPolyEthylene (LDPE) to allow placing them in contact to patient skin.  $CF_{\text{entrance}}$  for TLD and RCF were derived by comparing measured doses with the detectors against those measured with the EC. Devic *et al* showed that RCF correction factors for exit dose measurements  $CF_{\text{exit}}=1$ . This value was also applied to ultrathin TLDs when enclosed in LDPE, as their sensitive layer laid at a water equivalent depth of 70  $\mu\text{m}$ . A cumulative correction factor ( $CF^*$ ) was proposed for integrated dose measurements using 6 MV photon beams as a linear combination of  $CF_{\text{entrance}}$  and  $CF_{\text{exit}}$ . The combination coefficients were 1-PDD and PDD being PDD the depth dose for the average field size at the depth of the average phantom thickness for all beams.  $CF^*$  was tested with two phantom experiments:

1-Irradiation by two opposed fields of a *Plastic Water* slab phantom of 30X30  $\text{cm}^2$ . Three different thickness (10,15 and 20cm) of the phantom were considered. Measurements with only the entrance field and with both fields allowed us to know the delivered skin doses and compare them with those predicted by the model.

2-Delivery of a breast IMRT treatment plan on a QUASAR phantom. We compared the measurements of TLD and RCF in 8 consecutive points along the central axis at 2.5 cm distance one another.

### Results

Table 1 shows cumulative skin doses derived from measurements,  $D_{\text{skin,cumulative}}$ , and those calculated by the model ( $D_{\text{skin,cumulative}}^*$ ) as a function of the slab phantom thickness for 6MV photon beams. Differences between the skin doses derived from TLD measurements and those derived from RCF measurements were between 0 and 10%, with a RMS=5%. The RMS of the differences between the values derived from measurements and those calculated by the model was 2%.

Table 1. Cumulative skin doses derived from measurements ( $D_{\text{skin,cumulative}}$ ) and calculated by the model ( $D_{\text{skin,cumulative}}^*$ ) as a function of the slab phantom thickness for 6MV photon beams. The correction factors for *in vivo* cumulative measurements ( $CF^*$ ) are also shown.  $D_{\text{det,cumulative}}$  is the integrated dose measured by the detector without any correction.  $D_{\text{det,cumulative}}$  is the "true" cumulative dose, i.e., the entrance dose corrected by  $CF_{\text{entrance}}$  + the exit dose.  $D_{\text{skin,cumulative}}^*$  is  $D_{\text{det,cumulative}}$  multiplied by  $CF^*$ . Uncertainties are shown in brackets and expressed with  $k=1$ .  $\Delta_1$  are the percentage differences between skin doses determined from measurements and those calculated by the model.  $\Delta_2$  are the differences in skin doses determined by the model, comparing results calculated with EBT3 measurements to those calculated with TLD measurements.

Det.	Thickness (cm)	$CF^*$	$D_{\text{det,cumulative}}$ (Gy)	$D_{\text{skin,cumulative}}$ (Gy)	$D_{\text{skin,cumulative}}^*$ (Gy)	$\Delta_1$ (%)	$\Delta_2$ (%)
EBT3	10	0.895 (27)	0.351 (10)	0.992 (13)	0.872 (19)	0.888 (17)	1.8
	15	0.842 (26)		0.844 (13)	0.724 (19)	0.710 (16)	-1.9
	20	0.800 (24)		0.738 (13)	0.618 (19)	0.590 (15)	-5
TLD	10	1.00 (10)	0.231 (2)	0.804 (09)	0.802 (25)	0.802 (25)	0
	15	1.00 (10)		0.679 (07)	0.678 (24)	0.677 (24)	-0.1
	20	1.00 (10)		0.691 (11)	0.590 (26)	0.589 (26)	-0.1

Table 2 shows skin doses measured with TLD and RCF in eight points of the QUASAR phantom after delivering an IMRT treatment plan. Raw doses measured with TLDs and with EBT3 RCF, and corrected skin cumulative doses for EBT3 RCF are shown. The application of the proposed cumulative correction factor  $CF^*$  improved the Root Mean Square (RMS) of the differences between TLD measurements and RCF measurements from 19% to 5%.

Table 2. Cumulative doses measured with TLD and EBT3 radiochromic films after the delivery of a breast IMRT treatment plan, cumulative skin doses calculated from EBT3 measurements by applying  $CF^*$  ( $D_{\text{skin,cumulative}}$ ) for the same plan, and differences between doses measured with EBT and TLDs before ( $\Delta$ ) and after applying the correction ( $\Delta^*$ ). Uncertainties are shown in brackets and expressed with  $k=1$ .

Point #	$D_{\text{TLD,cumulative}}$ (Gy)	$D_{\text{EBT3,cumulative}}$ (Gy)	$\Delta$ (%)	$D_{\text{skin,cumulative}}^*$ ( $\Delta^*$ (%))	
				EBT3 (Gy)	
1	0.581 (8)	0.739 (13)	21	0.591 (29)	2
2	0.530 (6)	0.724 (13)	27	0.579 (26)	9
3	0.588 (2)	0.763 (13)	23	0.610 (27)	4
4	0.649 (11)	0.838 (09)	22	0.67 (3)	3
5	0.824 (14)	1.007 (07)	18	0.81 (4)	-2
6	0.795 (7)	0.954 (24)	17	0.76 (4)	-4
7	0.779 (13)	1.053 (20)	19	0.84 (4)	-1
8	0.853 (19)	1.047 (15)	26	0.84 (4)	7

### Conclusion

The proposed  $CF^*$  enables us to perform integrated skin dose measurements for IMRT with the lowest uncertainty reported to date.

### EP-1763 Monitoring total skin electron therapy using optically stimulated luminescence dosimeters

T. Kairn<sup>1</sup>, R. Wilks<sup>1</sup>, L. Yu<sup>1</sup>, S. Crowe<sup>1</sup>

<sup>1</sup>Royal Brisbane and Women's Hospital, Radiation Oncology- Cancer care Services, Herston, Australia

### Purpose or Objective

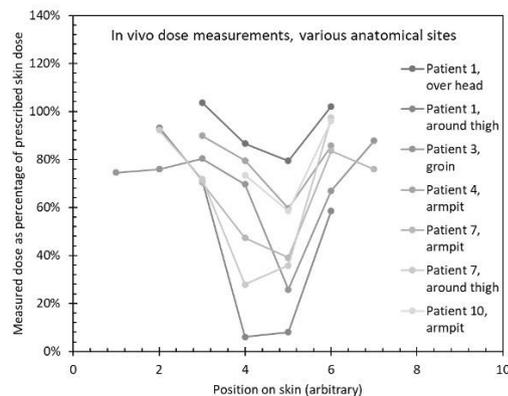

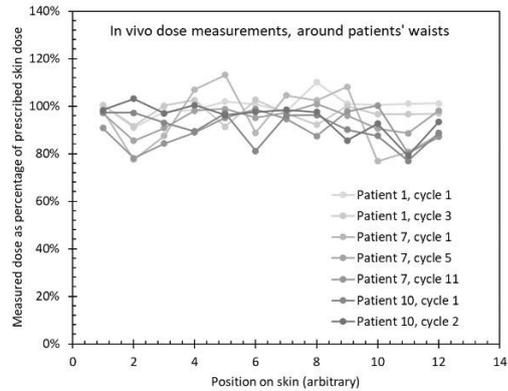

Total skin electron therapy (TSET, sometimes called TSEI or TSEBT) is delivered to patients who are standing in a series of well-established poses, rather than lying on a treatment couch. This unusual treatment geometry means that the dose received by each patient needs to be calculated without the use of a planning CT and usually without the use of a computerised treatment planning system. The treatment dose must therefore be verified, monitored and potentially adjusted throughout the treatment course, using *in vivo* dosimetry measurements. The aim of this study was to retrospectively examine a set of *in vivo* optically stimulated luminescence dosimetry (OSLD) measurements, and thereby provide an indication of the value of OSLD measurements for establishing and improving the dosimetric accuracy of TSET treatments, as well as proposed guidelines for completing such measurements in future.

### Material and Methods

Treatment records, including *in vivo* OSLD measurement data, were obtained for the ten patients who received TSET treatments during the last five years, at one large, metropolitan radiotherapy facility. Prescription doses ranged from 12 to 32.5 Gy, over 6 to 15 treatment cycles. Between 4 and 40 OSLD measurement points were used for each patient, at each cycle, depending on the number of areas of dosimetric concern identified by the prescribing oncologist or the physics team. All OSLDs were Landauer nanoDots, which were read out using a microStar reader (Landauer Inc, Glenwood, USA).

### Results

The *in vivo* dose measurements resulted in MU adjustments in five of the ten cases, to compensate for dose differences of 3.5% to 16% that resulted from changes in patient stance between treatment planning and delivery. Doses measured on the chest, back and around the waist were relatively consistent (see figure 1), under-doses were frequently identified at the top of the head, around the thighs and groin and in the armpits (see figure 2), and over-doses requiring the use of additional shielding were occasionally identified at extremities.

### Conclusion

OSLDs can be used to obtain measurements of TSET dose with sufficient accuracy to justify treatment dose adjustments and indicate the need for additional shielding or boost treatments. The identification and consistent use of a specific set of measurement points would increase the value of future in vivo measurement data, as a local audit and quality improvement resource.

### EP-1764 Portal dosimetry of the new O-ring system (Halcyon™): validation against a diode array

D. Nguyen<sup>1</sup>, F. Jossierand-Pietri<sup>1</sup>, G. Langeron<sup>1</sup>, M. Khodri<sup>1</sup>  
<sup>1</sup>Radiotherapie MACON, Medical Physics, Mâcon, France

### Purpose or Objective

The new fully pre-configured system dedicated for the fast delivery of IMRT/VMAT, Varian Halcyon™, a 6MV-FFF linac mounted on an O-ring gantry was installed in our centers. The Anisotropic Analytical Algorithm v15.6 (AAA) has been pre-configured to allow the calculation of patient dosimetry. It is also used to predict the dose in EPID for patient pre-treatment quality assurance (QA) with IMRT technique. With this one it is not possible to customize the beam modeling.

The purpose is to validate the Varian Portal Dosimetry (VPD) system against the standard QA system (diode array 2D), in order to use it for routine QA.

### Material and Methods

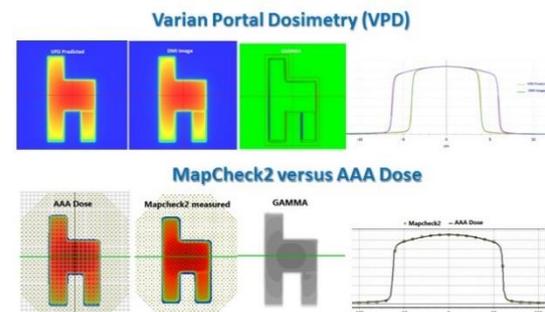

Dosimetric data were collected using the linac Varian Halcyon 2.0 with the 2D diode matrix Sun Nuclear MapCHECK2™ and the VPD with the AAA algorithm. Treatment Planning System (TPS) Eclipse™ version 15.6 was used to generate 26 alphabetical letters (A to Z) with the fluence brush tool (for example graph below for the letter h), 7 sweeping gaps (2, 4, 6, 10, 14, 16, 20mm) and 10 breasts cancers treatment with IMRT technique. The measured fluences with MapCHECK2™ were analyzed versus TPS dose water matrices (AAA V15.6) with the SNC software (V6.7.8) and predicted fluences with VPD (AAA V15.6).

### Results

For alphabetical letters and sweeps gaps, the mean passing rates of the global gamma evaluation were  $99.04 \pm 2.47\%$  and  $88.10 \pm 5.37\%$  and the local gamma evaluation were  $98.82 \pm 2.47\%$  and  $86.98 \pm 5.13\%$ , for the 2%/2 mm and 1%/1 mm criteria, respectively, for MapCHECK2.

In the case of the portal dosimetry, the mean passing rates of the gamma evaluation were  $99.18 \pm 3.73\%$  and  $90.75 \pm 8.77\%$  and the local gamma evaluation were  $99.15 \pm 3.75\%$  and  $89.72 \pm 8.77\%$  for the 2%/2 mm and 1%/1 mm criteria respectively.

For breast IMRT treatments, the mean passing rates of local gamma evaluation were  $99.9 \pm 0.28\%$  and  $99.9 \pm 1.68\%$  for VPD and  $99.56 \pm 0.65\%$  and  $97.49 \pm 1.86\%$  for MapCHECK2 for the 3%/3 mm and 2%/2mm criteria, respectively.

Example of h test results for mapcheck2 and VPD

### Conclusion

The pre-configured portal dosimetry beam modeling gives a very good results and close to the 2D array detector. It seems enough robust to use for routine QA without any need to customize.

### EP-1765 Adapted Delta4 phantom for EBT3 film based pre-treatment QA for lung SBRT VMAT: proof of concept

E. Bogaert<sup>1</sup>, F. Vanhoutte<sup>1</sup>, D. Dechambre<sup>2</sup>, Y. Lievens<sup>1</sup>, C. De Wagter<sup>1</sup>

<sup>1</sup>Ghent University Hospital, Radiotherapy and Oncology, Gent, Belgium ; <sup>2</sup>Cliniques Universitaires Saint-Luc, Radiotherapy and Oncology, Brussels, Belgium

### Purpose or Objective

Implementation of Lung SBRT in clinical routine requires an extensive quality control program to assure patient safety. Patient-specific evaluation of the measured dose against the treatment planning calculated dose is essential in this context. While several commercial 3-D detector arrays are available, they do not provide alone sufficient information to analyze complex dose distribution of highly conformal radiotherapy. Given the high resolution of Gafchromic films, we developed a proof of concept for a pre-treatment QA procedure using EBT3 films placed inside the body of a commercial X-shaped 3-D detector arrays phantom.

### Material and Methods

The Delta4 phantom has been modified by replacing the three detector plates (main board and wings) by EBT3 film placed in between 5mm thick PMMA slabs (Figure 1). Dose distribution of a three-arc VMAT (RayStation Version 6.0) plan for Lung SBRT (fraction dose of 15Gy, 6MV) was calculated on the homogeneous cylindrical body of the phantom and delivered using Elekta Synergy machine with Agility head. Calculated dose in the film planes (main plane 50° to the sagittal plane) was exported via a home-made script and compared to the measured film dose using FilmQPro software (Ashland ISP, USA) three-channel dosimetry. All specific film handling precautions were followed [1,2]. For quantitative evaluation, the gamma

index metric with 2%/2mm and 3%/3mm criteria was used in Film QA pro.

### Results

Relative and absolute dose comparison was performed with 2%/2mm gamma analysis of 92, 85 and 86% for the main and the wing films respectively; increasing up to 98, 93 and 96% using conventional 3%/3mm criterion. Results are presented in Figure 2 with vertical and horizontal line profiles couple to an isodose map of the main film. Having high resolution data into two perpendicular planes in a cylindrical phantom is advantageous against the classical setup in a cubic slab phantom. It provides more information than a single film in a coronal plane and reflects a geometry closer to the anatomical region treated as recommended by the NCS report 28 [3].

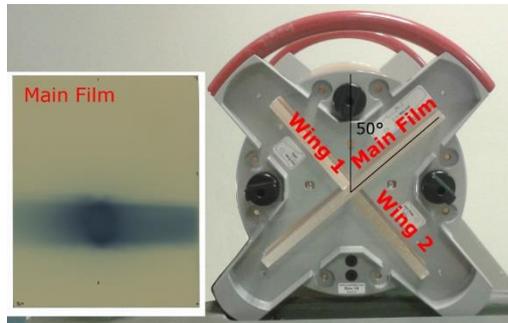

Figure 1. Adapted Delta4 phantom with film slabs. Left: Main film scanned image

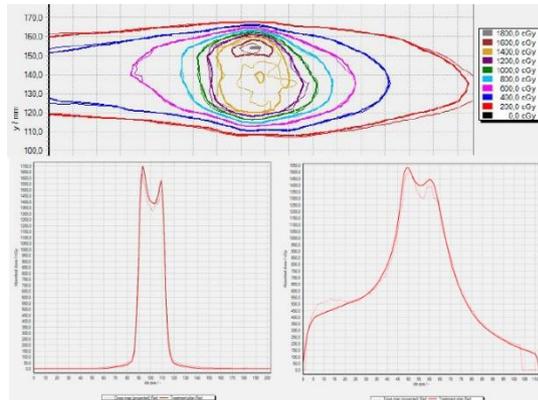

Figure 2. Film versus planned (solid line) isodose map and perpendicular dose profiles in the main plane

### Conclusion

Pre-treatment QA for Lung SBRT VMAT based on EBT3 film inside the body of the Delta4 phantom is feasible. Advantages are high spatial resolution and two-plane dose information in a cylindrical phantom. Further evaluation for more cases and different prescription doses is necessary.

### EP-1766 Application of Extended CT Scale and Metal Artefact Reduction Methods on Radiotherapy Planning

H. Yucel<sup>1</sup>, F. Biltekin<sup>1</sup>, G. Ozyigit<sup>1</sup>, G. Yazici<sup>1</sup>

<sup>1</sup>Hacettepe University, Department of Radiation Oncology, Ankara, Turkey

### Purpose or Objective

The main purpose was to investigate the effects of extended computed tomography (ECT) scale and single energy metal artifact reduction (SEMAR) algorithm on dose distribution during the use of metal implants in radiotherapy treatments using 3D-printed individualized phantoms.

### Material and Methods

In this study, measurement was performed for both mandible and spinal titanium alloy implants. To evaluate the effect of these implants on real treatment case, three individualized phantoms were printed using MakerBot Replicator Z18 3D printer. In the first case, mandible implant was fixed to sawbone mandible model and it was placed inside of the individualized phantom. In the second and third case, two different spinal implants for C1-C3 and C4-C7 vertebra were instrumented to bone equivalent sawbone cervical vertebra model and these model were placed into the 3D-printed phantoms. CT scans of these phantoms were performed in two different step, with and without SEMAR methods, using Toshiba Aquilion LB CT simulator. In the treatment planning Varian Eclipse Version 7.1.3 TPS was used and measurement was performed on Varian Clinac DHX High Performance linear accelerator. In the first case, IMRT plans were created for both standard CT Scale (from -1024 HU to 3071 HU) and ECT scale (from -1024 HU to 64.511 HU). In the second and third case, in addition to CT scale comparisons for 3D-CRT and IMRT techniques, effect of SEMAR methods on dose distribution were analyzed for 3D-CRT treatment plans. Measurements were performed with EBT3 gafchromic film and 5mm DTA/%5 DD criteria was used for gamma analysis criteria.

### Results

In the first case, significant difference was not observed for SEMAR +/-, ECTS +/- since the implant used in the mandible phantom was thin and small so that it did not create dominant artifacts in the CT image. However, in C1-C3 and C4-C7 scenarios, it was observed that the ECT scale results were generally better (2-16% better) than SCT scale. When analyzing the gamma analysis data obtained for the planning of vertebral phantoms, no significant difference could be obtained from SEMAR +/- conditions.

### Conclusion

in case of significant metal artefact, use of ECT scale can improve the dosimetric accuracy of treatment planning. However, in mandible implant dosimetric differences were not found, since thin and small implants were preferred in clinical use.

### EP-1767 Validation and clinical use of a commercial Monte Carlo algorithm for Cyberknife patient-specific QA

M.T.W. Milder<sup>1</sup>, M. Sohn<sup>2</sup>, M. Alber<sup>2</sup>, M.S. Hoogeman<sup>1</sup>

<sup>1</sup>Erasmus MC Cancer Center, Radiotherapy, Rotterdam, The Netherlands ; <sup>2</sup>Scientific RT GmbH, GmbH, Munich, Germany

### Purpose or Objective

To ensure safe dose delivery in radiotherapy, uncertainties and errors have to be minimized by an extended quality assurance (QA) protocol. An established part of this chain is pre-treatment verification of monitor units, which can be performed by an independent dose recalculation. Especially for complex non-isocentric treatment plans as delivered by the Cyberknife with multi-leaf collimator (MLC), the traditional point-based MU verification does not suffice and a 3D dose recalculation is preferred for plan QA. The purpose of this work was to commission the first commercially available 3D Monte

Carlo dose engine for Cyberknife offered by SciMoCa and to report on the clinical utility of the SciMoCa model for MLC by benchmarking it with our standard patient-specific QA procedure for 100 patients.

#### Material and Methods

A beam model was developed by SciMoCa based on the standard commissioning data set for the Cyberknife treatment planning system. The beam model was validated by comparing measured and calculated output factors (OFs), percentage depth dose curves (PDDs), off-centre ratios (OCRs) and a set of clinically relevant, irregular and off-axis MLC segments. For the clinical evaluation, treatment plan files of 100 consecutive patients were re-calculated using the SciMoCa dose engine. In parallel, our standard procedure for patient specific-QA was carried out by overlaying the beams on a slab phantom for SRS1000 (PTW, Germany) measurements. The measurements and SciMoCa recalculations were analysed respectively by 2D and 3D gamma analysis. Clinical results were evaluated with 3% dose difference (DD) and 3 mm distance to agreement (DTA). For the purpose of this study the data was re-evaluated using for measurements and recalculations 2%/1 mm gamma criteria.

#### Results

The agreement between measured and modelled beam data is shown in table 1 and is mostly within 2%.

Altogether, 5 QA plans that were measured with the SRS1000 failed the 90% pass rate using 3%/3mm criteria. All failures were attributed to measurement problems and inaccuracies and were clinically approved. Re-evaluation of the measurements with tighter criteria of 2%/1 mm resulted in 17 failed plans, 16 of which were attributed to measurement inaccuracies. However, one was identified to have a problem in the plan calculation. Independent of the measurements, the SciMoCa recalculations identified only 1 failed plan with the tight criteria of 2%/1 mm. Both in measurements and recalculations the same plan failed the criteria.

**Table 1:** Agreement between measured and modelled data, averaged over three collimators and two Cyberknife systems. The largest deviations in PDD are correlated to the smallest field sizes and are within 5%.

#### OF PDD OCR (0.5 mm DTA)

<1% 81% 26% 84%

<2% 97% 76% 100%

#### Conclusion

A commercially available 3D dose re-calculation for individual Cyberknife MLC plan QA has been successfully implemented in the clinic, replacing time-consuming SRS1000 measurements, with fewer false alarms and similar sensitivity.

#### EP-1768 A Feasibility Study of EPID-Based In-Vivo Dosimetry System in Machine Specific Quality Assurance

F.Y. Yedekci<sup>1</sup>, F. Biltekin<sup>1</sup>, G. Ozyigit<sup>1</sup>

<sup>1</sup>Hacettepe University - Oncology Institute, Radiation Oncology, Ankara, Turkey

#### Purpose or Objective

The main purpose of this study was to evaluate performance of iViewDose (Elekta AB, Stockholm, Sweden) in machine-specific quality assurances.

#### Material and Methods

Measurement were carried out on Versa HD linear accelerator (Elekta AB, Stockholm, Sweden) using iViewDose Version 1.0.1 EPID-based in-vivo dosimetry tool. In this study, three sets of measurement were performed for 6 MV and 6 MV-FFF photon beams. In the first step, the output factor correction as a function of the photon beam field size were measured with iViewDose

system, then results were compared with the beam commissioning data. In the second step, measured and calculated percentage depth dose differences between iViewDose and beam commissioning data at the depth of 1.5, 5, 10 and 15 cm were evaluated. In the last step, linear accelerator dose calibration was set to cause a dose differences of 2% and 4% to evaluate the sensitivity of iViewDose in detecting dose calibration errors in daily check.

#### Results

The measured and calculated output factor comparison between iViewDose and beam data commissioning was illustrated in Figure 1. It was found that the results were compatible within 1% for all field sizes and photon energies. The percentage depth dose differences were generally maintained within 3% until the depth of 10 cm. However, the deviations increase up to 6% at the depth 15 cm. In the last step of measurement, the output differences for 2% and 4% was detected as 2.25% and 4.25% for 6 MV, 2.25% and 4.4% for 6 MV-FFF, respectively.

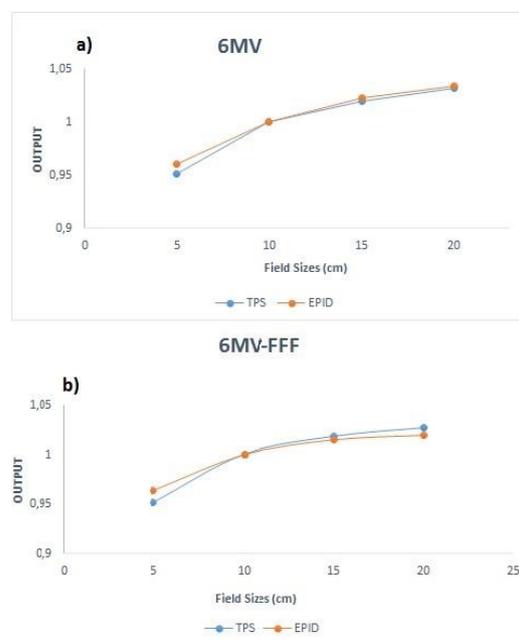

Figure 1. The measured and calculated output factor comparison between iViewDose and beam data commissioning

#### Conclusion

The EPID-based iViewDose tool proved to be a useful in daily check of output correction factors for different field size, depth dose at reference point and dose calibration constancy of linear accelerator.

#### EP-1769 Pre-treatment VMAT verification with SunCHECK Fraction 0 and Varian Portal Dosimetry - a comparison

N.I. Hoven<sup>1</sup>, J. Kalsnes<sup>1</sup>, P. Lønne<sup>1</sup>

<sup>1</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway

#### Purpose or Objective

Varian Portal Dosimetry (PD) is routinely used for pre-treatment VMAT verification in our clinic. We are considering replacing this system with SNC SunCHECK Fraction 0 (FZ), and want to explore the difference between the two systems.

#### Material and Methods

36 clinical VMAT plans with a total of 70 arcs were evaluated using FZ and PD, on a Varian Clinac with the aS1000 EPID (46 arcs) and a Varian TrueBeam with the

aS1200 EPID (24 arcs). The plans were created in Eclipse v13.6, and calculated with the AAA13.6 algorithm. For each linac, the dosimetric output was calibrated to within 0.3%, and the beam flatness and symmetry was confirmed to be within specs (103% and 101%, respectively). The two verification systems were calibrated according to vendor instructions. Treatment plans were verified with PD according to our clinical practice, and the same acquired EPID image was analyzed with FZ within the SunCHECK software. The measured dose was compared to the predicted dose using the gamma analysis method with 3 precision levels:  $\Gamma$  3%/3 mm (3% dose difference and 3 mm DTA),  $\Gamma$  2%/2 mm and  $\Gamma$  1%/1 mm (global normalization, dose threshold 10%). To pass the analysis, the pass rate (points with  $\Gamma \leq 1$ ) should be  $\geq 95\%$  for  $\Gamma$  3%/3 mm and  $\Gamma$  2%/2 mm, and  $\geq 90\%$  for  $\Gamma$  1%/1 mm.

**Results**

For both methods and both machines/EPIDs, all arcs passed the  $\Gamma$  3%/3 mm analysis used in clinical routine. With stricter criteria, there is a number of arcs where one method passes while the other fails, as shown in Figure 1. There is a tendency of more arcs passing with FZ than with PD.

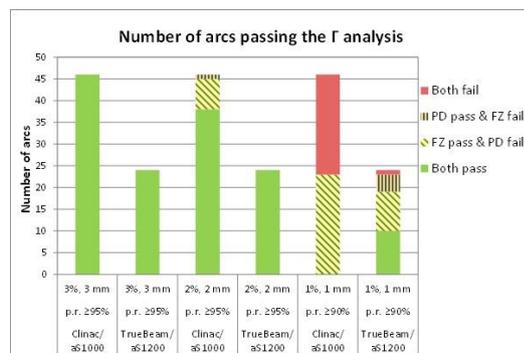

Figure 1: Number of arcs passing the gamma analysis with both methods, one of the methods or none of the methods, for various precision levels and pass rate settings.

The numbers of arcs that pass with one method but fail with the other were compared using Pearson's  $\chi^2$  test under the null hypothesis that "FZ pass & PD fail" is equally probable to "PD pass & FZ fail". The difference is statistically significant for measurements performed with Clinac/aS1000, as presented in Table 1.

**Table 1: Pearson's  $\chi^2$  comparison of numbers of arcs that pass one method but fail the other**

Precision Level	Machine/EPID	FZ pass & PD fail	PD pass & FZ fail	Significant ?
$\Gamma$ 2%/2 mm	Clinac/aS1000	7	1	Yes (p = 0,03)
$\Gamma$ 1%/1 mm	Clinac/aS1000	23	0	Yes (p = 0,00)
$\Gamma$ 1%/1 mm	TrueBeam/aS1200	9	4	No (p = 0,17)

The average  $\Gamma$  pass rate is higher with FZ than with PD for all precision levels (Figure 2), but the difference is not statistically significant. However, it's worth noting that most arcs have a higher pass rate with FZ than with PD.

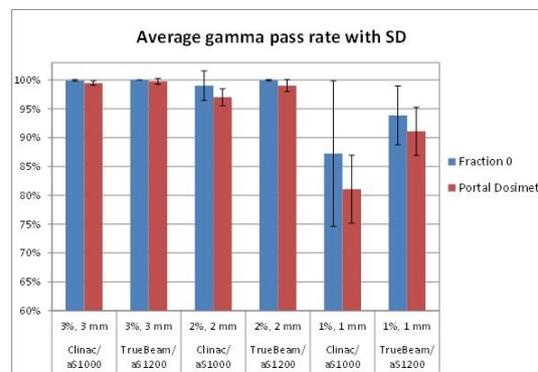

Figure 2: Average gamma pass rate with 1 standard deviation for various precision levels and pass rate settings.

**Conclusion**

Regardless of precision level, there's no significant difference between the average gamma pass rates from the two methods. For the criteria used in clinical routine, the two methods appear equivalent.

For the more stringent criteria there is a number of arcs where one method passes while the other fails, with a tendency of more arcs passing with FZ than with PD. This may be caused by the different approach to absolute calibration of the EPID. Future work will include 2D phantom measurements to determine which method corresponds better to the actual dose delivered.

**EP-1770 Investigation of Electronic Portal Imaging Based In-Vivo Dose Verification for Prostate SBRT**  
 F. Biltekin<sup>1</sup>, F.Y. Yedekci<sup>1</sup>, G. Ozyigit<sup>1</sup>  
<sup>1</sup>Hacettepe University - Oncology Institute, Radiation Oncology, ankara, Turkey

**Purpose or Objective**

The main purpose was to investigate electronic portal imaging based new in-vivo dosimetry tool iViewDose (Elekta AB, Stockholm, Sweden) for SBRT prostate cancer treatment in clinical use.

**Material and Methods**

The study was performed on Versa HD linear accelerator (Elekta AB, Stockholm, Sweden) and feasibility of iViewDose Version 1.0.1 tool was analyzed for prostate SBRT plans in clinical use. To validate this new quality assurance system in clinical facilities, fifteen prostate cancer patients were selected and iViewDose based in-vivo EPID dosimetry was performed. Treatment plans were generated with RayStation treatment planning system (RaySearch Lab., Stockholm, Sweden) and dose prescribed as 36.5 Gy in five fraction. For all SBRT patient, three dimensional gamma analysis results were evaluated. Additionally, measured and calculated dose in reference point (DRP) for CTV, rectum, bladder and femur heads were compared for all fraction.

**Results**

According to measurement results, mean gamma analysis ( $\gamma \leq 1$ ) passing rate of fifteen patient was found as 95.58% for  $\gamma 3D$  (criteria: 3% global dose difference/3 mm distance to agreement, threshold 50%). Additionally, mean DRP difference between measurement and calculated in treatment planning system for CTV, rectum, bladder, left and right femur heads were found as 1.97%, 10.04%, 18.318%, 3.19% and 4.56%, respectively. Maximum dose differences were found in rectum and bladder reference point due to the high dose gradient in these region. However, in medium and low dose gradient region measurements were compatible in 1% with calculated dose in treatment planning system.

**Conclusion**

iViewDose EPID-based in vivo dosimetry software provides an efficient safety check on the accuracy of dose delivery

during radiotherapy facilities. This is especially important in SRS/SBRT modalities which employ higher therapeutic doses in daily fraction.

### EP-1771 Measuring the influence of magnetic fields on the dose distributions of clinical electron beams

R. Kueng<sup>1</sup>, B.M. Oborn<sup>2</sup>, N. Roberts<sup>2</sup>, T. Causer<sup>2</sup>, M.F.M. Stampanoni<sup>3</sup>, P. Manser<sup>1</sup>, P. Keall<sup>4</sup>, M.K. Fix<sup>1</sup>

<sup>1</sup>Inselhospital- University Hospital Bern, Division of Medical Radiation Physics, Bern, Switzerland ; <sup>2</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia ; <sup>3</sup>University of Zurich and Swiss Federal Institute of Technology ETH, Institute for Biomedical Engineering, Zurich, Switzerland ; <sup>4</sup>Sydney Medical School- University of Sydney, ACRF Image X Institute, Sydney, Australia

#### Purpose or Objective

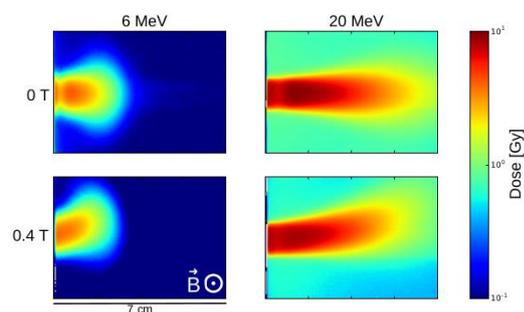

MRI-Linacs are a fast-growing area of cancer radiotherapy. To date only MRI-Linac photon beams have been investigated. However, radiotherapy quality can be improved for a wide range of clinical indications by using electron beams alone or in combination with photon beams. The objective of this work is to investigate the dosimetric impact of a magnetic field with different field strengths and orientations on therapeutic electron beams for three beam energies. For this purpose, an experimental setup for measuring dose distributions of clinical electron beams generated by a conventional linac in the presence of a magnetic field is established.

#### Material and Methods

A permanent magnet device was used to generate a magnetic field surrounding a solid water slab phantom. The magnetic field including maximal field strength  $B_{max}$  was varied by moving the permanent magnet banks and by insertion of focusing steel cones. Electron beams (6, 12 and 20 MeV) from a clinical linear accelerator (Varian Clinac 2100C) were incident perpendicular (transverse setup) and parallel (inline setup) to the main magnetic field direction. The magnet device was placed at a source to isocenter distance of 150 cm and the electron beams were collimated to a circle of 1 cm diameter and a square of 1.5 cm side length, respectively. Gafchromic EBT3 film was placed inside the homogeneous slab phantom, parallel to the beam (transverse setup) and perpendicular to the beam (inline setup) to measure two-dimensional dose distributions. Reference conditions with zero magnetic field were established by using identical collimation in an aluminum frame setup.

#### Results

As expected, for the transverse setup, substantial deflection of the electron beam was observed in the magnetic field, as indicated in figure (1). Consequently, a shift of lateral dose profiles and shift in distal dose fall-off (R50 up to -5 mm) was measured for all three electron beam energies. For the inline setup, focusing of electron beams was observed in magnetic fields compared to the zero field reference setup. An increase of measured dose of up to 100% (6 MeV beam, 0 vs. 0.7 T magnetic field) was shown, yielding a steeper lateral penumbra for a given dose level (FWHM -1.5 mm in 2 cm depth).

### Conclusion

Propagating in a magnetic field, substantial deflection (transverse setup) and focusing (inline setup) of all measured electron beams was observed. The inline setup shows steeper lateral penumbra of electron fields and thus the potential for enhanced plan quality for electron treatments.

### EP-1772 MLC parameters evaluation in a RT-dedicated MC environment (PRIMO) from static fields to VMAT plans

L. Paganini<sup>1</sup>, G. Reggiori<sup>1</sup>, A. Stravato<sup>1</sup>, V. Palumbo<sup>1</sup>, P. Mancosu<sup>1</sup>, F. Lobefalo<sup>1</sup>, A. Gaudino<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1,2</sup>

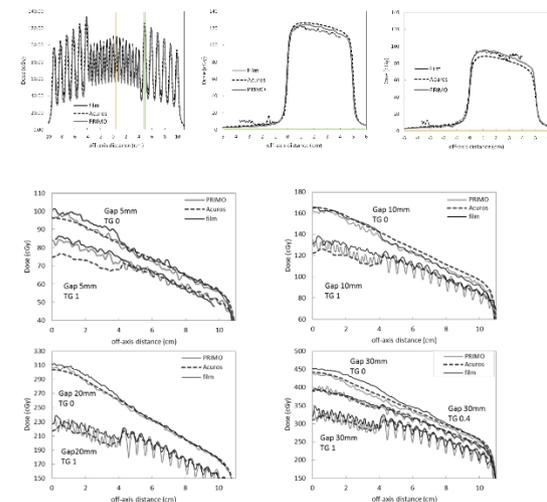

<sup>1</sup>Humanitas Clinical and Research Center, Radiosurgery and Radiotherapy, Rozzano, Italy ; <sup>2</sup>Humanitas University, Department of Biomedical Sciences, Rozzano, Italy

#### Purpose or Objective

PRIMO is a graphical environment for MonteCarlo (MC) simulations based on the Dose Planning Method (DPM), a fast MC algorithm specifically built for the simulation of the deposited dose in radiotherapy. The objective of this work was to validate the beams calculated by DPM against the ones from our Linac EDGE (Varian) and to compare PRIMO with the clinical algorithm Acuros (Varian) and film measurements with particular focus on the MLC parameters.

#### Material and Methods

In a first phase a full characterization of the 10MV FFF beam was performed. Then the 120 HD MLC modeling, particularly the Tongue and Groove effect, was investigated with two types of tests: static MLC fields in different settings and MLC plans configured in 'dynamic fence patterns'. These dynamic tests were planned with increasing leaf-ends, gap size and degree of TG effect. The dose distributions were measured using the IBA MultiCube phantom with GafChromic films positioned horizontally at 10cm depth. Finally a set of four clinical plans was selected from our database. All VMAT plans were optimized with 10MV FFF beam in Eclipse and calculated with Acuros. The DICOM files (plan, structures and images) were imported in PRIMO. DPM was used to calculate dose distribution in patients. The dose distributions were compared in terms of gamma analysis within BODY and PTV.

#### Results

Concerning the MLC modelling, static fields showed a good agreement between Acuros, PRIMO and film measurements, with slight differences in transmitted dose (Fig1). The comparison between dose profiles for the

dynamic fields highlighted differences between measurements and calculations. Discrepancies are higher for the MLC central region where leaves are thinner, and thus TG effect more consistent, with differences up to 8% for Acuros and 4% for PRIMO (Fig2). Differences in the external part of the MLC are below 3% for both algorithms. The differences in handling the MLC parameters between PRIMO and Acuros don't consistently affect the dose distribution resulting in Gamma Agreement Index (GAI) values (3%,2mm) always >97.5% for the PTV volume and 99.5% for the Body region. With more selective thresholds, however, these differences start to be noticeable, with mean GAI values of 98% (2%,2mm) and 90% (1%,1mm) for the Body and 92.2% (2%,2mm) and 65.5% (1%,1mm) for the PTV, confirming possible issues for the thinner leaves.

#### Conclusion

This study highlighted some critical issues in the MLC handling in both static and dynamic settings. PRIMO showed a better agreement with measurements compared to Acuros in all settings. In the considered clinical plans however, these differences lead to acceptable dose distributions for both Acuros and PRIMO though these results should be verified on a larger dataset of patients. In conclusion PRIMO can be an interesting tool to help the fine tuning of the TPS parameters in conditions where experimental measurements have high uncertainties and could benefit from simulations.

#### EP-1773 Radioiodine therapy: a dosimetric study in a patient with DTC after rhTSH stimulation

S. Mazzaglia<sup>1,2</sup>, L. Barone Tonghi<sup>2</sup>, A.M. Gueli<sup>1,3</sup>, C.N. Tuve<sup>1,3</sup>, G. Pellegriti<sup>1,4</sup>

<sup>1</sup>Specialization School of Medical Physics- University of Catania, Department of Medical- Surgical and Advanced Technologies "G. F. Ingrassia "DGFI, Catania, Italy ; <sup>2</sup>ARNAS Garibaldi - Catania, Medical Physics, Catania, Italy ; <sup>3</sup>University of Catania, Department of Physics and Astronomy, Catania, Italy ; <sup>4</sup>ARNAS Garibaldi - Catania, Endocrinology, Catania, Italy

#### Purpose or Objective

The main approach to the Differentiated Thyroid Cancer (DTC) therapy is still empiric, consisting of fixed activities administration, generally besides 1.1 GBq and 7.4 GBq. Repeated treatments, however, may cause stunning effect. An individualized dosimetric study may represent an important tool to determine the best activity to prescribe, in particular for patients with distant metastases or when therapy with rhTSH stimulation is deemed necessary.

We present the case of a patient underwent rhTSH stimulation before radioiodine therapy. This study illustrates the necessity of measuring both red marrow (RM) and blood (BL) absorbed dose during the treatment, because of estimating the activity that could be administered to the patient, in order to not exceed the dose limit of 2 Gy to RM, so as to avoid repeating radioiodine treatment several times. Afterward a variety of dosimetric approaches has been proposed.

#### Material and Methods

To calculate the absorbed dose to the RM it is necessary to know both the BL and whole-body (WB) residence times ( $\tau_{BL}$  and  $\tau_{WB}$ ) and the weight of patient,  $m_p$ , in kg. In this study, the BL absorbed dose was calculated using the EANM formulations and the dose to RM using the AIFM and the Traino methods. Dosimetry to the RM and BL were performed during the treatments, after administration of nominal therapeutic activity  $A_0$  of  $^{131}I$  equal to 3.7 GBq ( $3.3 \pm 0.2$  GBq measured), without modifying the fixed activity schema. Dosimetric calculations were carried out on blood samples of 3 ml at 2, 6, 24, 48, 144 hours after administration of the therapeutic activity, measured through a dose calibrator. Moreover, the patient underwent to WB measurements with an environmental ionization chamber at 2, 6, 24, 48, 144 hours after

therapeutic administration, with a full bladder. The first data after 2 hours correspond to effective administered activity  $A_0$ .

#### Results

$\tau_{BL}$  and  $\tau_{WB}$  by decreasing mono and bi-exponential fit of the experimental data were obtained [Fig.1-2]. Following the RM calculated dose was of  $411.53 \pm 14.68$  mGy for AIFM method,  $395.54 \pm 12.69$  mGy for Traino method, instead the BL calculated dose was  $527.32 \pm 19.48$  mGy, under the dose limit of 2 Gy. This result allows to estimate the maximum administrable activity, considering all approaches. The value obtained confirms that could have been administered to the patient an activity at least 4 times higher in a single treatment, after evaluation of the specialist.

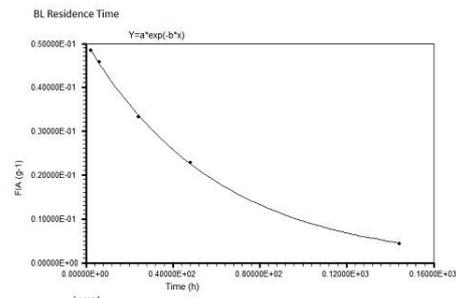

Fig.1

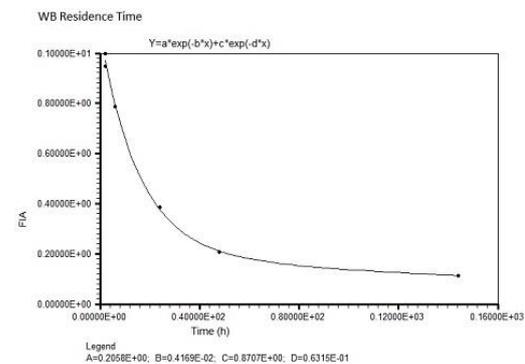

Fig. 2

#### Conclusion

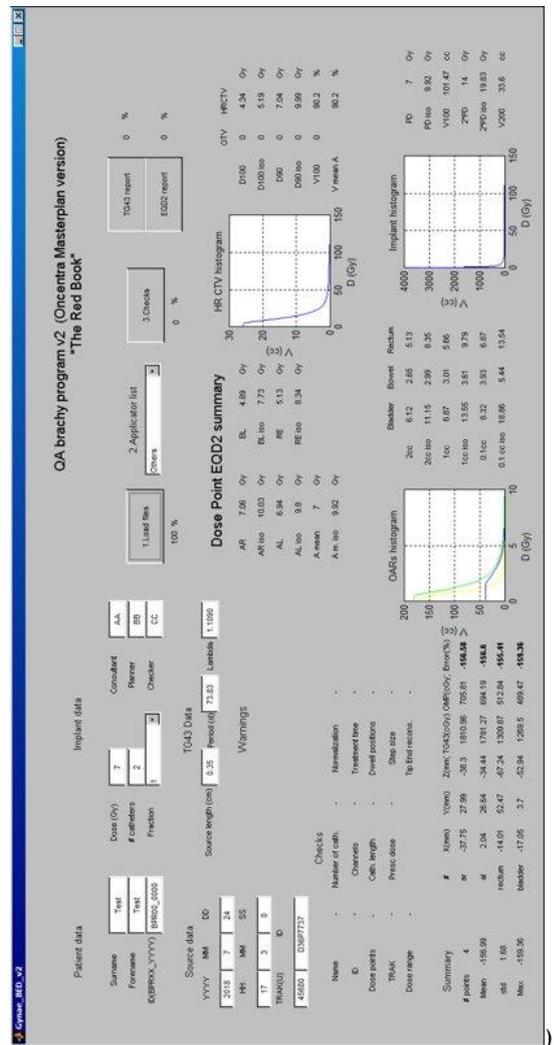

The results suggests the possibility to restrict the number of treatments, so reduced the risk of stunning effect and, where possible, eliminate an additional source of stress and dejection for patients. This is the most important result of this preliminary work. In fact, thanks to dosimetric study it was highlighted that it is possible to administrate individualized activities for DTC patients, in particular after rhTSH stimulation.

#### EP-1774 Independent dose verification of brachytherapy TPS and automation of EQD2 reports using Matlab Code

S. Esteve Sánchez<sup>1</sup>, A.B. Mohamed Yoosuf<sup>2</sup>, G. Workman<sup>1</sup>  
<sup>1</sup>Northern Ireland Cancer Centre, Radiotherapy Physics, Belfast, United Kingdom ; <sup>2</sup>King Abdulaziz Medical City, Radiation Oncology, Riyadh, Saudi Arabia

#### Purpose or Objective

To study the accuracy of an independent dose calculation of gynaecological treatments and develop an automated EQD2 report using a Matlab program (Figure 1

**Material and Methods**

For each fraction, DICOM RP and DVH text files are exported from the TPS, OncentraBrachy v4.5. The matlab program uses the source coordinates from the RP file along with published source data (Ir-192) as the primary input for dose calculation following TG 43 protocol and accounts for 2D anisotropy. The independent dose calculation was performed on point A and bladder/rectum dose points. The results were compared to the TPS calculation. Furthermore, the program verifies other treatments parameters which includes: total reference air kerma, dose prescription, applicator type, dwell positions, catheter length, total treatment time and a comparison to known standard time if appropriate.

The Matlab program also imports the tabular DVH file to interpolate the 2cc, 1cc and 0.1cc dose values of bladder, rectum and bowel and D100, D90 and V100 for the HRCTV. The program automatically exports the results to a patient report (Figure 2), and sums all doses at final fraction. Sensitivity of the program was studied by introducing deliberate errors.

**Results**

552 dose points have been checked with the independent dose calculation since the program was implemented in clinical practice. The EQD2 report created with Matlab has been used for 30 patients. The mean error in dose calculation between the Matlab code and TPS was  $-0.02\% \pm 0.61\% [-5.12, 1.51][YA1]$ . Largest errors were found on points created on the same plane as the ring applicator due to the different vectors used for each dwell position by the manufacturer and our measured ring path that affect the TG 43 interpolations. The OARs and HRCTV

values interpolated from the DVH text file agreed within 1% with the values calculated by the TPS.

The program was also found to be sensitive to errors created deliberately in dummy cases such as incorrect dose prescription, inconsistent catheter lengths and dwell positions and wrong reference source data. The process of exporting the files, running the program and creating the reports can be completed in less than 5 minutes.

**Conclusion**

The program is a useful tool to independently verify the dose calculation in brachytherapy treatments and had led to a more efficient workflow in the clinical sessions. The automated EQD2 report has reduced the possibility of transcription errors. The use of DICOM and DVH text files offers the possibility of extending the program to other TPS.

**EP-1775 Determination of tolerance criteria for the sliding leaf gap dynamic IMRT test**

S. Weston<sup>1</sup>, C. Thompson<sup>1</sup>, A. Esmail<sup>1</sup>, P. Rixham<sup>1</sup>, D. Paynter<sup>1</sup>

<sup>1</sup>Leeds Cancer Centre, Medical Physics and Engineering, Leeds, United Kingdom

**Purpose or Objective**

In the sliding leaf gap test a dynamic narrow field is moved across an ion chamber and the charge collected is normalised by an open field delivered using the same number of monitor units. This work determines clinically relevant tolerance criteria by introducing MLC errors into the delivery, and comparing VMAT verification results performed using Delta4 and ion chamber measurements within a phantom with sliding window output factor (SWOF) measurement.

**Material and Methods**

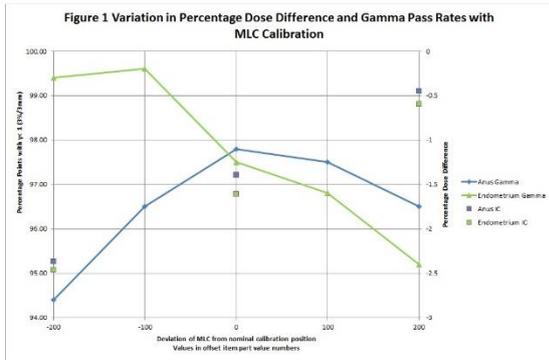

The MLC leaves on the LINAC were first calibrated and QA'd to ensure that the MLCs were performing optimally. The accuracy of treatment delivery was assessed by a measurement using Delta4 and by an ion chamber measurement in a phantom at the isocentre. Each leaf bank was adjusted by modifying the MLC calibration such that the subfields were made larger by 0.1 mm on each leaf. The verification measurements were repeated. This process of modifying the leaf bank calibration and verifying the VMAT deliveries was repeated until one of the deliveries failed the verification. The MLC calibration was restored and the process repeated this time reducing the subfield size.

A water phantom was placed at 100 cm SSD with an ion chamber on the CAX at depth of 5cm. The chamber was irradiated with a 200 MU 10x10 cm<sup>2</sup> field. The chamber was irradiated with a dynamic 200 MU 10 x 1 cm<sup>2</sup> field which moved across the field from -4.5 cm to 4.5 cm. The ratio of the dynamic field output to the open field is the sliding window output factor (SWOF). The SWOF was recorded for range of leaf calibration settings assessed as being clinically acceptable using the verification measurements of the two VMAT solutions.

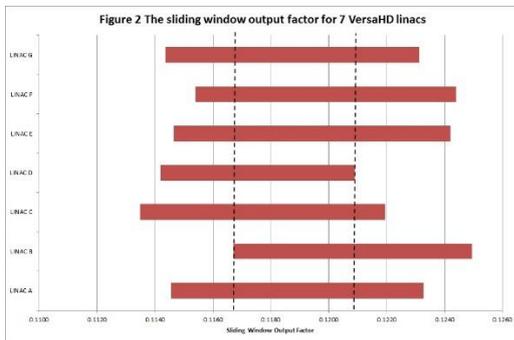

This process was repeated across 7 linear accelerators and the results from all linacs used to determine the clinical tolerances for the SWOF.

**Results**

The verification results for both anus and endometrium for LINAC A are shown in figure 1. The figure shows that as the leaf calibration is extended or withdrawn the verification results become poorer until eventually the verifications fail..

Note that this LINAC is resilient to leaf calibration changes of 200 item part value numbers, which equates to 0.2 mm, on each bank. This process was repeated on 7 linear accelerators in total.

By determining the SWOF at extremities of the leaf calibration range of each LINAC it is possible to determine the tolerance range for the SWOF. Figure 2 shows the SWOF tolerances for seven linear accelerators. The figure shows that sufficient overlap in the results to allow a single tolerance range for the whole fleet. The fleet wide SWOF tolerance range is 0.1169 to 0.1211, or 0.119 +/- 1.8 %.

### Conclusion

The sliding window output test can be used to monitor the MLC calibration. The sliding window output test has been benchmarked against standard verification measurements using two complex VMAT deliveries across seven linear accelerators. A single tolerance range for the sliding window output factor has been established that can be used across the fleet.

### EP-1776 Automated proton plan QA via independent Monte Carlo simulations

G. Guterres Marmitt<sup>1</sup>, A. Pin<sup>2</sup>, J.A. Langendijk<sup>1</sup>, S. Both<sup>1</sup>, A. Knopf<sup>1</sup>, A. Meijers<sup>1</sup>

<sup>1</sup>University Medical Center of Groningen, Department of Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>Ion Beam Applications, Research Group, Louvain-la-Neuve, Belgium

### Purpose or Objective

For radiation therapy, it is crucial to guarantee that the delivered dose matches the planned dose. Uncertainties in the dose calculations done in the treatment planning system (TPS), delivery errors or data corruption during transfer might lead to significant differences between predicted and delivered doses. As such, patient specific quality assurance (QA) of dose distributions, through experimental validation of individual fields, is currently necessary. In this work, we investigate the potential to replace the measurement-based patient specific QA with a simulation-based patient specific QA using a Monte Carlo (MC) code as independent dose calculation engine in order

to develop a fast, automated and accurate patient specific QA.

### Material and Methods

The QA platform is composed of a web interface, servers and computation scripts, and is capable to autonomously launch simulations, identify and report dosimetric inconsistencies. After plan approval in TPS, data are exported to a dedicated DICOM server, that triggers the QA workflow for the TPS-based plan. A preliminary dose recalculation automatically takes place and gamma analysis results, comparing original and recalculated dose maps, become available at the website. After review, the dry-run of the plan is performed to generate machine log files and, upload of the logs, triggers the log-based plan QA workflow. A log-based plan is reconstructed from the retrieved log files, and after the dose calculation, results for the 2<sup>nd</sup> workflow are available for review. For validation purposes of the MC beam model, a set of standardized plans (SOBPs) were designed and in-water calculations were compared between TPS and QA platform. Also, for a set of 10 clinical plans the QA results obtained from the QA platform were compared to the QA results from standard measurement-based approach.

### Results

To perform patient QA according to the proposed methodology 0-15 min of in-treatment-room time are required and additional 5-10 min for data export from TPS and retrieval of the log files. Independent MC calculations require 15-20 minutes. In-water simulations over 30 SOBPs plans with varying range and modulation showed a 99% ± 0.5% gamma pass ratio (2 mm, 2%) when compared to the TPS calculated dose maps. Comparison between QA platform and measurement-based results for 10 clinical cases, including the following indications: craniospinal axis, intracranial and head and neck, is summarized in Fig. 1. An example of calculated dose distributions for case #10 is shown in Fig. 2.

Patient	Measurement-based (gamma pass ratio %)	TPS-plan based recalculation (gamma pass ratio %)	Log-plan based recalculation (gamma pass ratio %)
#1	100	97.43	97.71
#2	99.81	98.75	-
#3	100	98.6	91.56
#4	100	98.43	98.59
#5	98.31	95.37	93.3
#6	98.55	96.05	95.54
#7	99.44	99.05	97.98
#8	99.12	99.14	98.99
#9	99.52	99.3	99.14
#10	99.31	96.02	94.97

Fig. 1. Gamma pass ratios for measurement-based plan QA, and the proposed TPS-based plan QA.

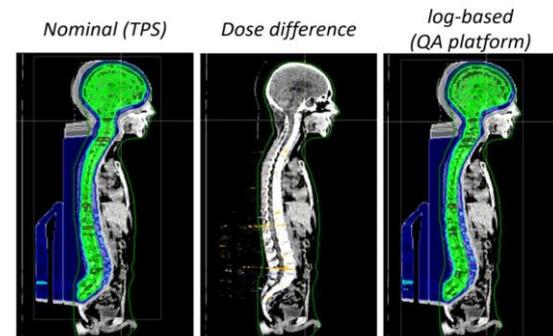

Fig. 2. Dose maps for the TPS calculated plan (left), the log-based recalculation (right) and the dose difference (center). For visualization purpose, recalculated dose maps have been imported in TPS. The dose maps are compared with gamma analysis (2 mm, 2%) and pass ratio is 95%.

### Conclusion

A new patient specific QA workflow was developed inside an automated web platform. The clinical application of this method has the potential to greatly reduce QA time. Validation with calculations in water shows great consistency of the MC engine over a wide range of beam-sets. The retrospective application of the approach for a set of 10 clinical plans implicate that the same decisions

would have been reached for either recalculation or measurement-based method.

### EP-1777 Improvements in pencil beam algorithm in proton therapy: do we still need Monte Carlo in brain?

L. Widesott<sup>1</sup>, S. Lorentini<sup>1</sup>, F. Fracchiolla<sup>1</sup>, P. Farace<sup>1</sup>, M. Schwarz<sup>1</sup>  
<sup>1</sup>APSS, Protonterapia, Trento, Italy

#### Purpose or Objective

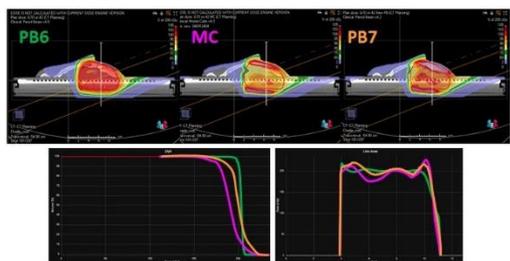

Dose accuracy in presence of heterogeneities and range shifter (RS) modelling are some of the reasons that have made in the last years Monte Carlo (MC) dose calculation algorithm increasingly present in the clinical routine in proton therapy. On the other hand, MC brings with it significantly higher calculation times, especially if you want to do robust optimization/evaluation and/or frequent re-planning. The purpose of this work is to evaluate the last version of the pencil beam (PB7) present in our TPS comparing it with measurements and observe how it behaves with respect to the previous version of the pencil beam algorithm (PB6) and MC.

#### Material and Methods

We compared the new RayStation 7 pencil beam (PB7) algorithm vs. MC dose engine and the previous one (PB6) clinically implemented so far, in critical conditions such as superficial targets (i.e. in need of range shifter), different air gaps and different gantry angles to simulate both orthogonal and tangential beam arrangements. For every plan the PB7, PB6 and MC dose calculation were compared to measurements using a gamma analysis metrics with passing criteria of 3% of maximum dose, 3mm distal-to-agreement, global approach, and dose threshold of 5%. Measurements were performed with a 2D ion chamber array detector (MatriXX PT, IBA Dosimetry GmbH) placed underneath the following targets: 1) anthropomorphic head phantom (with two different thickness) and 2) a biological sample (i.e. half lamb's head).

#### Results

For both the configurations of the head phantom (i.e. one and two slabs) the gamma passing rate (GPR) was almost always better for PB7 compared to PB6 (on average >92% for PB7 vs >85% for PB6) but still below MC GPR (on average >99%). Overall the PB6 algorithm tends to overestimate the dose to the target (up to 25%) and underestimate the dose to the organ at risk (up to 30%). PB7 performed significantly better but an overestimation of the hot spot compared to MC was found (Figure). We found similar results for the two targets of the lamb's head where only two beam gantry angles were simulated (Table). Each field was optimized with PB6, the final dose calculation time was the same for PB6 and PB7 (about 20 seconds) and ten times greater for MC (about 200 seconds).

**Figure .** PB6 optimized dose distribution on 1/6 head phantom (top left), MC recalculation (top center) and PB7 recalculation (top right), with proton field angle of 70° and range shifter 42 cm from ISO (i.e. air gap ~ 24 cm). The white lines represent the dose profiles (bottom right) extraction plans. In the bottom left of the figure, DVH of each dose distribution is displayed.

Gantry angle	Snout position (cm)	Gamma Analysis results – Passing Rate (%)		
		PB6	MC	PB7
60°	42	70.1	95.6	93.8
	30	81.6	97.0	90.6
	18	87.6	97.0	89.0
	Split	90.6	99.3	90.4
0°	42	85.0	100	86.3
	30	86.8	100	93.1
	18	89.5	100	94.1
	Split	95.4	100	99.5

**Table .** PB6 vs MC and PB7  $\gamma$  analysis (3%,3mm) comparison on transversal planes for eight fields with target in the brain region of the lamb's head.

#### Conclusion

Our data show very promising results with PB7 and much lower computation time than MC. Questions remain about the use of PB7 for brain tumors only for some specific scenarios as use of RS with very large air gaps and beam directions tangential to the patient surface. On the contrary, speed gained with PB7 is a very important issue in the context of multi-criteria-optimization and/or robust optimization and/or on-line re-planning.

### EP-1778 Accumulated dose prediction from pre-treatment dosimetric parameters in cervical cancer PotD method

S. Heijkoop<sup>1</sup>, J. Godart<sup>1</sup>, E. Novakova<sup>1</sup>, J.W. Mens<sup>1</sup>, B. Heijmen<sup>1</sup>, M. Hoogeman<sup>1</sup>

<sup>1</sup>Erasmus Medical Center Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

In our institute locally advanced cervical cancer patients are treated with an online adaptive Plan-of-the-Day (PotD) protocol. Daily CBCT scans are used to select a plan from the plan library that best fits the observed anatomy for that day. This radiotherapy technique allows for better sparing of organs at risk (OAR). However, due to organ motion and daily plan selection, accurate a-priori prediction of the total dose received at the end of the treatment course is challenging, which can lead to inaccurate prediction of normal tissue complications. The aim was to investigate whether pre-treatment established treatment plan parameters can predict accumulated OAR doses for the fractionated treatment.

#### Material and Methods

Treatment plans and daily CBCTs of 24 patients were included in the study. 14 patients had a tip of uterus displacement of more than 2.5 cm as measured with a full and empty bladder planning CT scan ('movers') and 10 patients had a motion less than 2.5 cm ('non-movers'). The movers had 3 plans in the plan library to cover the range of motion (full and empty-bladder IMRT plans with minimal adequate margins and a backup plan with an enlarged margin), whereas the non-movers had 2 plans in the plan library (1 IMRT plan with a minimal/adequate margin and a backup plan with enlarged margin). In all daily CBCT scans the bowel cavity, bladder and rectum were contoured. To calculate accumulated OAR doses non-rigid registration was used (1).

In clinical practice, the movers were on average in 50% of fractions irradiated with the full bladder plan and in the other 50% with the empty bladder plan. Therefore, in this study we investigated correlations ( $R^2$ ) between mean *planned* OAR dose parameters for the full and empty structure sets with the corresponding estimated *delivered* parameters derived with the CBCTs and dose accumulation.

### Results

Obtained  $R^2$  are presented in the Table with an overall average of 0.68. For rectum and bladder, V30 showed the strongest correlation. For the small bowel V20 correlated best, while  $R^2$  for V30 was still 0.74. The V40  $R^2$  for bladder, rectum and bowel were 0.75, 0.78 and 0.64, respectively. For bowel cavity V45,  $R^2$  was rather low. This may be related to the involved relatively small volumes combined with large mobility.

Table 1. Correlations between accumulated dose in bladder, rectum and bowel cavity with planned dose.

$R^2$	
<b>Bladder</b>	
• V20	0.39
• V30	0.76
• V40	0.75
• V45	0.67
<b>Rectum</b>	
• V20	0.45
• V30	0.90
• V40	0.78
• V45	0.67
<b>Bowel</b>	
• V20	0.90
• V30	0.74
• V40	0.64
• V45	0.48

### Conclusion

Especially the planned bladder, rectum and bowel cavity V30 and V40 correlated with accumulated dose.

### EP-1779 Impact of calculation grid resolution and CT slice thickness on TPS calculated small fields OF

M.D. Falco<sup>1</sup>, M. Fusella<sup>1</sup>, C. Fiandra<sup>1</sup>, S. Clemente<sup>1</sup>, C. Garibaldi<sup>1</sup>, M. Casati<sup>1</sup>, F.R. Giglioli<sup>1</sup>, E. Gallio<sup>1</sup>, T. Malatesta<sup>1</sup>, A. Delana<sup>1</sup>, C. Marino<sup>1</sup>, A. Soriani<sup>1</sup>, S. Linsalata<sup>1</sup>, P. Bagalà<sup>1</sup>, G. Benecchi<sup>1</sup>, R. Consorti<sup>1</sup>, M. Casale<sup>1</sup>, G. Reggiori<sup>1</sup>, E. Villaggi<sup>1</sup>, S. Russo<sup>1</sup>, P. Mancosu<sup>1</sup>  
<sup>1</sup>SBRT Working Group, AIFM - Italian Association of Medical Physics, Piazza della Repubblica- Milan, Italy

### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) is increasing thanks to modern technologies and integrated image-guided systems. The main objective of the study was to assess the influence of calculation grid size resolution and CT slice thickness on calculated small fields output factors (OFs) among a large number of centers, equipped with a wide variety of Linacs and Treatment Planning System (TPS).

### Material and Methods

A total of 700 measurements from twenty centers were collected. On three homogeneous phantoms of different slice thickness, i.e. 1,2 and 3 millimetres, small fields OFs were calculated using data commissioned in the TPS. OFs for 1x1 cm<sup>2</sup>, 2x2 cm<sup>2</sup>, 3x3 cm<sup>2</sup> were calculated in the following combination of grid-slice thickness (G-S): G1-S1, G1-S2, G2-S2, G1-S3, G2-S3 and G3-S3, respectively. Four different calculation algorithms were analyzed: AcurosXB (AXB), Analytical Anisotropic Algorithm (AAA), Collapsed Cone Convolution (CCC) and VMC MonteCarlo (MC). The measurement set-ups were: SSD=90,95,100 cm with depth= 10, 5 and 10 cm, respectively. Calculated and measured OFs were compared and the Dev[%]=ABS[(OF<sub>meas</sub>-

OF<sub>calc</sub>)/OF<sub>meas</sub>] was considered. A Multivariate analysis of Variance was performed to test the effect of G, S, field size (FS), calculation algorithm and measurements setup on the uncertainties of OF (Dev [%]) giving the p-values of each variance component. For each factor identified as a significant predictor, a post-hoc test was carried out in order to assess the significance of intragroup differences.

### Results

Results showed that OFs calculated by TPSs were generally larger than OFs measured. Statistical analysis shows that the uncertainties on OFs are not correlated with slice thickness alone, while they increase as the size of the calculation grid increases with a greater dispersion of the data dependent on the algorithm (Fig. 1 panel a) ( $p < 0.01$ ) and as the FS decreases (Fig. 1 panel b) ( $p < 0.001$ ). Also algorithm and measurement setup affect results ( $p < 0.01$ ) with a lower dependence on the setup for systems that have the collapse cone as an algorithm (Fig. 1 panel c). A post-hoc test has confirmed the effect on OF's calculation of field, grid, algorithm and measurement setup ( $p < 0.01$ ).

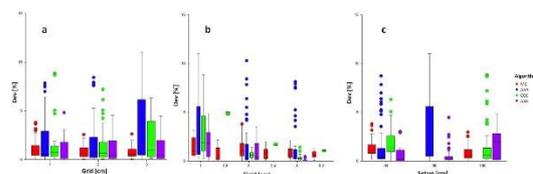

Fig 1. Box-Plot of the absolute difference of calculated and measured OFs in terms of calculation grid (panel a), field size (panel b) and measurement setup (panel c), grouped by algorithm.

### Conclusion

Our results indicate that modern TPS overestimate the calculated small fields OFs compared with measured ones. The overestimation increases with the grid resolution and decreases with the FS. Therefore, we suggest to use, in the SBRT treatment plans, a dimension of the calculation grid as lowest as possible taking account of the hardware capability of TPS and the calculation algorithm.

### EP-1780 Correlation between VMAT plans complexity indices and gamma passing rate by using three QA phantoms

I. Vacchieri<sup>1</sup>, P. Tabarelli De Fatis<sup>2</sup>, M. Liotta<sup>2</sup>  
<sup>1</sup>University of Milan, post graduate Medical Physics School, Milan, Italy ; <sup>2</sup>IRCCS Istituti Clinici Scientifici Maugeri, Medical Physics Unit, Pavia, Italy

### Purpose or Objective

to compare the correlation between VMAT plans complexity indices and local gamma passing rate obtained from three phantoms: ArcCHECK™ -Sun Nuclear Corp. (A), Octavius® 4D-PTW (O) and Delta4-ScandiDos (D<sup>4</sup>).

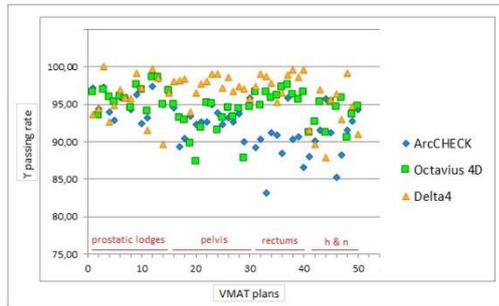

### Material and Methods

50 VMAT clinical plans that include 15 prostate tumor bed, 15 pelvis, 10 rectums and 10 head and neck have been planned with Philips Pinnacle<sup>3</sup> v9.0 for Varian Clinac iX with 120 Millenium MLC. For all plans, pre-treatment verifications have been performed with the three devices and a local gamma analysis (3%-3mm) has been made with a threshold of 10%. RTPlan files were analyzed with a homemade MATLAB (MathWorks®) program to obtain plan complexity indices: Modulation Complexity Score (MCS) and Normalize Leaf Travel LT<sub>i</sub> defined by Masi et al. [1], and Monitor Units (MU). Then, the correlations between gamma passing rate of the three devices and MCS, LT<sub>i</sub> and MU have been investigated by Pearson coefficient. The correlation were considered weak for  $|r| < 0.4$ , moderate for  $0.4 \leq |r| \leq 0.7$  and strong for  $|r| > 0.7$ . Furthermore statistical significance of the difference between the means of the gamma passing rate of the three phantoms

were assessed in pairs by employing a Student's T-test ( $p < 0.05$ ).

### Results

As the complexity of the plan grows the differences between the results obtained by the three instruments increase considerably (Fig. 1).

r Pearson	Device	Loggia	Pelvi	Retto	Testa-collo	Totali
MCS vs $\gamma$ passing rate	ArcCHECK	0,62	0,42	0,56	0,01	0,31
	Octavius 4D	0,90	0,58	0,22	0,17	0,71
	Delta4	0,72	0,20	0,07	0,65	0,51
MU vs $\gamma$ passing rate	ArcCHECK	-0,76	-0,51	0,02	-0,13	-0,08
	Octavius 4D	-0,84	-0,76	-0,21	-0,11	-0,76
	Delta4	-0,51	-0,30	-0,06	-0,73	-0,31
LTi vs $\gamma$ passing rate	ArcCHECK	0,36	-0,02	0,27	0,01	0,13
	Octavius 4D	0,35	-0,29	0,12	0,08	0,39
	Delta4	0,64	-0,60	-0,09	0,54	0,13

For the prostate tumor bed the correlation found with MCS and MU for the three devices were moderate and strong. With LTi the correlation was weak except for D<sup>4</sup>. For pelvis a moderate correlation was found with MCS for A and O while for the MU the correlation was moderate for A and strong for O. In the rectums a moderate correlation was found with MCS for A, the other correlations were weak or absent. For head and neck plans, the only device who found a moderate correlation with MCS and LTi and a strong one with MU was Delta<sup>4</sup>. Considering all 50 plans for A the correlation with MCS, MU and LTi was weak, a strong correlation was found for O with MCS and MU and a moderate one with LTi and finally for D<sup>4</sup> the correlation was moderate with MCS and weak for the other parameters.

A T-test was computed for the pairs: A-O, A-D<sup>4</sup> and O-D<sup>4</sup>. Considering all the 50 plans, we found statistically significance for all the pairs suggesting that the averages of the two distributions compared are different. Performing the test for individual anatomical districts, the results obtained show that for the prostate tumor bed all three devices seem to provide the same information ( $p > 0.05$ ). The same result was achieved in the pelvis for the couple A-O and for the head-neck for couples O-D.

### Conclusion

A strong dependence of the result of the gamma analysis from the instrument used was found. In fact the correlation was found only in few cases bringing out the limitations of the gamma metric, including the volumetric reconstruction algorithms and the differences in the measured dose.

### EP-1781 Ability of Modulation Complexity Score to predict the result of pre-treatment QA for VMAT plans

L. Vacchieri<sup>1</sup>, M. Liotta<sup>2</sup>, A. Malovini<sup>3</sup>, P. Tabarelli De Fatis<sup>2</sup>

<sup>1</sup>University of Milan, post graduate Medical Physics School, Milan, Italy; <sup>2</sup>IRCCS Istituti Clinici Scientifici Maugeri, Medical Physics Unit, Pavia, Italy; <sup>3</sup>IRCCS Istituti Clinici Scientifici Maugeri, Computer Science and Systems Laboratory for Clinical Research, Pavia, Italy

### Purpose or Objective

to evaluate the ability of the Modulation Complexity Score (MCS) to predict the result of the pre-treatment QA in

order to understand whether is necessary to perform the verifications for each VMAT plans or whether these can be replaced by a brief calculation of one or more parameters.

### Material and Methods

168 VMAT clinical plans that include 48 prostate tumor bed, 40 prostate pelvis, 40 rectums and 40 head and neck have been planned with Philips Pinnacle<sup>3</sup> v9.0 for Varian Clinac iX with 120 Millenium MLC. For all plans, pre-treatment verification have been performed with ArcCHECK (Sun Nuclear Corp.) with 2D local gamma analysis (3%-3mm) with a threshold of 10%. RTPlan files were analyzed with a homemade MATLAB (MathWorks®) program to obtain plan complexity indices: MCS and Leaf Travel LTi defined by Masi et al. (2013), and Monitor Units (MU). The correlations between gamma passing rate and MCS, LTi and MU have been investigated by Pearson coefficient. The correlations were considered weak for  $|r| < 0.4$ , moderate for  $0.4 \leq |r| \leq 0.7$  and strong for  $|r| > 0.7$ . Three ranges of values of the passing rate have been established:

- $\gamma < 88\%$  rejection area;
- $88\% \leq \gamma \leq 92\%$  verification area;
- $\gamma > 92\%$  acceptability area;

A machine-learning algorithm known as classification trees was used to identify threshold values for the calculated parameters that could predict at which range the study plane belongs. The discriminative performances were tested with the Leave One Out cross validation procedure. The accuracy of the results was expressed in terms of sensitivity and specificity, choosing to impose the values of 95% and 90% respectively.

### Results

The table shows the Pearson coefficients obtained.

r Pearson	Prostate tumor bed	Pelvis	Rectums	Head-Neck	Total
MCS vs $\gamma$ passing rate	0,69	0,38	0,48	0,41	0,51
Mu vs $\gamma$ passing rate	-0,77	-0,43	0,34	-0,40	-0,29
LTi vs $\gamma$ passing rate	0,50	-0,05	0,27	0,24	0,35

For the prostate tumor bed the correlations found with MCS and LTi were moderate and strong with MU. For the other districts,  $r$  is around 0.4 for MCS while MU appears to be moderately correlated with the exception of the rectum plans. The correlation with LTi was found to be weak or absent. Considering all plans the correlation with MCS is moderate while it appears weak for the other two parameters. The results show that the correlation found between complexity parameters and  $\gamma$  passing rate is strongly dependent on the anatomical district analyzed. For each parameter, it was possible to identify a threshold value. The best results, analyzing the data by categories, were obtained with MCS and MU in the pelvis district in identifying the rejected category: for MCS a threshold of 0.20 identifies the rejected plans with specificity 97% and sensitivity 46%; for MU, the threshold 752 achieves a specificity of 83% and a sensitivity of 46%. Analyzing all the data, the best result is achieved by LTi, whose threshold identifies the plans to be accepted with specificity 97% and sensitivity 50%.

**Conclusion**  
It was not possible to predict the results of the pre-treatment QA through MCS, LTi and MU with statistical reliability, not allowing us to avoid making the verification for each VMAT plans.

### EP-1782 Comparison of two commercial detectors and the influence of grid spacing calculations in SBRT

R. Gómez Pardos<sup>1</sup>, E. Ambroa Rev<sup>1</sup>, D. Navarro Giménez<sup>1</sup>, A. Ramírez Muñoz<sup>1</sup>, J. García-Miguel Quiroga<sup>1</sup>, M. Colomer Truyols<sup>1</sup>

<sup>1</sup>*Consorti Sanitari de Terrassa CST, Radiotherapy, Terrassa, Spain*

**Purpose or Objective**

With the increasing use of Stereotactic Body Radiation Therapy (SBRT) combined with VMAT technique the complexity of treatments has increased significantly. Now the dose distributions are less homogenous than with 3DCRT and the dose gradients are higher. We need to calculate and measure these dose distributions as accurately as possible.

The first objective of this work is to compare the dose distributions measured with two commercial array detectors against the calculated dose in Monaco TPS. The second objective is to evaluate the influence of the grid spacing used in the TPS calculation for the SRS1000 detector. In both we analyze lung and spinal SBRT cases separately.

**Material and Methods**

The SBRT plans were calculated in Monaco 5.10 TPS and did the QA with 1% statistical uncertainty and 2 and 1mm grid spacing. All the plans were delivered with an Elekta Synergy with Agility ML linac. We verified both 29 lung and 6 spinal SBRT cases.

The QA measurements were done with the PTW Octavius4D 1500 (1405 ionization chambers (ICs) of 0.06 cm<sup>3</sup> arranged in a 27x27cm matrix with a detector spacing of 7.1 mm) and PTW Octavius4D 1000SRS (977 liquid-filled ICs of 0.003 cm<sup>3</sup> arranged in a 10x10cm matrix with a detector spacing of 2.5 mm in the center area). We used the 3D gamma index  $\gamma(\%dose,DTA)$  to compare the measured and calculated dose distributions. Due to the special characteristics of SBRT treatments, we used  $\gamma(2\%,2mm)$  and  $\gamma(3\%,1mm)$  for the evaluations in the grid spacing case. In the 1500vs1000 comparison we evaluated just the  $\gamma(2\%,2mm)$ .

**Results**

Results are shown in Table 1. For the statistical comparison in both Lung and Spinal patients we first evaluated if the data was normally distributed. Lung data resulted not normally distributed so we did a Mann-Whitney-Wilcoxon test. Spinal data were normally distributed so we did a paired t test with a 95% confidence interval. For the 1000SRS grid comparison (2 vs 1mm) we found in both lung and spinal patients that the differences in the comparisons were statistically significant. For the 1500 vs 1000SRS gamma comparison, we had the same conclusion although the significance was weak.

TABLE 1

LUNG					
Detector: 1500 vs 1000		Grid spacing (with 1000 SRS): 2mm vs 1mm			
$\gamma(2\%,2mm)$ grid spacing 2mm		$\gamma(2\%,2mm)$		$\gamma(3\%,1mm)$	
	Octavius 1500	Octavius SRS1000	GS - 2mm	GS - 1mm	GS - 1mm
Mean (%)	95.3%	98.4%	98.4%	99.3%	94.9%
SD (%)	0.6%	1.0%	1.6%	0.8%	3.1%
Median (%)	99.0%	99.3%	99.1%	99.7%	95.7%

SPINAL					
Detector: 1500 vs 1000		Grid spacing (with 1000 SRS): 2mm vs 1mm			
$\gamma(2\%,2mm)$ grid spacing 2mm		$\gamma(2\%,2mm)$		$\gamma(3\%,1mm)$	
	Octavius 1500	Octavius SRS1000	GS - 2mm	GS - 1mm	GS - 1mm
Mean (%)	97.6%	94.3%	94.1%	96.1%	88.2%
SD (%)	0.6%	3.0%	3.0%	1.2%	4.5%
Median (%)	97.5%	94.2%	94.2%	96.3%	89.1%

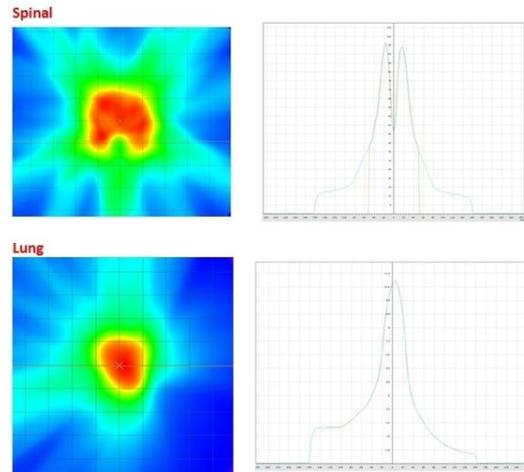

**Conclusion**

Comparing the 1000SRS measurements with 2 and 1mm calculation grids, we can conclude that for spinal cases 1mm grid represents better the dose delivered than 2mm grid. However, in lung cases that does not happen. We think that this happens because both dose distributions are in general very different. While in spinal SBRT we usually have large dose concavities with the corresponding dose fall-off, in lung SBRT we usually have approximately-rounded targets, were we hypothesize that spatial resolution is not that extremely crucial in calculations (Figure 1). In spite of that, both lung and spinal comparisons show statistically different results in both  $\gamma(2\%,2mm)$  and  $\gamma(3\%,1mm)$ .

In the 1500 vs 1000SRS comparison, assuming a grid of

2mm, we cannot assure that one matrix results are superior to the other ones.

Figure 1. Spinal and Lung SBRT examples

**EP-1783 Implementation of a fast method for routine linac-QA for VMAT with EPID dosimetry**

*P. Cambraia Lopes<sup>1</sup>, J. Van Egmond<sup>1</sup>, M. De Goede<sup>1</sup>, J. Van Santvoort<sup>1</sup>*

*<sup>1</sup>Haaglanden Medisch Centrum- Antoniusshove, Medical Physics, Leidschendam, The Netherlands*

**Purpose or Objective**

VMAT plans are rather complex and require continuous and synchronized change of many variables in time. It would therefore be desirable to regularly assess the quality of dynamic delivery, independent of any particular (patient) plan. We have developed a fast and simple method intended to detect suboptimal VMAT delivery by the linac, using EPID dosimetry.

**Material and Methods**

VMAT test plans were developed that contained relatively extreme dose rates (DR, range: -65-500 MU/min), gantry speeds (GS, range: -1-5 deg/sec), and MLC-leaf speeds (LS, up to 3.5 cm/sec), which can be found in clinical practice. The following linac states were constructed for the Pinnacle treatment planning system (TPS), by specifying for each VMAT segment the corresponding MU's and leaf positions: High-DR/High-GS (HH, 1.67 MU/deg), High-DR/Low-GS (HL, 10 MU/deg), and Low-DR/High-GS (LH, 0.22 MU/deg). Plans contained sharp transitions between these states, which also allowed to test for inertia effects (acceleration/deceleration) of the gantry, DR control, and for proper synchronization. Beam 1 contains linac states HH/HL, together with MLC movement, while beam 2 contains linac states HL/LH with static MLC (figure 1). The gantry travel between linac states was varied and kept as a multiple of 2 degrees. These plans were delivered on a cylindrical phantom while EPID frames were recorded. The delivered dose was then reconstructed with the iViewDose software from Elekta and the reconstructed dose was compared in 3D to the TPS dose. In addition, the test plans were benchmarked by independent dose measurements using a dedicated phantom for pretreatment patient-QA (ArcCHECK phantom), and by monitoring the linac parameters DR, GS, and LS, during delivery.

**Results**

It is necessary to explicitly define control points (CP) every 2 degrees, to get sufficiently detailed dose calculations from the TPS. By doing so, the agreement between the benchmark dose measurement and the TPS dose was found to be 78% for beam 1, and 95% for beam 2 (% gamma pass rate with criteria 3%/3mm). The agreement between iViewDose and the TPS was 97% for beam 1 (mean gamma

= 0.47) and 74% for beam 2 (mean gamma = 0.77), while the dose differences at the isocenter were 9.9% for beam 1, and -6.6% for beam 2 (iViewDose compared to TPS). These differences may be at least in part attributable to the presence of very small (=2 degrees) segments with different linac states, which may be challenging for accurate dose reconstruction. Except for some deviations in leaf position and speed for the very small segments at the end of beam 1, the linac accurately delivers the control points.

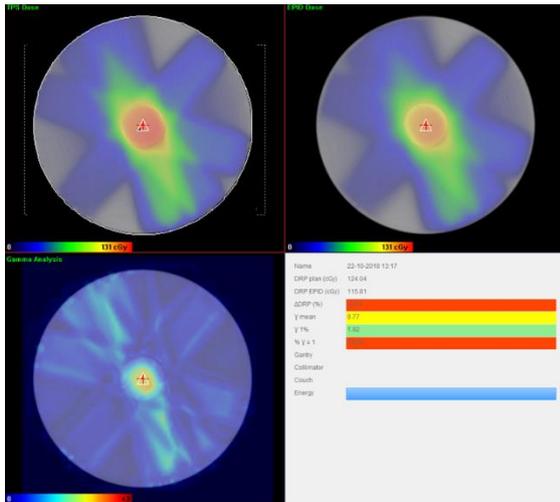

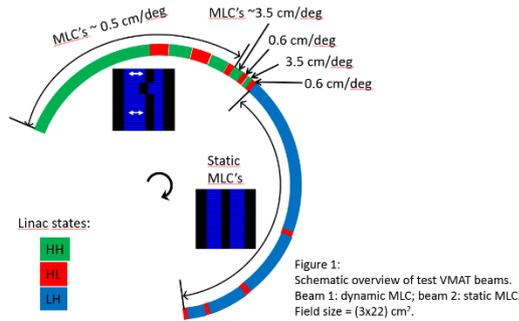

Figure 2: iView result for beam 2.

**Conclusion**

We have described a method to implement simple linac QA for VMAT using EPID dosimetry. The test beams have been successfully constructed and tested with benchmark measurements. The next step will be to determine reproducibility of results based on repeated measurements, in order to establish baseline values and possible action levels.

**EP-1784 ArcCheck HU setting influence on the uncertainty of pre-treatment verification results**  
 M. Giżyńska<sup>1,2</sup>, M. Bukat<sup>1</sup>, D. Szałkowski<sup>1</sup>, A. Walewska<sup>1</sup>  
<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics Department, Warsaw, Poland ; <sup>2</sup>University of Warsaw Faculty of Physics, Department of Biomedical Physics, Warsaw, Poland

**Purpose or Objective**

ArcCheck (SunNuclear) should be characterized in TPS by the HU value that would provide the best agreement of TPS vs measurement entrance to exit dose ratio (ratio test) for 10x10 field size. The purpose of this work was to examine whether the best ratio test results depend on the beam quality and field size. The influence of the HU setting on the results for gamma analysis made for clinical plans was also examined.

**Material and Methods**

Array and dose calibration was performed prior to measurement. ArcCheck was irradiated with 5x5, 10x10, 15x15 and 20x20 field sizes on TrueBeam machine (Varian) with different beam energies used: 6WFF, 15WFF, 6FFF and 10FFF. The ratio test was done for all beam qualities and field sizes. Calculations of TPS dose distribution was done in Eclipse (AAA 13.6.23) with different HU assigned for ArcCheck phantom. Entrance and exit dose for measurement was calculated from six diodes surrounding entrance/exit points. Standard deviation was treated as measurement uncertainty. In the second step of our study we performed analysis for clinical plans. We evaluated 10 IMRT and VMAT plans with different beam geometries: full and half arcs, IMRT with small and large field sizes. Dose calculations were performed for two different HU values - one recommended (246HU) and one achieved in former step of our work (150HU). In order to do the bias-free evaluation artificial measurements were created based on the calculations performed with 150HU and compared with dose distributions calculated for 246 HU. Artificial measurement is a file created with a Python script on the basis of TPS dicom dose distribution which mimics the real measurement file. Comparisons were done with the SNCPatient (SunNuclear, v.6.7.3) software. The 3mm/3%; 2mm/2%; 1mm/1% parameters for global and local gamma evaluation were used. Dose threshold was set to 5%.

**Results**

For 10x10 field size the HU achieved from the ratio test varies between 150HU and 246HU depending on the beam quality (see Figure 1). The ratio test gives also incoherent results for evaluated field sizes: 200-280HU for 6WFF, 160-190HU for 15WFF, 160-230HU for 6FFF, 130-160HU for 10FFF (see Figure 2). The difference in gamma evaluation between 150HU and 246HU dose distributions depended on patient geometry and was mostly observed in exit dose region, though influencing the local gamma evaluation. Percent of passing points varied between 100% and 93% for 3mm/3% local gamma analysis and between 100% and 79% for 2mm/2% local gamma analysis.

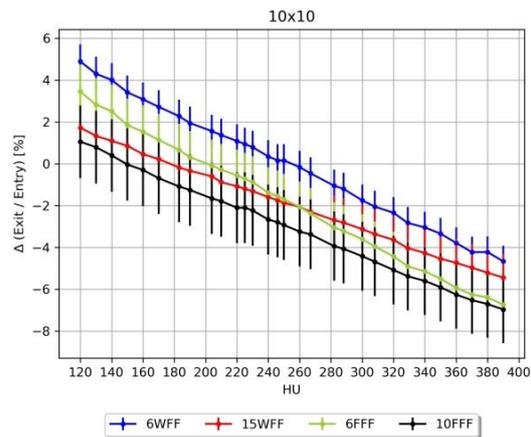

Figure 1. Ratio test result for 10x10 field and different beam qualities.

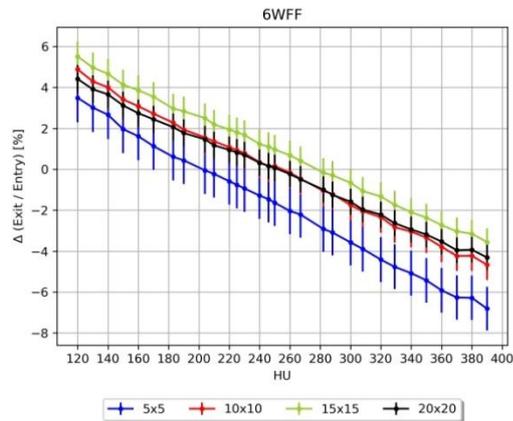

Figure 2. Ratio test result for 6WFF beam and different field size.

### Conclusion

Ratio tests performed for different beam qualities leads to range of HU values (150HU-250HU) which should be used to define ArcCheck phantom in TPS during preparation of pre-treatment verification plan. Choosing single HU value despite of beam quality can cause false negative result of pre-treatment verification if local gamma analysis is used. Special care should be taken while using ArcCheck for pre-treatment verification of multienergetic plans.

### EP-1785 Dosimetric verification of stereotactic treatment plans using 3D-printed phantom and GafchromicEBT3

M. Kruszyna<sup>1,2</sup>, A. Skrobala<sup>1,2</sup>, B. Pawalowski<sup>1</sup>, H. Szweda<sup>1</sup>  
<sup>1</sup>Greater Poland Cancer Centre, Medical Physics Department, Poznan, Poland ; <sup>2</sup>Poznan University of Medical Science, Department of Electroradiology, Poznan, Poland

### Purpose or Objective

The verification of stereotactic plans is usually performed with 2D-array of detectors, in the coronal projection. However, for complex cases, where localization of targets is proximity to organs at risk, there is necessity to use detectors with higher resolution and verification in other projections. The aim of this work was to design and build the 3D-printed phantom for verification with films dosimetry and evaluate the correctness of CyberKnife (CK) stereotactic plans' realization.

### Material and Methods

3D-printed phantom (PLA material) it is open cube (10x10x10cm<sup>3</sup>), filled with water, with the possibility to insert films in two projections: transversal and sagittal. The phantom was used in measurements on CK. The set of 3 to 5 sheets of Gafchromic EBT3 (Ashland) films were simultaneously placed and irradiated in the phantom, the films was placed at the center of target volume (reference position) and at distance of 1 to 2 cm from the reference position. A group of 10 intracranial cases with target's localization close to optical path (5 pts.) and close to brain stem (5 pts.) were evaluated. According to our clinical workflow all plans were verified and passed gamma criteria L2%/2mm, Th5% using the 2D-array SRS1000 (PTW, Freiburg) with mean result of 97,98%, additionally all were measured in 3D-printed phantom. Analysis were done in OmniProl<sup>m</sup>RT software (IBA Dosimetry, v1.6) using gamma evaluation method with criteria: 2%/2mm, 3%/3mm and threshold 5% and 20% of maximum dose, respectively.

### Results

The results for most distributions of planned doses showed high compliance with the obtained measurement data,

however, larger discrepancies were observed in areas of high dose gradients. For center position, score values were (2%/2mm: Th5%, Th20%): 93,73±6,95%, 96,66±5,00%; (3%/3mm: Th5%, Th20%): 98,57±2,04%, 99,14±1,89%, respectively. For others film's position, the results were (2%/2mm: Th5%, Th20%): 87,51±11,92%, 91,88±10,37%; (3%/3mm: Th5%, Th20%): 96,43±5,78%, 95,79±7,83%. The results presented above, confirm the usefulness of such specially design phantoms for more detailed dosimetric verifications.

### Conclusion

The 3D-phantom verification allows compact dosimetry with simultaneous measurements (saving time) in several planes and different than coronal projection. It's especially important for complicated intracranial cases (proximity to OARs) and multi-metastasis cases.

### EP-1786 Towards real-time Monte Carlo dose computation: muscle or brain?

M. Alber<sup>1</sup>, N. Saito<sup>1</sup>, M. Sohn<sup>2</sup>

<sup>1</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>Scientific RT, GmbH, Munich, Germany

### Purpose or Objective

Real-time Monte Carlo (MC) dose computation will soon be an essential pre-requisite for quality assurance of online-adapted treatment plans. Due to a surge in computation power by parallelization both in GPUs (muscle) and CPUs (brain), this goal is in reach. However, muscle and brain need very specific code optimization for full performance. Realistic benchmarks must be obtained with complete source and collimator models to avoid severe bias in timings. Here, we present how the capacity of CPUs to execute complex code can be harnessed by variance reduction (VR) techniques for high-accuracy MC calculations.

### Material and Methods

The SciMoCa code combines elements of the VMC/XVMC/VMC++ and EGSnrc family of codes with a 4D generic MLC model and a five-element virtual source model. Being optimized for CPU, it employs VR such as history repetition, particle splitting and their counterpart, Russian roulette. Source and collimator models can be much accelerated by VR, however, strong use of VR leads to widely varying particle weights, which slows down dose convergence. Ideally, all elementary energy deposition events (tallies) have the same magnitude. SciMoCa reduces the width of the tally distribution by dynamically adjusting the VR methods on the fly, from the particle source to full absorption. The code is further optimized for memory access, especially by an optimized representation of ICRU-derived cross-section tables.

### Results

In benchmarks against EGSnrc, SciMoCa agrees within statistical uncertainty, with a maximum error of 1.8% recorded for a 6 MeV pencil beam in a lung phantom. A density uncertainty of 1% in this geometry would produce a similar error magnitude. SciMoCa was experimentally validated for Elekta VersaHD, Varian TrueBeam and Accuray Cyberknife accelerators. Typical dose errors in commissioning conditions are in the order of 0.5%. Depending on plan and linac complexity, simulation of the source and collimators accounts for 3-20% of overall computation time, an acceleration by a factor 2-40 by dynamic VR tuning. Timing benchmarks show that SciMoCa is 2.5 times faster than XVMC. More importantly, performance scales almost linearly with logical CPU count (10% performance drop between 4 and 96 cores). This allows clinical dose computations with 1% uncertainty on 2 mm grid size in typically 10-60 seconds on contemporary entry-level server hardware (ca. 24 cores).

### Conclusion

Full source and collimator simulation increases the complexity of MC to an extent that puts GPUs at a

disadvantage, but can be addressed by leveraging the capabilities of CPUs. The advantages of dynamic VR tuning would be offset by thread divergence issues on GPU. The essential metric of code performance is its scaling capability with the number of CPU cores to be ready for the next level of parallelization in hardware. Real-time MC is rapidly becoming reality both with muscle and brain.

### EP-1787 Commissioning of the RayStation treatment planning system in a multi-vendor context

A. Savini<sup>1</sup>, F. Rosica<sup>2</sup>, V. D'Errico<sup>1</sup>, T. Licciardello<sup>1</sup>, E. Menghi<sup>1</sup>, F. Bartolucci<sup>2</sup>, F. Christian<sup>2</sup>, G. Orlandi<sup>2</sup>, A. Sarnelli<sup>1</sup>

<sup>1</sup>Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRST IRCCS, Medical Physics Unit, Meldola, Italy ; <sup>2</sup>Ausl 4, Medical Physics Unit, Teramo, Italy

#### Purpose or Objective

To present our procedure and results regarding the commissioning of the RayStation treatment planning system (TPS) in a multi-vendor context with several LINACs, beam qualities and multi-leaf collimators (MLCs).

#### Material and Methods

RayStation clinical version 7.0 was considered in this work. The available dose calculation algorithm was the collapsed cone convolution (version 3.3). LINACs, beam qualities, MLCs and radiotherapy techniques considered for implementation are reported in Tab.1. The clinical commissioning included several steps such as the acquisition of basic dosimetric measurements (i.e. percentage depth doses, profiles and output factors), the dosimetry of ad-hoc abutted fields for modeling the MLC, the beam modeling for reproducing experimental measurements and, finally, the validation of the model for each radiotherapy technique. Validation for basic dosimetry was conducted using the  $\gamma$ -confidence limit (CL) between measured and calculated dosimetric curves as addressed in the ESTRO booklet n.7. Validation for intensity modulated techniques was conducted following the AAPM-TG119 protocol. Finally, for each beam quality considered for implementation of intensity-modulated techniques, pre-treatment verifications of ten clinical cases were performed as end-to-end test.

ID	Linac	MLC	Wedge	Couch	Beam quality - Technique
SYN1	Elekta Synergy	MLC1	MW	iBEAM Evo	6MV SMLC, VMAT, 3DCRT 18MV 3DCRT
SYN2	Elekta Synergy	MLC2	MW	iBEAM Evo	6MV SMLC, VMAT, 3DCRT 15MV 3DCRT
TRI	Varian Trilogy	Millenium 120	PW, EDW	IGRT Couch	6MV SMLC, DMLC, VMAT 15MV 3DCRT
TRU	Varian Truebeam	Millenium HD	EDW	IGRT Couch	6MV VMAT, 3DCRT 10MV VMAT, 3DCRT 15MV 3DCRT 6FFF VMAT 10FFF VMAT

Tab.1 List to the LINACs, accessories, beam qualities and radiotherapy techniques considered within this work. MW: motorized wedge; PW: physical wedge; EDW: enhanced dynamic wedge.

#### Results

$\gamma$ -CL evaluation is reported in Fig. 1a. The RayStation beam modeling was able to satisfy the required criteria ( $\gamma$ -CL < 1) for 99.4% of the analyzed dosimetric curves. Out of tolerances results were found for large fields (i.e. 30x30 and 40x40 cm<sup>2</sup>) at large depth (i.e. 20 cm) with little clinical relevance. For TG119 verifications,  $\gamma$ -index pass-rates calculated with TG119 criteria (3%, 3mm, global normalization) are reported in Fig. 1b (only VMAT results are shown). For all cases the pre-treatment verifications gave clinical acceptable results (i.e. pass-rate > 95%). For pre-treatment verifications of VMAT clinical cases,  $\gamma$ -index pass-rates with stricter criteria (3%, 3mm local) were all above 90%.

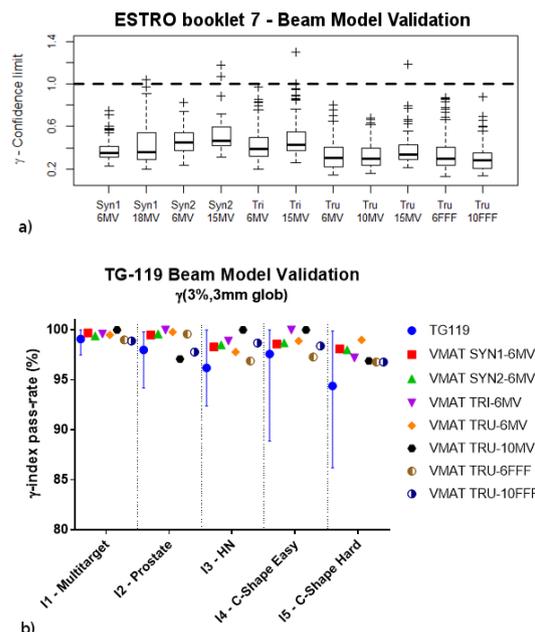

Fig.1

#### Conclusion

The RayStation TPS was modeled for different LINACs, beam qualities, MLCs and irradiation techniques. Following the presented procedure for modeling, we found a final accuracy that was comparable across the considered devices and clinically acceptable for each combination.

### EP-1788 Dose distribution for electron beam using Monte Carlo simulation with GATE

J. Leste<sup>1</sup>, M. Chauvin<sup>1</sup>, T. Younes<sup>1</sup>, L. Vieilleuvre<sup>1</sup>, M. Bardies<sup>1</sup>, X. Franceries<sup>1</sup>, R. Ferrand<sup>1</sup>, N. Pierrat<sup>2</sup>, L. Bartolucci<sup>2</sup>, L. Simon<sup>1</sup>

<sup>1</sup>CRCT, UMR 1037 Inserm, Toulouse, France ; <sup>2</sup>Institut Curie, Dpt. de Radiothérapie, Paris, France

#### Purpose or Objective

Limits of Treatment Planning Systems (TPS) for dose calculation of photon beams have been widely studied. There are fewer studies using Monte Carlo (MC) for electron beams. Although the use of advanced variance reduction technique (Macro Monte Carlo, MMC) to meet time clinical requirements leads to limited results in complex cases (heterogeneity, irregular surfaces). This study aims to assess a commercial algorithm, Fast electron Monte Carlo (eMC, Varian, Palo Alto, CA), based on MMC, and an in-house GATE model of a radiotherapy linac (TrueBeam, Varian) for electrons beams in complex cases. Algorithms are also evaluated for clinical cases (head & neck, breast).

#### Material and Methods

Validation of GATE model is performed with homogenous water phantom. Percentage depth dose curves (PDD) and lateral dose profiles (LDP) are compared with experimental measurement (6, 9, 12 and 18 MeV). For complex cases including heterogeneities (lung, bone) and irregular surface (step), results of dose calculation for eMC and GATE are compared using Gafchromic EBT3 (Ashland ISP, Wayne, NJ) films. LDPs are acquired at two different depths and normalized in a homogenous water region. Global Gamma Index Pass Rate (GIPR) 1D is computed to compare the data sets. For clinical case an absolute dose calibration of our MC model is achieved. Ten clinical cases are tested for several energies and for different inserts

(square, circular and personalized). The results of eMC and GATE dose distribution are compared using the GIPR 3D.

### Results

When comparing GATE and measurements, GIPR<sub>2%/2mm</sub> for PDD and LDP in homogenous water phantom is always superior to 96% for all energies. Field size difference is always inferior to 1%. GIPR<sub>3%/3mm</sub> for most of complex cases (lung, bone and step) is superior to 98.5% for GATE (6, 9, 12 MeV). In all configurations GIPR of eMC are always inferior to GATE except for two cases: 12 MeV at 20 mm for lung (100% and 96.1% for eMC and GATE respectively) and bone (68.9% and 66.2%). First results of clinical cases show discrepancies between GATE and eMC dose distribution calculation (especially in high density regions). GIPR<sub>3%/3mm</sub> ranged from 74.63 % to 77.25% for first tested patients.

### Conclusion

GATE model for electron beams is validated in reference conditions. When comparing to measurements for heterogeneous media and irregular surfaces, eMC was limited while GATE was satisfactory in almost all configurations. First dosimetric results of clinical cases show also relevant discrepancies with eMC. These differences must be confirmed by experimental investigations. The study shows that GATE could be proposed as a 3D dose check solution for complex electron beams. Using our regional meso-computer (>13000 cores) GATE computation takes less than 4 minutes.

### EP-1789 Repetitive use of TLD-100 without annealing for imaging doses in radiotherapy

M. Clausen<sup>1,2</sup>, P. Kuess<sup>1,2</sup>, D. Georg<sup>1,2</sup>, H. Palmans<sup>3,4</sup>

<sup>1</sup>Medical University of Vienna, Department of Radiotherapy, Vienna, Austria ; <sup>2</sup>Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Physics for Radiation Oncology, Vienna, Austria ; <sup>3</sup>MedAustron GmbH, EBG MedAustron, Wiener Neustadt, Austria ; <sup>4</sup>National Physical Laboratory, National Physical Laboratory, Teddington, United Kingdom

#### Purpose or Objective

Due to their small size and reusability thermoluminescence detectors (TLDs) are very practical and commonly used in various fields of radiation dosimetry. Before reusing the detectors, it is generally recommended to heat them in a TLD oven to achieve a complete reset via thermal annealing. This study investigates the repetitive use of TLDs, type TLD-100 (LiF:Mg,Ti, Thermo-Fischer Scientific), without intermediate annealing to improve the efficiency of measurements for the imaging doses (~ 50 mGy) in radiotherapy. Using the TLDs without the annealing process is time efficient. Moreover, since the consistency in the process of treating TLDs is a very crucial aspect, this can simplify the use and avoid possible errors coming from annealing.

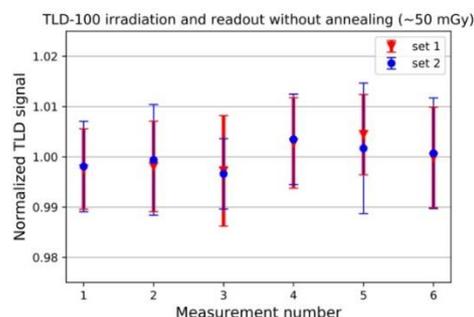

#### Material and Methods

20 TLDs were repetitively irradiated and read in a special-purpose reader (Risø, DTU Nutech, Denmark), with an inbuilt radiation (<sup>90</sup>Sr/<sup>90</sup>Y beta irradiator) source. For readout the temperature was increased at a rate of 5 °C/s up to the final temperature of 400 °C, in 400 steps. For the analysis, a region of interest (20 measurement points) around the dominant peak of the glow curve (5<sup>th</sup> peak, 250 °C) was evaluated. Individual sensitivity factors were applied for each specific TLD. The reproducibility of the dose measurements were studied as a function of irradiation time, and comparisons were made between TLD measurements with or without initial annealing.

#### Results

As a first step, TLDs were readout without irradiation. The TLD responses after the repetitive measurements without intermediate annealing are shown in figure below. Two

different measurement days (sets) are shown. The time between the six repetitions ranged from 1-3 hours. TLD signal was normalized to the mean of a measurement set. Calibration of TLDs was performed in a <sup>60</sup>Co beam. The precision of measurements was improved from 3% to 1.7% by applying the individual TLD sensitivity correction factors. By using the approach of repetitive measurements of the same dose (50 mGy) without annealing, the standard deviation was improved, in average from 1.7% to 1% compared to a readout process with prior annealing. Doses higher than 120 mGy led to an accumulated signal, for which the signal reset by readout was not sufficient. The number of repetitions, alternation of doses and the dose limits for the repetitive measurements need to be further investigated.

### Conclusion

The results indicate that the heating of the TLDs inside the reader for signal readout suffices to reset the TLDs to an acceptable level in the low dose range, which is typical for kV imaging procedures. Utilizing TLDs without annealing for this dose range can be beneficial for the dose assessment of imaging doses during X-rays, CT or microCT imaging, as this increases the workload efficiency and precision of measurements and simplifies the use of TLDs.

### EP-1790 TPS out of field dose accuracy: impact on dose volume histogram calculation of pacemaker devices

A. Delana<sup>1</sup>, A. Barbareschi<sup>2</sup>, F. Maria Daniela<sup>3</sup>

<sup>1</sup>S. Chiara Hospital- Azienda Provinciale Per I Servizi Sanitari-, Department of Medica Physics, Trento, Italy ;

<sup>2</sup>University of Roma Tor Vergata, Scuola di Specializzazione in Fisica Medica, Trento, Italy ;

<sup>3</sup>SS. Annunziata Hospital, Department of Radiation Oncology, Chieti, Italy

#### Purpose or Objective

As always more people carrying an electronic device such as pacemakers (PMK) undergo radiotherapy, an evaluation to the dose received by PMKs has to be made. As stated in AAPM TG 158, Treatment Planning Systems (TPS) show large error in the out of field region where PMK is typically placed, and the magnitude of dose calculation error should be known to ensure the proper categorization and clinical patients management. Aim of this multicenter study is to evaluate the behavior of three TPSs in the out of field dose region, comparing the dose volume histogram (DVH) of PMK placed in in-house built phantoms.

#### Material and Methods

Two phantoms were created with a PMK embedded in a PMMA slab with 2 cm or 1 cm of PTW Real Water 3 (RW3) over and 10 cm of RW3 under, to account for PMK depth inside the body and to ensure backscatter. CT datasets were acquired, PMK structure delineated, density corrections for the CT artifact performed; the CT datasets were then sent to the centers. TPSs considered are: Elekta-Monaco v.5.11 (C1), Philips-Pinnacle3 v.8 (C2) and Elekta-Oncontra Masterplan (C3). Linac commissioned is an Elekta Sinergy Agility; dose calculation algorithms are

XVMC for C1, collapsed cone convolution for the others. Each TPS calculated the dose for two plans (both with 6MV beams at DFA 95cm): a 10x10cm<sup>2</sup> beam and a dynamic multileaf collimator plan DMLC 10x10cm<sup>2</sup> field as a series of 10 rectangular strips in the lateral direction of 10 cm x 1 cm each. Each plan delivered 2Gy in one fraction, with a grid resolution of 2mm. TPSs calculated DVH for the PMK structure when its proximal edge was 1 cm to 10 cm to the field edge. Results are expressed as cGy/Gy. TPSs comparison is performed on the PMK maximum dose (D1cc) and mean dose (Dmean). An analysis is performed on the difference between these doses and the maximum discrepancies were evaluated.

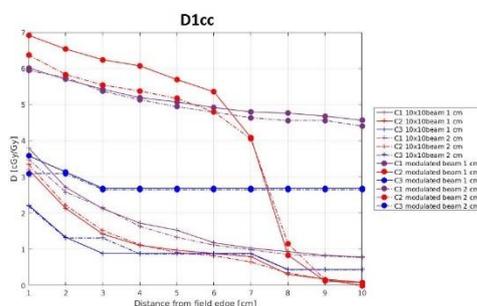

Figure 1: D1cc to the PMK as calculated by the TPSs at 1 cm and 2 cm depth for the two plans considered.

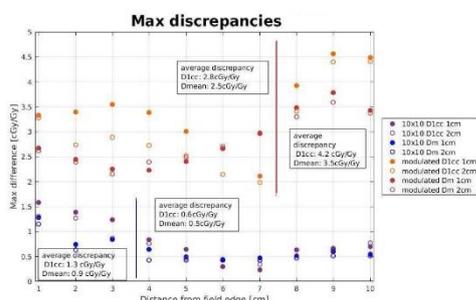

Figure 2: Highest discrepancies between TPSs calculation.

## Results

Out of field doses calculated at 1 cm and 2 cm depth are slightly the same for all TPSs: dose differences are less than 1 cGy/Gy for D1cc and Dmean, for both plans (see fig1). Discrepancies between D1cc and Dmean calculated from TPSs were higher for the DMLC plan than the 10x10cm<sup>2</sup> field as shown in fig2. For the square beam and DMLC plan, we identified two different regions of behavior calculations, as shown in fig2: for the square beam differences in D1cc and Dmean are higher close to the beam edge (distances  $\leq 3$  cm), whereas for the DMLC plan the discrepancies are greater at distances  $\geq 7$  cm from the beam edge. in the TPS

## Conclusion

While with the square beam all TPSs are in good accordance in the out of field dose calculation (maximum difference 1.6 cGy/Gy), in the DMLC plan the difference between TPSs is higher (up to 4.5 cGy/Gy). TPSs show different behavior in out of field dose for the square beam with respect to the DMLC plan, probably related to collimator scatter and head leakage modeling. All centers are currently working on measurements of such doses to better understand and evaluate TPS's reliability in estimating dose to a PMK.

## EP-1791 Correcting dose distributions to the magnetic field of a high-field MR-Linac using deep learning

R. Rozendaal<sup>1</sup>, W. Van den Wollenberg<sup>1</sup>, S. Van Kranen<sup>1</sup>, J. Sonke

<sup>1</sup>Netherlands Cancer Institute, Department of Radiotherapy Physics, Amsterdam, The Netherlands

## Purpose or Objective

The Elekta Unity MR-Linac integrates a high-field MR with a state of the art Linac. In order to exploit the potential of this device, the effect of the magnetic field must be taken into account when calculating dose. This is typically done using a Monte Carlo (MC) method, which is accurate but also computationally expensive. The associated computation time adds to the daily treatment time slots. The purpose of this study was to evaluate the potential of a convolutional neural network (CNN) to account for the presence of a magnetic field.

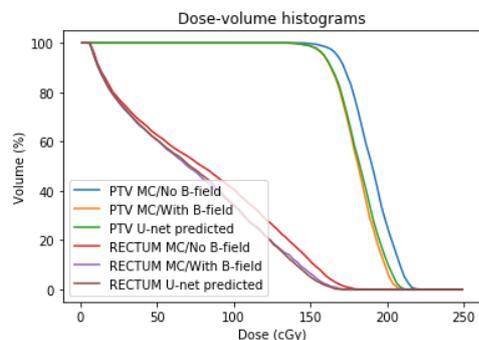

## Material and Methods

The CNN architecture chosen was a 3D U-net [1] like with 3-fold downsampling. Input data consisted of beam specific 3D dose distributions calculated using Unity treatment planning system (Monaco, Elekta AB, Stockholm) with the magnetic field effects switched off, desired output data were the same dose distributions with the magnetic field on. In total 7 patients, each with one treatment plan, were included; training and validation was done using leave-one-out cross validation. Training samples consisted of a full 3D dose distribution composed of 9 beams and were generated on the fly. Each plan had 27 treatment beams available: 9 beams at the (fixed) gantry angles used for plan optimization, and then each beam offset by +/- 10 degrees. By not using the anatomy of the patient as an input to the network, 18<sup>9</sup> possible dose distributions available for training: 6 (patients) \* 3 (beams per gantry angle) for 9 gantry angles. The loss function was a weighted mean squared error, with higher weights for higher doses. The network was implemented using python/keras; training was done on a NVIDIA GTX-1080 GPU. After training, the predicted dose distribution for validation was evaluated by inspecting parameters of the dose-volume histogram (DVH): D2 (near-maximum dose), D50 (median dose) and D98 (near-minimum dose) for the planned target volume (PTV); mean dose for two organs-at-risk (OARs), the rectum and the anal sphincter. Values were calculated for the baseline-situation (no magnetic field corrections) and the CNN-predicted dose distribution, both versus ground truth, MC with magnetic field on.

## Results

Training converged typically after ~2000 iterations, taking ~900s. A single prediction of the magnetic-field corrected dose took 1.64 ± 0.04 s. Table 1 shows average results, Figure 1 shows typical dose-volume histogram (DVH) curves. Average correspondence in the PTV is within 1%, correspondence in the OARs is at -3% and -2%. In general, the effect of the magnetic field is better modelled for higher dose regions.

Region	Parameter	Dose	Mean	S.D.
PTV	D2	MC, no magnetic field	+4.8%	±1.2%
PTV	D2	CNN prediction	+0.8%	±1.1%
PTV	D50	MC, no magnetic field	+4.5%	±2.0%
PTV	D50	CNN prediction	+0.7%	±2.3%
PTV	D98	MC, no magnetic field	+4.1%	±3.6%
PTV	D98	CNN prediction	-0.5%	±3.3%
Rectum	Dmean	MC, no magnetic field	+6.1%	±7.5%
Rectum	Dmean	CNN prediction	-1.7%	±8.1%
Anal Sphincter	Dmean	MC, no magnetic field	+7.1%	±9.0%
Anal Sphincter	Dmean	CNN prediction	-3.0%	±9.9%

## Conclusion

Even with a limited number of patients, a CNN can be quickly trained to accurately determine the magnetic field corrections on the dose distributions for the target volume of IMRT prostate treatments. In the lower dose regions, additional effort is still required. The ease and speed of training indicates that training patient-specific CNNs before treatment starts is also an option.

## EP-1792 Straightforward and easy way to determine MLC parameters (DLG, T) for FFF beams in Eclipse TPS

A. Walewska<sup>1</sup>, M. Giżyńska<sup>1,2</sup>, M. Fillmann<sup>1</sup>, P. Janiak<sup>1</sup>, M. Gruda<sup>1</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics Department, Warsaw, Poland ; <sup>2</sup>University of Warsaw Faculty of Physics, Department of Biomedical Physics, Warsaw, Poland

## Purpose or Objective

In order to perform dose calculations for dynamic techniques in Eclipse TPS (Varian) user has to set MLC parameters: Dosimetric Leaf Gap (DLG) and MLC Transmission (T). The values of DLG and T are usually obtained in trial and error process minimizing the difference between measurements and calculations in TPS [1]. Alternatively we propose to use gradient optimization method.

## Material and Methods

Chair shape plans were prepared for 6FFF and 10FFF beams for two SSD/depth setups (90/10cm and 95/5cm). Dynamic MLC pattern calculated on the basis of optimal fluence was saved. Measurements, corrected for beam stability, were done in water phantom with Semiflex Chamber (PTW 31010) on two TrueBeam machines. The chair shape dose distribution was divided into 9 regions (Fig. 1). The cost function  $F$  was defined as  $F = \sum_i w_i (D_c - D_m)^2$ , with  $i$  number of evaluated points,  $w$  - point priority,  $D_m$  - measured dose,  $D_c = D_c(DLG, T)$  - calculated dose being a function of DLG and T. Starting values for optimization were taken from sweeping gap measurements recommended by Varian to determine DLG and T values.  $F$  was calculated for 9 points surrounding starting value and  $gradF$  was calculated in both directions leading to a next iteration direction and step. Procedure was repeated until the global minimum was found. Priorities  $w$  were chosen arbitrarily (Fig. 1). Regions B, C and H in which the T has the higher role were given priority 3. Region A with higher DLG influence was given priority 9. Regions D, E and F for which both DLG and T have impact were given priority 2. Regions G and I with weak T impact get priority 1. Priorities used at both setups were the same. For each recalculation of dose distribution in TPS the same MLC pattern was used. Verification of optimized value of DLG and T was performed by comparing measured and calculated dose for sweeping gap performed with dynamic MLC (width: 0.2-20.0 mm). Pretreatment verifications for ten clinical IMRT/VMAT plans were performed as well. We used Octavius device with PTW729, EPID and measurement

done with ionization chamber in water and solid phantom.

Figure 1. Chair shape test divided into regions. Agreement between measurements and TPS calculations for 6FFF (left) and 10FFF (right) for two setups and optimal DLG and T are shown. Comparisons were done for points located in the center of each region.

## Results

The shape of quadratic cost function used in optimization procedure can be seen in Fig 2. The optimal values of DLG and T were: 0.75mm and 1.35% for 6FFF, 0.90mm and 1.60% for 10FFF beam. For chair pattern the greatest difference between measurement and TPS are obtained for regions strongly influenced by T (up to 2.6% for 6FFF, 2.9% for 10FFF). Dose difference between measurement and TPS for sweeping gap fields was not greater than 0.3%. Results of pretreatment verification for all clinical plans passed our institution QA criteria.

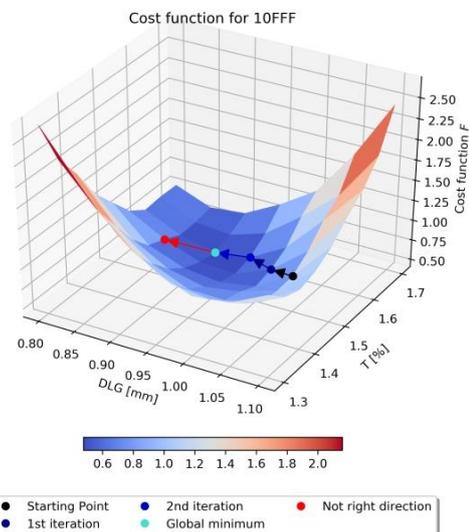

Figure 2. Shape of cost function. Starting point and points achieved in 3 following iterations are shown. Arrows indicate steps of iteration. The red dot is showing the next iteration step which would lead to a greater cost function and therefore was neglected.

## Conclusion

Proposed method of DLG and T determination is straightforward, easy, low time consuming and leads to a very good agreement between calculations and measurements confirmed in independent verification. The same methodology can be used for WFF beams.

### Purpose or Objective

Varian's Portal Dosimetry prediction algorithm was recently updated to improve the re-sampling of the fluence in the portal dose calculation algorithm (PDC). From version 13.5, the fluence resolution used in PDC inherits the dose calculation resolution used in AAA. Recently, the asynchronous sweeping gap (aSG) tests were introduced [1] to test the Tongue and Groove (TG) effect in the TPS with dynamic beams. The goal of this study is twofold: On one hand to perform a measurement of the TG effect with the EPID and on the other hand to study how the resolution used in AAA affects the agreement of the PDC with measurement.

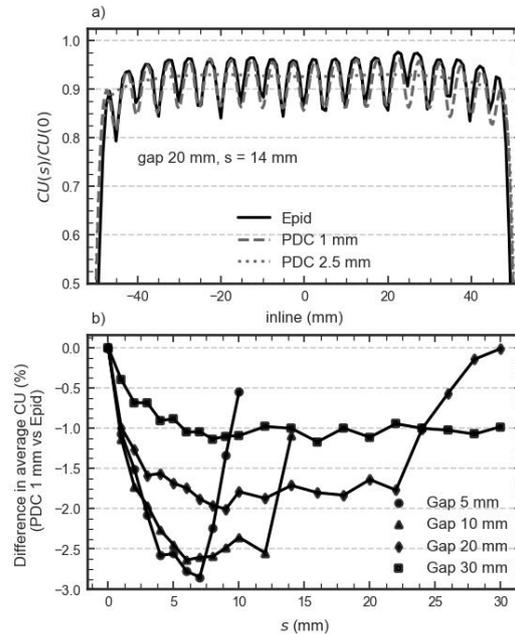

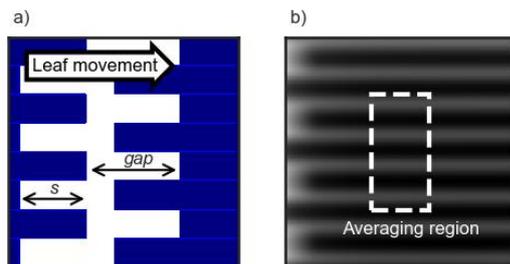

### Material and Methods

The aSG tests consist in different sweeping gaps where adjacent leaves are shifted a given amount  $s$  (see Figure 1a). When  $s=0$ , the standard sweeping gap test is recovered. We tested version 13.6 of the algorithms (PDC & AAA) with a Millennium MLC. First, we calculated the aSG tests in a water phantom in isocentric conditions for two resolutions: 2.5 and 1 mm. From the AAA calculation, verification plans were generated with the PDC algorithm (Fig1b shows the predicted planar dose for a 20 mm gap and  $s=14$  mm). The predicted planar dose distributions were exported and analyzed externally with an in-house software in MatLab that parsed the information contained in the \*.dxf files and calculated an average central value (see Fig1b) for each gap and leaf side  $s$ . In order to isolate the TG effect, for each gap, the ratio of dose for a given  $s$  to  $s=0$  was obtained. This ratio also allows to compare AAA with PDC despite the different dose units (Gy and CU).

Finally, the tests were irradiated on an aS500 EPID. The measured planar distributions were also exported for analysis and to obtain average values to compare with the PDC prediction.

### Results

The largest difference due to TG between PDC and AAA was  $<0.5\%$  regardless of the gap and dose resolution used. The predicted portal dose distributions with the 1 mm resolution exhibited excellent spatial agreement with the EPID measurements as shown in Fig2a. However, the average values obtained with the PDC algorithm overestimated the dose reduction due to the TG effect (see Fig2b). In particular, for the 1 mm-generated PDC the largest relative difference is  $-2.6\%$ , while for the 2.5 mm-generated PDC the largest difference is  $-1.6\%$  in both cases for the 10 mm gap and  $s=6$  mm. The overestimation of the average TG effect is particularly significant within the first 10 mm of  $s$  regardless of the gap and uncovers the fine details of the leaf tip model.

### Conclusion

The TG model of the MLC as used in AAA was adequately transferred to the fluence used in the PDC algorithm regardless of the resolution used. The response of the EPID captures the TG effect that causes a dose reduction for increasing sin the aSG tests. The agreement between PDC and EPID is excellent for a 1 mm dose resolution. PDC would thus benefit from always using a 1 mm fluence resolution regardless of the resolution used in AAA. [1] Phys Med Biol 62;2017:6688-6707

### EP-1794 Bias-free comparison of PTW arrays in terms of ability to detect clinically significant MLC errors

A. Walewska<sup>1</sup>, M. Giżyńska<sup>1,2</sup>, A. Paciorkiewicz<sup>1</sup>, D. Blatkiewicz<sup>1</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics Department, Warsaw, Poland ; <sup>2</sup>University of Warsaw Faculty of Physics, Department of Biomedical Physics, Warsaw, Poland

### Purpose or Objective

There are several types of pre-treatment verification QA devices with different types of detectors, resolution and design. Woon et al. (2018) and Saito et al. (2018) used the method of introducing known errors into the RT plans in order to analyze the sensitivity of various gamma index passing rates using different types of detectors with different resolution. To the best of our knowledge there is no work comparing three types of PTW arrays (Octavius: 729, 1500, 1000SRS). The aim of our study was to test ability of these arrays to detect clinically significant MLC errors.

### Material and Methods

We used 40 clinical plans (10 plans for each: brain, prostate, head & neck, gynecology) in the analysis. MLC errors: gap width (both banks moved in opposite direction) and shift error (both banks moved in the same direction) were introduced for all plans. Magnitudes of errors were 0.5 - 3.0 mm. Dose distributions were recalculated in patients' CT and Octavius 4D phantom (diameter 32cm) was used to create verification plans for all analyzed plans. Dose distributions were calculated in Eclipse (13.6.23 AAA, Varian). In order to get the bias-free comparison Python script was used to change the TPS dose distribution into the artificial measurement file mimicking the real measurement. So created artificial measurements

created are not biased by measurement uncertainty and have the same resolution as real measurements. Artificial measurement files were compared to the clinical (original) verification plan using gamma analysis (Verisoft v.6.1) with criteria: 1%/1mm, 2%/2mm, 3%/3mm both for local and max gamma. Dose threshold was set to 5%. DVHs for plans with introduced errors were also analyzed in order to find: 2% change in PTV mean dose, PTV D98%<95% and PTV D2%>107% (considered as clinically relevant).

### Results

Wilcoxon signed rank test was used to perform statistical comparison between array, p-value less than 0.005 was considered as significant. Significant difference between 729 and 1500 array was observed for most of the error types for 3%/3mm and 2%/2mm gamma analysis. It might be explained by impact of interpolated points included in evaluation. There is no significant differences between 1000SRS and 729 array for most of plans with shift error. However significant difference is noticed for gap width error showing greater capability for 1000SRS to detect plan with error (Fig. 1). The MLC errors without clinically relevant effect are marked in the Figure.

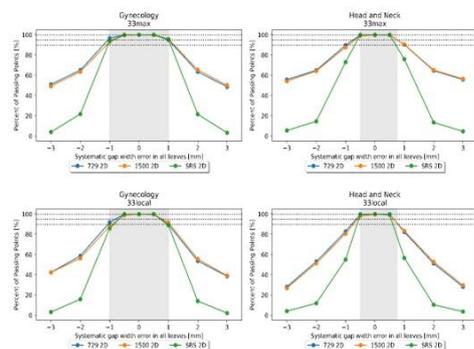

Figure 1. Example of gamma analysis results for gap width error for gynecology and head&neck plans.

### Conclusion

Analysis results for array 1500 and 1000SRS with Verisoft 6.1 may lead to false negative result (plan rejection with correct linac performance) due to including into gamma analysis not only measurement points but interpolated also. Higher detector resolution matters for gap width error but has no effect in case of systematic shift in MLC. The 1000SRS array, although dedicated to verification SRS plans, can also be used for larger PTV plans with high dose gradient even if it does not cover all irradiation area.

### EP-1795 HyperArc™ commissioning necessitates high-resolution measurements

M. Sjölin<sup>1</sup>, J.M. Edmund<sup>1</sup>

<sup>1</sup>University Hospital Herlev, Oncology, Herlev, Denmark

### Purpose or Objective

An integrated solution for linac-based stereotactic radiosurgery (SRS) has recently been introduced by Varian Medical Systems with an automated multiple non-coplanar arc beam arrangement. This technique calculates a high dosimetric target conformity with a rapid dose fall-off to critical organs and therefore requires careful dosimetric evaluation. The purpose of this study was to experimentally establish the accuracy of the dose modeling performed in the Eclipse treatment planning system (TPS) of this small target dosimetry technique manifested by high resolution measurements.

### Material and Methods

A set of 10 HyperArc™ treatment plans with single and multiple metastasis were optimized in Eclipse (v. 15.6) with the millennium MLC and 6 MV flattening filter free (FFF) beamlets. The planning target volume (PTV) measured as the effective equivalent sphere diameter,

ranged between 0.2 and 2.7 cm. The Acuros dose calculation algorithm was used after optimization with a dose grid resolution of 1.25 mm. Patient-specific measurements were carried out in the CIRS film QA phantom with GafChromic EBT3 film (Ashland Specialty Ingredients) located centrally in the frontal slice of the GTV and used for evaluation. The film calibration was cross-validated with ionization chamber (measurements) according to the IAEA TRS-398 protocol prior to measurements.

Fine-tuning of the calculation model was performed by varying the dosimetric leaf separation (dls) in the algorithm to best fit the measured dose distribution by visually inspection of the dose gradient together with gamma evaluation. A gamma criterion of 5%/1mm and 2%/2mm local normalization was used.

### Results

The mean fraction of  $\gamma_{5\%,1\text{mm}} \leq 1$  and of  $\gamma_{2\%,2\text{mm}} \leq 1$  was 94.5 % and 93.8 %, respectively, for all measurements after modifying the dls in the beam model. An adjustment of +0.5 mm was carried out on the dls parameter compared to the measured value at the machine, which corresponds to an increase in the effective MLC field size. Before dls adjustment, the measured maximum dose deviated around 8% as compared to the planned dose.

For the case with smallest target size (0.2 cm), an overestimation of about 4% in the maximum calculated dose as compared to measurements was observed. A tolerance of 5 mm in minimum equivalent sphere diameter of the PTV has therefore been introduced for treatment of SRS with the millennium MLC.

### Conclusion

For accurate modeling of the beam penumbra, which may have influence on the critical organ dosimetry, adjustments are warranted on the MLC modeling in the calculation model. High spatial resolution measurements therefore play an essential part in a safe delivery of HyperArc™.

### EP-1796 Comparison of Treatment Planning Systems' shallow depth dose prediction for IMRT

E. Bogaert<sup>1</sup>, G. Pittomvils<sup>1</sup>, C. De Wagter<sup>1</sup>

<sup>1</sup>Ghent University Hospital, Radiotherapy and Oncology, Gent, Belgium

### Purpose or Objective

Validation of a Treatment Planning System (TPS) for IMRT is well described e.g. NCS 22 report [1], but challenging. Dose contribution from outside IMRT segments' edges needs to be predicted correctly. QA patterns like Inverse Pyramids [2] are recommended at reference depths of 10 and 5 cm. However, at shallow depths primary scattered electron contamination causes head scatter conditions to differ. During photon beam modelling in RayStation v6.1 a rather high electron contribution was found to be necessary for modelling large open fields' depth dose curves. Our goal was to validate the need of this higher electron contribution by assessing the effects at shallow depths and by comparing RayStation planned doses to those retrieved from the two other TPS in use at our department.

### Material and Methods

For a Varian Clinac-IX (Millennium MLC; 6 and 18 MV), beam models were available in RayStation v6.1 (RaySearch Laboratories) and Eclipse v8.1 (Varian), whereas for Elekta Synergy (MLCi2; 6 and 15MV) models were available in RayStation v6.1 and Pinnacle v9.8 (Elekta). Predicted line dose profiles were evaluated against those measured in a polystyrene slab phantom with a PTW linear array LA48. Calculation grids were 2x2x2mm<sup>3</sup> for Synergy and 2.5x2.5x2.5mm<sup>3</sup> for Clinac-IX. The effective point of measurement (0.75mm below surface) was taken into account in all profiles. A local criterion of 3%/3mm (max dose) was used. For high energies and 1 cm depths, the effect of 0.5 mm shift in depth on the position for

extracting the line dose was evaluated. Cross calibration on reference field (10x10 cm<sup>2</sup>) and depth (10 cm) was applied on LA48-measured dose values.

#### Results

Figures 1 and 2 show Inverse Pyramid profiles for Elekta and Varian linac respectively. TPS beam modelling for head scatter conditions and MLC and jaw transmission are well within the criterion for all energies at depth of 3 cm. The modelling in Eclipse and Pinnacle show larger differences with measurements both at primary field dose region and scattered only regions for high energy and 1 cm depth. Beam modelling in RayStation shows agreement with the measurements within 3%/3mm for all regions, taken the spread-out of 0.5mm shift into account, whereas for the models in Eclipse and Pinnacle a 5%/5mm is met.

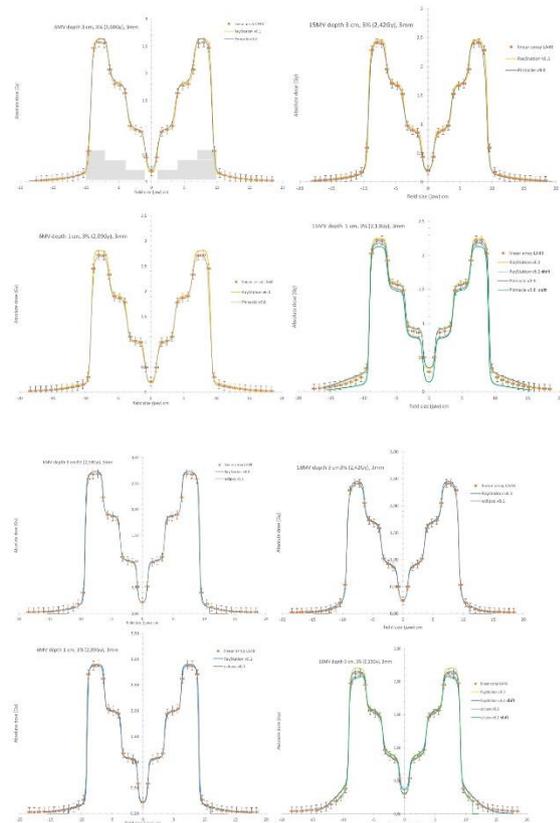

Figure 1 and 2. Inverse pyramid line dose profiles at 3- and 1-cm depths.

#### Conclusion

The higher electron contamination contribution in RayStation v6.1 modelling did not cause overdosage at shallow depths. Even for high energy and depths as low as 1 cm, the criterion of 3%/3mm was met. Extension of a QA protocol for IMRT beam model validation with dose calculation tests outside the fields at shallow depths is relevant.

#### EP-1797 Skin dose in HDR brachytherapy for breast cancers: our in vivo dosimetry protocol and data analysis

S. Fabiani<sup>1</sup>, M. Casale<sup>1</sup>, M. Italiani<sup>1</sup>, M. Muti<sup>1</sup>, E. Maranzano<sup>2</sup>

<sup>1</sup>"S.Maria" Hospital, Department of Radiation Oncology - Medical Physics Unit, Terni, Italy ; <sup>2</sup>"S.Maria" Hospital, Department of Radiation Oncology, Terni, Italy

#### Purpose or Objective

The aim of this work is to evaluate the skin dose in partial breast high dose rate brachytherapy (PB-BRT), developing a novel protocol for *in-vivo* dosimetry (IVD) and using two different dosimeter types.

#### Material and Methods

Currently there is not a general acknowledged constraint for skin dose in PB-BRT. Because of our center's experience (20 PB-BRT patients treated/year) we achieve a good cosmetic outcome if the TPS calculated skin dose is below 55% of the prescription of 32 Gy (4 Gy/fraction, twice daily). The skin dose, calculated by a TPS, is overestimated, assuming a homogeneous water medium and not accounting for the finite patient dimensions. IVD was performed on patients treated with multi-catheter brachytherapy, which involves the placement of 9-15 catheters through the breast. Both thermoluminescent dosimeters (TLDs) and MOSFET detectors were used in the IVD sessions and placed in five specific points on the skin: one close the nipple, two next to the entrance of the catheters (upper breast area) and two next to the exit (lower breast area). After a preliminary study using TLDs (IVD-TLD sessions), we performed MOSFET real time measurements to compare with TLD results and to further improve the estimation of the skin dose. We are currently implementing optical fiber real time measurements to test a new system based on the use of luminescent materials.

#### Results

The doses measured by both dosimeters were compared to those calculated by the TPS in the specific regions of interest. For a first group of three patients two IVD-TLD sessions were performed for each of them. A Gaussian fit of the percentage differences between measured and calculated doses yielded a mean overestimation value of 25% by the TPS. For a second group of seventeen patients IVD sessions were performed using MOSFET dosimeters, which were placed on the skin following the previous arrangement of TLDs. For each patient five IVD sessions were performed. Results showed a mean overestimation value of 28% by the TPS. The more accurate doses measured by MOSFETs indicated a different value when the dosimeter was placed on the upper or the lower breast area: the latter showed a smaller overestimation of the skin dose by the TPS.

#### Conclusion

We performed IVD on twenty patients, using two different dosimetry systems. We obtained a clear overestimation of skin dose by the TPS using both systems, because the TPS does not take into account the tissue-air interface. The different distribution obtained for MOSFETs placed on the lower breast area, is due to a possible reduction of the tissue-air interface. Preliminary measurements demonstrated the requirement to implement real time dosimeters in the *in vivo* sessions instead of using TLDs. Quantifying skin dose accurately does contribute to define a reliable constraint in PB-BRT, to achieve not only the tumor control but also a good cosmetic outcome to improve the quality of patient's life.

#### EP-1798 Calibration of the new RefleXion biology-guided radiotherapy unit in the context of the TRS-483 CoP

L. Mirzakhani<sup>1</sup>, R. Bassalow<sup>2</sup>, D. Zaks<sup>2</sup>, C. Huntzinger<sup>2</sup>, J. Seuntjens<sup>1</sup>

<sup>1</sup>McGill University, Medical Physics, Montreal, Canada ;

<sup>2</sup>Reflexion Medical, 25841 Industrial Blvd- Suite 275, Hayward- CA, USA

### Purpose or Objective

The design of the new Reflexion biology-guided radiotherapy (BgRT) system restricts the maximum field size to 2 cm in the International Electrotechnical Commission (IEC) Y dimension at the source-to-axis distance (SAD) of 85 cm. The closest field size to the conventional reference field in this machine is 2×10 cm<sup>2</sup> at the isocenter. The energy of the beam is 6 MV and the beam is flattening filter free (FFF). The 2×10 cm<sup>2</sup> field size does not meet the lateral charged particle equilibrium condition of the machine-specific reference (*msr*) field introduced in the IAEA TRS-483 Code of Practice (CoP). Therefore the IAEA TRS-483 CoP cannot be directly used for the calibration of this machine. In this study, two methods of calibration are proposed for the reference dosimetry of the BgRT Unit. The BgRT Unit is calibrated using the two methodologies and the results are compared.

### Material and Methods

The percent depth dose (PDD) and profile were measured in the BgRT unit using the Exradin A14SL chamber for the 2×10 cm<sup>2</sup> field size at SSD 85 cm. The BgRT system was modeled using the EGSnrc/BEAMnrc Monte Carlo (MC) code and the PDD and profile were calculated using EGSnrc/DOSXYZnrc. The beam model was tuned to achieve good agreement with the 2×10 cm<sup>2</sup> PDD and profile measurements. Two methods of calibration are suggested in this study. In the first method, the generic correction factors ( $k_{Q,F}, k_{Q,0}^{f,F}, f_{ref}$ ) are calculated directly using MC for Exradin A14SL. In this study the "F" Field refers to both *msr* and *non-msr* fields. In the second method, the IAEA TRS-483 protocol is extended to fields as small as 2 cm. The beam quality specifier and equivalent square field (S) are calculated and used to determine the beam quality correction factor ( $k_{Q,Q_0}$ ) using the analytical approach (IAEA TRS-398 CoP). The volume averaging and water to air stopping power ratio corrections are also applied to the  $k_{Q,Q_0}$  values to correct for the differences between the With Flattening Filter (WFF) and FFF beams.

### Results

The measured and calculated  $dd(10,S)$  are 57.15±0.40% and 57.06±0.07% respectively. When using the first method, the calculated  $k_{Q,F}, k_{Q,0}^{f,F}, f_{ref}$  value for Exradin A14SL is found to be 0.9965±0.0011. The equivalent field size S for the 2×10 cm<sup>2</sup> field size is determined as 3.5 cm. The  $k_{Q,Q_0}$  value corresponding to TPR<sub>20,10</sub>(10,3.5) in the TRS-398 CoP corrected for the volume averaging and water to air stopping power ratios is 0.9951.

### Conclusion

Good agreement is achieved between measured and MC calculated  $dd(10,S)$  values (0.16%). The correction factors determined using the two proposed approaches are in very good agreement (0.14% for Exradin A14SL). While the results of this study are promising, further studies are required to confirm that these two methodologies can be used for other small ionization chambers used in the calibration of BgRT.

### EP-1799 Characterisation of a commercially available large-area IC for dosimetry of scanned proton beams

S. Berke<sup>1,2,3</sup>, E. Almhagen<sup>3,4</sup>, L. Stolarczyk<sup>3,5</sup>

<sup>1</sup>The Clatterbridge Cancer Centre NHS Foundation Trust, Physics Department, Bebington, United Kingdom ; <sup>2</sup>The Royal Liverpool and Broadgreen University Hospitals NHS Trust, Department of Medical Physics and Clinical Engineering, Liverpool, United Kingdom ;

<sup>3</sup>Skandionkliniken, Physics Department, Uppsala, Sweden

<sup>4</sup>Uppsala University, Department of Immunology-Genetics and Pathology - Medical Radiation Science,

Uppsala, Sweden ; <sup>5</sup>Institute of Nuclear Physics PAN, Cyclotron Center Bronowice, Krakow, Poland

### Purpose or Objective

Large-area plane-parallel ionisation chambers are used to measure integrated depth dose curves (IDDCs) of proton pencil beams [1]. They have also been proposed for reference dosimetry, using the dose-area product of a single pencil beam instead of the dose at the centre of a broad field [2]. The larger the IC's diameter, the greater the part of the low-dose "halo" of proton pencil beams caused by scattered protons that is covered [1]. On the other hand, potential inhomogeneities in the chamber construction may influence measured doses and limit its usage in reference dosimetry [3].

A Stingray (IBA Dosimetry) IC with a diameter of 12cm has been characterised with respect to the measured proton range and IDDC shape compared to IDDCs measured with the 8cm Bragg Peak chamber (PTW 34070), and its response homogeneity. A method of chamber heterogeneity verification doable in clinical conditions has been proposed.

### Material and Methods

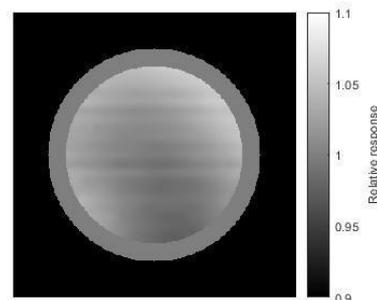

IDDCs were acquired for pencil beams with energies between 60 and 226 MeV using the 12cm and 8cm diameter ICs and a BP<sup>2</sup> water phantom (IBA Dosimetry). Differences in range parameters (R90, R80, R50, R20) and the relative dose difference between IDDCs measured with the two chambers were evaluated.

The chamber response homogeneity was examined by scanning the chamber across a 226MeV pencil beam in air and calculating the ratio between the measured signal at each position and the expected signal, assuming a 2D-Gaussian beam profile with  $\sigma_x=3.0\text{mm}$  and  $\sigma_y=3.1\text{mm}$  determined in air.

### Results

The range parameters measured with the two chambers agreed within 0.5mm. Relative dose differences between IDDCs measured with the two chambers were up to 4%. Generally, the difference was greater for higher energies and the maximum difference was observed at approximately half the proton range.

The IC homogeneity measurements revealed that differences between the expected and measured signal across the chamber area ranged from about -3% to +6% (ignoring points within 10mm of the chamber edge, where inaccurate assumptions about the beam profile might impact on the results; a relative response of unity was assumed there). The response variations were not symmetrical, as seen in the figure below (the stripes are a result of the scanning technique).

### Conclusion

The examined large-area plane-parallel ionisation chamber is suitable for its intended application of measuring IDDCs for routine QA.

For potential future use in reference dosimetry using a single proton pencil beam instead of a broad field, the observed inhomogeneities in the chamber response across its sensitive area require a correction map. The presented in air scanning of the sensitive chamber area provides a quick check of its response but with a limited accuracy. The observed -3% to +6% inhomogeneities had no significant effect on the measurement of IDDCs. References:

#### EP-1800 An Evaluation of Techniques for Dose Calculation on Cone Beam CT

V. Giacometti<sup>1</sup>, R.B. King<sup>2</sup>, C.E. Agnew<sup>2</sup>, D.M. Irvine<sup>2</sup>, S. Jain<sup>1</sup>, A.R. Hounsell<sup>2</sup>, C.K. McGarry<sup>2</sup>

<sup>1</sup>Centre for Cell Biology and Cancer Research- Queen's University Belfast, School of Medicine- Dentistry And Biomedical Sciences, Belfast, United Kingdom ;

<sup>2</sup>Northern Ireland Cancer Centre, Radiotherapy Physics, Belfast- Northern Ireland, United Kingdom

#### Purpose or Objective

This investigation assessed efficiency, accuracy and feasibility of four different techniques adopted to recalculate the dose delivered to the patients based on cone beam CT (CBCT) images acquired prior to treatment.

#### Material and Methods

Four established techniques (standard planning CT calibration curve, CBCT site specific calibration curve, HU density override and deformable registration) were investigated. Each technique was applied to 15 CBCT patients' images (5 prostate and pelvic nodes, 5 lung and 5 head and neck), and treatment planning dose calculations were performed in order to assess accuracy and efficacy of each technique. The patients were receiving volumetric modulated arc therapy to one of three treatment sites. Dose volume histogram metrics and 2.0% / 0.1 mm volumetric gamma analysis were employed to provide a quantitative analysis of the differences between planning CT and CBCT dose distributions.

#### Results

Dose volume histogram analysis indicated that all techniques yielded differences from expected results between -5.4% and +3.8% for both target volumes and organs at risk: -1.4% to 1.8% for prostate and pelvic nodes, -5.4% to 1.0% for head and neck, and -1.8% to 3.8% for lung. With volumetric gamma analysis, the median pass-rates at 10% threshold were 95.5%-97.2%, 92.6%-95.1%, and 85.2%-88.2% for prostate, head and neck and lung patients, respectively. Figure 1 shows the median pass-rates for standard planning CT calibration curve, CBCT site specific calibration curve, HU density override and deformable registration at 10% threshold for each treatment site. Deformed images yielded the highest pass-rates for prostate and head and neck patients, while site-specific calibration curve yielded the highest median pass-rate for lung patients.

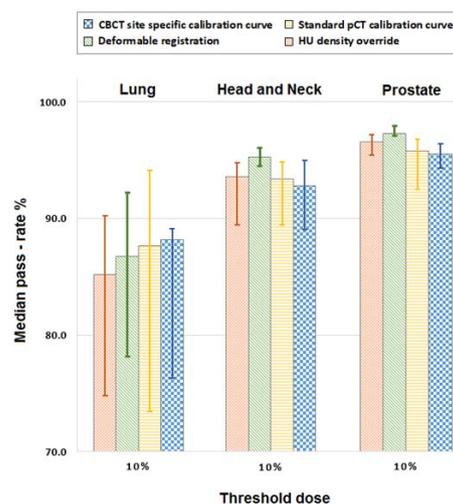

Figure 1: Median 2% / 0.1 mm gamma pass-rates (%) for dose thresholds of 10% for thorax, head and neck, and pelvis acquisitions. Note that the median pass-rate (y-axis scale) starts from 70%.

#### Conclusion

All four investigated techniques were identified as dosimetrically accurate and efficient methods to perform dose calculation based on CBCT images. The differences observed were treatment site dependent.

#### EP-1801 Automatic EPID based Beam QA : measurements become pleasure

A. Sors<sup>1</sup>, D. Perez<sup>1</sup>, P. Dudouet<sup>1,2</sup>, D. Franck<sup>2</sup>, M. Macé<sup>1</sup>, P. Boucarut<sup>1</sup>, C. Boutry<sup>1</sup>

<sup>1</sup>Clinique du Pont de Chaume - Groupe Oncorad Garonne, Service de Radiothérapie, Montauban, France ; <sup>2</sup>Clinique Pasteur - Groupe Oncorad Garonne, Service de Radiothérapie, Toulouse, France

#### Purpose or Objective

To demonstrate interest of automation for photon and electron beams Quality Assurance (QA) using EPID with a simple approach of absorbed dose to water reconstruction: the EpiDream method [1], integrated in the ARTISCAN Beam QA software (AQUILAB, France). The final aim of this study is to validate the use of EPID as a potential substitute to ionization chamber (IC) for routine beam QA.

#### Material and Methods

The study was performed on Clinac 2100CD and 2100EX (Varian Medical Systems, Palo Alto, CA) respectively equipped with on board As500 and As1000 EPID imager (pixel size of 0.784x0.784mm<sup>2</sup> and 0.392x0.392mm<sup>2</sup>). EPID has been calibrated based on EpiDream method and ARTISCAN software used to convert Grey Level integrated images into dose to water matrix for 6-25MV photons and 6-9-12-15-18MeV electron beams. A 4-month study was conducted to compare output constancy (including 5-10mm sliding windows (SW) for photons beams) and beam parameters (flatness, symmetry, penumbra and field size) obtained with EPID method and IC. Comparison was performed using MATLAB (MathWorks Inc., Natick, MA) between radial and transverse profiles measured with a 0.125cm<sup>3</sup> IC (PTW31010) and extracted from EpiDream converted matrices. Robustness of EPID vs. IC QA was estimated using standard deviation of each parameter. Time dedicated to daily and monthly QA for all energies using both methods was also evaluated.

#### Results

Table 1 reported the mean deviation for 6-25MV and 6-9-12-15-18MeV between EPID and IC for output constancy results (a), the mean deviation of EpiDream profiles with IC profiles (b) and robustness of EPID vs IC QA results (c).

As expected, our results show that with decreasing detector size, the measured penumbra width and therefore the distance to the point of inflection decreases [2]. Considering all energies, the mean time duration for linac output constancy daily measurement using EPID and IC was respectively 16 and 30 minutes. The mean time duration for beam parameters measurement using EPID and IC was respectively 14 and 200 minutes.

1. a	6MV				25MV				6MeV	9MeV	12MeV	15MeV	18MeV

Clinac	0.76%	-0.55%	-0.69%	0.10%	-0.21%	-0.43%	-0.53%	0.57%	0.38%	0.40%	0.56%		
2100CD	±0.59%	±0.64%	±0.71%	±0.41%	±0.75%	±0.89%	±0.54%	±0.50%	±0.49%	±0.44%	±0.51%		
Clinac	-0.41%	0.30%	0.04%	0.8%	0.59%	0.50%	0.16%	0.28%	0.31%	0.03%	-0.19%		
2100EX	±0.43%	±0.56%	±0.59%	±0.35%	±0.62%	±0.48%	±0.59%	±0.41%	±0.28%	±0.26%	±0.29%		

Table 1: Mean deviation for 6-25MV and 6-9-12-15-18MeV between EPID and IC for output constancy results (a), Mean deviation of EPIDream profiles with IC profiles considering flatness, symmetry, penumbra and field size values (b), Standard deviation of flatness, symmetry, penumbra and field size values of EPIDream and IC profiles (c).

## Conclusion

The use of automatic EPID based beam QA dramatically decreases the time dedicated to QA, eliminates manual steps in the process, reducing human errors, improving efficiency, robustness and productivity for radiotherapy providers with a significant decrease in waiting time for patients. In our institution we have chosen to use daily EPID QA to verify output constancy and beam uniformity without any modification on quality or tolerances of our QA process.

## EP-1802 Dosimetry verification of IntraOperative Radiation Therapy (IORT): a Monte Carlo Study

H. Alhamada<sup>1</sup>, S. Simon<sup>2</sup>, C. Philippson<sup>2</sup>, C. Vandekerckhove<sup>2</sup>, Y. Jourani<sup>2</sup>, N. Pauly<sup>3</sup>, N. Reynaert<sup>2</sup>, D. Van Gestel<sup>2</sup>

<sup>1</sup>Institut Jules Bordet ULB, Radiotherapy, Brussels, Belgium ; <sup>2</sup>Institute Jules Bordet, Radiotherapy Department, Brussels, Belgium ; <sup>3</sup>Nuclear Metrology, Université Libre de Bruxelles, Brussels, Belgium

## Purpose or Objective

Most of intraOperative Radiation Therapy (IORT) clinics have not a treatment planning system (TPS). High dose (up to 24 Gy) is given in one session depending only on manual calculation. This study investigates the feasibility of doing 3D dosimetry of IORT patients using post operation patient's CT images with Monte Carlo (MC) code.

## Material and Methods

Mobetron 1000® is a mobile linear accelerator was modeled using BEAMnrc MC code. MC model validation was done for 12, 9 and 6 MeV energies by comparing MC results with measurements according to MC model tuning of Laccarino et al (2011). Absolute dose calibration was done using methodology of Popescu et al (2005). CTCREATE code and home-made code were used to convert post operation CT DICOM images to MC phantom. Each voxel in patient's MC phantom is one of these materials (Air521ICRU, Lung521ICRU, Tissue521ICRU, Bone521ICRU, PMMA521ICRU, AL521ICRU, Steel521ICRU). Contouring of the planning target volume (PTV) and the organs at risk was done by the radiation oncologist. IORT parameters (applicator size and position, energy, Monitors Units, shielding disk, Bolus, ....) as they were used in the operation room simulated using BEAMnrc and DOSXYZnrc for each patient. Finally, dose calculation was done in each patient's MC phantom. This study was done for 20

patients with different tumor locations, applicator sizes, and with different energies.

## Results

MC model validation process ended with good match between measurement and MC PDDs, Profiles and Output factors as the maximum value of the root mean square deviation (RMSD) was less than 3% between them. Absolut and relative doses in PTVs and in Organ at risks were verified using DVH and color wash like any classical linear accelerator TPS. Alhamada et al (2018) and Kamomae et al (2017) have studied new shielding disks and tungsten paper for organs at risk protection, but they did their studies in water phantom. It is possible to study any shielding disk design in clinical usage. Dosimetry impact verification of using customized applicator or beam shaper is available using our methodology. Summation of 3D IOERT dose with other radiotherapy plans is possible and helpful for total overdose avoidance.

## Conclusion

This study provides a step forward for dosimetry verification of IOERT patients. More accurate dosimetry could be achieved by using DICOM images of CBCT inside the operation room which it will be available next year in our clinic.

## EP-1803 Advances in the Patient Specific QA applied to VMAT and Tomotherapy

M. Piccoli<sup>1</sup>, K. Torzsok<sup>1</sup>, A. Ruiz Plata<sup>1</sup>, F. Marangoni<sup>1</sup>, J. Aponte<sup>1</sup>, H. Broque<sup>1</sup>

<sup>1</sup>Fundacion Arturo Lopez Perez, Medical Physics, Santiago, Chile

## Purpose or Objective

It has been more than 20 years (1998) that patient specific quality assurance (PSQA) is playing an important role to verify plan deliverability and reliability for modulated treatments. Since then, there have been massive improvements in machine accuracy in terms of mechanic and dosimetric parameters. Likewise TPS algorithms and experience with these techniques has grown exponentially. However, the verification methodologies kept being almost the same over these years. In this work we have shown the factibility of an alternative prediction index for potential plan failure for Tomotherapy and VMAT.

## Material and Methods

A retrospective analysis over 1000 patients already treated was carried out for an Elekta Synergy equipped with Agily MLC and a Tomotherapy HD. Patient Specific QA have been measured for every single patient before treatment and results from both machines were analyzed and registered using IBA MatriXX Evolution and the criteria of 3%, 3mm, 10% threshold have been applied. Although both machines have different delivery procedures, the modulation factor calculated during planning have being shown to be the main predictive factor of plan complexity and had a direct impact on gamma results. As an example, the following equation describes the way the Modulation factor is calculated for VMAT plans:

$$MF = \frac{MONITOR\ UNITS}{\sum_{n=1}^N \left[ \frac{SEGMENT\ AREA \times SEGMENT\ MU}{TOTAL\ AREA\ FOR\ THE\ ARC} \right]}$$

On the other hand, for Tomotherapy, leaf open time (LOT) is the major factor used for calculating modulation in the TPS. Regardless the system being used, reducing the modulation during planning might be the most effective way of having more representative plans with better gamma values. For a better understanding on how it would affect QA results, modulation factors were classified in

terms of technique (VMAT or Tomotherapy), anatomic region, prescription and ordered from 1 to 6 to better filter the data.

### Results

As expected, results based on previous treatments shows that as higher the modulation factor gets, lower is the number of pixels passing the gamma criteria. For VMAT, minimum and maximum values of 94,6% y 99,9% in gamma were found to be related to plans having modulation factors of 3,56 y 1,24 respectively. For Tomotherapy the same behaviour was observed. Applying a class solution is also important to take into account prescription and volume of the targets. For Tomotherapy reducing the expected value for modulation factor during calculation also impacts plan quality, so a good bias must be found. Whilst for VMAT, rising the segment size during planning was determinant to reduce modulation factor.

### Conclusion

Currently, modern machines are capable of delivering modulated plans in better accordance with the planning theoretical data. Performing PSQA for every single patient might be evaluated depending on internal statistics for each department. More effective and representative plans yielding better QAs results could be achieved if there is a better understanding of the factors provided by treatment planning systems.

### EP-1804 Experimental validation of a novel technique to derive stopping power ratio from MRI in soft tissue

J. Scholey<sup>1</sup>, D. Chandramohan<sup>1</sup>, T. McClave<sup>1</sup>, A. Sudhyadhom<sup>1</sup>

<sup>1</sup>The University of California- San Francisco, Radiation Oncology, San Francisco, USA

### Purpose or Objective

to experimentally validate the Unified Composition (UC) method and compare to "ground truth" measurements for determining mean ionization potential ( $I_m$ ) and stopping power ratio (SPR) using MRI for dose calculation in proton therapy for soft tissues.

### Material and Methods

Porcine soft tissue types (muscle, liver, brain, and spleen) were cryoground to produce homogeneous samples. Tissues were divided into two groups for determination of  $I_m$  and SPR using 1) Bragg's additivity rule (BAR), considered the ground truth (GT) method, and 2) the Unified Compositions (UC) method. For the GT method,  $I_m$  values were calculated directly using BAR with elemental composition determined from chemical combustion analysis of each tissue, as shown in equation 1. SPR values were determined by the Bethe-Bloch equation through measurements of physical density and atomic composition. For the UC method, phantoms were created containing each tissue type and pure water, isopropyl alcohol, acetone, and propargyl alcohol, which were used for proton density and water fraction calibration curves for MRI. Phantom images were acquired using kVCT, MVCT, and 3T MRI.  $I_m$  values were calculated from percent water/organic material by mass and hydrogen content of organic material computed using water/organic <sup>1</sup>H separation and proton-density weighted MRI scans, respectively, as shown in equation 2. For calculation of SPR, relative electron density ( $P_e^{rel}$ ) was determined from MVCT using calibration of an electron density phantom. For comparison, SPR was also calculated for each tissue using kVCT and the stoichiometric calibration method.

$$\ln(I_m) = \left( \sum_i \frac{w_i Z_i^2}{A_i} \ln I_i \right) \left( \sum_i \frac{w_i Z_i}{A_i} \right)^{-1} \quad (1)$$

$w_i$  is fraction by mass,  $Z_i$  is atomic number, and  $A_i$  is atomic mass of element  $i$ .

$$\ln(I_m) \approx (w_{H_2O} \ln(I_{H_2O})) + (w_{org,total} [\ln A - B \frac{H_{org}}{w_{org,total}}]) \quad (2)$$

$w_{H_2O}$  is fraction by mass of water,  $I_{H_2O}$  is the mean ionization potential of water,  $w_{org,total}$  is fraction by mass of organic material, and  $B \frac{H_{org}}{w_{org,total}}$  is total organic molecule hydrogen density by fractional mass in the voxel.  $A$  and  $B$  are constants relating hydrogen content in organic molecules to mean ionization potential of organic materials.

Figure 1: Equations for (1) Bragg's Additivity Rule used for Ground Truth computation and (2) Unified Composition Method.

### Results

Of the tissues evaluated, SPR values computed with the UC method agreed on average to within 0.7% of the GT method, with results shown in table 1. SPR values computed from the stoichiometric calibration saw greater disagreement to GT values, with percent differences of 5.3, 5.2, 3.8, and 4.5% for muscle, liver, brain, and spleen, respectively.

	$P_e^{rel}$			$I_m$ (eV)			SPR		
	GT	UC	% diff	GT	UC	% diff	GT	UC	% diff
Muscle	1.022 ± 0.006	1.020	-0.17	77.55 ± 0.8	77.86	0.39	1.018 ± 0.06	1.016	-0.22
Liver	1.036 ± 0.006	1.030	-0.63	77.06 ± 0.8	77.73	0.87	1.033 ± 0.06	1.026	-0.73
Brain	1.016 ± 0.006	1.007	-0.90	75.55 ± 0.8	77.79	2.97	1.016 ± 0.06	1.003	-1.24
Spleen	0.986 ± 0.006	0.990	0.42	77.81 ± 0.8	77.73	-0.11	0.982 ± 0.06	0.987	0.43

Table 1: Relative electron density ( $P_e^{rel}$ ), mean ionization potential ( $I_m$ ), and stopping power ratio (SPR) calculated using Ground Truth (GT) and UC methods, along with percent difference.

### Conclusion

It is possible to achieve sub-percent accuracy using the UC method for determination of  $I_m$  and SPR from MRI and MVCT imaging as compared to direct computation using GT principles for soft tissues evaluated in this study. All SPR values determined by the UC method were within experimental error of GT determination. Of note,  $P_e^{rel}$  is a predominant source of error in SPR calculations (as SPR varies linearly with  $P_e^{rel}$  and logarithmically with  $I_m$ ) and ongoing investigations are looking to improve this accuracy. SPRs computed via the UC method saw closer agreement with those computed by GT than the widely-used stoichiometric calibration method.

### EP-1805 The Effect of Material Heterogeneity in Endorectal Brachytherapy with <sup>192</sup>Ir, <sup>75</sup>Se and <sup>169</sup>Yb Sources

T. Shoemaker<sup>1,2</sup>, T. Vuong<sup>3,4</sup>, H. Glickman<sup>1</sup>, S. Kaifi<sup>3</sup>, G. Famulari<sup>1</sup>, S.A. Enger<sup>1,2,4</sup>

<sup>1</sup>McGill University, Medical Physics Unit, Montreal, Canada; <sup>2</sup>McGill University Health Centre, Research Institute, Montreal, Canada; <sup>3</sup>Jewish General Hospital-McGill University, Department of Radiation Oncology, Montreal, Canada; <sup>4</sup>McGill University, Department of Oncology, Montreal, Canada

### Purpose or Objective

Differences between prescribed and administered dose in high dose rate endorectal brachytherapy (HDR-EBT) were investigated by evaluating dose to clinical target volume (CTV) and organs at risk (OARs) calculated with a Monte Carlo based dose calculation tool, RapidBrachyMC. In addition, dose coverage, conformity and homogeneity were compared between the radionuclides <sup>192</sup>Ir, <sup>75</sup>Se and <sup>169</sup>Yb for use in HDR-EBT.

### Material and Methods

RapidBrachyMC, which builds on the Geant4 MC-toolkit, was used to perform postimplant dosimetry using computed tomography (CT) images for 8 patients, each treated with 3 fractions of HDR-EBT at the Jewish General Hospital in Montreal, Canada. In the HDR-EBT treatment a <sup>192</sup>Ir MicroSelectron v2 source was used with a flexible intracavitary applicator capable of fitting a tungsten rod in its central lumen for OAR shielding. In combination with this applicator, two balloons filled with iodine solution were used, one used to fix the applicator to the rectum and the other to displace the contralateral rectal wall. Four segmentation schemes were simulated. 1) According

to the TG-43 formalism. 2) Applicator, shield, source and balloon materials with nominal densities specified, but patient geometry consists of water. 3) Tissue materials assigned to contoured organs in addition to foreign structures, densities overridden with nominal densities. 4) Materials specified as per segmentation 3, with organ densities based on CT densities. In addition, two novel sources were investigated and dosimetrically compared with <sup>192</sup>Ir: <sup>75</sup>Se and <sup>169</sup>Yb. The clinical TG-43 based plan optimized for <sup>192</sup>Ir was used for all simulations. The TG-43 results for <sup>169</sup>Yb and <sup>75</sup>Se were normalized to give the same D<sub>90</sub> as the clinical plan.

**Results**

CTV coverage and dose to the OARs, pelvic and femur bone are overestimated for <sup>192</sup>Ir TG-43 based dosimetry, while for <sup>175</sup>Se and <sup>69</sup>Yb dose to CTV and OARs are overestimated, but pelvic and femur bone doses are significantly underestimated. <sup>75</sup>Se delivers similar dose to OARs as <sup>192</sup>Ir but delivers slightly increased bone doses. <sup>169</sup>Yb delivers lower dose to the rectum but significantly higher bone dose. Dosimetric indices and comparisons between segmentation schemes for the CTV, rectum, and pelvis are given in Table 1. Colorwash comparison between segmentation schemes for <sup>192</sup>Ir is given in Figure 1.

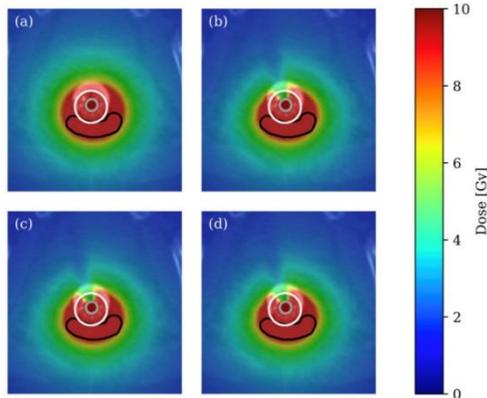

Figure 1: Colorwash comparison of four segmentation schemes for <sup>192</sup>Ir, with applicator contoured in white, tungsten shielding rod in gray and the CTV in black. (a) Segmentation scheme 1, (b) segmentation scheme 2, (c) segmentation scheme 3, (d) segmentation scheme 4.

Pelvis D <sub>90</sub> <sup>169</sup> Yb [Gy]	Segmentation 1	0.55 ± 0.04	-	-
	Segmentation 2	0.41 ± 0.03	-25	0.00003
	Segmentation 3	0.65 ± 0.06	19	0.0002
	Segmentation 4	0.75 ± 0.07	37	0.00003

Table 1: Mean dosimetric index values for three selected contours and three radionuclides, with percent differences from segmentation scheme 1. D<sub>90</sub> is the dose received by xx percentage of the contour.

**Conclusion**

Ignoring patient geometry and in particular high-Z materials such as the iodine radiographic contrast, bone and tungsten shielding in dose calculations contributes to significant inaccuracies which lead to sub-optimal dose optimization and disagreement between prescribed and

delivered dose, specifically for radionuclides with lower average energy than <sup>192</sup>Ir. In addition, our results show that with a future MRI-based treatment planning for HDR-EBT, loss of CT-density data will not significantly affect dosimetry if material composition and nominal mass densities are used.

**EP-1806 Commissioning an Independent Dose Calculation System for the Unity MR-Linac**

E. Goodwin<sup>1</sup>, S. Nill<sup>1</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>Royal Marsden / Institute of Cancer Research, Joint Department of Physics, London, United Kingdom

**Purpose or Objective**

An independent secondary monitor unit check is a quality assurance measure used throughout the radiotherapy community, and is a legal requirement in many European countries. The first patients on the Unity MR-Linac (Elekta AB, Stockholm, Sweden) have recently been treated at The Royal Marsden Hospital. There is no commercial software for performing an independent calculation for a 1.5 T MR-Linac. Therefore a solution using scripting tools for the RayStation (RaySearch, Stockholm) treatment planning system was developed.

**Material and Methods**

The primary dose calculation for the MR-Linac is carried out in Monaco 5.4 (Elekta) using a Monte Carlo algorithm that has been benchmarked against beam data. This was used to generate a series of square and rectangular fields on a model of water phantom, with a 2mm voxel size and 0.5% uncertainty per beam. Depth dose curves and dose profiles were extracted and used as the basis for the RayStation model.

An FFF beam model was created which matched the dose curves as closely as possible. RayStation requires that MLC-Y machines have a backup jaw, so a 'dummy' Y-jaw open beyond the MLCs was placed in each plan. Profiles from the MR-Linac are asymmetric due to the effect of the magnetic field on secondary electrons. This could not be modelled in RayStation. To first approximation, the difference could be accounted for by translating the fields laterally. Each beam isocentre was offset by an empirically derived factor of 0.16 cm (see fig. 1). Beam attenuation through MR components varies with gantry angle, so a monitor unit correction was applied to each beam.

Point dose measurements and qualitative comparisons of profiles were made between simple fields (from 1.5 x 1.5 cm<sup>2</sup> to 22 x 58.6 cm<sup>2</sup>), complex field shapes and IMRT fields calculated in Monaco and RayStation. Ten protocol prostate plans (6 offline, 4 adapted) were created in Monaco.

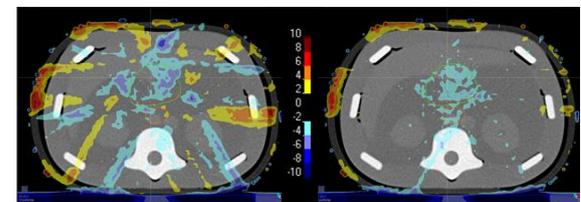

Figure 1: Dose difference (Monaco - RayStation) before the isocentre was offset perpendicular to the gantry angle, and in the direction of the Lorentz force (Left) and after (Right). Percentages are expressed relative to the prescribed dose (60 Gy).

**Results**

The RayStation profile and depth dose curves were in good qualitative agreement with Monaco for simple fields. In the centre of large fields, the dose difference was comparable to the statistical uncertainty of the Monaco calculation (0.5%). Elsewhere, agreement was worse due to the lack of asymmetry in RayStation. For complex field shapes the agreement was generally good, except near thin segments where RayStation would underestimate in-field dose by up to 3%. The RayStation calculated treatment plans yielded DVHs that were consistent with

Monaco for the OARs, but were approximately 1.5% hotter than the Monaco for the PTVs (see fig. 2).

Ratio of PTV DVH statistics (RayStation/Monaco)			
Dose at Volume (%)	Minimum	Mean	Maximum
5	1.002	1.012	1.018
50	1.007	1.017	1.027
95	1.006	1.016	1.025

Figure 2: The RayStation PTV DVH is approximately 1.5% hotter than the Monaco PTV DVH for the ten plans calculated. However, this is fairly consistent between patients and across the DVH.

**Conclusion**

It is possible to create a RayStation beam model for the Unity MR-Linac which is sensitive enough to detect gross errors in monitor unit calculations. With the prototype version of the MR-Linac beam model, the gynae and head and neck treatment sites had similar PTV DVH statistics to the prostate, however, additional sites will require validation before clinical implementation head and neck will require validation with this beam model. As the magnetic field is not modelled, care is required when interpreting doses near air interfaces.

**EP-1807 Use of SPC techniques to generate assessment criteria for transit dosimetry analysis**

A. Pyett<sup>1</sup>, C. Holmes<sup>1</sup>, C. Enever<sup>1</sup>, A. Fryer<sup>2</sup>, D. Paynter<sup>2</sup>, P. Rixham<sup>2</sup>, S. Weston<sup>2</sup>

<sup>1</sup>Leeds Cancer Centre, Radiotherapy Department, Leeds, United Kingdom ; <sup>2</sup>Leeds Cancer Centre, Medical Physics and Engineering, Leeds, United Kingdom

**Purpose or Objective**

When introducing a transit dosimetry programme the analysis criteria and the failure thresholds must be established. Conventional assessment of delivery using quasi-3D phantoms is usually performed using the  $\gamma$  parameter. A common threshold for gamma success is 95% of points with a  $\gamma < 1$  using parameters of 3%/3mm. However any transit dosimetry analysis must allow for clinically insignificant variation in the patient setup and the patients anatomy, effects which do not affect phantom measurement.

The aim of this work is to use measured data to establish clinically relevant parameters for the analysis of Lung SABR treatments

**Material and Methods**  
At X lung SABR treatments are planned on Elekta Monaco and delivered using a single arc 6MV FFF VMAT technique on Elekta VersaHD linacs. The patient position is verified using CBCT before every fraction. A portal movie image measured during the treatment is used to reconstruct the delivered dose distribution on the 3D planning CT using the Elekta iViewDose software.

iViewDose provides analysis of the delivered dose distribution in terms of

- Dose at the Dose Reference Point (DRP)
- Percentage of points that have a  $\gamma < 1$
- Mean  $\gamma$
- Near maximum  $\gamma$

During a pilot phase dose reconstructions were analysed using  $\gamma$  parameters of 3%/3mm. Mean values and confidence limits for all analysis parameters were calculated using SPC methodologies. The means and confidence limits were measured from the first twenty fractions to be analysed, ignoring the obvious outliers.

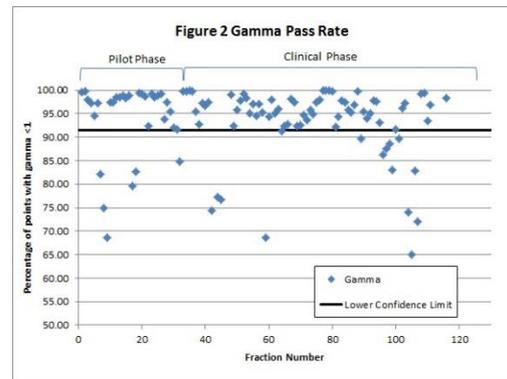

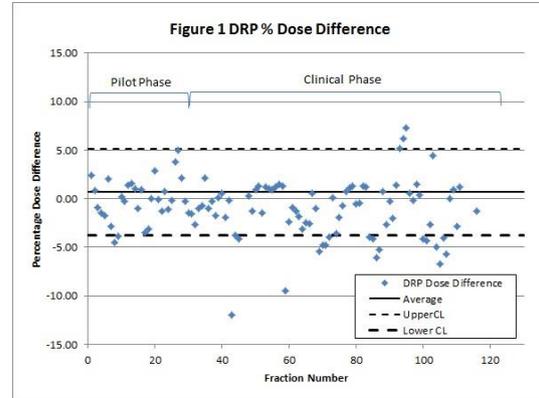

Following clinical implementation the reconstructions were analysed against the criteria established in the pilot phase. Where fractions passed all the criteria no further action was taken. Where one or more of the criteria failed the fraction was investigated.

**Results**

Parameter	Target	LCL	UCL	iViewDose	Tolerance
% DRP Deviation	0.67	-3.7	5.1	4%	

Gamma % < 1	100	91%	-	91%
Mean Gamma	0.42	0.28	0.55	0.6
Gamma > 1 %	1.09	0.72	1.46	1.5

84 fractions were analysed in the clinical phase. DRP and gamma results are shown in figures 1 and 2.

All of the fractions that failed at least one test were investigated. Almost all of the failures were true positives in that a reason could be identified for their failure: tumour motion, contour change, or oedema. One patient exhibited a failure which could not be explained due to anatomical changes. This was verified using a Delta4 system and the delivered distribution was found to be in good agreement with the planned distribution

**Conclusion**  
Transit dosimetry can be an effective tool in determining deviations from intended treatment. Errors identified using transit dosimetry correlated well with anatomical changes identified using CBCT. No errors were identified due to treatment delivery errors.

SPC techniques can be used to develop assessment criteria for transit dosimetry analysis. This should be performed on a site by site basis as different anatomical sites will yield different expected results and confidence levels depending upon the accuracy of the reconstruction and the normal anatomical variability of the site

**Electronic Poster: Physics track: Treatment plan optimisation: algorithms**

**EP-1808 Impact of the optimization-convergence errors on lung IMRT-SBRT plans computed with the Eclipse TPS**

J.F. Calvo Ortega<sup>1</sup>, H. Marcelino<sup>2</sup>, S. Moragues Femenia<sup>1</sup>, C. Laosa-Bello<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain ; <sup>2</sup>Hospital Universitario Valle de Hebrón, Servicio de Física y Protección Radiológica, Barcelona, Spain

### Purpose or Objective

To investigate the accuracy of the dynamic MLC patterns derived for lung IMRT-SBRT plans with normalization values differing in more than 5% respect to the inverse optimization calculation.

### Material and Methods

Ten cases of lung SBRT planned using Sliding and Window IMRT technique were included. IMRT optimizations were performed using the Dose Volume Optimizer (DVO, version 10.0.28) algorithm of the Varian Eclipse TPS (version 13.7.14). The Anisotropic Analytical Algorithm (AAA, version 10.0.28) was applied for the final dose calculation (2 mm grid size). Photons beams of 6 MV from a Varian linac equipped with the Millennium 120 MLC were used. Due to optimization-convergence errors [J Appl Clin Med Phys. 2009 Oct 14;10(4):3061], the final plans needed to be re-normalized to insure that 95% of the PTV received the prescribed dose. The required final re-normalization values (62%-85%) varied in more than 5% respect to the 100% value of DVO-base target DVH. To detect potential violations of the MLC operating limits, Varian advises to verify the MLC leaf sequence for normalization variations larger than 5%.

Each original SBRT plan (Plan\_Orig) was delivered onto the linac EPID (Varian PortalVision aS500) to evaluate the accuracy of the dynamic MLC patterns created by the Eclipse for these re-normalization values (62%-85%). Two kinds of verifications were done: 1) the actual field fluences of the Plan\_Orig were verified using the Varian Portal Dosimetry software (version 13.7.14). The 3%/3 mm and 2%/2 mm criteria, both with 10% of maximum dose as dose threshold, were applied for 2D global gamma-evaluation. A total of 85 IMRT fields were analyzed. 2) The Plan\_Orig was recalculated by keeping the MUs but using the MLC files reconstructed from the Dynalog files recorded by the MLC controller (Plan\_Actual). This DynaLog-to-MLC conversion was performed using a MATLAB-based code developed by Teke et al. [Radiother Oncol. 2007;84(Suppl 2):S92]. The reconstructed dose distribution was verified against the original dose distribution using a 1%/1 mm 3D global gamma-evaluation for the PTV structure. The Computational Environment for Radiotherapy Research (CERR) software was used for this task.

### Results

1. The average  $\pm$  1 SD of the 2D gamma passing rates were  $99.4\% \pm 0.9\%$  (range: 96.1%-100%) and  $97.6\% \pm 2.5\%$  (range: 89.2%-97.6%) at 3%/3 mm and 2%/2 mm criteria, respectively.
2. A 1%/1 mm 3D gamma passing rate of 100% was obtained for the PTV in all plans.

### Conclusion

The results demonstrated the reliability and accuracy of the IMRT-SBRT plans designed by the Eclipse TPS with normalization values differing in more than 5% respect to the inverse optimization calculation.

### EP-1809 Comparison of Photon Optimizer (PO) and Progressive Resolution Optimizer (PRO) for SRS VMAT Plans

Y. Akdeniz<sup>1</sup>, G. Ugurluer<sup>2</sup>, E.B. Ispir<sup>1</sup>, I. Kaptan<sup>1</sup>, M. Serin<sup>2</sup>

<sup>1</sup>Acibadem Adana Hospital, Department of Radiation Oncology, Adana, Turkey ; <sup>2</sup>Acibadem Mehmet Ali Aydinlar University, Department of Radiation Oncology, Adana, Turkey

### Purpose or Objective

Linac-based stereotactic radiosurgery (SRS) of brain lesions is typically performed by using volumetric modulated arc therapy (VMAT) technique. For SRS of small target SRS, the optimization algorithms might influence the treatment quality significantly as they model the 3D space in different way. In this study, we aimed to compare a new optimizer "photon optimizer" (PO) with its predecessor "progressive resolution optimizer" (PRO) for SRS VMAT plans.

### Material and Methods

For ten patients with single brain metastases planning-CT scans were acquired with a slice thickness of 1 mm. Planning Target Volume (PTV) which was converted to high resolution segment had a mean volume of 14.85 cm<sup>3</sup> (range 8.6-20 cm<sup>3</sup>). Each patient's treatment was planned using PO and PRO optimizers on version 13.6 of the Eclipse treatment planning system with 6 MV FFF photon beams. A template using the same objectives was used for each optimized plan without any intervention. For PO the highest resolution (1.25 mm) was selected and during optimization with PRO the point cloud model resolution for PTV was set to 1 mm. The prescribed dose was 18 Gy in a single fraction. Volumetric dose normalization was adopted, by normalizing 100% D<sub>p</sub> to 99% of the PTV. Plans which were optimized with PO and PRO were calculated with anisotropic analytical algorithm (AAA, v.13.6), with the same dose grid resolution (1 mm). PO and PRO plans were compared in terms of total number of monitor units (MU), Paddick conformity (CI) and gradient index (GI) for PTV and V<sub>12</sub> (the volume receiving more than 12 Gy) and D<sub>mean</sub> (mean dose) for the healthy brain tissue. Statistical analysis was performed using SPSS.

### Results

The values of the plan quality metrics for both PO and PRO plans are shown for all patients in Table 1. For CI<sub>Paddick</sub> significant advantage in favour of PRO plans were achieved. While mean CI<sub>Paddick</sub> value increased significantly from  $0.89 \pm 0.009$  (for PO plans) to  $0.941 \pm 0.017$  (for PRO plans) ( $p < 0.05$ ), there was no statistically significant difference between PO ( $3.084 \pm 0.242$ ) and PRO ( $3.031 \pm 0.184$ ) plans in terms of GI<sub>Paddick</sub>. We had significant reduction in V<sub>12</sub> from  $12.74 \pm 3.61$  cm<sup>3</sup> (for PO plans) to  $11.52 \pm 3.22$  cm<sup>3</sup> (for PRO plans) ( $p < 0.05$ ). Also, we found that the D<sub>mean</sub> decreased in favor of PRO in statistical analysis from  $124.2 \pm 41.3$  cGy (for PO plans) to  $119.7 \pm 39.6$  cGy (for PRO plans) ( $p < 0.05$ ). There was no significant difference between PO and PRO in terms of total number of MU.

Table 1. Values of plan quality metrics

Pt # / Plan	Total # of MU		D <sub>mean</sub> (cGy)		V <sub>12</sub> (cc)		CI <sub>Paddick</sub>		GI <sub>Paddick</sub>	
	PO	PRO	PO	PRO	PO	PRO	PO	PRO	PO	PRO

	NS		p<0.05		p<0.05		p<0.05		NS	

### Conclusion

This study compared plan optimization outputs for the two optimization algorithms (PO and PRO) which models 3D space differently in SRS VMAT plans. Our study showed that SRS VMAT plans optimized with PRO's point cloud model yield better results in terms of both target volume coverage and organ protection than PO. PRO might be preferred to newer algorithm PO in optimization of small target volumes.

### EP-1810 Comparison of absorbed dose between medium and water on Monte Carlo algorithm for VMAT plan

N. Bhalla<sup>1</sup>, M. Palanisamy<sup>1</sup>, G. Anand<sup>1</sup>, C. Saravanan<sup>1</sup>, T. Thangaraj<sup>1</sup>, P. Abhishek<sup>1</sup>  
<sup>1</sup>Fortis Cancer Institute, Radiation Oncology, Mohali, India

#### Purpose or Objective

A comparison of absorbed dose to water ( $D_w$ ) and absorbed dose to medium ( $D_m$ ) on Monte Carlo (MC) dose calculation algorithm used in Monaco™ treatment planning system (TPS) for different clinical sites.

#### Material and Methods

Four patients from each site, a total of 20 patients, namely, larynx, lung, prostate, and brain treated with VMAT technique were chosen for this study. All plans were generated using 6MV photon beam in Monaco™ TPSV5.10 for Elekta Synergy™ linear accelerator with leaf width of 1cm. The reference plan was generated using the MC dose calculation algorithm with absorbed dose to water during final dose calculation. By keeping all other parameters constant, plans were recalculated by changing the absorbed dose to medium. Plans were evaluated using dose-volume histogram (DVH). For plan comparison, conformity index (CI), homogeneity index (HI), planning target volume (PTV) covered by 98% prescribed dose, mean and maximum dose to PTV ( $PTV_{max}$ ) and organ at risk (OAR) dose was compared. In addition, the normal tissue volume receiving dose  $> 5Gy$  &  $> 10Gy$ , normal tissue integral dose (NTID), calculation time (mins), point dose measurement and gamma pass rate was compared.

#### Results

In all four sites, CI and HI value was 4.24%-12.4% and 3.49%-19.63% increased in  $D_w$  as compared to  $D_m$  with significant difference ( $p < 0.05$ ). The dose received by 98% volume and  $D_{max}$  to PTV was 0.42%-2.23% and 0.9%-6.2% increased in  $D_w$  as compared to  $D_m$  ( $p > 0.05$ ). No significant dose difference was observed in  $D_{mean}$  to PTV, OAR, normal tissue volume receiving dose  $\geq 5Gy$  &  $\geq 10 Gy$  and NTID. Similarly, no significant difference was observed in calculation time, gamma pass rate and point dose measurements ( $p > 0.05$ ).

#### Conclusion

The choice of either  $D_m$  or  $D_w$  during dose calculation was based on significant clinical effect in tumor control and OAR sparing. In all clinical sites, during MC dose calculation, there was a significant increase in the point dose and inhomogeneous dose in  $D_w$  as compared  $D_m$  within the target. However,  $D_m$  will be the preferred option to achieve better accuracy in future for Monaco™ TPS.

### EP-1811 Volumetric modulated arc therapy with robust optimization for larynx cancer

H. Miura<sup>1</sup>, D. Yoshiko<sup>2</sup>, O. Shuichi<sup>1</sup>, N. Minoru<sup>1</sup>, O. Keiichi<sup>2</sup>, K. Masahiko<sup>2</sup>, N. Yasushi<sup>2</sup>

<sup>1</sup>Hiroshima High-Precision Radiotherapy Cancer Center, Medical Physics, Hiroshima, Japan ; <sup>2</sup>Hiroshima High-Precision Radiotherapy Cancer Center, Radiation oncology, Hiroshima, Japan

#### Purpose or Objective

In the case of larynx cancer using 3D-CRT, common carotid arteries receive radiation doses essentially equivalent to the prescription due to their close proximity to the target. VMAT has been used to reduce the dose to the carotid arteries. Robust optimization plan provides significantly more robust dose distributions to targets and OAR than the PTV-based optimization plan. We speculated that a larynx cancer patient may benefit from a partial-arc VMAT robust optimization plan due to its location. The aim of this study was to perform a comparison between robust optimization and planning target volume PTV-based optimization plans using VMAT by evaluating perturbed doses induced by

localization offsets for setup uncertainties in larynx cancer radiation therapy.

#### Material and Methods

Ten patients with early-stage (T1-2N0) glottis carcinoma were selected. The CTV, carotid arteries, and spinal cord were contoured by an oncologist. PTV-based and robust optimization plans were normalized at  $D_{95\%}$  to the PTV and  $D_{98\%}$  to the CTV, respectively. Both optimization plans were evaluated using perturbed doses by specifying user defined shifted values from the isocenter. CTV dose ( $D_{98\%}$ ,  $D_{50\%}$ , and  $D_{2\%}$ ), homogeneity index (HI) and conformity index ( $CI_{95\%}$ ,  $CI_{80\%}$ , and  $CI_{50\%}$ ), as well as doses to the carotid arteries and spinal cord were compared between PTV-based and robust optimization plans. Monitor Unit (MU) was also investigated.

#### Results

In the original plan, the CTV doses, HI, CI, OAR doses and MU using PTV-based and robust optimization plans are shown in Table 1. The robust optimization plans exhibited superior CTV coverage and a reduced dose to the carotid arteries compared to the PTV-based optimization plans ( $p < 0.05$ ). HI,  $CI_{95\%}$  and the dose to the spinal cord did not significantly difference between the PTV-based and robust optimization plans ( $p > 0.05$ ). The robust optimization plans showed better  $CI_{80\%}$  and  $CI_{50\%}$  compared to the PTV-based optimization plans ( $p < 0.05$ ). The robust optimization plans were on average 18.6% less than the total MU compared to the PTV-based optimization plans ( $p < 0.05$ ). Table 2 compares the doses to the CTV, carotid arteries, and spinal cord obtained from the rigidly shifted plan between the PTV-based and robust optimization plans. Plan perturbed evaluations showed that the robust optimization plan has small variations in the doses to the CTV, carotid arteries, and spinal cord compared to the PTV-based optimization plan.

Table 1  
Doses to the CTV and OAR, HI, CI, and MU using PTV-based and robust optimization plans.

	PTV based plan	robust plan	p value
CTV: $D_{98\%}$ (cGy)	194.8 ± 2.0 (191.0 - 198.0)	200.0 ± 0.0 (200.0 - 200.0)	0.002*
CTV: $D_{50\%}$ (cGy)	202.1 ± 1.9 (200.0 - 207.0)	206.1 ± 1.4 (204.0 - 209.0)	0.002*

Table 2. Doses to the CTV and OAR for each plan at offset locations using PTV-based and robust optimization plans.

	PTV based plan	robust plan	p value
CTV: D <sub>95%</sub> (cGy)	193.7 ± 2.4 (185.0 - 199.0)	195.6 ± 2.9 (188.0 - 200.0)	< 0.001*
CTV: D <sub>50%</sub> (cGy)	201.1 ± 1.8 (196.0 - 207.0)	205.7 ± 1.9 (202.0 - 209.0)	< 0.001*
CTV: D <sub>2%</sub> (cGy)	209.8 ± 2.8 (205.0 - 218.0)	211.4 ± 2.7 (206.0 - 216.0)	0.003 *
carotid artery_left average dose (cGy)	89.5 ± 13.3 (72.0 - 130.0)	83.2 ± 9.7 (69.0 - 110.0)	< 0.001*
carotid artery_left: D <sub>2%</sub> (cGy)	126.8 ± 23.4 (92.0 - 177.0)	113.0 ± 16.5 (88.0 - 159.0)	< 0.001*
carotid artery_right: average dose (cGy)	94.3 ± 16.6 (74.0 - 140.0)	86.9 ± 14.6 (69.0 - 134.0)	< 0.001*
carotid artery_right: D <sub>2%</sub> (cGy)	133.7 ± 25.2 (96.0 - 190.0)	120.1 ± 22.8 (91.0 - 184.0)	< 0.001*
spina cord: average dose (cGy)	34.5 ± 6.0 (23.0 - 50.0)	32.7 ± 6.5 (21.0 - 66.0)	0.002 *
spinal cord: D <sub>2%</sub> (cGy)	45.5 ± 8.3 (30.0 - 69.0)	40.8 ± 5.3 (30.0 - 52.0)	< 0.001*

\*The Wilcoxon signed-rank test resulted in a statistically significant difference at the all parameter ( $p < 0.05$ ).

## Conclusion

The robust optimization plans yielded higher doses compared to the CTV and more spared dose to the carotid artery compared to the PTV-based optimization plans. With respect to the perturbed evaluation, the doses to the carotid arteries and spinal cord showed less variation with the robust optimization plans compared to the PTV-based optimization plans. The robust optimization plan may be a suitable treatment method in radiotherapy for larynx cancer patient.

**EP-1812 Outcome-optimized radiotherapy planning using risk modeling for lymphoma - a preliminary study**  
 L. Rechner<sup>1</sup>, A. Modiri<sup>2</sup>, L.B. Stick<sup>1</sup>, M.V. Maraldo<sup>1</sup>, S.R. Rice<sup>3</sup>, A. Sawant<sup>2</sup>, S.M. Bentzen<sup>4</sup>, I.R. Vogelius<sup>1</sup>  
<sup>1</sup>Rigshospitalet- University of Copenhagen, Department of Oncology- Section of Radiotherapy, Copenhagen, Denmark ; <sup>2</sup>University of Maryland- School of Medicine, Department of Radiation Oncology, Baltimore, USA ; <sup>3</sup>University of Maryland Medical Center, Radiation Oncology, Baltimore, USA ; <sup>4</sup>University of Maryland School of Medicine, Comprehensive Cancer Center and Department of Epidemiology and Public Health, Baltimore, USA

## Purpose or Objective

In current radiotherapy planning, a set of predefined, aggregated, population-based dose-volume constraints are used to maximize the therapeutic ratio. In this study, we introduce a novel radiotherapy planning approach which instead aims to maximize overall survival by incorporating risk of recurrence and mortality from late effects into inverse optimization.

## Material and Methods

We retrospectively analyzed 38 Hodgkin lymphoma patients (ages: 16-76) with mediastinal disease who were treated with 3D conformal radiotherapy. We used published data to develop risk models for lymphoma recurrence and late normal tissue complications, where we considered radiation-induced mortality from coronary heart disease, secondary lung cancer, and secondary breast cancer. Patient age, sex and cardiac risk factors (CRFs) as well as doses to heart, lung, breast, and tumor target were incorporated in the models. Patients were planned twice, once assuming the presence of CRFs and once assuming no CRFs. 16 co-planar gantry angles were chosen and 4 beam options per gantry angle were created and used for optimization. The dose from each beam option was calculated in a commercial treatment planning system and monitor units were optimized in our MATLAB-based, in-house, particle swarm optimization code to create outcome-optimized plans.

## Results

Outcome-optimized plans were created for 38 patients (Figure 1). The maximum reduction of the total risk (summed probabilities of recurrence and normal tissue complication) achieved by outcome-optimized plans compared to clinical plans was 8.1% for patient cases with cardiac risk factors (CRF) and 10.9% for cases without CRF (Figure 2). The total risk was reduced more than 1% for 9/38 patient cases with CRF and 10/38 patient cases without CRF. The results are, however, sensitive to the definition of risk models, in particular models of tumor control under inhomogeneous target coverage.

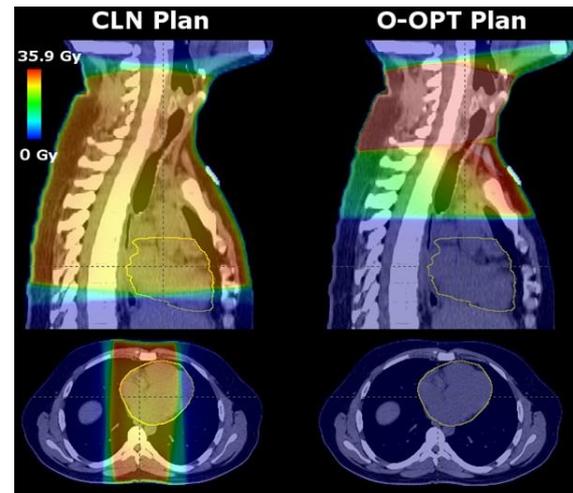

Figure 1. Example of a clinical (CLN) plan compared to an outcome-optimized (O-OPT) plan where the optimizer compromised the coverage of the target to spare the heart and lungs and improved risk of 9.9%.

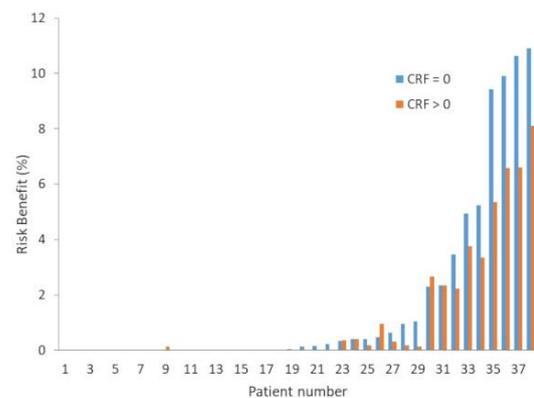

Figure 2. Reduction in risk (of recurrence and normal tissue complications) for outcome-optimized plans compared to clinical 3D conformal plans for the 38 patients with mediastinal Hodgkin lymphoma in this study with and without the presence of cardiac risk factors (CRF).

## Conclusion

We present a study of an individualized outcome-optimized radiotherapy planning technique based on metrics related to overall survival. A substantial potential benefit was observed in some patients, but the underlying knowledge of dose-response models is an important limitation.

**EP-1813 AAA vs Monte Carlo Dose Calculation Algorithm for Lung SABR**

I. Badrigan<sup>1</sup>, V. Huang<sup>1</sup>, D. Shellenberg<sup>2</sup>, A. Krauze<sup>2</sup>  
<sup>1</sup>BC Cancer Surrey, Medical Physics, Surrey, Canada ; <sup>2</sup>BC Cancer Surrey, Radiation Oncology, Surrey, Canada

### Purpose or Objective

To evaluate the dose calculation accuracy of the Varian Eclipse anisotropic analytical algorithm (AAA) for stereotactic ablative body radiotherapy (SABR) in comparison with Monte Carlo (MC) in order to investigate the dosimetric consequences to organs at risk (OAR) and coverage of planning target volume (PTV) in lung SABR plans.

### Material and Methods

25 cases of non-small-cell lung cancer (NSCLC) that were previously treated with SABR to 48 Gy in 4 fractions at our center were selected for this study. These cases were treated from March 2016 to February 2018 and were selected such that the PTV size covers a wide range, from 8.9 cc to 163.2 cc. The internal gross target volume (IGTV) has been contoured from the 4DCT and a 5 mm isotropic expansion was applied to form PTV. The original treatment plans were calculated with 6 MV flattening filter free (FFF) beams using AAA in Eclipse treatment planning system (TPS). The same plans were recalculated using MC for the purpose of this study. Dose volume histogram (DVH) data has been exported for all cases and later processed using in-house code developed in the R programming language. The following dose-volume parameters were used for the comparison:  $V_{100\%}$ ,  $V_{90\%}$  and  $D_{min}$ , to the PTV; conformity index ( $V_{100\%}/V_{PTV}$ ), low dose conformity ( $V_{50\%}/V_{PTV}$ ) and  $D_{2cm}$ ;  $V_{100\%}$  to IGTV;  $V_{20Gy}$  for the lung; dose parameters to OARs including chest wall, esophagus, great vessels, brachial plexus, trachea, heart, bronchial tree, skin and cord. The statistical comparison has been done by paired t-test analysis.

### Results

Comparable results were obtained for AAA and MC calculations except for  $V_{100\%}$  to the PTV ( $p < 0.001$ ), conformity index ( $p = 0.008$ ), low dose conformity ( $p < 0.001$ ) and lung  $V_{20Gy}$  ( $p < 0.001$ ). The largest difference was observed for  $V_{100\%}$  to PTV which in turn impacts the conformity index too. AAA calculations underestimated dose to lungs and PTV compared to MC. The dose differences in PTV  $D_{min}$  and PTV  $V_{90\%}$  as well as  $D_{2cm}$  were not statistically significant. No correlation has been observed between the PTV size and the dose differences between AAA and MC. Occasionally, MC revealed hot and cold spots which were not present in the AAA calculations.

### Conclusion

Our results demonstrate good agreement between AAA and MC doses to OARs for the most part. Lung is an exception as AAA underestimates  $V_{100\%}$  to PTV. AAA emerges a good choice for routine planning, but occasionally MC reveals hot or cold spots in sensitive places, e.g. the PTV center and therefore any plan-specific QA strategy should employ better algorithms to detect such instances. Further investigations are necessary in larger patient cohorts to determine whether AAA is still appropriate for dose calculations in cases of very small field size lung SABR treatment plans.

### EP-1814 On the aperture shape controller and the air cavity correction for lung plans using AcurosXB and AAA

L. Fog<sup>1</sup>, K. Offer<sup>1</sup>, N. Hardcastle<sup>1</sup>

<sup>1</sup>The Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia

### Purpose or Objective

Volumetric modulated arc therapy (VMAT) plan optimisation for radiotherapy in the thorax is subject to uncertainties in dose calculation algorithms during optimisation and to variations in plan complexity. The Eclipse™ v15.5 (Varian Medical Systems) Photon Optimiser incorporates two features: Air Cavity Correction (ACC) to improve the accuracy of scattered dose in the optimiser, and Aperture Shape Controller (ASC) to increase contiguity of apertures during VMAT delivery. We investigate the

effect of these features on dosimetry and delivery metrics for radiotherapy to locally advanced lung tumours.

### Material and Methods

12 randomly selected locally advanced NSCLC patients planned to 60 Gy in 30 fractions were prospectively re-optimised. All geometry and optimisation settings were constant except for ACC ('On' vs 'off') and ASC ('off', 'moderate', 'very high'). Two ipsilateral VMAT arcs were used and plans were calculated with AcurosXB (AXB,  $D_m$ ) and AAA (both version 15.5.11). To facilitate comparison of near minimum and near maximum doses the plans were normalised to median PTV dose received prescription dose. Intermediate dose was calculated during the optimisation. The following parameters were extracted: MU/Gy, edge metric (MLC open leaf edges/area), D98% for GTV and PTV, mean heart dose, D0.33cc for the oesophagus, and D5Gy and D20Gy for the (lungs-CTV) structure. Within each algorithm, ASC 'moderate' and 'very high' was compared with ASC 'off', and ACC 'off' was compared with ACC 'on', using paired two tailed t-test.

### Results

Table 1 shows the dosimetry variation for target and OARs, and plan complexity metrics. For AXB and AAA, as ACC was changed from 'off' to 'moderate' and 'very high' there was no statistical difference in GTV D98%, PTV D98%, PTV D2%, mean heart or oesophagus D0.33cc. Lung dose however increased slightly. Use of aperture shape controller decreased plan complexity (edge metric and MU/Gy). Turning ACC 'off' resulted in no difference in treatment plans for AXB, but worse GTV D98% for AAA. ACC had no impact on plan complexity.

Algorithm	ASC	ACC	GTV_D88[%]	PTV_D88[%]	PTV_D02[%]	Lungs <sup>1</sup> V <sub>100</sub> [%]	Lungs <sup>1</sup> V <sub>90</sub> [%]	Heart Mean [Gy]	Oesophagus D0.33cc [Gy]	Edge Metric	MU/Gy

		Very high	88.2 ± 1.9	89.4 ± 13.7	104.4 ± 1.5	93.3 ± 19.0	133 ± 4.0	9.9 ± 2.7	29.6 ± 2.6	0.09 ± 0.03	202 ± 104

Table 1: Mean ± st. dev. dosimetry and plan efficiency metrics for AXB and AAA plans optimised with varying ASC and ACC settings. Blue cells represent statistical significance at  $p < 0.0005$ , green at  $p < 0.005$  and red at  $p < 0.05$ , relative to ASC 'Off' for ASC variation and comparing ACC 'Off' against 'On'

### Conclusion

The Air Cavity Correction is useful for improving target coverage with AAA but not with AXB. Use of Aperture Shape Controller results in no difference in target coverage, but slightly worse lung dose. ASC reduces treatment plan complexity and monitor units.

### EP-1815 MCO in VMAT treatment planning for locally advanced head and neck cancer

B. Farnault<sup>1</sup>, V. Favre<sup>1</sup>, L. Moureau-Zabotto<sup>1</sup>, J. Rolland<sup>2</sup>, A. Tallet<sup>1</sup>, P. Fau<sup>1</sup>

<sup>1</sup>Institut Paoli Calmettes, Radiotherapy Oncology, Marseille, France ; <sup>2</sup>Centre Hospitalier Intercommunal des Alpes du Sud, Radiotherapy Oncology, Gap, France

### Purpose or Objective

Efficacy of inverse planning is becoming increasingly important for advanced radiotherapy techniques, and especially for head and neck cancer to decrease radiation therapy toxicity. However, the inverse planning process can create a suboptimal plan despite meeting all constraints. Multicriteria optimization (MCO) may improve doses at organs at risk (OARs) and provides better treatment planning without being time consuming. The aim of this study was therefore to evaluate the benefit of VMAT with multi-criteria optimization (MCO) in RayStation (v6.1.1.2, RaySearch Laboratories, Sweden) for head and neck cancer patients and compare the DVH difference

between MCO VMAT plans and standard optimization (SO) VMAT plans.

#### Material and Methods

SO VMAT plans and MCO VMAT plans were created for 15 patients with head and neck cancer. Three levels of dose were prescribed to all patients: PTV 70Gy, 63Gy, 56Gy in 35 fractions. Acceptable SO VMAT plans with minimal average dose to OARs were chosen for comparison with deliverable MCO VMAT plans. All the plans were reviewed, and the dose-volume parameters were compared between the MCO plans and the SO plans. VMAT pretreatment QA are performed comparing measured and calculated dose distribution in phantom (ArcCheck, SunNuclear) by means of gamma index (3% 3mm, Threshold 10%). A complexity metric of the MLC, calculated as a function of the shape and the aperture of MLC, and the monitor units (MU) number were compared.

#### Results

For both types of optimization, the dose values required to validate target coverage (D98% and D2%) were respected (< 1% difference). The dose to OARs and the conformation number (CN) for each PTV were compared, and a Wilcoxon signed-rank test was performed. MCO provided statistically significant reduction of Dmean (10% to 20%) for: parotid gland, larynx, oral cavity and Dmax for brainstem ( $p < 0.05$ ) in which the magnitude was related to the overlapping volume of the corresponding OAR and targets. The CN with MCO allowed a gain between 5% and 15%, and especially on the PTV 56Gy ( $p < 0.05$ ). For the spinal cord and the brachial plexus, the study did not show a significant difference ( $p > 0.05$ ). The active planning time was the same. The QA passing rate with gamma analysis was > 99% for both types of optimization. The complexity metric and the MU number are higher with MCO plans compared to SO plans (5% and 10% respectively).

#### Conclusion

MCO is feasible in head and neck cancer treatments and MCO plans significantly reduced the dose of OARs, without compromising the target coverage comparing to standard VMAT optimization. All the plans are deliverable by a Linac. MCO, with the navigation of Pareto plan, enables physicians to provide greater active clinical input into the VMAT planning process.

#### EP-1816 A robustness comparison of margin based and robust plans for head and neck VMAT patients

J. Robbins<sup>1</sup>, E. Vasquez Osorio<sup>1</sup>, A. Green<sup>1</sup>, A. McWilliam<sup>1</sup>, A. McPartlin<sup>2</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>University of Manchester, Radiation Related Research, Manchester, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

#### Purpose or Objective

PTV margins do not account for organs at risk (OARs). Using more advanced techniques such as robust or probabilistic planning can potentially help spare OARs close to the CTV while still guaranteeing CTV coverage. In this study we compared the robustness for random and systematic errors of head and neck (H&N) VMAT patients for PTV-based and robust plans.

#### Material and Methods

Data from 8 H&N cancer patients, all treated with 2 dose levels of 66Gy and 54Gy over 30 fractions were used. Delineations for CTV1, CTV2, brainstem, spinal cord (SC), and parotids were used for planning, using RayStation v6.99. Margin plans were created following clinical guidelines using 4mm isotropic PTV margins and 5mm PRV margins for the SC and brainstem. Robust plans included an isotropic robustness setting of 3mm for both CTVs and kept the rest of the objectives the same as the margin plan.

A plan evaluator was implemented to simulate treatments with different random and systematic translational set-up errors and collect relevant DVH parameters. For each

simulated treatment, one systematic error and 30 random errors were selected from a Gaussian distribution, and 100 treatments were simulated for each combination of random and systematic error SDs of 1, 2, 3 mm. The number of treatments achieving the clinical goals (Figure 1) were counted.

Structure	Constraint Type	Dose after 30 fractions
CTV1	Min 1cc	>90% prescribed (59.4Gy)
CTV2	Min 1cc	>90% prescribed (48.6Gy)
Spinal cord	Max	<4800
Brainstem	Max	<5400
Lt parotid	Mean	<2600
Rt parotid	Mean	<2600

Figure 1. Table showing the main clinical goals for the plan

#### Results

Figure 2 shows the mean and SD (over all patients) of the percentage of simulated treatments reaching the clinical goals for CTV1 and the SC as function of random and systematic error SD. These percentages decrease as the errors increase for both the OARs and the targets, with systematic errors having more effect than the random errors, as expected.

Comparing the two sets of plans, the margin plans have a consistently higher percentage of treatments in which the minimum dose across 1cc of CTV1 was above 90% of the prescribed dose. This same trend was seen in CTV2. At an SD combination of (1, 2 mm) the margin plans have ~90% of simulated treatments meeting the CTV1 constraint, which is consistent with the PTV margin used (2.5\*1mm + 0.7\*2mm = 4mm). The lower CTV coverage in the robust plan indicates that the robustness setting was too narrow compared to the utilised margin, and the closest to 90% coverage is the SD combination (1, 1 mm).

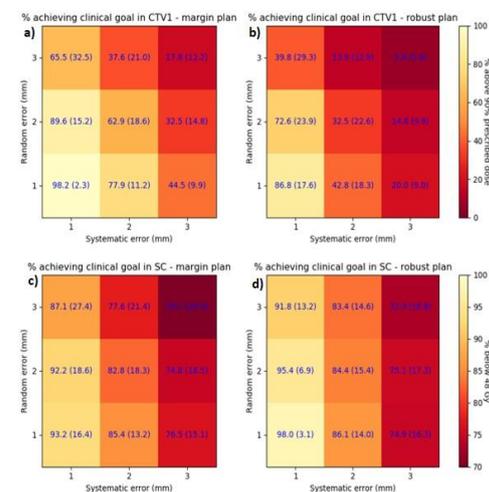

Figure 2. Colour plots showing the number of simulated treatments that achieve the clinical goal. The values for each error are displayed as 'mean (SD)' across all 8 patients. a) and c) show the margin plan, b) and d) the robust plan. a) and b) show the percentage with a minimum value across 1cc of CTV1 of at least 90% of the prescribed dose. c) and d) refer to the percentage with a maximum dose to the spinal cord less than 48Gy.

Comparing the SD combinations with close to 90% CTV probability, the percentage reaching a max dose of <48Gy

to the SC is 92.2% for the margin plan and 98% for the robust plan. This same trend was seen for the other OARs. That is, at a similar probability of CTV coverage the robust plan gives a higher probability of sparing the OARs.

#### Conclusion

A 3mm robustness setting is narrower in terms of CTV coverage compared to a 4mm margin plan. However, at a similar probability of CTV coverage, the robust plan gives a higher probability of sparing OARs. Future work will include analyses for varying robustness settings and include more complex uncertainties.

#### EP-1817 Comparison of 2 VMAT optimization algorithms using complexity metrics for breast cancer radiotherapy

L. Bartolucci<sup>1</sup>, E. Costa<sup>1</sup>, M. Robilliard<sup>1</sup>, A. Mazal<sup>1</sup>  
<sup>1</sup>Institut Curie, Radiation Oncology Department, Paris, France

#### Purpose or Objective

To compare 2 recent VMAT optimization algorithms used by 2 separated TPS for the radiotherapy treatment of breast cancer. For this purpose, complexity of each optimized plan was evaluated using complexity metrics and pre-treatment QA measurements.

#### Material and Methods

10 patients treated for non-metastatic breast cancer were included in the study. All patients received breast and lymph nodes irradiation along with a simultaneous integrated boost to the tumour bed. Prescription dose was 50.4 Gy in 28 fractions to the breast/lymph nodes, and 63 Gy in 28 fractions to the tumour bed. For all patients, VMAT plans were generated with 4 partial arcs of 230° amplitude each using both Eclipse (v.13.6) and RayStation (RS, v.7) TPS. Eclipse and RS optimization were respectively performed using Photon Optimizer and RS VMAT optimization algorithms. Plan optimization objectives, consistent for both TPS, were set to ensure acceptable PTV coverage and minimize dose to the surrounding OAR. For all plans, the following complexity metrics were calculated: MU (mean monitor unit per plan), MI (Park et al., 2014), MCSv, LT and LTMCS (Masi et al., 2013), and SAS with threshold 2 and 5 mm (Crowe et al., 2014). Pre-treatment QA were calculated using Varian's Portal Dose Image Prediction (PDIP) algorithm and delivered on a Varian TrueBeam. Agreement between planned and measured dose was evaluated using Varian Portal Dosimetry (PD) tool with global gamma index analysis (criteria: 3%/3mm). In order to use PD for both TPS, RS plans were recalculated with fixed MU on Eclipse. Statistical significance ( $p < 0.05$ ) was evaluated using a paired two-sided Wilcoxon signed-rank test.

#### Results

All plans were considered clinical acceptable and no statistical significance was observed between Eclipse and RS plans for PTV coverage and mean doses to the main OAR ( $p > 0.05$ ). Significant differences were found between Eclipse and RS for the metrics MU, MCSv and LT indicating that plans optimized with RS may be less complex than plans optimized with Eclipse and PO algorithm, unless for LT which showed more important leaf travel for RS plans ( $p < 0.05$ ). However, no statistical significances were found for MI, LTMCS and SAS metrics (Fig. 1). Pre-treatment PD QA showed significantly better gamma passing rate for RS plans ( $p < 0.005$ ) indicating a better agreement between calculated and measured dose (Fig. 2).

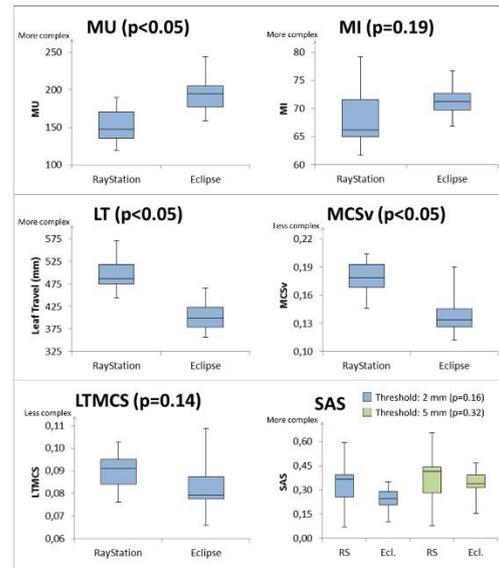

Fig. 1: Box plots for MU, MI, LT, MCSv, LTMCS and SAS complexity metrics for RayStation and Eclipse.

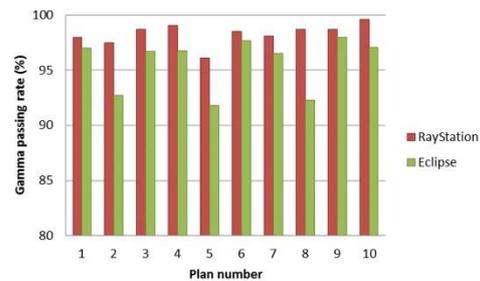

Fig. 2: Comparison of percentage gamma passing rates between RayStation and Eclipse using global 3%/3mm gamma index criteria.

#### Conclusion

Both VMAT optimization algorithms can produce equivalent dose plans regarding target coverage and OAR sparing for all patients of the study. Part of the complexity metrics analyzed in this work shows that, for a comparable dosimetric result, plans optimized with RS may be less complex than plans optimized with Eclipse and PO algorithm. PD results showed a higher degree of agreement for RS plans, indicating the influence of VMAT optimization algorithms on plan deliverability. Further work will include in depth analysis of the complexity metrics to better understand the impact of optimization algorithms on treatment delivery.

#### EP-1818 Comparison of two optimisation algorithms in Eclipse for VMAT in prostate: which one to choose?

D. Jurado-Bruggeman<sup>1</sup>, E. Sansalvador Boadas<sup>2</sup>, A. Onés Segarra<sup>1</sup>, D. Lambisto Castro<sup>1</sup>, M. Buxó<sup>3</sup>  
<sup>1</sup>Institut Català d'Oncologia, Medical Physics and Radiation Protection, Girona, Spain ; <sup>2</sup>Universitat de Barcelona, Física, Barcelona, Spain ; <sup>3</sup>Girona Biomedical Research Institute, IdibGi, Girona, Spain

#### Purpose or Objective

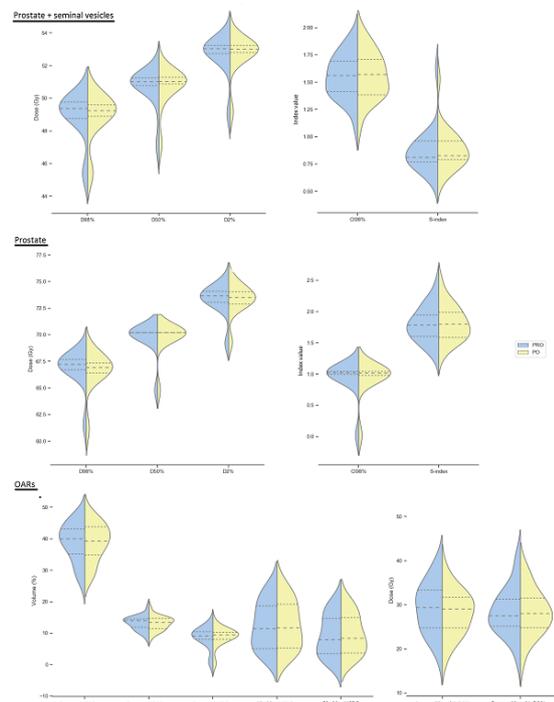

Eclipse TPS version 13.7 introduced Photon Optimizer (PO) optimisation algorithm. The previous Progressive Resolution Optimizer (PRO) engine is also available. The aim of this work is to evaluate the performance of PO against PRO for prostate VMAT treatments, both in terms of dosimetric quality and plan complexity, to aid choosing which one to use in clinical practice.

#### Material and Methods

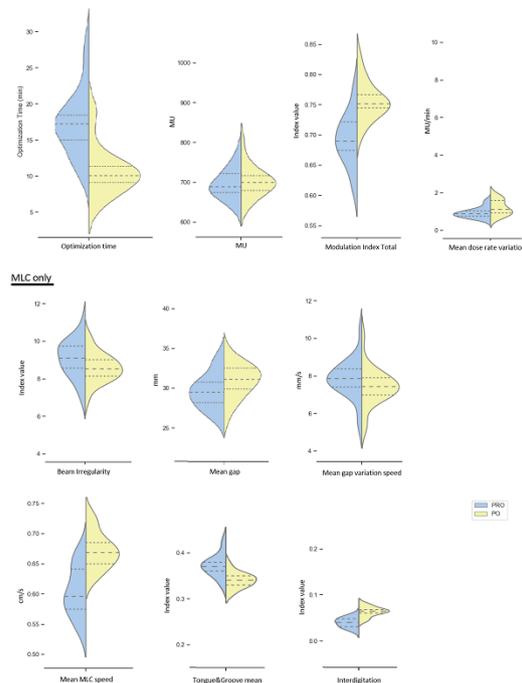

Twenty-two prostate cancer patients were randomly selected, all of them with seminal vesicles and a simultaneous integrated boost to the prostate. For each patient, two identical VMAT plans were created in Eclipse v13.7 using 2 arcs and 6 MV photons. One of the plans was optimised using PO v13.7 and the other using PRO v13.7 with the same optimisation goals. The dose distribution was calculated with Acuros XB in terms of dose-to-water and normalised to the median dose to the prostate. The dosimetric comparison of both plans was done for the PTVs by using Conformity Index (CI), Homogeneity Index (HI) and S-index, D98%, D50%, and D2%. Doses to OAR were also compared for the rectum (V44, V61, V65), bladder (V61, V65), and femoral heads (D2%, V50). Plan complexity was evaluated with a software developed in MATLAB by our National Society that returns several complexity indices and parameters: MUs, MLC information (speed and acceleration, gap and its variation speed), tongue-and-groove effect (T&G), interdigitation, Modulation Index Total, Modulation Complexity Score, Beam Irregularity, leaf travel, and dose rate and gantry speed variations. Optimisation times were also compared. The statistical analysis of the paired differences was performed using Wilcoxon tests.

### Results

The dosimetric differences are shown in Figure 1 as violin plots (median, quartiles, and density for each algorithm).

All these differences were not clinically relevant (below 1%). Optimisation time and plan complexity differences are shown in Figure 2.

Optimisation times were lower for PO (42%) than for PRO. Plan complexity was handled differently. PO plans had more MU and higher dose rate variations, total modulation, and MLC speed. Nevertheless, the MLC shape was simpler for PO: lower Beam Irregularity, higher and more stable (lower variation speed) mean gap between opposed leaves, and lower T&G. The interdigitation was higher for PO due to the pairs of leaves partially included in the limits in Y direction: PO moves its touching point outside the jaws whereas PRO puts it in the middle. There were no gantry speed variations in any case.

### Conclusion

PO and PRO optimisation algorithms implemented in Eclipse were analysed for prostate VMAT treatments in terms of dosimetric quality and plan complexity. PO optimisation times were much lower than PRO's. There were no clinically relevant differences in the dose distributions, but plan complexity was handled differently, with PO moving it from MLC shape to MLC speed and dose rate variations. Overall, PO is preferable over PRO for prostate VMAT treatments.

### EP-1819 Robustness to shifts in patient position with either knowledge based or multi-criteria optimisation

P. Houston<sup>1</sup>, D. Keiller<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy, Glasgow, United Kingdom

### Purpose or Objective

To perform a comparison of the robustness of two treatment planning optimisation methods to shifts in patient position for VMAT Pancreas Planning. The optimisation methods investigated were a knowledge based planning solution, RapidPlan (RP v15.5), and a multi-criteria optimisation solution (MCO v15.5).

### Material and Methods

Knowledge based planning was performed with RP. Multi-criteria optimisation was performed with MCO. All plans were two arc axial VMAT and were normalised to a PTV mean of 100% dose.

RP generates estimated DVHs and planning objectives based on the library of plans it is built from. MCO is a planning trade off tool that calculates multiple plans for each planning objective; this allows the planner to explore the Pareto surface of the ideal dose distribution to

determine the optimal trade off between PTV coverage and OAR doses.

RP and MCO were applied to 10 Pancreas planning cases. Previous work, Houston P., Laverick N. *Planning comparison of knowledge based planning and multi-criteria optimisation for VMAT pancreas planning. ESTRO 2017* compared the plans with regards to plan quality. The treatment plans were here investigated for robustness to patient set-up by shifting the patient and re-measuring dose volume statistics. Plans were shifted  $\pm 0.3\text{cm}$  and  $\pm 0.5\text{cm}$  in the x, y and z directions and worst case dose values recorded for each PTV and OAR.

## Results

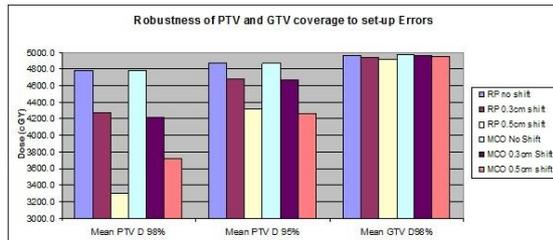

Figure1: Comparison of PTV and GTV coverage when shifts of 3mm and 5mm from planned position are applied.

MCO v15.5 and RP v15.5 plans show comparable robustness to 0.3cm shifts. MCO v15.5 gives higher PTV D98% coverage after a 0.5cm shift than RP v15.5. GTV coverage is not significantly affected by either a 0.3cm or 0.5cm shift, as expected due to GTV to PTV margins of 1cm.

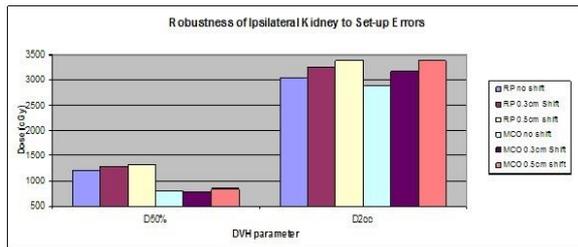

Figure 2: D50% and D2cc for ipsi-lateral kidney when shifts of 3mm and 5mm from planned position are applied.

The improvements in plan quality with MCO conferred a significant advantage in the robustness of OAR dose to shifts in patient position. Average ipsilateral kidney D50% was lower with MCO v15.5 shifted 0.5cm when compared to unshifted RP plans, 837cGy and 1200cGy respectively. Duodenum, which is often the dose limiting organ in pancreas planning, did not display a significant change in robustness of D33% or D2cc.

## Conclusion

MCO treatment planning does not degrade the robustness of PTV coverage to shifts in patient position and may in some cases improve that robustness. OAR doses are either comparable or improved when planned with MCO and possible shifts in patient are accounted for. This general robustness to changes in patient shifts indicates that current margins, imaging and set-up protocols are appropriate for MCO planned pancreatic radiotherapy treatments.

## EP-1820 Preliminary results of using artificial neural networks for prediction CK planning parameters

A. Skrobała<sup>1,2</sup>, J. Ginter<sup>3</sup>, B. Pawalowski<sup>1,4</sup>, M. Skowron<sup>3</sup>,

M. Adamczyk<sup>1</sup>, A. Jodda<sup>1</sup>, J. Litoborska<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Department of Medical Physics, Poznan, Poland ; <sup>2</sup>Poznan University of Medical Sciences, Department of Electroradiology, Poznan, Poland ; <sup>3</sup>University of Warsaw, Department of

Biomedical Physics, Warsaw, Poland ; <sup>4</sup>Poznan University of Technology, Faculty of Technical Physics, Poznan, Poland

## Purpose or Objective

Optimal values of treatment plans parameters for CyberKnife (CK) prostate's treatment, could varied from patients-to-patients. An artificial neural network (ANN) could be powerful tool for a radiotherapy technique for mapping individual patient anatomy and other treatment plan's parameters. ANN could be support tools for prediction optimal parameters for CK's treatment. This study was performed to investigate the feasibility of ANN in prediction CK treatment planning parameters for prostate cancer.

## Material and Methods

A set of retrospective clinical data from 200 patients with prostate cancer were used to build and train the ANNs to predict radiotherapy treatment plan parameters. 22 new patients were used to test the models. Inputs were chosen from general parameters such as: prescription dose, volumes of PTV and six OARs and geometry parameters defining distance between mass centers of PTV and OARs, respectively.

A fully connected ANN was used with two hidden layers of 150 neurons, 18 input and 14 output neurons. As an activation function the Rectified Linear Units (ReLU) were used, with 0.4 dropout rate in order to avoid over fitting. The net was trained in 2000 epochs, with mean squared error as a loss function.

## Results

Errors of ANN's prediction of the plans parameters for patients from test set were evaluated in terms of mean absolute value of differences (mean(abs(diff))) between predicted and original values and root-mean-squares (rms (diff)) of these values. Table 1 presents mentioned errors for chosen parameters (prescribed isodose (%), number (#) of nodes, beams and collimators, estimated treatment time (minutes), PTV CI and PTV Coverage (%)) in comparison with original mean values (mean test) of parameters in the test set.

Table 1. Values of evaluated parameters: mean absolute value of differences (mean(abs(diff))) between predicted (ANN) and original values, root-mean-squares (rms (diff)) and mean values (mean(test)) of parameters in the test set of these values for seven predicted treatment planning parameters for CyberKnife prostate's treatment.

parameters	isodose (%)	# of nodes	# of beams	# of collimators	time (minutes)	PTV CI	PTV Coverage(%)
mean(abs(diff))	2.7	6.2	20.3	0.4	2.4	0.04	3.2
rms(diff)	3.2	7.4	23.9	0.7	3.1	0.04	3.7
mean(test)	79.4	33	162.2	4.3	33	1.08	95.8

## Conclusion

This investigation was preliminary and lead us to confirm the feasibility of artificial neural network in prediction CyberKnife treatment planning parameters for prostate cancer. The errors in comparison with mean values of parameters in test set were not high, but not yet good enough to be useful for clinical purposes: the errors were comparable with standard deviations of parameters of test set. Moreover several steps have to be undertaken in future. In order to predict features of treatment planning parameters, the crucial information is in geometry dependencies of PTV and OARs, which could be found specially tailored parameters. We suppose it could be obtained by convolutional neural network with bigger amount of training examples.

## EP-1821 Fast Robust Optimization using a Patient-Specific Scenario Selection Methodology

G. Buti<sup>1</sup>, K. Souris<sup>1</sup>, J.A. Lee<sup>1</sup>, E. Sterpin<sup>2</sup>

<sup>1</sup>Université Catholique de Louvain, Molecular Imaging-Radiotherapy & Oncology, Brussels, Belgium ;

<sup>2</sup>Katholieke Universiteit Leuven, Experimental Radiotherapy & Oncology, Leuven, Belgium

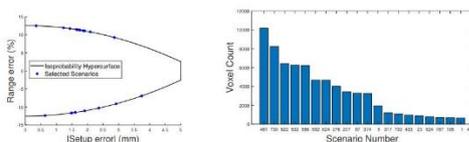

### Purpose or Objective

In proton therapy treatments, physical uncertainties can cause both aiming and range errors. Current planning strategies aim at achieving robust plans by optimizing an objective function over a discrete set of scenarios. As the problem complexity scales exponentially with the number of considered uncertainty sources, a pre-selection of scenarios is necessary to limit the computational burden and keep the computation time within clinically acceptable timescales.

The set of scenarios in conventional treatment planning is statistically inconsistent due to the use of unlikely scenarios (large setup error (SE) of 5 mm AND proton range error (PRE) of +/-3%) that lie outside of the planned confidence interval (CI), potentially compromising plan quality. This study aims to establish a novel treatment planning methodology that produces plans of acceptable robustness and guarantees coverage of a certain percentage of beam positions and proton ranges, defined by a priori chosen CI. The focus is to make the methodology statistically sound, fast and computationally cheap by efficiently pre-selecting relevant scenarios which are later fed to the robust optimizer.

### Material and Methods

We consider lung treatments with motion characterized by a 4DCT binned in ten breathing phases; robustness should be achieved for all phases. SE and PRE are distributed as Gaussian distributions with standard deviations of 2 mm and 1.6%, respectively. We perform two successive steps to determine the relevant scenarios: first, 12 scenarios are selected that cover extreme positions reached by the tumor during breathing together with spatial shifts of 5 mm and image density scaling of +/-2.5% (sampling of a 4D isoprobability hypersurface). The second selection is based on the magnitude of the PRE, estimated from maps of water-equivalent path lengths, computed for scenarios randomly sampled according to the distributions defined above. 20 scenarios are selected that produce the largest PRE evaluated for each voxel inside the CTV (see Fig. 1). All treatment plans were calculated for a lung tumor case and plan optimization was performed using the robust optimizer in RayStation 6. The dose prescription was 60 Gy (minimum coverage of 57 Gy). Conventional robustness optimization with SE of 5 mm, PRE of +/-3% and inhale/exhale breathing phases, was used as a reference. Plan robustness was evaluated with the MCsquare code by recalculating the dose distribution on a set of 100 randomly sampled error scenarios.

**Figure 1:** Scenario selection procedure. The left panel illustrates the isoprobability hypersurface with the selected scenarios. The right panel shows the scenario statistics, i.e. scenario  $i$  was counted as the worst case in  $x$  number of voxels of the CTV.

### Results

As shown by Table 1, an average right lung dose reduction of 3.1 Gy reduction is achieved, whilst reducing the average target dose ( $D_{98}$ ) by 2.1 Gy, with the scenario selection method as compared to a conventional one. Moreover, half of the number of optimization scenarios are necessary to produce this plan. Hence, the plan calculation time was reduced by half.

**Table 1:** DVH metrics for plans produced using the scenario selection (S.S.) and conventional (Conv.) methods.  $\bar{D}$  denotes the mean dose level.

	CTV		Heart	R. Lung
	$\bar{D}_{98}$ [Gy]	$\bar{D}_2$ [Gy]	$\bar{D}_{mean}$ [Gy]	$\bar{D}_{mean}$ [Gy]
Conv.	54.8 (53.8, 58.1)	65.2 (65.4, 62.5)	2.8 (3.5, 2.7)	16.3 (18.1, 16.3)
S.S.	52.7 (50.2, 55.6)	64.4 (64.6, 62.0)	2.6 (3.5, 2.4)	13.4 (15.0, 13.3)

\*The values between brackets ( $D_{worst}$ ,  $D_{nom}$ ) represent the worst case and nominal case scenarios, respectively, evaluated from the 90% best perturbed scenarios.

### Conclusion

Serious reduction of plan calculation time is achieved using the scenario selection methodology without significant compromise in treatment plan quality.

### EP-1822 Evaluation of plan robustness against tumor motion for lung SBRT treatment with non-coplanar VMAT

C. Garibaldi<sup>1</sup>, A. Bazani<sup>2</sup>, F. Pansini<sup>2</sup>, F. Emiro<sup>2</sup>, S. Trivellato<sup>2</sup>, S. Comi<sup>2</sup>, G. Piperno<sup>3</sup>, A. Ferrari<sup>3</sup>, B.A. Jereczek-Fossa<sup>3,4</sup>, M. Cremonesi<sup>1</sup>, F. Cattani<sup>2</sup>

<sup>1</sup>IEO-European Institute of Oncology IRCCS, Unit of Radiation Research, Milano, Italy; <sup>2</sup>IEO-European Institute of Oncology IRCCS, Unit of Medical Physics, Milano, Italy; <sup>3</sup>IEO-European Institute of Oncology IRCCS, Dept. of Radiation Oncology, Milano, Italy; <sup>4</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy

### Purpose or Objective

to investigate robust optimization for lung SBRT treatment using a non-coplanar VMAT technique, taking into account tumor motion due to respiration. Plan robustness was evaluated against variation in time spent in each breathing phase and variation of the mean tumor position. Robust plan was compared with the ITV-based plan for 3D dose and 4D dose accumulation.

### Material and Methods

Dynamic Wave Arc (DWA) is a novel non-coplanar VMAT technique implemented on the VERO system. The fluence modulation is achieved by a synchronized moving of gantry, ring and leaves at a fixed dose rate (400 UM/min). 4D CT of 2 patients treated for lung SBRT and CIRS phantom moving with 9 different breathing patterns (6 sinusoidal with A=5-15 mm and 3 with real patient breathing) were used for robust optimization using minimax optimization method in Raystation v8A (0.2 mm dose grid, Collapsed Cone Convolution Algorithm v3.5). Robust plan was calculated on the CT end-exale (CT<sub>EXP</sub>) and optimized on the GTV+5 mm on each respiratory phase, while ITV-based plan was calculated on the CT average intensity projection (CT<sub>AVE</sub>), obtained from all breathing phases, and optimized on ITV+5 mm with a prescription dose of 54 Gy in 3 fractions with a goal of  $D_{95\%}=95\%$  for GTV + 5 mm and ITV+5mm, respectively. Doses were calculated on each phase, deformed onto both CT<sub>AVE</sub> and CT<sub>EXP</sub> and accumulated over all phases. To assess robustness against realistic variation in time spent in each breathing phase, 3 methods of 4D dose accumulation were used: equivalent weight to all phases ( $\Sigma_{EQUI}$ ), more weight to expiration phases ( $\Sigma_{EXP}$ ), and more weight to the inspiration phases ( $\Sigma_{EQUI}$ ). To evaluate plan robustness against a baseline shift of the tumor, perturbed doses with a shift from the isocentre of  $\pm 5$  mm in CC and AP direction independently were calculated. Both 3D and 4D doses of the robust plan were compared with the conventional ITV-based approach.

### Results

Preliminary results for two patients and phantom with a tumor motion in CC direction of 10 and 15 mm are reported. All Robust and ITV-based plans satisfied criteria

for clinical acceptability. A reduced number of MU was obtained for the robust plan with a mean variation of -18% (-32%/-10%) compared to the conventional plan. Very small variation of dose metrics for GTV and OARs were obtained considering the 3 dose accumulation methods, as well as the perturbed doses. Small differences non clinically relevant were found between 3D and 4D dose calculation for both robust and ITV-based plan.

Plan	Dose difference (Gy)		GTV Dmin	GTV Dmean	GTV Dmax	Dmean lung	Dmax PRV cord
Robust	3D- $\Sigma_{EQUI}$	mean	-0.42	-0.06	0.26	-0.30	0.04
		SD	0.82	0.54	0.37	1.21	0.13
	$\Sigma_{EQUI} - \Sigma_{EXP}$	mean	0.08	0.08	0.09	-0.03	0.03
		SD	0.15	0.14	0.14	0.04	0.02
	$\Sigma_{EQUI} - \Sigma_{NSP}$	mean	-0.01	-0.06	-0.13	0.13	0.12
		SD	0.32	0.43	0.49	0.16	0.22
ITV-based	3D- $\Sigma_{EQUI}$	mean	0.29	0.19	0.62	-0.15	0.02
		SD	0.14	0.05	0.37	0.55	0.04
	$\Sigma_{EQUI} - \Sigma_{EXP}$	mean	-0.10	-0.04	-0.02	-0.03	0.01
		SD	0.07	0.10	0.23	0.04	0.03
	$\Sigma_{EQUI} - \Sigma_{NSP}$	mean	-0.08	-0.14	-0.34	-0.01	-0.03
		SD	0.19	0.24	0.27	0.04	0.05
Robust	perturbed dose (0, 0, $\pm$ 5mm)	mean	0.50	0.07	0.05	0.02	0.01
		SD	0.18	0.13	0.27	0.25	0.16

		SD	0.35	0.11	0.34	0.27	0.12

## Conclusion

Robust optimization to account for respiratory motion was investigated for DWA lung SBRT. Our preliminary results confirmed the robustness against realistic variation in respiratory motion. Further investigations are warranted to confirm the clinical effectiveness of this novel approach compared to the conventional margin-based approach.

**EP-1823 Analysis of treatment plans robustness for dynamic techniques in external beam radiotherapy**  
 E. Dabrowska-Szewczyk<sup>1,2</sup>, M. Bukat<sup>1</sup>, P. Kukolowicz<sup>1</sup>, D. Szalkowski<sup>1</sup>, A. Paciorkiewicz<sup>1</sup>, A. Zawadzka<sup>1</sup>  
<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Medical Physics, Warsaw, Poland ; <sup>2</sup>University of Warsaw, Department of Biomedical Physics, Warsaw, Poland

## Purpose or Objective

Uncertainty of patient positioning during treatment session have a significant impact on dose distribution in clinical target volume (CTV) and organs at risk (OARs). However, usually some discrepancy between DRR and daily set-up of the patient's position during the treatment are acceptable. The aim of our study was to evaluate the robustness of dynamic techniques dose distributions against isocentre shifts and to verify whether threshold used in patient position verification were chosen correctly.

## Material and Methods

For this study, plans prepared for 400 patients treated with VMAT or IMRT were retrospectively analyzed (50 plans per the following cases: brain-IMRT, head and neck-IMRT, head and neck-VMAT, breast-IMRT, breast VMAT, lung-VMAT, gynecology-IMRT, canal anal-VMAT). To estimate the robustness of analyzed plans against simulated isocenter shifts, tool named "Plan Uncertainty" was used (Eclipse TPS, Varian, version 15.6). For each plan the new 6 dose distribution were re-calculated with taking into account the positive and negative maximally acceptable threshold in our clinic during patient position verification. The values of acceptable shifts are as follow: 3 mm in case of brain and head and neck patients, 6 mm in case of breast patients and 4 mm in case of lung, gynecology and anal canal patients. For 400 references and 2400 re-calculated plans, near to minimum doses (D98%, D99%) and near to maximum doses (D1%, D2%) for CTV were investigated. Tolerance doses for relevant OARs were also evaluated according to our clinical protocol.

## Results

The dose distribution in CTV was not essentially affected by the isocenter shifts and still fulfilled constraints to be used in our clinic, regardless of tumor location, dynamic technique used and shift direction. Only in few cases CTV constraints were slightly violated on average by: 0,7%, 1,1%, 0,9, 0,3% of re-calculated plans for D98%, D99%, D1% and D2%, respectively. In case of rectum (gynecology, IMRT), jaw (head and neck, VMAT) and lungs (lung, VMAT) overdosage caused by isocenter shift was observed in more than 7% of re-calculated plans. For bladder and pelvic bones (gynecology IMRT), jaw (head and neck IMRT), optic nerves, optic chiasm and brainstem (brain IMRT) discrepancies below 3.3 % of simulated plans were observed. More detailed information was included in Table 1. No relevant impact was observed on rest of OARs, important in analyzed tumor locations.

Table 1. Percentage of re-calculated plans in which OARs tolerance doses were exceeded

TUMOR LOCATION	OAR	CONSTRAINTS	PERCENTAGE OF NUMBER OF PLANS (%)	MAXIMUM OAR'S OVERDOSAGE
brain (IMRT)	optic nerve left	d_max<54Gy	3.00	54.80y
	optic nerve right	d_max<54Gy	3.33	54.80y
	optic chiasm	d_max<54Gy	2.00	54.70y
brainstem	brainstem	d_max<54Gy	2.18	54.80y
	jaw	d_max<30Gy	7.00	74.3 Gy
head and neck (IMRT)	jaw	d_max<30Gy	12.57	74.3 Gy
	lungs	V20<15%	7.00	17.8%
lung (VMAT)	lungs	d_mean<20Gy	7.67	21.2 Gy
	rectum	V45<20%	13.37	73.01%
gynecology (IMRT)	bladder	V65<20%	2.00	92.3%
	pelvic bones	V20<75%	2.67	78.5%

## Conclusion

Based on 2400 simulated plans, dosimetric treatment plan parameters robustness was analyzed in the context of the daily patient positioning error. For all plans the dose distribution in the CTV fulfilled all investigated criteria. Analysis of OARs showed that in some cases isocenter displacement cause dose restrictions exceeding, however it is the worst-case scenario, when the systematic error would occur. In case of serial OARs, for which PRV concept was used, the maximum overdosage not exceed more than 1 Gy. Thresholds used in our clinic in patient position verification seem to be well adjust as to treat patients properly.

### EP-1824 Hybrid-Volumetric Modulated Arc Therapy in the Upper Thoracic Esophageal Cancer: A Planning Study

Y.E. Choi<sup>1</sup>, K. Sung<sup>1</sup>, H.J. Kim<sup>1</sup>, Y.K. Lee<sup>1</sup>  
<sup>1</sup>Gil Medical Hospital, Radiation Oncology, Incheon, Korea Republic of

## Purpose or Objective

To compare the dosimetric differences and lung sparing of three different treatment techniques - three-dimensional conformal radiotherapy (CRT), volumetric modulated arc therapy (VMAT) and Hybrid-VMAT (H-VMAT) in the treatment of upper thoracic esophageal cancer.

## Material and Methods

CRT, VMAT, and H-VMAT plans were regenerated for 14 upper thoracic esophageal cancer patients with T3N0-1M0. The target prescription dose was 50.4 Gy. All plans were optimized to reach clinically acceptable levels by the departmental plan criteria: the maximum dose for the spinal cord was less than 45 Gy, whereas the volume of the lung irradiated by a dose of 20 Gy (V<sub>20</sub>) and 30 Gy (V<sub>30</sub>) was less than 30% and 20%, respectively. For PTV coverage, 95% of PTV should be covered by 95% of the prescription dose, unless the spinal cord limit was violated. Plan quality was evaluated using: conformity index (CI), homogeneity index (HI), mean lung dose (MLD), lung volume receiving >5-30 Gy (lung V<sub>x</sub>), and maximum spinal cord dose (cord D<sub>max</sub>). The Wilcoxon Signed-Rank test was used to determine any differences between datasets with a Bonferroni's adjustment for multiple comparisons (p < 0.017).

## Results

In comparison with CRT, VMAT and H-VMAT yielded a better conformity and significantly lower MLD, cord  $D_{max}$ , and lung volume receiving >10-30 Gy. No differences were observed in lung  $V_5$  between CRT and VMAT (41.59% and 44.59%, respectively). VMAT plans represented the best conformity and the lowest cord  $D_{max}$ , whereas H-VMAT plans gave the lowest MLD and lung volume receiving 5-10 Gy.

## Conclusion

The H-VMAT technique was superior in lung sparing with comparable dose coverage for treating upper thoracic esophageal cancer compared to CRT and VMAT.

## EP-1825 Variability of PTV volume and target coverage for hypofractionated prostate treatments

E.M. Ambroa Rey<sup>1</sup>, A. Ramirez Muñoz<sup>1</sup>, J. Garcia-Miguel Quiroga<sup>1</sup>, R. Gómez Pardos<sup>1</sup>, D. Navarro Giménez<sup>1</sup>, N. Feltes<sup>2</sup>, J. Lozano<sup>2</sup>, A. Muñoz<sup>2</sup>, M. Galdeano<sup>2</sup>, M. Colomer Truyols<sup>1</sup>

<sup>1</sup>Consorti Sanitari de Terrassa, Medical Physics Unit-Radiation Oncology, Terrassa, Spain ; <sup>2</sup>Consorti Sanitari de Terrassa, Radiation Oncology, Terrassa, Spain

## Purpose or Objective

To study the variability of PTV volume and PTV coverage depending on the Radiation Oncologist (RO) who performs the contours and the Medical Physicist (MP) who executes or reviews the treatment plan, and to evaluate if the different combinations of MP and RO have an influence on the PTV coverage.

## Material and Methods

175 patients with low or intermediate risk prostate cancer were selected for this study. Patients were recruited following a strict protocol. The hypofractionated scheme was 60Gy in 20 fractions. VMAT plans were carried out using Monaco TPS (v5.10) based on a single arc arrangement.

Every patient was delineated by one RO and planned/reviewed by one MP. A total of 4 RO and 5 MP were evaluated. The same protocol for delineation, treatment planning and plan evaluation was used for all patients.

At least 98% of the PTV covered by 95% of the dose prescription is required and the OAR must satisfy a certain constraints otherwise patient is changed to another fractionation scheme.

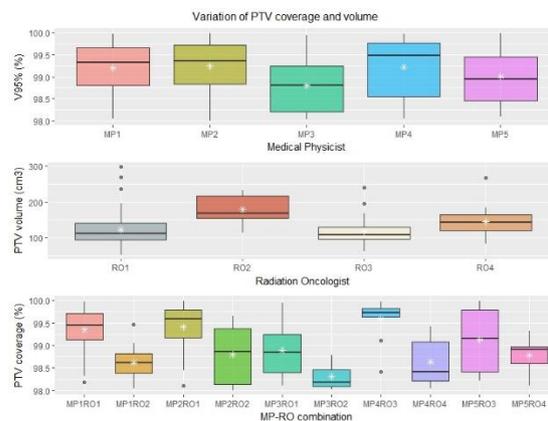

## Results

The number of patients contoured by each RO and reviewed by each MP is summarized in Table I; along with the different combinations of MP-RO (combinations with less than 5 patients were excluded).

Number of patients for each observer					
Medical physicist	Mean V95% (%)	Radiation oncologist	Mean PTV volume (cm <sup>3</sup> )	MP-RO combination	Mean V95% (%)
MP1: 48	99.2	RO1:106	122	MP1-RO1: 37	99.3
MP2: 57	99.2	RO2: 28	179	MP1-RO2: 9	98.6
MP3: 34	98.8	RO3: 25	118	MP2-RO1: 43	99.4
MP4: 18	99.2	RO4: 16	145	MP2-RO2: 12	98.8
MP5: 18	99.0			MP3-RO1: 26	98.9
				MP3-RO2: 7	98.3
				MP4-RO3: 11	99.6
				MP4-RO4: 7	98.6
				MP5-RO3: 12	99.1
				MP5-RO4: 6	98.8

Table I

Figure I show the median, mean, upper quartile and lower quartile for each RO, MP and combination of both.

A statistical analysis (Kruskal-Wallis test) was performed to analyze the differences between groups. The results show that there are significant differences in the PTV volume between different RO (p-value: 5.774e-09). No differences were found between MP in the PTV coverage. From the output of the test, we know that there is a significant difference in the average of the PTV volume between pairs of RO, but we don't know which pairs are different. To that end a pairwise comparisons using Wilcoxon rank sum test were performed. The results show that there are significant differences between RO1-RO2 (p-value: 8.1e-09), also between RO3-RO2 (p-value: 5.2e-06). Moreover, a medium effect size was found:  $d_{Cohen}=0.52$  (RO1-RO2),  $d_{Cohen}=0.66$  (RO3-RO2). In addition, 10 different combinations of MP-RO were analyzed and significant differences in the PTV coverage between groups were found (p-value = 3.595e-08).

## Conclusion

A strict treatment planning protocol helps to achieve a more homogeneous treatment plan with regardless of the MP that reviews the plan.

Target delineation is overall a major source of uncertainty in radiotherapy and delineation variation depends, among other things, on the observers and the delineation protocol. Thus, having a protocol helps to prevent these variations. From the results we can conclude that although we found similar results in the PTV volume for each RO, a review of the delineation protocol must be done in order to improve these differences.

Also, certain combinations of MP-RO could result in a slightly better target coverage.

## EP-1826 Comparison of two Volumetric Arc Therapy techniques for hippocampal sparing whole brain radiotherapy

A.I. Milanés<sup>1</sup>, A. Prado<sup>1</sup>, G. Pozo<sup>1</sup>, A. Ferrando<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de octubre, Radiofísica, Madrid, Spain

## Purpose or Objective

Whole brain radiotherapy (WBRT) is one of the main treatments for patients with multiple brain metastases. However, several studies showed that usual WBRT produces damage to hippocampi, entailing dementia and neurocognitive function decline. Nowadays, with the introduction of volumetric-modulated arc therapy (VMAT) it is possible to spare hippocampal regions maintaining PTV coverage. The aim of this study is to compare two different beam arrangements for hippocampal sparing WBRT utilizing VMAT.

## Material and Methods

A total of ten patients were selected for this study. Imaging of each patient consisted of a 3 mm slice thickness CT scan. Hippocampi were contoured according to RTOG 0933 contouring atlas. Hippocampal avoidance regions were defined as a 5 mm expansion of both hippocampi.

PTV was defined as the usual WBRT PTV minus the hippocampal avoidance regions.

Treatment plans were created in Eclipse v.11.0 TPS (Varian Medical Systems, Palo Alto, CA) using a 6MV Varian Unique linac with a maximum dose rate of 600 MU/min. The Anisotropic Analytical Algorithm (AAA) was used with the Progressive Resolution Optimizer (PRO3) for VMAT optimization.

The prescription dose was 30 Gy to the PTV in 10 fractions. The techniques compared are shown in table 1.

	Gantry angles (°)	Collimator angle (°)	Couch angle (°)
Technique 1	A1: 181 to 179 (CW)	30	0
	A2: 179 to 181 (CCW)	330	0
Technique 2	A1: 181 to 179 (CW)	30	0
	A2: 179 to 181 (CCW)	330	0
	A3: 21 to 179 (CW)	150	90
	A4: 179 to 21 (CCW)	210	90

Table 1: Beam arrangement, collimator angles and couch angles for both techniques studied

Regarding PTVs  $V_{25}$ ,  $V_{30}$ ,  $D_{50\%}$ ,  $D_{2\%}$ ,  $D_{98\%}$ , the Homogeneity Index (HI) and the Paddick Conformity Factor (CF) were evaluated for both techniques. For both eyes  $D_{max}$  and  $D_{avg}$  were considered.  $D_{max}$  for lenses and  $D_{max}$  and  $D_{100\%}$  for both hippocampi were also evaluated. Dose limits for OARs and dose objectives for PTVs were defined following the RTOG 0933 protocol.

### Results

Table 2 shows results obtained for evaluated parameters regarding PTV and OARs.

As it is shown in table 2, technique 2 achieved a better PTV coverage ( $p < 0.04$ ) and a more homogeneous and conformed dose distribution ( $p < 0.002$  and  $p < 0.005$ , respectively). Besides, hippocampi  $D_{max}$  and  $D_{100\%}$  are reduced compared to technique 1 results ( $p < 0.045$  and  $p < 0.04$ , respectively). Lenses and eyes  $D_{max}$  were also reduced ( $p < 0.003$ ). Technique 1 delivered a lower number of monitor units ( $683 \pm 38$ ) in a shorter time ( $2.49 \pm 0.2$  min), mainly due to the reduced number of arcs and the absence of couch angles different from  $0^\circ$  ( $p < 0.0012$ ). Plan 2 technique delivered 842 MU in 4.57 min.

PTV							
	$V_{25}$ (%)	$V_{30}$ (%)	$D_{50\%}$ (cGy)	$D_{2\%}$ (cGy)	$D_{98\%}$ (cGy)	HI	CF
Technique 1	98.9	91.1	3129.3	3250.2	2716.6	0.17	0.84
Technique 2	99.2	94.1	3126.3	3248.8	2847.9	0.13	0.89
Left eye		Right eye		Left Lens		Right Lens	
	$D_{max}$ (cGy)	$D_{avg}$ (cGy)	$D_{max}$ (cGy)	$D_{avg}$ (cGy)	$D_{max}$ (cGy)	$D_{max}$ (cGy)	$D_{max}$ (cGy)
Technique 1	1994.8	1347.0	2053.4	1099.1	799.9	810.9	
Technique 2	1755.5	897.7	1740.1	861.2	740.7	752.6	
Left hippocampus		Right hippocampus					
	$D_{100\%}$ (cGy)	$D_{max}$ (cGy)	$D_{100\%}$ (cGy)	$D_{max}$ (cGy)			
Technique 1	883.3	1559.2	891.8	1549.9			
Technique 2	864.9	1509.4	875.1	1440.5			

### Conclusion

In both cases, the RTOG 0933 dose criteria were achieved, not incurring in any acceptable or unacceptable deviation. Technique 2 was the best in terms of PTV coverage, HI and CF. Besides, it achieved a better sparing of hippocampi, lenses and eyes. On the contrary, the analysis of MU and treatment time indicated that technique 1 delivered the lowest number of MU in the shortest time. The election of one of these techniques also involves considering the workload of every specific institution.

### EP-1827 Influence of the optimization PTV structure on hippocampal sparing radiation therapy using VMAT

A. Prado<sup>1</sup>, A. Milanés<sup>1</sup>, R. Díaz<sup>1</sup>, E. Cabello<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de octubre, Oncología Radioterápica. Sección de Radiofísica, Madrid, Spain

### Purpose or Objective

Whole brain radiotherapy (WBRT) is one of the main treatments for patients with multiple brain metastases. However, several studies showed that usual WBRT produces damage to hippocampi, entailing dementia and neurocognitive function decline. Nowadays, it is possible to spare hippocampal regions maintaining PTV coverage using intensity modulation. The aim of this study is to compare how PTV coverage and hippocampi doses depend on the distance between hippocampi and the PTV optimization structure employed.

### Material and Methods

Hippocampi were contoured according to RTOG 0933 contouring atlas. Hippocampal avoidance regions were defined as a 5 mm expansion of both hippocampi. PTV was defined as the usual WBRT PTV minus the hippocampal avoidance regions. Treatment plans were created in Eclipse v.11.0 (Varian Medical Systems, Palo Alto, CA) using a 6MV Varian Unique linac with a maximum dose rate of 600 MU/min. The Anisotropic Analytical Algorithm (AAA) was used with the Progressive Resolution Optimizer (PRO3) for VMAT optimization. The prescription dose was 30 Gy to the PTV in 10 fractions. Two full arcs were used with collimator settings of  $30^\circ$  and  $330^\circ$ , respectively. PTV optimization structures were defined as the WBRT PTV minus the hippocampi avoidance regions plus a margin between 0 and 5 mm. Hence, PTVX represents the optimization structure which is at X mm from the hippocampi. Each PTV optimization structure was considered as the objective structure in the optimization process but the dose evaluation was always performed using the PTV. All parameters regarding the cost functions were set to the same values when optimizing using different PTVX structures as objective structures. To evaluate differences between plans  $D_{2\%}$  and  $D_{100\%}$  were considered for hippocampi and  $V_{25}$ ,  $V_{28}$  and  $V_{30}$  for PTV

### Results

Figure 1 depicts hippocampi and PTV results when optimizing using distinct PTV optimization structures. As the distance X is increased, PTV coverage decreased as a result of dose reduction nearby the hippocampal avoidance regions (table 1). Also, hippocampi  $D_{2\%}$  and  $D_{100\%}$  both decreased. This reduction in  $D_{2\%}$  and  $D_{100\%}$  seemed to be greater from PTV5 to PTV7 (210 cGy and 48 cGy, respectively) than from PTV7 to PTV9 (75 cGy and 27 cGy, respectively). For X values from 5 to 7 mm there was little reduction in PTV coverage (Table 1), increasing these differences for higher X values.

HIPPOCAMPI	PTV5	PTV6	PTV7	PTV8	PTV9
$D_{2\%}$ (cGy)	1515	1455	1305	1281	1257
$D_{100\%}$ (cGy)	891	843	816	801	789
PTV	PTV5	PTV6	PTV7	PTV8	PTV9
$V_{25}$ (%)	99,7	99,5	99,2	98,9	98,5
$V_{28}$ (%)	98,6	98,4	98	97,5	96,9
$V_{30}$ (%)	93,5	93,4	93,2	92,2	92

Table 1: Evaluated parameters for hippocampi and PTV when optimizing utilizing distinct PTVX objective structures. X stands for the distance between PTVX optimization structure and hippocampi in mm.

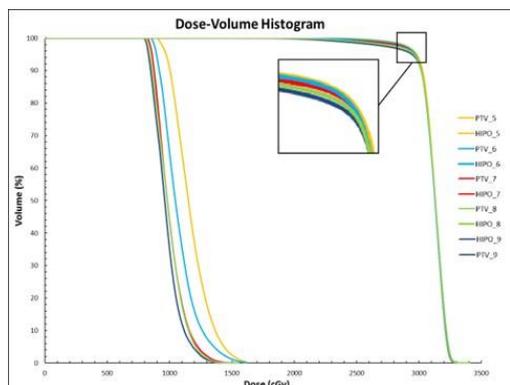

Figure 1: Dose volume histogram for the results obtained for PTV and hippocampi when optimizing utilizing distinct PTVX structures. X stands for the distance in mm from the PTVX structure to the hippocampi.

#### Conclusion

Optimizing using PTV7 structure as objective structure and evaluating final results on PTV implies maintaining PTV coverage and the achievement of an important reduction on hippocampi maximum dose.

#### EP-1828 Treatment plan comparison between SBRT techniques for recurrent nasopharyngeal carcinoma

Y. Lin<sup>1</sup>, H. Ho<sup>1</sup>

<sup>1</sup>Chi Mei Medical Center, Department of Radiation Oncology, Tainan, Taiwan

#### Purpose or Objective

To evaluate the potential benefit of HyperArc (HA) in previous treated, recurrent nasopharyngeal cancer treated with stereotactic body radiation therapy (SBRT).

#### Material and Methods

The twenty patients with recurrent nasopharyngeal cancer who were treated using CyberKnife (CK) for salvage treatment were enrolled. The median dose for the previous treatments for the twenty patients was 70Gy in 35 fractions. CK was delivered with a median 35 Gy in 5 fractions. The HA treatment plans were created for each patient to meet the same treatment plan criteria for CK. These two SBRT treatment plans were compared with target coverage, sparing of organs at risk, and dose distribution metrics, including conformity index, heterogeneity index, dose gradient index, and high/intermediate dose spillage. Monitor units (MU) were compared to assess as delivery efficiency.

#### Results

The HA plans consistently exhibited similar CTV and PTV coverage and significantly reduced the dose to organs at risk. The mean CTV coverage for CK and HA was 97.3% and 98.3%; the mean PTV coverage for CK and HA was 94.7% and 96.1%. Using HA plans, mean doses to the spinal cord, brainstem, optic nerves, and optic chiasm were reduced by 64%, 62%, 61% and 68%, respectively. The conformity and heterogeneity metrics of the HA plans were significantly better than the CK plans. With HA plans, the mean high dose spillage volumes were decreased by 54%. In average, the HA plans resulted in 56% less MUs than the CK plans (HA, 20643 MUs vs. CK, 47464 MUs).

#### Conclusion

Excellent sparing of organs at risk and good dosimetric distribution make HA an attractive SBRT technique for the treatment of recurrent nasopharyngeal cancer.

#### EP-1829 Clinical validation of knowledge-based planning for multiple brain metastases

N. Kishi<sup>1</sup>, M. Nakamura<sup>1,2</sup>, H. Hirashima<sup>1</sup>, N. Mukumoto<sup>1</sup>, K. Takehana<sup>1</sup>, M. Uto<sup>1</sup>, Y. Matsuo<sup>1</sup>, T. Mizowaki<sup>1</sup>

<sup>1</sup>Kyoto University Graduate School of Medicine, Department of Radiation Oncology and Image-Applied Therapy, Kyoto, Japan ; <sup>2</sup>Kyoto University Graduate School of Medicine, Department of Information Technology and Medical Engineering Human Health Sciences, Kyoto, Japan

#### Purpose or Objective

Recently, single isocenter volumetric modulated arc therapy (VMAT) has arisen as an alternative to whole brain radiotherapy when treating multiple brain metastases (BMs). The aim of this study was to evaluate the clinical validation of knowledge-based planning (KBP) for multiple BMs.

#### Material and Methods

Consecutive 56 patients treated with single isocenter VMAT for multiple BMs between October 2015 and September 2018 in our institute were enrolled into this study. The patient cohort was divided into two groups according to the number of BMs; model training (50 cases with 2-4 BMs) and validation (6 cases with 12-20 BMs). Four KBP models (M1-4) with different number of BMs per case were constructed using RapidPlan™ (Varian Medical Systems, Palo Alto, USA): M1, using all 50 cases with 2-11 BMs; M2, 40 cases with 2-6 BMs; M3, 30 cases with 2-4 BMs; and M4, 20 cases with 2-3 BMs. Then, the four KBP models were applied to each case in the validation group with the same beam arrangements as in a clinical plan (CL). The total number of BMs in the validation group was 96, whereas the clinical plans consisted of 88 planning target volumes (PTVs). One time of optimization per KBP model was performed for each case. The dosimetric differences between the KBP plans and CLs were assessed for PTVs and organs at risk (OARs). OARs included brain-PTVs, brainstem, chiasm, optic nerves, eyes, lens and skin. The following dose-volumetric parameters were recorded: PTV D<sub>2%</sub>, D<sub>50%</sub> and D<sub>98%</sub>, the maximum dose to OARs and V<sub>20Gy</sub> of brain-PTVs. Friedman test were performed for statistical analysis at  $\alpha = 0.05$ , followed by Wilcoxon signed-rank test with Bonferroni correction for multiple comparisons as a post hoc test. Statistical significance was set at  $p < 0.01$ .

#### Results

Three to seventeen (median, 7) optimizations were required until the CLs were obtained. Interquartile ranges were smaller in the KBPs than in the CLs for any dose-volumetric parameters (Fig. 1). The difference between the median values in the CLs and those in the KBPs was within  $\pm 1.7\%$  points and  $\pm 0.4\%$  points for PTV D<sub>50%</sub> and D<sub>98%</sub>, respectively. No significant difference was observed among these dose-volumetric parameters ( $p > 0.05$ ). Although the PTV D<sub>2%</sub> was significantly higher in the KBPs than in the CLs ( $p < 0.01$ ), the difference of its median value between the CLs and the KBPs ranged from 1.7 to 2.3% points. The maximum dose of brain-PTVs in the KBPs were decreased by 4.9% points (range, 1.5-11% points), compared with the CLs. The median values of difference in the maximum dose to other OARs and V<sub>20Gy</sub> of brain-PTVs between the CLs and KBPs were ranged from -5.6% points to +0.5% points.

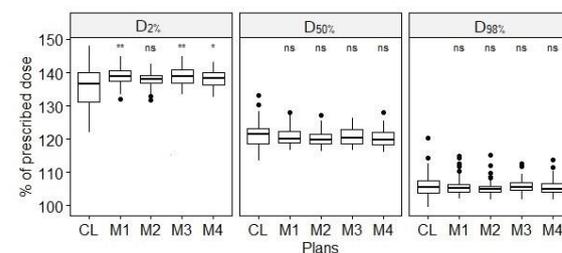

Fig. 1 Box-and-whisker plots of the difference between the CLs and the KBPs for the PTV D<sub>2%</sub>, D<sub>50%</sub>, and D<sub>98%</sub> for the planning target volumes. Notes: \* =  $p < 0.01$ ; \*\* =  $p < 0.001$ ; ns = not significant.

#### Conclusion

We have demonstrated that the KBPs for multiple BMs was dosimetrically equivalent to the CLs with a single time of optimization, even if the number of BMs included in the model training group was different from that in the validation group.

<sup>1</sup>Kokilaben Dhirubhai Ambani Hospital, Radiation Oncology, Mumbai, India ; <sup>2</sup>Yashoda Hospital, Neurosurgery, Hyderabad, India

##### Purpose or Objective

To investigate the dosimetric indices employing different techniques such as Static Conformal Fields(SCF), Intensity-Modulated Radiosurgery (IMRS), Dynamic Conformal Arc (DCA), Volumetric Modulated Arc Therapy (VMAT).

##### Material and Methods

Fifteen patients of Arteriovenous Malformations were included in the study of which 2 patients were grade 1, 7 patients were grade 2 and 6 patients were grade 3 by Spetzler Martin grading system. Thirteen out of 15 patients were unruptured and 2 were ruptured for which partial embolisation was done followed by radiosurgery. Range of target volume (0.7cc to 12.28cc Mean=7.94cc). A plan each of SCF, DCA, IMRS and VMAT were generated for each patient using MLC 2.5mm. For every patient fixed dose of 22Gy prescribed at 80%. All plans were compared using standard dosimetric indices. Dosimetric comparison includes target coverage, conformity index(CI), homogeneity index(HI), gradient index(GI). In addition maximum doses to OARs i.e Brainstem.

##### Results

Paddick CI for SCF is (0.58±0.08), DCA Paddick CI (0.580±0.09), IMRT Paddick CI (0.66±0.09) and VMAT Paddick CI (0.68±0.01), best Paddick CI observed in VMAT, P<0.05. HI for SCF is (1.05±0.04), HI for DCA (1.046±0.04), HI for IMRT (1.044±0.03), HI for VMAT (1.043±0.03) best HI observed in VMAT. Primary goal is to achieve 99% of target coverage by 1760cGy, minimum dose to target is 17.5Gy to V99%, VMAT had improved coverage but no significant difference, P>0.05. Best GI observed in DCA(3.13±0.5), GI for SCF is (3.22±0.55), GI for IMRT is (4.34±1.16), GI for SCF is (3.45±0.64), P<0.05. Dose Heterogeneity Index for SCF is (0.079±0.01), for DCA is (0.08±0.01), for IMRT (0.108±0.02), for VMAT DHI is (0.08±0.01), P<0.01. The dose received by 1 cc volume of brainstem were (5.33±5)Gy, (5.72±5)Gy, (5.85±5)Gy and (5.08±4)Gy for SCF, DCA, IMRS, VMAT plans respectively.

##### Conclusion

We have found that VMAT has shown better coverage as compared to other plans and it spares OARs, It is better in terms of 1 cc volume dose to the brainstem. This dosimetric comparison provides insight into selection of the right modality for the current treatment scenario.

#### EP-1831 Avoidance sector strategy to reduce healthy tissue dose in locoregional breast planning with VMAT

S. Thengumpallil<sup>1</sup>, J. Bezar<sup>1</sup>, K.H. Spruijt<sup>1</sup>, N. Peguret<sup>1</sup>, C. Vrieling<sup>1</sup>

<sup>1</sup>Clinique des Grangettes, Radiation Oncology, Geneva, Switzerland

##### Purpose or Objective

The benefit of the avoidance sector strategy for breast only VMAT radiotherapy planning has been proven to reduce significantly the healthy tissue dose levels (Fogliata A. Br J Radiol. 2017). Our aim is to explore whether this strategy leads to similar results in

locoregional breast planning, a more complex treatment volume.

##### Material and Methods

Two approaches were compared: VMAT partial arcs (without avoidance sectors) and VMAT with avoidance sectors. The latter was set in such a way that the arc arrangement was mimicking the tangential technique, thus allowing an optimal sparing of the heart and contralateral OARs. An avoidance arc of about 40 degrees was chosen for each patient based on particular clinical objectives. The same arc trajectory and same dose objectives were applied for both. The two approaches were evaluated based on DVH for both PTVs and OARs for 15 locoregional left breast patients. Homogeneity and conformity indices for PTVs, V5 for OARs as measure for low dose and number of monitor units (MU) were also compared.

##### Results

VMAT with avoidance sectors demonstrates a significant reduction of the low dose for almost all OARs with major impact on the contralateral OARs. From the preliminary results, we found a mean volume reduction for the V5 of 18% for the contralateral lung, 14% for the contralateral breast, 4% for the heart, 3% for the body-PTV (healthy tissues) and 0.4% for the ipsilateral lung. The trade-off was a slight increase of the V20 to the ipsilateral lung by 2% for the plan with avoidance sectors as expected due to the more tangential-like arc arrangement. However, the two approaches were able to fulfill the same initial dose objectives. The PTV criteria were met with both techniques, the V95 for the total PTV (breast + regional lymph node) were about 95%. The mean homogeneity index was 0.96 and 0.94 for the complete partial arcs and avoidance sectors, respectively. The mean conformity index was 0.88 and 0.87, respectively. The mean number of MU were similar between the two approaches.

##### Conclusion

The avoidance sector strategy shows significant improvement in decreasing the low-dose-bath to OARs while keeping an acceptable PTV coverage in agreement with the ICRU criteria. We encourage the use of VMAT with avoidance sectors as a solution to reduce possible late toxicities and secondary cancer induction in locoregional breast treatments. However, in the planning process, a complex anatomy and/or specific dosimetric objectives would require careful evaluation in the choice of the approach to use.

#### EP-1832 Dosimetric comparison of IMRT for early-stage glottic cancers with and without air cavity in the PTV

D. Asher<sup>1</sup>, W. Amestoy<sup>1</sup>, M. Studenski<sup>1</sup>, S. Samuels<sup>1</sup>, M. Abramowitz<sup>1</sup>, L. Freedman<sup>1</sup>, N. Elsayyad<sup>1</sup>, M. Samuels<sup>1</sup>  
<sup>1</sup>University of Miami, Radiation Oncology, Miami, USA

##### Purpose or Objective

For early-stage glottic cancers, intensity-modulated radiation therapy (IMRT) has been shown to have comparable local control to 3D-conformal radiotherapy with the advantage of decreased dose to the carotid arteries. The planning target volume (PTV) for early glottic cancers typically includes the entire larynx, plus a 3-5 mm uniform margin. The air cavity within the larynx creates a challenge for the inverse optimization process as the software attempts to "build up" dose within the air. This unnecessary attempt at dose build-up in air can lead to hot spots within the rest of the PTV and surrounding soft tissue. We hypothesized that removal of the air from the PTV would decrease hot spots and allow for a more homogeneous plan while still maintaining adequate coverage of the PTV.

##### Material and Methods

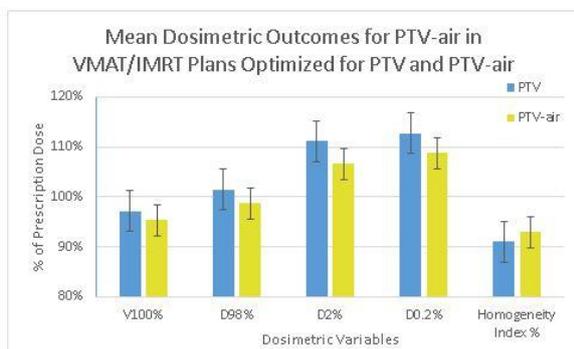

We analyzed 20 consecutive patients with early-stage glottic cancer, T1-2N0, who received IMRT at our institution from April 2015, to December, 2016. Each patient received 63-65.25 Gy in 2.25 Gy per fraction. Two

plans were created for each case: one in which the PTV included the laryngeal air cavity and one in which the air cavity was subtracted from the PTV to create a new PTV-air structure. Acuros XB (Varian Medical Systems, Palo Alto, CA) dose calculation algorithm was utilized. Dosimetric variables were collected for PTV-air structure from both IMRT plans, including V100% (volume that received the prescription dose), D98% (dose received by 98% of the volume), D2%, and D0.2%. Dosimetric variables for organs at risk (OARs), including spinal cord and the carotid arteries were also recorded. Homogeneity index (HI) defined as D98%/D2% was calculated. Two-sided t-tests were used to compare dosimetric variables.

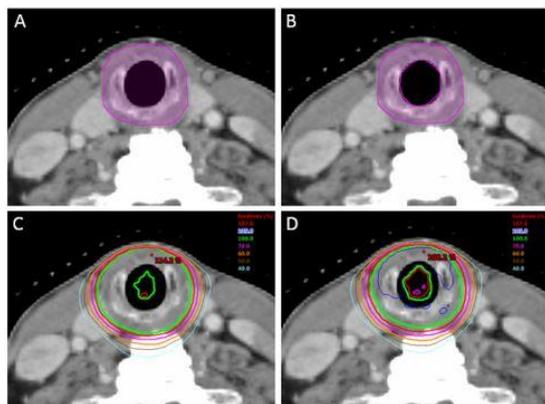

#### Results

The mean V100% was  $95.1 \pm 2.5\%$  for the PTV plans and  $95.4 \pm 0.9\%$  for the PTV-air plans, demonstrating adequate target coverage and no statistical difference between the plans ( $p=0.584$ ). The mean D0.2% (maximum dose) within PTV optimized plan was significantly lower for the PTV-air optimized plans at  $108.8 \pm 2.1\%$  compared to  $111.4 \pm 3.3\%$  ( $p=0.0002$ ). The HI also improved from  $0.90 \pm 0.03$  up to  $0.93 \pm 0.02$  ( $p<0.0001$ ). Even with these gains, there were no significant differences in any of the OARs.

When the PTV-air contour was superimposed onto the PTV plan, the V100% was significantly higher at  $97.2 \pm 2.3\%$  compared to  $95.4 \pm 0.9\%$  ( $p=0.003$ ), showing that the PTV plan was unnecessarily hot. The D2% and D0.2% were also significantly higher ( $p=0.0002$ ).

IMRT optimization using PTV-air (yellow) maintained adequate PTV-air coverage with reduction in V100%, D98%, D2%, and D0.2% and improvement in Homogeneity Index (D98%/D2%) compared to optimization using PTV (blue).

Representative case demonstrating dosimetric benefit of removal of air from PTV. On this planning CT with IV contrast, PTV and PTV-air are shown in (A) and (B). Isodose lines for VMAT/IMRT plans optimized for PTV (C) and PTV-air (D) are shown below. By removing air from the PTV, the hot spot within this single axial slice (shown in red located within the anterior cricoid cartilage) decreases from 114.2% of the prescribed dose to 108.2%.

#### Conclusion

The removal of the air cavity from the PTV for early-stage glottic cancers does not compromise PTV coverage or

sparing of OARs and can result in a more homogeneous IMRT plan.

#### EP-1833 Impact of physicist clinical practice on the quality of head and neck IMRT and VMAT plans

S. David<sup>1</sup>, M. Hermida-López<sup>1</sup>

<sup>1</sup>Hospital Universitari Vall d'Hebron, Servei de Física i Protecció Radiològica, Barcelona, Spain

#### Purpose or Objective

During treatment plan design many decisions are taken based on the planner's own experience and potential biases. Although the treatment planning system (TPS) is plenty of similar plans that could help in the decision making, it is not easy to access to all this information. These data can be more accessible using Mobius3D (Mobius Medical Systems, LP), an independent dose calculator, own database. We aimed to assess differences in treatment plan quality for head and neck IMRT and VMAT plans between three experienced physicists in our center.

#### Material and Methods

After a plan is created, the RTplan, the planning CT and the RTdose DICOM files are exported to Mobius3D (M3D) database. Using a Python script provided by M3D (slightly modified), an Excel file was created for every plan in M3D database. A Matlab script was used to filter the head and neck plans with only two dose levels (54 Gy for the nodes and 70 Gy for the high-dose PTV). Plans from replannings and clinical trials were excluded to ensure there was no bias during plan creation. Sixty-three plans approved by one of our three physicists (16, 15 and 6 years of experience, respectively) were studied. Monitor units (MU) and 40 dosimetric parameters for PTVs and OARs, the most common reported in the literature, were evaluated. Statistically significant differences were analyzed with two-tailed two-samples unpaired t-tests ( $\alpha=0.05$ ).

#### Results

As expected, IMRT plans resulted in a bigger amount of MU ( $1211 \pm 423$ ) than VMAT plans ( $556 \pm 89$ ). A statistically significant difference was found between physicists A and C for IMRT plans. Although VMAT MU values are consistent with those reported in the literature, IMRT MU values are higher with those published by Cozzi et al. [JROBP, 2004, 58.2]. A possible reason could be different fluence-smoothing procedures among physicists

Statistically significant differences were found between physicist A and physicist C for the mean dose and conformity index for the high-dose PTV and for the mean dose, homogeneity, D(2%) and V(107%) for the low-dose PTV.

Statistically significant differences were found between physicist A and physicist C for D(50%) and D(66%) for the left parotid, while between physicist A and B for mean dose, D(33%), D(50%) and D(66%) for the right parotid.

Physicist A achieved the best result in the 45% of the evaluated parameters, physicist B in the 40%, and physicist C in the 15% left. The standard deviation, taken as a surrogate for the planning consistency, was the smallest in 52.5% of the parameters for physicist A, in 20% for physicist B, and in 22.5% for physicist C.

#### Conclusion

Analyzing plan quality parameters have showed differences between physicists, which leads to an opportunity to share practices to improve dosimetric results and decrease self-bias, thus resulting in a better and more homogeneous treatment plan quality. The developed procedure can be easily implemented for other sites and prescriptions.

#### EP-1834 Feasibility study of extreme hypofractionated proton treatment planning for prostate cancer

P. Klinker<sup>1</sup>, C. Brouwer<sup>1</sup>, C. Roos<sup>1</sup>, C. Hammer<sup>1</sup>, H.

Vanhauten<sup>1</sup>, S. Bijmolt<sup>1</sup>, J. Langendijk<sup>1</sup>, S. Both<sup>1</sup>, A. Van den Bergh<sup>1</sup>, S. Al-Uwini<sup>1</sup>

<sup>1</sup>UMCG University Medical Center Groningen, Radiotherapy, Groningen, The Netherlands

### Purpose or Objective

Extreme hypofractionated radiotherapy is an efficient and convenient treatment option for prostate cancer (PCa) patients, mostly delivered by stereotactic body radiotherapy (SBRT). Recent improvements in proton planning techniques like robust proton pencil beam scanning (PBS) has the potential to deliver the same quality hypofractionated plans as SBRT with much lower exposure dose to the surrounding tissues. The purpose of this study is to investigate the feasibility of delivering clinically acceptable extreme hypofractionated proton plans.

### Material and Methods

Planning CT scans of 4 representative PCa patients treated at our department were used in this study. The organs at risk (OARs) (rectum, anal canal, urethra and bladder) and the CTV (prostate) were delineated by a radiation oncologist according to our SBRT protocol. For each CT scan, 4 plans were created: two fractionation regimen (4x9.5 Gy and 5x7.5 Gy) each having two different setup margins (3 and 5 mm). Treatment plans were robustly evaluated for the corresponding setup and  $\pm 3\%$  density changes. The considered protocol for target coverage and OAR constraints is listed in Table 1. For proton planning robust optimization and Monte Carlo based dose calculation in Raystation v6.99 was used. Target coverage was optimized without violating the OAR dose constraints. Clinically acceptable plans were those which met the protocol constraints with minor violation of max 5%. The endpoint of the study was percentage of acceptable plans for each fractionation regimen and each robustness setup margin.

Table 1. Clinical goals in treatment planning

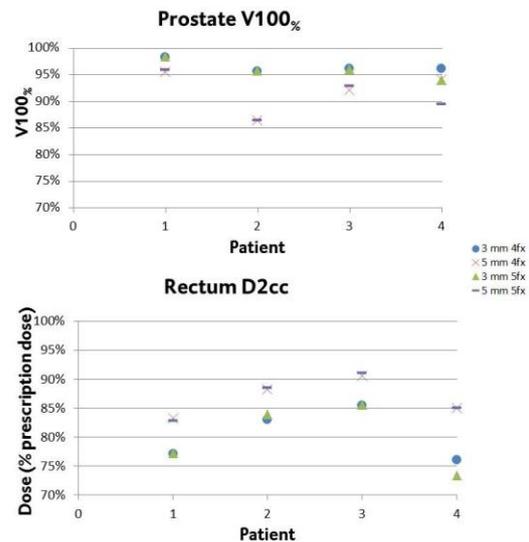

Organ	Parameter	Constraint
Prostate	V100%	$\geq 95\%$
	D90%	$\geq 100\%$
Rectum	D2cc	<100% PD
Anterior rectal wall	Dmax	<100% PD
Posterior rectal wall	Dmax	<40% PD
Anal canal	D5cc	<40% PD
	Dmax	<70% PD
Urethra	Dmax	<105 PD
Bladder	D20cc	<60% PD
	Dmax	<105 PD

PD= prescribed dose

### Results

The target coverage was acceptable in 7/8 plans with 3-mm margin, while only 3/8 plans (two in 4-fraction and one in 5-fraction regimen) with 5 mm margin were acceptable. Bladder constraints were acceptable in all plans with 3-mm margin, and in only 4/8 when 5-mm plans were used. In two patients, dose constraints were met in not any plan. All rectum constraints met the protocol constraints in both setup margin groups. There were no significant differences in target coverage and OAR constraints between 4 and 5 fractions regimen.

Figure 1. Prostate V100% and Rectum 2cc for the four different treatment plans

### Conclusion

Both fractionation regimen of 4 and 5 fractions met the dose constraints and are considered clinically feasible if 3-mm setup margin are used. The target coverage was suboptimal in most plans for 5 mm setup margin. A larger cohort of patients is needed to confirm our results.

### EP-1835 Use of the gEUD in modern TPSs for prostate radiotherapy with VMAT technique

L. Grimaldi<sup>1</sup>, V. Morandini<sup>1</sup>, S. Berlinghieri<sup>1</sup>, E. Castrezzati<sup>1</sup>, P. Frata<sup>1</sup>, N. Pasinetti<sup>1</sup>

<sup>1</sup>Esine Hospital, Radiation Oncology Service, Esine, Italy

### Purpose or Objective

Aim of this study is to find a starting point for gEUD parameters in the Philips Pinnacle<sup>3</sup> TPS to reach a comparable dose distribution to target and to maximize the OARs sparing irradiation in a normo-fractionated prostate RT schedule (74 Gy-2 Gy/fr).

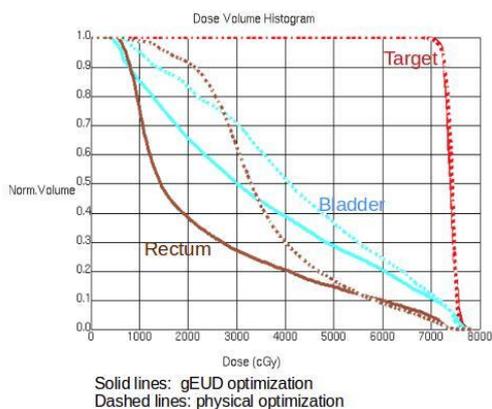

### Material and Methods

For 10 patients treated with prostate radiotherapy, two RT plans were optimized using VMAT technique. For the first plan only physical parameter was used, instead for the other one, the biological gEUD parameter were replaced to all OARs. The TPS was Philips Pinnacle<sup>3</sup> v9.10.

### Results

For the targets volumes the two plans show an equivalent dosimetry in term of Conformity Index ( $COIN = (V_{T,pi})^2 / (V_T * V_{pi})$ ), Homogeneity Index ( $HI = 100 * (D_{2\%} - D_{98\%}) / D_{pi}$ ) and Gradient Index ( $GI = V_{50\%} / V_{100\%}$ ). Instead for the principals OARs: the femoral heads don't put in evidence substantial differences, at absorbed doses of 30-40 Gy, the rectum volumes involved are halved and for bladder the reduction of absorbed medium doses are of about 30%. There isn't a significant reduction for absorbed dose of 65-70 Gy. To optimize a VMAT plan by using the Pinnacle<sup>3</sup> radiobiological function and obtain a dose distribution comparable to that based on a physical optimization, the following parameters have been set:

	Objective (Gy)	Weight	Parameter a
Target (ie 74 Gy)	74	14	-20
Rectum	32	3	1.5
Rectum OUT Target	35	5	3.6
Bladder	23	2	1.0
Bladder OUT Target	22	4	1.7
Head Fem DX	22	1	1.2
Head Fem SN	22	1	1.2

When using VMAT optimization based on the gEUD, the following differences emerge: the programmed number of MU increases by over 40%; on average, the size of the equivalent square field decreases by more than 13%; the absorbed dose at the middle and lower levels of the rectum and bladder are considerably decreased.

#### Conclusion

The use of gEUD parameters produce an increase in the mean times for the optimization of the treatment plan, but a considerable OARs sparing. Despite the risk of complications is predominantly determined by the high doses, it is necessary not to neglect the control over the low- and mid-dose range. The optimization with cost functions based on the gEUD concept is straightforward and numerically expedient. In fact, with the only parameter gEUD you can control both high and low dose values; however, the need remains to better determine the parameter “a” for these OARs.

#### EP-1836 Validation of a novel knowledge-based planning (KBP) model for lung cancer treatments with VMAT

N. Tambe<sup>1,2</sup>, C. Moore<sup>1</sup>, I.M. Pries<sup>2</sup>, C. Cawthorne<sup>3</sup>, A.W. Beavis<sup>1,2,4</sup>

<sup>1</sup>Hull and East Yorkshire Hospitals NHS Trust, Radiation Physics, Cottingham, United Kingdom ; <sup>2</sup>University of Hull, Faculty of Health Sciences, Hull, United Kingdom ; <sup>3</sup>KU Leuven, Nuclear Medicine and Molecular Imaging-Department of Imaging and Pathology- Biomedical Sciences Group, Leuven, Belgium ; <sup>4</sup>Sheffield-Hallam University, Faculty of Health and Well Being, Sheffield, United Kingdom

#### Purpose or Objective

Radiotherapy plan design can vary widely and is dependent on the experience of the treatment planning staff. Plans meeting planning objectives may still be suboptimal where there is scope to reduce OAR doses without compromising target coverage and deliverability.

This study aimed to develop a novel KBP model to reduce lung cancer plan variability, by predicting minimum achievable (or ideal) lung volume-dose measures  $V_5/V_{20}$  (volume of lungs receiving 5Gy/20Gy dose) and mean lung dose (MLD) based on previously treated patients using our VMAT technique. The effect of the KBP model on treatment plan complexity and treatment delivery was assessed.

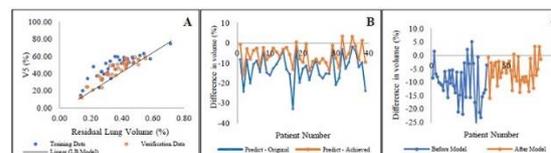

#### Material and Methods

36 previously treated lung cancer patients were randomly selected from the Eclipse database and their dosimetric data and normal and target structures analysed. The three lung metrics,  $V_5$ ,  $V_{20}$  and MLD, were correlated against residual lung volume (RLV) defined having iteratively searched for a lung volume construct that provided maximal correlation with all three metrics. It was found to be equal to the total lung volume excluding an isotropic 5 cm expansion of the PTV. A straight line was manually fitted to the correlation plots that demonstrated the lowest achieved dose metric values as a function of RLV. This was hence referred to as the lower-bound model.

The model was tested by re-planning a further 39 patients, using the model predicted values as ideal constraints to replace protocol values. Treatment plan complexity metrics (MU/Gy, islands <1cc, small aperture scores) for the KBP plans were extracted. The effect of the models application on treatment deliverability was assessed by measurements. Treatment beams were measured with EPID panel and processed in portal dose image prediction software within Eclipse.

#### Results

A significant reduction in mean (maximum)  $V_5$ ,  $V_{20}$  and MLD of 6.6% (19.8%), 1.1% (7.8%), and 0.7Gy (2.3Gy) respectively was achieved whilst maintaining optimal target coverage. The application of the model resulted in a 5.1% reduction in the number plans failing clinical constraints. A single observer study showed considerable reduction of variability in treatment plans. Plan complexity was observed to increase for KBP plans compared to the original plans, resulting in a small increase in measured delivery errors. Two of the 78 arcs failed the local optimal gamma pass criteria (3%/2mm $\geq$ 98%) however they passed the hard criteria (3%/2mm $\geq$ 95) and were therefore considered clinically acceptable.

**Figure 1:** Plots showing reduction in Lung  $V_5$  (Volume of Lung receiving 5Gy) pre- and post- model implementation. A - Lower bound model (straight line) and with training and verification data set. B - Reduction in the volume of lung receiving 5Gy with and without model. C - Reduction in variability in plans with the model.

#### Conclusion

Our study showed that our novel in-house KBP models allowed a reduction in heterogeneity in treatment plan quality, with a concurrent decrease in dose to lung volume for VMAT-treated patients. Treatment delivery verifications demonstrated the KBP model plans were deliverable. The model has been implemented clinically using Eclipse scripting.

#### EP-1837 A new hybrid approach to allow robust Monte Carlo-based multi-field optimization in proton therapy

F. Tommasino<sup>1</sup>, L. Widesott<sup>2</sup>, F. Fracchiolla<sup>2</sup>, S. Lorentini<sup>2</sup>, R. Righetto<sup>2</sup>, C. Algranati<sup>2</sup>, E. Scifoni<sup>3</sup>, F. Dionisi<sup>2</sup>, D. Scartoni<sup>2</sup>, D. Amelio<sup>2</sup>, M. Cianchetti<sup>2</sup>, M. Schwarz<sup>2</sup>, M. Amichetti<sup>2</sup>, P. Farace<sup>2</sup>

<sup>1</sup>University of Trento, Physics, Trento, Italy ; <sup>2</sup>Azienda Provinciale per i Servizi Sanitari APSS, Protontherapy Department, Trento, Italy ; <sup>3</sup>Istituto Nazionale di Fisica

### Purpose or Objective

Protontherapy treatments with pencil beam scanning (PBS) offer the highest flexibility when proton fields are optimized simultaneously (i.e. with multi-field optimization, MFO). Due to the high in-field dose gradients obtained with MFO, this might come at the price of reduced robustness. Robust optimization techniques have been proposed to handle this issue, but they require extensive computational power. Therefore, they are hardly compatible with the clinical application of Monte Carlo (MC) dose calculation algorithms, which have been demonstrated to significantly improve the accuracy of proton treatment plans. The purpose of this work is to implement a robust MFO technique compatible with the application of MC algorithm and to evaluate its robustness to both physical and biological uncertainties.

### Material and Methods

9 patients (3 brain, 5 head-and-neck, 1 spine) underwent proton treatment generated by a novel robust MFO technique. A hybrid (hMFO) approach was implemented, planning dose coverage on a PTV compensating for setup errors, whereas range calibration uncertainties are incorporated in PTV robust optimization process as CT calibration uncertainties (i.e.: three scenarios are optimized, corresponding to nominal and  $\pm 3.5\%$  uniform mass density scaling). A commercial MC dose calculation engine was adopted. hMFO was compared with single-field optimization (SFO), both by robustness analysis (considering both CT calibration uncertainties and isocenter shifts due to setup errors, for a total of 16 perturbed scenarios) on CTV and organs at risk (OARs) and by assessing in the nominal plans the potential impact of variable relative biological effectiveness (RBE).

### Results

Nominal hMFO plans were superior compared to SFO in terms of target coverage ( $p=0.004$ ), without difference for OARs sparing ( $p=0.280$ ). The improvement in target coverage obtained with hMFO is preserved in worst-case scenarios ( $p=0.004$ ), confirming that hMFO is as robust as SFO to physical uncertainties in terms of target coverage. This is summarized in the boxplots of Figure 1, showing the difference between prescription and actual CTV doses for the patients considered in the study. Similarly, the difference between OARs planning and prescription dose for the different scenarios is shown in Figure 2. On OARs, physical (i.e. worst-case scenario) and biological (i.e. variable RBE) uncertainties resulted into significant ( $p<0.01$ ) dose increase for both hMFO and SFO (by 3-7 Gy), but without significant difference between these two techniques.

### Conclusion

hMFO allows improving plan quality compared to SFO, without affecting robustness to setup, range and RBE uncertainties. We show that hMFO is compatible with the application of MC-based robust optimization with minimal impact on computation time. Our data also indicate that uncertainties due to variable RBE, even though generally neglected in clinical practice, might be comparable with those resulting from physical uncertainties.

### Figure 1

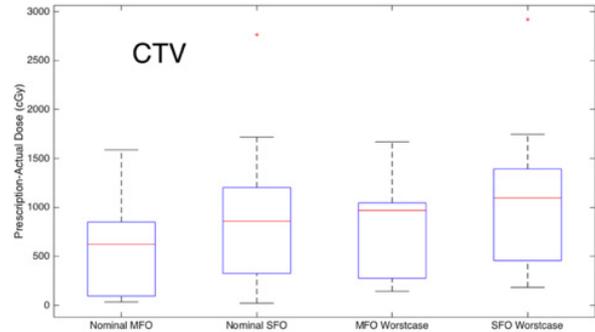

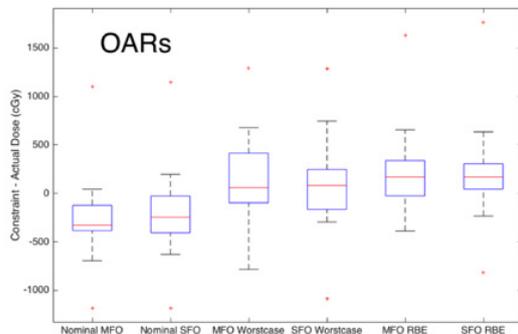

Figure 2

### EP-1838 Dosimetrical comparison of brain SRS treatment plans using IRIS and InCise 2 MLC of the CyberKnife

M. Vekas<sup>1</sup>, G. Stelczer<sup>1</sup>, L. January<sup>1</sup>, T. Major<sup>1</sup>, C. Polgar<sup>1</sup>  
<sup>1</sup>National Institute of Oncology, Center of Radiotherapy, Budapest, Hungary

### Purpose or Objective

A Cyberknife M6 (CK) system was installed at our institution in 2018 January. The aim was to compare the dosimetrical properties of the treatment plans and treatment times with IRIS and MLC collimator.

### Material and Methods

Ten patients with single brain tumours were selected for this study. For each patient three treatment plans were made. Optimal treatment plans were created with MLC and IRIS. Due to the big differences in treatment time between these two plans, one additional IRIS plan was made with time reduction (IRIS TR), to get as short treatment time as possible for a clinically still acceptable plan. The dose prescription of each IRIS plan was set in order to have the same target coverage as the MLC plan. MLC plans were compared to IRIS and IRIS TR plans pairwise with respect to PTV coverage ( $V_{100\%}$ ), treatment time, ICRU 83 homogeneity index (HI), conformity index (nCI), monitor units (MU),  $D_{0,04ccm}$ ,  $D_{0,5ccm}$  for brainstem,  $D_{0,2ccm}$ ,  $D_{0,04ccm}$  for optic pathway and maximum dose of a shell (one voxel thick ring ROI around the target at 10 mm distance). Wilcoxon matched pair test of Statistica 7 software was used for statistical analysis.

### Results

The average volume of PTVs was 13,4 cm<sup>3</sup>. There were no differences between the target coverages of the three plans. However, average MUs were significantly lower for the MLC plans compared to IRIS ( $p=0,005$ ) or to IRIS TR ( $p=0,005$ ) plans, 7908 MU, 23109 MU and 19467 MU respectively. The mean calculated treatment time was significantly less with MLC (18 mins) compared to IRIS (27 mins,  $p=0,008$ ) or IRIS TR (23 mins,  $p=0,008$ ). There was a trend for average HI where the IRIS plans had better values (0,15) than MLC (0,18), while IRIS TR (0,19) values were similar. IRIS plans resulted better nCI values (1,27) than

MLC plans (1,31), but the difference was not significant. The MLC plans had significantly ( $p=0,02$ ) lower average maximum doses for the shell (1282 cGy) compared to IRIS TR plans (1473 cGy), while IRIS plans (1281 cGy) showed similar maximum dose in the lower dose region. The  $D_{0,04ccm}$ ,  $D_{0,2ccm}$  for Optic Pathway and the  $D_{0,04ccm}$  and  $D_{0,5ccm}$  values for Brainstem were 733 cGy, 491 cGy, 761 cGy, 593 cGy with MLC and 744 cGy, 549 cGy, 828 cGy, 630 cGy with IRIS and 785 cGy, 578 cGy, 817 cGy, 633 cGy with IRIS TR, without significant differences.

#### Conclusion

The InCise 2 MLC offers shorter treatment time, less MU, higher conformality for low doses with same or better organs at risk protection. However, the IRIS plans had a slightly better homogeneity and conformity index values. The treatment time of IRIS TR plans are still more than MLC plans' if we insist on clinically acceptable plans. The further reduction of treatment time of IRIS TR plan results in a much worse plan quality, except with large spherical targets where the treatment time of IRIS plans could be reduced to the level of MLC plans, maintaining the same plan quality.

#### EP-1839 Development of Cardiac Avoidance Treatment Planning for Non-Small Cell Lung Cancer Patients

S. De Vos<sup>1</sup>, C. Rowbottom<sup>1</sup>, M. Gilmore<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre, Radiotherapy, Birkenhead, United Kingdom

#### Purpose or Objective

Lung cancer is the deadliest type of cancer, and eight in 10 lung cancers are non-small cell lung cancers (NSCLC). There is evidence that cardiac dose contributes to reduced overall survival in NSCLC patients. If cardiac dose can be minimised in the treatment of these patients, without impacting on planning target volume (PTV) dose, or other organs at risk (OARs), this may improve their prognosis. This study will aim to develop cardiac avoidance treatment planning techniques for NSCLC patients.

#### Material and Methods

Twenty-three patients who have received the standard Clatterbridge Cancer Centre (CCC) volumetric modulated arc therapy (VMAT) NSCLC protocol of 55Gy in 20 fractions (#) were included in the study. Three new plans were created retrospectively: a second plan (B) was morphed from the original delivered plan (A), where the cardiac dose objectives (mean heart dose (MHD), V5Gy and V30Gy) were pushed harder in the optimiser. For the third plan (C), the full or half arcs were replaced by partial arcs, with cardiac avoidance sectors, in a coplanar orientation. The fourth plan (D) has the same partial arcs as the third plan, but in a noncoplanar orientation, to further drive heart dose down. For a small subset of patients, a more extreme noncoplanar arc configuration (seven partial arcs) was created. Plans were compared and evaluated with statistical analysis, using a range of PTV and OAR dosimetric parameters.

#### Results

MHD, V5Gy and V30Gy were improved for all three new plans, compared with the clinical plan (A). The largest improvements in heart dose were observed for the noncoplanar partial arc geometry (D), followed by the coplanar full/half arc geometry with tighter planning objectives (B). MHD reduced by 32.4% for Plan D, compared with Plan A ( $P < 0.001$ ), whereas heart V5Gy and V30Gy saw a reduction of 26.1% ( $P < 0.001$ ) and 38.8% ( $P < 0.001$ ) respectively. For Plan B, compared to A, the mean reduction in MHD, heart V5Gy and V30Gy was 25.7% ( $P = 0.001$ ), 17.6% ( $P = 0.002$ ) and 35.7% ( $P < 0.001$ ) respectively. Oesophagus dose increased significantly for Plan B (2.2%,  $P = 0.009$ ), and Paddick Conformity Index (CI) decreased significantly for Plan D (3.3%,  $P = 0.02$ ) but on the whole OAR doses and PTV coverage either improved or remained similar between plans.

#### Conclusion

It is possible to develop cardiac avoidance treatment planning for NSCLC patients undergoing VMAT treatment (55Gy in 20#) without significantly compromising other OARs or PTV coverage.

#### EP-1840 comparing the dosimetric impact of omentum spacer in carbon-ion, proton and photon radiotherapy

M. Yamada<sup>1</sup>, H. Sato<sup>1</sup>, T. Ono<sup>2</sup>, Y. Ieko<sup>1</sup>, T. Kanai<sup>1</sup>, N. Yano<sup>1</sup>, H. Akamatsu<sup>1</sup>, M. Harada<sup>1</sup>, M. Ichikawa<sup>1</sup>, Y. Kikuchi<sup>2</sup>, K. Nemoto<sup>1</sup>

<sup>1</sup>Yamagata University Faculty of Medicine, Department of Radiation Oncology, Yamagata, Japan ; <sup>2</sup>Southern Tohoku Proton Therapy Center, Department of Radiation Oncology, Koriyama, Japan

#### Purpose or Objective

This study was an *in silico* planning study to compare carbon-ion (C-ion), proton and photon radiotherapy (RT) plans regarding dose reduction of the gastrointestinal (GI) tract by the greater omentum spacer (GO spacer).

#### Material and Methods

A total of 10 patients who received surgical spacer placement for abdominal and pelvic tumors were included in this study. In all patients, the tumor was adjacent to the GI tract, and GO spacer was inserted between the tumor and the surrounding GI tract. Simulation plans were created on pre-spacer CT and post-spacer CT for C-ion, proton and photon RT respectively. All plans prescribed 70 Gy (relative biological effectiveness (RBE) equivalent) delivered in 35 fractions to the PTV. They were normalized so that at least 95% of the PTV received the prescribed dose. The dose constrain for the spinal cord was maximum dose ( $D_{max}$ ) < 45Gy. All plans were created with the dose to the GI tract reduced as much as possible under the condition of meeting the dose constrains for the PTV and spinal cord. The GI tract to be evaluated was defined as that most adjacent to the PTV. We aimed to satisfy the dose constraints of the minimum dose received by the most exposed 2 cc volume of the organ ( $D_2$  cc) of the GI tract < 50 Gy. C-ion RT plans and proton RT plans were calculated by a spot scanning technique and photon RT plans were calculated employing fixed-field intensity-modulated radiation therapy (IMRT). We tested the difference in mean values of the  $D_2$ cc, the volume receiving 10 Gy or more (V10), V15, V20, V25, V30, V35, V40, V45, V50, V55, V60, V65 and V70 of the GI tract on pre-spacer CT and post-spacer CT for all three RT modalities. Statistical analysis was performed by the paired t-test.

#### Results

GO spacer significantly reduced  $D_2$  cc of the GI tract for C-ion RT (mean±SD: 65.4±5.2 vs 6.4±2.4 Gy,  $p < 0.0001$ ), proton RT (63.3±6.1 vs 6.4±2.9 Gy,  $p < 0.0001$ ) and photon RT (58.8±4.5 vs 24.4±5.2 Gy,  $p < 0.0001$ ). Reduction of  $D_2$  cc of the GI tract by GO spacer was more effectively achieved by C-ion RT and proton RT than by photon RT (C-ion vs photon  $p = 0.001$ , proton vs photon  $p = 0.002$ ). There was no significant difference between C-ion RT and proton RT in reduction of  $D_2$  cc of the GI tract by GO spacer (C-ion vs Proton  $p = 0.992$ ). In one patient on photon RT plan,  $D_2$  cc of the GI tract did not meet the constrain. The GTV of that patient was the left acetabular and sacral bone metastasis of uterine body cancer. In that patient, the GI tract most adjacent to the PTV on post-spacer CT was sigmoid colon and the separation distance from the PTV to the GI tract was 0.43 cm and  $D_2$  cc of the GI tract of C-ion RT, proton RT and photon RT were 22.4, 29.2 Gy and 61.3 Gy respectively.

#### Conclusion

GO spacer significantly reduced  $D_2$  cc of the GI tract for C-ion RT, proton RT and photon RT. Reduction of  $D_2$  cc of the GI tract by GO spacer was more effectively achieved by C-ion RT and proton RT than by photon RT.

### EP-1841 Couch modeling optimization for TomoTherapy planning and delivery

M. Tanooka<sup>1</sup>, W. Okada<sup>1</sup>, K. Sano<sup>2</sup>, S. Mayuri<sup>2</sup>, H. Doi<sup>3</sup>, M. Miyazaki<sup>1</sup>, R. Nakahara<sup>1</sup>, M. Sueoka<sup>1</sup>, H. Suzuki<sup>1</sup>, M. Fujiwara<sup>1</sup>, N. Kamikonya<sup>1</sup>, Y. Inomata<sup>2</sup>, K. Yamakado<sup>1</sup>  
<sup>1</sup>Hyogo College of Medicine, Department of Radiology, Nishinomiya, Japan ; <sup>2</sup>Takarazuka City Hospital, Department of radiotherapy, Takarazuka, Japan ; <sup>3</sup>Kindai University Faculty of Medicine, Department of Radiation Oncology, Sayama, Japan

#### Purpose or Objective

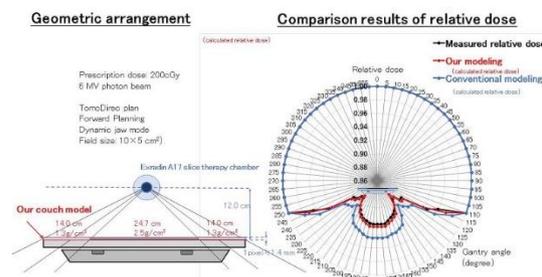

Carbon-fiber flat top couches have been widely used for radiotherapy. It was reported that the beam intensity attenuation inside the couch should be taken into account in treatment-planning system. From the start, TomoTherapy planning system (Accuray Precision) has been provided such a capability. However, this couch model does not have appropriate physical densities. Furthermore, it is not possible to correct these physical densities. Therefore, we performed a novel couch modeling optimization for TomoTherapy planning and delivery.

#### Material and Methods

The beam intensity attenuation caused by the TomoTherapy Radixact couch unit was evaluated by creating and adding a new optimized couch model in a planning support system (MIM Maestro). The couch modeling started with acquiring CT images, the images were transferred to the planning support system for contouring. Then these DICOM images data and a created DICOM RT structure set for couch modeling were transferred to the TomoTherapy planning system. Additionally, dose was compared between calculation and measurement in order to optimize the appropriate densities for the contoured couch region. To do this, a Exradin A17 chamber was placed on the couch. Doses were measured at gantry angles ranging from 0° to 355° in 5° increments for a 6 MV photon beam. This setup was replicated in the TomoTherapy planning system and dose was calculated using collapsed-cone-convolution (CCC) algorithm (TomoDirec plan, Forward Planning, dynamic jaw mode, Field size: 10×5 cm<sup>2</sup>). Interactive appropriate physical density optimization was performed by comparing calculated and measured doses in order to minimize the discrepancies. Finally, the optimized appropriate physical densities were employed in the typical QA plan of 14 patients to evaluate the impact of the treatment couch on the dosimetry validation.

#### Results

The presence of the treatment couch in a plan resulted in a decrease ranging from 3.0% up to 11.1%, depending on the beam angles. The conventional modeling decreased at isocenter dose discrepancy in the range of 0.9% to 2.3%. However, our modeling decreased dose discrepancy less than 0.5% except for gantry angles 115° and 245° (Figure 1). Our simple shape model with optimized physical densities was selected among the models considered, and the optimized physical densities of the treatment couch were 1.3 g/cm<sup>3</sup> and 2.5 g/cm<sup>3</sup>. A total average decrease in absolute dose at a selected point of 0.2% was calculated in the QA plans. Additionally, the dose distribution our modeling yielded an average pass rate using gamma index (3%, 2 mm) of 96.5% (max 99.7%, min 91.7%), and the pass rate was higher than conventional modeling (Table 1).  
**Figure 1**

**Table 1**

	Average absolute dose difference	Average pass rate of ArcCHECK using gamma index (3%, 2 mm)
Conventional modeling	0.0%	94.9%
Our modeling	0.2%	96.5%

#### Conclusion

We could successfully obtain an accurate couch model for TomoTherapy planning system by interactively optimizing the physical density of the couch using planning support system. Furthermore, this modeling proved to be an efficient way of correcting the dosimetric effects of the treatment couch in TomoTherapy planning and delivery.

### EP-1842 Automated treatment planning of prostate cancer using prioritized clinical-goal based optimization

R. Kierkels<sup>1</sup>, A. Fredriksson<sup>2</sup>, E. Hynning<sup>2</sup>, S. Both<sup>1</sup>, J.A. Langendijk<sup>1</sup>, B. Vanhauten<sup>1</sup>, E.W. Korevaar<sup>1</sup>  
<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>RaySearch Laboratories, Stockholm, Sweden

#### Purpose or Objective

To increase departmental efficiency and achieve high quality treatment plans for prostate cancer patients. Therefore, we implemented fully automated prioritized clinical-goal based treatment planning (ATP) for intensity modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) and evaluated the ATP plans with the clinical dosimetrist-optimized treatment plans.

#### Material and Methods

The clinical goals of prostate radiotherapy (patients containing gold markers) were extracted from our medical protocol and ordered by priority into a wishlist. The order and priorities of the clinical goals were fine-tuned based on the dosimetrist-optimized clinical VMAT plans of two previously treated prostate cancer patients. The final version of the wishlist was used by the ATP solution (RayStation v6.1, RaySearch Laboratories AB, Stockholm, Sweden) to automatically optimize treatment plans for novel patients. The ATP optimization is a lexicographic method that tries to fulfill the goals of the wishlist iteratively. A goal of higher priority will not be compromised to fulfill goals of lower priority.

To assess the quality of the wishlist, prostate IMRT and VMAT plans were automatically optimized by the ATP algorithm for eight previously treated prostate cancer patients. From these patients a dosimetrist-optimized prostate VMAT plan was also available. The treatment planning time of a representative dosimetrist-optimized prostate case was approximately 180 minutes. Target coverage, conformity index (CI95%) and homogeneity index (HI98%) as well as organ at risk dose values were compared between the ATP plans and the dosimetrist-optimized plans.

## Results

The wish list for prostate IMRT/VMAT comprised of 10 priority levels (see table 1). The first few levels focused on target coverage, followed by target homogeneity and conformity. The subsequent priority levels mainly accounted for organ sparing. The lowest priority further reduced the average organ at risk dose as much as possible. Studying ATP-IMRT an ATP-VMAT plans of the eight evaluation patients, we found similar target coverage (all ATP plans:  $V95 > 98.2\%$  for  $PTV_{77}$  and  $PTV_{70}$ ), target conformity (range:  $CI95\%_{PTV_{70}} = 0.64 - 0.81$ ), target homogeneity (range:  $HI98\%_{PTV_{77}} = 0.92 - 0.94$ ) as compared to the dosimetrist-optimized VMAT plans. Furthermore, ATP resulted in an averaged dose reduction of 3.3 Gy (range: Gy -0.8 - 11.9 Gy) to the bladder and 4.6 Gy (range: -2.6 - 6.3 Gy) to the rectum (representative case in figure 1). Preparation and post-processing took approximately 45 minutes for the ATP plans. All plans were approved by an experienced radiation-oncologist in prostate cancer treatments.

Table 1. Wishlist for prostate prioritized auto planning

Priority	Volume of Interest	Clinical goal
1	$PTV_{70}$	$D99 \geq 66.5$ Gy
	$PTV_{77}$	$D98 \geq 73.2$ Gy
2	$PTV_{70min}PTV_{77}$	$Dmax \leq 82.0$ Gy
	$PTV_{77}$	$Dmax \leq 75.0$ Gy
3	External	$V39 < 20000$ cc
4	Bladder	$Dmean \leq 40$ Gy
	Small bowel	$D2 \leq 58.0$ Gy
5	Rectum	$Dmean \leq 40.0$ Gy
	Bladder	$V80 \leq 1.0$ cc; $V75 \leq 25.0$ cc; $V70 \leq 35.0$ cc; $V65 \leq 50.0$ cc; $Dmean \leq 35.0$ Gy
6	Small bowel	$Dmax \leq 68.0$ Gy
	Rectum	$V77 \leq 1.0$ cc; $V72 \leq 25.0$ cc; $V70 \leq 35.0$ cc; $V65 \leq 50.0$ cc; $V60 \leq 50.0$ cc; $D50 \leq 50.0$ Gy; $Dmean \leq 35.0$ Gy
6	Hips	$Dmax \leq 50$ Gy
7	Bladder	$Dmean \leq 30.0$ Gy
	Rectum	$Dmean \leq 30.0$ Gy
8	$PTV_{70min}PTV_{77}$	$D2 \leq 75$ Gy
9	Bladder	$Dmean \leq 25$ Gy
	Rectum	$Dmean \leq 25$ Gy
10	Bladder	Reduce average dose
	Rectum	Reduce average dose

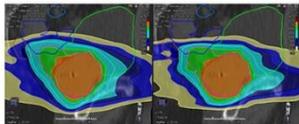

Figure 1. Sagittal view of a CT scan of a prostate cancer patient overlaid with a dose distribution of the (left) automated treatment plan and (right) dosimetrist-optimized treatment plan. The dose is indicated from low to high by a yellow to orange dose wash.

## Conclusion

The prioritized clinical-goal based ATP algorithm led to high quality IMRT and VMAT plans for prostate cancer patients. The plans were fully automatically optimized in the background resulting in an increased departmental efficiency (approx. 135 minutes reduction per prostate case).

## EP-1843 Evaluation of treatment efficiency for helical tomotherapy with TomoEdge technology

B. Yang<sup>1</sup>, W.W. Lam<sup>1</sup>, H. Geng<sup>1</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>  
<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China

## Purpose or Objective

Some previous studies analyzed the impact of modulation factor (MF) on both plan quality and treatment time by varying MF and pitch. Those studies usually drew conclusions based on a series of reference plans and focused on specific treatment region, e.g. head and neck. This study aims to evaluate the treatment efficiency based on large amount of clinical plans in different treatment regions by analyzing the treatment plan parameters of helical tomotherapy with TomoEdge technology, especially the correlation between actual modulation factor (MF) and gantry period.

## Material and Methods

A total number of 303 patients treated in head and neck (HN), breast/chest wall (BCW), brain, thorax, abdomen (ABD) and pelvis regions in our hospital using tomotherapy with TomoEdge technique were retrospectively studied. All treatment plans involved in this study were approved by oncologists with clinical goals achieved. The treatment

plan parameters including planned MF, actual MF, couch speed, gantry period, average leaf open time (LOT), pitch and jaw width were analyzed. Pearson correlation coefficient was calculated between the actual MF and the gantry period.

## Results

The distribution of actual MF for total cases is plotted in figure 1(a) and detailed data are listed in table 1. The mean value of actual MF didn't show much difference for different treatment regions. As shown in figure 1(b)-(c), the actual MF correlates with the gantry period with Pearson correlation coefficients of 0.70 and 0.84 for BCW(2.5D) and BCW(5D) respectively while  $p < 0.01$ . The minimum rotation time of 12s was not reached for any BCW case. If the gantry period less than 13s was taken as the end point for a conventional 2Gy/fr treatment when optimizing treatment efficiency, the current planned MF for BCW could be further decreased. Besides, the planning efficiency might also be improved by reducing the iteration based on the large discrepancy between planned and actual MF. Figure 1(d)-(e) show the correlation for HN(2.5D) and abdomen(2.5D) as well. A few HN cases with the maximum gantry speed indicated the current lower limit of 2 for the planned MF was proper, which had to be increased to 3 for some critical cases. However, the linear trend in figure 1(d) indicated the upper limit should be decreased and a value of 3.4 could be reasonable. Those outliers with gantry period larger than 20s were caused by large prescription dose. The same conclusions were drawn for thorax and pelvis region. For abdomen and brain cases, no linear correlation could be observed which meant the current planned MF had a reasonable range from 1.8 to 3.6 and 1.4 to 3.2, respectively.

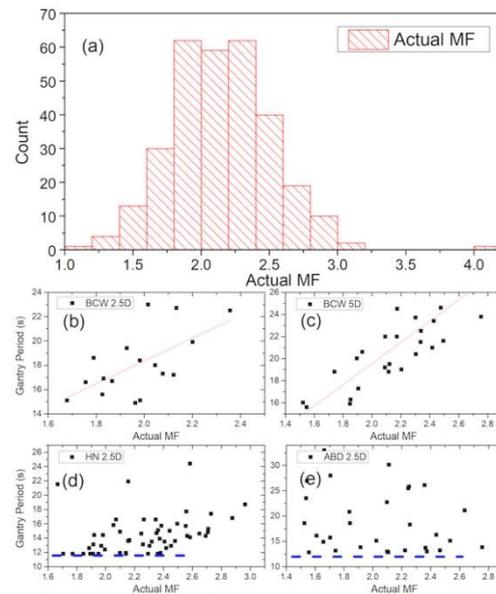

Figure 1 (a) Histogram of actual MF for all cases;(b)-(e) Scatter plots of gantry period versus actual MF for breast/chest wall, head and neck, and abdomen cases. Blue dash lines indicate the gantry speed limit

Table 1. Plan parameters for different treatment regions including planned actual MF, couch speed, gantry period, average LOT, proportion of different jaw widths and pitch value.

Tx Region	No. of cases	Planned MF	Actual MF	Couch Speed (mm/s)	Gantry Period (s)	Average LOT (°)	Proportion of Jaw Width (mm)			Pitch
							1(F)	2.5(D)	5(D)	
Abdomen	40	2.8110.51	2.06110.37	0.42720.213	24.613.3	0.24020.131	2.5%	75.0%	22.5%	0.287

Thorax+Abdomen	11	2.8710.50	2.00310.29	0.53310.190	19.916.8	0.19710.070	0.0%	83.6%	36.4%	0.287
Spine	3	2.2010.16	1.8810.07	1.16710.088	12.511.0	0.13010.066	0.0%	0.0%	100.0%	0.287
Overall	303	3.010.59	2.15310.38	0.47710.360	21.4112.2	0.20510.147	4.3%	77.9%	17.8%	0.287(98.7%)

## Conclusion

Actual MF values for BCW positive correlations with the gantry period, which indicates the treatment time could be potentially reduced by decreasing the planned MF value. Proper range of planned MF was present for HN, thorax, ABD, brain and pelvis regions based on the clinical data in our center.

## EP-1844 Re-irradiation with SBRT for pancreatic cancer: dose summation and toxicity

X. Zhu<sup>1</sup>, C. Yangsen<sup>1</sup>, Z. Xianzhi<sup>1</sup>, S. Yuxin<sup>1</sup>, J. Xiaoping<sup>1</sup>, Q. Shuiwang<sup>1</sup>, C. Fei<sup>1</sup>, J. Zhen<sup>1</sup>, F. Fang<sup>1</sup>, G. Lei<sup>1</sup>, Z. Huojun<sup>1</sup>

<sup>1</sup>Changhai Hospital, Radiation Oncology, Shanghai, China

## Purpose or Objective

A significant number of patients with pancreatic cancer may develop local recurrence after treatment. These patients may not be amenable for surgery due to its high complication rates. In addition to second-line chemotherapy regimens, re-irradiation with stereotactic body radiation therapy (SBRT) may be an alternative, which has been used in few studies. However, the techniques were conventional radiotherapy prior to re-irradiation with SBRT in previous studies and the dose constraints of organs at risk (OAR) were never reported. Therefore, the goal of the study was to determine the cumulative dose-volume parameters to OAR after two courses of SBRT.

## Material and Methods

All patients received two courses of SBRT for the same region with a partial or complete overlap of two previous dose distributions were enrolled. The maximum dose of OAR was calculated as 50% more than the normal constraint. Secondly, we allowed a dose reduction of 50% for a re-irradiation 12 months after the last radiation. A dose reduction of 25% was allowed for a re-irradiation after 6-12 months. No dose reduction was used when re-irradiation was done within 6 months. Due to different doses to target regions and OAR and fractionation schemes, all treatment schedules were recalculated to an Equivalent Dose of 2 Gy per fraction (EQD<sub>2</sub>). An  $\alpha/\beta$  value of 10 Gy (Gy<sub>10</sub>) was employed for the tumor dose and acute effects, and the value determined as 3 Gy (Gy<sub>3</sub>) concerning late effects. Dose distributions, structures sets and CT scans of two treatment plans were extracted from Multiplan<sup>®</sup> System (version: 4.0.2) and sent to MIM<sup>®</sup> System (version: 6.6.8) for analysis. Firstly, two CT scans were aligned rigidly via automatic bone matches (translation and rotations). Therefore, for each plan before summation, each of the contoured OARs was registered rigidly. Subsequently, a non-rigid registration was followed in dose summations. After non-rigid registration, the dose distributions of the first plan were projected to the second treatment with both of doses converted to EQD<sub>2</sub>, which were summed up finally.

## Results

A total of 41 patients were identified. The median accumulated D<sub>max</sub>, D<sub>1</sub> and V<sub>10</sub> of the stomach, duodenum

and the bowel were 36.75Gy<sub>3</sub>, 27.87 Gy<sub>3</sub> and 66.41cc; 30.36 Gy<sub>3</sub>, 22.13 Gy<sub>3</sub> and 18.66cc; 35.76 Gy<sub>3</sub>, 28.06 Gy<sub>3</sub> and 119.48cc, respectively. The median accumulated D<sub>max</sub> of the spinal cord was 6.42 Gy<sub>3</sub>. The median cumulative D<sub>mean</sub> and D<sub>2/3</sub> of the left and right kidney were 4.62 Gy<sub>3</sub> and 3.03 Gy<sub>3</sub>; 2.67 Gy<sub>3</sub> and 2.10 Gy<sub>3</sub>, respectively. The median cumulative D<sub>mean</sub> and D<sub>50%</sub> of the liver was 4.28 Gy<sub>3</sub> and 3.03 Gy<sub>3</sub>, respectively. The median summed dose to the radiation field was 93.38 Gy<sub>3</sub>. No grade 3-4 toxicity occurred. Partial response and a stable disease to the second irradiation was found in 4 and 33 patients.

## Conclusion

The cumulative doses to OAR as dose constraints were acceptable and safe, which could be used as a reference in the decision for re-irradiation with SBRT after prior SBRT for pancreatic cancer but required further validations with radiobiological models in cohorts.

## EP-1845 Proton beam therapy vs best photons for the management of mediastinal Hodgkin lymphoma: step by step

L. Abbassi<sup>1</sup>, F. Goudjil<sup>1</sup>, A. Arsène-Henry<sup>1</sup>, M. Amessi<sup>1</sup>, R. Dendale<sup>1</sup>, Y.M. Kirova<sup>1</sup>

<sup>1</sup>Institut Curie, Département Oncologie-Radiothérapie, Paris, France

## Purpose or Objective

Reducing treatment-related toxicity among survivors of Hodgkin lymphomas (HL) has been the cornerstone of recent advances in the treatment of hematologic malignancies. The purpose of this presentation is to describe the practical procedure inspired by the recently published ILROG Guidelines of treatment decision, preparation and treatment, illustrated with the presentation of the first reported case of localized HL treated with Protontherapy (PT) in Europe.

## Material and Methods

We present the case of 24 years old female patient with a mediastinal Bulky localized mixed cellularity classic HL who required an Involved-Site Radiation Therapy (ISRT) after complete response acquired with polychemotherapy. The 3D conformal radiotherapy (RT) was not acceptable due to high doses to breasts, heart and lungs. The first step was realizing a 4D CT-scan to evaluate target movements and another one with respiratory control (gating and breath-hold technique) by spirometer. Step 2: Delineation was realized on the 4D CT-scan as well as on the deep inspiration breath-hold CT-scan after images registration between initial PET-scan and the CT in treatment position, for photon RT and PT respectively. CTV/ITV and organs at risk (OAR) were delineated the same way for both technics, following ILROG Guidelines. Step 3: Realization of 2 dosimetric plans: one with rotational intensity modulated radiation therapy (IMRT) with a Helical Tomotherapy (HT) with the Tomotherapy Treatment Planning System (TPS) and one with conformational PT with Eclipse TPS.

## Results

The step 4 consisted of the choice of the best plan treatment for this patient after discussion between 2 senior radiation oncologists with comparison of the treatment volume coverage and evaluation of doses to OAR. Step 4a: volume coverage was good with 95% of PTV covered by 98% and 99% of the prescribed dose with PT and HT, respectively. Step 4b: sparing of OAR was better with PT for lungs, in terms of the mean dose (3.7Gy vs 8.4Gy), median dose (0.002Gy vs 6.9Gy) and low dose (V5 Gy = 17.8% vs 54.18%). Mean dose to the heart was higher with HT (3.7Gy) compared to PT (2.6Gy). Breast sparing was better with PT, with a mean dose of 2.4Gy to the right breast and 1.9Gy to the left breast versus 4.4Gy and 4.6Gy. Total dose chosen was 30Gy in 15 fractions of 2Gy with PT with direct anterior field using Pencil Beam Scanning (PBS). Step 5: Treatment delivery and follow-up during PT. We observed only grade 1 skin erythema, no

dysphagia, and no other symptom. Step 6: follow-up after PT. Three months after PT, the patient is PS 0, with no symptom, normal blood tests and metabolic CR according to the LUNAGO criteria on PET-scan (DEAUVILLE score at 2).

#### Conclusion

The use of PT for HL engaging the mediastinum is promising and there is a dosimetric advantage of reducing the dose to OAR. However, the limited availability of PT calls for case selection based on a clear understanding of which patient will most benefit from PT compared to advanced photon techniques.

#### EP-1846 Cloud-based contouring education system supporting access from multi-devices

H. Takegawa<sup>1,2</sup>, S. Nakamura<sup>1,2</sup>, N. Tanigawa<sup>1</sup>

<sup>1</sup>Kansai Medical University, Department of Radiology, Osaka, Japan ; <sup>2</sup>Kansai Medical University Hospital, Division of Radiation Oncology, Osaka, Japan

#### Purpose or Objective

Contouring uncertainties is sensitive to clinical outcomes in intensity-modulated radiation therapy due to its steep dose gradient around tumors and organs at risk. To reduce contour uncertainties among radiation oncologists and institutions, contouring seminars and workshops are held. However, contouring education systems used in those seminars does not often support access from multi-devices and multi-platform environments. The purpose of this study was to develop a cloud-based contouring education system supporting access from multi-devices.

#### Material and Methods

The system overview is shown in figure 1. A fundamental desktop application of the system was developed in MATLAB language and basic functions of contouring education were implemented as described below. It is considered that the system is used by experts (teachers) and beginners (students). Experts prepare educational data with their treatment planning systems (TPS) at their institution and send them to the cloud system and then beginners can access these data according to their privilege. Educational image resources such as treatment planning CT, MR and PET/CT are imported, and image fusion are performed based on a DICOM image registration object exported from a TPS to ensure same image registration results as those of TPS. Data of structure sets which experts prepared are also imported to the system. Beginners draw contours on planning images without any contours in the structure sets and experts can modify beginners' contours to give them feedback. Educational effects can be measured by evaluating dice similarity coefficients of contours between experts and beginners. To allow users access the developed desktop application from multi-devices, it was deployed to a cloud system, Amazon Workspaces, which is a virtual desktop infrastructure (VDI) on Amazon Web Services. Access from desktop and laptop computers, and tablet with the VDI client application and from HTML5-compatible web browsers to the system were verified.

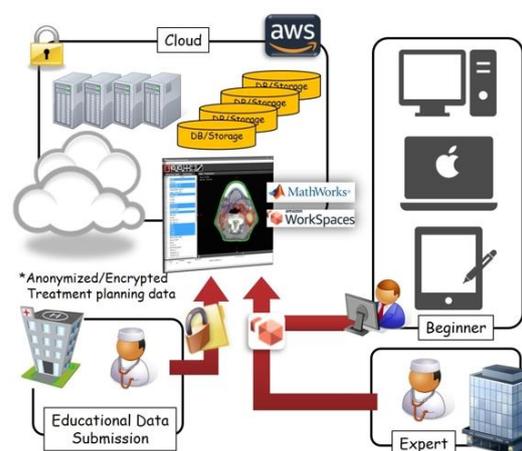

Figure 1. Overview of the cloud-based contouring education system.

#### Results

All devices successfully accessed the system with the VDI client and the deployed application worked without any problems. A modern input device such as a stylus pen also worked and so it was possible to contour targets and organs at risk as drawing pictures. The delay in display and input were quite less even though the access was performed through 4G mobile network. Not all the web browsers accessed the system and input with a touch screen did not work.

#### Conclusion

The cloud-based contouring education system supporting access from multi-devices was developed and its access from multi-devices was verified.

#### EP-1847 Automatic optimization of Head and Neck treatments with multicriteria radiobiological cost functions

M. Esposito<sup>1</sup>, A. Ghirelli<sup>1</sup>, S. Pini<sup>2</sup>, S. Russo<sup>1</sup>, G. Zatelli<sup>3</sup>, P. Alpi<sup>4</sup>, R. Barca<sup>4</sup>, S. Fondelli<sup>4</sup>, B. Grilli Leonulli<sup>4</sup>, L. Paoletti<sup>4</sup>, F. Rossi<sup>4</sup>, P. Bastani<sup>4</sup>

<sup>1</sup>Azienda Sanitaria USL Centro, S. C. Fisica Sanitaria-Firenze Empoli, Bagno a Ripoli, Italy ; <sup>2</sup>Azienda Sanitaria USL Centro, S. C. Fisica Sanitaria-Firenze Empoli, Bagno a Ripoli, Italy ; <sup>3</sup>Azienda Sanitaria USL Centro, S. C. Fisica Sanitaria-Firenze Empoli, Bagno a Ripoli, Italy ; <sup>4</sup>Azienda Sanitaria USL Centro, S. C. Radioterapia, Bagno a Ripoli, Italy

#### Purpose or Objective

The optimization of Head and Neck treatments is one of the most complex task for planners; skills and experience can influence planning results. Automatic planning can help standardize plan quality and is needed for adaptive radiotherapy. Aim of this study is to construct and evaluate a template for automatic optimization of Head and Neck treatments using multicriteria radiobiological cost function of the treatment planning system Monaco 5.10.

#### Material and Methods

The automatic workflow was tested on ten previously treated Oropharyngeal Head and Neck cases. Each treatment consisted in multiple prescription target volumes (PTV): high dose PTV (between 66 and 70 Gy), intermediate dose PTV of 60 Gy and a low dose PTV of 54 Gy in 32 fractions. Constraints for organ at risk (OAR) were: Parotid  $D_{\text{mean}} < 26$  Gy, Cord planning risk volume (PRV)  $D_{1\text{cm}^3} < 50$  Gy, esophagus  $D_{\text{mean}} < 34$  Gy, the patient  $D_{\text{max}} < 110\%$  of the higher PTV dose. Planning objectives were to cover at least the 95% of each PTV with the 95% of the prescription dose. The radiobiological functions used in the template are shown in Table1. To each function a dosimetric objective was assigned; when all

objectives were fulfilled the multi-criterial optimizer reduced the dose to all organs at risk until doses to PTVs were not affected. For each case, the automatic plan was compared with the approved plan manually optimized. The following dosimetric parameters were recorded: PTV D95, Parotid D<sub>mean</sub>, PRV Cord D<sub>1cm3</sub>, esophagus D<sub>mean</sub>. For each plan a modulation degree index (MD) was computed: MD= Total MU/[Sum of (Segment Area x Segment MU)/Total Beam Area].

Contour	Cost function	Objective	Multicriterial
Parotids	Mean dose	30 Gy	yes
Parotids	Serial	22 Gy (20)	yes
Cord	Serial	37 Gy (18)	yes
Esophagus	Serial	40 Gy (15)	yes
Larynx	Serial	42 Gy (19)	yes
PTV	Target EUD	Prescription dose	no

Table1 Cost function used in automatic template. In brackets the exponents of the serial cost functions are shown

### Results

The plans produced automatically fulfilled OAR constraints and reach objectives in 9/10 case. In the remaining case the plan produced automatically was not able to reach a minimum requirement of PTV coverage. Plan comparison is shown in table2. Automatic plans achieved lower dose to both parotids at the cost of a little reduction of dose to the high dose PTV and increase of dose to PRV cord. Modulation degrees of automatically produced and approved plans were not statistically different.

	Approved Plans	Automatic plans	p
PTV 70 D <sub>95</sub>	68.5 (1.4) Gy	66.5 (2.4) Gy	0.02
PTV 54 D <sub>95</sub>	51.1 (1.1) Gy	53.6 (1.2) Gy	0.001
Parotid Ipsilateral	29.3 (12) Gy	25.3 (6.4) Gy	0.06
Parotid Controlateral	26.5 (4.1) Gy	23.4 (3.7) Gy	0.03
PRV Cord 1cm <sup>3</sup>	39.5 (3.7) Gy	43.5 (1.5) Gy	0.001
Esophagus	39.3 (9.1) Gy	34.7 (3.7) Gy	0.09
Larynx	37.6 (1.7) Gy	42.5 (2.4) Gy	0.001
MD	6.2 (0.5)	5.8 (0.5)	0.22

Table2 Comparison of automatic vs approved plans. Average value are shown, in bracket standard deviations are reported.

### Conclusion

In this study the feasibility of the automatic plan generation using the multicriteria function of Monaco has been shown.

### EP-1848 Inaccuracies in proton dose calculation may be as significant as setup and range uncertainties

M. Schwarz<sup>1,2</sup>, M. Innocenzi<sup>1,3</sup>, I. Giacomelli<sup>1</sup>, F.

Fracchiolla<sup>1</sup>, V. Patera<sup>3</sup>, R. Righetto<sup>1</sup>

<sup>1</sup>Centro di Protonterapia, Protontherapy, Trento, Italy ;

<sup>2</sup>TIFPA-INFN, Medical Physycs, Trento, Italy ; <sup>3</sup>Università degli Studi di Roma, Basic and Applied Sciences for Engineerin, Roma, Italy

### Purpose or Objective

Plan robustness with respect to setup and range errors is considered a priority in protontherapy. However, geometrical uncertainties are not the only source of error in proton treatment planning. In this work we evaluate the effects of setup errors, range uncertainties and dose calculation algorithms on protontherapy dose distributions, to assess which uncertainties affect the most the difference between the nominal and actual dose distribution.

### Material and Methods

12 treatment plans used for clinical treatment at our centre were selected, covering four treatment sites: brain, head&neck, chordoma of the spine, and craniospinal axis. The plans, which were initially optimized with a PTV-based single field optimization technique and pencil beam (PB) dose algorithm, were

recalculated with a validated Monte Carlo(MC) code with a statistical uncertainty of 1%. We evaluated the effect of setup and range uncertainties on the planned dose distribution with an in-house software simulating 8 setup errors and 2 range errors (16 calculations per plan in total), to estimate near worst-case scenarios for target volume and organs at risks (OAR). We evaluated the differences between MC and PB distributions and the plan robustness using the same dosimetric indices used to optimize the plan (e.g. D1 and D99 for the target volume, D1 for serially responding OARs, etc.).

### Results

For the intracranial lesions, the differences between PB and MC was small (mostly <1%) and setup&range error were causing the largest differences between nominal and actual(perturbed) dose. For the remaining treatment sites, CTV coverage in MC plans was always lower than in PB plans, in some cases with difference in CTV D99 by more than 10%(Table1). The differences were the largest when a preabsorber was needed to irradiate the shallowest part of the target. Concerning the OAR, the differences between MC and PB algorithm were typically lower than in CTV coverage, without a very clear trend in the differences (Table1).Except for intracranial treatments, the differences in the CTV due to the dose calculation algorithm MC dose were in general larger than the difference between the nominal plan and worst-case scenario after robustness evaluation (see example in fig. 1).

Site	ROI	Dose Index	PB(cGy(RBE))	MC(cGy(RBE))	PB-MC(%)
Brai n	CTV	D99	5623	5601	0.4
H&N	CTV	D99	5917	5592	6%
CSI	PTVBrain	D99	3456	3124	11
Brai n	Brainstem	D1	5770	5823	-1%
H&N	Lacrimal gland	Mean dose	1993	1829	9%
CSI	Kidney	Mean dose	597	586	2%

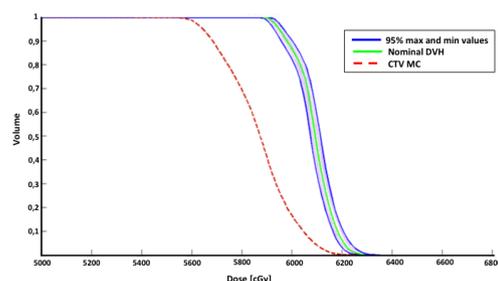

Fig. 1 - Comparison between the nominal DVH calculated with PB, the overall variations due to setup and range error (band between the blue lines) and recalculation with MC for a head and neck case.

### Conclusion

In protontherapy, the effect of using two dose calculation algorithms may be larger than the effect of setup errors and range uncertainties, especially in CTV coverage for shallow targets. The minimum dose to the CTV is not guaranteed when plans are designed with PB, in particular for shallow targets. Ensuring plan robustness is important, but it should not come at the cost of less accurate dose calculation.

With significant tissue heterogeneities and/or shallow

targets, robust optimization should be performed with Monte Carlo to provide reliable results.

**EP-1849 Evaluation of plan modulation parameters on pre-treatment QA results during VMAT and SABR**

M. Chun<sup>1</sup>, J. Kim<sup>1</sup>, C.H. Choi<sup>1</sup>, J. Yoon<sup>1</sup>, H.J. An<sup>1</sup>, J. Son<sup>1</sup>, O. Kwon<sup>1</sup>, J.M. Park<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

**Purpose or Objective**

To rigorously demonstrate how well the plan parameters and modulation indices impact on the pre-treatment quality assurance on gamma passing rates (GPR) for patient-specific quality assurance of volumetric modulated arc therapy (VMAT) and stereotactic ablative body radiotherapy (SABR).

**Material and Methods**

A total of 332 VMAT and 339 SABR patients' plan with TrueBeam STx linear accelerator (Varian Medical System) was selected. Two-dimensional gamma analysis were performed between calculated and measured dose distribution with 2 mm/2% criteria for VMAT, and 1 mm/2% for SABR, respectively. Modulation indices by considering the speed of MLC (MI<sub>s</sub>), acceleration of MLC (MI<sub>a</sub>), both MLC properties, gantry rotation, and dose rate variation (MI<sub>t</sub>), and also modulation complexity score for VMAT (MCS<sub>v</sub>), and leaf travel MCS (LTMCS) were obtained. Plan parameters of mean aperture, total monitor unit (MU), and the percentage of jaw tracking (%JT) were also acquired. Statistical analysis between GPR and plan modulation parameters were performed with Spearman's rank correlation coefficient ( $r_s$ ) with respect to single and multiple parameter regressions to find the most influencing parameters for each treatment technique.

**Results**

In VMAT plans, the  $r_s$  to GPRs with MI<sub>s</sub>, MI<sub>a</sub>, and MI<sub>t</sub> were -0.392, -0.374, and -0.375, respectively, which showed the MLC, gantry rotation, and dose rate variation largely impacted on the GPR while the majorities were with speed of MLC. MCS<sub>v</sub> and LTMCS showed  $r_s$  to GPR of -0.155 and -0.028, relatively less than MI<sub>s</sub>, MI<sub>a</sub>, and MI<sub>t</sub>. In SABR plans, MCS<sub>v</sub> and LTMCS showed  $r_s$  to GPR of 0.261 and 0.310, which was higher than those with MI<sub>s</sub>, MI<sub>a</sub>, and MI<sub>t</sub> (-0.044, -0.108, and -0.102), presenting the definition of modulation complexity score highlighted more on MU in MCS<sub>v</sub> and LTMCS. The  $r_s$  to GPR for MU and the %JT were -0.299 and -0.265 in SABR while those in VMAT were -0.116, and -0.036, respectively. The highest  $r_s$  to GPR in multiple parameter regression was 0.425 with MI<sub>s</sub> and %JT combination in VMAT, while those in SABR was with MU and %JT combination (0.376).

**Conclusion**

The MLC modulation mostly affected the GPR when delivering the VMAT plans, while these representing tendencies moved to total monitor unit, and the percentage of jaw tracking for SABR.

**EP-1850 Intensity modulated protons: feasibility for hypofractionated hepatocellular carcinoma treatment**

L. Cozzi<sup>1</sup>, T. Comito<sup>2</sup>, A. Fogliata<sup>2</sup>, C. Franzese<sup>2</sup>, S. Tomatis<sup>2</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital and Humanitas University, Radiation Oncology Dept and Biomedical Science Dept, Milan-Rozzano, Italy ; <sup>2</sup>Humanitas Research Hospital, Radiation Oncology Dept, Milan-Rozzano, Italy

**Purpose or Objective**

The radiation treatment of hepatocellular carcinoma HCC with a spot scanning protonic approach is challenging due to the respiratory induced motion of the target. In the absence of complex rescanning and gating procedures, a simple approach is here explored, based on the combination of an abdominal compression to reduce the internal motion, and a robust optimization in the planning

phase of the intensity modulated proton treatment, IMPT. A plan uncertainty analysis was carried out to assess the feasibility, at planning level, compared to the consolidated VMAT photonic approach.

**Material and Methods**

Twenty patients presenting advanced stage HCC, unsuitable to other loco-regional therapies, and treated with VMAT 60 Gy in 6 fractions, were selected from the institutional database for this study. They were all immobilized with thermoplastic body mask including a styrofoam block as abdominal compressor. 4D-CT was acquired to evaluate and account for any residual respiratory related motion, and CTV delineated after co-registration with MRI. CTV to PTV margin was 4 to 7 mm. IMPT plans were generated for a Varian ProBeam system using spot scanning, optimized with the Nonlinear Universal Proton Optimizer (v. 15.07) using the robust optimization tool Proton Dose Perturbation PDP, and calculated with the Proton Convolution Superposition algorithm with a 2.5 mm grid. Two to three fields were arranged, according to the patient anatomy. The perturbation features used for the robust optimization were the CT calibration variation of  $\pm 3\%$ , and the isocentre localisation uncertainty of 6 mm to cover the worst case scenario.

VMAT plans were designed for a Varian TrueBeam linac, with two 10MV FFF partial arcs, optimized with PRO (v. 15.07) and calculated with Acuros dose calculation algorithm with a 2.5 mm grid.

Quantitative metrics to compare IMPT and VMAT plans were derived from the DVHs.

**Results**

The target coverage was fully achieved by both VMAT and IMPT plans, as well as all the OAR objectives. The inclusion of the uncertainties in the IMPT optimization lead to some deterioration in the target dose homogeneity, while none of the coverage parameters or OAR objective was violated. Comparison, in the worst case scenario of 3% HU and 6 mm isocentre position errors, between robust IMPT and VMAT yield to PTV coverage in terms of D<sub>98%</sub> of 58.7 $\pm$ 0.6 and 58.8 $\pm$ 0.4 Gy, respectively. For the liver deducted the PTV volume, the V<sub><21Gy</sub> (goal <70 cm<sup>3</sup>) was 1081  $\pm$ 105 and 965 $\pm$ 120 cm<sup>3</sup>, the integral dose was 2.8 $\pm$ 1.2 and 7.5 $\pm$ 2.9 Gy $\cdot$ cm<sup>3</sup> $\cdot$ 10<sup>5</sup> for IMPT and VMAT, respectively.

**Conclusion**

Robust optimization IMPT with the support of abdominal compression, can be considered a viable solution also for advanced HCC patients.

**EP-1851 VMAT versus 3D-CRT for the irradiation of left breast or chest wall plus supra/infraclavicular nodes**

M.A. Gilio<sup>1</sup>, R. Bagnoli<sup>2</sup>, M. Mignogna<sup>2</sup>, A. Tofani<sup>3</sup>, S. Linsalata<sup>3</sup>

<sup>1</sup>University of Pisa, Medical Physics, Pisa, Italy ; <sup>2</sup>Azienda USL Toscana nord ovest, Radiotherapy, Pisa, Italy ;

<sup>3</sup>Azienda USL Toscana nord ovest, Medical Physics, Pisa, Italy

**Purpose or Objective**

The aim of the present study is to compare a dual arc VMAT technique and half beam block 3D-CRT technique for the irradiation of left breast or postmastectomy chest wall plus supra- and infraclavicular lymphnodes. The two techniques were compared in terms of target coverage, doses to OAR and total MU.

**Material and Methods**

26 planning CT were segmented for left breast or chest wall, supra/infraclavicular nodes, heart, omolateral and controlateral lungs, spine and controlateral breast. For every CT two plans were generated: a 3D-CRT with two tangential half beam block for the breast or chest wall and two nearly opposed half beam block for the supra/infraclavicular lymphnodes, using the same isocenter for all the beams (6MV, 10MV or 15MV - Philips

Pinnacle3 TPS) and a dual arc VMAT of  $240^\circ \pm 20^\circ$  starting from gantry at  $180^\circ$  (6MV - Elekta Monaco TPS). Both plans were optimised in order to obtain the best compromise between target dose distribution and OAR sparing. For each planning CT were registered: target coverage of the two PTVs in terms of  $V_{95}$ ,  $V_{98}$ , mean dose, Conformity Index (CI) and Homogeneity Index (HI);  $V_{20}$ ,  $V_5$  and mean dose for ipsilateral, contralateral and total lung;  $V_{30}$ ,  $V_5$  and mean dose for heart; right breast  $V_5$  and mean dose; spine maximal dose; total MU. In order to encompass the inter-subjects variability, for each planning CT the differences of each parameter in the two competitive plans were evaluated by means of two tailed paired t-test.

**Results**

Mean  $\pm$  SD of each parameter in each group of 26 plans (3D and VMAT) are reported in Table, together with the statistical analysis. VMAT plans show highly significant better coverage both for breast or chest wall and lymphnodes and result in highly significant better CI and HI. Moreover, in VMAT, due to the better conformity of the technique, heart  $V_{30}$  is significantly lower than in 3D ( $p=0.002$ ) and  $V_{20}$  of ipsilateral and total lung are lower, although not significant, than in 3D. OAR low doses are higher for VMAT:  $V_5$  for ipsilateral, contralateral and total lung are significantly higher ( $p<0.001$ ), similarly heart  $V_5$  and mean dose ( $p<0.001$ ) and also right breast  $V_5$  and mean dose ( $p<0.001$ ). Finally, total MU are significantly higher in VMAT ( $p=0.01$ ).

**Conclusion**

Our results show that VMAT technique for the irradiation of left breast or chest wall plus supra\infraclavicular nodes offers better target coverage and superior CI and HI than 3D-CRT. VMAT shows better  $V_{30}$  for heart and  $V_{20}$  for lung and higher low dose parameters for all the observed OAR. In our department VMAT is becoming the favourite technique because of its better target conformity and coverage and considering that, as reported in recent literature, nor low dose bath, nor MU increase, with consequent out-of-field dose, observed in VMAT, seems to determine higher detriment to healthy tissues, which is instead frequently reported in the medium-high dose region usually larger in the 3D technique.

**EP-1852 Dosimetric comparison of techniques for left-sided breast and regional lymph node radiotherapy**  
 T. Joslin-Tan<sup>1</sup>, R. Maggs<sup>1</sup>, C. Pembroke<sup>2</sup>, J. Lambert<sup>3</sup>, K. O'Neill<sup>3</sup>, J. Staffurth<sup>2</sup>

<sup>1</sup>Velindre Cancer Centre, Medical Physics, Cardiff, United Kingdom ; <sup>2</sup>Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom ; <sup>3</sup>Rutherford Cancer Centre South Wales, Physics, Newport, United Kingdom

**Purpose or Objective**

Inclusion of supraclavicular fossa (SCF), axillary, and internal mammary nodes (IMN) as target volumes in breast cancer radiotherapy (RT) has been shown to give clinical benefits for certain patient cohorts. However, heart and ipsilateral lung doses have been shown to increase when treating the nodes with 3D conformal radiotherapy (3D-CRT) using a wide tangent and matched field approach. Concerns also exist over planning complexity with 3D-CRT. Deep inspiration breath hold (DIBH) has been shown to reduce heart and lung doses while maintaining target coverage. Intensity modulated radiotherapy (IMRT), volumetric modulated arc therapy (VMAT), and spot scanning proton beam therapy (PBT) have been shown to improve plan quality over 3D-CRT with free-breathing patients. A dosimetric study was performed to compare these three techniques in DIBH.

**Material and Methods**

CT datasets of 10 patients previously treated with RT in DIBH for left-sided breast cancer were used in the study. IMRT (four-field), VMAT (two  $200^\circ$  arcs), and PBT (anterior and 'en-face' beams) plans were created in Nucletron Oncentra Masterplan v4.3 with a view to creating class solutions to treat the breast (40Gy [100%] in 15 fractions) and regional nodes (36Gy [90%] in 15 fractions). Target coverage, organ at risk (heart, lungs, contralateral breast), and other normal structure (including the left anterior descending coronary artery and brachial plexus) doses were reviewed and statistical significance was evaluated using paired two-tailed t-tests.

**Results**

Plans were created for 9/10 patients. VMAT and PBT plans met all mandatory planning objectives compared with 7/9 IMRT plans. PBT plans had lower mean heart dose, left lung V17Gy, and mean contralateral breast dose than IMRT and VMAT while achieving better coverage. VMAT had superior target coverage, conformity, and breast PTV uniformity over IMRT with similar heart and left lung doses, but with increased contralateral breast mean dose and V5Gy. Dosimetric values are summarised in Table 1.

Structure	Metric	Mean $\pm$ S.D.			Paired t-test p-values		
		IMRT	VMAT	PBT	IMRT v VMAT	IMRT v PBT	VMAT v PBT
Heart	Mean (Gy)	4.4 $\pm$ 0.6	4.1 $\pm$ 0.4	0.6 $\pm$ 0.4	0.172	<0.001	<0.001
Left Lung	V17Gy (%)	30.9 $\pm$ 3.3	32.1 $\pm$ 0.1	11.0 $\pm$ 1.6	0.158	<0.001	<0.001
Contralateral Breast	Mean (Gy)	2.7 $\pm$ 0.5	3.2 $\pm$ 0.1	0.1 $\pm$ 0.1	0.017	<0.001	<0.001
	V5Gy (%)	6.7 $\pm$ 3.1	12.9 $\pm$ 2.6	0.2 $\pm$ 0.2	0.005	<0.001	<0.001
Breast PTV	V38Gy (%)	94.1 $\pm$ 2.8	96.7 $\pm$ 1.7	99.1 $\pm$ 0.5	0.005	0.001	0.007
IMN PTV	V36Gy (%)	93.2 $\pm$ 2.3	98.5 $\pm$ 1.6	99.6 $\pm$ 1.1	<0.001	<0.001	0.022
L1-L4 Nodes PTV	V36Gy (%)	93.2 $\pm$ 3.2	98.0 $\pm$ 1.4	99.7 $\pm$ 0.6	0.002	<0.001	0.024

Table 1 - Summary of dosimetric parameters for OARs considered during plan optimisation and PTVs.

**Conclusion**

PBT gave better overall plan quality than both photon modalities but is not currently available to all regional nodal RT patients in the UK. The dosimetric benefits in target coverage coupled with a more robust class solution made VMAT the preferred choice over IMRT. Where VMAT is not possible and lower nodal target coverage is acceptable IMRT may be suitable for most patients. Lower contralateral breast doses may make IMRT advantageous when secondary cancers are of concern.

**EP-1853 Dosimetric comparison of helical tomotherapy and intensity-modulated radiotherapy in cervical cancer**

J. Liu<sup>1</sup>, L. ZHU<sup>1</sup>, S. Li<sup>1</sup>, S. Gao<sup>1</sup>, J. Yan<sup>1</sup>, L. Xie<sup>1</sup>, Z. Hou<sup>2</sup>, X. Zhou<sup>1</sup>, B. Liu<sup>1</sup>

<sup>1</sup>Nanjing Drum Tower Hospital- Medical School of Nanjing University, The Comprehensive Cancer Centre, Nanjing, China ; <sup>2</sup>School of Biological Sciences and Medical Engineering, Southeast University, State Key Laboratory of Bioelectronics

### Purpose or Objective

To compare the dosimetric differences between helical tomotherapy (HT) and seven-field intensity-modulated radiotherapy (7F-IMRT) in the pelvic irradiation of patients with cervical cancer.

### Material and Methods

Twenty-five patients with cervical cancer who received pelvic external beam radiation therapy by HT from March 2015 to October 2017 were retrospectively studied. Total dose of 4600 to 5000 cGy was delivered in 23 to 25 equal fractions. The 7F-IMRT planning was inversely carried out for comparison using Pinnacle<sup>3</sup> 9.10 planning system according to the original computed tomographic simulation data of each patient. Dose to target volumes, organs at risk, homogeneity, and conformity indexes were evaluated for each case according to the dose volume histogram.

### Results

1) For planning target volumes (PTV) in HT vs. 7F-IMRT, average conformity index (CI) was  $0.898 \pm 0.017$  vs.  $0.834 \pm 0.013$  ( $P < 0.001$ ) and average homogeneity index (HI) was  $0.062 \pm 0.012$  vs.  $0.109 \pm 0.019$  ( $P < 0.001$ ), both of which were significantly higher in HT planning than in IMRT planning. The maximal doses of 1% and 2% target volume ( $D_1$ ,  $D_2$ ) in HT group were lower than those in IMRT group ( $P < 0.001$ ), while mean dose ( $D_{mean}$ ), and minimal doses of 95% and 98% target volume ( $D_{95}$ ,  $D_{98}$ ) were higher than IMRT group ( $P = 0.048$ ,  $P = 0.015$ ,  $P < 0.001$ ). 2) For OARs, HT had superior organ sparing advantages. The maximal dose ( $D_{max}$ ),  $D_{mean}$ ,  $V_{30}$  and  $V_{40}$  of small bowel, colon, rectum and bladder in HT group were all significantly lower than IMRT group ( $P < 0.001$ ,  $P < 0.001$ ,  $P < 0.001$ ,  $P = 0.001$ ).  $V_{50}$  was slightly lower in HT group without statistical difference ( $P = 0.13$ ). As for femoral head,  $V_{25}$ ,  $D_5$ ,  $D_{mean}$  and  $D_{max}$  in HT group were lower than those in IMRT group ( $P < 0.001$ ). The treatment linac outputs of HT were significantly higher than those of the IMRT group.

Dosimetric comparison for PTV parameters between HT and 7F-IMRT (x±s)

	CI	HI	$D_{mean}$ (Gy)	$D_1$ (Gy)	$D_2$ (Gy)	$D_{95}$ (Gy)	$D_{98}$ (Gy)

	7F-IMRT	70.17±9.02	60.03±9.32	23.69±19.60	40.44±2.86	53.13±2.17	
	P	$P < 0.001$	$P < 0.001$	$P = 0.309$	$P < 0.001$	$P < 0.001$	

Note: PTV: planning target volume; CI: conformity index; HI: homogeneity index;  $D_{mean}$ : mean dose;  $D_1$ ,  $D_2$ : the maximal doses of 1% target volume ( $D_1$ ) and 2% target volume ( $D_2$ );  $D_{95}$ ,  $D_{98}$ : the minimal doses of 95% target volume ( $D_{95}$ ) and 98% target volume ( $D_{98}$ ); HT: helical tomotherapy; 7F-IMRT: seven-field intensity-modulated radiotherapy; OARs: organs at risk

### Conclusion

HT achieved better conformity, uniformity and OARs protection than IMRT. The treatment outputs were higher for the HT group compared with the IMRT group indicating less beam utilization. As a conclusion, HT showed dosimetric advantages and great promise in the clinical application of image-guided radiotherapy in patients with cervical cancer.

### EP-1854 Application of a tool for bulk treatment plan evaluation in advanced treatment planning training

M. Van Herk<sup>1</sup>, N. Burnet<sup>2</sup>, N. Dinapoli<sup>3</sup>, G. Meijer<sup>4</sup>, U. Nestlé<sup>5</sup>, D. Van den Bongard<sup>4</sup>, M. Stock<sup>6</sup>

<sup>1</sup>Christie Hospital NHS, Division of Molecular & Clinical Cancer Sciences, Manchester, United Kingdom ; <sup>2</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom ; <sup>3</sup>Agostino Gemelli University Polyclinic Foundation, Polo Oncology and Hematology Sciences, Rome, Italy ; <sup>4</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands ; <sup>5</sup>Medical Center - University of Freiburg, Department of Radiation Oncology, Freiburg, Germany ; <sup>6</sup>EBG MedAustron GmbH, Division of Medical Physics, Wiener Neustadt, Austria

### Purpose or Objective

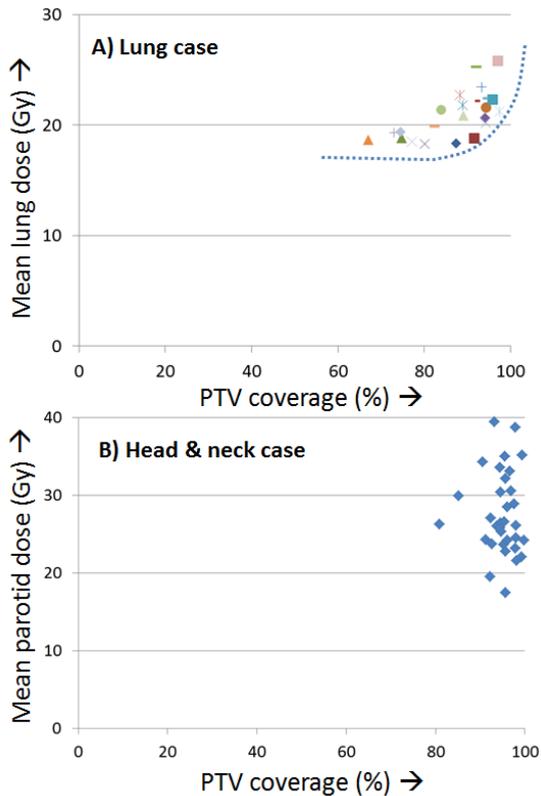

Hands-on training and group review is an essential part of learning how to create a good treatment plan. In an international training course, students tackled challenging study cases each day and 3 selected plans were reviewed together. So far, by necessity, plan selection was performed rather qualitatively by the faculty. It is the purpose of this work to develop and test a tool for bulk plan evaluation - applied in the context of training. The system aims to evaluate all plans, extract statistics in terms of target coverage and organ at risk (OAR) sparing, illustrate compromises made, and select most interesting plans for review and group discussion.

### Material and Methods

98 students worked in pairs on 48 treatment planning systems provided by 5 vendors for 4 complex cases: locally advanced breast cancer with involved internal mammary lymph nodes, locally advanced lung cancer, bilateral oropharyngeal cancer and meningioma. Dose cubes (RTDose files) were collected for all finalized plans - albeit finalized in limited time and often on unfamiliar planning systems. These were then loaded into the tool and processed. For selected structures, DVHs and previously defined DVH parameters were re-calculated. By plotting parameters for target coverage against OAR dose, plan quality could be estimated taking trade-offs into account. In addition, by highlighting plan-parameter combinations where the parameter is clinically acceptable and/or reasonable close to the best plan, the 'winner' could be selected, i.e., the plan with most highlights.

### Results

23 plans were collected for the breast case, 23 for the lung case, 34 for the head and neck case, and 29 for the meningioma case. All plans could be read, although student identification was sometimes difficult. Students often modified structures as part of the planning process, showing the importance of evaluating against identical structures. Some planning systems showed significant differences in coverage of superficial PTVs, which was mainly due to differences in dose grid voxel assignment at the patient surface (up to 2 mm). Most but not all cases showed a Pareto-front like trade-off of PTV coverage versus OAR dose for different planners (Fig. 1). The qualitative selected best plan never coincided with the best plan based on quantitative analysis of all parameters. General observations were that recently introduced automatic planning tools tended to perform quite well under time constraints, and different planning systems excelled at different cases.

### Conclusion

In conclusion, it is feasible and useful to collect and compare plans in bulk in a teaching situation, as it allows selection of good plans taking trade-offs into account and can be used to illustrate behaviour of different planners and treatment planning systems. It also allows individual participants to benchmark their results to the others. Lastly, it gives important feed-back to the faculty on the complexity of the study cases.

### EP-1855 Retrospective review of brain dose from cranial stereotactic radiosurgery treatments of metastases

T. Kairn<sup>1</sup>, Y. Ikeda<sup>2</sup>, M. West<sup>2</sup>, D. Schlect<sup>2</sup>, S. Crowe<sup>1</sup>  
<sup>1</sup>Royal Brisbane and Women's Hospital, Radiation Oncology- Cancer care Services, Herston, Australia ;  
<sup>2</sup>Genesis Care, Genesis Cancer Care Queensland, Auchenflower, Australia

### Purpose or Objective

The planning and delivery of cranial stereotactic radiosurgery (SRS) treatments is changing. New treatment planning and delivery technologies are extending the numbers of lesions that can be treated using linacs without shifting the patient position. In order to understand the potential benefits or relative limitations of these new "single-isocentre" techniques, it is important to understand the plan quality achievable using older, more-established techniques, for comparison. This study therefore investigated achievable SRS treatment plan quality, in terms of dose to planning target volumes (PTVs) and to healthy brain tissue, using a retrospective analysis of cranial metastasis treatment plans.

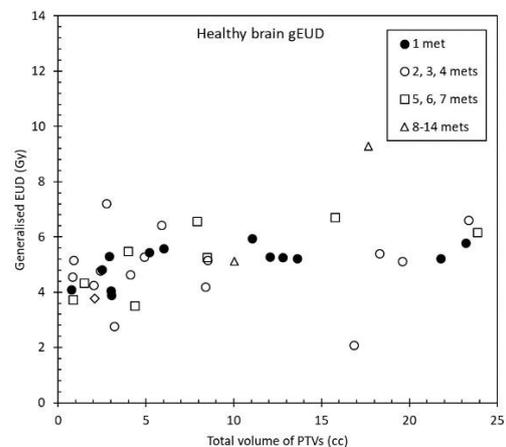

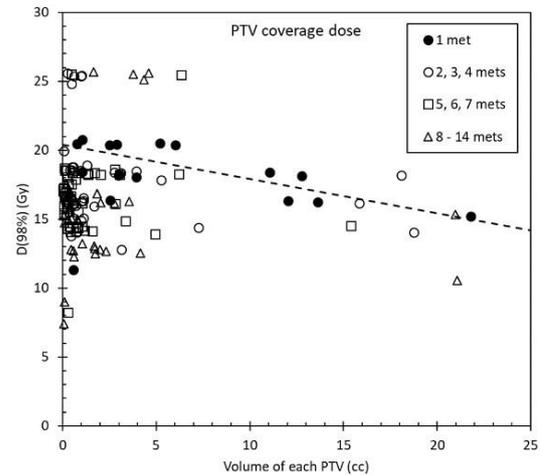

### Material and Methods

In-house Treatment and Dose Assessor (TADA) software was used to evaluate 60 single-fraction stereotactic radiosurgery treatment plans, 46 of which were identified as involving multiple metastases. All treatments were planned using a multiple-isocentre technique (one isocentre per metastasis), with the Brainlab iPlan treatment planning system, for delivery using a linac

equipped with a Brainlab m3 microMLC (Brainlab AG, Munich, Germany). Having previously established that iPlan's pencil beam algorithm provides a useful worst-case estimate (slight over-estimate) of the out-of-field dose, we used DICOM dose files exported from the planning system to calculate fractionation-insensitive generalised equivalent uniform doses (gEUDs) for brain structures with PTVs subtracted, while also evaluating the dose to the PTVs and other relevant structures.

### Results

For cases with one metastasis, the PTV coverage dose trended downward with increasing metastasis volume (Figure 1), conforming with the established local practise of optimising prescription doses to minimise dose to the healthy brain, which would otherwise increase with increasing metastasis volume. Prescribed PTV doses were generally lower for multiple metastases cases, and similarly followed the trend of decreasing with increasing PTV volume (Figure 1). The effects of this careful optimisation of prescription dose are apparent in the comparatively low brain doses that were produced by these treatment plans, even for relatively large PTV volumes (Figure 2).

### Conclusion

The results of this retrospective analysis of cranial SRS treatment plans provide a valuable example of the plan quality that can be achieved using a multiple-isocentre technique, and may therefore stand as a useful baseline for comparing the results of single-isocentre treatment planning techniques, in the future.

### EP-1856 Dose escalation potential for hypofractionated radiotherapy in locally advanced pancreatic cancer

J. Bertholet<sup>1</sup>, A. Hunt<sup>2</sup>, A. Dunlop<sup>1</sup>, T. Bird<sup>2</sup>, A. Mitchell<sup>1</sup>, U. Oelfke<sup>1</sup>, S. Nill<sup>1</sup>, K. Aitken<sup>2</sup>  
<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom ; <sup>2</sup>The Royal Marsden NHS Foundation Trust, Department of Radiotherapy, London, United Kingdom

### Purpose or Objective

Dose escalation to a biological effective dose (BED<sup>10</sup>) of 100 Gy may improve overall survival in locally advanced pancreatic cancer (LAPC). The ability to dose escalate is limited by the risk of toxicity for organs-at-risks (OAR) close to the planning target volume (PTV). A BED of 100Gy may be easier to achieve in a moderate hypofractionated regimen (15 fractions (#)) compared to 5# stereotactic body radiotherapy (SBRT). We evaluated the potential for dose escalation in 5 or 15# for 10 LAPC patients and investigated the correlation between OAR/PTV overlap and achievable PTV coverage.

### Material and Methods

The study included ten LAPC patients (table). The PTV was defined as the gross-tumour volume (GTV) plus 3 mm isotropic margin, assuming treatment delivery in breath-hold under active breathing coordination. The duodenum, bowel (large and small), stomach, spinal cord, liver and kidneys were delineated as OAR. Two regimens, 5 and 15#, were compared. The aim was to cover 95% of the PTV with a BED of 54Gy (base dose=33Gy in 5#, 42.5Gy in 15#) while respecting OAR constraints. For duodenum, stomach and bowel, previously published constraints (table) were used: V<sub>15Gy</sub><9cc, V<sub>20Gy</sub><3cc, V<sub>33Gy</sub><1cc in 5# and D<sub>0.5cc</sub><45Gy in 15#. Once the highest PTV coverage while respecting OAR constraints was achieved, dose escalation to a BED>98Gy (prescription dose=50Gy in 5#, 67.5Gy in 15#) was attempted up to 95% PTV coverage, limiting the PTV maximum dose to 130% of the prescription. Plans were generated using Raystation 6.99 (RaySearch Laboratories) with a single 6MV FFF VMAT arc (179-181° gantry rotation, collimator rotation 5°).

The OAR/PTV overlap (PTV<sub>OAR</sub>) and proximity (OAR<sub>prox</sub>) volumes were calculated using eq.1 and 2 respectively (table) and their effect on PTV coverage was evaluated using Pearson's correlation coefficients (significance level of 5%).

### Results

The patients presented a range of PTV<sub>OAR</sub> and OAR<sub>prox</sub> volumes leading to varying PTV coverage (table, Fig1). In 5#, 95% PTV coverage by the escalated dose was only achievable for patient 1 with PTV<sub>OAR</sub>=0. In all other patients, coverage even by 33Gy had to be compromised to comply with OAR constraints. In 15#, 95% PTV coverage by 42.5Gy was feasible for all patients and coverage by the escalated dose was higher than in 5# in eight patients. The target coverage by the base dose was correlated with PTV<sub>OAR</sub> in 5 and 15# and with OAR<sub>prox</sub> in 15#. The target coverage by the escalated dose was correlated with PTV<sub>OAR</sub> in 15# (Fig2).

Table: Patient characteristics and target coverage by base and prescription dose.

Patient	PTV volume [cc]	PTV <sub>OAR</sub> [%] (eq. 1)	OAR <sub>prox</sub> [%] (eq. 2)	5# [1] base dose = 33Gy, prescription = 50Gy		15# [2] base dose = 42.5Gy, prescription = 67.5Gy	
				PTV V <sub>33Gy</sub> [%]	PTV V <sub>50Gy</sub> [%]	PTV V <sub>42.5Gy</sub> [%]	PTV V <sub>67.5Gy</sub> [%]
				1	12.38	0	2.02
2	58.41	12.10	43.21	66.77	22.83	95.1	24.2
3	37.58	7.98	67.78	76.28	12.74	95.54	54.06
4	58.05	19.67	56.16	59.44	30.48	95.00	8.53
5	101.33	1.36	29.45	82.50	8.42	98.81	70.49
6	212.36	5.10	24.58	67.70	11.84	96.10	17.34
7	83.99	7.89	32.19	81.86	52.62	95.80	41.51
8	105.85	11.19	15.31	57.63	6.33	97.40	21.40
9	63.72	11.39	42.31	73.83	20.79	96.20	38.17
10	237.27	4.76	23.54	63.26	6.31	95.44	12.05
Mean (SD)	97.09 (73.07)	8.14 (5.79)	33.66 (19.38)	72.93 (12.87)	26.74 (27.85)	96.54 (1.68)	38.28 (27.91)

OAR constraints: [1] Alliance trial A021501 (NCT02839343) [2] ABC-07 Trial (EudraCT 2014-003656-31)

PTV<sub>OAR</sub> = 100 \*  $\frac{\text{volume}(PTV \cap OAR)}{\text{volume}(PTV)}$  (eq. 1)      OAR<sub>prox</sub> = 100 \*  $\frac{\text{volume}(PTV_{min} \cap OAR)}{\text{volume}(PTV)}$  (eq. 2)  
 where PTV<sub>rim</sub> = (PTV + 1cm) \ PTV and OAR = (duodenum U stomach U bowel).

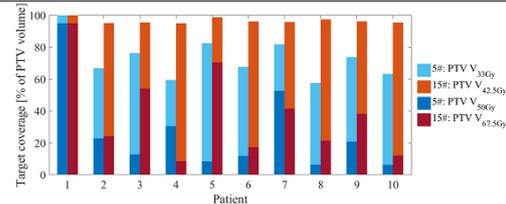

Figure1: PTV coverage by the base dose (BED=54Gy) and by the escalated dose (BED>98Gy) in 5 (blue) or 15 (red) #.

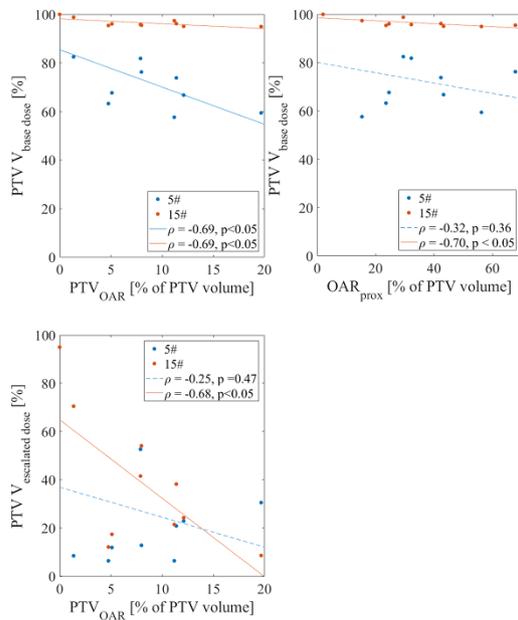

Figure2: Correlation between PTV/OAR overlap (left) or proximity (right) and target coverage by the base dose (top) or escalated dose (bottom).

### Conclusion

The potential for dose escalation was higher in 15 than in 5# except for patients 4 and 7. Patient 4 had the largest PTV<sub>OAR</sub> volume and would likely benefit from the improved coverage by BED=54Gy in 15# compared to 5# (table). Patients with favourable anatomy (OAR>1cm away from PTV) can be treated in 5# to a high BED. Moderate hypofractionation is better suited if the PTV is overlapping with OARs. Using a daily adaptive approach, the PTV coverage by the escalated dose can be increased on days with favourable anatomy.

### Purpose or Objective

For electron beam radiation therapy of irregularly shaped tumors adjacent to critical organs, it is necessary to form complex fields with due consideration of the patients' anatomical features. Consequently, there is a need to apply special tools in addition to standard applicators and blocks that come with a clinical electron accelerator. For example, customized complex-shape metal collimators produced by melting or cutting.

This study proposes an alternative approach where polymer objects produced by rapid prototyping serve as electron beam-forming elements.

The purpose of this study is to assess the applicability of the proposed approach. For this purpose numerical simulation of the clinical electron beams interaction with tissue-equivalent media, including polymeric materials suitable for the products creation by fused deposition modeling (FDM) was carried out.

### Material and Methods

A numerical model simulating the external electron beam of a clinical accelerator and parameters of the polymer materials under study was developed on the basis of the GEANT4 mathematical and physical modeling libraries.

For verification of the electron beam model, we used clinical dosimetry data of the ONCOR Impression Plus medical linear accelerator obtained in the 3D Scanner water phantom.

To construct a model of polymer materials, we manufactured a set of products by fused deposition modeling from ABS, PLA and HIPS plastics and determined their actual density.

The depth dose distributions of clinical electron beams in polymer objects were studied experimentally on the ONCOR Impression Plus accelerator using GafChromic EBT3 dosimetry films. Then we compared the results obtained with the calculated data.

### Results

The developed numerical model of a clinical electron beam with near-real radiation parameters makes it possible to evaluate such characteristics of the depth dose distribution curve in a water phantom as  $R_{50}$  (cm) with an accuracy of 0.05 cm,  $R_{90}$  (cm) with an accuracy of 0.1 cm,  $d_{max}$  (cm) with an accuracy of 0.2 cm and  $R_p$  (cm) with an accuracy of 0.3 cm.

The calculated and experimental data are in good agreement, which makes the numerical model suitable for determining the minimum thickness of a polymer absorber for developing collimating devices in the range of electron beam energies from 6 to 18 MeV.

It was shown that the polymer thickness required for the absorption of the electron beam with an energy of 6 MeV is 4 cm, for an energy of 12 MeV, it is 8 cm, and for 18 MeV, 11 cm. The difference in thickness depending on the type of plastic (ABS, PLA and HIPS) is  $\pm 0.5$  cm.

### Conclusion

The numerical model of a clinical electron beam developed in this study allows estimating the distribution of ionizing radiation in tissue-equivalent media, exploring new approaches to the generation of irregularly shaped therapeutic fields with complex geometry, and predicting the dimensions to produce forming objects by fused deposition modeling.

**EP-1858 Inter-observer variability in rectal target delineation on MRI for MR image-guided radiotherapy**  
I. White<sup>1</sup>, A. Hunt<sup>1</sup>, T. Bird<sup>2</sup>, S. Settatree<sup>3</sup>, H. Soliman<sup>3</sup>, S. Bhide<sup>3</sup>

<sup>1</sup>Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Academic Radiotherapy, London, United Kingdom ; <sup>2</sup>University Hospitals Bristol NHS Foundation Trust, Oncology, Bristol, United Kingdom ; <sup>3</sup>Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Oncology, London, United Kingdom

### Purpose or Objective

Evaluate inter-observer variability (IOV) in mesorectum and pelvic lymph node clinical target volume (CTV) delineation on 2D and 3D MRI sequences optimised for MR image-guided radiotherapy.

### Material and Methods

Radiotherapy treatment planning MRI were acquired in 3 rectal radiotherapy patients. MRI sequences, which had been optimised for MR image-guided radiotherapy on a 1.5T Siemens radiology scanner, included high resolution 2D T2W and 3D T2W sequences with field of view to encompass the entire pelvis. 5 experienced radiation oncologists in rectal radiotherapy contoured the mesorectum, pre-sacral and right and left pelvic lymph node (LN) CTV regions of interest (ROI) on each 2D and 3D MRI sequence using Elekta MR Linac consortium rectal contouring guidelines. A simultaneous truth and performance level estimation (STAPLE)<sup>(1)</sup> was created for each ROI, on each MRI data set using Monaco ADMIRE software v2.0 (Research version, Elekta AB). Observer contours on each image data set were compared to the STAPLE contour by calculating the Dice similarity coefficient (DSC) and the mean and maximum distance to agreement (DTA). Analysis between MRI sequences was performed using Wilcoxon signed-rank test with GraphPad Prism,  $p < 0.05$  was considered statistically significant.

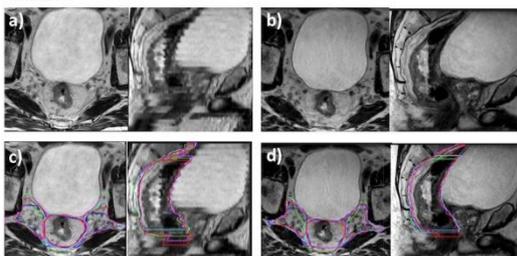

### Results

IOV for the different target volumes on 2D T2W MRI and 3D T2W MRI is illustrated in table 1. There was very good agreement between observers and the STAPLE reference contours for both MRI sequences (Figure 1). DSC  $> 0.8$  was observed for all CTV ROIs, except for the presacral LN region when delineated on the 2D T2W MRI sequence (DSC 0.69).

**Table 1.** Inter-observer variability for the different clinical target volume regions of interest (ROIs) when delineated on 2D T2W MRI and 3D T2W MRI. The median and range for the Dice similarity coefficient (DSC) and the mean and maximum distance to agreement (DTA) are reported.

Target ROI	Interobserver variability measure	MRI sequence	
		2D T2W MRI Median (range)	3D T2W MRI Median (range)
Mesorectum	DSC	0.92(0.86- 0.95)	0.94 (0.87- 0.95)
	Mean DTA (cm)	0.12 (0.08- 0.12)	0.1 (0.10- 0.18)
	Maximum DTA (cm)	1.05 (0.97- 1.33)	0.14 (0.13- 0.15)
Right pelvic LN	DSC	0.87 (0.81- 0.88)	0.87 (0.84- 0.88)
	Mean DTA (cm)	0.13 (0.10- 0.14)	0.12 (0.10- 0.12)
	Maximum DTA (cm)	1.09 (0.99- 1.21)	1.14 (1.08- 1.27)
Left pelvic LN	DSC	0.86 (0.80- 0.87)	0.88 (0.85- 0.88)
	Mean DTA (cm)	0.14 (0.10- 0.14)	0.11 (0.11- 0.11)
	Maximum DTA (cm)	1.37 (0.87- 1.44)	1.09 (1.02- 1.15)
Pre-sacral LN	DSC	0.69 (0.63- 0.72)	0.82 (0.77- 0.82)
	Mean DTA (cm)	0.08 (0.08- 0.09)	0.07 (0.05- 0.08)
	Maximum DTA (cm)	0.74 (0.73- 0.97)	0.78 (0.67- 0.93)

**Figure 1.** Example axial and sagittal imaging in a) 2D T2W MRI and b) 3D T2W MRI. c) and d) show the same images with observer contours for the mesorectum and right and left pelvic lymph node CTVs

## Conclusion

Very good IOV is seen in mesorectum and pelvic lymph node CTV delineation for rectal radiotherapy when using consensus contouring guidelines and MRI sequences optimised for MR image-guided radiotherapy.

**EP-1859 Investigating the feasibility of boosting 18F-FLT-PET-CT volumes to 75 Gy in oropharyngeal cancer**  
 J. Wyatt<sup>1</sup>, G. Petrides<sup>2</sup>, C. Kelly<sup>1</sup>, R. Maxwell<sup>3</sup>, R. Plummer<sup>1,3</sup>, R. Pearson<sup>1</sup>

<sup>1</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom ; <sup>2</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Department of Nuclear Medicine, Newcastle upon Tyne, United Kingdom ; <sup>3</sup>Newcastle University, Northern Institute of Cancer Research, Newcastle upon Tyne, United Kingdom

## Purpose or Objective

Radioresistance is a major cause of radiotherapy failure within Head And Neck Squamous Cell Carcinoma (HNSCC), with many tumour recurrences occurring within the gross tumour volume. Dose escalation to the active tumour sub-volume may overcome this problem. <sup>18</sup>F-FLT-PET-CT is a proliferation biomarker which has been investigated for staging and treatment response for HNSCC. This was a planning study investigating the technical feasibility of treating <sup>18</sup>F-FLT-PET-CT identified boost volumes to 75 Gy in 30 fractions.

## Material and Methods

Five patients diagnosed with HNSCC received <sup>18</sup>F-FLT-PET-CT scans in the radiotherapy planning position. 2.59 MBq/kg <sup>18</sup>F-FLT was administered between 45-60 minutes before imaging started. The 75 Gy boost volume was defined as 70% of the maximum Standard Uptake Volume (SUVmax) plus a 5 mm isotropic margin. Gross Tumour Volumes, Clinical Target Volumes and Organs at Risk were contoured according to the clinical routine.

Two treatment plans were created for each patient. Plan 1 delivered the clinical standard 65 Gy to the primary tumour and involved lymph nodes and 54 Gy to the prophylactic lymph nodes. Plan 2 included 75 Gy to the PET-defined boost volume in addition to the clinical standard dose prescriptions. Both plans were created with a 6 MV dual 360° arc Volumetric Modulated Arc Therapy (VMAT) technique with a 5° collimator rotation. The plans were compared for each patient on the doses to the targets and Organs At Risk (OAR), the body integral dose and beam delivery time.

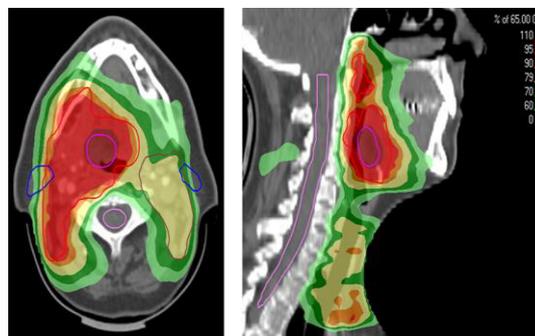

## Results

The mean boost volume was 16 ± 9 cm<sup>3</sup> (sd, range 7 - 27 cm<sup>3</sup>). The mean dose differences to the targets and OAR's are shown in table 1. An example dose distribution is shown in figure 1. The dose differences to the targets were within 1 Gy except for the boost PTV.

The mean difference in dose statistics for all OAR's was ≤ 1 Gy. OARs that did not meet dose constraints in Plan 2 did not meet them in Plan 1. The mean body integral dose was 3 ± 1 % lower for Plan 2 than for Plan 1. There was no difference in beam delivery time (mean difference 0.00 ± 0.02 minutes).

**Table 1** Mean differences (Plan 2 - Plan 1) between Plan 2 and Plan 1 in dose statistics for targets and organs at

Structure	Dose Statistic	Mean Difference/Gy
Boost PTV (75 Gy)	D5	9.6 ± 1.0
Boost PTV (75 Gy)	D50	9.0 ± 0.4
Boost PTV (75 Gy)	D95	8.3 ± 0.6
Primary PTV (65 Gy)	D5	1.0 ± 1.1
Primary PTV (65 Gy)	D50	0.0 ± 0.2
Primary PTV (65 Gy)	D95	-0.6 ± 0.8
Prophylactic PTV (54 Gy)	D5	0.1 ± 0.5
Prophylactic PTV (54 Gy)	D50	0.0 ± 0.3
Prophylactic PTV (54 Gy)	D95	-0.4 ± 0.9
Spinal Cord	D0.1cc	-0.3 ± 1.2
Brain Stem	D0.1cc	0.8 ± 2.2
Ipsilateral Parotid Gland	Mean	0.2 ± 0.7
Contralateral Parotid Gland	Mean	0.3 ± 1.0
Ipsilateral Submandibular Gland	Mean	-1.0 ± 1.4
Contralateral Submandibular Gland	Mean	-0.2 ± 1.2
Larynx	Mean	0.3 ± 2.6

**Figure 1** Example dose distribution showing dose to boost volume (pink structure), primary target (red), and prophylactic target (brown), and OAR's spinal cord (pink) and parotid glands (blue).

## Conclusion

Doses to <sup>18</sup>F-FLT-PET-CT identified boost volumes can be escalated to 75 Gy without substantially impacting other target doses, OAR doses, body integral dose or beam delivery time using VMAT. Treating patients with <sup>18</sup>F-FLT-PET-CT boost volumes could improve local recurrence rates for HNSCC patients. A prospective trial is required to assess the safety of delivering the boost plan.

**EP-1860 Dosimetric and physical aspects of APBI techniques: External Beams vs IntraOperative Radiotherapy**

P. Tabarelli de fatis<sup>1</sup>, M. Liotta<sup>1</sup>, I. Meaglia<sup>2</sup>, M. Paolini<sup>2</sup>, C. Bocci<sup>2</sup>, G.B. Ivaldi<sup>2</sup>

<sup>1</sup>Istituti Clinici Scientifici Maugeri, Medical Physics, Pavia, Italy ; <sup>2</sup>Istituti Clinici Scientifici Maugeri, Radiotherapy, Pavia, Italy

## Purpose or Objective

To evaluate dosimetric and physical aspects of two techniques used in ICS Maugeri hospital to deliver Accelerated Partial Breast Irradiation (APBI).

## Material and Methods

From 2012 to 2018 we treated 57 APBI patients (pts). 26 with Photon Beam Radiotherapy (EPBRT) and 31 with electron Intra Operative Radiotherapy (eIORT). 25 EPBRT pts were treated with multiple no-coplanar 6 MV 3DCRT and 1 patient with IMRT technique. The irradiation geometry has been planned on pt's CT images (5 mm spaced) by Philips Pinnacle treatment planning system to fulfill dosimetric criteria on organs at risk (ORs): <50% and 100% of prescribed dose received by 60% and 35% of omolateral breast respectively, <30% prescribed dose received by 15% omolateral lung, <5% prescribed dose on

40% of heart (PBI on left breast), and on 5% of the heart (PBI on right breast). Homogeneity index (HI: ratio between D2% and D98%) and conformity index (CI: ratio between 95% isodose volume and PTV volume) for PTV coverage and OR dosimetric criteria have been calculated. The 31 eIORT pts were treated with a single dose (21 Gy prescribed to 90%). During eIORT a shielding disc, with diameter 2-3 cm larger than electron applicator, has been placed between the gland and pectoralis muscle to spare internal structures. In vivo dosimetry with gafchromic films has been performed to check accelerator output accuracy and the alignment between electron field and shielding disc. One piece of film has been positioned on the tumour bed and another circular films with the same dimension of the shielding disc has been put on the upper surface of the disc (immediately below the tumour bed). The HI (ratio between maximum and mean dose received by tumour bed) has been computed and the agreement between expected and measured entrance and exit dose on the tumour bed and the alignment of the shielding disc with the irradiation beam, considering isodoses > 85% inside the film, have been evaluated.

#### Results

Concerning EPBRT the mean HI is  $1.12 \pm 0.13$  while for CI is  $1.8 \pm 0.7$ . The OR doses have been always below the criteria except for the omolateral breast volume receiving 50% of prescribed dose in the range from 82.6% to 37%. 38% of the pts have been exceeded the limit due to the large PTV volumes respect to the whole breast. For eIORT the average HI value is  $1.12 \pm 0.07$ , the mean entrance dose is  $2.8 \pm 2\%$ , while the median difference between expected and measured dose (corrected for backscatter factor estimated in phantom) on the shielding disc is 2.7% (from 0.1 to 12.3%). For 68% of the pts the shielding disc has been aligned to the electron applicator.

#### Conclusion

Both APBI techniques give good and similar homogeneous irradiations. In EPBRT the irradiation is poorly conformed, but OR doses are well observed. Instead eIORT is well conformed to tumour bed but the sparing of normal tissue is not always satisfied for the critical alignment of shielding disc to electron applicator.

#### EP-1861 Simultaneous truth and performance level estimation method for contouring assessment in radiosurgery

H. Sandstrom<sup>1</sup>, I. Toma-Dasu<sup>2</sup>, C. Chung<sup>3</sup>, H. Jokura<sup>4</sup>, A. Dasu<sup>5</sup>

<sup>1</sup>Medical Radiation Physics, Stockholm University and Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Medical Radiation Physics, Department of Physics- Stockholm University, Stockholm, Sweden; <sup>3</sup>University of Texas, MD Anderson Cancer Center, Houston, USA; <sup>4</sup>Jiro Suzuki Memorial Gamma House, Furukawa Seiryō Hospital, Osaka, Japan; <sup>5</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden

#### Purpose or Objective

Target contouring variability has shown to be an intrinsic problem for stereotactic radiosurgery. Several methods have been developed for evaluating the contouring accuracy. The aim of this work was to analyse and quantify the contouring variability and to estimate the true volume based on multiple delineations using the Simultaneous Truth and Performance Level Estimation (STAPLE) algorithm. In addition, the analysis of the robustness of the STAPLE method for the assessment of the true target with respect to the number of contours available as input was also assessed.

#### Material and Methods

A multicentre analysis of the variability in contouring of three metastases (diameters 30 mm, 20 mm and 13 mm) and three common targets treated with Gamma Knife radiosurgery, a cavernous sinus meningioma, a vestibular schwannoma and a pituitary adenoma was performed with

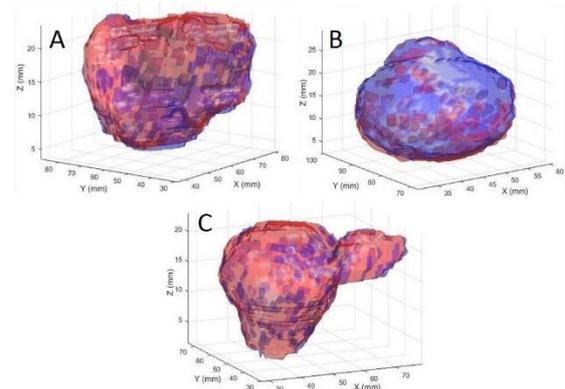

the STAPLE approach, an iterative algorithm which generates an estimate of the true volume together with the sensitivity and specificity of each segmentation input. Twelve contours were provided for each case by experienced planners for Gamma Knife. The robustness of the STAPLE method, with respect to the number of contours, was analyzed by randomly and repeatedly selecting sets of 6-12 contours for each case. A previously developed method based on the agreement volume was also applied. The STAPLE true volume was compared to the 50% agreement volume, AV50.

#### Results

In the evaluation when all 12 available contours were used as input, the similarity between the STAPLE true volume and the 50% agreement volume was high (90-100% similarity). A graphical illustration of the results for the cavernous sinus meningioma (A), the pituitary adenoma (B) and the vestibular schwannoma (C) showing the 3D surface plots of the STAPLE true volume (red) using all the segmentations available as input together with the AV50 (blue) is displayed in Figure 1. The similarity decreased as the number of contours included in the calculations decreased. Random removal of up to 5 input contours might lead to a difference between the STAPLE-generated true target and the 50% agreement volume between 10-70% for all cases. The magnitude of the actual variability in the contours is directly impacting the robustness as the minimum number of input contours required increases with a higher variability.

#### Conclusion

The STAPLE method is a valuable tool for the estimation of a true target based on multiple contours if a high enough input number of contours is available. The robustness of the STAPLE method for rendering the true target volume depends on the number of contours provided as input and their variability with respect to shape, size and position. The additional benefit of employing this method for contouring variability analysis is the simultaneous generation of sensitivity and specificity for each input, thus for each delineated structure, relative to the true volume of that structure.

#### EP-1862 A comparative study of male pelvis CT auto-segmentation and its clinical utility

J. Wood<sup>1</sup>, M. Aznar<sup>2</sup>, P. Whitehurst<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Christie Medical Physics & Engineering, Manchester, United Kingdom; <sup>2</sup>The University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom

#### Purpose or Objective

This work investigated the geometric accuracy of auto-segmented structures from multiple providers within the male pelvis and their utility for prostate VMAT treatment planning.

#### Material and Methods

SPICE (Philips Radiation Oncology, Andover MA), Mirada RTx (Mirada Medical, Oxford UK) and ADMIRE (Elekta, Stockholm Sweden) were used to segment the bladder, rectum, femoral heads, prostate and SV in 11 pelvic CT scans. For Mirada RTx and ADMIRE atlases were generated from local manual outlines. Atlases in SPICE cannot be customised and so the proprietary 'Male Pelvis' atlas was used.

DICE and mean distance to agreement (DTA) were used to assess the geometric accuracy of the auto-segmented structures compared to 'ground-truth' manual outlines drawn by expert clinical oncologists and treatment planners. Manual contours were drawn purely on CT without MR fusion.

PTVs and optimisation volumes were expanded and VMAT treatment plans generated using each set of auto and manual structures in the Pinnacle TPS. Hybrid-plans were also created using manual targets (prostate and SV) and auto OARs. The same optimisation objectives and beam parameters were used for all plans. Auto- and hybrid-plan dose distributions were compared to manual-plans using standard prostate VMAT DVH statistics (all reported to the 'ground-truth' manual outlines) and gamma analysis at 3% / 3 mm inside the 30% and 50% isodoses - the two lowest doses reported on clinical treatment plans based on the CHHiP protocol.

### Results

In terms of DICE and mean DTA, SPICE and ADMIRE performed the best for the bladder, rectum and SV. Mirada RTx and ADMIRE performed the best for the femoral heads and all three packages were comparable for the prostate. Figure 1 shows boxplots for each structure and variation across the 11 patients.

Gamma analysis pass rates are presented in Table 1 and show that the dose distributions for all hybrid-plans are comparable to the corresponding manual-plans at doses > 50%. For the hybrid-plans, all reported DVH statistics were within 3% of those achieved with the manual outlines (mostly within 2%). No correlation was found between any of the geometric evaluations of the auto-segmented structures and treatment plan doses.

### Conclusion

Overall, SPICE and ADMIRE gave the best geometric agreement with manual outlines. The utility of auto-segmented target volumes for treatment planning is severely limited. However, hybrid-plans using manual target volumes and auto-segmented OARs demonstrate good agreement with manual-plans. Further work is required to refine the hybrid treatment planning solution, but this work demonstrates promise for the approach, which could generate significant treatment planning efficiencies.

### EP-1863 Semi-Automatic Planning in head and neck VMAT treatments

A.F. Monti<sup>1</sup>, M. Brambilla<sup>1</sup>, C. Carbonini<sup>1</sup>, M.B. Ferrari<sup>1</sup>, H.S. Mainardi<sup>1</sup>, S. Nici<sup>1</sup>, A. Lassy Taty<sup>1</sup>, D. Zanni<sup>1</sup>, A. Torresin<sup>1</sup>

<sup>1</sup>ASST Ospedale Niguarda, Medical Physics, Milano, Italy

### Purpose or Objective

Automation or semi-automation greatly facilitate IMRT and VMAT planning potentially removing some biases afflicting manual procedures. Such biases are mainly related to operators' skills and the level of stress they accumulate during the working day. In this work, we evaluated the (semi)automatic abilities of a biological constrained based TPS (Monaco 5.11 - Elekta, SWE).

### Material and Methods

Monaco is a double step TPS (S1, optimization - S2, segmentation) which tries to fulfil the PTVs and OARs dose requirements in two modalities: the "Constrained" (C) and the Pareto (P) one. In C modality the cost function is optimized to fulfil OARs dose limitations; in P modality the priority is focused in PTVs coverage. In both modalities it

is possible to activate a Multicriterial (M) option for OARs. In M, the cost function is treated as a multicriterial objective and the optimizer works harder on the constraints to lower them beyond what the user set. In this work manual procedures (C-C), based on consolidated H&N templates, were compared to two semi-automated approaches: the CM-CM, in which the C modality with M is used in S1 and S2, and the CM-P, in which the C modality with M is used in S1 and the P one for S2. The first combination should reduce the dose to OARs, while the second should guarantee a better PTV coverage than CM-CM. H&N cases were divided into different groups (G) of complexity in order to explore the potentialities of each combination. G1 is a light case group with only one PTV far or not so near many OARs; G2 is a more complex situation, with two or more PTVs near many OARs and overlapping them, but without compromising dose constraints; G3 is a harder situation similar to G2, with a very large overlapping of the PTVs and one or more OARs.

### Results

Table 1 regards preliminary results of ten cases. The comparison is between each group/combination plan and the corresponding manual plan. G1 shows a dramatic decrease in dose to OARs, the PTV coverage is also decreased but still acceptable and none of the automatic plans was rejected. G1 CM-CM combination is surprisingly better than CM-P also in PTV coverage, due to the easy situation that promotes OARs' sparing. In group G2 improvements versus manual treatments are clearly evident even if not as in G1. G2 gives OARs better results in all combinations with a light superiority of CM-P particularly on parotids and brain stem. When the situation gets worse, as in G3, the semi-automatic approach fails, giving conflicting results: the PTVs coverage increases but some OARs receive higher doses.

		AG1 (%)		AG2 (%)		AG3 (%)	
		CM-CM	CM-P	CM-CM	CM-P	CM-CM	CM-P
PTVt	D98%	-3.6	-3.9	0.0	-0.7	0.7	1.2
	D2%	1.6	3.0	0.6	0.7	-0.8	-0.8
PTVn	D98%			0.0	-1.0	0.9	0.9
	D2%	-55.2	-53.6	-6.0	-4.7	-6.9	-7.5
Brain St.	D2%	-74.7	-73.4	-12.4	-17.5	13.4	10.4
Parotids	Dmean	-55.4	-51.7	-17.6	-19.0	-3.8	3.7
	Oral C.	Dmean	-12.7	-9.3	-2.1	-2.5	-10.1
Mandibula	Dmean	-18.6	-17.4	-2.6	-3.3	1.3	4.0
	Tyroid	Dmean	-0.4	0.2	-2.6	-3.7	1.1
Larinx	Dmean	-46.6	-42.9	-1.0	-1.6	7.3	0.8
RVR	Dmean	-18.5	-17.9	-5.8	-6.5	1.8	1.3

### Conclusion

This approach is a semi-automatic one, having to manually select C or P modality and the M option. A semi-automatic plan is usually better than a manual one, if a small reduction in PTV coverage can be accepted when occurring. Very complex cases are not easily automated, as the results are often conflicting and even worse than in a manual approach.

### EP-1864 Dose optimization research of esophageal cancer with automatic treatment planning module

M. Mingchang<sup>1</sup>, W. Ma<sup>1</sup>, R. Zhang<sup>1</sup>, Z. Chi<sup>1</sup>

<sup>1</sup>Fourth Hospital of Hebei Medical University, Department of Radiation Oncology, Shijiazhuang, China

### Purpose or Objective

Compared with the manual planning, evaluating the dosimetric characteristics of the esophageal cancer planning based on the automated planning module and the feasibility of clinical application.

### Material and Methods

Ten treated IMRT plans of upper thoracic esophageal cancer and ten treated IMRT plans of thoracic esophageal cancer were re-planned with Auto-planning module. Only one cycle of automated optimization of the Auto-Planning module was performed for each plan without any manual intervention. Compare the dosimetric parameters of the two IMRT plans, paired t-test was used for statistical analysis.

## Results

All esophageal cancer plans generated with the auto-planning module met the clinical dose requirements. In comparison group of upper thoracic esophageal cancer plan, homogeneity index has no significant differences between two groups ( $P=0.115$ ), the conformity Index of targets was superior in the automated plans than in manual plans ( $P=0.027$ ). In addition, the automated plans had significantly reduced the dose of lung received, lung's  $V_5$ ,  $V_{10}$ ,  $V_{20}$ ,  $V_{30}$  was reduced by 2.1%, 1.6%, 3%, 1.2% respectively ( $P=0.001$ , 0, 0, 0.01). The dose of cord received was not significant differences between two groups ( $P=0.892$ ). In comparison group of thoracic esophageal cancer plan, homogeneity index was not significant differences between two groups ( $P=0.428$ ), the conformity Index of targets was superior in the manual plans than in automated plans ( $P=0.048$ ). Lung's  $V_5$  had no significant differences ( $P=0.053$ ), lung's  $V_{10}$ ,  $V_{20}$ ,  $V_{30}$  was reduced by 2%, 3.1%, 1.3% ( $P=0.032$ , 0, 0.008). The dose of cord and heart received has no significant differences between two groups ( $P=0.204$ , 0.894).

## Conclusion

Auto-Planning module can improve the overall quality of treatment plans, reduced plans quality differences due to inexperienced planners. Compared with the manual planning, the Auto-planning have substantially shorter manual planning time and improved planning efficiency. It is feasible to generate automated IMRT plans with automated planning module for esophageal cancer patients. The relatively complex esophageal cancer plans still needs to be manually optimized after an automatic planning of optimization.

## EP-1865 A feasibility study: 6 VMAT arcs full collimator opening for hippocampal sparing

M. Maffei<sup>1</sup>, S. Bou Selman<sup>1</sup>, H. Stefan<sup>2</sup>, M. Haller<sup>2</sup>, P. Ferrari<sup>2</sup>

<sup>1</sup>Azienda Sanitaria dell'Alto Adige, Servizio di radioterapia oncologica, Bozen, Italy ; <sup>2</sup>Azienda Sanitaria dell'Alto Adige, Servizio di fisica sanitaria, Bozen, Italy

## Purpose or Objective

to assess the feasibility of 6 arcs with full collimator opening for an efficient VMAT planning approach for hippocampal-avoidance whole-brain radiation therapy

## Material and Methods

11 patient were considered, prescribed dose was 30 Gy in 10 fractions. Contouring was in accordance to RTOG 0933. VMAT Treatment Planning Techniques was applied using 6 coplanar arcs. Full collimator opening was used with the following parameters: arc1 181°-179° clockwise and 95° collimator, arc2 179°-181° counterclockwise and 265° collimator, arc3 181°-300° clockwise and 350° collimator, arc4 60°-179° clockwise and 350° collimator, arc5 179°-60° counterclockwise and 10° collimator and arc6 300°-181° counterclockwise and 10° collimator. Specific physical objective were used for PTV coverage and hippocampal sparing as RTOG protocol suggested. Conformity and homogeneity index were calculated. Statistical analysis was performed.

## Results

The coverage of PTV was warranted  $D_{90\%} = 28.8 \pm 0.3$  Gy,  $D_{2\%} = 31.6 \pm 0.4$  Gy and for Hippocampal  $D_{100\%} = 8.5 \pm 0.6$  Gy, max dose =  $14.9 \pm 0.3$  Gy. Conformity and homogeneity index were equal to  $1.11 \pm 0.01$  and  $0.86 \pm 0.03$  respectively.  $600 \pm 10$  segments and a total of  $1170 \pm 150$  MU were used. Total delivery time  $516 \pm 16$  sec.

## Conclusion

6 VMAT arcs full collimator opening for hippocampal sparing was feasible and showed a easy coverage in PTV saving hippocampal in accordance of RTOG 0933 constrains. The specific rotation of collimator in the 6 arcs, warranted a easy calculation and deliverability of the plan, with 1000 MU and 500 sec of delivery time.

## EP-1866 An interplay effect study comparing two different VMAT techniques for free-breathing moving targets

M. Gil Conde<sup>1</sup>, Á. Seguro<sup>1</sup>, F. Campos<sup>1</sup>, M.J. Albertos<sup>1</sup>, M.A. Iborra<sup>1</sup>, L. Díaz<sup>2</sup>

<sup>1</sup>Hospital de Jerez, Radiation Physics and Radiological Protection, Jerez de la Frontera, Spain ; <sup>2</sup>Hospital de Jerez, Radiation Oncology, Jerez de la Frontera, Spain

## Purpose or Objective

Dosimetric impact due to interplay effect is studied in VMAT plans for lung tumors in free-breathing patients. The magnitude of this effect is compared in two treatment planning techniques: pure VMAT and hybrid VMAT.

## Material and Methods

A programmable respiratory motion phantom was used, simulating a typical breathing pattern with a maximum longitudinal amplitude of 20 mm and a variable period around 5 s. A Pinpoint chamber (0.016 cc) was introduced inside the phantom in a methacrylate holder that moved in the longitudinal direction following the mentioned pattern.

5 VMAT plans that had been previously planned for real patients were used as irradiation technique in a Varian Truebeam. They used 6 MV, variable dose rate of maximum 600 MU/min and 2 half-arcs of  $180.1^\circ-0^\circ/0^\circ-180.0^\circ$ , depending on the laterality of the tumor.

Alternatively, a hybrid plan (80% 3DCRT - 20% VMAT) was designed for each patient, consisting of 3 conformal 6 MV static fields plus a 6 MV half-arc to homogenize the plan. The phantom was positioned aligning the chamber with the Linac isocenter so during the breathing cycle the chamber moved around this point. Absolute dose was measured under these conditions for each plan in 5 treatment fractions.

## Results

Measured dose per fraction and after the 5 fractions of each plan was obtained separately. For all the patients studied, the mean deviation of the measured dose ( $D_{meas}$ ) from the expected one ( $D_{exp}$ ) after 5 fractions for VMAT and hybrid plans was 0.43% and -0.64%, respectively. Mean standard deviation of  $D_{meas}$  in all fractions was of 4.85 cGy for VMAT versus 2.96 cGy for the hybrid plans, however. Maximum deviation found of  $D_{meas}$  in one fraction between all the VMAT and hybrid plans was of -4.00% and -3.58%, respectively. The maximum mean dose deviation along 5 fractions in a single beam was of 16.7% with VMAT and -8.50% when using the hybrid technique. This last deviation was observed in an arc. Maximum mean dose deviation found between all the 3DCRT beams was of 3.18%, being the average standard deviation for the 5 patients 0.14 cGy.

	$\overline{D_{meas}}$ dev. %	$\sigma$ ( $\overline{D_{meas}}$ ) cGy	Max( $D_{meas}$ dev./fr) %	Max( $\overline{D_{meas}}$ dev./beam) %
VMAT	0,43	4,85	-4,00	16,7
Hybrid	-0,64	2,96	-3,58	-8,50
3DCRT	-	0,14	-	3,18

## Conclusion

Despite the standard deviation of absolute dose values between fractions for the same patient is higher with VMAT than with the hybrid technique and even higher when compared to 3DCRT, differences in the mean dose after 5 treatment fractions between both cases are not significant. Interplay effect when combining VMAT with respiratory movement is observed in single arcs. Nevertheless, the random character of this effect makes deviation of different arcs in the same plan or inter-fraction dose deviation cancel out, not being clinically relevant after adding all the fractions.

### EP-1867 SBRT automatic treatment planning as a dose escalation strategy in pancreatic cancer

S. Cilla<sup>1</sup>, A. Ianiro<sup>1</sup>, F. Deodato<sup>2</sup>, G. Macchia<sup>2</sup>, V. Picardi<sup>2</sup>, P. Viola<sup>1</sup>, M. Craus<sup>1</sup>, M. Buwenge<sup>3</sup>, S. Cammelli<sup>3</sup>, V. Valentini<sup>4</sup>, A.G. Morganti<sup>3</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Medical Physics Unit, Campobasso, Italy ; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Radiation Oncology Unit, Campobasso, Italy ;

<sup>3</sup>Department of Experimental- Diagnostic and Specialty Medicine - DIMES- University of Bologna- S. Orsola-Malpighi Hospital, Radiology Oncology Department, Bologna, Italy ; <sup>4</sup>Fondazione Policlinico Universitario A. Gemelli - Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

#### Purpose or Objective

Stereotactic body radiation therapy (SBRT) has been suggested as a new treatment strategy for locally advanced pancreatic cancer. However, the close proximity of highly radiosensitive organs prevent the administration of high doses to the vascular infiltration areas, aiming for a radical resection. Aim of this study was to perform a planning feasibility analysis of an automated planning system (Pinnacle<sup>3</sup> AutoPlanning) using a VMAT-SIB technique as a dose escalation strategy.

#### Material and Methods

Twelve patients with unresectable pancreatic head adenocarcinoma due to vascular infiltration, were included in this study. CTV<sub>v</sub> was defined as involved vessels plus 5 mm or contact between the gross tumor volume (GTV) and vessels. The vascular PTV (PTV<sub>v</sub>) was obtained adding an anisotropic margin (5 mm craniocaudal direction, 3 mm in other directions). The tumor PTV (PTV<sub>t</sub>) was defined as the GTV plus an anisotropic margin (5 mm craniocaudal direction, 3 mm in other directions) and including the PTV<sub>v</sub>. A duodenum-PRV was defined by adding an isotropic 5 mm margin. SBRT was delivered in 5 fractions with a SIB strategy. For each patient 3 plans were optimized. Plan 1: 30 Gy (6 Gy/fraction) to PTVs; plan 2 and plan 3 escalated PTV<sub>v</sub> dose to 40Gy (8 Gy/fraction) and 50Gy (10 Gy/fraction), respectively. Corresponding EQD2 were 40Gy, 60Gy and 83.3Gy (a/b equal to 10). The dose-volume constraints for OARs were based on the AAPM TG101 recommendations. Automated plans were generated by Pinnacle AutoPlanning module by means of VMAT dual-arc. A progressive optimization algorithm is used to continually adjust initial targets/OARs objectives while tuning structures are automatically added to increase the dose fall-off outside targets. The primary endpoint was to achieve PTV<sub>t</sub> and PTV<sub>v</sub> coverage in terms of D95%>95%, respecting all OARs constraints.

#### Results

OARs constraints were achieved in all patients. PTV<sub>v</sub> D95% was 30.8±0.1Gy, 36.1±5.4Gy and 39.2±12.0Gy at level 1, 2 and 3, respectively. In particular, the primary endpoint D95%> 95% was achieved in 12 patients (100%), 8 patients (67%) and 7 patients (58%) for level 1, 2 and 3, respectively. The mean dose to PTV<sub>v</sub> was 40.6±1.1 Gy and 49.7±2.3 Gy at level 2 and 3, respectively. PTV<sub>v</sub> mean dose was >90% in all patients.

#### Conclusion

AutoPlanning reported a great potential for a tailored SBRT in advanced pancreatic cancer, allowing dose escalation and showing the feasibility to administer in all patients strongly differentiated doses.

### EP-1868 Automated VMAT planning in Pinnacle3: a dosimetric study in high-risk prostate cancer

S. Cilla<sup>1</sup>, A. Ianiro<sup>1</sup>, P. Viola<sup>1</sup>, G. Macchia<sup>2</sup>, M. Buwenge<sup>3</sup>, A. Arcelli<sup>3</sup>, S. Cammelli<sup>3</sup>, V. Valentini<sup>4</sup>, A.G. Morganti<sup>3</sup>, F. Deodato<sup>2</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Medical Physics Unit, Campobasso, Italy ; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"- Università Cattolica del Sacro Cuore, Radiation Oncology Unit, Campobasso, Italy ;

<sup>3</sup>Department of Experimental- Diagnostic and Specialty Medicine - DIMES- University of Bologna- S. Orsola-Malpighi Hospital, Radiation Oncology Department, Bologna, Italy ; <sup>4</sup>Fondazione Policlinico Universitario A. Gemelli - Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

#### Purpose or Objective

Treatment plans for high-risk prostate cancer are highly complex due to large irregular shaped target volumes, multiple dose prescription levels and several OARs close to the target. The quality of these plans is highly inter-planner dependent. We aimed to assess the performance of the Auto-Planning module present in the Pinnacle TPS (version 16.0), comparing automatically generated VMAT plans (AP) with the historically clinically accepted manually-generated ones (MP).

#### Material and Methods

Twelve consecutive patients treated with VMAT-SIB for high-risk prostate cancer were re-planned with the Auto-Planning engine. The PTV1 included the prostate and the seminal vesicles; the PTV2 included the pelvic lymph nodes. Both PTVs were simultaneously irradiated over 25 daily fractions at 65Gy (2.6 Gy/fraction) and 45Gy (1.8 Gy/fraction). All manually (MP) and automatically (AP) generated plans were created by means of the "dual arc" feature. For the MP plans, additional non-anatomical structures needed to be delineated in order to interactively guide the optimization process. For AP plans, a progressive optimization algorithm is used to continually adjust initial targets/OARs objectives; tuning structures are automatically added during optimization to increase the dose fall-off outside targets. Various dose and dose-volume metrics (D98%, D95%, D50%, D2%, Dmean, V95% for target volumes; Dmean, Dmax and various Vx% for OARs), as well as conformity (CI) indexes and healthy-tissue integral dose (ID) were evaluated. A Wilcoxon paired test was performed for plan comparison with statistical significance set at p<0.05.

#### Results

Differences in all dose coverage metrics (in terms of V95%, D98%, D50%, D2% and Dmean) for both PTVs were not statistically significant (p<0.05). Differences in CI reached significance only for PTV2 (MP:1.59 vs. AP:1.48). Differences in DVHs were no significant in overall dose range for rectum, bladder and small bowel (rectum: V<sub>50Gy</sub>: 31.7 vs. 32.2Gy, V<sub>60Gy</sub>: 21.1 vs. 22.5Gy, Dmean: 40.6 vs. 40.5Gy; bladder: V<sub>65Gy</sub>: 19.6 vs. 20.6, Dmean: 44.3 vs. 43.8Gy). For small bowel: V<sub>15Gy</sub>: 105.0 vs 119.1cc, Dmean: 13.3 vs. 12.8cc. AP plans provided a decrease in Integral Dose of 5.1%. The mean number of MUs was not statistically different: MP (537) and AP (546), p=0.887.

#### Conclusion

The Pinnacle Auto-Planning module achieved highly consistent treatment plans in the cases of complex anatomical sites. The working time was substantially reduced with Auto-Planning.

#### **Purpose or Objective**

Treatment plans for head-neck cancer are highly complex due to large irregular shaped target volumes, multiple dose prescription levels and to several OARs close to the target. We assessed the performance of the Auto-Planning module present in the Pinnacle TPS (version 16.0), comparing automatically generated VMAT plans (AP) with the historically clinically accepted manually-generated ones (MP) for head-neck cancer patients.

#### **Material and Methods**

Twelve consecutive patients treated with VMAT-SIB for bilateral head-neck cancer were re-planned with the Auto-Planning engine. The PTV1 included the primary tumor, PTV2 and PTV3 included the high-risk and low-risk lymph-nodal areas, respectively. PTV1, PTV2 and PTV3 were simultaneously irradiated over 30 daily fractions at 67.5Gy, 60.0Gy and 55.5 Gy, respectively. All manually (MP) and automatically (AP) generated plans were created by means of the 'dual arc' feature. For the MP plans, additional non-anatomical structures needed to be delineated in order to interactively guide the optimization process. For AP plans, a progressive optimization algorithm is used to continually adjust initial targets/OARs objectives; tuning structures are automatically added during optimization to increase the dose fall-off outside targets and improve the dose conformity. Various dose and dose-volume metrics (D98%, D95%, D50%, D2%, Dmean, V95% for target volumes; Dmean, Dmax and various Vx% for OARs), as well as conformity (CI) indexes and healthy-tissue integral dose (ID) were evaluated. A Wilcoxon paired test was performed for plan comparison with statistical significance set at  $p < 0.05$ .

#### **Results**

Differences in all dose coverage metrics (in terms of V95%, D98%, D50%, D2% and Dmean) for all PTVs were not statistically significant ( $p < 0.05$ ). AP plans reported a better CI for PTV3 (MP:1.43 vs. AP:1.35,  $p = 0.01$ ). No significant differences in maximum doses were found for eyes, lens and optic chiasm. AP plans reduced maximum doses to PRV spinal cord and brainstem by 1.3Gy ( $p = 0.04$ ) and 4.3Gy ( $p = 0.02$ ), respectively, and mean dose for parotids by 3.4Gy ( $p = 0.02$ ). In addition, AP plans provided a significant decrease in Integral Dose of 6.6%. The mean number of MUs was higher for AP (586 vs. 451,  $p = 0.01$ ), suggesting an increased degree of fluence modulation.

#### **Conclusion**

The Pinnacle Auto-Planning module was able to produce highly consistent treatment plans for this complex anatomical sites. The working time was substantially reduced with Auto-Planning.

#### **EP-1870 Dosimetric assessment of metal artefact corrected CT images use for pelvis treatment planning**

*E. Jaegle<sup>1</sup>, E. Cordier<sup>2</sup>, M. Alayrach<sup>1</sup>, A. Badey<sup>1</sup>, V. Bodez<sup>1</sup>, C. Khamphan<sup>1</sup>, P. Martinez<sup>1</sup>, R. Garcia<sup>1</sup>*

*<sup>1</sup>Institut Sainte Catherine, Physique, Avignon, France ;*

*<sup>2</sup>Institut National des Sciences et Techniques Nucléaires, Medical physics, Gif sur Yvette, France*

#### **Purpose or Objective**

Single Energy Metal Artefact Reduction algorithm (SEMAR, Canon Medical Systems) provides modified Hounsfield Unit (UH) Computed Tomography (CT) images by correcting artefacts related to photon starvation induced by metallic prostheses. The aim of this study is to assess the dosimetric impact of using such images for treatment planning with Eclipse™ (Varian Medical Systems VMS).

#### **Material and Methods**

Gammex RMI@465 CT Electron Density Phantom (Gammex Inc.) with titanium insert was used to get SEMAR-off and SEMAR-on HU-Electron Density (HU-ED) calibration curves for both voltages: 120 kVp and 135 kVp. 8 patients with metallic prosthesis, divided in 2 groups (limbs, prostate), were selected to the compare following dose calculation conditions (Anisotropic Analytical Algorithm 13.5, VMS):  
 Condition 1 : SEMAR<sup>off</sup> CT // SEMAR<sup>off</sup> UH-ED (clinical use)  
 Condition 2 : SEMAR<sup>on</sup> CT // SEMAR<sup>off</sup> UH-ED  
 Condition 3 : SEMAR<sup>on</sup> CT // SEMAR<sup>on</sup> UH-ED  
 Monitor Units (MU) resulting from the condition 1 were used for each calculation.

Mean, minimal and maximal PTV dose were recorded. Results were expressed as prescription percentage.

UH-ED curve impact

Dose Comparison between conditions 2 and 3.  
 UH modification impact

Dose Comparison between conditions 1 and 2.

For VMAT prostate patients, results from inverse planning (Photon Optimizer 13.5,VMS) with SEMAR<sup>on</sup> CT // SEMAR<sup>off</sup> UH-ED were also compared to the reference plan (clinical use). For identical PTV coverage, MUs and global Gamma index passing rates with [2% / 2 mm criteria] (Portal Dose Image Prediction 13.5, VMS) were compared.

#### **Results**

The difference between SEMAR<sup>off</sup> and SEMAR<sup>on</sup> is smaller than the difference between 120 kV and 135 kV regarding the UH value of Titanium. No differences were recorded around pelvis densities.

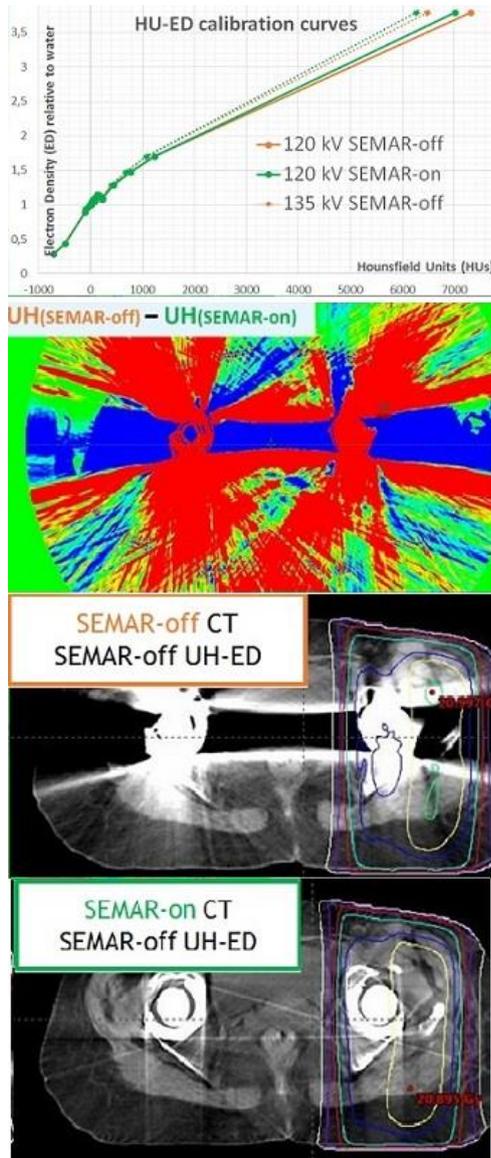

UH-ED curve impact

Adapting the UH-ED did not modify the average mean dose calculated over the 8 patients.

UH modification impact

Mean PTV dose increased by 0.5% for the 8 patients. Concerning limbs group, the minimal dose was strongly impacted (+1.9%). Prostate cases for which beams do not enter through metal, did not show such differences even if higher dose indices were recorded comparing to clinical use.

Results from optimizing on SEMAR<sup>on</sup> followed the same trend found with dose indices, with fewer MUs needed to get identical coverage. Gamma passing rates remained in our tolerance.

**EP-1871 Can the use of a hydrogel spacer enable intra-prostatic boosts without increasing rectal doses?**  
 N. Laverick<sup>1</sup>, S. Currie<sup>1</sup>  
<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Glasgow, United Kingdom

**Purpose or Objective**

To assess the impact of using a hydrogel spacer (SpaceOAR®, Augmenix Inc. Waltham, MA, USA) on plan quality in prostate patients when including an intra-prostatic focal boost.

**Material and Methods**

Treatment plans were created on scans of ten patients pre- and post-implantation of the hydrogel spacer. All plans used VMAT with two coplanar arcs to treat the prostate to 60Gy in 20 fractions (PTV60) and the seminal vesicles to 47Gy (PTV47). All plans were optimised using the Centre’s RapidPlan model (Varian Medical Systems, Palo Alto, CA, USA). A boost volume was then identified for each patient and outlined on both the pre- and post-scan sets with the aid of MRI imaging. These boost volumes were planned to two separate dose prescriptions, 67Gy and 78Gy. Plans were compared in terms of target coverage and doses to bladder and rectum. Paired two-tailed t-tests were used to examine for statistical significance.

For the plans without the focal boost and the 78Gy boost plans, the robustness of the OAR doses was also assessed by inducing a 5mm target shift in all directions and recording the poorest rectal and bladder doses.

**Results**

Target coverage was not affected by the presence of the hydrogel spacer; however rectal doses were reduced post-implantation. As Figure 1 shows, the volume of rectum receiving both intermediate and higher doses is reduced with the spacer. The implantation of the spacer has allowed boosting of in intra-prostatic volume to 78Gy whilst still achieving lower rectal doses than the treatment plans produced on the pre-implantation scans with no boost volume. Using p<0.01 as the limit for statistical significance, significant increases were found in rectal dose when boosting without the hydrogel spacer, whereas increases with boosting with the spacer in place were not significant.

The mean dose to the rectum, which is associated with faecal incontinence and high stool frequency following radiotherapy, is also reduced; the reduction is such that similar levels (p = 0.04) are achieved for the pre-implantation with no boost (median 19.6Gy) and the post-implantation with 78Gy boost (median 17.0Gy). No overall change in bladder dose was seen.

Median Rectal DV Statistics

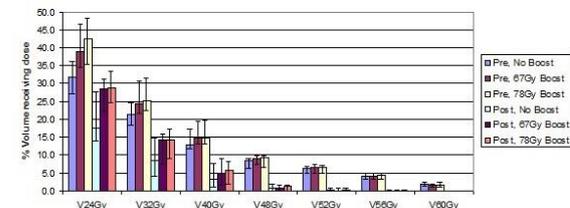

Figure 1: Median values of rectal DV statistics pre and post implantation of hydrogel spacer for different boost dose prescriptions. Error bars represent the IQR.

As seen in Figure 2, the worst-case increase in rectal doses was reduced when using the hydrogel spacer, especially the volume of rectum receiving the higher dose levels which are associated with rectal bleeding. No meaningful change in the robustness of bladder dose was observed.

**Conclusion**

SEMAR dedicated UH-ED curves don’t seem necessary to compute dose with SEMAR<sup>ON</sup> CT.

When beams do not enter through metallic implants, slight dosimetric differences caused by UH modification are negligible. When PTV encompasses metal and beams pass through it, PTV coverage may be strongly modified. Further investigations (Acuros® XB dose calculation, Monte Carlo simulation) need to be done to improve the real irradiation knowledge.

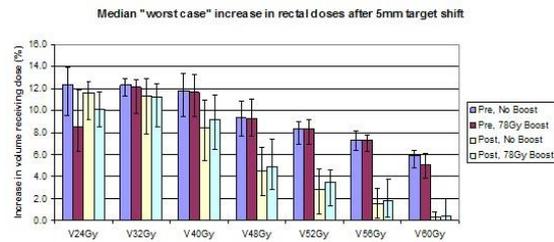

Figure 2: Median "worst case" increases in rectal DV statistics when shifting target by 5mm. Error bars represent the IQR.

#### Conclusion

The implantation of the hydrogel spacer enables the use of intra-prostatic focal boosts whilst maintaining similar or reduced rectal doses to those achieved pre-implantation and also improving the robustness of these doses to PTV shifts.

#### EP-1872 Combining multi-criteria optimisation and a hydrogel spacer for intra-prostatic focal boosts

N. Laverick<sup>1</sup>, S. Currie<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Glasgow, United Kingdom

#### Purpose or Objective

To assess whether using multi criteria optimisation alone or in combination with a hydrogel spacer (SpaceOAR®, Augmenix Inc. Waltham, MA, USA) can improve plan quality in prostate patients when including an intra-prostatic focal boost.

#### Material and Methods

Multi-criteria optimisation (MCO) is a planning tool which creates multiple treating plans for each planning objective; the aim is to enable the planner to explore the Pareto surface to find the optimum clinical planning solution. Plans created using MCO may be able to achieve lower OAR doses whilst maintaining target coverage. Hydrogel spacers are also of interest in prostate radiotherapy, aiming to lower rectal doses and therefore toxicity by increasing the separation between the prostate and rectum.

Plans were created on patient (n=10) scans pre- and post-implantation of a hydrogel spacer which treated the prostate to 60Gy and seminal vesicles to 47Gy using the Centre's RapidPlan model (Varian Medical Systems, Palo Alto, CA, USA). Boost volumes were identified on both sets of scans with the aid of MRI imaging and further plans created treating these volumes to 78Gy. Finally, MCO was used to further optimise all plans. Plan quality was compared through target coverage and doses to bladder and rectum and paired two-tailed t-tests were used to examine for statistical significance.

#### Results

PTV coverage and bladder doses were similar across all plan types. When MCO was applied to the pre- hydrogel plans, the rectal doses were significantly reduced across all dose levels ( $p < 0.01$ ) for both plans with and without the focal boost. Applying MCO to the focal boost plans reduced doses to the same level as the standard plans without the boost.

When the hydrogel spacer was implanted, MCO was found to only significantly affect the lower dose metrics (V24Gy and V32Gy) and the mean dose. However, this is likely due to the extremely low volumes of rectum receiving the higher dose levels when the spacer is present. Figures 1 and 2 show the median pre- and post-implantation dose statistics. The combination of using the hydrogel spacer and MCO in the focal boost plans resulted in significantly lower rectal doses than were achieved in the standard pre-implantation plan without the boost ( $p < 0.01$ ).

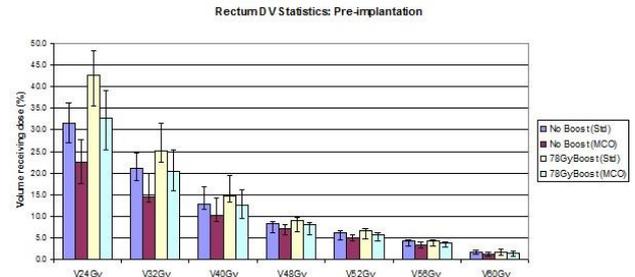

Figure 1: Median Rectal DV statistics pre-implantation of hydrogel spacer. Error bars represent IQR

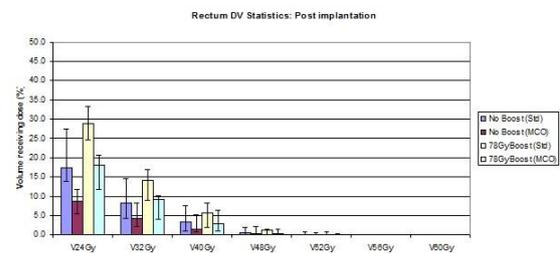

Figure 2: Median rectal DV statistics post-implantation, Error bars represent IQR

#### Conclusion

Using multi-criteria optimisation allows for boosting of an intra-prostatic volume up to 78Gy without significantly increasing rectal doses. Rectal doses are further reduced when MCO and the hydrogel spacer are used in combination.

#### EP-1873 Reducing OAR doses in prostate patients: use of a hydrogel spacer and multi-criteria optimisation

N. Laverick<sup>1</sup>, D. Church<sup>1</sup>, S. Currie<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy Physics, Glasgow, United Kingdom

#### Purpose or Objective

To assess the impact of using a hydrogel spacer (SpaceOAR®, Augmenix Inc. Waltham, MA, USA) with and without multi-criteria optimisation on bladder and rectum doses in moderately hypo-fractionated prostate treatments.

#### Material and Methods

Plans were created using Eclipse v15.5 (Varian Medical Systems, Palo Alto, CA, USA) on ten patient scans pre- and post-implantation of the hydrogel spacer treating the prostate to 60Gy in 20 fractions in accordance with the CHHiP trial protocol. All plans were optimised using the Centre's RapidPlan™ model. Finally, the post-implantation plans were further optimised using multi-criteria optimisation. Plans were compared in terms of target coverage and doses to bladder and rectum. Paired two-tailed t-tests were used to examine for statistical significance.

#### Results

PTV coverage was similar between all plan types. The table below shows the mean rectal doses across the ten patients. Statistically significant differences between plan types are highlighted in green.

Test	Rectum						Bladder			
	V25	V32	V41	V49	V53	V57	V60	V41	V49	V60
	<65%  < <80%	<60%  < <65%	<50%  < 60%	<30%  < <50%	<20%  < <30%	<10%  < 15%	<3%  < <2%	<30%  < <50%	<20%  < <25%	<3%  < 5%
Mean Std	47.0	35.6	23.4	14.2	9.7	4.8	0.0	23.9	17.3	0.9
Mean SpaceOAR	48.1	29.5	15.8	7.6	4.3	1.8	0.0	20.2	14.0	0.8
Mean Space+MCO	27.9	18.1	10.5	5.4	3.4	1.8	0.1	17.6	12.4	0.9
Std vs Space	0.864	0.066	0.010	0.003	0.004	0.013	0.223	0.419	0.337	0.352
Std vs Space + MCO	0.000	0.000	0.001	0.001	0.002	0.009	0.378	0.209	0.187	0.869
Space vs Space+MCO	0.000	0.000	0.000	0.002	0.004	0.430	0.306	0.005	0.000	0.788

The hydrogel spacer was effective at reducing rectal doses in the intermediate dose range, with very little volume receiving 60Gy and above for all plan types. Using MCO on the post-implantation plans resulted in even lower rectal doses alongside a significant reduction in bladder doses compared to the spacer alone.

#### Conclusion

The implantation of a hydrogel spacer can significantly reduce rectal doses for patients treated with moderately hypofractionated prostate radiotherapy without compromising PTV coverage. Using multi-criteria optimisation alongside the hydrogel spacer can further reduce these rectal doses and results in lower bladder doses than are achieved using the spacer only.

#### EP-1874 Multiple brain metastasis radiosurgery using dedicated treatment planning system: a dosimetric study

M. Biston<sup>1</sup>, M. Ayadi<sup>1</sup>, P. Dupuis<sup>1</sup>, T. Baudier<sup>2</sup>, C. Malet<sup>1</sup>, M. Sunyach<sup>1</sup>

<sup>1</sup>Léon Bérard Cancer Center, Radiotherapy, Lyon, France ; <sup>2</sup>Lyon university, Creatis, Lyon, France

#### Purpose or Objective

The objective was to compare the performances of conventional versus dedicated linear accelerator for the stereotactic treatment of multiples brain metastases. Cyberknife® plans were compared to those obtained with a treatment planning system (TPS) designed for treating multiple brain metastases on conventional linac and to another one used in routine for volumetric modulated arc therapy planning (VMAT).

#### Material and Methods

Eight previously treated patients with 2 to 8 tumors representing 37 gross target volumes (GTV) were selected. GTV-to-Planning target volume (PTV) margins were 2 mm in all directions. PTV sizes were under 2 cm<sup>3</sup>. The prescribed dose was 20 Gy in single fraction prescribed at the isodose 80% and covering 96-99% of the PTVs. The original treatments planned with Multiplan® (V3.2.0, Accuray) delivered on a Cyberknife® (Accuray) using 2 or 3 fixed-size collimators were replanned in dynamic conformal arctherapy (DCAT) with dedicated automated brain metastases TPS Elements® (v.1.5, Brainlab) and with Monaco TPS (V 5.11.02, Elekta) using VMAT. Plans were delivered using 6-MV photons with an Agility® MLC consisting of 80 paired leaves each measuring 5 mm in width at the isocenter. The dose distributions were compared using Paddick conformity index (CI), mean dose to the PTVs, and volume of healthy brain receiving 10 (V10), 12 (V12) and 5 (V5) Gy. Delivery efficiency was compared throughout the number of monitor units (MUs), delivery time and logfiles analyses.

#### Results

A better CI was found with the Cyberknife (1.26 ±0.06) than with Elements® DCAT (1.29 ±0.12) or Monaco VMAT (1.33 ±0.11). Mean dose to the PTVs were found higher for Cyberknife (22.47 Gy±0.29) and VMAT (22.27 Gy±0.43) plans than for DCAT plans (22.06 Gy±0.55). The healthy

brain was better spared with Elements® DCAT than with the Cyberknife and VMAT. VMAT gave significantly higher doses to the brain than the 2 other techniques (Table 1). Mean estimated delivery time was 78 min, 20 min and 25min for the Cyberknife®, DCAT and VMAT techniques, respectively. Logfile analysis showed that VMAT plans had more MUs than DCAT plans (8477±1651 vs 5037±1090), smaller segments, and more important fluctuations in dose rate and gantry speed.

	Multiplan® Cyberknife	Elements®DCAT	Monaco® VMAT
V5 Gy (±SD)	94 (74.02)	82.75 (67.07)	146.16 (133.6)
V10 Gy (±SD)	22.22 (12.7)	19.43 (11.11)	30.58 (18.04)
V12Gy (±SD)	16.09 (8.90)	13.78 (7.76)	20.73 (11.65)

Table 1: Volume (cm<sup>3</sup>) of healthy brain receiving a critical dose level for each technique

#### Conclusion

Elements® DCAT is a robust automatic planning solution for treating multiple brain metastasis. The planning time is considerably reduced compared to the 2 other techniques, and the system is nearly operator independent. For clinically acceptable plan quality the delivery efficiency is considerably better with linac-based stereotactic radiosurgery than with Cyberknife. Further investigations are in progress to examine whether tumor size/location and number of lesions have an impact on the results.

#### EP-1875 Compare OAR dose of breast cancer using sequential boost and simultaneous integrated boost technique

L. Chou<sup>1</sup>, T. Wang<sup>2</sup>, C. Shiau<sup>1</sup>, P. Huang<sup>1</sup>, Y. Lin<sup>1</sup>, C. Lin<sup>1</sup>  
<sup>1</sup>Taipei Veterans General Hospital, Oncology, Taipei City, Taiwan ; <sup>2</sup>China Medical University Hospital, Radiation Oncology, Taichung, Taiwan

#### Purpose or Objective

Thanks to advances in treatment and diagnosis, the mortality of breast cancer has decreased. Radiotherapy is an indispensable part in adjuvant treatment for patients undergoing breast-conserving surgery. However, inevitable radiation exposure to the heart and lung may cause serious long-term toxicities. Besides whole breast irradiation, tumor bed boost can be delivered in sequential (SEQ) or simultaneously integrated boost (SIB) techniques. This study aimed to compare the dosimetric outcome of two techniques.

#### Material and Methods

Eighty node-negative left breast cancer patients receiving breast-conserving surgery were evaluated, of which 47 patients received 45Gy in 25 fractions to the whole breast and then 10 Gy in 5 fractions to tumor bed, while 33 patients received 55Gy to tumor bed and 45Gy to whole breast in 25 fractions using SIB technique. All treatment plans were based on CT imaging and consisted of two tangential fields with 6MV photon to whole breast and 1-2 beams to tumor bed. If necessary, we used 1-2 additional beams to improve whole breast homogeneity and normal organ sparing. Conformal index, homogeneity index, heart dose, ipsi-lateral lung dose were compared between SEQ and SIB technique. (Table 1)

#### Results

The median age of SEQ and SIB group were 48 (25-71) and 54 (33-74) respectively and the PTV<sub>boost</sub> volume were similar (110.7±84.6 c.c. for SEQ and 108.7±66.4 c.c. for SIB). Both SEQ and SIB plans demonstrated similar homogeneity (p>0.05) but significant difference of conformity (p<0.01). In addition, SEQ plans provided significantly less lung radiation exposure (V5, V10 and mean left lung dose) than SIB plans (p<0.05). Heart dose were similar in two groups crossing V5, V10, V30, and mean heart dose (all p>0.05).

Table 1. Dosimetric parameters of Heart and Lung

		SEQ	SIB	difference	P value

	V <sub>30</sub> (%)	12.1±4.8	13±3.5	-0.9	0.33
	V <sub>40</sub> (%)	10.2±4.3	10.7±3.2	-0.5	0.52
	V <sub>50</sub> (%)	7.4±3.6	7.1±2.7	0.3	0.62
	mean(Gy)	2.2±1	2.8±1.1	62.4	0.01

### Conclusion

Although SIB technique is more convenient due to the shorter treatment time and well tolerated in previous study, we found that lung dose was higher than in SEQ technique. More efforts should be made when using this technique.

### EP-1876 Level II volume and parotid doses during nasopharyngeal radiotherapy: what relationship?

Z. Fessi<sup>1</sup>, N. Fourati<sup>1</sup>, W. Mnejja<sup>1</sup>, L. Farhat<sup>1</sup>, T. Sahnoun<sup>1</sup>, W. Siala<sup>1</sup>, J. Daoud<sup>1</sup>  
<sup>1</sup>Hopital Habib Bourguiba, Radiation Oncology, Sfax, Tunisia

### Purpose or Objective

High dose to parotid gland may increase the risk of xerostomia during radiotherapy for nasopharyngeal carcinoma (NPC). This dose is essentially correlated to the proximity of the target volume, mainly linked to the level II lymph node invasion. The aim of this study was to evaluate the relationship between parotid doses and level II lymph node volume.

### Material and Methods

Retrospective study of 45 patients with NPC treated by intensity modulated radiotherapy (IMRT) in our institution during 2 years (2016-2018). The 2 parotid glands were delineated as a single structure and we noted the mean doses (Dmean) received at their level. We then retrospectively delineated Level II lymph node separately to determine its volume. The results were analyzed by SPSS v20. Pearson Test was used to determine the correlation between Dmean and Level II lymph node volume. We then determine the function that links the 2 variables according to a linear model: Dmean = a + b Level II lymph node volume.

### Results

Median Dmean dose was 35.54 Gy (23.36-53.34). Median Level II lymph node volume was 9.8 cc (0-93 cc). The correlation between the two variables showed a proportional relationship with a Pearson r coefficient of 5.23 (p <0.001). According to the linear model, the relationship between Dmean and level II lymph node volume was as follows: Dmean = 33.56 + 0.15 Level II lymph node volume.

### Conclusion

Level II lymph node involvement is common in NPC and is found in more than 80% of cases. The results of our study found that parotid mean doses, which represent a significant risk organ during IMRT planning, are correlated with level II lymph node volume. It is therefore difficult to respect parotid doses in the presence of a level II invasion. In this situation, the choice would be between excluding the part of the target volume extending at the parotid and taking into account only the superficial lobe of the parotid.

### EP-1877 Proton vs photon deep inspiration breath-hold planning study for left-sided breast cancer patients

K. Czernska<sup>1</sup>, P. Winczura<sup>2</sup>, J. Wejs-Maternik<sup>2</sup>, A. Blukis<sup>2</sup>, M. Antonowicz-Szydlowska<sup>2</sup>, A. Rucinski<sup>3</sup>, P. Olko<sup>3</sup>, R. Kopec<sup>1</sup>, A. Badzio<sup>2</sup>

<sup>1</sup>Institute of Nuclear Physics PAN, Cyclotron Center Bronowice, Krakow, Poland ; <sup>2</sup>Radiotherapy Center Elblag, Radiotherapy, Elblag, Poland ; <sup>3</sup>Institute of Nuclear Physics PAN, Proton Radiotherapy Group, Krakow, Poland

### Purpose or Objective

Deep inspiration breath-hold (DIBH) is an effective approach to reduce the dose to the heart and coronary vessels in left-sided breast radiotherapy. The aim of this study was to compare doses to organs at risk between 3D photon DIBH technique and an Intensity Modulated Proton Therapy (IMPT) planning using a deep inspiration and free breathing (FB).

### Material and Methods

Six patients with early left-sided breast cancer were planned on a computed tomography datasets acquired for FB and DIBH, with a 3D photon (6 MeV tangential fields with additional lower weight fields to ensure homogeneity of the plan) and IMPT proton technique (with the application of 3 anterior-oblique fields). All cases were planned to the whole breast only. Prescribed dose was 50 Gy for photons and 50 Gy(RBE) for protons in 25 fractions. Main goal was to achieve acceptable target coverage with dose reduction to the organs at risk, which could reflect to the clinical satisfactory plans. Dosimetric comparison was made by using a paired, two-tailed Student's t-test and Wilcoxon signed rank test.

### Results

With regard to doses to the heart and coronary vessels, there was no difference between DIBH and FB for proton plans. However proton FB technique, as compared to the photon DIBH, ensured significant dose reduction to the organs at risk. Mean heart dose was lower in proton plans comparing to photons (0,5 Gy(RBE) vs 1,6 Gy; p=0,0096). Also the mean dose to the ipsilateral lung was reduced from 9,0 Gy to 5,4 Gy(RBE); (p=0,0006) for photons and protons, respectively. Several parameters were taken into account to depict the benefit for the Left Anterior Descending Artery (LAD): mean, maximum dose, D<sub>max</sub>0,2cm<sup>3</sup> and V45Gy. We found profound decrease of the D<sub>max</sub>0,2cm<sup>3</sup> by a factor of 3 for proton plans comparing to photons (8,2 Gy(RBE) vs 22,0 Gy; p=0,0687). The volume of LAD receiving dose of 45 Gy was very low for both techniques. Detailed dosimetric comparison between both techniques is presented in table 1.

		PHOTONS (A)	PROTONS (B)	p-Value
		Breath-hold	Free breathing	
heart	Dmean	1,6 ± 0,6 Gy	0,5 ± 0,2 Gy(RBE)	0,0096
	Dmax	9,0 ± 1,3 Gy	5,4 ± 0,8 Gy(RBE)	0,0006
left lung	V20Gy	17,2 ± 4,5%	9,5 ± 1,5%	0,0114
	Dmean	9,9 ± 6,8 Gy	4,1 ± 2,3 Gy(RBE)	0,0509
LAD	Dmax	29,2 ± 18,3 Gy	23,5 ± 11,8 Gy(RBE)	0,3470
	V45Gy	0,1 ± 0,2 cm <sup>3</sup>	0,0 ± 0,0 cm <sup>3</sup>	0,3008
	Dmax 0,2 cm <sup>3</sup>	22,0 ± 19,3 Gy	8,2 ± 6,1 Gy(RBE)	0,0687

### Conclusion

Breath-hold approach for photon planning already ensures a significant dose reduction to the heart and coronary vessels. This study shows that the application of proton FB technique leads to better dose reduction to the organs at risk. No further benefit was achieved with proton DIBH technique. Proton FB radiotherapy could be a promising solution for patients with more demanding anatomies, these with serious cardiac comorbidities or patients unable to perform deep inspiration breath-hold.

**EP-1878 PRV brainstem during the nasopharyngeal IMRT: margin calculation and dosimetric implications**  
 N. Fourati<sup>1</sup>, L. Farhat<sup>1</sup>, W. Mnejja<sup>1</sup>, Z. Fessi<sup>1</sup>, T. Sahnoun<sup>1</sup>, W. Siala<sup>1</sup>, J. Daoud<sup>1</sup>  
<sup>1</sup>Hopital Habib Bourguiba, Radiation Oncology, Sfax, Tunisia

#### Purpose or Objective

According to the ICRU 83 recommendations, a margin around the organ at risk is necessary to define the planning organ at risk volume (PRV). However, for brain stem this margin is not well defined in the literature and remains non-consensual. The aim of this study was to evaluate the margin around the brainstem in relation to setup errors in intensity modulated radiotherapy (IMRT) of nasopharyngeal carcinomas (NPC) and determine the dosimetric implication of this additional margin.

#### Material and Methods

Data from 33 patients with NPC treated by IMRT in our institution was analyzed. A five points mask was used for patient's immobilization. For the definition of the optimization objectives an artificial structure was created by adding 5 mm margin around the brain stem whereas for the dosimetric validation the doses were noted at the level of the brainstem. From the portal imagery (PI) database, we retrospectively calculated the margin for set up errors required for the brain stem PRV using the McKenzie formula. We then noted the volumes, maximum doses (Dmax) and the dose received by 2% (D2%) of the brain stem and the PRV brain stem.

#### Results

A total of 1250 PIs were analyzed. The mean antero-posterior, right-left and super-inferior movements were +0.39 mm (-5mm to 8 mm), +0.24 mm (-5 to 18 mm) and +0.15 mm (-7 to 7 mm), respectively. Calculated PRV margin was 2mm. The median volume was 27.5 mm (18.7-37.3) for the brainstem and 40.9 mm(29.7-56.8) for the PRV brainstem with a median increase of 5.68% (13.46-62.44). The median Dmax was 54.45 Gy (48.42-60.78) for brain stem and 58.7 Gy (53.49-65) for PRV brain stem with a median variation of 3.23 Gy (0-9.15) between brain stem and PRV brain stem. The median D2% was 51.84 Gy (43.91-58.66) for brain stem and 53.07 Gy (45.46-59.23) for PRV brain stem.

#### Conclusion

The brainstem is a critical organ that deserves special attention when planning NPC radiotherapy especially in cases of massive posterior invasion. The creation of a PRV brainstem to account setup errors is necessary. The dose analysis must be done on the PRV especially as the doses respected at the level of the brainstem can be exceeded on the PRV. But, given the increase in volume during the creation of the PRV, we can evaluate the D2% of the PRV before deciding whether or not to validate the treatment plan.

**EP-1879 HyperArc for stereotactic radiosurgery: comparison of planning options**

D. Kearns<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Care, Treatment Planning, Glasgow, United Kingdom

#### Purpose or Objective

To evaluate treatment plan quality metrics produced for four different plans for stereotactic radiosurgery treatments using HyperArc and investigate the optimal choice. The methods investigated were two different energy modes 6FFF and 10FFF and different multi-leaf collimators systems, standard 120 leaves and high definition (HD-MLC) 120 leaves.

#### Material and Methods

Ten multiple metastatic cranial patients previously treated with HyperArc utilizing 10FFF and HD-MLC were retrospectively planned using the Eclipse Treatment

Planning System v15.5 [Varian Medical Systems, Palo Alto, CA, USA]. The following planning options were investigated: 6FFF, 10FFF with both MLC standard and high definition MLCs.

The cohort of patients included a range of patients with two to ten lesions. Total PTV volumes varied from 2.9cc to 21.0cc. All plans included four non-coplanar arcs with a single isocentre placed at the centre of mass of the total target volume whilst respecting the delivery capabilities of the treatment linear accelerator. All plans were optimised using standard objectives to meet clinical constraints based on SRS guidelines. All plans were normalized such that 80% of the highest prescription target volume (primary target volume) received the prescribed dose.

Plan quality was evaluated by; volume of the brain receiving 20%, 40% and 60% of the maximum PTV prescription for that patient; and median brain dose.

#### Results

Primary target volume coverage was achieved by normalisation in each case. All plans met local constraints and were suitable for treatment.

The dose to brain was reduced in all plans using 6FFF together with HD MLC for all metrics. When compared with 10FFF HD-MLC selection, this was significant statistically at both the 20% and 40% values (p<0.05). There was no significant statistical variation in brain optimized when comparing the 10FFF HD-MLC plan and 6FFF standard MLC plan, however the median dose was reduced with the 10FFF plan.

The least conformal plan was the 10FFF plan with the standard MLC. This showed a significant statistical increase in brain center when compared with the 6FFF HD-MLC plan. The median dose was also higher than the other plan situations, however this was not found to be significant. The number of PTVs did not influence optimal plan selection and plan quality metrics.

#### Conclusion

The use of 6FFF and a HD-MLC provided the optimal solution to provide the sharpest dose gradient and to minimise brain dose but all plan types provided clinically acceptable plans. The disadvantage of 6FFF in relation to 10FFF is the treatment delivery time with dose rates being reduced from 24Gy to 14Gy per minute that may impact the selected PTV margins. This is equivalent to an increase in treatment delivery time of 41%. The reduction in dose rate would however allow increased MLC modulation. Current practice is being reviewed to produce two HD MLC plans at both energies to help determine plan selection.

**EP-1880 A planning study evaluating the use of 4DCT vs 3DCT in pancreas planning, both conventional and SABR**

E. Tait<sup>1</sup>, O. Byrne<sup>1</sup>, D. O'Doherty<sup>1</sup>, B. Evans<sup>1</sup>, T.

Ajithkumar<sup>2</sup>, G. Begum<sup>2</sup>, A. Ho<sup>2</sup>

<sup>1</sup>Addenbrookes Hospital, Medical Physics, Cambridge, United Kingdom ; <sup>2</sup>Addenbrookes Hospital, Radiation Oncology, Cambridge, United Kingdom

#### Purpose or Objective

Acquiring a 4DCT scan in pancreas planning allows the use of an ITV to PTV margin which is smaller than the GTV to PTV margin used in conventional 3D planning, generally leading to a smaller PTV. We aim to evaluate the dosimetric difference between plans created where the PTV was created using 4DCT or 3DCT only and to review the impact of this on SABR planning.

#### Material and Methods

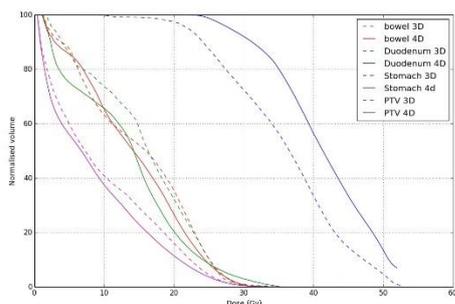

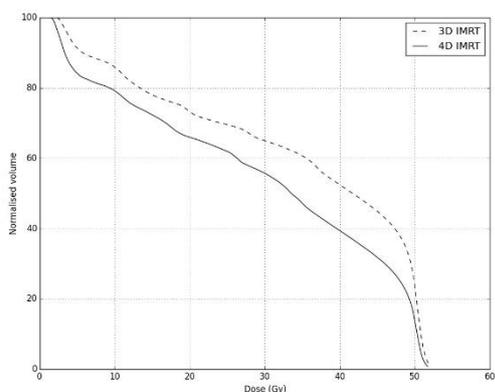

Patients who had previously been treated for pancreatic cancer planned using 4DCT were retrospectively outlined using 3D scans only and the volume of the new PTVs was assessed. 6MV conformal IMRT plans were then re-created in Pinnacle; plans were created using the same beam

parameters and conventional fractionation (50.4Gy in 28 fractions) as originally used but optimised to the new PTV. In order to investigate the dosimetric difference between 4DCT and 3DCT for pancreas SABR planning patients were outlined according to the SPARC protocol. The PTV was prescribed 35Gy in 5 fractions and the area at risk (PTV\_M) was prescribed a dose of 45-50Gy in 5 fractions and the OAR constraints from the SPARC trial were used. PTV coverage was compromised to meet mandatory OAR constraints in both the 3D and 4D plans.

### Results

The average PTV volume dropped by 33% and we saw reductions to the mean dose of all OARs in the conventional fractionation. There was no correlation observed between the magnitude of the tumour motion and the reduction in OAR dose. The drop in dose to OAR is highly dependent on tumour position. The most significant OAR improvement was seen in the duodenum with an average mean dose difference of 5.3Gy (range 2.4-6.9Gy), other OAR mean dose reductions are as follows: spine 2.6Gy, bowel 2.9Gy, stomach 4.3Gy, liver 2.2Gy and kidneys 1.4Gy. Figure 1 shows the mean duodenum DVH for conventional 3D and 4D plans.

The dose constraints for the SABR plans were challenging for both 3D and 4D as the majority of patients had OARs overlapping the PTV which had to be carved out. As expected PTV coverage was improved in the 4D plan as there was less overlap with the OARs and OAR doses were generally lower. The mean V95% dropped from 85.5% using the 4D plan to 62.4% using the 3D plan when all mandatory OAR constraints were met. Figure 2 shows the mean DVH for the dose limiting OARs and the PTV receiving 35Gy for SABR 3D and 4D plans. PTV\_M coverage was very similar for both plan types. This level of PTV coverage could lead clinicians to dose deescalate, the SPARC protocol also allows 30Gy in 6 fractions and 6.5Gy in 6 fractions.

### Conclusion

The use of a 4DCT in pancreas planning results in lower dose to the OARs, improved PTV coverage in the case of SABR planning and the potential for dose escalation.

### EP-1881 Sequentially- versus co-optimized plans for pelvis and prostate bed: time efficacy and plan quality

A. Gulyban<sup>1</sup>, E. Marques<sup>1</sup>, O. Michel<sup>1</sup>, A. Rijnders<sup>1</sup>, C. Salembier<sup>1</sup>

<sup>1</sup>Europe Hospitals - Site St Elisabeth, Radiation department, Brussels, Belgium

### Purpose or Objective

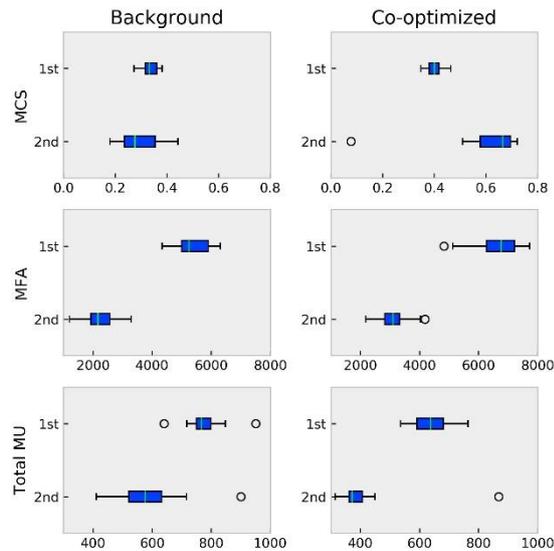

To evaluate the performance of sequentially- and co-optimized treatment planning approaches for pelvic lymph node and prostate bed irradiation in terms of required time, plan quality and modulation complexity.

### Material and Methods

Twenty consecutive patients were included in this investigation. For all patients the prescription dose consisted of 50 Gy in 25 fractions for the pelvic lymph node region planning target volume (*1<sup>st</sup> phase, PTV\_LD*), followed by 16 Gy in 8 fractions for the prostate bed (*2<sup>nd</sup> phase, PTV\_HD*). Rectum, bladder and small bowel were delineated as organs at risk (OARs), and used for optimization (by excluding the area overlapping with PTV\_LD+2mm). Sequential and combined planning were performed. The sequential approach (background dose based "BG") consisted in a standalone *1<sup>st</sup> phase* planning, followed by a linked *2<sup>nd</sup> phase* and total plan optimization, while the combined one (co-optimized "CO") used separate and pooled planning objectives simultaneously for the *1<sup>st</sup>, 2<sup>nd</sup>* and *combined* phases. For all treatment planning Raystation (version 6.1.1.2, Stockholm, Sweden) was used by the same planner with identical initial optimization parameters. Seven field (45 segments) Direct Machine Parameter Optimization (DMPO) class solutions were used for the *1<sup>st</sup> phase*, while single full rotation modulated ARC (37 segments, sector size of 10° and 4° arclets/sector) for the *2<sup>nd</sup> phase*, with five field (40 segments) DMPO as backup in case initial arc sequencing failed. Time required to achieve a clinically acceptable plan was measured, followed by a qualitative comparison of relevant dose parameters and assessment of plan Modulation Complexity Score (MCS). Results were compared using paired t-test with p<0.05 significance level

### Results

Eighty plans were analyzed. The average (range) time (min:sec) required for BG based planning was 7:29 (4:20-10:02), 5:27 (3:50-07:36) and 12:56 (8:19-16:17) for *1<sup>st</sup> phase*, *2<sup>nd</sup> phase* and total planning respectively. For CO on average 4:24 (-2:42-23:29) more time was required, leading to an average planning time of 17:20 (10:46-39:46)(p=0.01). For *2<sup>nd</sup> phase* all BG plans consisted of a mARC, while for CO only one plan succeed with proper arc sequencing. On average (±standard deviation) 26.9±9.5%, 40.5±15.8% and 3.3±1.6% of the rectum, bladder and small bowel were overlapped with the PTV\_LD+2mm respectively. Statistically significant (p<0.01) differences were observed in MCS (Figure): 0.32 (0.18-0.44) vs. 0.51 (0.08-0.72) between BG and CO respectively without significant differences neither in PTV coverage nor in integral dose (Body V5/20Gy). Furthermore majority of OAR parameters were significantly better using the BG approach (Table).

ROI	Dose parameter	Plan Phase	Background planning Mean (SD)	Co-optimized planning Mean (SD)	p-value
Rectum	V50Gy(%)	Total	25.9 (7.9)	33.2 (9.2)	<0.001

Bladder	V20Gy(%)	Total	77.6 (10.5)	85.2 (10.7)	<0.001
	V35Gy(%)	Total	54.2 (15.1)	59.0 (15.2)	<0.001
	V50Gy(%)	Total	37.2 (14.5)	40.0 (14.3)	<0.001
	V60Gy(%)	Total	27.1 (12.7)	28.8 (12.6)	<0.001
	Dmean (Gy)	Total	40.0 (6.7)	42.5 (6.4)	<0.001
Small bowel	V20Gy(%)	Total	60.2 (13.8)	65.5 (16.8)	0.028
	V35Gy(%)	Total	19.2 (7.0)	24.3 (10.7)	<0.001
	V50Gy(%)	Total	0.7 (0.6)	0.9 (0.7)	0.036
	Dmean (Gy)	Total	23.6 (3.4)	25.3 (4.7)	0.006
Body	V5Gy (cc)	1st Phase	1500 (289)	1696 (330)	0.059
	V5Gy (cc)	2nd Phase	10781 (1838)	10956 (1799)	0.765
	V5Gy (cc)	Total	11494 (1960)	11300 (1800)	0.101
	V20Gy (cc)	Total	5364 (914)	5492 (780)	0.240
PTV_LD	D98%(Gy)	1st Phase	46.9 (0.3)	46.8 (0.5)	0.782
	D2%(Gy)	1st Phase	52.0 (0.1)	52.1 (0.2)	0.116
	V47.5Gy(%)	1st Phase	96.3 (0.8)	96.2 (1.2)	0.741
	V53.5Gy(%)	1st Phase	0.0 (0.1)	0.0 (0.1)	0.381
PTV_HD	D98%(Gy)	2nd Phase	15.2 (0.3)	15.1 (0.2)	0.301
	D2%(Gy)	2nd Phase	16.4 (0.2)	16.6 (0.2)	0.002
	V15.2Gy(%)	2nd Phase	96.2 (5.1)	97.0 (2.1)	0.562
	V17.12Gy(%)	2nd Phase	0.0 (0.1)	0.1 (0.3)	0.449
	D98%(Gy)	Total	64.1 (0.4)	64.7 (0.3)	<0.001
	D2%(Gy)	Total	68.0 (0.3)	67.7 (0.4)	0.003
	V62.7Gy(%)	Total	99.7 (0.4)	100.0 (0.1)	0.004
V70.62Gy(%)	Total	0.0 (0.0)	0.0 (0.0)	0.330	

**Conclusion**

Sequential plan optimization should be preferred for pelvic lymph node irradiation of 50 Gy followed by 16 Gy boost for the prostate bed, as it resulted in significantly better plan quality in shorter time compared to combined optimization. Modulation Complexity Scores were higher with sequential plans.

**EP-1882 Dosimetric comparison between proton SFUD, IMPT and SBRT Boost in clivus chordoma radiotherapy**

M. Vidal<sup>1</sup>, A. Gerard<sup>1</sup>, C. Barnel<sup>1</sup>, C. Peucelle<sup>1</sup>, D. Maneval<sup>1</sup>, A. Claren<sup>1</sup>, F. Guedea Edo<sup>2</sup>, J. Doyen<sup>1</sup>  
<sup>1</sup>Centre Antoine Lacassagne, Institut Méditerranéen de Protonthérapie, Nice, France ; <sup>2</sup>Institut Català d'Oncologia, Servicio de Oncología Radioterápica, Barcelona, Spain

**Purpose or Objective**

Clivus chordoma is a recognized indicator for protontherapy treatment [1]. Dose escalation is very challenging in this localization due to chiasma, optic nerves and brainstem proximity and their low dose tolerance. The idea of this work is to dosimetrically test different treatment techniques available at Centre Antoine Lacassagne (Nice, France) to reach the therapeutic dose (72-74 Gy RBE), including proton therapy

single-field uniform dose (SFUD) and intensity modulated protontherapy (IMPT) both for sequential and integrated proton boost (SIB) and stereotactic body radiotherapy (SBRT) (Cyberknife®) for sequential boost. The hypothesis was that SBRT could achieve better coverage and conformity than IMPT for the boost.

**Material and Methods**

10 patients with a clivus chordoma were included in this study. Protontherapy SFUD and IMPT plans were computed with RayStation 6.0 (RaySearch Laboratories, Sweden) and realized with a CTV-based robust optimization with parameters as follow: 3% of the range for range uncertainties and 3 mm for metric uncertainties (patient positioning, contouring, robot couch accuracy...). SBRT treatments were planned with Multiplan (Cyberknife®, Accuray, USA). Plans were calculated for sequential boost with proton SFUD, IMPT and SBRT with 50.4 Gy RBE (1.8Gy RBE/fraction) delivered to the low dose CTV and 23.4 Gy RBE (1.8Gy RBE /fraction) for PT plans or 22 Gy RBE (2Gy RBE /fraction) for SBRT plans to reach 73.8 Gy RBE for PT plans and 72.4 Gy RBE in SBRT. SIB plans were computed to deliver 73.5 Gy RBE (2.1 Gy RBE /fraction) to this volume, the low dose CTV receiving 56 Gy RBE (1.6 Gy RBE /fraction). SBRT was not used for the planning of the low dose CTV because of its large size.

**Results**

The dose constraints to the OAR were evaluated following the ICRU91 recommendations for SBRT plans and ICRU78 recommendations for PT plans. All plans were performed to be clinically deliverable and to respect the OAR constraints - the difference between the plans is about the tumor coverage, conformity and homogeneity. In general, plans comparison showed that IMPT SIB achieved better tumor coverage for the boost than SFUD SIB (50.8% vs 70.9% for the example patient shown in Fig.1 and Fig.2); this was also better than sequential SFUD (60.4% vs 70.9%); the best tumor coverage was however reached with SFUD + SBRT technique (80.2% tumor coverage for the example patient). This tendency was observed for 7 patients over 10. For the other patients the SIB strategy was adopted due to the CTV geometries (large high dose target volume).

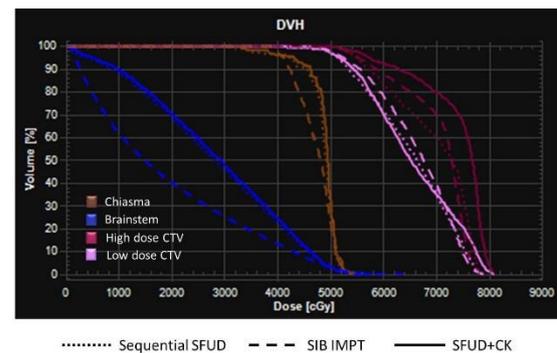

Figure 1. Dose Volume Histogram for sequential SFUD, IMPT SIB and SFUD combined with SBRT plans computed for 2 critical OAR (brainstem, chiasma) and the 2 target volumes for one patient of the cohort.

Figure 2. Dose distribution for IMPT SIB (left), sequential SFUD (center) and SFUD combined with SBRT (right) plans computed for one patient of the cohort.

**Conclusion**

7 over 10 patients were treated with the SBRT technique to reach the therapeutic dose of 73.8 Gy RBE in addition to the SFUD irradiation for the low dose volume, due to

the better coverage of the high dose CTV, while respecting the constraints of the critical OAR (brainstem, chiasma, optic nerves).

#### EP-1883 Lung tumor target delineation: different segmentation strategies

C. Gasperi<sup>1</sup>, S. Borghesi<sup>2</sup>, L. Noferini<sup>1</sup>, C. Sottocornola<sup>1</sup>, A.S. Curion<sup>1</sup>, F. Zenone<sup>1</sup>, P. Pernici<sup>2</sup>, R. De Majo<sup>2</sup>, S. Nucciarelli<sup>2</sup>, S. Nanni<sup>2</sup>, S. Bertocci<sup>2</sup>, P.G. Gennari<sup>2</sup>, A. Rampini<sup>2</sup>, L. Lastrucci<sup>2</sup>, C. Iermano<sup>2</sup>, E. Tucci<sup>2</sup>  
<sup>1</sup>San Donato Hospital, Health Department Staff - Medical Physics, Arezzo, Italy ; <sup>2</sup>San Donato Hospital, Radiotherapy Department, Arezzo, Italy

#### Purpose or Objective

Precise definition of the target volume is one of the crucial factors in the management of Non-Small Cell Lung Cancer (NSCLC) with Stereotactic body radiotherapy (SBRT). It is widely recognized that the motion pattern of lung tumors varies greatly among patients. Therefore tumor motion should be assessed with patient specific image acquisition, to ensure adequate tumor coverage and minimizing dose to the Organs at Risk. The "gold standard" approach for defining an Internal Target Volume (ITV) is to use gross tumor volume (GTV) delineated over several phases in course of one respiratory cycle. It is a time consuming method and different Institutions have adopted several alternative techniques which compress all temporal information into one CT image set, to optimize work flow efficiency. The purpose of this study is to evaluate alternative target segmentation strategies with respect to the gold standard.

#### Material and Methods

Twenty lung cancer SBRT patients, treated on a linac with 4 mm width multileaf-collimator (MLC), were analyzed retrospectively. From the acquisition of a low-pitch helical CT scan (Untag CT) combined with a respiratory monitor system signal, four-dimensional CT (4D-CT) scans were reconstructed for each patient. GTV was delineated based on 4 single respiratory phases and on Maximum Intensity Projection (MaxIP), Minimum Intensity Projection (MinIP), Mean Intensity Projection (MeanIP) CTs and Untag CTs. Comparison was performed on Dice similarity coefficient (DSC). The relative position between the delineated target was evaluated calculating the centroid distance between volumes.

#### Results

GTVs derived from different MaxIP and MeanIP image sets were at least comparable with the single phase ITV delineation, with DSC values varying from 0.551 to 0.936 for Untag, from 0.331 to 0.877 for MaxIP, from 0.354 to 0.877 for MeanIP. MinIP GTV delineation was less comparable to the 4D-CT ITV with DSC range between 0.07 and 0.8. The differences in relative position of target volume localization were small and in all cases < 3mm. The mean differences  $\pm$  SD of the centroid distances for ITV and GTV\_Untag, GTV\_maxIP, GTV\_meanIP, GTV\_minIP were 0.18 $\pm$ 0.16 cm, 0.18 $\pm$ 0.16 cm, 0.23 $\pm$ 0.19 cm, 0.26 $\pm$ 0.19cm respectively.

#### Conclusion

Our results indicate that the delineated targets were comparable for Untag, MaxIP and MeanIP CT with respect to the standard ITV from 4DCT single phase method. The use of the MinIP leads to an underestimation of the contoured volume. The spatial accuracy of the tumor volume is limited to a range within 3 mm (mean distance of the volume centroids) and this leads to a good spatial agreement between PTVs, if generated by expanding an uniformly isotropic 5 mm margin from ITV and GTVs. Among various techniques used for image segmentation, Untag, MaxIP and MeanIP GTVs could be considered as a geometrical surrogate of the standard ITV.

#### EP-1884 Commissioning and clinical validation of FRED: Monte Carlo on GPU for proton beam therapy

Rucinski<sup>1</sup>  
<sup>1</sup>Institute of Nuclear Physics PAN, Proton Radiotherapy Group, Krakow, Poland ; <sup>2</sup>INFN, Sezione di Milano, Milan, Italy ; <sup>3</sup>TIFPA, Trento Institute for Fundamental Physics and Applications, Trento, Italy ; <sup>4</sup>CNRS/CREATIS, Umr 5220, Lyon, France ; <sup>5</sup>Sapienza Università di Roma, Dipartimento di Scienze di Base e Applicate per Ingegneria, Rome, Italy ; <sup>6</sup>ZonPCT/Maastro Clinic, ZonPCT/Maastro Clinic, Maastricht, The Netherlands ; <sup>7</sup>Maria Skłodowska-Curie Institute - Oncology Center, Oncology Clinic, Krakow, Poland ; <sup>8</sup>AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland ; <sup>9</sup>University of Trento, Department of Physics, Trento, Italy

#### Purpose or Objective

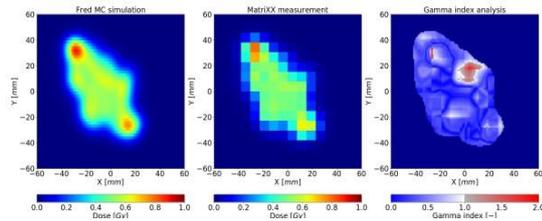

This work presents commissioning and validation of GPU-accelerated Monte Carlo (MC) code FRED at proton beam therapy (PBT) facility in Krakow. The aim of this study was to develop fast proton beam model phase space implementation method exploiting experimental data acquired during the facility start-up. We validate FRED simulations against patient quality assurance (QA) measurements following clinical acceptance procedures. Ultimately we utilize time performance of FRED for recalculation of clinical treatment plans with variable radiobiological effectiveness.

#### Material and Methods

A GPU-accelerated MC tool FRED (Fast pArTicle thErapy Dose evaluator; Schiavi et al. 2017) was developed at Sapienza University of Rome and is investigated at Krakow PBT centre. FRED was already validated against FLUKA and GEANT4, as well as clinical data from CNAO facility. The depth-dose distributions (DDD) of single pencil beams measured in water phantom and lateral beam profiles in air for 17 energies in 70-226.1 MeV range were used to build a FRED dedicated phase space library. The validation procedures included QA measurements of spread out Bragg peak (SOBP) of different range in water and comparison of more than 182 measurements of Krakow patient treatment fields. The gamma index (GI) analysis were used to evaluate the dosimetric results of MC calculations.

#### Results

The DDDs of a single proton pencil beam in water for various energies simulated in FRED MC code were in agreement with the commissioning measurements: the range (R80%) of the pencil beams agreed within 0.1 mm, the absolute dose difference along the pencil beam profile was below 5%, the FWHM of the Bragg peak agreed within 0.3 mm, the distal fall-off width between 80% and 20% Bragg peak dose agreed within 0.07 mm. The simulations of verification plans in water were performed and evaluated against measured data using GI method with 3%/2mm passing criteria (see example field in Figure). The dose distributions from FRED fulfill the Krakow facility QA acceptance criteria (passing rate > 90% for dose > 10% of maximum dose) with average passing rate 96.28(3.3)% (1 sigma). For a patient verification treatment plan the average tracking rate was 8.5(1.6)x10<sup>6</sup> protons / sec (1 sigma).

### Conclusion

FRED was commissioned and validated against the experimental data acquired during the start-up of PBT centre in Krakow. A fast procedure for phase space library implementation was developed. FRED passed clinical acceptance tests required to admit certified TPS for clinical use. Once commissioned and tested with patient CT data, FRED can be used for fast recalculation of clinical treatment plans.

### EP-1885 Neutron beam design and dosimetric evaluation for accelerator-based Boron Neutron Capture Therapy

S. Bortolussi<sup>1</sup>, I. Postuma<sup>2</sup>, N. Protti<sup>2</sup>, S. Fatemi<sup>2</sup>, C. Magni<sup>1</sup>, S. Gonzalez<sup>3</sup>, S. Altieri<sup>1</sup>

<sup>1</sup>University of Pavia and INFN, Department of Physics, PAVIA, Italy ; <sup>2</sup>INFN, Unit of Pavia, Pavia, Italy ; <sup>3</sup>CNEA, Computational Dosimetry and Treatment Planning group, Buenos Aires, Argentina

### Purpose or Objective

Boron Neutron Capture Therapy (BNCT) is a form of hadrontherapy based on the administration of a drug able to concentrate adequate quantities of <sup>10</sup>B into the tumour and on the subsequent irradiation with low-energy neutrons. At these energies, the neutron capture reaction in <sup>10</sup>B occurs with a cross section of almost 4000 b. The reaction produces two high-LET, short-range particles (alpha particle and <sup>7</sup>Li ion) that cause non-reparable damage only to the cell where they are created. If <sup>10</sup>B concentration is higher in the tumour than in normal cells, it is possible to deliver a therapeutic dose to the malignancy while sparing the healthy tissues. A project to build a clinical BNCT facility in Italy based on a proton accelerator is underway. The proton beam produces neutron by (p,n) reaction in a Be target and a Beam Shaping Assembly (BSA) has been designed to obtain an epithermal neutron beam to treat deep-seated tumours. To optimize the beam, the geometry of BSA was first set-up to comply with physical in-air figures of merit, traditionally used to evaluate the suitability of a neutron facility for BNCT. The beam has been then improved according to its dosimetric performance in real cases of deep-seated tumours and taking into account peripheral dose in-patient and in the environment.

### Material and Methods

The clinical neutron beam has been designed by MCNP. The BSA geometry and materials have been selected among different possibilities according to the in-air physical characteristics of the beam, such as epithermal flux and contaminations from thermal and fast dose components and from gamma. The selected beams have been tested on a real case of limb osteosarcoma to evaluate the potentiality to deliver a high radiation dose with a uniform distribution in the tumour while keeping the dose to the most radiosensitive organ below the tolerance limit. The treatment planning system NCTPlan, already used for clinical BNCT, has been employed. Finally, radioprotection calculation in the treatment room and peripheral dose in a human model in the irradiation position has been used to further optimize the beam.

### Results

An epithermal beam peaked around 1 keV has been obtained with a BSA whose main component is aluminum

fluoride, a material obtained by an original procedure based on powder sintering. Dosimetric results obtained with the final beam design show that BNCT can deliver high doses to tumour respecting the dose constraints in the critical organs.

### Conclusion

As the selectivity of BNCT is due to boron uptake more than to the neutron beam itself, BNCT can be an option to treat tumours that are too large or infiltrated into the normal tissues or too close to very radiosensitive organs. Moreover, it could be exploited for metastatic spreads. Clinical experience show that a favorable dose distribution is possible also for tumours that have no other treatment options, and treatment planning simulations with this neutron beam demonstrate that clinical BNCT is possible with this technology.

### EP-1886 Efficacy of a hydrogel spacer in 3D-CRT for prostate cancer

M. Ogita<sup>1</sup>, H. Yamashita<sup>1</sup>, S. Sawayanagi<sup>2</sup>, W. Takahashi<sup>1</sup>, K. Nakagawa<sup>1</sup>

<sup>1</sup>The University of Tokyo Hospital, Radiology, Tokyo, Japan ; <sup>2</sup>Teikyo University Hospital, Radiology, Tokyo, Japan

### Purpose or Objective

Intensity-modulated radiotherapy (IMRT) can reduce the toxicity of prostate RT, but three-dimensional conformal radiotherapy (3D-CRT) is still used in many facilities. Insertion of a hydrogel spacer creates the space between prostate and rectum. We aimed to evaluate the 3D-CRT plan using a hydrogel spacer can fulfill the dose constraints of IMRT for prostate cancer.

### Material and Methods

From April 2017 to July 2018, the planning computed tomography (CT) scans of 39 consecutive prostate cancer patients received stereotactic body radiotherapy in our institution were used in this analysis. All patients inserted a hydrogel spacer before the treatment and underwent CT scans before and after the hydrogel insertion. The planning CT scan was taken with a full bladder and empty rectum. The 3D-CRT plan was made based on three types of risk groups based on NCCN classification; low, intermediate, and high risk. CTV included prostate + seminal vesicle (SV) 2cm for high risk, prostate + SV 1cm for intermediate, and prostate only for low risk. PTV margin of 7 mm except for 5 mm posterior around the CTV were added. The 3D-CRT plan included 10 MV of coplanar seven photon beams, and 76 Gy/38fr delivered to isocenter. Dose constraints for rectum and bladder were V70 Gy ≤ 15%, V65 Gy ≤ 30%, V40 Gy ≤ 60%, and V50 ≤ 50% for femoral head.

### Results

Thirteen (33%), 19 (49%) and 35 (90%) patients before the spacer insertion fulfilled the rectum dose constraints, and 34 (87%), 38 (97%), and 38 (97%) after the spacer fulfilled rectum dose constraints for high, intermediate, and low risk planning, respectively. A hydrogel spacer use significantly increased the dose constraints fulfilment rate in high risk (P < 0.001) and intermediate risk (P = 0.004), but no difference was found in low risk planning (P = 0.25). The mean rV70 Gy, rV50 Gy, and rV40 Gy were 12% vs 23%, 17% vs 29%, and 52% vs 62% in high risk group (with vs without spacer, P < 0.001, P < 0.001, P < 0.001, respectively). Thirty-three (85%) vs 23 (59%) in high risk, 35 (90%) vs 29 (74%) in intermediate risk, and 38 (97%) vs 36 (92%) in low risk planning fulfilled bladder dose constraints, (with vs without spacer, P = 0.006, P=0.03, P = 0.25, respectively). Mean PTV D95 was 72 Gy, 72 Gy and 71 Gy in high, intermediate and low risk with a spacer, respectively. The patient who had a large prostate had difficulty to fulfill the dose constraints even with a spacer.

### Conclusion

Most of the 3D-CRT plan fulfilled IMRT dose constraints by using a hydrogel spacer. If IMRT is not available, a

combination of 3D-CRT and a hydrogel spacer may become a treatment option for prostate RT.

**EP-1887 Dosimetric and volumetric evaluation of MR-only planning for radiotherapy of rectal cancer**  
 S. Vieira<sup>1</sup>, O. Pares<sup>1</sup>, N. Loução<sup>2</sup>, J. Stroom<sup>1</sup>, I. Santiago<sup>3</sup>, C. Greco<sup>1</sup>, C. Matos<sup>3</sup>  
<sup>1</sup>Fundação Champalimaud, Radiotherapy, Lisboa, Portugal; <sup>2</sup>Philips Iberia, Radiology, Lisbon, Portugal; <sup>3</sup>Fundação Champalimaud, Radiology, Lisboa, Portugal

#### Purpose or Objective

MR delineations in radiotherapy are generally more accurate than on CT but for dose calculations CT data are mandatory. However, software has become available that transforms MR data into pseudo-CT data. In this abstract we study the pros and cons of switching to MR-only planning for radiotherapy of rectal cancer.

#### Material and Methods

Preliminary data of five patients with locally advanced rectal cancer were available. Radiotherapy VMAT plans (Varian) were developed using our clinical simulation protocol that includes the use of FDG PET/CT. Magnetic Resonance for Calculating Attenuation (MRCAT, Philips®) images with five different grey values were generated from 3D T1-weighted mDIXON images (outside the clinical protocol). We used 2 echoes, 1x1x2.5 mm spatial resolution, TR/TE1/TE2 1.64/3.8/5.7(ms), and scan time 3min16s. Two aspects of the new procedure were studied: Part 1: We compared dose calculation on the MRCAT and on the planning CT. MRCAT was matched with the planning CT and the treatment plan with tumor and OAR delineations was copied to the MRCAT. Then the dose was recalculated on the MRCAT (figure 1a/b).

Part 2: A radiation oncologist and radiologist, both specialists in rectal cancer, together delineated MRI-only target volumes and OARs (figure 1c/d). New radiotherapy plans were then generated and compared with the existing clinical plans.

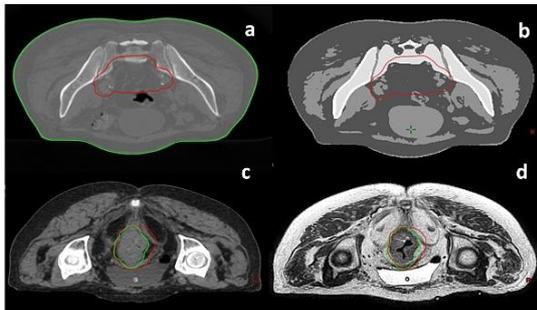

Figure 1—Part1: Target volume in the planning CT (a) and copied to the MRCAT (b) for patient 1. Part2: Target volume boost segmented by the radiologist (green) and the radiation oncologist (red) for patient 4.

#### Results

Part 1: Regarding the dose comparison, doses in target volumes and critical organs calculated on MRCAT differed only slightly from clinical doses: on average mean doses in target and OARs <1%, with standard deviations of 0.4-2.2% (figure 2). Deviations could be explained more by differences in patient anatomy between planning CT and MRCAT than by differences in Hounsfield units.

Part2: MRI-only pelvic PTV volumes were on average 14% ( $\pm 19\%$ , 1SD) smaller than clinical volumes. Just one case actually presented a larger MRI-only target volume due to better visualisation of the anterior mesorectal fascia. MRI-only boost PTV volumes were on average 40% ( $\pm 5\%$ , 1SD) smaller. Dose coverage of tumor volumes was similar in both MRI-based and clinical plans.

A disadvantage of the MRCAT-based planning was that online matching with CBCT on the linac appeared hardly feasible due to the limited number of grey values in the

MRCAT CT. Therefore, rectum cancer cases are now being tested with improved MRCAT software which is able to generate pseudo-CT images with infinite number of grey levels.

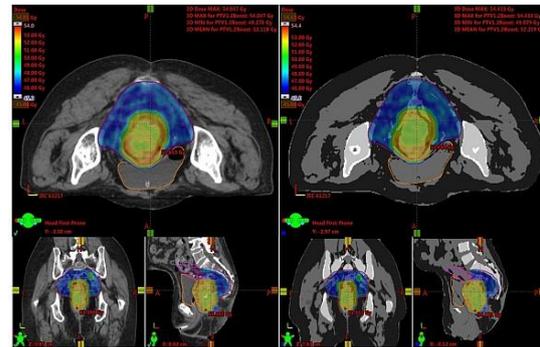

Figure 2—Part1: Dose distribution of the clinical plan calculated on the planning CT (left) and on the MRCAT (right) for patient 1.

#### Conclusion

Dosimetrically even low-resolution MRCAT images are suitable for planning rectum cancer patients. Using MRI only for target delineation reduced the CTV size considerably. When higher resolution MRCAT images become available for better online matching, planning CTs may be discarded completely for rectum radiotherapy.

#### EP-1888 Validation of automated planning with RapidPlan for prostate bed VMAT radiotherapy

B.L. Rekstad<sup>1</sup>, P. Lønne<sup>1</sup>

<sup>1</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway

#### Purpose or Objective

RapidPlan is a module for automated planning (AP) in the Varian Eclipse treatment planning system based on DVH-estimation from previous treatment plans. We wanted to explore and validate the module for prostate bed VMAT, prescribed with only one target volume dose level and rectum, bladder, anal canal, femoral heads and penile bulb as organs at risk (OARs). The aim of the study was to investigate possible use of AP and to what extent AP is comparable to or better than manual treatment planning regarding target volume coverage, dose to OARs.

#### Material and Methods

A model was built in Eclipse 13.6 based on 70 clinical prostate bed VMAT plans. Treatment was given with 6 MV on a Varian Clinac 2300iX equipped with Millennium 120 MLC. Either one (n=55) or two (n=15) full arcs were used. Prescribed dose to the prostate bed CTV was 66 - 70 Gy delivered in 33 -35 fractions. The model was tuned by slightly varying the normal tissue objective (NTO) function parameters and also adding a maximum dose constraint to rectum, bladder and anal canal. A validation of the model was then performed by applying the model to 30 other prostate bed cases and comparing with manual clinical plans. Isocenter was the same in clinical and AP plans. All AP plans were made with one arc. With AP the model was applied and run through optimization once without further interaction.

#### Results

Target volume doses were comparable for manual and AP plans. Mean CTV D<sub>98%</sub> was 98.3 % and 98.5 % and mean PTV D<sub>98%</sub> was 95.8 % and 95.3 % for manual and AP plans respectively. This equal target volume coverage is also evident from the mean DVHs for CTV and PTV for the 66 Gy cases (n=23) (Figure 1). For OARs mean DVHs show lower AP doses for rectum, anal canal, femoral heads and penile bulb in medium dose regions, and slightly higher AP doses for bladder (Figure 1). Also, the rectal dose tends to be higher in the high dose region for some of the AP plans. This should be explored more before clinical use. For

clinical and AP plans mean rectal dose was 40.2 Gy and 36.8 Gy, mean bladder dose was 44.6 Gy and 44.1 Gy, and mean anal canal dose was 29.9 Gy and 27.7 Gy.

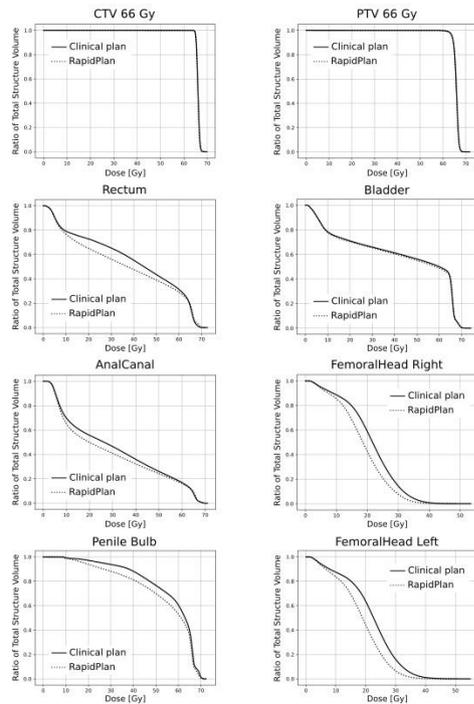

Figure 1. Mean dose volume histograms for prostate bed target volumes and organs at risk for clinical plans and RapidPlan plans.

#### Conclusion

Automated prostate bed VMAT planning with RapidPlan results in clinically acceptable and possibly favorable treatment plans from a DVH perspective. Dose distributions should also be thoroughly analyzed before clinical implementation.

#### EP-1889 Evaluation of organ-motion based robust optimisation for RT of the breast, axilla, and IMC

I. Blasiak-Wal<sup>1</sup>, A. Dunlop<sup>1</sup>, R. Colgan<sup>1</sup>, A. Ranger<sup>2</sup>, A. Kirby<sup>2</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy Physics, Sutton, United Kingdom ; <sup>2</sup>ICR and Royal Marsden NHS Foundation Trust, Clinical Oncology, Sutton, United Kingdom

#### Purpose or Objective

Simultaneous irradiation of the internal mammary chain (IMC) alongside treating the whole breast and axilla nodes using VMAT (in breath-hold) is increasing. A concern of VMAT delivery for breast RT is the lack of skin flash that is utilised in tangent-based delivery to account for setup uncertainties and increases in the patient contour. We aimed to develop and validate a methodology using organ-motion based robust optimisation, to generate VMAT plans for simultaneous irradiation of the whole breast, IMC, and axilla nodes.

#### Material and Methods

Non-robust plans were initially generated in order to determine a patient-specific optimal objective function. In order to account for changes in position, size, and shape of the breast target tissue, organ-motion simulation available within a commercial treatment planning system (TPS) (RayStation 7.0, RaySearch Laboratories, Stockholm) was used to simulate CTs exhibiting worst-case breast swelling scenarios. Robustly-optimised plans were generated using the simulated CTs and the objective function from the non-robust plan. For five patients,

including one who demonstrated significant breast swelling, the robust plans were compared to the corresponding non-robust plans by comparing the nominal dose distributions on the planning CT and by calculating daily delivered doses using cone beam CT (CBCT) images (n = 67) taken prior to each treatment delivery.

#### Results

No significant differences were observed between the robust and non-robust plans for the nominal dose distributions on the planning CT with both techniques able to meet all mandatory clinical goals taken from the HeartSpare Plus trial. Figure 1 illustrates the skin flash that can be achieved using organ-motion based robust optimisation.

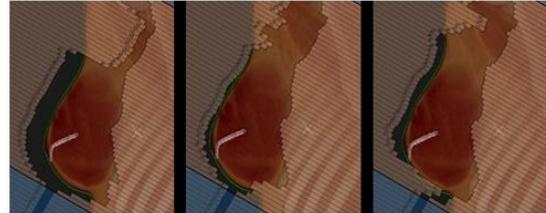

Figure 1: Beams-eye-view of typical segment for: (left) robustly-optimised plan; (centre) non-robust plan; and (right) plan generated using a virtual bolus technique. The patient external region of interest is shown as a green contour.

When considering the daily delivered doses, the robust plans demonstrated significantly better whole breast clinical target volume (CTV) coverage (Table 1) and this is particularly evident in the patient who demonstrated significant breast swelling. The robust plans demonstrated a significant advantage in covering the superficial part of the breast CTV with prescription dose. Delivered doses to organs at risk and IMC and Axilla CTVs were similar for the robust and non-robust plans (Table 1).

Table 1: Estimation of delivered dose statistics for the robust and non-robust plans. Both plans were calculated on 67 CBCTs using bulk-density overrides for dose calculation. The superficial breast region of interest consisted of the outermost 5 mm of the breast CTV.

ROI	Statistic	Dose statistics for all CBCT-based delivered dose estimation			
		Robust plans		Non-robust plans	
		Average	SD	Average	SD
Breast CTV	D98 (Gy)	38.3	0.5	37.6	1.2
	D95 (Gy)	38.7	0.4	38.3	0.7
	D50 (Gy)	40.1	0.3	40.0	0.3
	D2 (Gy)	41.7	0.3	41.4	0.3
Axilla CTV	D98 (Gy)	39.0	0.9	39.1	0.9
	D95 (Gy)	39.4	0.7	39.5	0.6
	D50 (Gy)	40.3	0.5	40.4	0.6
	D2 (Gy)	41.4	0.6	41.6	0.7
IMC CTV	D98 (Gy)	37.7	1.6	38.1	2.0
	D95 (Gy)	38.2	1.4	38.6	1.6
	D50 (Gy)	40.2	0.8	40.5	0.7
	D2 (Gy)	41.7	1.0	41.8	0.8
Superficial Breast	D98 (Gy)	37.4	1.6	35.9	2.4
	D95 (Gy)	38.3	0.6	36.8	1.7
Heart	mean (Gy)	4.5	1.3	4.5	1.2
Ipsi-lateral Lung	V17G (%)	31.0	1.9	31.0	1.7
	mean (Gy)	13.3	0.6	13.2	0.6
Contra-lateral Lung	mean (Gy)	3.1	0.1	3.0	0.2
Contra-lateral Breast	mean (Gy)	3.3	0.1	3.3	0.1
Humeral Head	mean (Gy)	11.5	5.1	11.0	4.7

#### Conclusion

Organ-motion-based robust optimisation available within a commercial TPS is able to generate plans that are clinically acceptable in the nominal (planning CT) scenario and are more robust, when compared to the non-robustly optimised plans, to both typical changes in patient shape and cases of significant breast swelling.

#### EP-1890 Patient specific conversion of CBCT images for proton therapy treatment planning

N. Krah<sup>1</sup>

<sup>1</sup>CNRS / University Lyon, Creatis lab UMR 5220, Lyon, France

### Purpose or Objective

Cone beam CT (CBCT) is becoming a commonly available imaging technology in radiotherapy. However, the presence of artifacts and poor accuracy of Hounsfield Units (HU) preclude its use for treatment planning purposes in proton therapy where range accuracy is crucial. We investigate whether a sufficiently accurate proton relative stopping power (RSP) map can be obtained from a CBCT image when using a patient specific calibration of the HU-RSP conversion curve based on proton radiographic images.

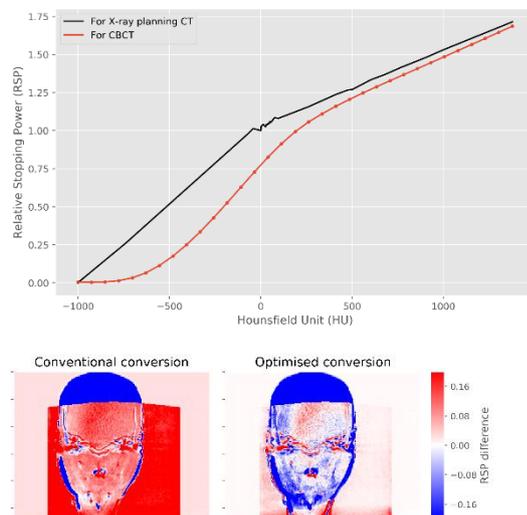

### Material and Methods

We employ a calibration procedure which on one hand uses a proton radiographic image potentially acquired with readily available detector hardware in pencil beam scanning delivery and on the other hand a proton digitally reconstructed radiography based on a CBCT image. The difference between the two is minimized using a recently developed regularized optimization method. The result is a HU-RSP curve which can be used as input to the treatment planning system in combination with the CBCT image instead of the conventional X-ray planning CT.

We applied the calibration to head and neck patient cases who were scheduled for proton therapy and received regular CBCT scans prior to treatment sessions. The CBCT images were rigidly registered to the planning CT. Tomographic reconstruction of the CBCT images was performed with the vendor software including only basic artifact correction for now. Proton radiographies were simulated with the GPU accelerated Monte Carlo code "Fred" using an idealized range telescope set-up and the same data processing chain which we apply to experimental data. The X-ray planning CT converted to RSP through a stoichiometric HU-RSP conversion curve was used as simulation input.

### Results

Figure 1 shows an example of an optimized HU-RSP conversion curve to be applied to a CBCT image. It differs noticeably from the conventional one especially in the range of lower HU values. The HU intervals of the curve, which are usually chosen in accordance with human tissue properties, need to be adjusted in this special application and a regular spacing appeared to yield most reasonable results. Figure 2 shows the difference of RSP values between the CBCT and the planning CT. Agreement is overall much better when using the optimized curve, although spatially dependent discrepancies are still visible. We are currently investigating to which extent more advanced artifact correction during the CBCT reconstruction can improve this. Preliminary results of treatment plan recalculation on CBCT images already showed great improvement when using the optimized HU-RSP.

### Conclusion

Our results suggest that this novel way of converting and correcting CBCT images to RSP for the use in proton therapy treatment planning is feasible. The use of readily available artifact correction techniques are expected to further improve RSP accuracy. The technique could be easily employed in practice using readily available detector hardware.

### EP-1891 A new hotspot correction algorithm in Modulated Electron Radiation Therapy utilizing 3D printed boli

B. Basaric<sup>1</sup>, J. Robar<sup>2</sup>, R. Orbovic<sup>1</sup>, A. Dennis<sup>1</sup>, C. Majcher<sup>1</sup>

<sup>1</sup>Adaptiiv Medical Technologies Inc., Research and Development, Halifax, Canada ; <sup>2</sup>Nova Scotia Health Authority, Department of Medical Physics, Halifax, Canada

### Purpose or Objective

Modulated Electron Radiation Therapy (MERT) modulates the electron beam by changing the thickness of the bolus resulting in a 3D printed non-uniform thickness bolus that conforms the prescribed dose to the distal part of the PTV. However, there may be a certain trade-off between the resulting conformity and dose homogeneity to the PTV depending on shapes of the PTV and modulated bolus and on the energy of the beam. The objective of this work is to introduce a new hotspot algorithm that changes the shape of the modified electron bolus in such a way it reduces hotspots and keeps dose conformity to the PTV similar to the initial modified electron bolus.

### Material and Methods

Initial modulation of the 3D printed bolus that insures the conformity of the prescribed dose to the distal part of the PTV was designed in the "3D Bolus" software (Adaptiiv Medical Technologies Inc.). Overall, 6 MERT plans were calculated in Eclipse TPS (Varian Medical Systems, Inc.). 5 plans were calculated on a phantom where different shaped PTVs were drawn which RT plans ultimately resulted in different dose homogeneity and an overall good conformity in all cases. Hotspots ranged from 114% (1 small peak case) to 142.2% (1 large peak case). A new hotspot correction algorithm uses PTV, contoured hotspot and modulated bolus RT Structures to estimate the location of peaks in a 3D modulated bolus winged edge mesh in order to reduce the height of these peaks in respect to the corresponding valleys resulting in less scattered radiation toward the hotspot area. The amount of peak reduction on the modulated bolus was scaled from 100% (intact modulated bolus) to 0% (completely reduced peaks resulting in flattened modulated bolus). For each of the 6 cases, hotspot corrected modulated bolus was produced using peak reduction scaling factors of 80%, 60%, 40%, 20% and 0%.

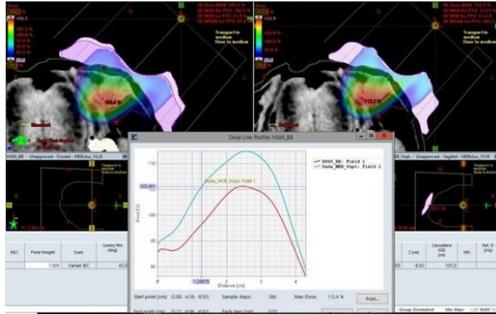

### Results

In all cases, a significant hotspot reduction was noticed which ranged from 23-40% in the 1 large case, 24-33% in the 2 large peaks case, 6-15% in the 1 small peak case, 8-22% in the 2 small peaks case, 10-20% in the no-peaks case and 6-9% in the patient case. In all cases, a progressive reduction of maximum dose to the plan was noticed as the peak reduction scaling factor was closer to 0% while at the same time a progressive loss of conformity of the prescribed dose to the PTV was also noticed. All cases produced at least 1 plan (with one particular peak reduction scaling factor) that satisfied both clinically acceptable level of maximum dose to the plan and conformity of the prescribed dose to target volume that was comparable to the initial modulated bolus electron plan.

### Conclusion

The new hotspot correction algorithm showed in all cases that by scaling the height reduction of the bolus peaks, a clinically acceptable plan can be achieved that satisfies

both the maximum dose to the PTV as well as the conformity of the prescribed dose to the PTV.

Picture 1: Dose comparison before hotspot correction (right) and after (left)

**Electronic Poster: Physics track: Radiobiological and predictive modelling, and radiomics**

**EP-1892 Predictive Response To Radiotherapy Of Head And Neck Cancer Using Radiomics Analyses Of Cbct.**

S. Sellami<sup>1</sup>, D. Bouzid<sup>2</sup>, M. Hatt<sup>2</sup>, D. Visvikis<sup>2</sup>, F. Lucia<sup>1</sup>, O. Pradier<sup>1</sup>, U. Schick<sup>1</sup>

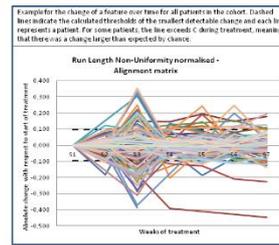

<sup>1</sup>University Hospital- Brest Morvan, Radiation Oncology Department, Brest, France ; <sup>2</sup>LaTIM- University of Brest, Imaging Research Laboratory- INSERM- UMR 1101, Brest, France

**Purpose or Objective**

Radiotherapy for head and neck cancer (HNC) is now guided by cone-beam computed tomography (CBCT). Advanced imaging features (radiomics) extracted from diagnostic imaging have already been shown to predict outcome in several tumor models. The aims of this study were to investigate a methodology for feature selection of a longitudinal radiomics approach and to develop a radiomics signature based on CBCT to predict response to radiotherapy.

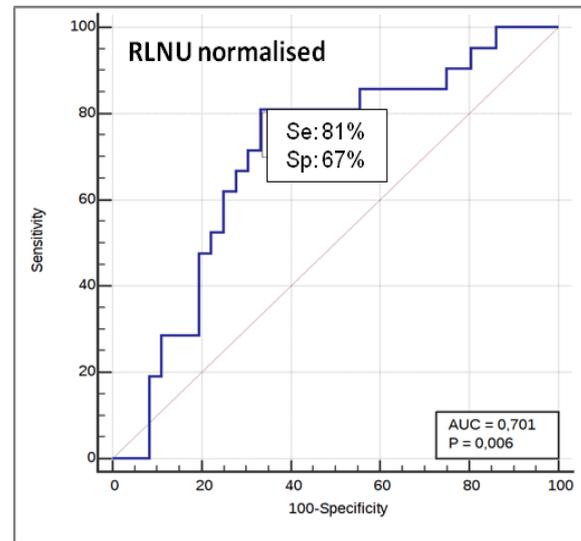

**Material and Methods**

In 102 HNC patients grouped in a training (=68) and validation (=34) cohorts, Gross Tumor Volumes of the primary tumor (GTVT) and metastatic lymph nodes (GTVN) used for the planning were registered to the weekly CBCT images using a deformable registration followed by manual correction. 88 features were extracted from the GTVs on each CBCT. Receiver operating characteristic (ROC) curves were plotted at each week to evaluate the predictive power of response of each feature. Only significant features at each week and independent of volume were pre-selected (AUC) >0.65). Absolute differences (CBCTn-CBCT1, called delta-radiomics) were calculated between features from each weekly CBCT images and the baseline CBCT1 performed before the first fraction. The smallest detectable change (C) with his confidence interval (95%) was determined for each radiomics using the formula  $C=1.96 \cdot SD$ , SD being the standard deviation of differences between features values calculated on CBCT1 and CBCT2. We then selected the features for which the change was more than C for at least 10% of patients at least for one week (Fig.1). A radiomics-based model was built at the time-point that showed most changes. Finally, we compare the prognostic performance of 3 models: clinical, radiomics, and combined.

**Results**

For GTVT, four radiomics features met all criteria. For GTVN, none of the radiomics had an AUC>0.65 at each week, so that we selected the two features with the highest and significant AUC. The number of patients having an absolute delta features variation out of the boundaries was the highest at the third week, thus, this time point was chosen to drive our models. For GTVT, AUCs for predicting the therapeutic response were 0.782 (p<0.001), 0.701 (p=0.0059) and 0.740 (p<0.001) for clinical, CBCT3-radiomics (Run Length Non-Uniformity (RLNU) normalized)(Fig.2) and combined models, respectively. For GTVN, the clinical based model (AUC 0.736, p<0.001) did better than the combined model (AUC 0.563, p=0.143) or the radiomics based model (Elongation, AUC : 0.569). On the validation cohort, the best prediction was given by radiomics for GTVT (AUC:0.639) and by clinical parameters for GTVN (AUC:0.685).

**Conclusion**

We described a feature selection methodology for longitudinal radiomics that is able to select reproducible delta radiomics features which are informative due to their change during treatment. Nonetheless, the prognostic value of the selected delta radiomics features did not seem to improve the prediction already given by the clinical data.

**EP-1893 A machine learning based stain-free method for classification of cell apoptosis stages**

J. Feng<sup>1</sup>, P. Wang<sup>2</sup>, N. Zhang<sup>1</sup>, S. Yu<sup>1</sup>

<sup>1</sup>Tianjin University, Biomedical Engineering, Tianjin, China ; <sup>2</sup>Tianjin Medical University Cancer Institute and Hospital, Radiation Therapy, Tianjin, China

### Purpose or Objective

Cell apoptosis plays critical roles in cancer research and treatment. The most commonly used methods for high-throughput detection of cell apoptosis are based on flow cytometry (FCM) in combination with the dyes which bond to different components in the cells. Despite of the accuracy, these methods are characterized with higher cost and time consuming associated with staining cells. Here we represent a stain-free method based on diffraction imaging flow cytometry and machine learning techniques for detecting cell in different apoptosis stages.

### Material and Methods

For apoptosis induction, human erythroleukemia K562 cells were treated with cisplatin (DDP) in a concentration of 25 mg/ml for 24. And the cell samples without any treatment were used as the control group. Annexin V-PE and SYTOX® Green Dead cell stain were used for cell sorting using fluorescence activated cell sorting (FACS). After cell sorting K562 cells were separated into three sub-groups which were viable, early apoptotic, and late apoptotic/necrotic cells. These sub-groups were measured with our polarization diffraction imaging flow cytometry (p-DIFC) system and the cell images were acquired. In processing the image pairs with s and p polarizations of single cells, a new method based on uniform and rotation invariant local binary patterns (LBP) algorithm for feature extraction was developed. This algorithm has advantages in gray-scale and rotation invariant and dimension reduction of the features. Each image was separated into 100 sub-images, features of each sub-image were extracted and then all features from the 100 sub-images were put together sequentially as a representation (feature vector) of the diffraction image. 2000 feature vectors were constructed for each image pair of a cell. A software tool based on support vector machine (SVM) with linear kernel and radial basis function (RBF) kernel were developed for classification. The training dataset consisted of samples of 2000 early apoptotic cells, 2000 viable cells and 1000 apoptotic/necrotic cells. In the test dataset, numbers of cell samples of these three sub-groups were 250, 250 and 80. After 10-fold cross validation, precision, Kappa statistic, mean absolute error and the area under the curve of the receiver operating characteristic (ROC area) were introduced to evaluate the prediction and classification model.

### Results

Fig.1 shows typical diffraction images of K562 cells in different apoptotic stages. The Kappa statistic, mean absolute error and ROC area showed that the RBF kernel performed better than the linear kernel on the dataset (Table 1). Classification precision of 93.276% on the independent test dataset was obtained.

### Conclusion

With the new method, stable and accurate classification of cells in different apoptotic stages can be achieved.

### EP-1894 On the possibility of estimating the radiosensitivity range in a cell mixture

N. Stavreva<sup>1</sup>, P. Stavrev<sup>1</sup>, D. Penev<sup>1</sup>, A. Nahum<sup>2</sup>, R. Ruggieri<sup>3</sup>, D. Pessyanov<sup>1</sup>

<sup>1</sup>SRD Sofia University "St. Kliment Ohridski", Scientific Research Dpt, Sofia, Bulgaria ; <sup>2</sup>Liverpool University, Physics Department, Liverpool, United Kingdom ; <sup>3</sup>Sacrocuore - don Calabria<sup>1</sup> Hospital, Department of Radiation Oncology, Negrar VR, Italy

### Purpose or Objective

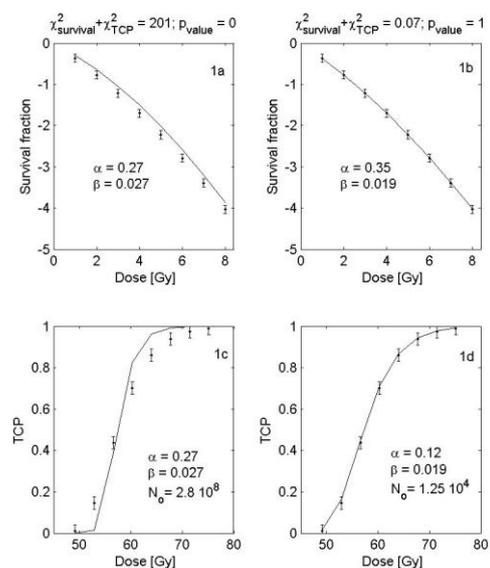

To expand a previous study [1] on tumours that are heterogeneous in cell radiosensitivity and on the observed differences between the values of the effective cell radiosensitivity extracted from fits to pseudo-experimental cell survival data and from fits to pseudo-experimental tumour control probability (TCP) data.

### Material and Methods

A heterogeneous tumour is assumed to consist of the following mixture of cells varying only in  $\alpha$  :  $\alpha_i = [0.1; 0.15; 0.2; 0.25; 0.3; 0.35]$  Gy<sup>-1</sup>,  $\log(N_{0,i}) = [3.7; 4; 4.3; 5; 7; 8]$  with  $B = 0.02$  Gy<sup>-1</sup>; sub-population 'i' consists of initial cell number  $N_{0,i}$  with radiosensitivity  $\alpha_i$ . For this tumour a theoretical cell survival curve is constructed according to the linear-quadratic (LQ) model of cell killing. Also a TCP vs (total) dose curve is constructed based on the Poisson TCP model for  $n = 20$  equal fractions. Both curves consist of 8 points corresponding to different doses. The error in the cell-survival data was considered to be 10% and the error in the TCP data 3%. In this study the two data-sets are then *simultaneously* fitted with a single-component (homogeneous) LQ model of cell killing and a single-component Poisson TCP model respectively. The  $\chi^2$  method of fitting is used on whose basis a p-value is calculated serving as a measure of the goodness of the fit.

### Results

Two different versions of fitting were used. It was firstly assumed that the two data sets may be described with one unique value of the radiosensitivity  $\alpha$ . The result is shown in figs 1a) and 1c) respectively. The p-value is 0. In figs 1b) and 1d) are shown a fit of the LQ model to the pseudo-experimental cell-survival curve and a simultaneous fit of the TCP model to the TCP curve, where two separate values of  $\alpha$  for the two models are assumed. The p-value of the fit is 1. The pseudo-experimental data points are shown in the figures with their assumed error bars.

### Conclusion

A p-value of 0 renders the first version statistically unacceptable. This means that cell survival and the TCP experiments cannot be both described with a single a radiosensitivity value. This conclusion is confirmed by the high p-value (p=1) of the second fit, where two distinctly different best-fit values of  $\alpha$  were obtained. A high value of  $\alpha=0.35$  Gy<sup>-1</sup> from the fit to the cell-survival curve corresponds to the most sensitive sub-population and a relatively low value of  $\alpha=0.12$  Gy<sup>-1</sup> from the fit to the TCP curve corresponds approximately to the most resistant cell subpopulation of the heterogeneous tumour. It should be noted that the best fit value of  $N_0$  also corresponds to the number of cells of the most resistant component of the tumour.

### EP-1895 Multicenter CT phantoms public dataset for radiomics reproducibility studies

P. Kalendralis<sup>1</sup>, A. Traverso<sup>1</sup>, Z. Shi<sup>1</sup>, I. Zhovannik<sup>1,2</sup>, R. Monshouwer<sup>2</sup>, M.P.A. Starmans<sup>3</sup>, S. Klein<sup>3,4</sup>, P. Elisabeth<sup>5</sup>, R. Boellaard<sup>6</sup>, A. Dekker<sup>1</sup>, L. Wee<sup>1</sup>

<sup>1</sup>Maastricht Clinic, Department of Radiation Oncology Maastricht- GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre+- Maastricht- The Netherlands, Maastricht, The Netherlands ; <sup>2</sup>Radboud University Medical Center- Nijmegen- The Netherlands, Department of Radiation Oncology, Nijmegen, The Netherlands ; <sup>3</sup>Erasmus Medical Centre- Rotterdam- The Netherlands, Department of Radiology and Nuclear Medicine, Rotterdam, The Netherlands ; <sup>4</sup>Erasmus Medical Centre- Rotterdam- The Netherlands, Department of Medical Informatics, Rotterdam, The Netherlands ; <sup>5</sup>University Medical Center Groningen- Groningen- The Netherlands, University Medical Center Groningen- Groningen- The Netherlands, Groningen, The Netherlands ; <sup>6</sup>VU Medical Center- Amsterdam- The Netherlands., Department of Radiology and Nuclear Medicine- VU Medical Center- Amsterdam- The Netherlands., Amsterdam, The Netherlands

#### Purpose or Objective

Reproducibility is a fundamental requirement for radiomics-based clinical prediction models. The aim of this study is to describe and provide an open-access Computed Tomography (CT) phantoms image dataset acquired at three different Dutch centers. The data was acquired for radiomics reproducibility studies with respect to variations in acquisition settings, scanners and reconstruction algorithms.

#### Material and Methods

The CT images of the Catphan 700, COPDGene Phantom II (Phantom Laboratory, Greenwich, NY, USA), and the Triple-modality 3D Abdominal Phantom (CIRS, Norfolk, Virginia, USA) were exported in Digital Imaging and Communications in Medicine (DICOM) format from Siemens and Philips scanners. Participating centres were MAASTRO Clinic (Maastricht, NL), Radboud University Medical Center (Nijmegen, NL), and University Medical Center Groningen (Groningen, NL). The scans were acquired by varying the parameters of slice thickness, reconstruction kernels, and tube current. The regions of interest (ROIs) of the COPDGene and Abdominal phantoms were delineated manually in MIRADA DBx (version 1.2.0.59, Mirada Medical, Oxford, United Kingdom). The Catphan700 was used for quality assessment of the scans. Representative axial slices of phantoms and the delineated ROIs of the scans are shown in Figure 1.

#### Results

The scans are publically accessible and reusable via an instance of the eXtensible Neuroimaging Archive Toolkit (XNAT) hosted within the national Dutch research infrastructure (TraIT, www.ctmm-trait.nl). The Phantom Laboratory images have been uploaded to the XNAT collection STW-STRATEGY-Phantom\_Series1: (<https://xnat.bmia.nl/data/projects/stwstrategygs1>). The CIRS multimodality Abdominal Phantom images have been uploaded to the SNAT collection STW-STRATEGY-Phantom\_Series2: (<https://xnat.bmia.nl/data/projects/stwstrategygs2>). An overview of the parameters and protocols used is presented in Table 1.

**Conclusion**  
The phantoms dataset are offered to the radiomics community for the comparison of simple features extracted with different software pipelines. The dataset could be potentially useful for the identification of unstable features with respect to different scanning and acquisition parameters.

<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Radiotherapy, Milano, Italy ; <sup>3</sup>San Raffaele Scientific Institute, Radiology, Milano, Italy ; <sup>4</sup>San Raffaele Scientific Institute, Gastroenterology Surgery, Milano, Italy

#### Purpose or Objective

A radiobiological parameter (early regression index,  $ERI_{TCP}$ ) based on early tumor (GTV) regression was previously found to predict pathological complete remission (pCR) after neo-adjuvant radio-chemotherapy (RCT) of locally advanced rectal cancer (Rca). In current investigation,  $ERI_{TCP}$  was tested against conventional clinical and pathological biomarkers in predicting long-term outcome after RCT delivered within an observational study testing an early regression- guided adaptive boosting technique (ART).

### Material and Methods

Complete data of 65 patients (pts), including overall, loco-regional relapse and distant metastasis-free survival (OS, LRFS, DMFS) information were available. Pts received 41.4Gy in 18 fr (2.3 Gy/fr) delivering ART concomitant boost on the residual GTV in the last 6 fr (3 Gy/fr, GTV  $D_{mean}$ : 45.6Gy). Chemotherapy consisted of oxaliplatin (OXA) 100 mg/m<sup>2</sup> on days -14, 0 (start of RT), and +14, and 5-fluorouracil (5-FU) 200 mg/m<sup>2</sup>/d from day -14 to the end of RT. Uni- and multi-variable Cox regression models for OS, LRFS and DMFS were assessed considering several clinical (age, sex, OXA dose, 5-FU dose, time to surgery, stage) and histological (pCR, pCR or clinical complete response (cCR) followed by surgery refusal (pCR/cCR), Tumor regression grade, Residual vital cells <5%, <10%) variables. High resolution T2-weighted MRI taken before RT (MRI<sub>pre</sub>) and at half RT (MRI<sub>half</sub>) were available and GTVs were contoured by a single clinician ( $V_{pre}$ ,  $V_{half}$ ). The parameter  $ERI_{TCP} = -\ln[(1 - (V_{half}/V_{pre}))^{V_{pre}}]$ , previously introduced to quantify early response, was considered. Models including/not including  $ERI_{TCP}$  (CONV\_model and REGR\_model respectively) were assessed and their ability in discriminating relapsing pts compared.

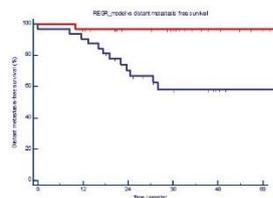

### Results

The median time between RCT and surgery was 11w (range:7-19); 63 pts were operated and two refused surgery after cCR; pCR were 20/63 (32%). The median follow-up was 30 months (range: 5.5-100). OS, LRFS and DMFS at 30 months were 96%, 97% and 80% respectively. Due to the few events the analysis was focused on DMFS: the best CONV\_model included pCR/cCR (HR:0.12,p=0.038) and 5-FU dose>90% (HR: 0.35,p=0.039), with AUC=0.73 (95%CI: 0.62-0.83). The best REGR\_model included  $ERI_{TCP}$  (HR:1.019, p<0.0001) and 5-FU dose>90% (HR:0.18,p=0.005); AUC was 0.87 (95%CI: 0.76-0.94), significantly higher than CONV\_model (p=0.03, Figure 1). When grouping pts according to the best cut-off value for REGR\_model, DMFS at 30 months was 97 % vs 63 % (p=0.0006) for pts below (n=33, 1 event) and above (n=32, 12 events) this value (Figure 2). Higher  $ERI_{TCP}$  values were also associated to worse OS (p=0.036).

### Conclusion

Early regression during RCT for Rca pts as modeled by a Poisson-based TCP formula predicted DMFS better than pCR. An independent impact of the individually administered drug dose was also quantified.  $ERI_{TCP}$  should be considered as a strong outcome predictor with large potentials in treatment individualization.

**EP-1897 Texture analysis of the initial CT to predict the response to neoadjuvant CRT in rectal cancer**  
B. Vandendorpe<sup>1</sup>, C. Durot<sup>2</sup>, L. Lebellec<sup>3</sup>, M. Le Deley<sup>3</sup>, D. Sylla<sup>3</sup>, A. Bimbai<sup>3</sup>, K. Amroun<sup>4</sup>, F. Ramiandrisoa<sup>1</sup>, A. Cordoba<sup>5</sup>, X. Mirabel<sup>5</sup>, C. Hoeffel<sup>2</sup>, D. Pasquier<sup>5</sup>, S. Servagi-Vernat<sup>1</sup>

<sup>1</sup>Institut Jen Godinot, Radiation Oncology, Reims, France ; <sup>2</sup>Centre Hospitalier Universitaire de Reims, Radiology, Reims, France ; <sup>3</sup>Centre Oscar Lambret, Biostatistics unit, Lille, France ; <sup>4</sup>Institut Jen Godinot, Surgery, Reims, France ; <sup>5</sup>Centre Oscar Lambret, Radiation Oncology, Lille, France

### Purpose or Objective

Baseline contrast-enhanced Computed Tomography (CT)-derived texture analysis in locally advanced rectal cancer could be useful in order to offer the best personalised treatment. The purpose of this study was to determine the value of baseline-CT texture analysis in the prediction of downstaging in patients with locally advanced rectal cancer.

### Material and Methods

We retrospectively included all consecutive patients treated with neoadjuvant chemoradiation therapy (CRT) followed by surgery for locally advanced rectal cancer. Tumour texture analysis was performed on the baseline pre-CRT contrast-enhanced CT. Based on the selected model of downstaging with a penalized logistic regression in a training set, a radiomics score (Radscore) was calculated as a linear combination of selected features. A multivariable prognostic model was built including Radscore and clinical factors.

### Results

Among the 121 patients included in the study, 109 patients (90%) were T3-T4 and 99 (82%) N+ at diagnosis. A downstaging response was observed in 96 patients (79%). In the training set (79 patients), the best model (ELASTIC-NET method) reduced the 36 texture features to a combination of 6 features. The multivariate analysis retained, as independent factors, the Radscore (Odds Ratio, OR=13.25; 95%-Confidence Interval, 95%CI, 4.06-71.64; p<0.001) and the age (OR=1.10/1 year; 1.03-1.20; p=0.008). The model was evaluated in the test set leading to an area under the curve of 0.70 (95%CI, 0.48-0.92).

### Conclusion

This study presents a prognostic score for downstaging, from initial computed tomography derived texture analysis in locally advanced rectal cancer, which may lead to a more personalised treatment for each patient.

### EP-1898 Encouraging the use of decision support systems in routine clinical practice

R. Fijten<sup>1</sup>, B. Reymen<sup>2</sup>, R. Houben<sup>3</sup>, P. Fick<sup>4</sup>, T. Hendrik<sup>4</sup>, S. Puts<sup>1,4</sup>, J. Veugen<sup>4</sup>, A. Dekker<sup>1</sup>

<sup>1</sup>Maastricht University Medical Centre, Department of Radiation Oncology Maastricht, Maastricht, The Netherlands ; <sup>2</sup>Maastricht Clinic, Department of Radiotherapy, Maastricht, The Netherlands ; <sup>3</sup>Maastricht Clinic, Data Center Maastricht, Maastricht, The Netherlands ; <sup>4</sup>Maastricht Clinic, Informatisering and Services, Maastricht, The Netherlands

### Purpose or Objective

In the current era of machine learning, many new predictive models are generated yearly. In routine clinical practice, predictive models can assist physicians in interpreting multidimensional clinically relevant data and therefore aiding the (shared) decision making process. However, their use is not widespread due to a number of reasons, such as time constraints during consultations and the difficulty of accessing relevant models. In order to alleviate these concerns and encourage the use of predictive models in routine clinical practice, we have developed an easily accessible web-based interface to host clinically relevant models.

### Material and Methods

A linear regression model was created to determine the survival probability of small-cell lung cancer patients 26 weeks after the start of Prophylactic Cranial Irradiation (PCI). The model was based on data from 151 patients and was internally validated.

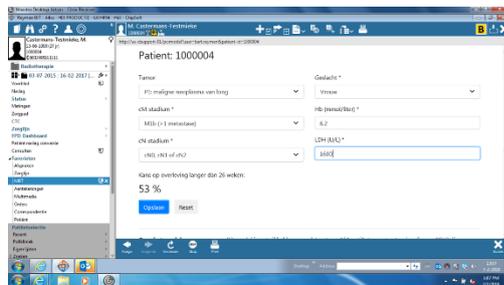

A web-based interface was then created to incorporate this model and make it accessible to physicians. A Java service was built at the back-end of the interface to allow direct communication between the model and the EHR system (HiX, Chipsoft, The Netherlands). Communication was performed by SOAP (Simple Object Access Protocol) queries through a business intelligence software suite (BusinessObjects) which acted as an intermediary. This allowed for automated filling of the input parameters and subsequent calculations.

### Results

The internally validated AUC was 0.71 and provides the probability of surviving 26 weeks after the start of PCI radiation. Input parameters included the tumour N- and M-staging, gender, and concentrations of lactate dehydrogenase (LDH) and haemoglobin (HB) in the blood upon diagnosis.

A web-based interface was created in which the model was plugged in. The architecture of the interface was set up in such a way that other models could be plugged in easily. Because of the direct communication with the HiX EHR system, real-time retrieval of the most recent information was possible so that the model input parameters are up-to-date at any time. Additionally, even though the input parameters are filled in automatically, clinicians are able to adjust all input parameters, after which the model instantly recalculates the outcome. Finally, accessibility of the model was improved by adding it as an option inside the HiX EHR system, allowing physicians to access the model directly from within the system that they use during the consultation. The interface is currently being tested in a prospective clinical trial.

Fig 1: Screenshot of the interface inside the HiX EHR system

### Conclusion

The interface described in this abstract allows for automated generation of model outcomes at a moment's notice with up-to-date information and within the EHR system. By increasing the usability of a model using this interface, clinicians are encouraged even more to utilize the added benefit that predictive models can bring in routine clinical practice.

### EP-1899 Prediction of outcomes in lung SBRT with dosimetric variables and machine learning techniques

D. Sevillano<sup>1</sup>, C. Martín<sup>2</sup>, C. Vallejo<sup>3</sup>, M. Martín<sup>3</sup>, R. Colmenares<sup>1</sup>, R. Morís<sup>1</sup>, B. Capuz<sup>1</sup>, J.D. García<sup>1</sup>, M. Cámara<sup>1</sup>, A. Martínez<sup>1</sup>, F. Orozco<sup>1</sup>, M.J. Béjar<sup>1</sup>, D. Prieto<sup>1</sup>, S. Sancho<sup>3</sup>, F. García-Vicente<sup>1</sup>

<sup>1</sup>Hospital Universitario Ramón y Cajal, Medical Physics, Madrid, Spain ; <sup>2</sup>ETSIT. Universidad Politécnica de Madrid, Biomedical Engineering, Madrid, Spain ; <sup>3</sup>Hospital Universitario Ramón y Cajal, Radiation Oncology, Madrid, Spain

### Purpose or Objective

To find models based on dosimetric variables that allow prediction of outcomes in primary lung tumor SBRT.

### Material and Methods

94 patients with primary lung tumor treated with SBRT from September 2010 to December 2016 were retrospectively analysed (mean follow-up time= 2.6 years). All patients were treated with a 3DCRT technique and a dose prescription of 60 Gy in 3, 5 or 8 fractions. Three dosimetric/radiobiological variables of the PTV, ITV and GTV were used in the analysis (BED<sub>2</sub>, BED<sub>mean</sub>, BED<sub>98</sub>, with  $\alpha/\beta=10$ ) as well as their volumes. Treatment outcomes analysed were local recurrence (LR, 13 cases), nodal recurrence (NR, 13 cases), distant recurrence (DR, 33 cases) and death from disease (DD, 23 cases). Three different machine learning techniques were used in this work: logistic regression, linear Support Vector Machines (SVM) and decision trees (DT).

Validation of the machine learning techniques were performed with 10-fold cross validation due to the limited data available, while Lasso regularization was employed for feature selection. The objective was to use no more than two variables for the model.

In all outcomes but DR, Synthetic Minority Over-sampling Technique (SMOTE) was employed. This technique creates new instances of positive cases from real ones in order to balance the number of positive and negative cases.

### Results

Areas under receiving operating characteristics curve (AUC) of different outcomes with the three methods are shown in Table 1. Best results of AUC are highlighted. For LR, the features used where PTV volume and GTV BED<sub>mean</sub> and the best method was logistic regression with AUC close to 0.75. In case of NR, selected features were ITV volume and GTV BED<sub>mean</sub>, and the method with a best performance was again logistic regression. In the case of DR, none of the methods were able to predict it, as values of AUC close to 0.5 are obtained. Finally, the best AUC obtained for DD was 0.67 for both Decision Trees and SVM using PTV volume and PTV BED<sub>2</sub>. In this case, we can see that the method clearly benefits from using SMOTE.

	AUCs (SD) using SMOTE			AUCs (SD) without SMOTE		
	Logistic Regression	Decision trees	Linear SVM	Logistic Regression	Decision trees	Linear SVM
Local Recurrence	<b>0.75 (0.01)</b>	0.67 (0.03)	0.72 (0.03)	0.737 (0.009)	0.66 (0.04)	0.70 (0.04)
Nodal Recurrence	<b>0.73 (0.01)</b>	0.60 (0.04)	0.72 (0.02)	0.705 (0.006)	0.57 (0.02)	0.52 (0.08)
Distant recurrence				0.49 (0.02)	0.51 (0.05)	0.48 (0.06)
Death from disease	0.62 (0.01)	0.67 (0.02)	<b>0.67 (0.01)</b>	0.586 (0.009)	0.56 (0.03)	0.56 (0.08)

Table 1. AUCs of different methods for all treatment outcomes analysed

For those outcomes where we found AUCs>0.7, we will be able to develop models for treatment outcome probabilities. In this case, we developed models for LR and NR with the method with a better performance, which is logistic regression. To do this, we trained the model with the whole dataset using the hyperparameters and features obtained during cross validation. Models are shown in Table 2.

	Recurrence prob $\frac{1}{1 + e^{-\beta_0 - \beta_1 x_1 - \beta_2 x_2}}$				
	$\beta_0$	$\beta_1$	$x_1$	$\beta_2$	$x_2$
Local Recurrence	-0.57	0.018	PTVvol (cm <sup>3</sup> )	-0.014	GTVBEDmean (Gy <sub>2D</sub> )
Nodal Recurrence	-0.7	0.033	ITVvol (cm <sup>3</sup> )	-0.015	GTVBEDmean (Gy <sub>2D</sub> )

Table 2. Final models for local recurrence and nodal recurrence probability

### Conclusion

Machine learning techniques permit to obtain fair predictions of LR and NR in our clinical practice. Furthermore, those models yield reasonable conclusions regarding tumor volume (volume of PTV and ITV) and dose prescription (GTV BED<sub>mean</sub>).

Logistic regression was the most accurate method, being also the one with a closest relationship to recurrence probability.

These results should be considered as preliminary considering that only cross validation was performed, the

inclusion of more patients would allow a for better validation of the model.

#### EP-1900 Predictive parameters for long-term cardiac mortality excess related to left breast radiotherapy

N. Pasinetti<sup>1</sup>, V. Morandini<sup>1</sup>, S. Berlinghieri<sup>1</sup>, E. Castrezzi<sup>1</sup>, S. Pedretti<sup>2</sup>, L. Spiazzi<sup>3</sup>, P. Frata<sup>1</sup>, L. Grimaldi<sup>1</sup>

<sup>1</sup>Esine Hospital, Radiation Oncology service, Esine, Italy ;

<sup>2</sup>Spedali Civili Hospital, Department of Radiation Oncology, Brescia, Italy ; <sup>3</sup>Spedali Civili Hospital, Department of Medical Physics, Brescia, Italy

#### Purpose or Objective

As shown by Early Breast Cancer Trialists' Collaborative Group(\*) breast cancer radiotherapy is considered mandatory in patients treated with breast conserving surgery or in mastectomy to improve cancer death rate and disease recurs. However, treatment of patients with left breast cancer is burdened by the risk of long-term secondary cardiac effects that may be added to those known induced by chemotherapy (anthracyclines, trastuzumab). Consequently, careful evaluation of the heart-absorbed dose is necessary and, although a risk of cardiac death <1% after breast RT is considered acceptable, the QUANTEC constraint  $V_{25Gy}<10\%$  is not sufficient to limit the excess cardiac mortality risk for each patient and for every RT schedule of tangential beams left sided breast RT. Aim of this work is to find a group of patient for which the dose constraint, above mentioned, is respected, but at a further investigation the excess cardiac mortality probability results greater than 1%. Correlation with new "predictive" dosimetric parameters and cardiac mortality risk was investigated and verified on a control group of patients.

#### Material and Methods

Analyzing the DVHs on TPS Philips Pinnacle<sup>3</sup> of 240 women, who underwent to left sided breast tangential beams RT, came out that the constraint  $V_{25Gy}<10\%$  was always respected. By inspecting the integral DVHs some patients were individuated as "probable false negatives". For each heart absorbed dose distribution the EQD2 was calculated and the Relative Seriality model ( $\alpha/\beta=3Gy$ ,  $s=1$ ,  $D_{50}=52.4Gy$  and  $g=1.28$ ) was used as method to evaluate the probability of late cardiac mortality.

#### Results

For 19 patients the  $V_{25Gy} <10\%$  was satisfied, but by analyzing the differential DVHs the probability of long-term cardiac mortality was found >1% and up to 6%. The dosimetric heart constraints  $V_{40Gy}$  and  $D_{2\%}$  showed a good correlation ( $R=0.97$  and  $R=0.90$  respectively) with the risk of cardiac death. To keep the probability lower than 1%, the cut off levels were determined by the simultaneous occurrence of the conditions:  $V_{40Gy}<2\%$ , and  $D_{2\%}<38Gy$ . On a control group of 15 other patients (or whom  $V_{25Gy}<10$  was satisfied) these parameters were tested. What emerged is that if both parameters were satisfied the long term cardiac mortality probability resulted, with an explicit calculation, <1%.

Constraint extrapolated by patients data analysis			
parameters	relationship	Dose constraint	Volume constraint
$D_{2\%}$	<	38 Gy	
$V_{40Gy}$	<		2%

#### Conclusion

Our "predictive" parameters, although they are only a calculation and not an observation of mortality, are closely connected to the irradiation technique used and aimed to specific end-points. Anyway modern TPSs should promote, even more, the use of either radiobiological DVHs or algorithm optimization, especially in the era of hypofractionation.

#### EP-1901 Identifying organs at risk for radiation-induced dysphagia in head and neck cancer patients

J. Hedström<sup>1</sup>, L. Tuomi<sup>1</sup>, C. Finizia<sup>1</sup>, C. Olsson<sup>2</sup>

<sup>1</sup>Inst of Clinical Sciences, Dept of Otorhinolaryngology, Göteborg, Sweden ; <sup>2</sup>Inst of Clinical Sciences, Dept of Radiation Physics, Göteborg, Sweden

#### Purpose or Objective

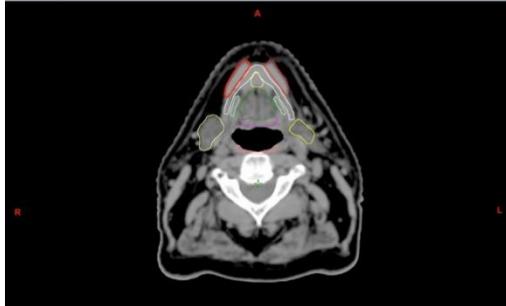

Dysphagia is a common and severe dose-limiting toxicity after oncological treatment of head and neck cancer (HNC). This study aims to investigate the relationship between radiation dose to structures involved in normal swallowing and patient-reported as well as clinically measured swallowing function in HNC patients after curative (chemo)radiotherapy (RT).

#### Material and Methods

Patients (n=90) with tumours of the tonsil, base of tongue, hypopharynx, and larynx curatively treated with radiation therapy +/- chemotherapy in 2007-2015 were assessed for dysphagia post-treatment by telephone interview and videofluoroscopy (VFS). A study-specific symptom score, accounting for presence of drinking, eating, swallowing difficulties, and coughing when eating/drinking, was used to determine patient-reported dysphagia (DESdC). The penetration-aspiration scale (PAS) was applied to determine swallowing function by VFS. Anatomical structures involved in normal swallowing were individually delineated on the patients' original planning CT scans. Radiation dose-volume relationships for these structures were investigated, including ipsi- and contralateral structure dose for the bilateral structures. Univariate logistic regression analysis was performed with structure mean and maximum absorbed doses as predictors for dysphagia. Multivariate regression analysis was subsequently performed to identify the most statistically critical structures associated with swallowing impairment according to DESdC and PAS. Potential effects by relevant clinical factors (comorbidity as scored by ACE-27, age, smoking and BMI) were accounted for.

**Figure 1.** Delineation of organs-at-risk. One representative cross-sectional slice of a pre-treatment planning CT with OARs delineated. A=anterior; R=patient's

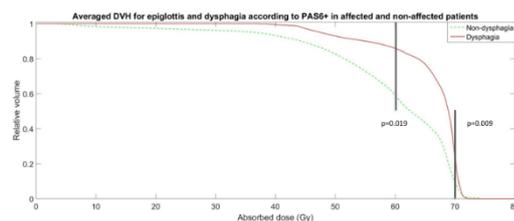

right; L=patient's left. Dark green=Genioglossus muscle/Tongue; Dark yellow=Submandibular gland; Light green=Hyoglossus muscle; Light yellow=Geniohyoideus muscle; Pink=Upper pharyngeal constrictor muscle; Purple=Base of tongue; Red=Anterior digastric muscle; White=Mylohyoideus muscle.

## Results

Dose to several swallowing structures was associated with dysphagia post-RT in univariate analysis. When applying a multivariate model, the mean dose to the larynx and the epiglottis as well as the maximum dose to the contralateral submandibular gland were associated with  $PAS \geq 4$ ,  $PAS \geq 6$  and  $PAS \geq 4$  as well as  $PAS \geq 6$  respectively. The mean dose to the contralateral submandibular gland and the maximum dose to the contralateral anterior digastric muscle were associated with  $DESdC \geq 3$ .

**Figure 2.** Dose-volume histogram for epiglottis, the structure with the best discrimination power for dysphagia according to MVA and associated statistically significant volume differences between dysphagia and non-dysphagia patients.

## Conclusion

Dose-response relationships were found for specific dysphagia endpoints.

### EP-1902 S32: A decision Support System to predict radiation toxicity in lung cancer patients

F. Núñez Benjumea<sup>1</sup>, J. Moreno Conde<sup>1</sup>, A. Moreno Conde<sup>1</sup>, S. González García<sup>1</sup>, M.J. Ortiz Gordillo<sup>2</sup>, J. Riquelme<sup>3</sup>, M.D.C. Fernández Fernández<sup>2</sup>, C.L. Parra Calderón<sup>1</sup>, J.L. Lopez Guerra<sup>2</sup>

<sup>1</sup>Hospital Universitario Virgen del Rocío, Group of Technological Innovation, Sevilla, Spain; <sup>2</sup>Hospital Universitario Virgen del Rocío, Radiation oncology, Sevilla, Spain; <sup>3</sup>University of Sevilla, Department of Computer Language and Systems, Sevilla, Spain

### Purpose or Objective

Decision support systems are a growing class of tools with the potential to impact healthcare. The S32 project aims to develop an informatics infrastructure oriented towards

standardizing, analyzing and reusing retrospective lung cancer patients' information to generate radiation-induced toxicity predictive models that could be actioned in real-time during the treatment planning process. A prospective trial will be developed in a real environment in order to elucidate the accuracy of the predictions yielded by the system and its impact in health-related quality of life, among other endpoints. In this work, the preliminary results of the feature selection methods and prediction models investigated for this purpose are presented.

### Material and Methods

As a preliminary step for the radiation-induced toxicity prediction process, several Feature Selection (FS) methods based on either feature sub-setting or forward selection techniques have been tested along with two different prediction models based on Support Vector Machines (SVM) and Artificial Neural Network (ANN) for predicting radiation-induced acute esophagitis and pneumonitis. The following sub-setting algorithms were applied to both SVM and ANN prediction models: 1) Correlation-based Feature Selection (CFS); 2) Random Forest-based (Boruta); and 3) Chi-Squared filter. In addition, the prediction models were also trained with those features which appeared in two or more of the FS methods listed above (which we called the "polling" method). In addition, the following forward selection techniques were applied only to the SVM-based prediction model for exploratory purposes: 1) Minimum Redundance-Maximum Relevance (mRMR); 2) Relief; 3) Random Forest (RF); and 4) Information Gain (IG). The SVM-based prediction model was also trained with those features which appeared in two or more of the FS methods listed above. Furthermore, and for comparison purposes, the performance of the SVM-based prediction method was also tested without applying any FS method, i.e., with all the available features.

### Results

FS methods and predictive models have been tested with a retrospective dataset with information gathered during routine care for the last 5 years. Radiation-induced prediction models were developed for the two most common side effects found in the dataset: acute esophagitis (N = 406) and acute pneumonitis (N = 408). The models were trained with the 80% of the samples, leaving the remaining 20% for testing purposes. Accuracy of the prediction was measured in terms of AUC (Table).

	ACUTE ESOPHAGITIS			ACUTE PNEUMONITIS			
	Algorithm	Features selected	SVM	ANN	Features selected	SVM	ANN
Sub-setting	CFS	9	0.60	<b>0.71</b>	8	0.61	0.66
	Boruta	21	0.58	0.50	24	0.67	0.59
	Chi-Squared	33	0.57	0.42	23	0.59	0.62
	Polling	15	0.57	0.57	15	<b>0.88</b>	0.47
	mRMR	20	0.63	N/A	120	0.55	N/A
Forward selection	Relief	14	0.51	N/A	72	0.60	N/A
	RF	66	0.62	N/A	27	0.67	N/A
	IG	15	0.60	N/A	67	0.56	N/A
	Polling	17	0.63	N/A	46	0.54	N/A
None	172	0.61	N/A	172	0.51	N/A	

### Conclusion

The best prediction model found for predicting acute esophagitis was the ANN trained with the features yielded by the CFS method. The highest AUC found for predicting acute pneumonitis was related to the model built upon the SVM and Polling of the sub-setting algorithms investigated. This tool could help to define new lung patients care protocols based on predictive models for patient toxicity.

### EP-1903 Learning from scanners: radiomics correction modeling

I. Zhovannik<sup>1,2</sup>, J. Bussink<sup>1</sup>, R. Fijten<sup>2</sup>, A. Dekker<sup>2</sup>, R. Monshouwer<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Radiation Oncology,

Nijmegen, The Netherlands ; <sup>2</sup>Maastricht University Medical Center +, Radiation Oncology - Maastricht Clinic, Maastricht, The Netherlands

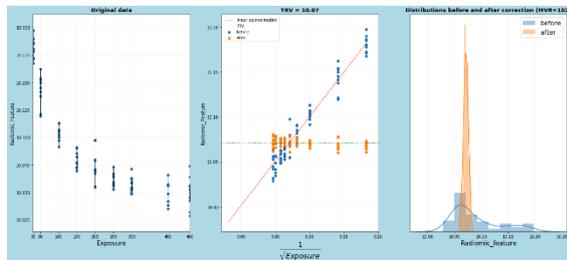

### Purpose or Objective

Every cancer patient treated with radiotherapy undergoes imaging. This is imaging intended primarily for staging and treatment planning, however, there is increasing interest to use this data to support clinical decision making based on imaging. To build a reliable model 'big data' are necessary, involving data from hospitals located in different locations and countries to generalize well across the patient population.

Cancer prediction modeling based on image biomarkers is referred to as radiomics. Although radiomics have predictive power, generalizability is often poor in cross-institutional studies because the institutions have different scanners with various acquisition protocols. The question in this study is whether there is a way to correct for the influence of these image acquisition parameters on the radiomics?

### Material and Methods

We used a Gammex 467 CT phantom to build a training (default configuration) and validation (home-made plugs) sets for radiomics. As an example for scanner variation, we varied the X-ray tube exposure (mAs) used in the scans. To extract radiomic features we used an open-source tool PyRadiomics. Linear regression with X-ray tube exposure as a predictor was used to predict the relationship between X-ray tube exposure and a radiomic feature target value (TRV). Spearman rank was used to evaluate the relationship monotony between a radiomic feature and the X-ray tube exposure. Mean variance ratio (MVR) - variance ratio before and after correction averaged for each delineation - was used to evaluate the correction model.

### Results

In 88 out of 92 radiomic features we found a positive correction in both training and validation sets (MVR > 1). Spearman rank test showed to be a good metric of correctability.

### Conclusion

There is a straightforward way to correct on redundant radiomics variance caused by X-ray tube exposure variation. Radiomics correction modeling may be used to pre-process local institutional data to reduce scanner induced noise in cross-institutional studies involving radiomics.

### EP-1904 3T CE-MRI (peri)tumoral radiomics for prediction of lymphovascular invasion in early breast cancer

M. Avanzo<sup>1</sup>, L. Vinante<sup>2</sup>, G. Pirrone<sup>1</sup>, J. Stancanello<sup>3</sup>, A. Revelant<sup>2</sup>, A. De Paoli<sup>2</sup>, A. Drigo<sup>1</sup>, L. Barresi<sup>1</sup>, L. Balestrieri<sup>4</sup>, M. La Grassa<sup>4</sup>, M. Urbani<sup>4</sup>, N. De Pascalis<sup>4</sup>, S. Massarut<sup>5</sup>, M. Mileto<sup>5</sup>, G. Franchin<sup>2</sup>, G. Sartor<sup>1</sup>

<sup>1</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Medical Physics Department, Aviano, Italy ; <sup>2</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Department of Radiation Oncology, Aviano, Italy ; <sup>3</sup>Oncoradiomics SA, Oncoradiomics SA, Liege, Belgium ; <sup>4</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS,

Department of Radiology, Aviano, Italy ; <sup>5</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Breast Surgery Unit, Aviano, Italy

### Purpose or Objective

The presence of lymphovascular invasion (LVI) in early stage breast cancer patients is related to worse outcome. For patients undergoing partial breast irradiation with intraoperative radiotherapy (IORT), if LVI is found in pathological examination, then the local treatment is completed with external beam whole breast irradiation. The purpose of this investigation was to predict presence of LVI in patients with early-stage invasive breast cancer by use of radiomics of tumor and peritumoral volume (PV) in 3.0-T, contrast enhanced MRI (CE-MRI).

### Material and Methods

50 patients diagnosed with early-stage invasive breast carcinoma had bilateral 3.0-T breast CE-MRI before surgery and IORT, which was delivered using low-energy photon source, the Intrabeam System (Carl Zeiss, Oberkochen, Germany). The gross target volume (GTV) was contoured by an experienced radiation oncologist in the T1-MRI series with maximum contrast enhancement. The PV was automatically contoured by generating a 1 cm thickness shell around the GTV. The 3D images were pre-processed with re-sampling and 3-D filtering using Gaussian, Laplacian of Gaussian, and Median filters.

A total of 228 radiomic histogram-based and textural features were calculated in the GTV and PV (456 in total). Sequential feature selection was used to identify a subset of features that best predicts the data and remove redundant or not significant predictors. A support vector machine learning classifier was trained on the patient dataset for prediction of presence of LVI in the treated site assessed by pathology (positive classifier for presence of LVI).

The predictive power of the model was assessed using sensitivity (probability that test is positive on patients with LVI), specificity, and Youden's index in five-fold cross validation.

### Results

In 20 out of 50 patients (40.0%) LV was found in pathology. The features selected for prediction of LV were 8 from the PV, 3 from GTV, all of which were textural features derived from the GLRLM, GLCM, NGTDM, and GLSZM matrices. The classifier scored sensitivity 90.0%, specificity 80.0%, and Youden's Index of 0.7 in the cross validation.

### Conclusion

These preliminary findings show that radiomic variables extracted from the PV and GTV in 3.0-T CE-MRI can predict LVI and may help to better select patients candidate to exclusive partial breast irradiation with IORT.

### EP-1905 CT /PET based dosiomics and radiomics model predicts local control of nasopharyngeal carcinoma

M. Avanzo<sup>1</sup>, G. Pirrone<sup>1</sup>, C. Avigo<sup>2</sup>, G. Fanetti<sup>3</sup>, J. Stancanello<sup>4</sup>, A. De Paoli<sup>3</sup>, P. Elisa<sup>3</sup>, A. Drigo<sup>1</sup>, P. Chiovati<sup>1</sup>, A. Dassie<sup>1</sup>, E. Borsatti<sup>5</sup>, T. Baresic<sup>5</sup>, G. Franchin<sup>3</sup>, G. Sartor<sup>1</sup>

<sup>1</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Medical Physics Department, Aviano, Italy ; <sup>2</sup>ULSS 1 Dolomiti - S. Martino Hospital, Medical Physics Department, Belluno, Italy ; <sup>3</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Department of Radiation Oncology, Aviano, Italy ; <sup>4</sup>Oncoradiomics SA, Oncoradiomics SA, Liege, Belgium ; <sup>5</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Department of Nuclear Medicine, Aviano, Italy

### Purpose or Objective

to develop and validate a model predictive for local control, based on CT-PET radiomics and planning CT

dosiomics features, of nasopharyngeal carcinoma (NPC) treated by Intensity Modulated Radiation Therapy (IMRT).

#### Material and Methods

Patients diagnosed with NPC treated with RT were included in this study. Clinical and instrumental follow-up was performed every month for the first 2 years, then every 6 months. Pre-treatment PET and CT-scans were collected as well as the three dimensional dose distribution calculated on the CT. The CT, PET images and the calculated dose distribution were pre-processed with re-sampling and 3-D filtering using Gaussian, Laplacian of Gaussian, and Median filters. 728 radiomic shape, size, histogram-based and textural features were calculated from the filtered and unfiltered images and dose in the gross target volume, which was contoured using CT and PET. Sequential feature selection was used to identify a subset of features that best predict the data and remove redundant or not significant predictors. An ensemble learning classifier with adaptive boosting was trained on the patient dataset for prediction of local control (positive classifier for appearance of disease in the treated site during follow-up, negative otherwise). The predictive power of the model was assessed using sensitivity (probability that test is positive on patients with recurrence) and specificity in five-fold cross validation. The area under ROC curve (AUC) was used to investigate correlation of features with recurrence.

#### Results

After a median follow-up of 31.4 (95%CI 3.8-86.7) months, 49 out of 60 (82.6%) patients were free from local recurrence. The features selected were 1 shape (solidity), 1 CT (Low Gray level zone emphasis from GLSZM), 1 PET (Second measure of information correlation of GLCM) and 3 dose features (Percentile area 90, Strength of NGTDM, Small Zone high grey level emphasis of GLSZM). The classifier scored sensitivity 72.7% and specificity 89.8% in the cross validation. The single most predictive feature for recurrence was PET (AUC=0.712). The category with highest AUC was dose, as the combined features had AUC of 0.735.

#### Conclusion

These findings show that PET radiomic and dosiomic variables are correlated with local control of NPC. The model incorporating radiomic features from imaging and dose can predict local control in this type of head and neck cancer.

#### EP-1906 CBCT delta-radiomics for predicting complete pathological response of rectal cancer after CT-RT

G. Pirrone<sup>1</sup>, E. Palazzari<sup>2</sup>, F. Navarra<sup>2</sup>, R. Innocente<sup>2</sup>, J. Stancanello<sup>3</sup>, G. Fanetti<sup>2</sup>, G. Franchin<sup>2</sup>, C. Cappelletto<sup>1</sup>, A. De Paoli<sup>2</sup>, G. Sartor<sup>1</sup>, M. Avanzo<sup>1</sup>

<sup>1</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Medical Physics Department, Aviano, Italy; <sup>2</sup>Centro di Riferimento Oncologico di Aviano CRO IRCCS, Radiation Oncology Department, Aviano, Italy; <sup>3</sup>Oncoradiomics SA, Oncoradiomics SA, Liege, Belgium

#### Purpose or Objective

The study of the variation of radiomic features extracted from cone-beam CT (CBCT) acquired for Image-Guided Radiotherapy (IGRT) opens a promising scenario for assessing tumor response during chemo-radiotherapy (CT-RT). The objective of this study is to determine whether variation of radiomic features (delta-radiomics) predicts complete pathological response (pCR) of patients treated with RT for rectal cancer.

#### Material and Methods

The analysis was conducted on daily-setup imaging data of a total of 19 patients diagnosed with rectal cancer who received preoperative volumetric arc therapy (VMAT) with a prescribed dose of 54 Gy in 25 fractions. All the CBCT images were acquired with 125 kVp and 80 mA with a Varian Trilogy LinAc. An expert radiation oncologist contoured the gross volume target (GTV) for each patient

on three CBCTs acquired on the first, middle (12<sup>th</sup> fraction) and last fraction of the treatment. The image intensity levels were normalized using the mean value of a region of interest in the bladder, and a voxel re-sampling was performed to obtain isotropic voxel spacing. To denoise images and enhance image characteristics all the CBCTs were convolved with different kernels (Gaussian, Laplacian of Gaussian, and Median). Radiomic features were extracted from 3D tumor regions and the delta-features, i.e. the relative feature values change were evaluated between the mid and last fraction of the RT (Delta1), the first and mid-fraction of the CT-RT (Delta2), and the first and last fraction of CT-RT (Delta3). Wilcoxon signed-rank test was used to evaluate if delta-features in patients with pCR after CT-RT were significantly different from patients with partial or no response.

#### Results

Nine patients had pCR after CT-RT. Eleven Delta1, five Delta2, and twelve Delta3 features were significantly different ( $p < 0.05$ ) in patients with pCR.

#### Conclusion

These preliminary results show the potential of delta-radiomics for predicting pCR of rectal cancer patients early during the CT-RT.

#### EP-1907 Which FDG-PET features are robust enough for Radiomic studies in pancreatic cancer patients?

L. Presotto<sup>1</sup>, M. Mori<sup>2</sup>, P. Passoni<sup>3</sup>, M.L. Belli<sup>4</sup>, S. Broggi<sup>2</sup>, G.M. Cattaneo<sup>2</sup>, M. Picchio<sup>1</sup>, N.G. Di Muzio<sup>3</sup>, V. Bettinardi<sup>1</sup>, C. Fiorino<sup>2</sup>

<sup>1</sup>IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milano, Italy; <sup>2</sup>IRCCS San Raffaele Scientific Institute, Medical Physics, Milano, Italy; <sup>3</sup>IRCCS San Raffaele Scientific Institute, Radiotherapy, Milano, Italy; <sup>4</sup>IRST Istituto Scientifico Romagnolo per lo Studio e la Cura dei tumori, Medical Physics, Meldola, Italy

#### Purpose or Objective

FDG-PET Radiomics is promising for the characterization of pancreatic cancer (Pca). However, uncertainties due to delineation/segmentation and to acquisition/processing may affect its reliability. Aim of this study was to assess robust radiomic features (RF) based on the impact of delineation uncertainty and of parameters affecting image acquisition/processing.

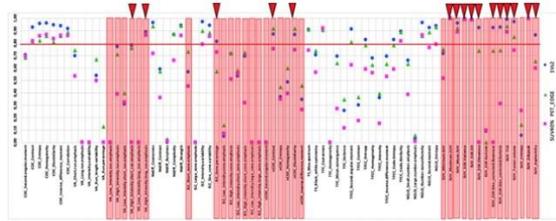

#### Material and Methods

Twenty-five Pca patients previously treated with IMRT were considered. Four PET Pca contours were available: 2 manual, 1 semi-automatic (based on SUV maximum gradient: PET\_Edge) and 1 automatic (40%SUV\_max thresholds); 72 RF were extracted with CGITA software (v. 1.4). The stability of RF against inter-observer variability was quantified by Intra-Class Correlation Coefficient (ICC); the robustness of RF for PET\_Edge and 40%SUV was assessed against manual delineation. The impact of acquisition/processing on RF was tested on uniform and purpose built heterogeneous phantoms. Statistical effect size indicators were used to determine: i) the impact of each nuisance factor (discretization, acquisition statistics, reconstruction algorithm, filtering), and ii) the discriminating power. Based on the robustness with respect to all factors, we categorized RF based on repeatability and on heterogeneous PET patterns discrimination, leading to the definition of a list of robust RF. Among them, the ones showing an ICC $\geq$ 0.80 (for "inter-observer variability") in the delineation study were finally defined as suitable for Pca Radiomics.

#### Results

Inter-observer agreement was moderate (median DICE: 0.73); 35 (47%) RF showed an ICC $<$ 0.80, mostly in the Voxel-Alignment (VA) matrix and in the Intensity-Size Zone (ISZ) matrix families. The number of RF with ICC $<$ 0.80 for PET\_Edge and SUV40% (considering the worst ICC value against observers) increased to 44 and 54 respectively. Regarding image acquisition/processing,

the discretization method based on relative range outperformed those based on bins of fixed width in units of SUV and was then adopted. The less robust families considering repeatability and discrimination were the Gray Level Run Length Matrix (GLRLM) and the Neighborhood Gray Tone Difference (NGTD) while the Grey Level Cooccurrence Matrix (GLCM) and the SUV first order RF were the most suitable. In Figure 1, the red bars indicate the most robust RF considering acquisition/processing, 14 of first and 20 of higher order. The resulting RF suitable for radiomic studies shown in Figure 1 were 11 of first and only 5 of higher order. Relaxing the limit for delineation agreement to  $ICC \geq 0.60$ , the numbers increased to 12 and 8 respectively.

### Conclusion

Based on a large set of phantom experiments, a list of 34 FDG-PET RF (from 72) was suggested as sufficiently robust against both repeatability and pattern discrimination. Delineation uncertainty for Pca is quite large, reducing the number of robust RF to 16/34, increased to 20 for a lower ICC threshold (0.60) for contouring agreement.

### EP-1908 A Guide For Predicting Normal Tissue Dose in Stereotactic Radiosurgery

D. Cummins<sup>1</sup>, C. Skourou<sup>1</sup>, S. O'Sullivan<sup>2</sup>, P. Davenport<sup>1</sup>, D. Fitzpatrick<sup>2</sup>, C. Faul<sup>2</sup>, M. Javadpour<sup>3</sup>, M. Dunne<sup>4</sup>  
<sup>1</sup>St. Luke's Radiation Oncology Network, Radiotherapy Physics, Dublin, Ireland; <sup>2</sup>St. Luke's Radiation Oncology Network, Radiation Oncology, Dublin, Ireland; <sup>3</sup>St. Luke's Radiation Oncology Network, Beaumont Hospital National Centre for Neurosurgery, Dublin, Ireland; <sup>4</sup>St. Luke's Radiation Oncology Network, Clinical Trials, Dublin, Ireland

### Purpose or Objective

The defining factors for selecting a prescription dose for intracranial metastases in stereotactic radiosurgery (SRS) are the size of the target and consequently the dose received by surrounding normal brain tissue. Prescription dose is recursively adjusted [24Gy-18Gy] following completion of a plan, until the normal brain tissue dose constraints are met. The availability of a nomogram to inform dose selection from the time of diagnosis would reduce planning time by eliminating the recursive adjustment of the prescription. This paper describes the development of such a guide using a knowledge-based method for predicting normal tissue dose as a function of target diameter in SRS.

### Material and Methods

Data from 50 previous SRS treatment plans (completed on iPlan with non-co-planar dynamic conformal arcs) was used to extract the terms for the key planning metrics (conformity index and gradient index) and define them as a function of target volume.

The relationship between the measured target diameter and the dose to normal tissue volume (NTV) was established by approximating a spherical target volume covered by the prescription dose which could inform the expected  $V_{40\%}$ . A scaling parameter described by a modeled non-linear fall-off of dose beyond the target was then used to scale  $V_{40\%}$  in order to provide a first order approximation of the resulting NTV

The predictive model was retrospectively validated against calculated NTV (chosen as  $V_{12Gy}$  for this study)

obtained from a total of 26 single fraction clinical plans created for solitary lesions ranging in diameter (equivalent sphere) from 0.5cm to 3cm.

### Results

For the 26 plans investigated, the model predicted the  $V_{12Gy}$  to within 0.67cc on average with a standard deviation of 0.53cc. Predictions were found to be most sensitive to the sphericity and size of the target, where small changes in gradient and conformity had the largest impact on the final NTV volume.

### Conclusion

This knowledge-based method for NTV prediction in intracranial SRS could be used as a guide for deciding the prescription dose to targets prior to treatment planning in a busy clinical environment.

### EP-1909 Delta-radiomics signature predicts outcomes after preoperative chemoradiotherapy in rectal cancer

C. Song<sup>1</sup>, J. Seung Hyuck<sup>1</sup>, K. Bohyoung<sup>2</sup>, K. Jae-Sung<sup>1</sup>  
<sup>1</sup>Seoul National Univ. Bundang Hospital, Radiation Oncology, Seongnam- Gyeonggi-Do, Korea Republic of; <sup>2</sup>Hankuk University of Foreign Studies, Division of Biomedical Engineering, Yongin, Korea Republic of

### Purpose or Objective

To develop and compare delta-radiomics signatures from 2- (2D) and 3-dimensional (3D) features that predict treatment outcomes following preoperative chemoradiotherapy (CCRT) and surgery for locally advanced rectal cancer.

### Material and Methods

In total, 101 patients (training cohort, n = 67; validation cohort, n = 34) with locally advanced rectal adenocarcinoma between 2008 and 2015 were included. We extracted 55 features from T2-weighted magnetic resonance imaging (MRI) scans. Delta-radiomics feature was defined as the difference in radiomics feature before and after CCRT. Signatures were developed to predict local recurrence (LR), distant metastasis (DM), and disease-free survival (DFS) from 2D and 3D features. The least absolute shrinkage and selection operator regression was used to select features and build signatures. The delta-radiomics signatures and clinical factors were integrated into Cox regression analysis to determine if the signatures were independent prognostic factors.

### Results

The radiomics signatures for LR, DM, and DFS were developed and validated using both 2D and 3D features. Outcomes were significantly different in the low- and high-risk patients dichotomized by optimal cutoff in both the training and validation cohorts. In multivariate analysis, the signatures were independent prognostic factors even when considering the clinical parameters. There were no significant differences in C-index from 2D vs. 3D signatures.

### Conclusion

Delta-radiomics signatures from both 2D and 3D features successfully predicted the outcomes and were independent prognostic factors irrespective of other conventional clinicopathologic factors. External validation is warranted to ensure their performance.

### EP-1910 CT image standardization is superior to larger but heterogeneous datasets for robust radiomic models

D. Vuong<sup>1</sup>, M. Bogowicz<sup>1</sup>, J. Unkelbach<sup>1</sup>, R. Foerster<sup>1</sup>, S. Denzler<sup>1</sup>, A. Xyrafas<sup>2</sup>, M. Pless<sup>2</sup>, S. Thierstein<sup>2</sup>, S. Peters<sup>3</sup>, M. Guckenberger<sup>1</sup>, S. Tanadini-Lang<sup>1</sup>  
<sup>1</sup>University Hospital Zurich and University of Zurich and Swiss Group for Clinical Cancer Research SAKK, Radiation Oncology, Zürich, Switzerland; <sup>2</sup>Swiss Group for Clinical Cancer Research SAKK, Coordinating Center, Bern, Switzerland; <sup>3</sup>Centre Hospitalier Universitaire Vaudois CHUV, Oncology, Lausanne, Switzerland

### Purpose or Objective

Radiomics is a promising tool for identification of new prognostic biomarkers. Radiomic models are often based on single-institution data. However, multi-centric data that are highly heterogeneous due to different scanning protocols reflect better the clinical reality. Robustness studies are crucial to find features independent from e.g. scanner settings. We studied if a CT radiomics overall survival (OS) model trained on multi-centric data with prior robust feature selection can achieve a similar performance as a model on standardized data.

### Material and Methods

Pre-treatment CT data from 121 stage IIIA/N2 NSCLC patients from a prospective Swiss multi-centric randomized trial (SAKK 16/00, neoadj. chemo- or radiochemotherapy prior to surgery) were used to calculate 1404 radiomic features on the primary tumor. Two OS radiomic models were trained on (1) a patient sub-cohort characterized by standardized imaging protocol (native CT, standard kernel,  $n = 84$ ) and on (2) the entire heterogeneous patient cohort but with pre-selection of robust radiomic features. Robust features were extracted from four distinct robustness studies (contrast, convolution kernel, motion, delineation). Stability measure was the intra-class correlation coefficient ( $> 0.9$  considered stable). Principal component (PC) analysis was performed for feature selection and PCs describing in total 95% of data variance were selected. Features were selected separately for the entire and standardized dataset. The feature with highest correlation to the PCs served as a surrogate for the multivariate Cox model. Finally, backward selection was performed. Model performance was quantified using Concordance Index (CI). 10-fold cross-validation and bootstrap with resampling were used both to verify and compare model performances.

### Results

Robustness studies revealed 113 stable features ( $n_{\text{shape}} = 8$ ,  $n_{\text{intensity}} = 0$ ,  $n_{\text{texture}} = 7$ ,  $n_{\text{wavelet}} = 98$ ). The convolution kernel was the largest influence on the robustness of the radiomic features. The final OS model on the entire non-standardized dataset consisted of four and the model on standardized data of six features (all identified as unstable). The model on standardized imaging data showed significant better prognostic performance compared to the model with robust feature pre-selection based on the entire heterogeneous imaging data (CI = 0.64 and 0.61,  $p < 0.05$ , resp.).

### Conclusion

For our prognostic NSCLC radiomic models, image protocol standardization appears superior to using larger but heterogeneous imaging data combined with robust feature selection.

### EP-1911 Treatment response on MR during radiotherapy in patients with head and neck squamous cell carcinoma.

B. Peltenburg<sup>1</sup>, M. Philippens<sup>1</sup>, R. De Bree<sup>2</sup>, C. Terhaard<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands ;  
<sup>2</sup>UMC Utrecht, Head and Neck Surgical Oncology, Utrecht, The Netherlands

### Purpose or Objective

In head and neck radiotherapy, early recognition of patients with poor response to treatment is important and might allow for treatment modification. Conventionally, tumor volume changes are used to assess treatment response. Recently, apparent diffusion coefficient (ADC) determined by diffusion weighted magnetic resonance imaging (DW-MRI) has been introduced as a prognostic factor in patients with head and neck squamous cell carcinoma. Aim: To follow treatment response on DWI and T2 weighted images of head and neck tumors.

### Material and Methods

Twenty patients with stage II, III or IV head and neck squamous cell carcinoma were included in the PREDICT study. Two patients had HPV positive tumors. Treatment consisted of radiotherapy with or without concurrent chemotherapy. All patients underwent MRI prior to and during week 2, 3, 4 and 5 of the radiotherapy treatment. Imaging was obtained with the patient positioned in the radiotherapy mask. Tumor delineation was performed on T2 weighted images for the baseline MRI and each subsequent MRI. Volume changes were determined using these delineations. For the ADC changes the tumor was again delineated on the baseline  $b=800$  s/mm<sup>2</sup> images using a semi-automatic method. This delineation was copied to the corresponding ADC map and ADC maps of subsequent weeks. Median ADC values for each available delineation were extracted. A follow up of at least 3 months was available for all patients.

### Results

During (chemo)radiotherapy tumors generally reduce in size with each passing week. On average the tumors were only 50% of their original size at the end of the third week of treatment. However due to the treatment effects, tumors are increasingly harder to differentiate from nonmalignant tissues in the treatment area. At the end of the fifth week only 20% of the original tumor volume was visible on T2. In one patient the tumor visibly increased in size from the third week onward. This patient had a local recurrence within 3 months after treatment. In total four patients had a recurrence. ADC generally increases during therapy. The fractional change in median ADC between the baseline and third week of treatment ( $fADC_3$ ) was on average 1.25 and the most discriminating between patients with recurrence and with response. A cutoff of 32% increase in ADC at week 3 resulted in a sensitivity of 100% and specificity of 81%.

### Conclusion

During (chemo)radiotherapy, T2 images can be used to measure tumor volume. Generally tumors decrease in size during treatment. A large increase at week 3 however, might predict a recurrence of tumor. Figure 1. Fraction tumor change volume of patients (black), average of all patients with recurrence (red) and average of patients without recurrence (green).

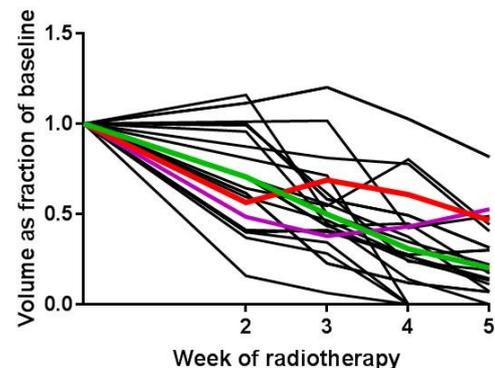

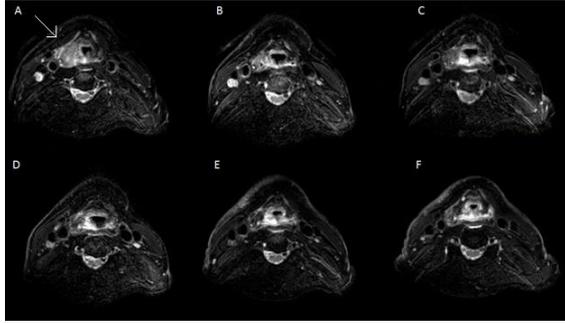

Figure 2. T2 weighted MRI images of the patient with a local recurrence within 3 months after treatment. A) Pretreatment MRI with the tumor in the hypopharynx (white arrow). B) Week 2 C) Week 3, D) Week 4, E) Week 5 of radiotherapy. F) MRI of local recurrence 3 months after radiotherapy.

### EP-1912 Outcome prediction with CT radiomics and random forests in primary lung tumor treated with SBRT

C. Martín<sup>1</sup>, D. Sevillano<sup>2</sup>, C. Vallejo<sup>3</sup>, M. Martín<sup>3</sup>, J. .D. García<sup>2</sup>, R. Colmenares<sup>2</sup>, R. Moris<sup>2</sup>, B. Capuz<sup>2</sup>, M. Cámara<sup>2</sup>, A. Martínez<sup>2</sup>, F. Orozco<sup>2</sup>, M.J. Béjar<sup>2</sup>, D. Prieto<sup>2</sup>, S. Sancho<sup>3</sup>, F. García-Vicente<sup>2</sup>

<sup>1</sup>ETSIT. Universidad Politécnica de Madrid, Biomedical Engineering, Madrid, Spain ; <sup>2</sup>Hospital Universitario Ramón y Cajal, Medical Physics, Madrid, Spain ; <sup>3</sup>Hospital Universitario Ramón y Cajal, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

To predict treatment outcomes from radiomics information of tumor images in the planning CT.

#### Material and Methods

87 patients treated from September 2012 to December 2016 (median follow-up time=25.2 months) were retrospectively analyzed for this work. Radiomic features from the tumor contoured by the radiation oncologist in the planning CT were obtained with IBEX software (Zhang *et al*, *IBEX: an open infrastructure software platform to facilitate collaborative work in radiomics*, *Med Phys* 2015 (42)3, 1341-53). From there, 766 features regarding tumor shape, intensity levels, Co-occurrence matrix, gradient orientations and intensity difference between neighboring voxels were obtained. Analyzed treatment outcomes were Distant recurrence (DR, 26 cases) and death from disease (DD, 23 cases)

For feature selection, a Random Forests algorithm was used with the whole dataset features. Importance of each feature was obtained by permuting the values of each variable and calculating the variation in Out-of-Bag (OOB) error prediction. This process was repeated ten times and mean error increase calculated. Those features with higher mean error increase are those with more prediction power. Once features are selected, Random Forests with only those features was used for prediction. Area under the ROC curves (AUC) were obtained from OOB predictions of the algorithm

Kaplan-Meier (K-M) plots were obtained by dividing our patient population in half according to median score of the random forests algorithm. Logrank test was performed in order to check if there was a significant difference between both patient populations.

#### Results

For DR, two features regarding Co-occurrence Matrix maximum probability and local standard deviation of intensity values were selected. The algorithm achieved an AUC of 0.76 (SD= 0.02).

Also, a value of  $p=3.10^{-5}$  was obtained in the logrank test. In the case of DD, features selected were related to information measure of the Co-occurrence matrix and maximum probability in co-occurrence matrix. The value of AUC was 0.79 (SD= 0.01) and logrank test yielded a value of  $p=0.03$ . K-M plots are shown in Figure 1.

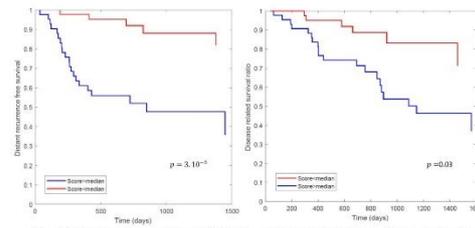

Figure 1. K-M plots of the population divided by the median score of the Random Forests algorithm for distant recurrence and death from disease.

### Conclusion

Random Forests performed well in the prediction of DR and DD with Radiomics features. The nature of Random Forests and the use of OOB prediction prevents for overfitting. Also the low standard deviation of AUC values when repeating the training are encouraging. Nevertheless, patient population needs to be enlarged in order to be able to perform validation in an independent dataset.

### EP-1913 Distributed rapid learning made easy: a user-friendly dashboard for model development and execution

J. Van Soest<sup>1</sup>, C. Masciocchi<sup>2</sup>, P. Fick<sup>1</sup>, T. Hendriks<sup>1</sup>, R. Negro<sup>2</sup>, A. Damiani<sup>2</sup>, V. Valentini<sup>2</sup>, A. Dekker<sup>1</sup>  
<sup>1</sup>Maastricht Radiation Oncology Maastricht Clinic, Knowledge Engineering, Maastricht, The Netherlands ;  
<sup>2</sup>Università Cattolica del Sacro Cuore, Radiotherapy, Rome, Italy

#### Purpose or Objective

Data analysis is becoming more apparent in radiotherapy and medicine in general. Next to the technical skills, interpretation and clinical usefulness of results is of major importance. Hence, visual representations of data and outcomes (plots, charts, nomograms) can help in exploring the data and analysis results. However, the number of people managing both technical and clinical skills is limited, introducing a challenge to leverage from all available (and continuously updated) data. The aim of this abstract is to develop a user-friendly dashboard to ask different types of questions (e.g. showing basic cohort statistics or learning a prediction model). This dashboard triggers these tasks on multiple routine clinical datasets; performing a distributed and privacy-preserving analysis without requiring in-depth technical skills.

#### Material and Methods

The datasets available in participating institutes contained 2469 and 837 routine clinical rectal cancer patients. Information regarding age, gender, clinical TNM stage, prescribed RT dose, overall survival status and time were available for inclusion and/or analysis. Three distributed algorithms were developed to perform: a) general statistics, b) plotting one integrated Kaplan-Meier graph, c) learning a Cox proportional hazards model. We developed a dashboard to select the distributed algorithm (A, B or C) and define inclusion criteria. The dashboard also shows previous executions of algorithms (including selected inclusion criteria) and visualizes the result (tables/figures/text) for every algorithm execution. When Algorithm C is selected, the dashboard can show an interactive prediction model executor. In this model executor, users can enter patient-specific criteria whereafter the predicted probabilities over time are shown.

#### Results

The developed dashboard is publicly available at <http://coraldashboard.jvsoest.eu>. Results of algorithms are visualized (e.g. variable distributions, KM curve for inclusion criteria, prediction model), and stored in the history of algorithm executions. This means users can

come back at a later convenient time to e.g. apply the trained model in practice.

#### Conclusion

We developed an easy to use distributed learning dashboard. Statistical information about the datasets available can be requested using algorithm A. Algorithm B gives users the opportunity to search for treatment outcomes for similar patients treated in the past. Definition of clinical similarity can be set by the user him/herself using broader/smaller inclusion criteria. Algorithm C can be triggered, and afterwards directly applied for new patients, as a true rapid learning platform. All algorithms can be triggered as often as needed, to update when new information becomes available. Furthermore, both algorithms and connected hospitals are configurable, allowing dashboards for specific collaborations and algorithms.

#### EP-1914 A method to deal with highly correlated explanatory variables in the development of NTCP models

A. Van Der Schaaf<sup>1</sup>, L. Van den Bosch<sup>1</sup>, S. Both<sup>1</sup>, E. Schuit<sup>2</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University of Groningen- University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht- Utrecht University, Utrecht, The Netherlands

#### Purpose or Objective

Data-driven modelling of patient outcomes is often impeded by high correlation between explanatory variables (EVs), resulting in unstable variable selection and inflated variance. This problem can lead to models that highly depend on specific correlations between EVs and, therefore, generalise poorly to other populations. We modified a frequently used model development method (MDM) to deal with this problem and tested the performance and generalizability of the resulting models in realistic simulations.

#### Material and Methods

As reference MDM we used stepwise logistic regression with forward variable selection based on the Bayesian Information Criterion (BIC). To deal with high correlation between EVs we modified this MDM using four steps. First, the EVs were assigned to overarching EV groups with mutual correlations  $\leq 0.8$  and that were as large as possible. Second, for each such group, a prediction model was developed using the reference MDM. Third, models with good performance were selected based on the BIC with a range equivalent to one degree of freedom. Finally, we combined all models with good performance into a single logistic model by averaging their linear predictors. We simulated random datasets with 10 EVs drawn from a standard Gaussian distribution with autoregressive correlation structure and a correlation of 0.9 between neighbouring EVs. A binary response variable was added according to a logistic response relation with 5 randomly chosen EVs with coefficients drawn from a standard uniform distribution. Datasets of varying size of 100 up to 500+ observations were generated and used to develop prediction models using the reference and modified MDM. Using the same response relation we generated 3 validation sets, each containing 1000 observations. The first validation set had the same correlation structure of the EVs as the training set, to test the model performance in the same population. The other validation sets had 0.5 and 0 correlation between EVs, to test model generalizability. Calculated measures included the mean absolute prediction error (MAE), loss of log-likelihood (LoLL), and loss of area under the receiver operating characteristic curve (LoAUC). Of these measures we calculated the average relative difference between the

modified and reference MDM, and how often each MDM was better than the other.

#### Results

On average, for data set sizes up to 500 observations, the modified MDM performed and generalized better than the reference MDM, but not in each single simulation, as shown in the Table and Figure. For larger data sets the performance of both MDMs stabilized at a constant high level, with only small differences between both methods, which were on average slightly in favour of the reference method.

Table: Relative performance of the modified MDM compared to the reference MDM, expressed as mean relative difference (positive means an improvement), and the percentage of simulations in which the modified MDM was better, equal, or worse than the reference MDM.

	Performance in same population	Generalizability to 0.5 correlation	Generalizability to 0 correlation
MAE	+14% Better: 69% Equal: 11% Worse: 20%	+15% Better: 61% Equal: 13% Worse: 26%	+16% Better: 62% Equal: 12% Worse: 26%
LoLL	+28% Better: 73% Equal: 7% Worse: 21%	+32% Better: 64% Equal: 11% Worse: 25%	+34% Better: 66% Equal: 10% Worse: 24%
LoAUC	+35% Better: 65% Equal: 13% Worse: 22%	+26% Better: 55% Equal: 15% Worse: 30%	+13% Better: 51% Equal: 12% Worse: 37%

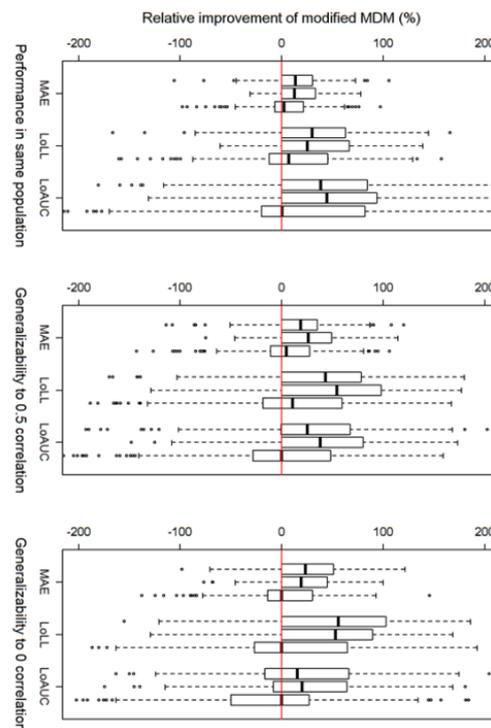

Figure: Boxplot of all results of all simulations with data set sizes up to 500 observations. The grouped bars represent data set sizes of 100-200 (upper), 300 (middle), and 400-500 (lower) observations.

#### Conclusion

We modified an existing MDM to deal with high correlation between EVs. On average, the modified models predict and generalize better than the reference models, up to the point where sufficient data is available to reliably estimate all model parameters.

### EP-1915 Modelling framework for FMISO and FDG PET imaging tailored dose prescription

M. Lazzeroni<sup>1</sup>, A. Ureba<sup>2</sup>, D. Baltas<sup>3</sup>, A.L. Grosu<sup>3</sup>, I. Toma-Dasu<sup>1</sup>

<sup>1</sup>Stockholm University, Medical Radiation Physics- Dept. Physics, Stockholm, Sweden ; <sup>2</sup>Skandionkliniken, Skandionkliniken, Uppsala, Sweden ; <sup>3</sup>Medical Center-Medical Faculty Freiburg- German Cancer Consortium DTK Partner Site Freiburg, Department of Radiation Oncology-, Freiburg, Germany

#### Purpose or Objective

Positron emission tomography (PET) may play a central role in personalized radiation therapy when aiming at a dose prescription based on the functional and biological properties of the tumor, such as hypoxia. Hypoxia is well known for increasing cell radioresistance and it is considered as one of the main determinants of locoregional failure.

This study aims at setting the modelling framework for combining the metabolic tumor information derived from fluorodeoxyglucose (FDG) PET images together with tumor hypoxia imaging with fluoromisonidazole (FMISO) PET to quantify the tumor clonogenic cell and oxygen distributions for a tailored dose prescription.

#### Material and Methods

A modelling approach for assessing the dose to be prescribed in order to achieve a predefined level of tumour control probability accounting for hypoxia and density of clonogens was proposed. Two scenarios were considered regarding the initial distribution of clonogens in the clinical target volume, a homogeneous density of the clonogens and a heterogeneous one. The heterogeneous distribution of clonogens was hypothesized that could be derived based on the FDG avidity extracted from PET images. Linear and non-linear conversion functions of FDG uptake into number of clonogenic cells were considered. For each of these scenarios, the required radiation doses to counteract the increased tumor cell radioresistance at voxel level were calculated based on maps of oxygen partial pressure derived from FMISO PET images by the use of conversion functions of radiotracer uptake.

#### Results

The framework for dose calculation was implemented as a scripted module to a research version of a treatment planning system, RayStation (RaySearch Laboratories AB, Stockholm). For exemplifying the results of applying the proposed formalism for personalised treatment planning, the distribution of oxygen partial pressure in one of the clinical target volumes for a head and neck cancer patient, the clonogenic cell distribution obtained when a linear and a sigmoidal conversion function of uptake into clonogenic cell number and the corresponding dose distributions to counteract the radiation resistance at voxel level are shown in Figure 1.

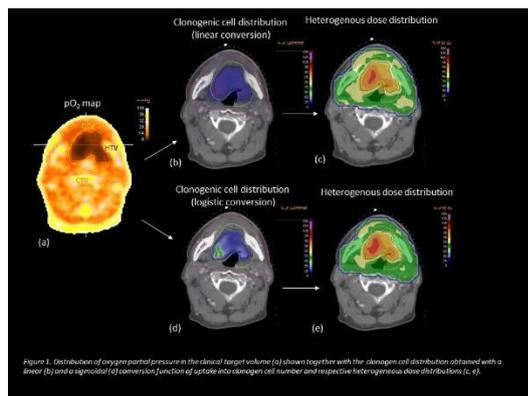

Figure 1. Distribution of oxygen partial pressure in the clinical target volume (a) shown together with the clonogen cell distribution obtained with a linear (b) and a sigmoidal (c) conversion function of uptake into clonogen cell number and respective heterogeneous dose distributions (d, e).

#### Conclusion

A modelling framework was developed and implemented in a research version of a treatment planning system allowing for different radiobiology-based strategies for dose prescription at voxel level targeting hypoxia and enhanced density of tumour clonogens. This modelling framework could be used for further development of individualized radiation therapy dose prescription approaches. Further validation based on patient treatment outcome is however warranted and it is pursued in an ongoing study.

### EP-1916 Predictive model of the dose to the heart based on geometry evaluation in left breast radiotherapy

S.M. Tomatis<sup>1</sup>, E. Esposito<sup>1,2</sup>, A. Gaudino<sup>1</sup>, F. Lobefalo<sup>1</sup>, P. Mancosu<sup>1</sup>, L. Paganini<sup>1</sup>, V. Palumbo<sup>1</sup>, A. Stravato<sup>1</sup>, E. Tomatis<sup>3</sup>, M. Rossi<sup>3</sup>, E. Merati<sup>3</sup>, F. De rose<sup>1</sup>, G. Reggiori<sup>1</sup>, M. Scorsetti<sup>1,4</sup>

<sup>1</sup>Humanitas Research Hospital, Medical Physics of Radiotherapy, Rozzano Milan, Italy ; <sup>2</sup>Università degli studi di Milano, facoltà di medicina, Milano, Italy ; <sup>3</sup>liceo classico giosuè carducci, alternanza scuola lavoro, Milano, Italy ; <sup>4</sup>Humanitas University, Department of Biomedical Sciences, Rozzano MI, Italy

#### Purpose or Objective

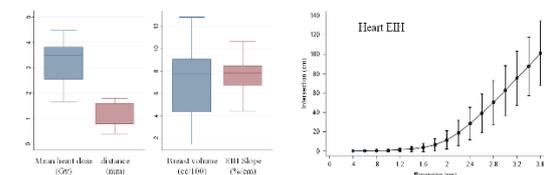

Radiotherapy treatment of the left breast can be difficult due to heart proximity. Conservative dose constraint with mean heart dose (MHD) < 4 Gy was suggested for minimizing heart late effects. Deep Inspiration Breath Hold (DIBH) was demonstrated to help in reducing MHD. In this study a predictive model was developed to correlate MHD to the patient geometry aiming to select the best patients that would benefit to DIBH.

#### Material and Methods

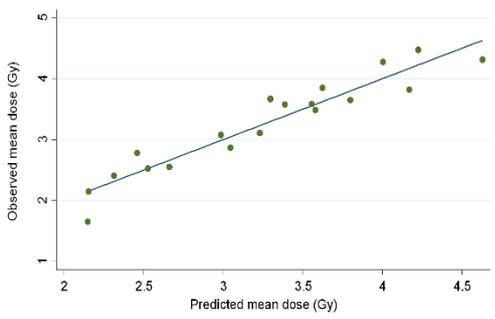

Nineteen patients treated in our facility for left breast cancer were randomly selected and considered in this study. All cases were subjected to a treatment course of 15 fractions for a total dose of 48 Gy to the surgical bed and 40.5 Gy to the whole breast. Patients were treated with volumetric modulated arc therapy (VMAT) with two or four arcs. The model was developed by target expansion and overlap procedure following the Expansion Intersection Histogram (EIH) method (1). This procedure operates by progressive target isotropic expansions and mapping the corresponding intersection with the critical organ into the EIH graph. From this graph the distance (max non zero overlap expansion) and slope (mean EIH derivative) are extracted and added to the target volume as input variables for a simple linear model. All variables are subjected to function transforms in order to approach a gaussian shaped distribution. All calculations and tests were made with stata software and the "ladder" function was used to generate the proper variable transform.

#### Results

Parameter distribution and overall EIH graph (mean ± SD) for the 19 patients are represented in figure 1.

After data extraction, variables were selected by the ladder command as follows: 1) square root of breast volume. 2) distance (not modified). 3) 1/average slope. All variables resulted to be Gaussian ( $p > 0.05$ ).

The linear model, adjusted by the number of arcs, resulted to have a  $R^2$  of 0.9. All three input parameters were significant ( $P < 0.05$ ). A representation of the linear fit is reported in figure 2

**Conclusion**

These data could be used as predictive model to assist in risk evaluation and decision for appropriate technique, such as breath hold or other suitable techniques

**EP-1917 Variable versus conventional inter-fraction intervals in SBRT**

P. Stavrev<sup>1</sup>, N. Stavreva<sup>1</sup>, A. Nahum<sup>2</sup>, R. Ruggieri<sup>3</sup>, P. Tsonev<sup>1</sup>, D. Pressyanov<sup>1</sup>  
<sup>1</sup>SRD Sofia University “St. Kliment Ohridski”, Scientific Research Dpt, Sofia, Bulgaria ; <sup>2</sup>Clatterbridge Cancer Centre, Formerly at Physics Dpt, Bebington, United Kingdom ; <sup>3</sup>Sacrocuore - don Calabria’ Hospital, Department of Radiation Oncology, Negrar VR, Italy

**Purpose or Objective**

To investigate theoretically the maximal possible difference in local tumor control that can be achieved with SBRT regimens with conventional and with variable inter-fraction intervals.

**Material and Methods**

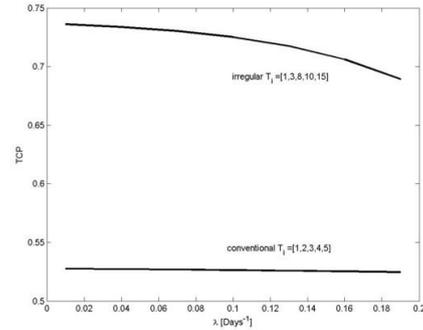

This study was stimulated by [1] which reported that a higher local tumor control (by 30%) was observed clinically for a SBRT regimen employing non-consecutive, i.e. irregular rather than consecutive (conventional) inter-fraction intervals. The fractionation schemes compared in [1] are  $T_{i,1} = \{1,2,3,4,5\}$  and  $T_{i,2} = \{1,3,8,10,15\}$ , delivering otherwise equal total dose to the tumor. They are studied here employing a TCP model accounting for tumor hypoxia [2,3,4]; this TCP model includes re-sensitization of the tumor cells through re-oxygenation during a prolonged treatment and therefore may potentially explain the improved treatment outcome of the non-conventional SBRT schedule.

The parametric space of the applied TCP model was searched in order to investigate the dependence of the obtained TCP difference on the values of the model parameters. A dose per fraction of 11 Gy was assumed, consistent with [1].

**Results**

There exist a parameter set presented in the table for which the difference in the predicted TCPs is around 20%. The TCP dependence on the repopulation rate for both schedules is shown in the figure.

$N^0_a$	$N^0_{sb}$	$N^0_{ah}$	$\alpha_a$ (Gy <sup>-1</sup> )	$\beta_a$ (Gy <sup>-2</sup> )	$\alpha_{sb}$ (Gy <sup>-1</sup> )	$\beta_{sb}$ (Gy <sup>-2</sup> )	$\alpha_{ah}$ (Gy <sup>-1</sup> )	$\beta_{ah}$ (Gy <sup>-2</sup> )	$\alpha$	$C$
$1.4 \cdot 10^7$	$1.0 \cdot 10^6$	$6 \cdot 10^6$	0.18	0.02	0.08	0.012	0.05	0.005	0.08	0.1

**Conclusion**

Although the maximal TCP difference obtained theoretically in this study is lower than the one reported in [1], where a difference of 30% was obtained, it supports the reported clinical finding. A more detailed investigation will be carried out with this and an alternative model [5] which also accounts for re-oxygenation of the tumor during treatment in order to investigate whether the observed TCP difference can be predicted by existing TCP models.

**EP-1918 Active bone marrow identification in the pelvis using texture analysis of CT features**

E. Gallio<sup>1</sup>, S. Rosati<sup>2</sup>, C. Fiandra<sup>3</sup>, F. Arcadipane<sup>3</sup>, A. Lesca<sup>4</sup>, P. Silveti<sup>3</sup>, G. Balestra<sup>2</sup>, U. Ricardi<sup>3</sup>, P. Franco<sup>3</sup>  
<sup>1</sup>A.O.U. Città della Salute e della Scienza, Medical Physics Unit, Turin, Italy ; <sup>2</sup>Politecnico of Turin, Department of Electronics and Telecommunications, Turin, Italy ; <sup>3</sup>University of Turin, Radiation Oncology-Department of Oncology, Turin, Italy ; <sup>4</sup>A.O.U. Città della Salute e della Scienza, Nuclear Medicine Unit, Turin, Italy

**Purpose or Objective**

For anal cancer patients, hematologic toxicity (HT) may influence compliance to therapy (concurrent chemoradiation). It is crucial to implement strategies able to identify and spare active bone marrow (aBM). Several methods exist to locate aBM, based on PET or MR images. The aim of this study is to evaluate the feasibility of detecting aBM on CT images with radiomics.

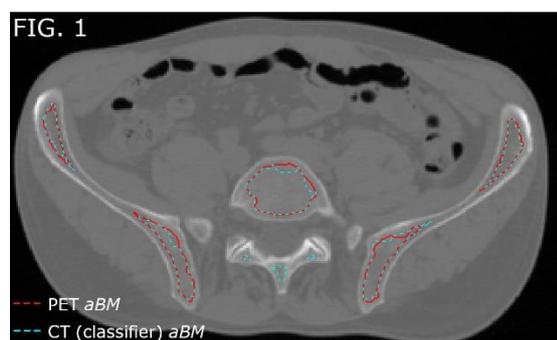

**Material and Methods**

Five patients were included in the study. For all patients, aBM was manually drawn on PET images (pixel size: 4x4mm<sup>2</sup>, spatial resolution: 6 mm) and divided in three ROIs (subregions): iliac bone marrow (iBM), lower pelvis (LPBM) and lumbosacral (LSBM) one. For identifying aBM on CT (pixel size: 1x1mm<sup>2</sup>), three classifiers were implemented. For training of the classifiers, pelvic bone marrow (PMB) was segmented on CT images according to Mell L.K. et al. (*Int.J.Radiat.Oncol.*, 2006, p. 1356-1365) procedure. The aBM was selected by PMB applying k-means algorithm (k=2), removing the pixel with the highest mean intensity (corresponding to cortical bone) and overlapping with PET aBM ROIs (after deformable registration). For all elements overlapping PET aBM, a set of 36 radiomics features was calculated: 4 first-order statistical features and 32 second-order ones. For each aBM subregion, a training set was obtained by randomly selecting 1/4 of elements from five slices for each subject.

Each training set was used for constructing a Support Vector Machine (SVM) classifier that was employed to segment the specific *aBM* subregions on CT images of the five patients. A comparison between PET *aBM* ROIs and CT ones was carried out with respect to DICE index, precision and recall for elements with at least 64 pixels.

### Results

Fig.1 shows an example of *aBM* manually drawn on PET and the segmentation of the classifier on CT images. Tab. 1 sums the values of DICE index, precision and recall found for the five patients for *LSMB*, *IBM* and *LPBM* ROIs. The highest indices values were obtained for *LSMB* and *IBM* subregions, where the DICE index was  $\geq 0.75$  and precision was  $\geq 0.80$  in 4 out of 5 patients. The high values of recall for these two subregions (average values: 0.80 and 0.73 respectively) means that the *aBM* was correctly recognized by the classifier on CT images. For the *LPBM*, supoptimal results were achieved (average DICE index was 0.5). The identification of *aBM* in the *LPBM* might be influenced by the presence of the coxa.

Patients	LSBM			IBM			LPBM		
	DICE	Precision	Recall	DICE	Precision	Recall	DICE	Precision	Recall
1	0.86	0.89	0.86	0.85	0.87	0.85	0.62	0.55	0.89
2	0.84	0.90	0.80	0.85	0.91	0.82	0.38	0.29	0.68
3	0.79	0.82	0.79	0.75	0.78	0.74	0.48	0.37	0.80
4	0.90	0.90	0.92	0.82	0.94	0.74	0.50	0.43	0.66
5	0.67	0.86	0.62	0.64	0.96	0.51	0.53	0.43	0.74
Mean	0.81	0.87	0.80	0.78	0.89	0.73	0.50	0.41	0.76
± S.D.	± 0.09	± 0.03	± 0.11	± 0.09	± 0.07	± 0.14	± 0.09	± 0.09	± 0.09

### Conclusion

A classifier based on texture analysis features for the automatic segmentation of active bone marrow in pelvic region was created. The obtained results were promising, especially for the lumbosacral and iliac structures. A larger population of patients will be included in future studies, to better test the generalization capability of this approach. Furthermore, to improve the detectability in the *LPBM* subregion, other classifiers, may be employed and/or combined among them.

### EP-1919 Voxel-based assessment of proton RBE in paediatric brain cancer radiotherapy from multimodal imaging

M. Skaarup<sup>1</sup>, A. Appelt<sup>2</sup>, M. Lundemann<sup>1</sup>, S. Darkner<sup>3</sup>, M. Jørgensen<sup>4,5</sup>, C. Thomsen<sup>6</sup>, I. Law<sup>7</sup>, D. Mirkovic<sup>8</sup>, R. Mohan<sup>9</sup>, D. Grosshans<sup>3</sup>, C. Peeler<sup>3</sup>, I. Vogelius<sup>1,9</sup>

<sup>1</sup>The Finsen Center - Rigshospitalet, Clinic of Oncology, Copenhagen, Denmark ; <sup>2</sup>University of Leeds and Leeds Cancer Centre- St. James's University Hospital, Institute of Cancer and Pathology, Leeds, United Kingdom ; <sup>3</sup>University of Copenhagen, Department of Computer Science, Copenhagen, Denmark ; <sup>4</sup>Rigshospitalet, Clinic of Nephrology, Copenhagen, Denmark ; <sup>5</sup>Sjællands Universitetshospital, Radiology department, Roskilde, Denmark ; <sup>6</sup>Rigshospitalet, Department of Radiology, Copenhagen, Denmark ; <sup>7</sup>Rigshospitalet, Department of Clinical Physiology- Nuclear Medicine and PET, Copenhagen, Denmark ; <sup>8</sup>The University of Texas- MD Anderson Cancer Center, Department of Radiation

Physics- Division of Radiation Oncology, Houston, USA ; <sup>9</sup>Copenhagen University, Faculty of Health and Medical Science, Copenhagen, Denmark

### Purpose or Objective

Clinical proton radiotherapy (RT) currently assumes constant spatial relative biological effectiveness (RBE). In vitro data have demonstrated a dependence of RBE on local linear energy transfer (LET), but in vivo data are lacking. In order to model the relationship between dose, LET and RBE in clinical settings, tissue response must be assessed on the same voxel-to-voxel level as the 3D treatment plan information. We investigated a hybrid image registration methodology that utilizes multimodal anatomical imaging to deform functional images (diffusion tensor imaging [DTI] and 18F-FET-PET) between different timepoints, to relate local tissue response to dose and LET on a voxel-to-voxel basis.

### Material and Methods

Multimodal MRI sequences were acquired at baseline and in follow-up as part of a prospective study. Here we present the first results of multimodal hybrid image registration on a single patient with suspicion of progression due to anatomical changes leading to 18F-FET-PET scans on clinical indication in addition to the protocol MRI scans. All anatomical scans at a given timepoint were rigidly co-registered to create a hybrid template. Multimodal deformable image registration was used to relate templates between timepoints. The resulting deformation matrix was used to map functional imaging between baseline and all follow-ups. Functional imaging response was related to dose and LET on a voxel-by-voxel basis by co-registering planning CT to baseline MRI. Dose cubes were corrected for fraction size effects and LET RBE dependence by calculating:

$$EQD(d_x)_x = D_p \cdot [((\alpha/B)_x \cdot RBE_{max} + RBE_{min}^2 \cdot d_p) / ((\alpha/B)_x + d_x)]$$

(where  $d_x$  is dose per fraction,  $d_p$  is the proton dose per fraction and  $D_p$  is the total proton dose,  $(\alpha/B)_x = 2.1Gy$ ,  $RBE_{max} = \alpha_p/\alpha_x$  and  $RBE_{min}^2 = \beta_p/\beta_x$ ). Two models for dose correction were examined, in order to evaluate the impact of LET variation on RBE: (1) Fixed  $RBE_{max} = RBE_{min} = 1.1$ ; and (2) model-based (McNamara et al 2015)  $RBE_{max} = 0.99 + LET \cdot 0.36 / (\alpha/B)_x$ ,  $RBE_{min} = 1.10 - 0.0039 \cdot (\alpha/B)_x^{0.5} \cdot LET$ . Response was evaluated using change in fractional anisotropy (FA) MRI (loss of signal related to white matter changes) as well as 18F-FET-PET.

### Results

The image registration pathway is illustrated in Figure 1. For the example patient, imaging changes were noted at follow-up nine months after start of treatment (FU2), where multimodal MRI and FET-PET were performed. Average change in FA from baseline (DFA) and 18F-FET-PET signal as function of EQD2 are shown in Figure 2: Fig 2a for constant RBE (1), and Fig 2b for LET-dependent RBE (2). The constant RBE (1) dose shows very limited dose-response relations, while the LET-dependent RBE dose

seems to relate to local response in high dose regions.

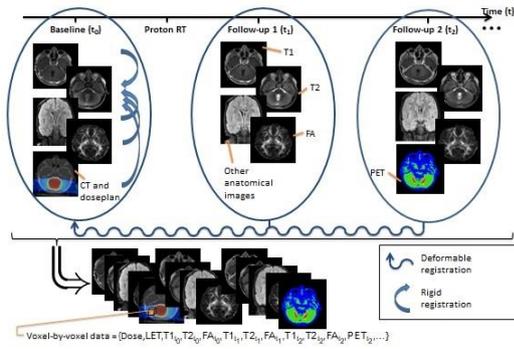

Figure 1. Schematic overview of the registration process. Time-interval between follow-ups was 3 months. Anatomical MRIs (T2 FLAIR, T1) and functional MRIs (diffusion tensor) were co-registered to a hybrid template, and then each hybrid template was registered with deformable image registration.

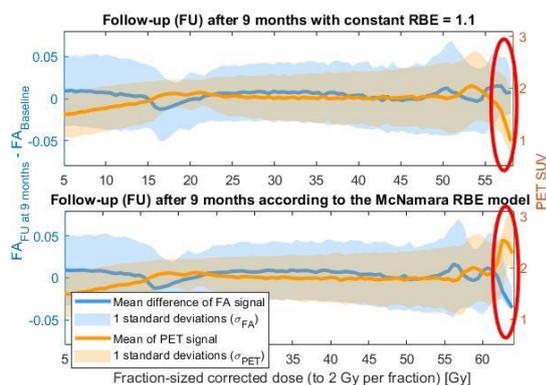

Figure 2. The difference between (1) the fixed RBE model with RBE=1.1 (top plot) and (2) the McNamara model for RBE dependence on LET (bottom plot) in terms of proton radiation response as measured by loss of fractional anisotropy signal (light-blue) and increase in 18F-FET-PET uptake (orange). Mean values of the signals are shown as solid lines while one standard deviation is shown as the corresponding highlighted regions.

## Conclusion

This framework uses multimodal deformable anatomical image registration to relate functional imaging changes to treatment information (dose and LET). This may allow in vivo assessment of RBE dependence on LET for proton RT in larger patient cohorts.

## EP-1920 ADC mean versus fractional volume to predict radiation sensitivity of HNSCC xenografted in nude mice

<sup>3</sup>Department of Preclinical Imaging and Radiopharmacy- Werner Siemens Imaging Center, Eberhard Karls University Tübingen, Tübingen, Germany ; <sup>4</sup>German Cancer Consortium DKTK- partner site Tübingen, and German Cancer Research Center DKFZ, Heidelberg, Germany

## Purpose or Objective

Pre-therapy diffusion weighted MR imaging (DW-MRI) has been associated with clinical RT outcome in various studies. In most studies the mean apparent diffusion coefficient (ADC) in the gross tumor volume (GTV) has been investigated for patient stratification. To further explore the potential of pre-therapeutic ADC, ADC maps obtained in pre-clinical head and neck squamous cell carcinomas (HNSCC) tumor models were studied for their

potential to stratify for cell line-specific radiation sensitivity.

## Material and Methods

The study was performed on immuno-deficient nude mice with tumors from different HNSCC cell lines grown in the hind leg (n=46) that had been measured on a 7T-PET/MR scanner (Bruker Biospec). The imaging protocol included anatomical T2w MRI and DW-MRI using 8 b-values between 0 and 800 s/mm<sup>2</sup>. Based on previously published tumor control doses 50% (TCD50) [1], the cell lines were grouped into three categories of radiation sensitivity: high (H), medium (M), and low (L) (cf. Table 1).

The GTV was defined manually on T2w MRI for each mouse by an experienced radiation oncologist. ADC maps were derived from the DW-MRI images by a mono-exponential fit. Two methods were used to define ADC-based variables for stratification according to radiosensitivity: mean ADC (M1) and volume fraction of ADC voxels below a pre-determined threshold (M2). For M2, the threshold was determined on a sub-group of the total cohort (n=30) based on optimal separation of the groups H-M and M-L. Final analysis of stratification potential using the determined threshold was performed on all samples.

## Results

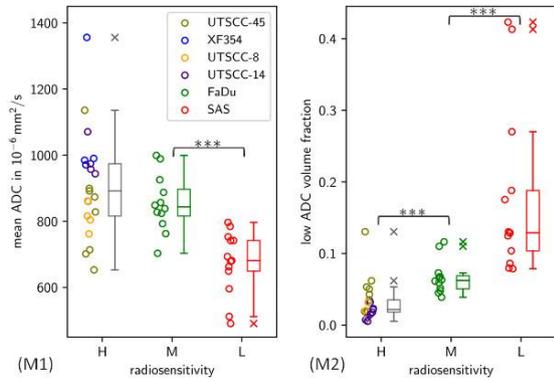

The optimal threshold derived for M2 was ADC = 450E-6 mm<sup>2</sup>/s. The results of the two ADC-based variables for each sample are shown in Figure 1. M1 could stratify groups M and L (p = 7.83E-5, U-test), but not groups H and M (p = 0.17). M2 allowed to stratify all three groups (H-M: p=9.82E-5, M-L: p=7.83E-5). UTSCC-45 seems to have higher volume fractions in M2 compared to other high-sensitive cell groups (cf. Figure 1, M2). Possibly this is due to the fact that this cell line is HPV positive in contrast to all other cell lines.

## Conclusion

ADC was found to be a good biomarker for stratification of GTVs into different radiosensitivity groups in small-animal tumors. Particularly, the fractional volume of low ADC (M2) outperformed mean ADC (M1). These findings are being translated into a currently running clinical study to explore the performance of fractional volumes of low ADC against the more commonly used mean ADC. **Purpose or Objective**

To decode tumour phenotype in prostate cancer (PCa) using a radiomic approach based on multiparametric magnetic resonance imaging (MRI).

**Material and Methods**

Give-me-five trial is a prospective phase II study designed for the treatment of PCa patients with ultra-hypofractionated radiotherapy scheduled in 5 fractions with 36.25 Gy delivered to the whole prostate and a concomitant boost of 37.5 Gy to the dominant intraprostatic lesion (DIL) identified by multiparametric MRI. T2-weighted (T2W) MRI sequences acquired on a 1.5T Magnetom Avanto<sup>Fit</sup> scanner (Siemens) with homogenous characteristics in terms of acquisition protocol were selected and the prostate gland contours were analysed. The extraction of radiomic features (shape, first-order statistics and textural features) was performed using the IBEX software after applying a 8 bit 3-sigma normalization and hierarchical clustering was applied to reduce features redundancy. We tested univariate association of each feature with Gleason score (GS, 3+3 vs 3+4 vs 4+3), extracapsular extension (ECE, 1/2 vs 2 vs 3) score, Prostate Imaging - Reporting and Data System (PIRADS, 2/3 vs 4 vs 5) score and risk class (intermediate vs low) by Kruskal-Wallis test and selected the feature with the lowest p-value in each cluster. We calculated both original p-values and False Discovery Rate (FDR) corrected p-values to adjust for multiple testing. We performed multinomial cumulative logistic regression models and

reported the c-statistic for model discrimination (results not shown). Statistical analysis was performed with SAS/STAT® software.

**Results**

Of the 65 prospectively enrolled patients, 49 T2W-MRI sequences fulfilled the inclusion criteria. Baseline characteristics of the study population are reported in Table. For each patient, 636 radiomic features were identified and then grouped in 10 clusters to reduce dimensionality. At univariate analysis, higher GS was associated with higher values of the texture feature GLRLM25\_LongRunLowGrayLevelEmpha (p=0.005, FDR adjusted p=0.05) and lower values of the shape feature Compactness2 (p=0.02, FDR adjusted p=0.08). Higher ECE score was associated with lower values of the histogram feature ID\_GlobalEntropy (p=0.03, FDR adjusted p=0.10). Higher PIRADS score was associated with lower values of the texture feature GLCM25\_45-4Entropy (p=0.01, FDR adjusted p=0.06). Higher risk class was associated with higher values of the texture feature GLCM25\_135-4Energy (p=0.01, FDR adjusted p=0.06). Boxplots in Figure show the distribution of these radiomic features according to the prognostic factors.

Table – Baseline characteristics of the study population (N=49).

**Conclusion**

MRI-based radiomics in PCa for the prediction of tumour phenotype is a feasible and promising approach. It might lead to a semi-automated definition of tumour characteristics and thus reduce the intra/inter-operator variability in the radiologic image interpretation. We plan to increase the dataset dimensionality in order to strengthen the statistical power and to validate results.

### Purpose or Objective

Daily imaging facilitates investigation of the impact of anatomical changes on the delivered dose. Conventional dose accumulation averages the fraction dose which introduces a systematic mathematical underestimate of the achieved biological effect in the presence of dose variations. To overcome this inconsistency in the use of the total delivered dose for biological models, we introduce an EQD-based formalism to accumulate the total biological dose. The difference with respect to conventional dose accumulation is investigated for two different patient cohorts using daily imaging.

### Material and Methods

We adapted the standard EQD-formalism to compare a treatment of constant fraction dose  $d$  to a treatment of daily varying doses  $d_i$ . The derived  $EQD_d(d_i)$  yields the total biological dose under consideration of the varying delivered doses and the tissue radiosensitivity. An initial cohort of 9 patients treated for prostate carcinoma with IMRT was studied using daily imaging with an in-room CT-on-rails system. Gamma index analysis (3%/3mm) is used to compare both the conventionally accumulated ( $D_a$ ) and the biologically accumulated ( $EQD_d$ ) with the planned dose. The second test cohort consisted of 30 out of 194 available patients treated for head and neck (H&N) tumours recruited in the VoxTox programme that underwent TomoTherapy and daily MVCT imaging.

### Results

$EQD_d$  is systematically higher than  $D_a$  with highest deviations in dose gradient regions around the target and in areas of strong motion amplitudes. In the pelvic cases, deviation hot spots in the bladder and rectum wall around 4 Gy were found for 5/9 patients. In 6/9 cases for both bladder and rectum using  $EQD_d$ , 2-4 Gy are added up locally in regions where the gamma criterion already failed using  $D_a$ , and furthermore leading to a failure rate increase of up to 3%. H&N patients showed an overall smaller difference between the two accumulation methods. Deviations are below 1 Gy for most volumes but deviation hotspots between 1 Gy and 8 Gy in OARs around the target volume were found in 20% of cases.

### Conclusion

The systematic underestimation of the biological effect from dose accumulation can potentially impair dose-response modelling and treatment adaptation. The presented approach of biological dose accumulation can avoid this inaccuracy. Stronger day-to-day motion amplitudes in the pelvic region compared with the H&N cases resulted in higher deviations of several Gy. Individual cases of high local deviation occurred in both

cohorts, highlighting the importance of daily imaging and the use of  $EQD_d$  rather than  $D_a$ . The impact of  $EQD_d$  on NTCP outcome is being investigated. Building on the results presented, the study of pelvic and H&N cases is being extended, exploiting the 194 available H&N cases as well as a dataset of 250 pelvic cases from the VoxTox programme. For local analysis, dose surface maps of the rectum are obtained for both  $D_a$  and  $EQD_d$ , and are compared for dose-response modelling.

### Purpose or Objective

Radiomic features (RFs) dimensionality represents a critical challenge to be addressed to lower the overfitting risk in radiomic studies. Assess a methodology for a-priori selection of non-redundant RFs from MR acquisitions and investigate its robustness over different clinical scenarios.

### Material and Methods

T2-weighted (T2W) images of 20 patients (pts) with locally advanced cervical cancer, treated with 4 session MR-guided adaptive brachytherapy were considered. Within ~12days, all pts underwent multiple MR with a standardized acquisition protocol. Fig. 1 illustrates study workflow: 77scans acquired with 2 different 1.5T scanners (same manufacturer) were uploaded to Image Biomarker EXplorer (IBEX) for RF extraction. Cylindrical regions of interest (ROIs) were manually drawn on 3 different anatomical regions, possibly representing 3 different radiomic scenarios: the left gluteus muscle (ROIg), outside treatment region (variation in RFs due to factors other than treatment); the cervix tumor target volume (ROIc), (variation in RFs induced by treatment); the bladder (ROIb), which is usually filled before each scan (uniform texture). From these ROIs 279 RFs were extracted for *Gray Level Cooccurrence Matrix 25 (GLCM25)*, *Gray Level Run Length Matrix 25 (GLRLM25)*, *Gradient Orient Histogram (GOH)* categories.

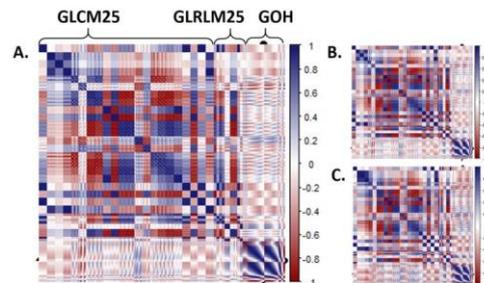

To explore linear associations among RFs and to investigate clustering coherence under different clinical/technical scenarios (inter-scanners, intra-patient, inter-ROIs), correlation matrices were computed for the whole dataset and for data grouped according to MR scanner, to ROI type (i.e.: ROIg/ROIc/ROIb) and to acquisition session. For each correlation matrix, clusters of highly correlated RFs (threshold  $r=0.85$ ) were identified and a "class label" assigned to the RF with the simplest mathematical definition. Redundant RFs (i.e., RFs with similar definition) were filtered out from the dataset for further analyses.

**Fig 1.** Study workflow: I, for each patient (pts) multi-MR scans were acquired, at different times, with 2 different scanners (A/B); II: on each scan 3 ROIs (regions of interest) were manually delineated; III: selected categories of texture based radiomic features (RFs) were extracted; IV: correlation matrices for different scenarios, i.e.: different ROI type (ROIg/ROIc/ROIb) and acquisition session (g1/g2/g3/g4,...), were computed and clustering coherence was investigated. Non-redundant sets of 26 and 28 RFs were obtained for scanner A and B, respectively.

## Results

Correlation analysis on the whole dataset highlights presence of several disjoint clusters made up of many highly correlated RFs, see **Fig. 2A**. Intra-scanner analysis, **Fig. 2B-C**, also revealed similar structures. Using a threshold of 0.85, 27 and 25 nonredundant RFs were selected for ROIg, considering, separately, data acquired with scanner A and B. The selected RFs were 27 and 30 for ROIc, 26 and 30 for ROIb. Strong clustering coherence was observed for GLRLM25 features (all the examined ROIs have the same class label set in common). Also, GOH RFs have a higher number of stable clusters in common among all the ROIs compared to GLCM25. Likewise, preliminary intra-patient analysis confirmed the same clustering coherence for GLCM25 and GOH features.

**Fig 2.** A. Correlation matrix computed on the whole dataset (20pts, 231ROIs); B.-C. Correlation matrices obtained for scanner A and B, respectively. Blu blocks along the diagonals represent highly positively correlated clusters of features.

## Conclusion

The proposed methodology of clustering coherence analysis allowed to reduce to about 1/10 the number of RFs to be used for further analyses. A-priori reduction of RF number will enhance generalization capability of radiomic signatures and speed up implementation of radiomic approaches into clinical practice.

### EP-1924 Are spatial dose metrics predictive of oral mucositis duration in oropharyngeal cancer?

A. Carver<sup>1</sup>, M. Hickman<sup>2</sup>, S. Warren<sup>1</sup>, M. Ward<sup>1</sup>, A. Thomas<sup>2</sup>, P. Sanghera<sup>3</sup>, C. Fong<sup>3</sup>, A. Hartley<sup>3</sup>

<sup>1</sup>University Hospital Birmingham NHS Foundation Trust, Medical Physics, Birmingham, United Kingdom ;

<sup>2</sup>University Hospital Birmingham NHS Foundation Trust, Radiotherapy, Birmingham, United Kingdom ; <sup>3</sup>University Hospital Birmingham NHS Foundation Trust, Clinical Oncology, Birmingham, United Kingdom

### Purpose or Objective

In patients with oropharyngeal cancer treated with chemoradiotherapy oral mucositis is very likely to occur at a significant grade and the pertinent question is the duration rather than the probability of occurrence. It has been established that simple dosimetric parameters do not correlate well to the duration of toxicity in these patients (Hickman, M. 2017). This study uses spatial dose metrics to try to establish whether there is a more complex relationship between dose and toxicity duration.

## Material and Methods

The duration of significant mucositis in 81 patients with oropharyngeal cancer was measured via four outcome metrics (CTCAE versions 3 and 4 (grade 3 or greater), patient reported duration of interference in daily activities (quite a bit or very much) and patient reported duration of severity (severe or very severe)). The oral mucosa volume was outlined according to international consensus guidelines. The section of the dose grid intersecting the oral mucosa was extracted and converted to BED. Thirty nine intensity and spatial metrics were extracted from the dose grid using Pyradiomics (van Griethuysen, J. J. M et al, 2017). Varimax rotated PCA was used to de-correlate the data and reduce the thirty nine dimensions down to the ten dimensions with the greatest variance. These ten variables were combined into a single model predicting the duration of toxicity. The dose bin width for the calculation of dose metrics was set to be 1 Gy<sub>10</sub> BED wide.

## Results

The median duration was 7 weeks for all toxicities except for patient reported severity which was 6 weeks. The interquartile range was 4-5 weeks with outliers ranging from 0 to 15 weeks. When correlating the principal components against toxicity duration two components remained statistically significant after applying a Benjamini-Hochberg correction namely CTCAE V4 and the patient reported duration of severity outcomes. These two features were strongly anti-correlated although the dominant features in the components were different. The first component was dominated by metrics related to the spread of doses such as variance. The other component was dominated by the median and image coarseness, a measure of the rate of change of the dose. A third component was also significant until the multiple comparison correction. Lasso regression identified similar metrics to be important as those found by varimax rotated PCA analysis.

## Conclusion

Spatial metrics were not found to correlate any more strongly to the duration of mucositis than simpler metrics. The most strongly correlated factors were metrics such as median dose and variance rather than the spatial metrics. Factor analysis suggested metrics related to the variance in the dose delivered to the oral mucosa and the rate of change in dose within a region was correlated to duration of toxicity. Outcome modelling with regression and classification is difficult with no strong classifiers. Work is ongoing to try and create a model to identify patients at risk of long toxicity duration.

### Purpose or Objective

Radiomics focuses on extracting a large number of quantitative imaging features correlated with clinical characteristics. We propose a radiomic approach using magnetic resonance imaging (MRI) to decode tumour phenotype and treatment response in oropharyngeal squamous cell carcinoma (OPSCC).

### Material and Methods

The T1-weighted MRI sequences of OPSCC patients treated between 2008 and 2016 were retrospectively selected. The extraction of radiomic features was performed using the IBEX software, and hierarchical clustering was applied to reduce features redundancy. The association of each radiomic feature with grading, HPV status and loco-regional recurrence within 2 years, considered as main endpoints, was assessed by univariate analysis and then corrected for multiple testing. Statistical analysis was performed with SAS/STAT® software

### Results

Thirty eligible cases were identified. For each patient, 1286 radiomic features were extracted, subsequently grouped into 16 clusters. Higher grading (G3 vs. G1/G2) was associated with higher values of *GLCM3/0-1MaxProbability* and lower values of *GLCM25/135-1ClusterShade* ( $p=0.03$  and  $0.04$ , respectively). Positive HPV status was associated with higher values of *GLCM3/11-4Contrast*, *GLCM3/6-1ClusterProminence*, *GLCM25/180-1InformationMeasureCorr2* ( $p=0.03$ ,  $0.02$  and  $0.04$ , respectively) and lower values of *GLCM3/11-4Correlation* and *GLCM3/11-7Correlation* ( $p=0.04$  and  $0.01$ , respectively). Loco-regional recurrence within 2 years was associated with higher values of *GLCM3/4-7Correlation* ( $p=0.04$ ) and lower values of *GLCM3/2-1InformationMeasureCorr1* ( $p=0.04$ ). Results lost statistical significance after correction for multiple testing.

### Conclusion

MRI-based radiomics in OPSCC for the prediction of tumour phenotype and treatment response is a feasible and promising approach. Larger collaborative studies are warranted in order to increase the statistical power and to obtain robust and validated results.

### EP-1926 Radiomics in rectal cancer: prognostic significance of 3D features extracted from diagnostic MRI

C. Piazzese<sup>1</sup>, P. Whybra<sup>1</sup>, E. Qasem<sup>2</sup>, D. Harris<sup>2</sup>, R. Gtaes<sup>3</sup>, K. Foley<sup>4</sup>, E. Spezi<sup>1</sup>

<sup>1</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom ; <sup>2</sup>Singleton Hospital, Department of Surgery, Swansea, United Kingdom ; <sup>3</sup>Singleton Hospital, Medical Physics, Swansea, United Kingdom ; <sup>4</sup>Cardiff University, School of Medicine, Cardiff, United Kingdom

### Purpose or Objective

Many radiomic studies have successfully demonstrated the potential value of PET and CT image features to predict patient outcomes. MRI can be susceptible to greater technical heterogeneity during its acquisition but, compared to PET and CT, relatively few studies have assessed the added value of MRI radiomics. In this work, we aimed at assessing the prognostic value of 3D textural features extracted from MR images of patients with locally advanced rectal cancer (LARC).

### Material and Methods

A cohort of 29 patients with LARC were investigated in this study. All patients underwent anatomical T2 MRI examination before preoperative chemoradiotherapy (CRT) and were followed up for at least 98 months. All MRI scans were processed using the CERR package<sup>1</sup> and a range of radiomics features developed in-house and compliant with the IBSI initiative<sup>2</sup>. The voxels within the tumour region with intensities outside the range  $\mu \pm 3\sigma$  were rejected and the intensity range obtained was then quantized to 6 bits. Radiomic features were automatically extracted using in-house developed image and data analysis software<sup>3</sup>. Pearson coefficient was computed and used to rank the features so to retain the 25 most variant ones. Each feature was then compared to the remaining ones and if the Pearson correlation coefficient was outside the range  $[-0.4, 0.4]$  the feature with the highest rank was removed. A prognostic model (Cox regression) was

developed by using filtered features and clinical characteristics. The calculated median prognostic score was used to separate patients into two groups and differences in overall survival (OS) were evaluated.

### Results

A total of 138 3D imaging features were computed for each patient. Six uncorrelated features were used to construct a Cox regression model together with 3 clinical variables (age, pre-treatment tumour stage and tumour regression grade). The model identified 1 feature (morphologic elongation) that was significantly associated with OS ( $p$ -value  $< 0.05$ , HR = 0.004, 95% CI = 0 - 1.17). There was a significant difference ( $X^2= 8.485$ , df = 1,  $p$ -value  $< 0.05$ ) in OS according to the median prognostic score (Figure 1).

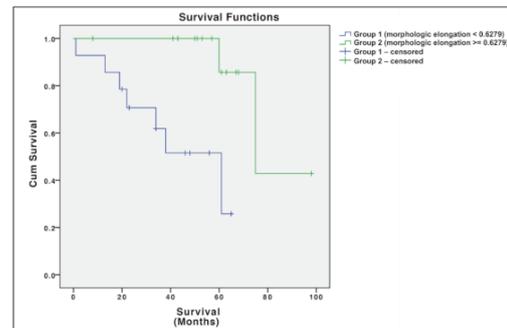

Figure 1. Kaplan-Meier plot of the patients separated in two groups based on the prognostic score.

### Conclusion

MRI radiomics could provide additional information in LARC patients before preoperative CRT. Although based on a relatively small sample size, these preliminary results show that morphologic elongation are correlated with OS. Further work is needed to test the stability of MRI radiomic features and validate their predictive potential in larger cohorts of patients with LARC.

### EP-1927 Mechanistic modelling of RT damage to microvasculature and of its effect on tumour microenvironment

A. Cicchetti<sup>1</sup>, F. Laurino<sup>2</sup>, E. Pascucci<sup>2</sup>, T. Rancati<sup>1</sup>, P. Zunino<sup>2</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate cancer program, Milan, Italy ; <sup>2</sup>Politecnico di Milano, MOX - Department of Mathematics, Milan, Italy

### Purpose or Objective

There is evidence that radiotherapy affects the morphology and the function of small vessels, such as capillaries, of healthy and neoplastic tissues exposed to radiation. However, the underlying mechanisms of this effect are still poorly understood. Here, we present a mathematical model for the tumor microenvironment, with the unique ability to describe (i) realistic vasculature; (ii) capillary flow with non-Newtonian blood rheology and capillary leakage; (iii) coupling of capillary flow and interstitial flow; (iv) capillary deformation and occlusion; (v) mass, heat and particle transport. This model embraces enough of the fundamental physics regulating the tumor microenvironment such that it is

suitable to describe the effects of radiation on the fluid balance at the microvascular level. We will discuss different scenarios that illustrate this dependence.

**Material and Methods**

The model describes the tumor microenvironment in a three-dimensional setting representing a tissue slab of about 0.5 mm size (Fig.2). The model consists of a system of coupled partial differential equations that are solved numerically, by means of an in house code based on the finite element method. This approach has been already successfully applied to model drug delivery and hyperthermia (*Int J Numer Meth Biomed Engng* 2014).

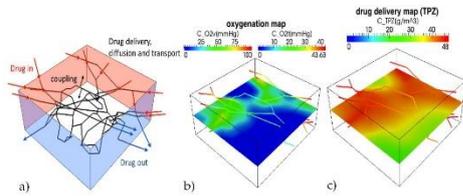

Fig. 1: the in-silico model consists of a tumour slab of R3230AC mammary carcinoma in rat dorsal skin flap preparation. The boundary conditions (inflow/outflow) are shown in panel (a); the simulated map of oxygen released from the vasculature to the tissue is shown in panel (b); Panel (c) shows the drug injected at the inflow points and delivered to the tissue.

**Results**

We study interplay between radiotherapy and microcirculation in the early phase, namely within 24 hours from treatment. The effect of radiation on microvasculature is primarily represented in the model by means of an increase of vascular permeability and degradation of the mechanical properties of the vascular walls (in terms of thinning and decrease of the Young modulus). We show that the combination of these effects entails a cascade of phenomena involving interstitial hypertension, capillary constriction and finally occlusion of the weakest channels, which correspond to the observed outcomes of radiotherapy, such as decrease of the volumetric density of functional capillaries.

More precisely, the fundamental governing equations (Fig.2) are solved with numerical simulations. Possible effects of radiation on the functional parameters are also shown.

The exact tuning of the parameters describing damage as a function of dose/dose fractionation (for example the constitutive relation for  $L_p$  increasing with increasing RT dose) will be performed by measuring damage to microvessels on microfluidic chips as a function of dose, using a clinical linear accelerator.

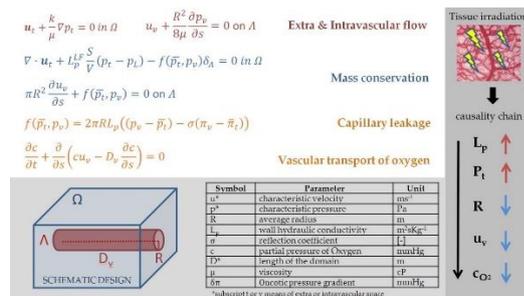

Fig.2: Set of equations (and parameters) included into the simulation code. On the right side a possible causality chain activated by the irradiation of the intra and extravascular space.

**Conclusion**

The results of this study represent a first step towards the challenging objective of understanding, and describing in a mechanistic way, the effect of radiation on the vascular microenvironment. Combining such mechanistic causality laws with patient specific data about the vascular environment, will enable prescription of radiotherapy treatment based on additional/patient specific guidelines that improve the treatment efficacy and preserve the

functionality of tissue/structures/organs neighboring the treated region.

**EP-1928 Radiomic features and local response in Lung Cancer treated with Stereotactic Radiation Therapy**

Dinapoli<sup>3</sup>, F. Cellini<sup>1</sup>, A. D'Aviero<sup>1</sup>, G.C. Mattiucci<sup>1</sup>, G. Mantini<sup>1</sup>, M. Balducci<sup>1</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Fondazione Policlinico A. Gemelli IRCCS- Università Cattolica Sacro Cuore, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche- Istituto di Radiologia, Rome, Italy ; <sup>2</sup>Università Cattolica del Sacro Cuore- Roma Italia, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche- Istituto di Radiologia, Rome, Italy ; <sup>3</sup>Fondazione Policlinico A. Gemelli IRCCS, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche- Istituto di Radiologia, Rome, Italy

**Purpose or Objective**

Stereotactic ablative radiation therapy (SABR) is a treatment option for early-stage lung cancer. This study investigates the prognostic performance of radiomic features for disease recurrence in early stage non-small cell lung cancer (NSCLC) patients treated with stereotactic ablative radiation therapy (SABR).

**Material and Methods**

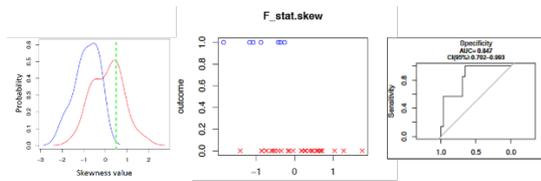

Patients with early stage NSCLC, treated with SABR were considered for this study. The lung lesions received a total dose of 42 Gy in 3 fractions or 50 Gy in 5 fractions according to the site.

A 4D-CT was performed to delineate the internal target volume (ITV) and the radiomic features were extracted from the ITV reported on average intensity projection (AIP), through the use of a dedicated software. The Wilcoxon Mann Whitney test was applied to evaluate the significance of the radiomic features; afterwards a Logistic Regression model was built for each significant feature. We considered as main outcome the response to SABR according to RECIST Criteria. The clinical response was evaluated during the follow up through the CT and PET-CT scans.

**Results**

Forty-two early stage NSCLC patients and 47 lesions, receiving SABR, were considered for this analysis. Thirteen lesions presented a local recurrence.

Ninety-four features were extracted using a dedicated software. The correlation between the radiomic features and the local recurrence at 12-24 and 36 months was investigated. Seventeen features showed a significant correlation ( $p < 0.01$ ) with local recurrence at 12 and 24 months at Wilcoxon Mann Whitney test: 3 intensity based statistical features; 2 Grey level co-occurrence based features-Texture features (GLCM); 6 Grey level run length based features-Texture features (GLRLM); 6 Grey level size zone based features-Texture features (GLDZM), according to Image biomarker standardization initiative v.7 (<https://arxiv.org/abs/1612.07003>). No correlation was found between radiomic features and local recurrence at 36 months. At the kernel density estimation of Skewness ( $p < 0.01$  at the Mann Whitney test) is shown on the picture on the left for both, the positive (blue) and negative (red) lesions, on Figure 1. In the middle the distribution of positive and negative outcomes (same colors) depending on the value of Skewness and on the right the ROC curve of the associated Logistic Regression model (AUC = 0.847).

## Conclusion

These results suggest that radiomics can help in detecting, under specific circumstances (e.g. Skewness greater or equal than 0.5) local recurrence at 12 months after SABR and that this decision support system could potentially allow for early salvage therapy. A multicentric study in order to increase the number of patients and to confirm the interesting results is ongoing.

## EP-1929 Prediction of voxelwise mandibular osteoradionecrosis maps in HNC patients using deep learning

L. Humbert-Vidan<sup>1</sup>, I. Oksuz<sup>2</sup>, V. Patel<sup>3</sup>, A.P. King<sup>2</sup>, T. Guerrero-Urbano<sup>4</sup>

<sup>1</sup>Guy's and St Thomas' NHS Foundation Trust / King's College London, Radiotherapy Physics, London, United Kingdom ; <sup>2</sup>King's College London, School of Biomedical Engineering & Imaging Sciences, London, United Kingdom ; <sup>3</sup>Guy's and St Thomas' NHS Foundation Trust, Oral Surgery, London, United Kingdom ; <sup>4</sup>Guy's and St Thomas' NHS Foundation Trust, Clinical Oncology and Radiotherapy, London, United Kingdom

### Purpose or Objective

Head and neck cancer (HNC) incidence accounts for 3% of all cancers in the UK. Radiotherapy is one of the main treatments for HNC, either alone or combined with chemotherapy, surgery or hormones. Radiation-induced toxicity to healthy tissue can be a limiting factor for the successful treatment of HNC. Mandibular osteoradionecrosis (ORN) is one of the most severe complications in patients with HNC undergoing radiation therapy. Normally, the risk of toxicities such as ORN is assessed using dose-volume histograms (DVH), but DVH-based parameters ignore the spatial component of radiation dose distribution. We propose the use of deep learning to predict 3D ORN toxicity maps based on 3D dose distribution maps and CT volumes using a U-net convolutional neural network. The ability to predict spatial toxicity maps has the potential to assist decision making in the radiotherapy treatment planning process.

### Material and Methods

Our current deep CNN design is based upon the original U-net deep CNN (see Figure 1). Our model is trained to predict 2D ORN toxicity maps based on corresponding slices extracted from 3D dose distribution maps and CT volumes. The CT and dose map imaging data were used as two channels of input to the network. A total of 232, 59 and 16 sets of slices (i.e. dose map, CT slices and ORN masks) were used for training, validation and testing respectively. Data augmentation was implemented on the training dataset.

The Dice Similarity Coefficient loss function was used to train and validate the CNN and the Adam optimiser was used to minimise the loss function. Dropout regularisation (20%) was used to prevent the model from overfitting. A basic manual grid search of parameter values was performed to find the optimal combination of training parameters for the CNN. Based on this search, the best performance was achieved by training the network for 500 epochs with a batch size of 40 and a learning rate of 0.00001.

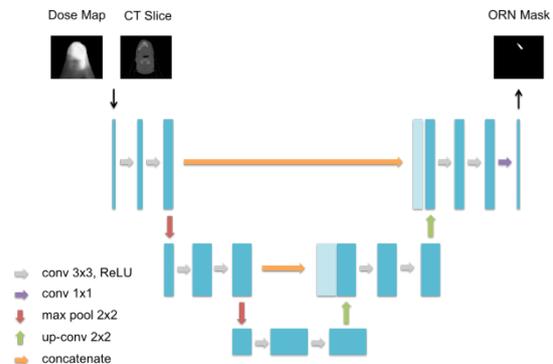

Figure 1. Schematics showing our U-net deep CNN design.

## Results

The training, validation and testing Dice coefficients obtained so far are 0.90 (max), 0.51 (max) and 0.13 (mean), respectively. An improvement in all three coefficients was observed when training the network with the augmented dataset. A maximum test dice coefficient of 0.83 was obtained (see Figure 1). However, in the current ORN predictions of the network, some segmentations appear on the wrong side of the mandible; adding more training cases could help to improve the prediction of ORN location. In addition, some predictions do not contain any ORN at all. A custom loss function could be considered to try to improve performance in such cases.

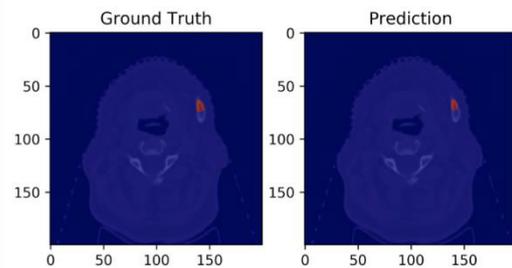

Figure 2. Example of a good agreement (test Dice coefficient of 0.83) between the ground truth (left) and predicted (right) segmentations.

## Conclusion

Our current design of the U-net is able to produce ORN masks based on CT images and dose distribution maps. The results obtained so far are encouraging but the accuracy of the ORN predictions could be improved. Further work is required in both data processing, CNN design and parameter optimisation to achieve these improvements. The predicted toxicity spatial maps will provide more specific information on what normal tissue regions are at a higher risk.

## EP-1930 Hypoxia induced by vascular damage could impact on the outcome of stereotactic body radiotherapy

E. Lindblom<sup>1</sup>, A. Dasu<sup>2</sup>, I. Toma-<sup>3</sup>

<sup>1</sup>Stockholm University, Medical Radiation Physics, Stockholm, Sweden ; <sup>2</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden ; <sup>3</sup>Stockholm University and Karolinska Institutet, Department of Physics and Department of Oncology and Pathology, Stockholm, Sweden

### Purpose or Objective

Recent years have seen an increasing interest in studying the vascular response from large fractional doses delivered in stereotactic body radiotherapy (SBRT). While the vascular effect is extensively discussed as a potential source for tumour cell kill, the observed vascular response after doses of 10-15 Gy appears to be highly dynamic. With an initial reduction in blood flow that persists for various lengths of time, the actual vascular effect could be highly dependent on the time point at which treatment fractions are delivered with respect to each other. Thus, rather than leading to an increased cell kill, an increased radioresistance could be expected during the limited SBRT treatment if the total fraction of acutely hypoxic cells is increased. This study investigated the impact of temporary vascular collapse on tumour control probability (TCP) in SBRT, taking into account the different radiosensitivity of chronically and acutely hypoxic cells.

### Material and Methods

Three-dimensional tumours were simulated based on tumour vessel distributions assuming different fractions of collapsed vessels at every treatment fraction. Thus, the simulated tumours contained both chronically and acutely hypoxic regions before the start of the treatment, the chronically hypoxic subvolume having a size of 30-60% of the tumour diameter, and a hypoxic fraction <5mmHg of 30-50%. The rest of the tumours were in general well-oxygenated at the start of the treatment. A radiation-induced increase in the acutely hypoxic fraction was simulated following the first fraction. SBRT-fractionation schedules of 3, 5, and 8 fractions were considered, and cell survival was calculated with a modified linear-quadratic model taking into account different radiosensitivities of chronically and acutely hypoxic cells. The simulated treatments were evaluated by calculating the TCP.

### Results

A complex interplay between the radiation-induced and chronic hypoxia was observed for different fractionation schedules. For an eight-fraction treatment, for example, delivering 60 Gy in total, the TCP for a tumour with no treatment-induced vascular collapse in the well-oxygenated region and a chronically hypoxic subvolume with a diameter corresponding to 30% of the tumour size, was 97%. Assuming a vascular collapse of 35% induced by the first fraction and persisting throughout the remainder of the treatment resulted in a TCP of only 2% while the TCP was 83% for an identical tumour except for a much larger chronically hypoxic subvolume with a diameter of 60% of the tumour size. Thus, radiation-induced increase in acute hypoxia had a worse impact on the outcome of the treatment than an increase diameter of the chronically hypoxic subvolume.

### Conclusion

The timing of SBRT fractions leading to vascular damages and thus increased acute hypoxia could impact on the efficacy of the treatment, and should be considered together with the tumour oxygenation to avoid loss of TCP for SBRT treatments.

### EP-1931 Photon vs proton therapy for reduction of cardiac toxicities in locally advanced lung cancer

S. Teoh<sup>1</sup>, F. Fiorini<sup>1</sup>, B. George<sup>1</sup>, K.A. Vallis<sup>1</sup>, F. Van den Heuvel<sup>1</sup>

<sup>1</sup>CRUK/MRC Oxford Institute for Radiation Oncology, Oncology, Oxford, United Kingdom

### Purpose or Objective

Identify a sub-group of patients with locally advanced lung cancer who would benefit most from proton therapy compared to photon therapy for reduction of cardiac toxicities using the model-based approach.

### Material and Methods

Dual-arc volumetric modulated arc photon therapy (VMAT) and robust-optimised intensity modulated proton

therapy (IMPT) plans were created in twenty proxy patients with locally advanced lung cancer to a physical dose of 70Gy in 35 fractions. Proxy patients were selected to represent varying anatomical locations of the primary tumour and nodal involvements (15/20 had nodal involvement). Contouring, treatment planning and organs-at-risk constraints followed RTOG 1308 trial. The following cardiac sub-structures were delineated- right and left: atriums, ventricles and coronary arteries, and sino-atrial node. Dose calculation and optimisation of IMPT plans were done using Monte-Carlo dose engine. Dose to the heart and sub-structures were compared. Risk estimates of grade 3+ cardiac toxicities were calculated based on normal tissue complication probability models which incorporated dose metrics and patients' risk-factor - pre-existing cardiac disease (CD). Wilcoxon signed-rank test was used to assess statistical significance of the difference.

### Results

There was no statistically significant difference in target coverage between VMAT and IMPT. Overall IMPT delivered lower doses to the heart (mean heart dose (MHD), V5 and V30). In VMAT plans, there were statistically significant positive correlations between heart dose and thoracic vertebral level (MHD, V5 and V30; Pearson correlation coefficient,  $r$ : 0.67, 0.79, 0.48,  $P < 0.05$ ). Between VMAT vs IMPT, there was no statistically significant difference in the mean cardiac dose or its sub-structures when the tumour (primary and nodes) extended above T7 vertebrae ( $n = 4$ ). When tumour extended to and below T7 vertebrae ( $n = 16$ ) IMPT delivered lower cardiac doses (MHD, V5 and V30, and mean dose to all sub-structures,  $P < 0.001$ ). Risk of G3+ cardiac toxicities when tumour extended to and below T7 vertebrae are presented in Table 1.

Table 1: Risk estimates of G3+ cardiac toxicities with tumour extension to and below T7 vertebrae

Cardiac Risk	VMAT (95% CI)	IMPT (95% CI)
Pre-existing CD		
AR (based on MHD, %)	19 (16-20)	11 (10-13)
AR (based on V5, %)	25 (20-30)	9 (8-10)
RR reduction (based on MHD)		0.39 (0.31-0.47)
RR reduction (based on V5)		0.59 (0.50-0.69)
No pre-existing CD		
AR (based on MHD, %)	7 (4-9)	3 (3-4)
AR (based on V5, %)	11 (8-13)	3 (3-4)
RR reduction (based on MHD)		0.45 (0.34-0.57)
RR reduction (based on V5)		0.62 (0.51-0.73)

CI - confidence interval, CD - cardiac disease, AR - absolute risk, MHD - mean heart dose, RR - relative risk

### Conclusion

Proton therapy has the potential to reduce cardiac toxicities compared to photon therapy. This analysis suggests that patients with tumour extension to and below T7 vertebrae would benefit most from proton therapy over photon therapy. The absolute benefit is higher in patients with underlying cardiac disease.

### EP-1932 Development of a deep learning network using a pre-trained convolutional neural network

M. Rooney<sup>1</sup>, J. Mitchell<sup>2</sup>, D.B. McLaren<sup>2</sup>, W.H. Nailon<sup>1,3</sup>

<sup>1</sup>NHS Lothian, Department of Oncology Physics-Edinburgh Cancer Centre, Edinburgh, United Kingdom ;

<sup>2</sup>NHS Lothian, Department of Clinical Oncology-Edinburgh Cancer Centre, Edinburgh, United Kingdom ;

<sup>3</sup>The University of Edinburgh, School of Engineering, Edinburgh, United Kingdom

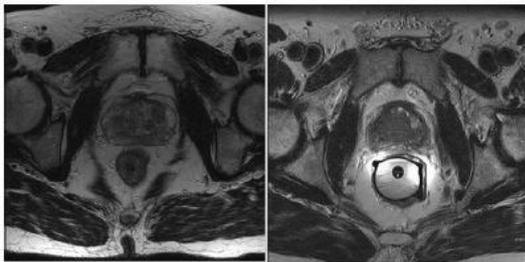

### Purpose or Objective

The use of machine and deep learning is rising in oncology. Discrimination of tissue types using texture analysis is a long standing technique. Texture features are often used to train machine learning models. Deep learning, a subfield of machine learning, overcomes the need to calculate features by allowing the machine to learn directly from the image. However, a large amount of labeled image data is required to train deep learning models, this is a difficulty in oncology. The aim of this

work was to investigate the feasibility of applying a pre-trained CNN to a set of medical T2 MRI images with the intent to identify areas of disease in the prostate using texture analysis as a baseline.

#### Material and Methods

T2 MRI studies of 16 patients with localised prostate cancer were studied. The MRI images were rigidly registered to the planning CT and the OAR's, prostate and the focal lesion were contoured by a consultant oncologist. Using Matlab, three workflows were investigated. Firstly, 32 texture features were calculated to characterise the image properties of healthy and diseased tissues and used to train four different machine learning algorithms. Secondly AlexNet, a CNN trained on > 1 million images containing 1,000 classes was used as a feature extractor for later classification. Lastly, AlexNet was adapted for use on MRI images using transfer learning. Each was initially developed on Brodatz images containing strong textural features. This was then translated onto a set of 40 prostate MRI images published as part of a MICCAI grand challenge, Figure 1, to test performance on a set of medical images. The models were assessed in terms of accuracy, sensitivity, specificity and AUC (Table 1).

**Figure 1:** An example of the T2 MRI images included in the MICCAI dataset with and without an endorectal coil, only cases without an endorectal coil were considered.

#### Results

Findings from Brodatz images showed the ability to obtain high levels of classification accuracy using texture analysis and CNNs. Application to the MICCAI data showed that superior sensitivity can be achieved using a fine-tuned CNN over texture analysis. Transfer learning was successful in identifying prostate from surrounding structures in T2 prostate MRI images with the hypothesis being that the CNN would identify generic features common to most images such as colour, contrast and repetitive patterns. Application to the local dataset showed promise. Using AlexNet, the results were on par with those of machine learning but low sensitivity was observed. This is likely due to the high level of imbalance inherent to this data type.

Data Set	Method	Accuracy	Sensitivity	Specificity	AUC
Brodatz	Texture Features	0.924	0.924	0.924	0.978
	CNN Derived Features	0.818	0.701	0.867	0.899
	Fine-tuned CNN	0.966	0.918	0.989	0.996
MICCAI	Texture Features	0.595	0.492	0.716	0.651
	CNN Derived Features	0.529	0.241	0.867	0.568
	Fine-tuned CNN	0.593	0.830	0.367	0.635
T2 Prostate Cancer Positive	Texture Features	0.682	0.454	0.710	0.641
	CNN Derived Features	0.674	0.632	0.679	0.682
	Fine-tuned CNN	0.783	0.227	0.852	0.663

**Table 1:** Results of each method on all datasets. Overall, the AUC indicates that the performance of the CNN is on par with machine learning methods. These data strengthen the claim that pre-trained CNN's are suitable to identify prostate cancer on MRI images.

#### EP-1933 A deep learning approach for identifying focal prostate cancer from multi-parametric MRI

M. Rooney<sup>1</sup>, A. Killean<sup>2</sup>, J. Mitchell<sup>2</sup>, D.B. McLaren<sup>2</sup>, W.H. Nailon<sup>1,3</sup>

<sup>1</sup>NHS Lothian, Department of Oncology Physics-Edinburgh Cancer Centre, Edinburgh, United Kingdom ;

<sup>2</sup>NHS Lothian, Department of Clinical Oncology-Edinburgh Cancer Centre, Edinburgh, United Kingdom ;

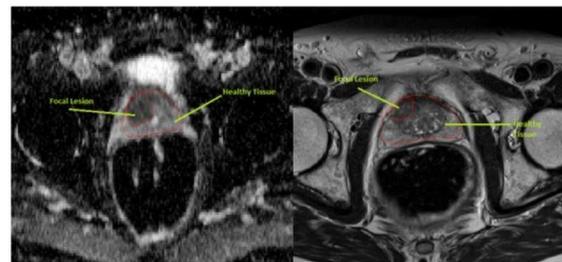

<sup>3</sup>The University of Edinburgh, School of Engineering, Edinburgh, United Kingdom

#### Purpose or Objective

There are no technical barriers to delivering radiotherapy to small focal lesions within the prostate gland, however, reliably identifying focal disease is challenging. Multi-parametric magnetic resonance imaging (mp-MRI) has significant potential for this and in addition because of the improved image resolution may be combined with machine learning techniques to assist with tumour delineation. The aim of this work was to combine information from T2 weighted, apparent diffusion coefficient (ADC), and diffusion weighted (DW) MRI to train machine learning models to automatically identify focal disease within the prostate.

#### Material and Methods

Two datasets were utilised from previously treated patients with localised prostate cancer. The first included 16 patients with diagnostic T2 MRI, the second included 12 patients with diagnostic T2 and ADC studies. The planning CT, T2 and ADC images, where available, were registered rigidly using a Varian Eclipse workstation. An experienced clinician contoured the prostate and focal lesion on both images, Figure 1. Matlab was used to process the images in this study, where sub images were extracted from each before 32 texture features were calculated. These features were used to train SVM, k-NN, decision tree and Ada-boost classification algorithms. In addition, AlexNet, a pre-trained convolution neural network was fine-tuned to classify each sub image as healthy or diseased tissue. The performance of each model was assessed in terms of sensitivity, specificity and AUC (Table 1).

**Figure 1:** An example of the clinically defined area of disease on both ADC (left) and T2 (right) MRI scans used in this study.

#### Results

The results demonstrate that multimodality imaging data, in the form of T2 MRI and ADC images, can be successfully combined to build models for the identification of focal disease within the prostate. This was achieved through the creation of co-trained classification models using texture and CNN image features derived from the MRI sequences from a cohort of 12 patients. Overall, it can be noted that texture features yield more sensitive results versus the fine-tuned CNN. This novel approach achieved very high classification performance when tested on T2 images with a maximum AUC of 0.935 compared to the highest result of 0.663 AUC found using single sequence MRI studies.

Data Set	Method	Sensitivity	Specificity	AUC
T2	Texture features + classification	0.454	0.710	0.641
	Fine-tuned CNN	0.227	0.852	<b>0.663</b>
Mp-MRI	Texture features + classification	0.384	0.976	<b>0.935</b>
	Fine-tuned CNN	0.244	0.892	0.892

**Table 1:** Summary of classification results from both data groups testing using T2 images

### Conclusion

These results are promising, a larger data set is required to further develop these approaches. However, in the absence of this, there are many areas of improvement still to be explored.

### EP-1934 A study of RBE and NTCP uncertainties underlying model-based patient selection to proton therapy

S.N. Fly<sup>1</sup>, J. Pedersen<sup>1</sup>, J.B. Petersen<sup>1</sup>, C.H. Stokkevåg<sup>2</sup>, L.P. Muren<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark ; <sup>2</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway

### Purpose or Objective

Normal tissue complication probability (NTCP) models have been proposed for patient selection to proton therapy (PT). NTCP model parameters from different (mostly photon-based) studies often show large variability with wide confidence intervals. PT dose distributions should also be corrected for the higher and variable relative biological effectiveness (RBE) of protons. A number of different models for variable RBE are available, with their inherent model parameter dependencies. The aim of this study was to investigate how the choice of RBE model and their uncertainties relate to the uncertainties of current NTCP model parameters.

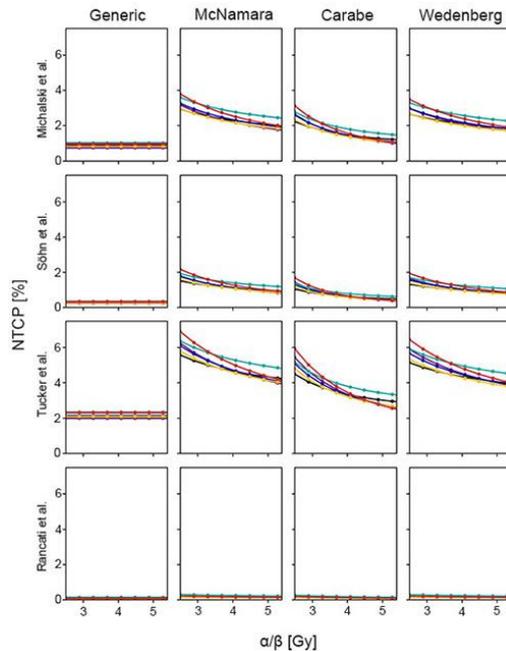

### Material and Methods

Three published variable RBE models (McNamara et al., Wedenberg et al., and Carabe et al.) - as well as the generic (constant RBE = 1.1) alternative - were applied when analysing spot scanning PT plans of six prostate cancer patients (prescription doses of 78 Gy (RBE = 1.1)). The RBE corrected dose volume histograms of the rectum and bladder were adjusted for fractionation effects using the linear-quadratic model (EQD<sub>2Gy</sub>) before entered into the Lyman-Kutcher-Burman (LKB) NTCP model. Nine different published LKB parameter sets (including the QUANTEC parameters, Michalski et al) were used for the rectum and three sets for the bladder. The effect of varying  $\alpha/\beta$ -ratio within the range of published values was investigated. Uncertainties in the NTCP values were calculated from the confidence intervals of the published NTCP parameters using both error propagation and Monte Carlo simulations.

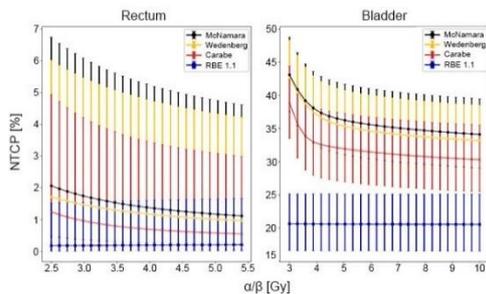

### Results

The choice of NTCP model parameter sets had a much larger influence on the resulting NTCP predictions than the choice of variable RBE model (Fig. 1). The value of the  $\alpha/\beta$ -ratio had a considerable effect on the resulting NTCP estimates for the variable RBE models (Fig. 1). The McNamara model resulted in higher NTCP values than the Wedenberg and Carabe models (Fig. 1) while all three variable RBE models resulted in higher NTCPs than the generic constant RBE alternative, with the differences increasing for lower  $\alpha/\beta$ -ratios. The uncertainty in the NTCP parameters had a large impact on the NTCP values, with differences up to 5% for the rectum (with the QUANTEC parameters) and more than 10% for the bladder (Fig. 2).

**Figure 1:** NTCP values for four different parameter sets (in papers of Michalski et al., Söhn et al., Tucker et al., and Rancati et al.) of the rectum and four different RBE scenarios (McNamara, Carabe, and Wedenberg models as well as the generic RBE = 1.1) are plotted against  $\alpha/\beta$ -ratio for six patients (in different colours). The differences in NTCP between the different NTCP parameter sets were larger than between the variable RBE models. The NTCPs calculated with the variable RBE models increased for decreasing  $\alpha/\beta$ -ratio. Two of the five other NTCP parameter sets (data not shown) also resulted in NTCP = 0 (as for the Rancati et al. parameters).

**Figure 2:** NTCP values and their confidence intervals for one parameter set of the rectum (Michalski et al.) and one parameter set of the bladder (Thor et al.), for four different RBE scenarios (McNamara, Carabe, and Wedenberg models as well as the generic RBE = 1.1) plotted against  $\alpha/\beta$ -ratio for one patient. The confidence intervals of the NTCPs from the variable RBE models have some overlap with the corresponding intervals for constant RBE for the rectum (left), but not for the bladder (right).

### Conclusion

The choice of NTCP model parameters has a much larger influence on resulting risk predictions than the choice of variable RBE model, even for the rectum where there are more published morbidity studies than for most other organs. The three variable RBE models resulted in higher NTCPs than the generic constant RBE, with the differences increasing for lower  $\alpha/\beta$ -ratios. Even without considering implications of potential differences in volume effects between photons and protons (due to the reduced dose bath of PT), this study clearly shows that model-based patient selection to PT should be performed with caution, taking current model and parameter uncertainties into account.

Gemelli IRCCS, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche- Istituto di Radiologia, Rome, Italy

#### Purpose or Objective

Different investigations have focused on the GBM's heterogeneous features to develop an individualized patient management. A multi-institutional study, the GLI.F.A. (Glioblastoma: advanced Imaging Features Analysis) Project, was performed for a comprehensive analysis of GBM heterogeneity in order to create a multidimensional map for predictive models (PM) and decision support systems (DSS) in GBM

#### Material and Methods

Adult patient with newly diagnosed GBM, that undergo surgery and chemo-radiotherapy according to EORTC 26981-22981-NCIC trial were analyzed in this first phase of the study. Gross Tumor Volume (GTV) was contoured in the T1 post contrast and T2-FLAIR weighted images. A brain ontology and a platform for sharing and combining multiple datasets (BOA-WEB System) were created in order to standardize data. MRI features were extracted by the dedicated software. Two analysis were conducted: the study of imaging features of MRI at diagnosis and a delta radiomics study oriented to evaluate the evolution of imaging features, considering all MRI performed. In both of the studies, the Wilcoxon Mann Whitney test and the Log-rank test for Kaplan-Meier curves were applied to evaluate the significance of the radiomic features on the T2-Flair and T1 images, using the median value of the radiomic features to categorize the continue variables. We considered as main outcomes the local control (LC), the progression free survival (PFS) and the response to radio-chemotherapy (RTCT).

#### Results

We enrolled in this study 43 patients, treated from July 2014 to February 2018. Median age was 63 years (45-80) and 27 patients were still alive at the time of the analysis. The MODDICOM software analyzed image features. Significant features of MRI images at diagnosis divided by MRI sequence and outcome are reported in Fig1. The second order, textural features order, describing the spatial correlation between images voxel, resulted significant for PFS, LC and response to RTCT on the contrast-enhanced T1 weighted MRI. Regarding the delta radiomics features analysis, 18 patients were considered and the CTV segmentation and feature extraction was performed on 68 post contrast T1 weighted MRI. After extracting 92 features, we observed a significant correlation, defined by the adjusted p value, for PFS and LC on pre-RT MRI and on MRI after the 6th chemotherapy cycle. The significant features belong to the first, the second and the third order are reported in Fig2. Almost significant features are morfological and could describe quantitatively something that usually is only qualitatively described

#### Conclusion

This preliminary univariate analysis suggests that the radiomic features relates to survival and clinical outcomes and that is possible to stratify patients according MR based quantitative imaging. A higher number of patients, multivariate analysis and external validation are next steps for getting reliable predictive model.

#### EP-1936 PET/CT Radiomics predict local recurrence in patients treated with SBRT for early-stage NSCLC

G. Dissaux<sup>1</sup>, M. Hatt<sup>2</sup>, D. Visvikis<sup>2</sup>, O. Pradier<sup>1</sup>, E. Chajon<sup>3</sup>, I. Barillot<sup>4</sup>, L. Duverge<sup>3</sup>, I. Masson<sup>5</sup>, R. Abgral<sup>6</sup>, M. Santiago-Ribeiro<sup>7</sup>, A. Devillers<sup>8</sup>, F. Kraeber-Bodéré<sup>9</sup>, M. Mahé<sup>3</sup>, R. De Crevoisier<sup>3</sup>, U. Schick<sup>1</sup>

<sup>1</sup>University Hospital, Radiation Oncology department, Brest, France ; <sup>2</sup>Univ Brest, LaTIM- INSERM- UMR 1101, Brest, France ; <sup>3</sup>Centre Eugène Marquis, Radiation Oncology department, Rennes, France ; <sup>4</sup>University Hospital, Radiation Oncology department CORAD, Tours, France ; <sup>5</sup>Institut de Cancérologie de l'Ouest Cancer Center, Radiation Oncology department, Nantes, France ; <sup>6</sup>University Hospital, Nuclear Medicine department, Brest, France ; <sup>7</sup>University Hospital, Nuclear Medicine department, Tours, France ; <sup>8</sup>Centre Eugène Marquis, Nuclear Medicine department, Rennes, France ; <sup>9</sup>Institut de Cancérologie de l'Ouest Cancer Center, Nuclear Medicine department, Nantes, France

#### Purpose or Objective

The aim of this French multicentric study was to develop and validate an FDG PET/CT radiomics signature with prognostic value in patients treated with stereotactic radiotherapy (SBRT) for early-stage non-small cell lung cancer (NSCLC) and to assess its incremental value with respect to the standard clinical and imaging features.

#### Material and Methods

Patients from Rennes (n=27), Tours (n=29) and Brest (n=8) were pooled to constitute the training set, whereas the patients from Nantes (n=23) were used as the testing set. The primary endpoint of study was local control. For each patient, the primary tumour was delineated automatically in the PET images using the FLAB algorithm, and manually in the low-dose CT images, and IBSI-validated radiomic features were extracted. A total of 184 radiomic features (92 in both FDG PET and low-dose CT), 7 clinical and histopathological parameters (age, gender, tumour size, stage, localization, OMS status, histology) and one treatment parameter (biologically equivalent dose, BED) were included. In order to pool together radiomics features extracted from the four institutions relying on different PET/CT scanners and associated protocols, we used the posteriori harmonization method ComBat. In the training set, variables found significant in the univariate analysis were fed into a multivariate Cox proportional hazard regression model. The area under the ROC curve (AUC) was used to evaluate the performance of the resulting model in the testing set.

#### Results

Median follow-up was 22.7 (3.2 - 63.4) and 22.2 (1.7 - 58.1) months, in training and testing sets respectively. In univariate analysis, none of the clinical variables, 2 PET features and 3 CT features were significant. The best performance in the training set was obtained with the model combining the two PET features, reaching an AUC of 0.94 (sensitivity 100%, specificity 88%) to predict local recurrence, with a HR undefined (p<0.001). This model obtained an accuracy of 0.91 (sensitivity 100%, specificity 81%), with a HR undefined (p = 0.023) in the testing set. The models relying on CT radiomics features or the combination of PET and CT features reached lower accuracy.

#### Conclusion

We showed that two radiomic features derived from FDG PET were independently associated with local control in patients with NSCLC undergoing SBRT and could be combined in an accurate predictive model. This model could provide recurrence-related information and could be helpful in clinical decision-making, especially regarding dose escalation.

### EP-1937 Distributed AUC algorithm: a privacy-preserving approach to measure the performance of Cox models

C. Masciocchi<sup>1</sup>, A. Damiani<sup>1</sup>, N.D. Capocchiano<sup>1</sup>, J. Van Soest<sup>2</sup>, J. Lenkovicz<sup>1</sup>, E. Meldolesi<sup>1</sup>, G. Chiloiro<sup>1</sup>, M.A. Gambacorta<sup>1</sup>, A. Dekker<sup>2</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>*Policlinico Universitario Agostino Gemelli - Divisione di Radioterapia Oncologica - Gemelli ART, Roma, Italy* ;

<sup>2</sup>*GROW School for Oncology and Developmental Biology, Department of Radiation Oncology Maastricht, Maastricht, The Netherlands*

#### Purpose or Objective

Recent years have brought both a notable rise in the ability to efficiently harvest vast amounts of information, and a concurrent effort in preserving and actually enforcing the privacy of patients and their related data, as evidenced by the European GDPR. In these conditions, the Distributed Learning Ecosystem has shown great potential in allowing researchers to pool the huge amounts of sensitive data need to develop and validate prediction models in a privacy preserving way and with an eye towards personalized medicine.

The aim of this abstract is to propose a privacy-preserving strategy for measuring the performance of Cox Proportional Hazard (PH) model.

#### Material and Methods

A privacy-preserving AUC strategy has been proposed, developed and tested. The algorithm is mainly composed of 4 distinct steps:

- Each site calculates the vector of the linear predictor based on the sites' local data and sends to the results to the master.
- The master merges the received lists of linear predictors and sorts them by calculating the threshold values. This vector is then sent back to each site.
- All sites then calculates the confusion matrix for each value of the threshold and sends the results back to the master;
- The master sums up the confusion matrices for each value of the threshold, and subsequently calculates the true positives and false negatives to plot the ROC points. The area under the ROC curve is finally computed by using trapezoidal approximation.

The proposed method has been tested on a centralized and a distributed infrastructure, with real rectal cancer clinical data, with the data split into 2 random and independent datasets. Age, gender, clinical TNM stage, overall survival status and time were considered in the analysis. The resulting ROC and AUC from both the centralized and distributed infrastructure have then been analyzed and compared.

#### Results

A total number of 945 rectal cancer patients (pts) were selected to develop and validate the proposed model. The whole dataset was split into two distinct sites: site A with 473 pts and site B with 472 pts. A description of the available data is summarized in figure 1.

Once set up and launched, 9 iterations were needed for all sites to converge on a result and compute a distributed Cox model and an additional 2 iterations for the algorithm to calculate the ROC and AUC, for a total of 11 iterations over the course of 172 seconds. The results of the computation are shown in figure 2 with an additional comparison between the distributed and centralized approaches.

Death	0	1	Gender	
Split1	429 (90,70%)	44 (9,30%)	Split1	170 (35,94%) 303 (64,06%)
Split2	436 (92,37%)	36 (7,63%)	Split2	179 (37,92%) 293 (62,08%)

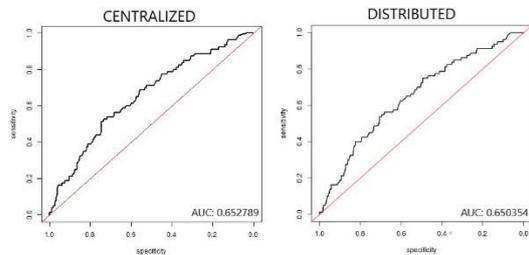

cT	1	2	3	4
Split1	1 (0,21%)	47 (9,94%)	355 (75,05%)	70 (14,80%)
Split2	3 (0,64%)	51 (10,81%)	358 (75,85%)	60 (12,71%)

cN	0	1	2	3
Split1	92 (19,45%)	215 (45,45%)	165 (34,88%)	1 (0,21%)
Split2	92 (19,49%)	229 (48,52%)	148 (31,36%)	3 (0,64%)

age	min	median	max
Split1	0	63	95
Split2	0	60	93

#### Conclusion

The distributed AUC algorithm we developed fills an important void in the current distributed learning environment, as up until now there was, to the best of our knowledge, no practical way of measuring the performance of a privacy preserving and distributed Cox model. This additional step is fundamental to evaluate the model performance of final distributed models.

### EP-1938 A high precision irradiation system for in vivo RBE measurements with ion beams

J. Besuglow<sup>1,2,3</sup>, G. Echner<sup>4</sup>, A. Mairani<sup>3,5,6</sup>, M. Alber<sup>1,2,3</sup>, E. Bahn<sup>1,2,3,7</sup>

<sup>1</sup>*Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg, Germany* ; <sup>2</sup>*NCT, National Center for Tumor Diseases, Heidelberg, Germany* ; <sup>3</sup>*HIRO, Heidelberg Institute of Radiation Oncology, Heidelberg, Germany* ; <sup>4</sup>*Division of Medical Physics in Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg, Germany* ; <sup>5</sup>*Heidelberg Ion-Beam Therapy Center HIT, Department of Radiation Oncology- Heidelberg University Hospital, Heidelberg, Germany* ; <sup>6</sup>*National Centre of Oncological Hadrontherapy CNAO, Medical Physics, Pavia, Italy* ; <sup>7</sup>*Clinical Cooperation Unit Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg, Germany*

#### Purpose or Objective

Research platforms for experimental small animal irradiation can foster to the acute need of robust in vivo data for current challenges in radiotherapy, such as the determination of the RBE of high-LET radiation in the brain. Due to the strong dependence of dose response on the volume of the small irradiation fields employed in these experiments, highly identical dose distributions are required for inter-comparison of different ion types, which presents a major challenge for experimental design.

We devised a multi-component system that meets the requirements of a precise comparative RBE measurement within the pristine Bragg peak of ion beams. Via a passive collimation system, we obtain range adjustment to sub-millimetre precision and sharp lateral beam collimation, combined with precise and rapid animal positioning.

#### Material and Methods

The model requires irradiation of the frontal lobe of a mouse brain with a pristine Bragg peak while sparing sensitive adjacent regions. The dose volume is a 3.5 mm x 7 mm wide cuboid of 4 mm depth for proton, helium, carbon and oxygen ion irradiation. This is achieved via passive collimation with a 3D printed bolus that can be

accurately adjusted relative to the fixated animal head. The collimator was optimized by Monte Carlo (FLUKA) based beam simulation in water and on CT scans. Doses were weighted by LEM I and IV model predictions. Lateral and depth dose distributions in the original collimation geometry were validated by combined dosimetry with gafchromic films and ionization chambers.

### Results

Placement of animals and collimators is rapid, precise and easily reproducible. The entrance field exhibits a lateral dose fall off  $x_{80-x_{20}} = 0.3$  mm (oxygen) to 1.1 mm (protons), see also Fig. 1a. We obtain highly pristine Bragg peaks with very low ion beam energies of 48.12, 50.57, 88.83 and 103.77 MeV/u for protons, helium, carbon and oxygen ions respectively, requiring range shifting by 11.15, 12.59, 10.93 and 10.78 mm PMMA for a residual range R80 of 4 mm. The Bragg peaks are highly similar in beam direction for all ion types (distal dose fall off  $z_{80-z_{20}} = 1.24 \pm 0.02$  mm and peak width  $w_{80} = 2.15 \pm 0.01$  mm), only protons show a slightly wider peak (2.51 mm) and a steeper fall off (1.11mm), see Fig. 1b. Very high LET variations can be achieved. Dosimetric film measurements show a dose homogeneity of  $\pm 2.0\%$ .

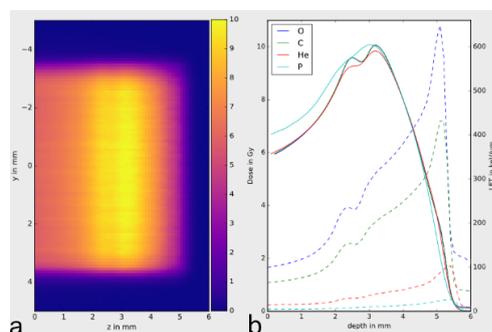

Fig. 1: Dose distribution obtained by Monte Carlo simulation in water. a) Projected dose distribution for He ions. b) Depth-dose curves (solid lines) and depth-LET curves (dotted lines) for the four studied ion types.

### Conclusion

We have shown that conformity of dose distributions between highly different ion types is achievable. The proposed setup allows a detailed examination of biological effects at the distal end of the Bragg peak, thus providing valuable in-vivo data of high RBE irradiation.

### EP-1939 Repeatability of FDG PET/CT based radiomic features using wavelet and Laplacian of Gaussian filters

S. Kyzalas<sup>1</sup>, L. Nygård<sup>2</sup>, B.M. Fischer<sup>3</sup>, J.M. Edmund<sup>1,4</sup>, I.R. Vogelius<sup>2</sup>

<sup>1</sup>Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark ; <sup>2</sup>Rigshospitalet, Department of Oncology, Copenhagen, Denmark ; <sup>3</sup>Rigshospitalet, Department of Clinical Physiology- Nuclear Medicine & PET, Copenhagen, Denmark ; <sup>4</sup>Copenhagen University Hospital, Radiotherapy Research Unit- Department of Oncology, Herlev, Denmark

### Purpose or Objective

Pre-processing of medical images prior to radiomics feature analysis is an important step which is often under-analyzed or documented. One aspect is the use of filtering, which has sometimes been applied to yield (more) significant correlations [1]. Here we analyze the value of a filtering process in terms of repeatability of radiomics features in a prospective scan-rescan study of non-small cell lung cancer (NSCLC) patients [2]. Furthermore, we report how the features depend on the applied filtering.

### Material and Methods

We compare the repeatability of 51 radiomic features, extracted from unfiltered and filtered images, using 8 commonly applied wavelet and 10 Laplacian of Gaussian (LoG) filters. 19 patients were included in a previously published study of both free-breathing PET/CT and deep inspiration breath hold PET/CT. Both breathing modalities were repeated a few days apart without any active therapy in between to form a scan-rescan study [2]. CT images were discretized in 64 bins with saturation thresholds at  $\pm 465$  Hounsfield Units [HU]. The PET images were converted into square root SUV maps, and discretized in 64 bins with saturation thresholds at  $\sqrt{\text{SUV}} = \pm 3.2$ . For the computation of the features, a Matlab radiomics package was used, originally developed by Martin Vallieres [3], although several adjustments to the original script were introduced. Repeatability of the features was based on Pearson's intraclass correlation coefficient (ICC), and the dependence between features with different filters was assessed with Spearman's rank correlation coefficient.

### Results

Most features were found to be more robust on original scan than features based on commonly used, LoG or wavelet filters, cf. Figure 1. On CT, the average ICC for the LoG-based features was  $0.91 \pm 0.12$ ,  $0.81 \pm 0.30$  for the wavelet-based, and  $0.92 \pm 0.10$  for the unfiltered. The ICC differences across the different filters were consistent between PET and CT. Features extracted from images based on the same filter type, were found to be highly correlated, as shown in figure 2.

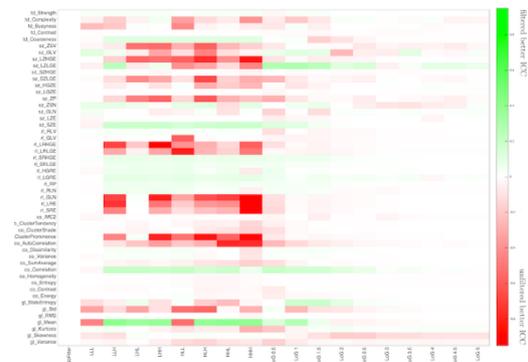

Figure 1: Comparison of repeatability of filter-based features to unfiltered. The values of the heatmap are produced by subtracting the ICC (Pearson) of the filtered features from the unfiltered ones, on CT.

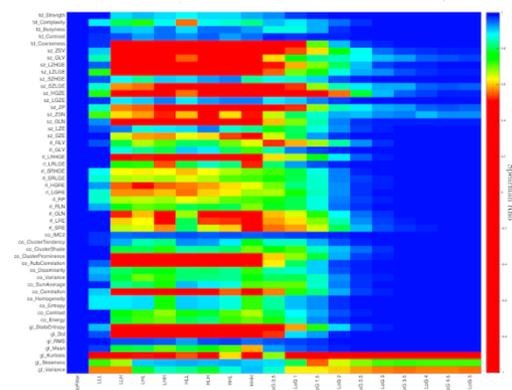

Figure 2: Spearman's rank correlation between features obtained from differently filtered images, in relation to unfiltered, on CT.

### Conclusion

Most of the investigated radiomic features were found to be more robust without the use of any image filters.

Because of the high dependence across features extracted from images based on the same filter type, the number of redundant features may be reduced in future studies.

#### EP-1940 Impact of respiratory motion on the robustness of 18F-FDG PET/CT radiomic features

S. Kyzalas<sup>1</sup>, L. Nygård<sup>2</sup>, B.M. Fischer<sup>3</sup>, J.M. Edmund<sup>1,4</sup>, I.R. Vogelius<sup>2</sup>

<sup>1</sup>Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark ; <sup>2</sup>Rigshospitalet, Department of Oncology, Copenhagen, Denmark ; <sup>3</sup>Rigshospitalet, Department of Clinical Physiology- Nuclear Medicine & PET, Copenhagen, Denmark ; <sup>4</sup>Radiotherapy Research Unit- Department of Oncology, Herlev, Denmark

#### Purpose or Objective

We investigate the repeatability of 18F-FDG PET/CT radiomic features, based on scans obtained in deep inspiration breath-hold (DIBH) and free breathing (FB) in a prospective scan-rescan study of patients with non-small-cell lung cancer (NSCLC) [1].

#### Material and Methods

18F-FDG PET/CT scans from 19 NSCLC patients were analyzed. DIBH and FB scans were obtained twice, a few days apart, with the same fixation in a prospective study without any active treatment between scans [1]. CT images were discretized in 64 bins with saturation thresholds at  $\pm 465$  Hounsfield Units [HU]. The PET images were converted into square root SUV maps, and discretized using a fixed bin width of 0.03  $\sqrt{\text{g/ml}}$ . For the computation of the features, a Matlab radiomics package was used, originally developed by Martin Vallieres [2], although several adjustments to the original script were introduced. The evaluation of the feature repeatability was based on Fisher's intraclass correlation coefficient (ICC).

#### Results

Breathing modality (FB or DIBH) affected the value of many features. However, DIBH vs. FB have negligible impact on the repeatability, as long as the respiratory patterns are not interchanged. The results on the repeatability of the most stable, and least codependent features, are shown in table 1, while the mean effect is shown in figure 1. Additionally, CT-based features were found to be more stable as compared to PET-based features.

CT			
Features	DIBH	FB	Mixed

sz SZLGE	0.948	0.854	0.694
td Strength	0.935	0.873	0.811

Table 1: Feature ICC (Fisher) values, calculated from DIBH and FB scans on PET and CT, of the most stable and least codependent features. "Mixed" corresponds to interchanged patterns, where the ICC is calculated between one day of DIBH and one of FB.

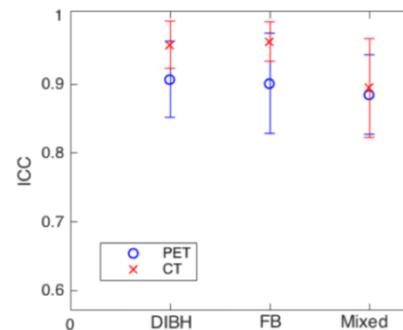

Figure 1: Mean ICC comparison of the features extracted from different respiratory patterns and imaging modalities (shown in table 1), where the errorbars represent  $\pm$ one standard deviation. "Mixed", corresponds to interchanged patterns, where the ICC is calculated between one day of DIBH and one day of FB.

#### Conclusion

The majority of feature values are affected by the use of different respiratory patterns. When it comes to feature robustness, our data found no support to choose DIBH over FB. To maximize feature reproducibility upon multiple scanings, it is advisable to maintain a consistent respiratory pattern.

#### EP-1941 MRI-based radiogenomics analysis of 1p/19q codeletion in grade II and III gliomas

W. Takahashi<sup>1</sup>, T. Nakamoto<sup>1</sup>, H. Akihiro<sup>2</sup>, T. Satoshi<sup>3</sup>, T. Shota<sup>3</sup>, S. Aoki<sup>1</sup>, T. Kiritoshi<sup>1</sup>, M. Ogita<sup>1</sup>, H. Yamashita<sup>1</sup>, K. Nakagawa<sup>1</sup>

<sup>1</sup>University of Tokyo, Department of Radiology, Tokyo, Japan ; <sup>2</sup>Tokushima University, Department of Medical

*Image Informatics, Tokushima, Japan ; <sup>3</sup>University of Tokyo, Department of Neurosurgery, Tokyo, Japan*

#### **Purpose or Objective**

Gliomas with 1p/19q codeletion are diagnosed as oligodendrogliomas and associated with better prognosis than their 1p/19q nondeleted counterparts. The purpose of this study was to investigate feasibility for predicting the 1p/19q codeletion status of the gliomas based on the radiogenomic analysis using T2-weighted magnetic resonance (MR) images (T2WIs).

#### **Material and Methods**

We analyzed the institutional database, for adult patients with a diagnosis of World Health Organization grade II and III gliomas from 1995 to 2017. Based on multiplex ligation-dependent probe amplification (MLPA) or microsatellite analysis, 38 patients underwent testing for 1p/19q codeletion (23 with codeleted and 15 with nondeleted). Pretreatment T2WIs of all patients were retrospectively evaluated. Gross tumor volumes (GTVs) were manually contoured and radiogenomic features (shape, size, histogram, and texture features) were extracted in the GTVs. Data were analyzed using L1-norm regularized logistic regression. A leave-one-out cross validation was employed in order to evaluate performance of a prediction model. Accuracy, sensitivity, specificity, and area under the receiver operating characteristics (ROC) curve (AUC) value were calculated as evaluation indices. This retrospective data evaluation was approved by the local ethics committee.

#### **Results**

Total number of the radiogenomic features was 476. Accuracy, sensitivity, specificity, and AUC values of the prediction models were 0.711, 0.697, 0.733, and 0.736, respectively. The 1p/19q codeletion could be moderately predicted using the proposed framework.

#### **Conclusion**

We developed a radiogenomics-based framework for non-invasively predicting the 1p/19q codeletion in grade II-III gliomas using the T2WIs. The proposed framework would be feasible to preoperatively predict genomic status of the gliomas using the MR images. Further validation studies at multi-centric level are mandatory and scheduled to confirm our findings.

#### **EP-1942 Combining radiomic and dosimetric parameters to predict chemoradiation response of EC patients**

X. Jin<sup>1</sup>, C. Xie<sup>1</sup>

<sup>1</sup>The 1st Affiliated Hospital of Wenzhou Medical University, Radiation and Medical Oncology, Wenzhou, China

#### **Purpose or Objective**

The treatment response prediction capability of radiomics features extracted from PET and CT images had been extensively investigated. However, radiotherapy dosimetric parameters, which are the key parameters that affect the treatment response, were not included in the response studies. The purpose of this study is to investigate the prediction feasibility and accuracy of an integrated model with combined radiomic features and dosimetric parameters for esophageal cancer (EC) patients underwent concurrent chemoradiation (CRT) using machine learning techniques.

#### **Material and Methods**

Ninety-four patients underwent CRT for primary EC between Oct 2012 and Oct 2015 were enrolled in this study. The primary target volumes (GTVs) of these patients were delineated by two expert oncologists. DICOMs files were exported from TPS to an open infrastructure software platform: IBEX for preprocessing and feature extraction. Dosimetric parameters were extracted from DVH. The response of these patients to treatment was evaluated three months after the

treatment. Xgboost was applied to build a model to predict the correlation between parameters and treatment response.

#### **Results**

There were total of 42 radiomics features and 18 dosimetric parameters extracted for these 94 cases, together with sex, age and radiotherapy modalities were included in the modeling. According to the results of data visualization using parallel coordinates, prescription dose, GTV, heart and cord related dosimetric parameters, as well GlobalMean X.33.1, Correlation, Coarseness, Skewness have a strong correlation with treatment response. The prediction accuracy and precise of training and validation data were 0.9, 0.86 and 0.54, 0.6, respectively. Remodeling after principal components analysis (PCA), the prediction accuracy and precise of training and validation data were 0.79, 0.76 and 0.75, 0.76, respectively. According to the Gain calculated for each parameter in the prediction model, image features of GlobalMean X.333.1, Coarseness, Skewness, GlobalStd were contributed most to the model. Dosimetric parameters of PTV HI, Cord Dmax, Prescription dose, Heart-Dmean and Heart-V50 also have a strong contribution to the model. The Area under curve (AUC) of receiver operating characteristics (ROCs) for dosimetric features alone and combined dosimetric features and dosimetric parameters were 0.6 and 0.75, respectively.

#### **Conclusion**

Models combining radiomics features and dosimetric parameters is capable of and outperform those with radiomics features alone in predicting the treatment response for EC patients underwent CRT.

#### **Electronic Poster: Physics track: Intra-fraction motion management**

---

#### **EP-1943 Intra-fractional respiration monitoring for patients undergoing lung SBRT**

E.P.S. Sande<sup>1</sup>, T.P. Hellebust<sup>1</sup>

<sup>1</sup>Oslo University Hospital, Dep. of Medical Physics, Oslo, Norway

#### **Purpose or Objective**

The Varian TrueBeam (TB) Respiratory Gating System (RGS) tracks respiratory motion via a reflector block placed on the patient's chest. The system may interrupt the beam when detected motion exceeds pre-defined thresholds, due to sudden or gradual involuntary patient motion - such as coughing or baseline drift. The purpose of this study was to investigate the feasibility of using the TB RGS for intra-fractional monitoring during free breathing (FB) stereotactic lung radiotherapy (SBRT) to possibly increase the accuracy in dose delivery.

#### **Material and Methods**

Firstly, intra-fractional respiratory motion curves were recorded for 31 lung SBRT treatment sessions (9 patients). Thresholds were not applied, ensuring no RGS-related beam interruptions. Post-treatment analysis assessed the fraction of treatment sessions in which the beam would have been interrupted due to sudden motion or baseline drift, if thresholds had been set prior to treatment. Findings were used to determine suitable thresholds, given possible clinical implementation of RGS intra-fractional monitoring. Secondly, possible dosimetric disadvantages of interrupting the delivery of SBRT plans were investigated. A 6 MV FFF VMAT plan and a 10 MV FFF static plan (PTV D<sub>min</sub> 15 Gy/fraction) were delivered to a stationary ArcCheck phantom (Sun Nuclear Corp.). Respiratory motion of the reflector block was simulated during delivery using a CIRS (CIRS Inc.) respiratory motion phantom. Plans were delivered using three duty cycles (DC) - defined as the ratio of beam-on time to the total

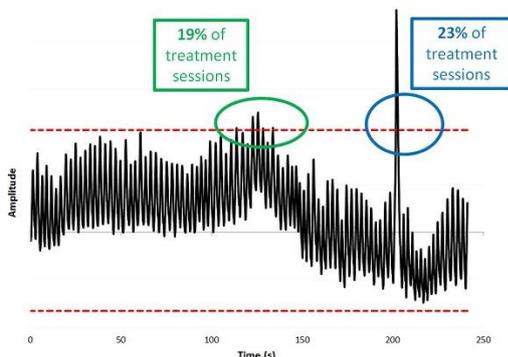

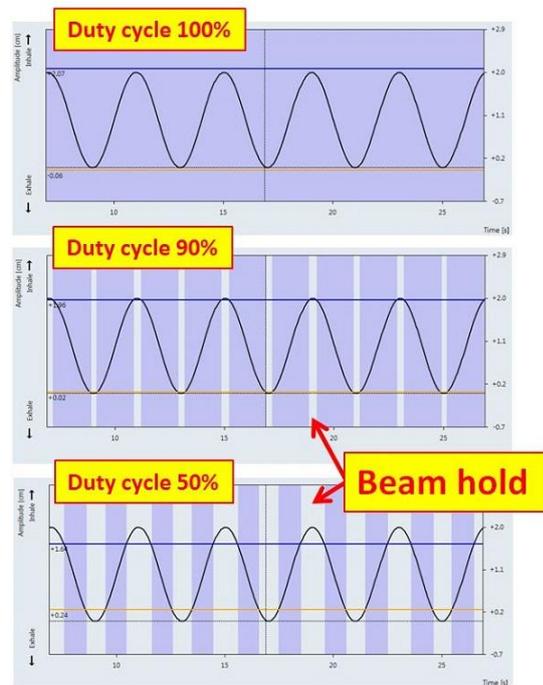

beam time: 100% (no beam interruptions), 90% and 50% (Fig. 1).

**Results**

Post-treatment analysis of recorded motion curves was done assuming upper and lower thresholds of 3 mm above normal inhale and below normal exhale, respectively. Normal inhale and exhale was defined as the average maximum and minimum block positions, respectively, based on the first four respiratory cycles following setup. Results are summarized in Fig. 2, illustrated by a recorded curve. Thresholds are shown as red dotted lines. 19% and 23% of treatment sessions had gradual intra-fractional drift or sudden motion, respectively, which would lead to beam interruption given the above mentioned thresholds. Gamma passing rates for plans delivered to the ArcCheck phantom, using different DC, are shown in Table 1. A 3%/3 mm criterion was used. Gamma passing rates for plan delivery using different DC differed less than 0.5%, even with only a 50% DC - the latter implying an unlikely high rate of beam interruptions.

	γ passing rate (%):		
	100% DC	90% DC	50% DC
6 FFF VMAT	99.5	99.5	99.0
10 FFF static	97.5	97.4	97.4

**Table 1:** Gamma passing rates for plans delivered to the ArcCheck phantom using different DC.

**Conclusion**

It seems feasible to use the TB RGS as a system detecting patient motion during delivery of FB lung SBRT - with the additional benefit of pausing the beam when motion exceeds pre-defined thresholds. Repeated beam interruptions during delivery appear to have little dosimetric impact.

**EP-1944 Automated respiratory cycle binning for liver 4D-MR imaging**

B. L'Home<sup>1</sup>, L. Parent<sup>1</sup>, O. Bieri<sup>2</sup>, Z. Celicanin<sup>3</sup>, P. Cattin<sup>4</sup>, S. Ken<sup>1</sup>

<sup>1</sup>Institut Universitaire du Cancer de Toulouse, Department of Engineering and Medical Physics, Toulouse, France ; <sup>2</sup>University Hospital Basel, Department of Radiology, Basel, Switzerland ; <sup>3</sup>Intuitive Therapeutics SA, Radiotherapy and Radiosurgery Planning Treatments, Saint-Sulpice, Switzerland ; <sup>4</sup>University of Basel, Department of Biomedical Engineering, Basel, Switzerland

**Purpose or Objective**

Stereotactic body radiation therapy (SBRT) has proven its benefit for local control of liver lesions<sup>1</sup>. Because high dose per fraction is delivered on small volume, very accurate lesion segmentation is necessary and respiratory gating enables safe margin reduction on the planning target volume (PTV). MRI is the preferred imaging modality for detection and characterization of hepatic lesions, but it is prone to motion artifacts if breathing is not managed. As external device for breathing movement detection may be inaccurate, the tracking of the sub-diaphragmatic organs movements with very fast 2D sagittal images appeared to be an interesting retrospective strategy using a previously validated 4D-MRI sequence for the liver<sup>2</sup>. In this study, an automated method was developed to sort images according to the respiratory phases with the sub-diaphragmatic organ movements.

**Material and Methods**

The 4D-MRI acquisition is performed with an experimental sequence (bSSFP TrueFISP<sup>3</sup>) on a 1.5T system (Magnetom Aera, Siemens). This sequence allows very fast interleaved axial and sagittal 2D acquisition (0.44 sec/slice) during free breathing. In order to correctly sample the entire breathing magnitude, 20 axial acquisitions are collected every 2.5 mm in the cranio-caudal direction. A sagittal slice (the navigator) is always acquired at the same position in the imaging volume and at 0.44 sec from the associated axial slice. According to the sub-diaphragmatic organs position on navigators, axial slices are automatically sorted in 6 phases (0% = inspiration, 16%, 33%, 50% = expiration, 66%, 83%). Automatic binning is performed by comparing the relative translation (white arrow on Figure 1) of each navigator (green slice, Figure 1) regarding a reference navigator (purple slice).

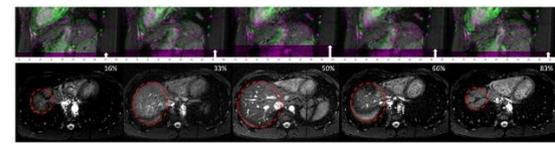

Figure 1: Axial slice sorting (with liver movement highlighted with red contour) by sub-diaphragmatic organs tracking on navigators

The sequence was evaluated on 5 volunteers with an audio coaching (5 and 6 sec period) and 2 patients without audio coaching.

**Results**

Retrospective axial slices binning according to their positions in the breathing cycle was achieved by automated motion tracking of sub-diaphragmatic organs on navigators. All axial slices of the 6 respiratory phases were imported into the treatment planning system (TPS) Eclipse 13.7 (Varian) allowing the reconstruction of the sagittal and coronal images. The 50% phase appears as the

most reproducible phase (with the lowest standard deviation on all respiratory cycles, *figure 2*) confirming the treatment strategy to target the PTV on the phase 50% during the expiratory phase.

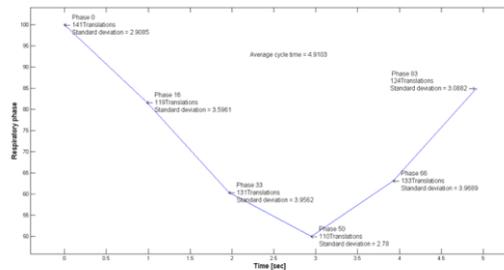

Figure 2: Average cycle calculated from all the navigators of the exam.

### Conclusion

Images from volunteers and patients were acquired using a 4D-MRI bSSFP (TrueFISP) sequence. After automated sorting with the method developed in this study, all the respiratory phases were imported into our TPS. Patient 4D-MRI could be registered with 4D-CT to capture the entire organs movements (liver cranio-caudal movements in red, Figure 1) during respiratory cycles and improve lesion delineation.

**EP-1946 First french clinical experience using the Calypso tracking system for the prostate treatment**  
 J. Prunaretty<sup>1</sup>, D. Cirella<sup>1</sup>, P. Debuire<sup>1</sup>, N. Ailleres<sup>1</sup>, A. Morel<sup>1</sup>, S. Simeon<sup>1</sup>, S. Valdenaire<sup>1</sup>, P. Fenoglio<sup>1</sup>  
<sup>1</sup>CRLC Val d'Aurelle - Paul Lamarque, Radiotherapy, Montpellier, France

### Purpose or Objective

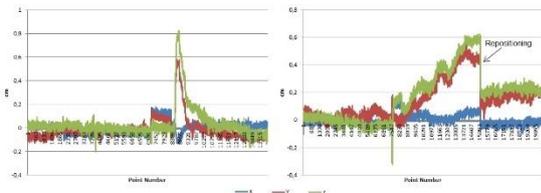

To report the intrafraction prostate displacement using the Calypso system through a randomized phase II study (RCMI-GI).

### Material and Methods

The Calypso System consists in an electromagnetic detection of implanted transponders. It is a real-time target tracking system that takes into account both inter- and intrafractional target motion. The RCMI-GI study will include 166 patients into arm 1 and arm 2 in 1:1 ratio. 83 patients will be treated with standard set-up margins (1 cm all around the prostate except 5mm in the posterior direction) and conventional IGRT protocol (daily CBCT). For the other ones, the treatment will be performed with reduced margins (3mm all around the prostate) using the Calypso® system. The prescribed dose is 80Gy in 40 fractions. To date, 21 patients were treated in arm 2 using VMAT and Calypso. At the beginning of each fraction, a CBCT was performed and "Set zero and track" function of the Calypso was applied. A 3mm-gating threshold was used during the treatment. The displacements  $\geq 3$ mm in all directions were evaluated qualitatively and quantitatively.

## Results

A total of 787 sessions were analyzed. An intrafraction motion  $\geq 3$ mm was detected for 77 fractions (9.8%). Visually, the shifts were unpredictable and varied from a transient evolution (left figure) continuous drift to a continuous drift (right figure). For each patient, from 0% to 23% of fractions were impacted by a displacement  $\geq 3$ mm. 12,4% of movements were in the lateral direction, 48,8% in the axial direction and 38.8% in the longitudinal one. The mean time of the treatment interruption was ranged from 0.01' to 09.52 minutes and increased the mean session time of 24.7% in comparison with a fraction without motion. Forty six percent of 77 fractions required couch shift corrections using kV imaging (as mandatory in our protocol) and explained a longer treatment.

## Conclusion

The intrafraction motions of the prostate are unpredictable and not negligible during the treatment. The Calypso system performs an accurate and continuous monitoring of the target and allows a safe margin reduction.

### EP-1947 RCMIGI randomized phase II study using Calypso system. First dosimetric results on CBCT acquisitions

<sup>1</sup>Institut du Cancer de Montpellier ICM, Radiothérapie, Montpellier, France

### Purpose or Objective

In the RCMIGI randomized phase II study, two treatment techniques of prostate cancer are compared in terms of radiation late toxicities, depending on the irradiated volumes. One of these techniques is a non-irradiative real-time tracking which uses electromagnetic implanted transponders (Calypso, Varian Medical System) to detect and follow submillimetric motions of a target. This way, the margin around the prostate can be reduced and a correlation may be found with late toxicities by studying the daily patient treatment deliveries. Here we present the results of dose calculation on daily CBCT images leading to the real treatment delivery knowledge.

### Material and Methods

25 prostate cancer patients were treated using RapidArc technique on a TrueBeam linear accelerator (Varian Medical System). In each arm of the study, 80 and 56 Gy were prescribed to the prostate and seminal vesicles (SV) in 40 fractions. The Calypso arm included 14 patients, each with 3 transponders implanted in the prostate that can be tracked before and during the irradiation. This allows to reduce the margin used to create the Planning Target Volume (PTV<sub>2</sub> = Prostate + 3 mm). Eleven patients were included in the standard arm, without real-time tracking and with standard margins (1 cm, 0.5 cm posterior). For every patient, Cone Beam Computed Tomography (CBCT) imaging was performed at each fraction before irradiation. Target volumes and Organs at Risk (OAR) were contoured and the original Eclipse (Varian medical system) treatment plan was calculated on the CBCT images. Thus 40 daily Dosimetric Volume Histograms (DVHs) were obtained per patient (1000 CBCTs in total). The averaged prostate, SV, bladder and rectum DVHs were then compared to the original treatment plan DVHs, for both arms of the study.

## Results

Figure 1 shows the averaged target volumes' DVHs on CBCTs and original dosimetry CT match each other in both arms. There are some discrepancies for rectum and bladder in both arms. DVHs of the CBCTs bladder are always lower than dosimetry because the bladder is empty during the original dosimetric scanner (CBCTs mean volume is 125 cc and 97.4 cc for the original CT), leading to higher relative volume doses. Rectum DVHs are on average higher on CBCTs, with an important uncertainty due to the high variation in rectum shape. Calypso SV, bladder and rectum DVHs are lower than those of the standard arm because of the lower irradiated volume induced by the reduced PTV margin. For instance, Calypso bladder D50 is 14 Gy (23 Gy for standard arm) and V70 is 5% (13%). There is also a 6 Gy lower rectum D50% on the Calypso patients, and V72 is 6% versus 10.5% for the standard arm.

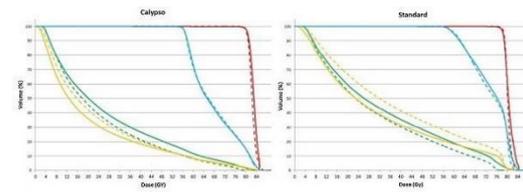

Figure 1: Average CBCTs DVHs vs dosimetry in Calypso arm (left) and standard arm (right)

## Conclusion

Calypso system allows submillimetric tracking of the prostate and therefore a reduction in the irradiated volume as shown in these first patient dosimetric results. Associated with long-term life quality follow-up, this could lead to the correlation of late toxicities versus dose statistics.

### EP-1948 Deep-inspiration breath-hold and free-breathing in left breast cancer irradiation: a dosimetric study

D. Aiello<sup>1</sup>, G.R. Borzi<sup>2</sup>, L. Marino<sup>2</sup>, V. Umina<sup>2</sup>, A.M. Di Grazia<sup>2</sup>

<sup>1</sup>Fondazione Istituto Oncologico del Mediterraneo, Radiotherapy, Viagrande, Italy; <sup>2</sup>REM Radioterapia, Radiotherapy, Viagrande, Italy

### Purpose or Objective

To analyze organs at risk dose reduction between voluntary deep inspiration breath hold (DIBH) and free-breathing (FB) techniques in left breast irradiation.

### Material and Methods

Between January 2018 and October 2018, eighty RT plans, based on DIBH and FB scans, were generated for forty breast left cancer patients who received three-dimensional conformal (3D) adjuvant RT and were retrospectively analyzed. Treatment plans were generated on both DIBH and FB CT scans. The scans were monitored by the Varian RPM™ respiratory gating system. The patients were asked to breathe freely and then inhale and hold their breath at a comfortable level, for at least 15 seconds. The treatment planning was performed with conformal tangential fields by means of 6, 10, or 15 MV photon fields. Treatment schedule were 40.05 Gy in 15 fractions (hypofractionated schedule) or 50 Gy in 25 fractions (conventional schedule) with or without sequential boost to tumor bed. Dose-volume histograms (DVHs) were compared for all plan. For the comparison, we considered: the mean dose to the heart (D<sub>meanheart</sub>), left anterior descending coronary artery (D<sub>meanLADCA</sub>) and ipsilateral lung (D<sub>meantlung</sub>), the volume receiving 20 Gy (V<sub>20Gylung</sub>) and the volume receiving 30 Gy (V<sub>30Gylung</sub>) for the ipsilateral lung, the volume receiving 20 Gy for LADCA (V<sub>20GylADCA</sub>) in conventional schedule, the volume receiving

19 Gy for LADCA ( $V_{19GyLADCA}$ ) in hypofractionated schedule. Quantitative statistical analysis of plan dose differences were generated. Maximum heart distance (MHD) was defined as the maximum distance between the anterior cardiac contour and the posterior tangential field edges. In order to correlate each measure of cardiac dose with MHD a linear regression model was used. Statistical level significance was set with a p-value <0.05.

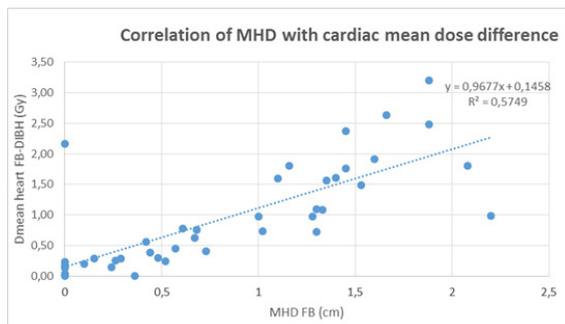

### Results

A statistical significant reduction of cardiac and pulmonary doses was achieved using DIBH technique compared to FB plans (Table 1) maintaining an equal coverage of planning target volume (PTV). A positive correlation was found between MHD and mean heart dose reduction (Fig.1).

Table 1

Organ	Technique	Mean dose (Gy)	SD	Mean difference dose (Gy)	p-value	Mean dose reduction (%)
Heart Dmean	FB	2.25	1.27	0.98	0.0000	43.5
	DIBH	1.27	0.65			
Heart Dmax	FB	39.61	12.57	19.09	0.0000	48.2
	DIBH	20.52	16.17			
LADCA Dmean	FB	13.39	10.02	8.39	0.0000	62.7
	DIBH	5.00	5.69			
LADCA Dmax	FB	39.17	11.04	20.29	0.0000	51.8
	DIBH	18.88	14.97			
Mean Lung Dose	FB	7.82	2.76	1.16	0.0354	14.8
	DIBH	6.66	2.02			
		Mean volume (%)		Mean difference volume (%)		Mean volume reduction (%)
Lung left V20Gy	FB	13.56	5.70	2.35	0.0390	17.3
	DIBH	11.21	4.20			
Lung left V30Gy	FB	11.52	5.58	2.18	0.045	18.9
	DIBH	9.34	3.83			
LADCA V20Gy	FB	27.64	27.72	21.93	0.0025	79.4
	DIBH	5.71	15.98			
LADCA V19Gy	FB	20.25	19.02	18.14	0.0004	89.6
	DIBH	2.11	5.54			

Fig. 1

### Conclusion

Our study confirms literature data about DIBH technique advantage in terms of reduction of cardiac and pulmonary doses for tangentially treated left sided breast cancer patients. Further research is warranted to evaluate potential long-term clinical implications of these relevant dosimetry results.

**EP-1949 Heart position reproducibility in deep inspiration breath hold radiotherapy for lung cancer**  
M. Josipovic<sup>1</sup>, M.C. Aznar<sup>1,2,3</sup>, J.B. Thomsen<sup>1</sup>, J. Scherman<sup>1,4</sup>, S.M.S. Damkjær<sup>1</sup>, L. Nygård<sup>5</sup>, L. Specht<sup>3,5</sup>, M. Pöhl<sup>5</sup>, G.F. Persson<sup>1,3,6</sup>

<sup>1</sup>Rigshospitalet, Dept. of Oncology\Section of Radiotherapy, Copenhagen, Denmark ; <sup>2</sup>Manchester Cancer Research Centre, Division of Cancer Science, Manchester, United Kingdom ; <sup>3</sup>University of Copenhagen, Department of Clinical Medicine- Faculty of Health and Medical Sciences, Copenhagen, Denmark ; <sup>4</sup>Skåne University Hospital, Dept. of Radiation Physics, Lund, Sweden ; <sup>5</sup>Rigshospitalet, Dept. of Oncology, Copenhagen, Denmark ; <sup>6</sup>Herlev Hospital, Dept. of Oncology, Copenhagen, Denmark

### Purpose or Objective

Heart dose has been linked to both increased mortality (McWilliam 2017) and cardio-vascular toxicity (Wang 2017) in patients with locally advanced non-small cell lung cancer (NSCLC), treated with modern chemo-radiotherapy. Residual setup errors, with tumour position closer to the heart than planned, had negative impact on overall survival (Johnson-Hart 2018).

We have shown, that treating this patient group in deep inspiration breath hold (DIBH) is well tolerated, improves image guidance and, in majority of patients, facilitates reduced dose to the heart (REF XXX).

The purpose of this study was to assess the reproducibility of the heart position between the consecutive DIBHs.

### Material and Methods

Patients participating in a single institution DIBH radiotherapy trial (2015-2017) were included. Voluntary DIBHs were supported by use of an optical marker system and a visual feedback of the patient's DIBH level. The patients underwent three consecutive DIBH CT scans as part of the imaging for radiotherapy planning. DIBH CT no. 2 and no. 3 were rigidly registered on DIBH CT no.1 with focus on the heart. In 15 patients, all registrations were repeated after two months to evaluate the uncertainty of the manual registration process.

The positional variations of the heart position were compared to previously evaluated variations in position of the peripheral tumour (T) and the lymph nodes (N).

### Results

In total 60 patients were available for the analysis. Mean ± standard deviations (SD) in the heart position between the DIBH CTs were 0.3±1.2 mm in left-right (LR), -0.1±1.3 mm in antero-posterior (AP) and 0.0±2.0 mm in cranio-caudal direction (CC). Over 90% of the deviations were < ±3mm (Figure 1). Intra-observer variation of the manual registration was 0.8mm in LR, 0.7mm in AP and 1.0mm in CC direction.

Heart-to-T position deviations were (mean±SD): 0.1±1.4 mm in LR, 0.3±1.8 mm in AP and -0.4±1.8 mm in CC, with 79% of deviations < ±3mm. Heart-to-N position deviations were 0.2±1.2mm in LR, 0.2±1.4mm in AP and -0.1±1.4 mm in CC direction, with 90% of deviations < ±3mm (Figure 1). During the image registration process, differences in heart circumference of >1cm were observed in some patients, despite reproducible lung volume and chest elevation (Figure 2).

Largest heart position deviation was in the CC direction and may only in part be explained with higher observer uncertainty in this direction. It was possibly a result of cardiac motion, its impact on image quality and heart deformations between the consecutive DIBHs.

Figure 1 – Box & beeswarm plot of variation in the heart position between consecutive DIBHs (top panel), and differences between the position of the heart and the peripheral tumour (middle panel) and between the heart and the lymph nodes (bottom panel). Thick line represents the median, box the 1<sup>st</sup> & 3<sup>rd</sup> quartile, whiskers are set at the 1.5 times interquartile range of the lower and upper quartiles. Points above and below the whiskers are considered outliers (deviating more than 2.7SD from the median).

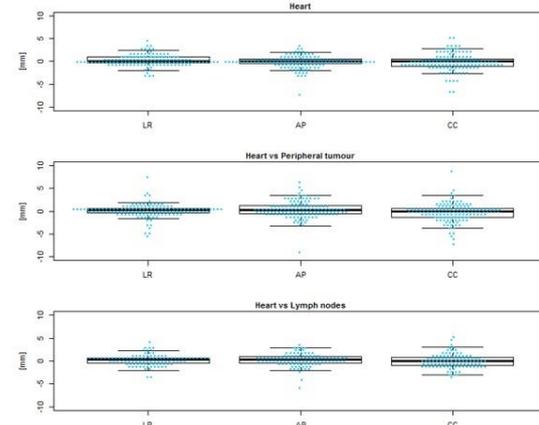

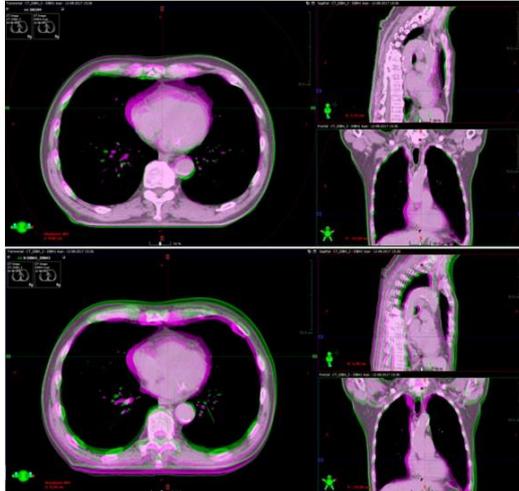

Figure 2 – green/magenta overlay of 1<sup>st</sup> (green) and 3<sup>rd</sup> (magenta) DIBH CT in patient #44. Top panel: registration between DIBH1 and DIBH3, based on DICOM origin: bones are well aligned, no major differences in lung volume or thorax surface, but clearly extended heart volume anteriorly. Bottom panel: CT scans are registered on the heart (3<sup>rd</sup> DIBH CT shifted 0.9 mm to the right, 7.4mm shift posteriorly and 3 mm cranially). There is still clear difference in heart circumference on both scans, while it fits well in cranio-caudal direction. DIBH lung volume increased by 54% compared to FB.

### Conclusion

The position of the heart was reproducible between consecutive DIBHs. Deviations between heart and N were smaller than between heart and T.

Further investigations on the variations in the position and shape of the heart and its substructures are warranted, for both free breathing and DIBH, and in combination with the variation in the position of the lung tumour (due to the baseline shift and anatomical changes).

### EP-1950 Phase gated lung SBRT verified by fluoroscopy

P. Wright<sup>1</sup>, S. Ramadan<sup>1</sup>, S. Suilamo<sup>1</sup>, P. Mali<sup>1</sup>, H. Minn<sup>1</sup>  
<sup>1</sup>Turku University Central Hospital, Radiotherapy and Oncology, Turku, Finland

### Purpose or Objective

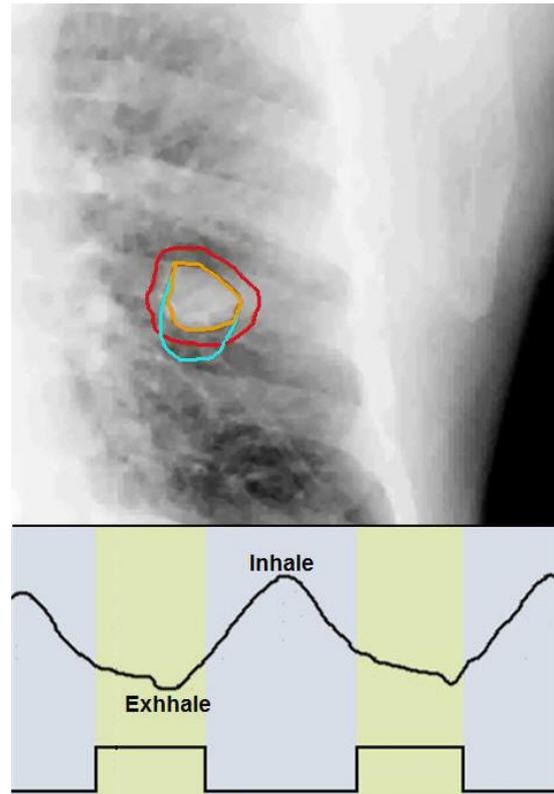

Diaphragm motion may cause large motion of lung tumours. A resulting large internal target volume (ITV) may limit the possibility of stereotactic body radiotherapy (SBRT). By delivering radiotherapy phase gated during the mid-vent breathing phase the resulting ITV may be remarkably reduced thus enabling SBRT for otherwise unsuited patients. This retrospective study presents treatment management and reproducibility of free breathing mid-vent phase gated lung SBRT.

### Material and Methods

During 2014-2018 30 patients have been treated for either primary lung cancer or metastatic disease with mid-vent phase gated lung SBRT. Treatment was planned on the average 4D-CT image created from the 30-70% breathing phases. The achieved reduction in ITV and resulting planning target volume (PTV) as compared with the full breathing cycle 4D-CT volumes were recorded for all patients. During treatment the patients breathed freely while their breathing amplitude was monitored with the Varian respiratory management system. Treatment was delivered mid-vent gated i.e. during the 30-70% phases of the breathing cycle (figure 1). Patient positioning was based on on-line cone beam computed tomography (CBCT) reconstructed with a 2 mm slice thickness and transaxial resolution of 1 x 1 mm. Following initial CBCT the match results was verified with on-line fluoroscopic images. A total of 198 fluoroscopic breathing cycles, acquired from 12 of the patients, were available for off-line analysis. From these images the tumours' cranio-caudal motion relative to that in the planning 4D-CTs was measured

(figure 1). All individual cycles were controlled for the tumour being within the PTV during the gating interval as well as if the tumour's exhale maximum deviated from its position in the 4D-CT. Furthermore, it was analysed if the observed deviations from the exhale baseline correlated with variation in either the patient's cycle time or monitored breathing amplitude.

Figure 1: Fluoroscopic view (top) with ITV mid-vent (orange), ITV full cycle (blue) and PTV (red). Mid-vent gating interval (lower) indicated by yellow bars.

### Results

The median ITV and PTV reductions were 40% (SD. 10%) and 30% (SD. 10%), respectively. The ITVs relative cranio-caudal motion between fluoroscopic images and planning 4D-CTs was on median 1.0 (SD. 0.2, p-value 0.82). Of the analysed fluoroscopic breathing cycles the tumours fitted into the ITV outline of the average 30-70% 4D-CT within  $\pm 1$  mm and  $\pm 2$  mm in 70% and 85% of the cycles, respectively. Thus a deviation larger than the CBCT resolution was observed in 15% of the cycles. In one patient the tumour moved outside the PTV during the gating interval. Deviations of the tumour's exhale maximum position did neither correlate with variations in breathing cycle length nor breathing amplitude.

### Conclusion

Free-breathing mid-vent phase gated lung SBRT was clinically feasible and the exhale maximum was stable. Due to its better resolution fluoroscopic images may be used for correcting the on-line CBCT match.

### EP-1951 Clinical feasibility of whole brain radiation therapy without a mask

J. Dekker<sup>1</sup>, T. Rozema<sup>2</sup>, F. Böing-Messing<sup>3</sup>, W. De Kruijff<sup>1</sup>, M. Garcia<sup>4</sup>, D. Washington<sup>4</sup>  
<sup>1</sup>Instituut Verbeeten, Klinische fysica & instrumentatie, Tilburg, The Netherlands ; <sup>2</sup>Helios Radiotherapie B.V., Radiotherapie, Tilburg, The Netherlands ; <sup>3</sup>Jheronimus Academy of Data Science, n/a, 's-Hertogenbosch, The Netherlands ; <sup>4</sup>Instituut Verbeeten, Radiotherapie, Tilburg, The Netherlands

### Purpose or Objective

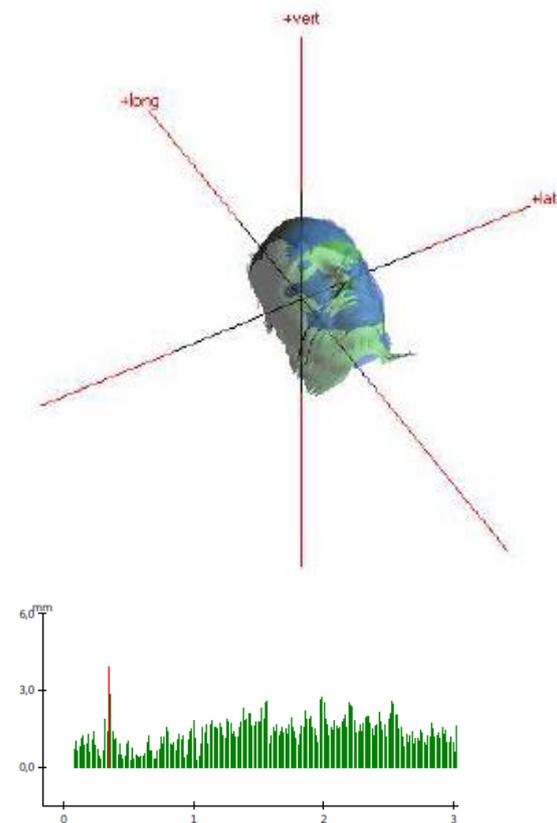

Patients complain about the tightness of thermoplastic masks and experience anxiety when the mask tightly encloses the head. Especially for patients suffering from claustrophobia, wearing a mask can be intolerable. Hence, a treatment method without the necessity of fixating the head is of advantage for patients. In order to ensure a reproducible position and to control intra-fraction motion, an alternative is needed. For this purpose, optical surface imaging is used. The aim of the study is to investigate the clinical feasibility of whole brain radiation therapy without a mask.

### Material and Methods

In total 30 patients received palliative, whole brain radiation therapy (5 fractions of 4 Gy) with the intention not to use a thermoplastic mask. The CTV-PTV margin is 5 mm. In case of participation, informed consent was signed. The surface scanner used for this study is the Catalyst™ (C-RAD AB, Sweden). Patients are instructed to lie as still as possible on the treatment couch. Positioning is done using surface scanning (see Figure 1) and an online matching procedure is performed. This is verified by making an anterior-posterior and a medio-lateral kV image. Motion monitoring starts as soon as the patient is positioned. The threshold for motion of the head is set to 3 mm, since this is an acceptable deviation taking the CTV-PTV margin of 5 mm into account. Figure 2 gives an example of the calculated iso-center shift. If the movement exceeds the threshold the radiation beam is interrupted and the patient may be repositioned. When more than two repositioning procedures are required, the fraction is labelled unsuccessful. Success of the treatment is defined when three or more fractions of one patient have been successful. Clinical feasibility in this study is defined as: more than 70% of the patients can complete the radiation treatment successfully, which is tested by using a one-tailed binomial test ( $p$  value  $< 0.05$ ).

### Results

Two patients out of the total population were not able to lie still and continued the treatment by using a mask. For one of them it was already decided at the CT to make a mask. The other patient completed a successful and an unsuccessful fraction without mask, before it was decided to use a mask for the remaining fractions. All other patients completed their treatment successfully with only one unsuccessful fraction (4 repositioning procedures) for one of these patients. With a probability of success of 93,3% (28 out of 30), we accept the hypothesis that more than 70% of the patients can complete radiation treatment successfully ( $p$  value is 0.0021, 95%-confidence interval 0.80-1.0). Intra-fraction motion data is available for further analysis.

### Conclusion

Patients receiving whole brain radiation therapy have been treated without a thermoplastic mask. In this study it is observed that patients are able to lie still below the threshold of 3 mm. Hence, it can be concluded that irradiation without a mask is a clinically feasible method for whole brain radiation therapy.

### EP-1952 Intra-fraction motion assessment of frameless intracranial radiosurgery using 1.5T MR simulator

J. Yuan<sup>1</sup>, G.G. Lo<sup>2</sup>, O.L. Wong<sup>1</sup>, K.F. Cheng<sup>3</sup>, W.W.K. Fung<sup>3</sup>, Y.H. Zhou<sup>1</sup>, G. Chiu<sup>3</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Hong Kong, Hong Kong SAR China ;

<sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Diagnostic & Interventional Radiology, Hong Kong, Hong Kong SAR China ;

<sup>3</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Hong Kong, Hong Kong SAR China

### Purpose or Objective

The intra-fraction motion of intracranial radiosurgery is usually investigated by using the online X-ray-based imaging. We aim to retrospectively assess the intra-fraction motion shift of a thermoplastic mask immobilized intracranial radiosurgery using MRI data acquired on a 1.5T MR-simulator by taking the advantage of superior MRI image contrast.

### Material and Methods

The simulation MRI scan data at 1.5T of 27 patients (brain metastases  $n=23$ , others  $n=4$ ) prior to Cyberknife intracranial radiosurgery were retrospectively assessed. All patients were scanned in the identical treatment position with a thermoplastic mask fixation. MRI protocol included at least two (T2w and post-contrast T1w+c, ~10min) sequences for all patients. A third T1w+c sequence (~5min) was included in 10 patients. All MRI images had isotropic 1mm voxel size. T1w+c MRI (represented the position at 5min and 10min respectively)

was rigidly registered to T2w (represented the position at 0min) based on mutual information and the intra-fraction motion shifts were calculated from transformation matrix.

#### Results

At the time point of 5min, the intra-fraction translation shifts (mm) were  $0.03 \pm 0.29$  (mean $\pm$ SD),  $0.08 \pm 0.11$ ,  $-0.53 \pm 0.72$  and  $0.71 \pm 0.62$  in LR, AP, SI and 3D, and rotational shifts ( $^{\circ}$ ) were  $-0.06 \pm 0.19$ ,  $0.00 \pm 0.00$ , and  $-0.01 \pm 0.20$  in roll, pitch and yaw, respectively. At the 10min point, the corresponding translation became  $0.02 \pm 0.35$  (mean $\pm$ SD),  $0.10 \pm 0.15$ ,  $-0.96 \pm 0.72$  and  $1.03 \pm 0.72$  in LR, AP, SI and 3D, and rotation ( $^{\circ}$ )  $-0.09 \pm 0.37$ ,  $-0.00 \pm 0.01$ , and  $-0.26 \pm 0.33$  in roll, pitch and yaw. The 3D intra-fraction shift at two time points was illustrated in Fig. 2. Most patients had excellent positional stability during the first 5min, but an apparent time trend of shift was observed at 10min. 7 out of 10 patients exhibited a much larger shift at 10min than at 5min. The superior soft tissue contrast of MRI facilitated more precise image registration and assessment of intra-fraction motion than X-ray skull tracking. So, our results might faithfully reveal the true intra-fraction shift magnitude of the intracranial target during radiosurgery and be helpful for planning margin setting. The limitations of this study included the off-line nature, small sample size, and limited duration and time points.

#### Conclusion

Our results suggested that thermoplastic mask immobilized frameless intracranial radiosurgery could achieve excellent positional stability within the initial 5min of treatment. The frameless immobilization might have high possibility of larger positional shifts that should be substantially compensated after 10min of treatment.

#### EP-1953 Lung tumour dynamics during SABR: Analysis of 415 CBCTs using a semi-automated contouring technique

E. Chandu<sup>1</sup>, L. Conway<sup>2</sup>, G. Distefano<sup>2</sup>, J. Earley<sup>2</sup>, K. Lamont<sup>2</sup>, M. Long<sup>2</sup>, I. Phillips<sup>3</sup>, H. Saxby<sup>2</sup>, C. South<sup>2</sup>, C. West<sup>2</sup>, V. Ezhil<sup>2</sup>

<sup>1</sup>Royal Marsden Hospital, Clinical Oncology, London, United Kingdom ; <sup>2</sup>Royal Surrey County Hospital, Radiotherapy, Guildford, United Kingdom ; <sup>3</sup>Western General Hospital, Clinical Oncology, Edinburgh, United Kingdom

#### Purpose or Objective

SABR (Stereotactic Ablative Body Radiotherapy) is an effective and increasingly utilised treatment in patients with early lung cancer. Because it relies on hypofractionation and a steep dose gradient, the ability to precisely target the tumour with tight margins is of paramount importance. Cone-Beam computed tomography allows online soft tissue matching during SABR to lung cancers. The data from these scans can be harvested to formally verify geometrical conformity and to extract radiobiological information about early response to treatment.

#### Material and Methods

415 CBCTs of 44 lung cancer patients treated with SABR were contoured using a semi-automated technique. The volume of tumour at each CBCT was determined in order to verify geometric conformity with the planning scan and to elucidate the radiobiology of tumours during SABR. The contoured CBCT was registered to the planning CT scan with the online match used at radiation delivery. Formal geometric verification was performed and any volume of tumour not within the reference planning structures was recorded. Counterfactual planning tumour volumes (PTVs) with reduced margins were created to evaluate the potential consequences of smaller PTV margins in clinical practice. (Figure 1)

#### Results

Lung tumours increased before reducing in volume during SABR. The mean volume of tumour at fraction 5 was

significantly smaller than at fraction 2 (6.07 vs. 7.25 cm<sup>3</sup>,  $p = <0.04$ , figure 2). Formal geometric verification confirmed that an isotropic 5 mm PTV margin reliably captured tumour, despite changes in volume and shape during treatment. The volume of tumour not captured by the PTV was trivial (range = 0.00-0.70 cm<sup>3</sup>, median = 0.00 cm<sup>3</sup>). 3 mm and 4 mm margins also consistently captured tumour and may be appropriate in clinical practice. Reasons for tumour falling outside the ITV included change in geometry, imperfect online match and CBCT artefact.

#### Conclusion

Semi-automated contours are effective for analysing Cone Beam CTs scans during SABR.

Our cancer centre delivers SABR with excellent geometrical precision.

5 mm PTV contours effectively capture change in tumour dynamics during treatment.

Smaller PTV margins may be appropriate in SABR for thoracic tumours.

#### EP-1954 The role of 4D cone beam CT and abdominal compression in motion management for Liver SABR

M. Nix<sup>1</sup>, G. Ward<sup>1</sup>, R. Goody<sup>2</sup>, J. Lilley<sup>1</sup>, N. Casanova<sup>2</sup>, R. Garratt<sup>3</sup>, K. Picken<sup>3</sup>, B. Al-Qaisieh<sup>1</sup>

<sup>1</sup>Leeds Cancer Centre, Radiotherapy Physics, Leeds, United Kingdom ; <sup>2</sup>Leeds Cancer Centre, Clinical Oncology, Leeds, United Kingdom ; <sup>3</sup>Leeds Cancer Centre, Radiotherapy, Leeds, United Kingdom

#### Purpose or Objective

Liver SABR relies on IGRT to ensure liver motion and organ at risk (OAR) position are reproducible from simulation through the treatment course. Motion management may include abdominal compression where possible. 4D cone beam CT (4DCBCT) on-set imaging allows verification of motion extent at each fraction and may lead to modifications prior to treatment delivery.

#### Material and Methods

A review of 19 patients treated with 5 fraction SABR for primary or metastatic liver cancer was performed. Total doses delivered were individualised based on OAR constraints and ranged from 40-50Gy. At simulation a multi-phase CT scan was obtained in voluntary exhale breath hold (ExBH), with bolus tracking to obtain arterial, portal venous and delayed phase scans. Oral contrast or water helped visualise duodenum. A 4DCT was acquired to determine extent of tumour motion. When required for target delineation, a treatment position contrast enhanced MRI was obtained. Where possible a CIVCO abdominal compression device was used for all imaging. The GTV was delineated on contrast enhanced ExBH CT or, where obtained, on MRI registered to ExBH CT. In most cases GTV was not visible on 4DCT datasets; ITV margins were determined based on assessment of surrogate liver motion. Maximum inhale and exhale liver contours were generated from 4DCT to aid motion assessment at 4DCBCT. As fiducials are not available in this centre, liver position was used as a surrogate for tumour location. Matching of liver position on maximum exhale phase of 4DCBCT to planning contour was performed. When a full liver match could not be obtained, accuracy of the match in the target region was favoured. A review of the motion and position of any dose-limiting OARs was then performed. Two pre-treatment 4DCBCTs were performed to ensure positioning and motion were stable. 4DCBCT was repeated after each fraction to ensure no change occurred during treatment. Cases were reviewed to assess impact of 4DCBCT.

#### Results

All 19 patients completed treatment. 6 (32%) patients were unsuitable for abdominal compression due to abdominal girth or intolerance of the device. 5 (38%) of the abdominal compression patients required modification to the compression device setting during treatment, to ensure liver motion observed on 4DCBCT was within limits

of motion observed at simulation. The mean absolute paddle height modification required was 7.4 mm (range 4-13 mm). 3 cases were modified prior to the first fraction, 2 later in treatment. Of the patients treated without compression, 3 required coaching to improve breathing to match liver motion limits based on 4DCBCT.

#### Conclusion

4DCBCT IGRT identified 5/13 cases where modifications to abdominal compression were required to achieve liver and OAR motion equivalent to simulation. For patients unsuitable for abdominal compression, 3/6 cases were identified where coaching was required. 4DCBCT is a valuable tool in ensuring the planned dose is successfully delivered.

#### EP-1955 Increased accuracy in setup position by using surface scanning

M. Garcia<sup>1</sup>, J. Dekker<sup>2</sup>

<sup>1</sup>Dr. Bernard Verbeeten Institute, Radiotherapy, Tilburg, The Netherlands ; <sup>2</sup>Dr. Bernard Verbeeten Institute, Medical Physics, Tilburg, The Netherlands

#### Purpose or Objective

The radiotherapy lung patients are traditionally setup using permanent tattoos en laser. During the setup the positioning of the arms can be difficult to position. Depending on the GTV and PTV repositioning can be necessary. The objective of this study was to investigate the accuracy and reproducibility of the arm and body position using surface scanning, compared with our standard positioning method using lasers and pointguards.

#### Material and Methods

- Twenty healthy test subjects participated in this study.
- Initial position: The test subjects were first positioned on the treatment couch according to our standard setup protocol for lung patients. The body and arms were marked in the Z (vertical), Y1, Y2 (longitudinal), and X (lateral) direction. The marked direction are showed in figure 1
- Positioning: Two positioning methods were compared, both using absolute table positions<sup>1</sup> :
  - Standard method: Positioning with laser alignment and pointguards.
  - Surface scanner: Positioning with a Catalyst™ surface scanner.
- Analysis: For both positioning methods, the deviation of the markings in the Z, Y1, Y2, and X directions was measured. To establish the efficiency of both positioning methods, the setup time per positioning method was also measured.

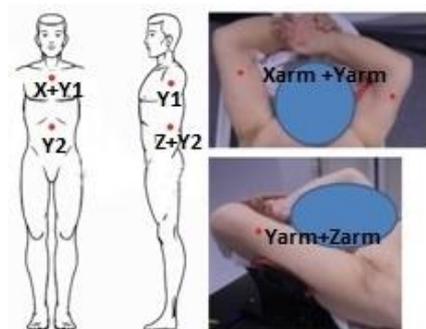

Figure 1. Location of the pointguards in the Z, Y1, Y2 and X direction on the body and arms.

#### Results

A tolerance margin of 3 mm (millimeters) was applied as a criterion for an accurate setup position.

#### Results:

- Body position: The deviation in X, Y and Z direction was within the tolerance margin for 78% of the measurements using the standard positioning method, compared to 75% using the surface scanner.
- Y<sub>2</sub> longitudinal body deviation: With 59% of the measurements, the positioning using laser alignment and pointguards showed a deviation that was smaller than or equal to 3 mm. When using the surface scanner, this occurred in 76% of the measurements.
- Arm position: In 27% of the measurements, the deviation was within the tolerance margin when using the standard method, while this was increased to 42% when using the surface scanner. The results of the arm positioning are showed in figure 2.
- Setup time: The average setup time was 1 minute and 7 seconds for the standard positioning. This was increased to 2 minutes and 17 seconds for the setup using the surface scanner.

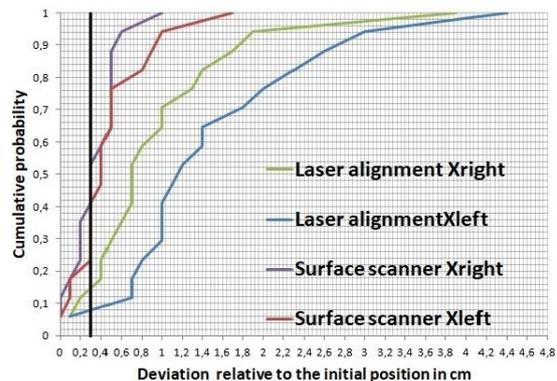

Figure 2. Cumulative histogram for the arm laser positioning in the X right direction (green) and X left direction (blue) and for the arm surface scanner positioning in the X right direction (red) and X left direction (violet). The vertical line (black) mark the 3 mm tolerance margin. This tells what percentage of the total number of measures has a deviation equal to 3 mm or smaller than 3mm.

#### Conclusion

The positioning method using the surface scanner showed an improved body (Y<sub>2</sub> direction) position, especially with regard to the arm position. As the positioning method with the surface scanner entails a new positioning technique, it took relatively longer to set up the patient than with the positioning standard method using laser alignment and pointguards.

#### EP-1956 Image quality of in-treatment 4D-CBCT obtained at various doses in VMAT for SBRT: a phantom study

Y. Shimohigashi<sup>1</sup>, Y. Doi<sup>1</sup>, M. Maruyama<sup>1</sup>, Y. Yotsuji<sup>1</sup>, Y. Kai<sup>1</sup>, R. Toya<sup>2</sup>

<sup>1</sup>Kumamoto University Hospital, Radiological Technology, Kumamoto, Japan ; <sup>2</sup>Kumamoto University Hospital, Radiation Oncology, Kumamoto, Japan

#### Purpose or Objective

In-treatment four-dimensional cone beam computed tomography (4D-CBCT) is a useful tool for assessing the intra-fractional location of a moving tumor and determining planning target volume (PTV) margin. However, in-treatment 4D-CBCT projection data acquired during volumetric modulated arc therapy (VMAT) depends

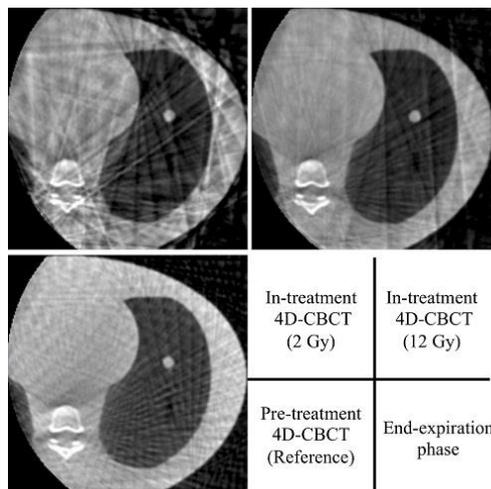

on the delivery time and includes a scatter component arising from treatment using MV beams. These factors may affect the image quality of in-treatment 4D-CBCT. This study aimed to quantitatively evaluate the image quality of in-treatment 4D-CBCT with various prescription doses (PDs) for accurately assessing tumor location in VMAT for stereotactic body radiation therapy (SBRT) of lung tumor.

#### Material and Methods

Spherical targets of diameters 10, 20, and 30 mm inserted in a dynamic thorax phantom moved sinusoidally with respiratory cycles of 4 s and amplitudes (A) of 5 and 10 mm along the superior-inferior direction. The target volumes were contoured from 4D-CT and merged into internal target volume (ITV). The PTV was defined by adding a uniform 5-mm margin to the ITV. The treatment plan was created with a D95 prescription of 2, 6, 7.5, 10, and 12 Gy for PTV using a single-arc VMAT with 6 MV. Pre-treatment 4D-CBCT (Elekta Symmetry™) scans were performed with an acquisition time of 3 min for the phantom setup, and those images were defined as reference images. The in-treatment 4D-CBCT images with various PDs were compared with the reference images using image quality metric. The image quality was evaluated by using signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and dice similarity coefficient (DSC; to evaluate the spatial overlapping of target volumes with pre- and in-treatment 4D-CBCT). A Kruskal-Wallis test was performed for the statistical analysis of the results obtained with various PDs, and a P value < 0.05 was regarded as a significant difference.

#### Results

The figure shows representative images of pre- and in-treatment 4D-CBCT for the 10 mm target with A of 10 mm. The streak artifacts on the in-treatment 4D-CBCT images decreased as the PDs increased from 2 Gy to 12 Gy. For the 10 mm target with A of 10 mm, the mean values ( $\pm$  SD) of the SNR and CNR increased from  $9.8 \pm 0.8$  to  $17.4 \pm 1.5$  and from  $6.4 \pm 1.1$  to  $8.3 \pm 1.4$ , respectively, as the PDs increased from 2 to 12 Gy. The mean values ( $\pm$  SD) of the DSC were not statistically significant from  $0.75 \pm 0.15$  to  $0.7 \pm 0.11$  ( $P = 0.669$ ) as the PDs increased from 2 to 12 Gy. A similar tendency was observed for target sizes of 20 and 30 mm with A of 5 and 10 mm, respectively.

#### Conclusion

PD is an important factor that affects the image quality in in-treatment 4D-CBCT image acquisition. Moreover, in-treatment 4D-CBCT obtained with PDs > 2 Gy is acceptable for assessing tumor location in VMAT for SBRT of lung tumor.

#### EP-1957 An MR-based simulation procedure for individual assessment of tumor motion in MR-guided lung SABR

M. Palacios<sup>1</sup>, J.R. Van Sornsens de Koste<sup>1</sup>, F.O.B. Spoelstra<sup>1</sup>, C.J.A. Haasbeek<sup>1</sup>, A.M.E. Bruynzeel<sup>1</sup>, B.J. Slotman<sup>1</sup>, F.J. Lagerwaard<sup>1</sup>, S. Senan<sup>1</sup>  
<sup>1</sup>VU University Medical Center, Radiation Oncology Department, Amsterdam, The Netherlands

#### Purpose or Objective

To evaluate a simulation protocol to account for irregular breathing patterns in MR-guided SABR for lung tumors, and to report on the reproducibility of GTV position and duty-cycle efficiency during treatment.

#### Material and Methods

A workflow for initial simulation for MR-guided SABR was developed using MR-planar acquisitions (TR/TE = 2.41ms/1.09ms, FA=60°, 4 frames-per-second) in sagittal, coronal and axial planes, allowing for an individualized assessment of tumor motion in three directions for each patient. MR-planar acquisitions allowed the choice of the most suitable breathing-phase for SABR delivery and evaluation of the tracking performance during simulation. A 4D-CT scan was omitted. Ten patients who exhibited variable tumor motion and were treated using two dose schemes (8x7.5Gy and 5x11.0Gy) were identified for this study.

Treatment was delivered with GTV contour tracking during repeated breath-holds based on real-time deformable image registration using MR-planar acquisitions in the sagittal plane. PTV (GTV+3mm) was used as gating window. Treatment delivery performance was analyzed by quantifying the fraction of GTV inside the PTV in each frame during beam-on and corresponding duty-cycle efficiency for a total of 67 fractions.

#### Results

Substantial and variable tumor motion during respiration was observed: range 0.3 - 6.5 mm (AP), 0.2 - 4.7 mm (LR) and 1.5 - 27.1 mm (CC). Five patients were treated during shallow inspiration and five during expiration breath-hold. Reasons for expiration breath-hold were: lateral tumor movements, irregular tumor trajectories, and fast and substantial tumor motion in CC-direction.

Patients treated in expiration breath-hold with MR-guided SABR exhibited better reproducibility of the GTV inside the PTV and higher duty-cycle efficiencies, than patients treated during shallow inspiration. On average across all fractions, 96.9% (SD: 2.1%) and 94.3% (SD: 2.2%) ( $p < 0.001$ ) of the GTV area displayed on the MR-cine during treatment beam-on was inside the PTV for expiration and inspiration patients, respectively. Corresponding duty-cycle efficiencies were 71.9% (SD: 10.5%) and 64.5% (SD: 16.0%) ( $p = 0.016$ ), respectively.

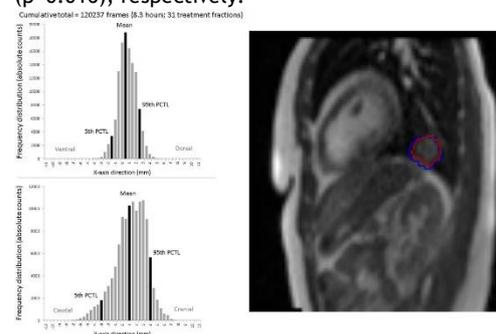

Figure: Frequency distribution of GTV-centroid position with respect to PTV-centroid in AP- and CC-direction for five patients treated with expiration breath-hold (left panel). Example of an MR-sagittal frame during treatment delivery (right panel).

#### Conclusion

An MR-based workflow for simulation prior to SABR for lung patients allowed individualized assessment of tumor motion and irregular breathing trajectories. Complex motion patterns observed led to use of SABR in expiration

breath-holds, and such patients exhibited higher reproducibility for the GTV position and duty-cycle efficiencies than patients treated in inspiratory phase.

#### EP-1958 Eight different open face masks compatibility with surface guided radiotherapy

M. Kügele<sup>1</sup>, E. Konradsson<sup>1</sup>, M. Nilsing<sup>2</sup>, S. Ceberg<sup>3</sup>

<sup>1</sup>Skåne University Hospital, Department of Hematology-Oncology and Radiation Physics, Lund, Sweden ; <sup>2</sup>C-rad Positioning AB, Research and development, Uppsala, Sweden ; <sup>3</sup>Lund University, Medical Radiation Physics-Department of Clinical Sciences, Lund, Sweden

#### Purpose or Objective

Open face masks can be combined with optical surface scanning (OSS) for patient positioning and real time monitoring during radiotherapy treatment. For the open mask, the OSS system aims to detect the patient skin surface only and any unwanted signal from the mask might affect the OSS performance. An increasing number of mask materials are about to be introduced to the radiotherapy environment, but few studies have been carried out investigating the compatibility with OSS system. Also, in this study we had access to new masks which are not yet available on the commercial market.

The aim of this study was to evaluate 1) eight different open face masks compatibility with the optical surface scanning system Catalyst™ (C-RAD Positioning AB, Uppsala, Sweden) and 2) the positioning accuracy using a novel surface algorithm for stereotactic radiosurgery (SRS).

#### Material and Methods

Eight open face masks from several vendors were molded onto a head phantom (Little Junior, Laerdal Medical, Orpington, UK). The OSS system automatically cropped away the mask and only used the skin surface for positioning. Markers were placed onto the skin surface of the phantom for CBCT evaluation purposes. Due to the different designs of the masks, the area of the surface visible for the OSS system varied (figure 1). The phantom was initially positioned on the treatment couch in an open mask at the reference position in isocenter and a CBCT was acquired to register the position. In order to test the novel SRS algorithms accuracy, an offset in the phantom position of 1 cm in all translational directions was introduced. The OSS system calculated couch shifts were sent over to the linac and was automatically shifted, using the auto couch function. A CBCT was acquired to verify the phantom position. For each mask, the marker position was evaluated using the Hounsfield unit profile extracted from the image registration in the treatment planning system (Eclipse 13.6, Varian Medical Systems, Palo Alto, CA). The position of the marker was evaluated in Matlab (Toolbox Release 2015b, The MathWorks, Inc., Natick, MA) in anterior-posterior (AP-PA), left-right (L-R), superior-inferior (S-I) position, respectively.

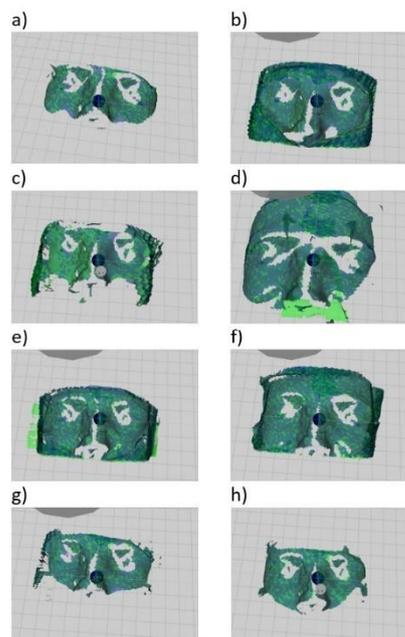

Figure 1. Surface scanned by the optical surface scanning (OSS) system for eight open masks, showing the different sized surfaces the OSS system used for the positioning. The novel stereotactic radiosurgery (SRS) algorithm was used to match the live surface (green) and the reference surface (blue) for positioning.

Table 1. The positioning result from the CBCT for eight different open masks positioned with the OSS system.

	Anterior- Posterior (mm)	Left- Right (mm)	Superior- Inferior (mm)
Mask a	-0.1	0.1	-0.1
Mask b	0	0	0
Mask c	0.1	0	-0.1
Mask d	0	0	0.5
Mask e	-0.1	0.1	0
Mask f	0	0.1	0.1
Mask g	0	0.1	0.1
Mask h	0	-0.1	0.1

#### Results

The range of the width and height of the masks were 6-12 cm and 12.5-29 cm, respectively, which resulted in different sized surfaces for the OSS system to use for the positioning calculation (figure 1). The median (range) position of the marker on the phantom surface for all masks were 0.0 (-0.1 - 0.1), 0.1 (-0.1 - 0.1), 0.1 (-0.1 - 0.5) mm in AP-PA, L-R and S-I directions, respectively (table 1).

#### Conclusion

Overall, all of the masks were compatible in combination with the OS system and the novel SRS algorithm. Regardless of the size of the skin surface, a high accuracy for surface based positioning using the novel SRS algorithm was observed.

#### EP-1959 Performance of Marker-less Tracking for Gimbaled Dynamic Tumor Tracking

M. Ziegler<sup>1</sup>, S. Lettmaier<sup>1</sup>, R. Fietkau<sup>1</sup>, C. Bert<sup>1</sup>

<sup>1</sup>University Hospital Erlangen, Radiation Oncology, Erlangen, Germany

### Purpose or Objective

Dynamic tumor tracking (DTT) is an advanced treatment technique to treat intra-fractionally moving tumors. Until now, the CyberKnife (Accuray Inc., Sunnyvale, CA, USA) and the Vero 4DRT system (BrainLab AG, Munich, Germany) are the only two commercially available systems which can perform a DTT treatment. Both systems detect the internal target position from X-ray images. Until recently, the Vero system required implanted fiducial markers to extract the target position from the X-ray images. Recently, marker-less DTT (MLDTT) was introduced to the Vero 4DRT system with ExacTrac 3.6.1. This work evaluates the accuracy of the new MLDTT method of the Vero 4DRT system and reports the results of the first patients treated with MLDTT at the Vero system.

### Material and Methods

The BrainLab Gating Phantom was used in combination with a QA-tool provided by the vendor (an inhomogeneous "egg" made from a gypsum-like material on an acrylic plate) to measure the detection accuracy of the new MLDTT software. The phantom consists of a vertical and a horizontal one-dimensional drive. A patient breathing curve was used as an input for the phantom and the accuracy was measured for all three spatial directions of the Vero system.

Three patients have been treated with MLDTT at the Vero system of the University Hospital Erlangen. During a MLDTT treatment additional kV images are acquired to determine a template of the day used for tumor detection during treatment delivery. The additional dose delivered by the additional images was determined using the CTDI Set for CT Dosimetry (PTW, Freiburg, Germany) and a log-file analysis was performed to evaluate the MLDTT treatment.

### Results

The accuracy of the MLDTT detection is  $0.12 \text{ mm} \pm 0.12 \text{ mm}$ ,  $0.12 \text{ mm} \pm 0.11 \text{ mm}$  and  $0.20 \text{ mm} \pm 0.21 \text{ mm}$  for the x-, y- and z-direction, respectively which is comparable to the accuracy of the marker-based DTT target detection ( $0.08 \text{ mm} \pm 0.09 \text{ mm}$ ,  $0.07 \text{ mm} \pm 0.08 \text{ mm}$  and  $0.07 \text{ mm} \pm 0.06 \text{ mm}$ ).

The median treatment time for the MLDTT patients was 18 min 25 seconds. On median 65 additional kV images were acquired per treatment fraction to determine the template for the target detection. In comparison to DTT, this results in an additional isocenter dose of 257.4 mGy over the course of the entire treatment.

### Conclusion

Three patients were treated with MLDTT at the University Hospital Erlangen. The accuracy of the MLDTT target detection and the treatment time of a MLDTT treatment were comparable to the marker based marker DTT of the Vero system. The additional imaging dose administered during the treatment can easily be justified since it spares the imaging dose of a CT guided marker implantation into the lung which is an interventional procedure carrying a great risk of pneumothorax.

### EP-1960 A comparison of positioning accuracy for frameless lung SBRT using two immobilization systems

J.M. Penedo Cobos<sup>1</sup>, J. Luna<sup>1</sup>, M.A. Garcia<sup>1</sup>, E. Lopez<sup>1</sup>, K. Aguilar<sup>1</sup>, R. Gonzalez<sup>1</sup>, A. Sanchez<sup>1</sup>, S. Gomez-Tejedor<sup>1</sup>, M. Rincon<sup>1</sup>, M. Alarcia<sup>1</sup>, S. Martin<sup>1</sup>, D. Gonsalves<sup>1</sup>, J. Olivera<sup>1</sup>

<sup>1</sup>Capio-Fundación Jimenez Diaz, radiotherapy oncology, Madrid, Spain

### Purpose or Objective

To quantify the localization accuracy and intrafraction stability of lung cancer patients treated with frameless stereotactic body radiotherapy (SBRT) using two different immobilization systems and to calculate the Internal Target Volume (ITV) margins in both cases to account for the setup errors.

### Material and Methods

19 patients with a single peripheral lung tumor, smaller than 30 cc, were included in this study. Two different immobilization systems were used: 9 patients were immobilized using the Elekta WingSTEP device (system1) and 10 patients using the Qfix Arm Shuttle with Vac-Qfix vacuum bag (system2). For each patient a 4dimensional-CT was acquired in a Philips Brilliance Big Bore CT. The ITV was delineated according to six breathing phases.

In total, 35 fractions were delivered in system1 and 32 fractions in system2. Two risk risk-adapted fractionation schemes were used: 3 fractions of 18 Gy and 5 fractions of 10 Gy. For each fraction, three 4-dimensional Cone Beam CT (4D-CBCT) scans were acquired: before treatment to measure and correct the mean tumor position (initial set-up), after correction to validate the correction applied, and after treatment to estimate the intrafraction stability. (In system2, after correction 4D-CBCT was not acquired).

These scans were volume registered with the localization CT, using a soft-tissue match, in the Elekta XVI software. Corrections were performed by a robotic patient positioning platform that enables sub-millimeter accuracy (Elekta HexaPOD evo RT system). Treatment was delivered using 6 MV photons generated from an Elekta Synergy Beam Modulator Linac.

Patient positioning data from all scans were recorded to determine systematic ( $\Sigma$ ) and random ( $\sigma$ ) set-up errors for initial set-up, after correction and after treatment imaging, in the left-right (X), craniocaudal (Y) and anteroposterior (Z) directions. The ITV to PTV margin (M) was also calculated for after correction and after treatment imaging, using the Van Herk formula:  $M=2.5 \Sigma + 0.7 \sigma$

### Results

A summary of patient set-up errors, intrafraction stability and ITV to PTV margins, in the three orthogonal directions, is shown in Table I.

Calculated margins do not account for target delineation and organ motion uncertainties and are consistent with our current 7 mm margins in all directions.

Table I. Summary of set-up errors and ITV margins

Immobilization system	Directions	CBCT initial Set-up(mm)		CBCT after correction(mm)			CBCT after treatment (mm)		
		$\Sigma$	$\sigma$	$\Sigma$	$\sigma$	M	$\Sigma$	$\sigma$	M
		WingSTEP	X	2.1	2.2	0.7	1.0	2.5	1.1
	Y	5.4	3.6	1.3	1.2	4.0	1.5	1.4	4.6
	Z	2.6	2.7	0.3	0.8	1.4	1.0	1.2	3.3
Vac-Qfix	X	3.4	2.9	---	---	---	0.8	0.8	2.5
	Y	3.9	2.0	---	---	---	1.0	0.7	3.0
	Z	2.3	3.8	---	---	---	1.0	0.7	3.0

### Conclusion

Patients treated using frameless SBRT are well immobilized in both systems studied. This is demonstrated with small intrafraction movements after initial set-up correction using imaging guidance. Therefore this technique can be safely administered using 4D-CBCT. ITV margins are smaller and intrafraction stability improves using the Vac-Qfix immobilization system compared to WingSTEP device.

Vac-Qfix immobilization system can be more convenient for patients with certain clinical conditions.

### EP-1961 Evaluation of dosimetric and anatomic parameters in Deep Inspiratory Breath Hold breast Radiotherapy

A. Nachankar<sup>1</sup>, A. Pawar<sup>1</sup>, A. Jadhav<sup>1</sup>, N. Burela<sup>1</sup>, A. Kakade<sup>1</sup>, P. Dandekar<sup>1</sup>

<sup>1</sup>Sir H N Reliance Foundation Hospital and Research Center, Radiation Oncology, Mumbai, India

### Purpose or Objective

Cardiovascular morbidity following radiotherapy to left sided breast cancers is significant. Several options have

been proposed to reduce cardiac morbidity. We evaluated dosimetric and anatomic characteristics of patient undergoing Deep Inspiratory Breath Hold Technique (DIBH).

#### Material and Methods

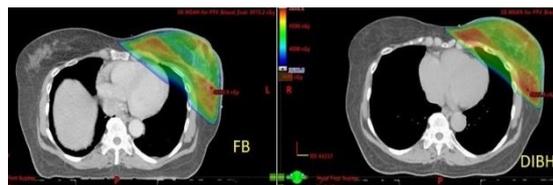

A total of 35 patients were analyzed retrospectively undergoing DIBH for adjuvant radiotherapy for left breast/ chest wall (CW) [BCS (n = 24) or CW (n= 11)] with or without regional nodes irradiation. 20/35 patients were treated with 40Gy/15 fractions and 15/35 patients were treated with 50Gy in 25 fractions +/- 12.5-15 Gy tumor bed boost. All patients trained for DIBH on Real-Time Position Management (RPM) system (Varian Medical Systems). All patients underwent Free Breathing (FB) and Breath-hold scans and were planned on both with tangential field in field technique. Doses to heart, left anterior descending artery (LAD), contralateral breast and lung were documented. Anatomical parameters like sternal angle, Haler's index, maximal heart distance (MHD) and heart and left ventricle to chest wall contact were calculated.

#### Results

Average Breath-hold amplitude was 1.96 cm (Breast), 1.75cm (CW) and average Breath hold duration was 20.8 sec (Breast), 21sec (CW). Average mean heart dose in DIBH patients receiving 50Gy/25fr is 2.24Gy vs 2.96 Gy in patients receiving 40Gy/15fr. Average reduction in mean heart dose in BCS was 56.5% vs 40.9% in CW patients. Average V30% of heart reduced from 6.58 to 1.36 % in 50Gy/25 fr subgroup (p= <0.001) and 7% to 3.03% in 40Gy/15fr subgroup (<0.001) from FB to DIBH respectively. Average MHD reduced from 1.35cm to 0.52cm in 50Gy/25fr subgroup (<0.001) and 1.89 to 1 cm in 40Gy/15fr subgroup (<0.001) from FB to DIBH respectively. Average reduction in irradiated volume of heart (50% isodose line) from 36.8 cc to 7.2cc in 50 Gy/25fr subgroup (<0.001) and 40.5cc to 18.2cc in 40Gy/15fr subgroup (<0.001) from FB to DIBH respectively. Average mean LAD dose reduced from 21.76Gy to 12.16 Gy in 50 Gy/25fr subgroup (<0.001) and 18.5 Gy to 13.4Gy in 40Gy/15fr subgroup (<0.001) from FB to DIBH respectively. Average maximum LAD dose reduced from 40.9 Gy to 32.4 Gy in 50 Gy/25fr subgroup (p=0.04) and 37.6 Gy to 31.9Gy in 40Gy/15fr subgroup (p=0.03), from FB to DIBH respectively. Average reduction in Mean LAD was 42.25 % in BCS patients compared to 25.96% in CW patients. There was statistically significant difference between sternal angle (p= 0.003), MHD (p=<0.001) and heart and left ventricle to chest wall contact (p=<0.001) in FB vs DIBH which correlated with decrease in cardiac and LAD doses. No significant difference in lung V20, mean lung dose & dose to the contralateral breast between FB and DIBH.

Table (1): Anatomical and Morphologic parameters significant for cardiac sparing DIBH for 50Gy/25fr vs 40 Gy/15fr subgroup

	50Gy/25#				40Gy/15#			
	BCS		CW		BCS		CW	
	FB	DIBH	FB	DIBH	FB	DIBH	FB	DIBH
Mean Heart Dose (Gy)	8.65	2.55	5.89	2.67	3.74	2.17	7.32	5.33
Heart V5%	35.03	8.55	13.53	8.13	12.66	6.39	21.33	16.37
Heart V25%	20.1	2.93	7.15	2.27	6.29	1.79	13.55	9.14
Heart V30%	18.31	2.36	6.31	1.87	5.19	1.33	12.45	8.11
Maximal heart Distance (cm)	1.61	0.55	1.46	0.69	1.73	0.88	2.08	1.38

Lung V20	22.98	16.24	17.77	16.18	14.09	14.69	18.97	18.27
Mean Lung dose (Gy)	10.99	8.78	9.30	8.80	6.91	7.03	8.88	8.58

#### Conclusion

DIBH is effective tool for cardiac sparing showing significant dose reduction to heart, and LAD. Changes in anatomical parameters in FB and DIBH scan, like MHD, Sternal angle and heart/ left ventricle contact with chest wall can be helpful in predicting the dose reduction.

#### EP-1962 A simple and low-cost method of deep inspiration breath-hold irradiation for breast cancer

Y. Koide<sup>1</sup>, T. Kitagawa<sup>1</sup>, T. Aoyama<sup>1</sup>, H. Shimizu<sup>1</sup>, H. Tanaka<sup>1</sup>, H. Tachibana<sup>1</sup>, T. Kodaira<sup>1</sup>

<sup>1</sup>Aichi Cancer Center, Radiation oncology, Nagoya, Japan

#### Purpose or Objective

Voluntary deep inspiration breath-hold (DIBH) was useful technique for cardiac dose reduction in left-sided breast cancer radiotherapy. It usually needs some devices to trace patients' respiratory cycle. However, there is a problem of expense and technical challenges of its implementation. Our institution started DIBH with the combination of video-monitoring thoracic motion and the setup using cine-images on an electronic portal imaging detector (EPID) and digitally reconstructed radiograph (DRR). The purpose of this study is to evaluate the accuracy and the reproductivity of this DIBH technique and to compare dose metrics of DIBH and free-breathing (FB) plans.

#### Material and Methods

Ten patients with left-sided breast cancer were included in this study. They were coached and must voluntarily hold their breath during the treatment. Each patient was performed DIBH and FB computed tomography (CT) and created both treatment plans. Patients' thoracic motion was traced with video-monitoring, and the treatment beam was delivered manually when their surface marker was within the acceptable position. Treatment setup was verified comparing DRR and an EPID image. The inter-fractional variation was measured using DRR and the first frame of cine-EPID images acquired during each irradiation. The intra-fractional variation was measured from comparing cine-EPID images from the first frame to the last one at each irradiation. The dose metrics of breast planning target volume (PTV), heart, left ascending artery (LAD), and lung contours were compared between the DIBH plan and the FB plan. Reported results are mean ± SD (DIBH plan vs. FB plan).

#### Results

Eligible patients were all completed planned treatment. The average median inter-fractional movement in the left-right direction (X axis in our study) and in the cranio-caudal direction (Y axis in our study) was  $-0.05 \pm 1.61$  mm and  $1.2 \pm 1.58$  mm, and median intra-fractional movement was  $0.01 \pm 0.49$  mm and  $-0.2 \pm 0.27$  mm. The mean volume of PTV, heart, LAD, and lung between DIBH and FB plan were  $500 \pm 232$  mL vs.  $475 \pm 224$  mL (p = 0.42),  $587 \pm 153$  mL vs.  $584 \pm 130$  mL (p = 0.48),  $2.5 \pm 0.58$  mL vs.  $2.3 \pm 0.62$  mL (p = 0.26), and  $3591 \pm 574$  mL vs.  $2246 \pm 418$  mL (p = 0.0003), respectively. The mean PTV dose was  $42.3 \pm 0.40$  Gy vs.  $42.1 \pm 0.64$  Gy (p = 0.25) and conformity index of PTV was  $0.3 \pm 0.094$  vs.  $0.29 \pm 0.079$  (p = 0.42). The mean heart dose was  $0.76 \pm 0.11$  Gy vs.  $1.33 \pm 0.52$  Gy (p = 0.02), the mean LAD dose was  $2.6 \pm 0.85$  Gy vs.  $7.8 \pm 5.6$  Gy (p = 0.03), and the mean lung dose was  $1.7 \pm 0.42$  Gy vs.  $1.8 \pm 0.45$  Gy (p = 0.29).

#### Conclusion

As only minor inter-fractional and intra-fractional movements were observed, this simple low-cost DIBH technique could ensure a feasible method of voluntary DIBH irradiation. It could reduce the mean heart dose and mean LAD dose with maintaining PTV coverage compared to FB plans.

#### EP-1963 IGRT to improve accuracy in lung SBRT

C. Anson Marcos<sup>1</sup>, D. Hernández<sup>1</sup>, P. Castro Tejero<sup>1</sup>, M. Roch González<sup>1</sup>, A. Valiente González<sup>2</sup>, P. García Castañón<sup>1</sup>, A. Viñals Muñoz<sup>1</sup>, R. Fayos-Sola Capilla<sup>1</sup>, L.

Pérez González<sup>1</sup>, M.T. Murillo González<sup>3</sup>  
<sup>1</sup>University Hospital La Princesa, Medical Physics, Madrid, Spain ; <sup>2</sup>University Hospital La Princesa, Radiation Therapist, Madrid, Spain ; <sup>3</sup>University Hospital La Princesa, Radiation Oncology, Madrid, Spain

### Purpose or Objective

Patient motion and breathing cause misalignment of the tumor and toxicities to the healthy tissue during lung Stereotactic Body Radiation Therapy (SBRT). In order to ensure the accuracy of dose delivering, correction motion can be applied by using Image-Guided Radiation Therapy (IGRT). The aim of this work is to describe our IGRT Protocol for Lung SBRT.

### Material and Methods

Data from 31 patients undergoing SBRT for lung cancer have been analysed for this study. Our IGRT protocol involves the use of time-resolved four-dimensional CT (4DCT) scanning technique (Real-Time Position Manager by Varian) in a Toshiba AquilionLB unit in the simulation phase, and the use of Cone Beam Computed Tomography (CBCT) and fluoroscopy images (On-Board Image by Varian) in the treatment phase in a Clinac 2300 iX.

- Simulation phase: during the scan, the patient is instructed to breathe normally. A 4DCT scan of 10 respiratory phases is reconstructed using phase sorting. After that, contour of the target volume in the 10 sets of CTs is performed. The used approach is creating an internal target volume (ITV) which encompasses the entire tumor displacement in a breathing cycle. ITV is expanded with a margin of 5 mm to create the PTV.

- Treatment phase: radiation delivery consists on three coplanar dynamic hemi-arc fields with RapidArc. Before dose deliver, a full rotation pre-CBCT is performed in the OBI system. Our deviation tolerance in the tumor from the reference setup, determined in three dimensions, is 1cm. Between field activation, intra-fraction anterior-posterior projection fluoroscopy imaging is performed to confirm tumor motion within the PTV contour. If the tumor is not visualized in the fluoroscopy image or the motion exceeds the PTV contour, intermediate CBCT image is performed. Finally, after treatment a post-CBCT assesses intra-fraction tumor displacement.

### Results

For the group of 31 patients, the 84% were able to be performed intra-fraction fluoroscopy against 16% in which the image contrast was low for visualization of the tumor. By using fluoroscopy imaging tumor motion within the session was verified in 61% of the patients. On the other hand, fluoroscopy images showed intra-fraction tumor displacement, and therefore the need of reposition, in 23% of the patients (Figure 1).

The average and standard deviation of the setup errors for all the patients are showed in Table 1. Pre-CBCT presents larger setup errors than post-CBCT, since tumor position is verified, and corrected if necessary, with the fluoroscopy imaging.

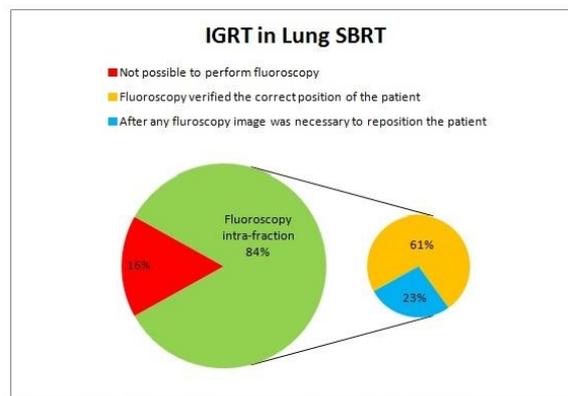

Figure 1. Intra-fraction fluoroscopy imaging performed to verify tumor position.

	IGRT Registration					
	pre-CBCT			post-CBCT		
	X (cm)	Y (cm)	Z (cm)	X (cm)	Y (cm)	Z (cm)
Average	-0,03	-0,18	0,01	-0,01	-0,07	-0,02
Σ	0,29	0,33	0,30	0,06	0,10	0,08

Table 1. Errors in position in CBCT images before and after fractions

### Conclusion

IGRT is an important motion management strategy for tumor motion, as in SBRT lung cancer. Fluoroscopy manages to verify tumor position accuracy and in comparison to CBCT intra-fraction, it involves reducing treatment duration and minimizing dose to patient.

Even though fluoroscopy depends on high contrast for visualization, in conjunction with CBCT, it may be used to confirm motion during the treatment.

### EP-1964 Setup verification and Intrafraction motion monitoring with Optical Surface Imaging for frame-less SRS

A. Nachankar<sup>1</sup>, A. Pawar<sup>1</sup>, A. Jadhav<sup>1</sup>, P. Dandekar<sup>1</sup>  
<sup>1</sup>Sir H N Reliance Foundation Hospital and Research Center, Radiation Oncology, Mumbai, India

### Purpose or Objective

Accurate positioning, rigid immobilization and image verification is crucial in high precision stereotactic radiosurgery. We evaluated setup accuracy using frameless open mask stereotaxy system with optical surface monitoring (OSMS) as an adjunct to gold standard Cone Beam CT (CBCT) scan.

### Material and Methods

We retrospectively analyzed 12 patients treated with frameless cranial stereotactic radio surgery (SRS) during August 2016 and June 2018, at our institution. Patients were immobilized using Q fix immobilization system (Q-fix Aquaplast mask, Head & Neck base plate, MOLDCARE® Cushion & Silverman head support). All patients were aligned to the isocenter with lasers on Perfect Pitch 6 DoF couch. Set up errors were calculated by OSMS prior to acquiring CBCT by comparing surface data to planning CT scan in translational and rotational directions. All the patients underwent CBCT based for correction of setup errors pretreatment and posttreatment verification CBCT. OSMS continuously monitored for intrafraction motion and threshold for beam holding for translational motion was 3 mm and rotational motion was 2 degrees. Data was analysed by Paired T test and Pearson correlation coefficient.

### Results

A total of 24 CBCT scans were analyzed for 12 patients undergoing cranial SRS. Setup errors documented by CBCT were compared with the shifts computed by OSMS. Mean translational errors documented by pretreatment OSMS

are comparable to CBCT setup errors [1.4 +/-1mm vs 1.3 +/-0.09mm in vert (p= 0.87), 1.4 +/-1mm, vs 1.7 +/-0.8mm in long (p= 0.75), 1.5 +/-1mm vs 1.6 +/- 1mm in lat (p= 0.53) directions respectively]. Mean rotational errors documented by OSMS and CBCT system are [1.02 +/-0.8° vs 1.2 +/-0.8° pitch (p= 0.12), 0.6 +/-0.4°, vs 0.7 +/-0.6° roll (p= 0.77), 0.96 +/-0.5° vs 0.98 +/- 0.6° in rotation (p= 0.82) directions respectively]. Mean translational errors documented by post treatment OSMS are comparable to CBCT setup errors (0.3 +/- 0.4 mm vs 0.5 +/-0.4 mm in vert, 0.5 +/-0.2 mm vs 0.6 +/-0.5mm in long and 0.3 +/- 0.4 mm vs 0.8 +/-0.3mm in lat direction respectively). Mean rotational errors post treatment documented with OSMS and CBCT (0.4 +/- 0.5° vs 0.3 +/-0.4° pitch, 0.3 +/- 0.4° vs 0.3 +/- 0.3° in roll, 0.3 +/- 0.2° vs 0.2 +/- 0.3° in rotation respectively). Average intrafractional translational errors were (0.5 +/- 0.3 mm in vert, 0.7 +/-0.2 mm in long and 0.5 +/- 0.4mm in lat directions respectively), and mean rotational errors (0.45 +/- 0.3°, in pitch, 0.3 +/- 0.3° in roll and 0.33 +/-0.2° in rotation respectively). Pearson's correlation coefficient for pretreatment setup verification by OSMS compared to CBCT was (r = 0.12) in vert, (r = 0.16) in long, (r=0.24) in lat, (r= 0.5) in pitch, (r = 0.04) in roll and (r= -0.41) in rotation.

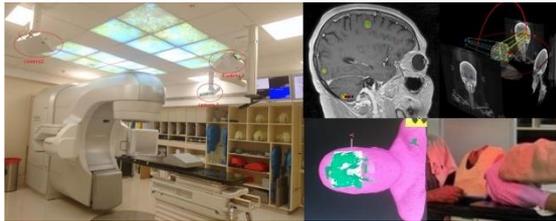

Figure (1): Frame-less, open mask Stereotactic Radiosurgery system with OSMS

#### Conclusion

Setup accuracy of shifts computed by OSMS is comparable to CBCT data. Overall, there is positive correlation between OSMS and CBCT documented setup errors ( $0 < r < 1$ ).

#### EP-1965 RealSense™ Camera Technology for Real Time Surface Monitoring During Radiotherapy

A. Fielding<sup>1</sup>, Y. Jonmohamadi<sup>1</sup>, S. Lee<sup>1</sup>, A. Pandey<sup>1</sup>  
<sup>1</sup>Queensland University of Technology, Science and Engineering Faculty, Brisbane, Australia

#### Purpose or Objective

The aim of this work is to investigate the use of the latest generation of the Intel® Real Sense™ SR300 camera technology for real-time measurement of radiotherapy patient positioning. The systems make use of optical camera technology that measures the distance to a surface; rapid image acquisition can then enable real time motion detection of the location of the surface. The measurement based study investigated the accuracy and precision of the camera system through a series of controlled measurements of static and moving objects.

#### Material and Methods

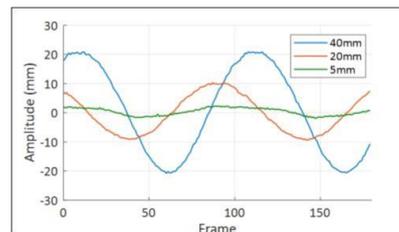

This work is a feasibility study of the use of an Intel® Real Sense™ SR300 camera for measuring patient position and motion for radiotherapy applications. The camera was connected to the USB port of a laptop running the Windows 10 operating system. Frame capture was performed using the free RealSense™ Software Development Kit (SDK 2.0) and cross-platform libraries. 30 frames were captured at a rate of 30 fps with each frame having 640x480 pixels. Measurements were performed on the flat surface of a static object with a range of camera-object distances between 100 and 1000 mm. The 30 frames were averaged and the mean and variance of the depth values in a 10 x 10 region of pixels was calculated

for each dataset. For each camera-object distance four repeat datasets were acquired to assess reproducibility. Further measurements were performed with the object moving on a Standard Imaging respiratory gating platform (Standard Imaging Inc, USA) with a range of 1D motion amplitudes (5, 20, and 40 mm) and frequencies (0.18, 0.22 and 0.29 cycles/sec).

#### Results

The results of the camera depth measurements on the static object are shown in table 1. For distances between 300 and 600 mm the camera was able to measure the distance to an accuracy better than 1 mm. The measured depth values over a 10 x 10 pixel region of interest on the object had a maximum variance of 5 mm (0.5%) at a camera-object distance of 1000 mm. The variance was less for shorter camera-object distances. Figure 1 shows the measured depth as a function of time for motion amplitudes of 5, 20, and 40 mm with a frequency of 0.29 cycles/sec. The measured amplitudes of the motion from the camera depth data in figure 1 were 4.2, 19.4 and 41.6 mm respectively.

Distance (mm)	Depth value (mm)				Variance (mm)				Percentage (%)			
	1	2	3	4	1	2	3	4	1	2	3	4
100	99.6	99.6	99.6	99.6	0.014	0.015	0.021	0.024	0.013	0.015	0.021	0.023
200	198.0	198.0	198.0	198.0	0.005	0.005	0.005	0.004	0.002	0.003	0.002	0.002
300	300.8	300.8	300.7	300.8	0.13	0.14	0.13	0.13	0.050	0.046	0.046	0.042
400	400.5	400.5	400.4	400.5	0.53	0.51	0.52	0.54	0.130	0.130	0.130	0.134
600	601.0	600.9	600.9	600.9	1.28	1.31	1.39	1.33	0.21	0.22	0.23	0.22
800	795.5	795.5	795.5	796.4	2.08	2.45	2.76	2.11	0.26	0.31	0.35	0.27
1000	995.6	995.5	995.5	995.5	5.13	5.00	4.13	5.50	0.51	0.5	0.42	0.55

#### Conclusion

The results of this preliminary work showed the Intel® RealSense™ SR300 camera to be able to measure the respiratory like 1D cyclical motion of a test object with an amplitude of 5 mm with an accuracy better than a mm. The camera was able to operate at camera-object distances of up to 1000 mm with pixel noise levels of 0.5% making the camera a feasible option for measuring patient position and motion during radiotherapy.

#### EP-1966 Deep inspiratory breath hold versus free breathing techniques in breast cancer radiotherapy

A.D. Tawfik<sup>1</sup>, A. Ali<sup>1</sup>, S. Talima<sup>1</sup>, M. Mousa<sup>1</sup>  
<sup>1</sup>Cairo University, Department of Clinical Oncology, Cairo, Egypt

#### Purpose or Objective

It has been theorized that radiation therapy to the breast using deep inspiratory breath hold (DIBH) technique can reduce cardiac doses by moving the heart away from the target volume. In addition, lung expansion during inspiration can decrease the relative volume of irradiated lung. To test this hypothesis, dosimetric and geometric comparisons were conducted between DIBH and conventional free breathing (FB) treatment delivery techniques in breast cancer patients.

### Material and Methods

Eligible patients, who had the intellectual and physical capacity to perform reproducible DIBH during training, underwent DIBH CT simulation and treatment delivery using the Varian surface-based real-time position management (RPM) tracking system. Treatment planning was carried out on the Varian Eclipse treatment planning system v.11. Patients received a prescription dose of 45Gy in 20 fractions. A second series of CT images was taken during FB for each patient, for which a second treatment plan was generated. Accordingly, a comparison between the DIBH and FB sets of plans, in terms of certain lung and heart dosimetric and geometric parameters, was conducted. Paired t-test was used to compare means for both data sets.

### Results

Thirty consecutive breast cancer patients were treated with DIBH radiation therapy technique. Twenty patients (67%) had left breast cancer, nine patients (30%) were right-sided and one patient (3%) had bilateral disease. Dosimetric comparison between DIBH and FB plans revealed a lower heart V18 with DIBH at  $4.7 \pm 4.7\%$  vs.  $12.1 \pm 11.1\%$  in FB ( $p=0.001$ ), a lower heart V28 with DIBH at  $3 \pm 3.3\%$  vs.  $10.3 \pm 10\%$  in FB ( $p=0.0002$ ) and a lower mean cardiac dose of  $4.1 \pm 3\text{Gy}$  with DIBH vs.  $6.7 \pm 4.9\text{Gy}$  in FB ( $p=0.009$ ). There was also a reduction in the left anterior descending coronary artery (LAD) V18 with DIBH at  $43.5 \pm 42.1\%$  vs.  $68 \pm 43.2\%$  in FB ( $p<0.0001$ ), a lower mean LAD dose of  $18.2 \pm 15\text{Gy}$  with DIBH vs.  $28.3 \pm 18\text{Gy}$  in FB ( $p=0.006$ ) and a lower maximum LAD dose of  $27.5 \pm 17.8\text{Gy}$  with DIBH vs.  $32.9 \pm 17.9\text{Gy}$  in FB ( $p=0.007$ ). In addition, DIBH yielded a lower ipsilateral lung V18 at  $20.5 \pm 4.8\%$  vs.  $25.7 \pm 8.1\%$  in FB ( $p<0.0001$ ) and a lower ipsilateral lung mean dose of  $11.1 \pm 3.7\text{Gy}$  vs.  $12.3 \pm 3.2\text{Gy}$  in FB ( $p=0.026$ ). With regard to the geometric parameters, DIBH reduced the cardiac contact distance with the chest wall, both in the axial ( $0.4 \pm 0.8\text{cm}$  vs.  $3.9 \pm 2.2\text{cm}$  in FB;  $p<0.0001$ ) and sagittal planes ( $2.5 \pm 1.9\text{cm}$  vs.  $4.2 \pm 2.1\text{cm}$  in FB;  $p<0.0001$ ), see figure 1. Moreover, DIBH significantly decreased the maximum heart distance inside the treatment field compared with FB ( $1.6 \pm 0.6\text{cm}$  vs.  $2.7 \pm 0.5\text{cm}$ , respectively;  $p<0.0001$ ).

### Conclusion

Compared to FB, DIBH technique results in marked reduction of the doses to the heart, LAD and lungs. In addition, it decreases the cardiac volume in contact with the chest wall as well as the maximum heart distance inside the treatment field. Thus, DIBH appears to be a promising technique to mitigate long-term cardiac and pulmonary toxicities in breast cancer survivors.

### EP-1967 Relationship of uncertainty due to respiratory motion with amplitude in SBRT treatments

J. García Ruiz-Zorrilla<sup>1</sup>, M.A. De la Casa de Julián<sup>1</sup>, P. García de Acilu Laa<sup>1</sup>, O. Hernando Requejo<sup>2</sup>, C. Rubio Rodríguez<sup>2</sup>, J. Martí Asenjo<sup>1</sup>, P. Fernández Letón<sup>1</sup>, D. Zucca Aparicio<sup>1</sup>, J.M. Pérez Moreno<sup>1</sup>

<sup>1</sup>Hospital Universitario HM Sanchinarro, Radiofísica, Madrid, Spain ; <sup>2</sup>Hospital Universitario HM Sanchinarro, Oncología Radioterápica, Madrid, Spain

### Purpose or Objective

Quantify the experimental relationship between the uncertainty due to respiratory motion (RM) and the peak to peak amplitude (A) of this movement in liver, lung, pancreas and breast tumors treated with stereotactic body radiation therapy (SBRT) and ExacTrac Adaptive Gating® with intra-fractional IGRT.

### Material and Methods

Fifty five fractions (15000 cycles) of liver, 41 fractions (14000 cycles) of lung, 76 fractions (34000 cycles) of pancreas and 70 fractions (14000 cycles) of breast tumors were treated with SBRT using ExacTrac Adaptive Gating® in a Novalis® linac. This system uses external markers to monitor the respiratory cycle and internal fiducial markers to set up the patient and measure the movement of the tumor.

All the magnitudes of the respiratory motion of tumor were analyzed through a linear regression between the motion of external markers and internal fiducial markers (surrogate to tumor motion).

The uncertainty due to respiratory motion (SD(RM)) is estimated measuring directly the standard deviation (SD) of the respiratory motion (RM).

### Results

Table 1 shows the amplitude (A), the standard deviation of the amplitude [SD(A)] and the uncertainty due to respiratory motion {SD(RM)}.

	Amplitude [SD(A)] [SD(RM)]		
	SI (mm)	AP (mm)	LAT (mm)
Liver	9.7 [5.1] [5,3]	4.0 [2.5] [2,3]	1.6 [1.3] [1,2]
Lung	3.9 [3.4] [3,2]	2.0 [1.7] [1,6]	1.7 [1.7] [1,6]
Pancreas	7.7 [4.6] [4,6]	2.6 [2.4] [2,2]	2.1 [1.5] [1,5]
Breast	1.5 [0.9] [1,1]	1.7 [1.0] [1,1]	1.1 [0.7] [0,9]

Table 1

The SD(RM) is usually estimated as A/3, this is valid for an ideal respiratory cycle represented by  $RM = A \cdot \sin^{2n}(wt)$ , in which the amplitude is not variable. But it may not be true if SD(A) is substantial.

In this study SD(RM) is significantly larger than A/3 ( $p<0.001$ ) in all directions of all localizations due to the intrafraction variability of A.

The univariate analysis revealed a statistical significant linear correlation between SD(RM) and A and between SD(RM) and SD(A) both with  $p<0.001$  in all directions of all localizations.

On the other hand, the multivariate regression  $SD^2(MR) = a \cdot A^2 + b \cdot SD^2(A)$  showed statistical significant correlation with  $SD^2(A)$  and  $A^2$  ( $p<0.05$ ) in all cases, except in lung tumors in which the  $A^2$  correlation was not significant. In addition, for liver and pancreas tumors the  $SD^2(A)$  contribution to the respiratory motion variance is the greatest but not in a significant way.

### Conclusion

Whereas for ideal respiratory cycles the uncertainty in tumor position due to respiratory motion can be estimated accurately with A/3, in real respiratory cycles is necessary to include the SD(A) beside A to avoid underestimation of this uncertainty. Further studies are necessary to demonstrate if those findings have any repercussion on PTV margin estimation.

### EP-1968 Respiratory-gated carbon-ion beam treatments of abdominal targets: clinical introduction of 4DMRI

A. Vai<sup>1</sup>, G. Meschini<sup>2</sup>, S. Molinelli<sup>1</sup>, C. Paganelli<sup>2</sup>, D. Maestri<sup>1</sup>, G. Magro<sup>1</sup>, E. Mastella<sup>1</sup>, A. Mairani<sup>1,3</sup>, A. Baroni<sup>2,6</sup>, M. Ciocca<sup>1</sup>  
<sup>1</sup>National Center for Oncological Hadrontherapy CNAO, Medical Physics Department, Pavia, Italy ; <sup>2</sup>Politecnico di Milano, Department of Electronics- Information and Bioengineering, Milan, Italy ; <sup>3</sup>Heidelberg Ion Beam Therapy Center HIT, Physics Department, Heidelberg, Germany ; <sup>4</sup>National Center for Oncological Hadrontherapy CNAO, Radiology Department, Pavia, Italy ; <sup>5</sup>National Center for Oncological Hadrontherapy CNAO, Radiotherapy Department, Pavia, Italy ; <sup>6</sup>National Center for Oncological Hadrontherapy CNAO, Bioengineering Department, Pavia, Italy

**Purpose or Objective**

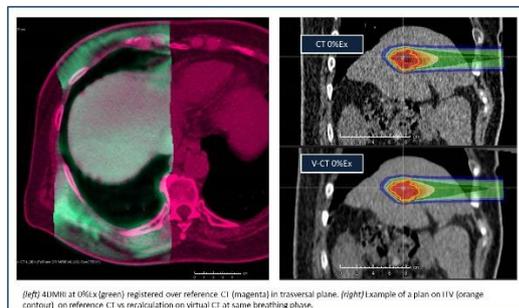

Irradiation geometry for abdominal targets in which a carbon-ion beam passes at the lung-diaphragm interface for a gated scanning treatment is not robust in our experience of plan recalculations on re-evaluative 4DCTs. In this work the potentialities of patient-specific virtual CTs, deformed on extracted 4DMRI vector fields (VFs) to quantify and mitigate the impact of motion pattern variations in respiratory-gated carbon ion treatments of the abdominal site were investigated.

**Material and Methods**

3 patients (2 liver, 1 pancreas) treated at CNAO with a respiratory-gated carbon-ion plan were selected. In addition to the 4DCT imaging workflow, 4DMRI images were obtained by retrospective sorting of multi-slice 2DMRI acquisition, covering a limited field-of-view of 10 cm in the L-R direction. Virtual CTs were generated by applying the 4DMRI-extracted motion fields (VFs) to the acquired 0%Ex (full-exhale) CT.

Range of motion (ROM) for the right kidney was calculated as centroid distance between 100%In (full-inhale) and 0%Ex phases, and the difference was computed between 4DMRI and 4DCT. GTV ROMs were also compared to a population of 10 patients (averaged ROM derived on 4DCT data) treated at our facility. The GTV was then warped from 0%Ex to the other breathing phases in the 4DMRI datasets and the ITV was defined.

For each patient, a single-beam carbon-ion plan was optimized delivering uniform dose to the ITV on the 0%Ex CT. Recalculations were carried out both on the 100%In CT and on virtual-CTs depicting 0%Ex and 100%In phases. D<sub>2%</sub>, D<sub>50%</sub>, D<sub>98%</sub> were calculated for ITV and GTV<sub>100In</sub>.

**Results**

ROM differences between 4DCT and 4DMRI for the kidney were <2% on average. GTV ROM were within the population range (2-12mm). ITV volume differences were <5%. Target DVH parameters discrepancies between dose distributions evaluated on acquired and virtual CT at corresponding phases were <1% on average.

Range of Motion (ROM) for right kidney [cm]				ITV (VX + 2018 + 10%) Volume <sup>1</sup>				Carbon-ion plan opt. for uniform dose on ITV (%) CT vs virtual CT

**Conclusion**

Consistency between 4DMRI and 4DCT was verified on kidney MR, ITV definition, and by plan recalculation on virtual CTs. Validation on a larger group of patients is needed.

**EP-1969 Dosimetric effect of diaphragm motion on target volume coverage for oesophageal cancer**

R. Stansbridge<sup>1</sup>, M. Borland<sup>1</sup>, B. Stewart Thomson<sup>2</sup>, M. Gilmore<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre, Physics, Liverpool, United Kingdom ; <sup>2</sup>Clatterbridge Cancer Centre, Radiation Services, Liverpool, United Kingdom

**Purpose or Objective**

Intra-fraction diaphragm motion for oesophageal cancers can result in dosimetric uncertainty due to changes in the electron density of individual voxels during the breathing cycle. The objective of this study is to quantify the dosimetric impact of diaphragm motion on PTV coverage over the breathing cycle to provide evidence for 3D planned VMAT.

**Material and Methods**

Radical oesophagus patients with significant diaphragm overlap of the PTV were identified to demonstrate the largest potential effect on plan dosimetry. All had received a prescription of either 50.4Gy/28# (n=2), 50Gy/25# (n=4) or 55Gy/20# (n=4). At our centre, for patients with a regular breathing trace, a 4DCT is acquired and a VMAT plan produced on the Average Intensity Projection (AIP) with a PTV margin of 0.5cm. For patients who do not have a regular breathing trace, a 3DCT scan is acquired as this may catch the diaphragm at an extreme that is not representative of the average diaphragm position during treatment, these patients are currently treated with a conformal plan. In order to verify the resilience of VMAT plans to this potential discrepancy, individual bins from the 4DCT were used as a surrogate for a 3DCT taken at the extremes of diaphragm motion (peak inspiration and peak expiration). A simulated plan was optimised on each of the two extreme cases with the PTV copied from the original plan. After optimisation, the plan was then recalculated on the AIP to represent the full respiratory motion during treatment delivery and assessed for changes in dosimetry.

**Results**

The mean peak to peak diaphragm motion was 2.3 ± 0.9cm with a maximum of 3.5cm. The mean difference from peak inspiration to AIP for D<sub>98%</sub> was -0.81 ± 0.45% and peak expiration to AIP was 0.48 ± 0.22%. All hotspots remained within the PTV as defined on the AIP with the mean change in D<sub>2%</sub> from peak inspiration to AIP was -0.26%. Hotspots were enhanced in the plans recalculated from peak expiration to AIP with an average increase of 1.83%. Doses to proximal OAR were also assessed, with minimal changes to mean dose and <0.3Gy change over the whole prescription. It should be noted, however, that structures were not changed from those outlined on the original AIP. Hotspots became apparent in the peak expiration plan onto AIP but still deemed clinically acceptable according to local protocols. The hotspots were the result of change in density from liver to lung tissue and created at the lung-tissue interface within the PTV, the maximum D<sub>2%</sub> was 106.9% (3.9% change between peak to AIP).

**Conclusion**

This study suggests that VMAT plans are sufficiently robust to diaphragm motion to allow VMAT planning of 3D scanned oesophagus patients. Patients will now be treated with an increased PTV margin of 1cm to account for PTV motion not captured. It is also recommended that diaphragm motion is monitored at treatment to ensure consistency. Further investigation is planned for patients with diaphragm motion >4 cm.

## EP-1970 2D and 3D dose verification for a gated irradiation on a 0.35 T MR-LINAC

P. Mann<sup>1,2</sup>, K. Spindeldreier<sup>2,3</sup>, G. Echner<sup>1,2</sup>, S. Klüter<sup>2,3</sup>, C. Karger<sup>1,2</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>National Center for Radiation Research in Oncology NCRO, Heidelberg Institute for Radiation Oncology HIRO, Heidelberg, Germany ; <sup>3</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

As MRgRT becomes increasingly important in clinical applications, the development of new QA methods is needed. Especially for the verification of MR-based gating techniques, workflows tests with 2D and 3D dose verification prior clinical implementation are desirable. In this work, we present an MR compatible motion phantom that can hold both film and polymer gel (PG) inserts to perform 2D and 3D dose measurements for gated treatments.

### Material and Methods

A water-filled cylindrical phantom (d = 22 cm, l = 50 cm) holding a movable smaller water-filled cylinder (d = 9 cm, l = 50 cm) that can be combined with (1) film and (2) PG inserts was developed. For (1), an elliptical silicone insert with high MR contrast served as a target, while for (2), an oxygen sealed BAREX™ container filled with in-house produced PAGAT dosimetry gel was used as target. Both inserts were irradiated in separate experiments at an MR-Linac (MRIdian, ViewRay®) with a dose of up to 5 Gy. To test the influence of motion and gating on the target coverage with dose, three different irradiations were carried out:

- (i) Static target
- (ii) Dynamic target without gating
- (iii) Dynamic target with gating

For all experiments, the target volume was delineated in the Viewray TPS. Phantom motion for (ii) and (iii) was set to a cos<sup>4</sup> trajectory with an amplitude of 1.5 cm and a motion cycle of 10 cycles/min. For (iii) an additional gating margin of 3 mm was added allowing for 10% of the target being outside of the contour.

The film was scanned (10000XL, Epson) 1 h after irradiation and the red channel was evaluated. PG was scanned on a 3 T MR device (Biograph mMR, Siemens) 48 h after irradiation using a multi spin-echo sequence. Results were evaluated using the 2/3D -criterion (2%/2mm and 3%/3mm). For the film, the relative profiles were compared (using experiment (i) as reference) and the PG results were compared against TPS calculations.

### Results

For both film and PG measurements, results showed a homogeneous target coverage for (i), a significant dose smearing in motion direction for (ii) and a restored dose distribution with a homogeneous target coverage for (iii). The respective passing rates are shown in table 1.

Table 1: Comparison of film and PG measurements for three different experiments (i-iii).

Experiment	Insert	$\gamma_{2,3D}$ passing rate 3%/3mm; 2%/2mm
(i) Static target	Film	-
	PG	99.7%; 95.1%
(ii) dynamic target without gating	Film	61.1%; 50.9%
	PG	68.6%; 39.6%
(iii) dynamic target with gating	Film	100%; 99.1%
	PG	98.6%; 92.1%

### Conclusion

The developed phantom in combination with film and PG inserts has shown to be a valuable tool to test new treatment techniques like gating on a commercial MR-Linac device. Three different scenarios have been tested and gating revealed nearly the same accuracy as a static

treatment. Future experiments will focus on the verification of dose accumulation algorithms that are used to calculate the final dose in case of dynamic treatment.

## EP-1971 Comparison of pancreatic respiratory motion using three abdominal corsets for particle therapy

S. Schneider<sup>1,2</sup>, K. Dolde<sup>3,4,5</sup>, M. Alimusay<sup>6</sup>, B. Fluegel<sup>6</sup>, N. Saito<sup>7</sup>, A. Hoffmann<sup>1,2,8</sup>, A. Pfaffenberger<sup>3,4</sup>

<sup>1</sup>Helmholtz-Zentrum Dresden-Rossendorf, Radiooncology-OncoRay, Dresden, Germany ; <sup>2</sup>OncoRay - National Center for Radiation Research in Oncology, Medical Radiation Physics, Dresden, Germany ; <sup>3</sup>German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany ; <sup>4</sup>National Center for Radiation Research in Oncology, Heidelberg Institute for Radiooncology, Heidelberg, Germany ; <sup>5</sup>University of Heidelberg, Department of Physics and Astronomy, Heidelberg, Germany ; <sup>6</sup>Heidelberg University Hospital, Center for Orthopedic and Trauma Surgery, Heidelberg, Germany ; <sup>7</sup>University Clinic Heidelberg, Department of Radiation Oncology, Heidelberg, Germany ; <sup>8</sup>Faculty of Medicine and University Hospital Carl Gustav Carus at the Technische Universität Dresden, Radiotherapy and Radiation Oncology, Dresden, Germany

### Purpose or Objective

Particle therapy (PT) has the potential to reduce the risk of toxicity in patients with pancreatic cancer beyond that of photon therapy. Since PT is strongly susceptible to anatomical changes during dose delivery, strategies for pancreatic motion management are mandatory.

The purpose of this study was to compare the usability of different corsets for abdominal compression by measuring their effect on the respiration-induced motion of the pancreas as well as their water equivalent ratio (WER) for PT. **Material and Methods**

Three types of abdominal corsets were used that differed in material composition (polyethylene (PE) vs. polyurethane (PU)), material thickness (2.5mm - 24mm), and construction method (patient individual vs. patient independent). A healthy volunteer was scanned on a 1.5T MR scanner (Magnetom Aera, Siemens Healthineers) on two consecutive days for four subsequent scenarios: with and without wearing the three corsets. A gradient echo sequence with radial golden angle acquisition (field of view = 384×384×288 mm<sup>2</sup>, voxel size = 1.5×1.5×3 mm<sup>3</sup>, spokes per partition = 2100, bandwidth = 610 Hz/pixel, TE = 1.5 ms, TR = 3.3 ms, ) was used and reconstructed to a 4D-MR data set comprising 20 breathing phases. The pancreas was delineated in the maximum inhale and exhale phases using the open-source software MITK (Fig. 1). Its centre of mass was calculated as a surrogate for the respiratory motion in each of the four scenarios for both days.

CT scans of the three corsets were acquired (field of view = 388×388×476mm<sup>3</sup>, voxel size = 0.73×0.73×2mm<sup>3</sup>, tube voltage = 120kVp, Tube current time product = 148mAs) to assess the material homogeneity and thickness constancy. WER measurements were performed at two different proton energies (150MeV, 200MeV) using a high-resolution multi-layer ionization chamber (Giraffe, IBA Dosimetry).

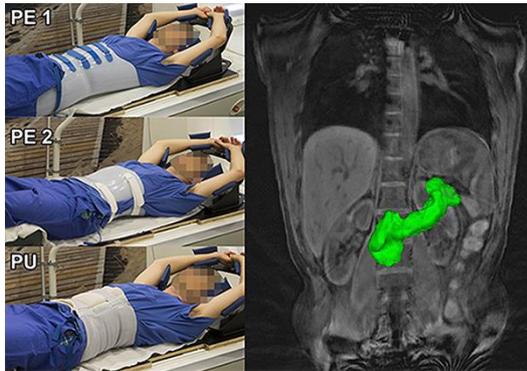

Figure 1. [left] Volunteer with three different abdominal corsets (PE1, PE2, PU) in scanning position. [right] Coronal slice of resulting 4D MRI in expiration phase with 3D segmentation of pancreas in green.

## Results

All three corsets reduced the pancreatic motion by a similar amount, mainly in inferior-superior direction (Table 1). As expected, the CT scan showed that the two PE corsets were made of homogeneous material that had a constant thickness of  $2.5 \pm 0.1$  mm and  $4.9 \pm 0.1$  mm, respectively. The PU corset was inhomogeneous due to the presence of small air inclusions throughout the whole corset. Furthermore, its thickness varied between 8.0 - 24.2 mm. The WER of the two PE corsets was 0.990 and 0.956, while the average WER of the PU corset was 0.298.

Table 1. Centre of mass motion of segmented pancreas between maximum inhale and maximum exhale. Motion was assessed while volunteer was wearing three different corsets as well as a free breathing scan for reference.

	No Corset	PE 1	PE 2	PU
Amplitude LR [mm]	$2.6 \pm 0.5$	$1.9 \pm 0.7$	$2.9 \pm 0.6$	$0.8 \pm 0.4$
Amplitude AP [mm]	$1.6 \pm 1.4$	$0.3 \pm 0.2$	$0.2 \pm 0.2$	$0.4 \pm 0.1$
Amplitude IS [mm]	$12.5 \pm 1.4$	$5.6 \pm 1.4$	$4.0 \pm 0.2$	$3.5 \pm 1.7$

## Conclusion

While all three corsets significantly reduce the respiratory-induced pancreatic motion, the PU corset is not suitable for PT due to its irregular material structure and thickness. The two PE corsets both show stable material conditions which could easily be included in treatment planning. Preferences for any of the two PE corsets will mainly depend on differences in fit, flexibility, cost and the time required for preparation.

## EP-1972 Transit-Guided RadioTherapy (TGRT): a novel intra-fraction patient monitoring approach

A. Latorre-Musoll<sup>1</sup>, P. Delgado-Tapia<sup>1</sup>, M. Lizondo<sup>1</sup>, N. Jonet<sup>1</sup>, P. Carrasco<sup>1</sup>, A. Ruiz-Martinez<sup>1</sup>, I. Valverde-Pascual<sup>1</sup>, M. Barceló<sup>1</sup>, M. Ribas<sup>1</sup>  
<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain

## Purpose or Objective

IGRT is an effective tool to reduce patient positioning uncertainties. However, intra-fraction motion component is not completely removed by conventional daily imaging protocols. We propose a novel approach to correct intra-fraction patient positioning shifts based on transit portal images (TGRT) which does not add extra time nor imaging dose.

## Material and Methods

We propose a pixel-based exponential model to relate the measured transit images ( $P_{ij}$ ), the pre-patient fluence ( $F_{ij}$ ) and the mass attenuation thickness map ( $x_{ij}$ ) for each field:

$$P_{ij} = P_0 F_{ij} \exp(-\mu x_{ij}),$$

where  $P_0$  and  $\mu$  are free scalar parameters. A first-order approximation of the directional derivatives of this model gives us the BEV shift estimation maps ( $s_{ij}$ ) as:  $s_{ij} = (P_{ij}/P_{ij}^0 - 1) \cdot [\mu(\partial x/\partial s)_{ij}]^{-1}$ , where  $P_{ij}^0$  is a convenient reference image (after IGRT corrections). Finally, the gantry angle is used to transform  $s_{ij}$  from the BEV reference frame to patient/couch coordinates  $s_{ij}'$ .

We validated the model for the following sites and techniques using a RANDO anthropomorphic phantom (Eclipse v13.5, Varian):

- A head-and-neck IMRT plan with 7 sliding-window 6 MV fields (1.6/1.8/2.12 Gy/fx @ low/intermediate/high risk areas).
- A whole-breast IMRT plan with 7 quasi-tangential sliding-window 6 MV fields (2 Gy/fx).
- A whole-breast 3DCRT plan with 2 tangential + 2 field-in-field 6 MV fields (2 Gy/fx).

We delivered these plans on a Clinac 2100C/D equipped with a Millenium 120 MLC (Varian). We shifted the phantom between fractions by moving the couch top from  $s = -10$  to 10 mm in 1 mm steps along the three axes. We acquired transit images ( $P_{ij}$ ) in integrated mode by placing the EPID at 140(150) cm for the head-and-neck(breast) plans.

We obtained  $F_{ij}$ ,  $x_{ij}$  and  $(\partial x/\partial s)_{ij}$  using the Eclipse Scripting API v13.5. We developed an in-house code (MATLAB v2015b, MathWorks) to fit  $P_0$ ,  $\mu$  and to obtain  $s_{ij}$ . Finally, we compared the per-beam pixel-averaged shift estimations  $\langle s_{ij}' \rangle$  against the real shifts  $s$  for all plans and irradiations.

## Results

Figure 1 compares the 723 model shift estimations against the real shifts. Estimations showed good linearity up to 5 mm (slope =  $0.854 \pm 0.016$ , RMS of residuals = 1.03 mm). Linearity decreased for larger shifts due to the first-order nature of the model (slope =  $0.820 \pm 0.011$ , RMS of residuals = 1.65 mm) but, even in this setting, estimations led to minimize positioning errors after correction. Figure 2 shows that only 12% of the estimations differed from the real shifts by more than 3mm (only 1% corresponded to shifts  $\leq 5$  mm). Therefore, cumulative corrections after each field irradiation may rapidly converge to target position.

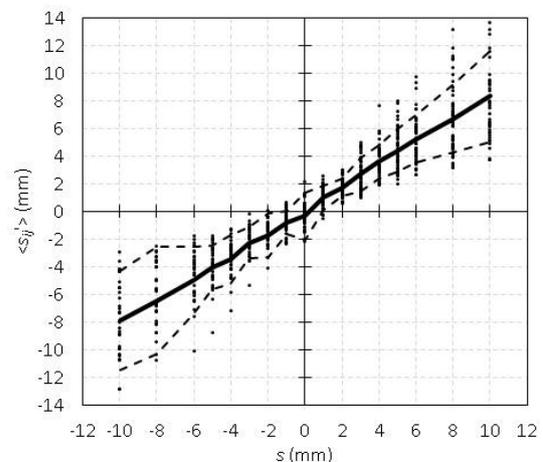

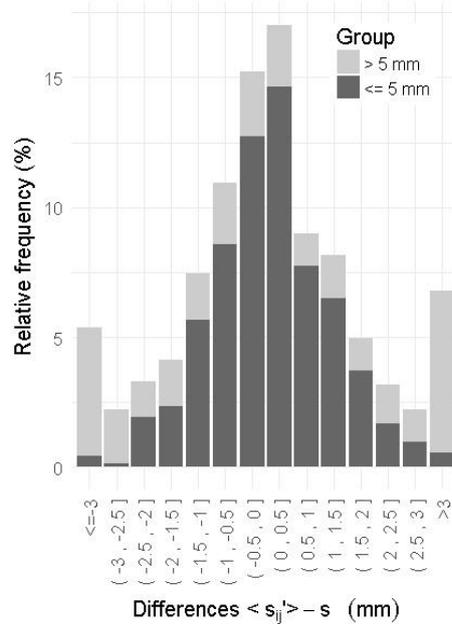

Figure 1. DOTS: model shift estimations  $\langle s_{ij}' \rangle$  against couch top shifts  $s$ , for all plans, fields and directions. LINES: mean (solid line)  $\pm$  standard deviation (dashed lines) of all data.

**Figure 2.** Distribution of residual differences between model shift estimations and real shifts. Data is split into two subsamples:  $s \leq 5$  mm and  $s > 5$  mm.

### Conclusion

A simple, robust and reliable approach (TGRT) has been validated to correct patient positioning shifts. TGRT may add intra-fraction monitoring capabilities to conventional IGRT by providing real-time convergent corrections after every beam irradiation. Initial testing in patients and model extrapolation to VMAT techniques are work in progress.

This work was partially financed by FIS PI15/00788.

### EP-1973 Cardiac dose sparing with active breath coordinator in breast radiotherapy: a dosimetric analysis

Gemelli"- Università Cattolica del Sacro Cuore, Radiation Oncology Department, Roma, Italy

### Purpose or Objective

Cardiac toxicity is a major concern for left breast tangential field irradiation. Moderate deep inspiration breath hold (mDIBH) during radiation treatment delivery helps in reducing the cardiac dose. In this dosimetric study, the doses to heart were compared between free-breathing (FB) and mDIBH during tangential IMRT breast irradiation.

### Material and Methods

Twenty consecutive patients with left-sided breast cancer who underwent adjuvant tangential IMRT with ABC mDIBH were analyzed in this study. All patients underwent CT

simulation in both free breathing (FB) and mDIBH setup. The Elekta ABC spirometer was used for respiratory control and breath-hold period of 20-30 s. A simultaneously integrated boost (SIB) plan was created for both simulation CTs (FB and mDIBH) consisting of a prescription dose of 50 Gy to the whole breast and 60 Gy to tumor bed in 25 fractions. The heart and the left ventricle were contoured according to the Feng et al. heart atlas. Dose volume histograms were analyzed to assess the heart mean dose (MHD) and the volume of left ventricle receiving 5Gy (V5), since these dosimetric metrics have been demonstrated to be the best predictors of acute cardiac events. Data were analyzed using a Wilcoxon signed-rank test with a level of significance set at  $p < 0.05$ .

### Results

The use of ABC mDIBH resulted in similar target coverage with no significant statistical differences. For PTV1 median D95% and V95% were 58.5 Gy (range: 57.3-59.5 Gy) and 98.6% (range: 96.0-100.0%) in FB, and 58.5 Gy (range: 57.0-60.1 Gy) and 98.7% (range: 95.0-99.9%) in mDIBH. For PTV2 D95% and V95% were 48.8 Gy (range: 43.4-50.5 Gy) and 97.0% (range: 91.4-99.4%) in FB and 49.3 Gy and 98.0% (range: 92.3-99.8%) in mDIBH. Median MHD was 3.7 Gy (range: 2.8-6.2 Gy) in FB and 2.5 Gy (range: 1.6-4.1 Gy) in mDIBH ( $p < 0.05$ ), resulting in absolute and relative reduction of 1.3 Gy (range: 0.2-2.5 Gy) and 35.0% (range: 4.7-53.6%), respectively. Median LV-V5 was 27.4% (range: 1.8-44.0%) in FB and 8.2% (range: 0.0-25.9%) in mDIBH ( $p < 0.05$ ). The use of ABC mDIBH reduced MHD by 20% or greater and LV-V5 by 35% or greater in 90% of patients.

### Conclusion

The use of the ABC spirometer for mDIBH resulted in a significant reduction in cardiac dose for left sided breast radiotherapy. The significant cardiac dose sparing may translate in reduction of excess risk of acute cardiac events.

### EP-1974 Usage of computer generated 4D CTs for interplay effect studies in scanned proton therapy

T. Pfeiler<sup>1,2,3</sup>, C. Bäumer<sup>1,2,4</sup>, E. Engwall<sup>5</sup>, D. Geismar<sup>1,2,4,6</sup>, U. Mäder<sup>7</sup>, B. Spaan<sup>3</sup>, B. Timmermann<sup>1,2,4,6</sup>, J. Wulff<sup>1,2,7</sup>

<sup>1</sup>University Hospital Essen, West German Proton Therapy Centre Essen WPE, Essen, Germany ; <sup>2</sup>University Hospital Essen, West German Cancer Centre WTZ, Essen, Germany ; <sup>3</sup>TU Dortmund University, Experimental Physics 5, Dortmund, Germany ; <sup>4</sup>German Cancer Consortium DKTK, Radiation Oncology and Imaging, Heidelberg, Germany ; <sup>5</sup>RaySearch Laboratories AB, Development, Stockholm, Sweden ; <sup>6</sup>University Hospital Essen, Department of Particle Therapy, Essen, Germany ; <sup>7</sup>TH Mittelhessen, Radiation Protection Institute, Gießen, Germany

### Purpose or Objective

There is a need for realistic 4D data-sets in radiation therapy, especially in scanned proton therapy to systematically investigate interplay effects for moving targets. The production of physical phantoms representing the entire spectrum of patients is generally not feasible and the availability of suitable, clinical 4D CTs is limited. Recently, the 4D XCAT phantom, a whole-body computer model of human anatomy and physiology, became available and allows generation of virtual 4D CTs (v4D CTs). Their application was tested in a proof-of-concept study investigating the magnitude of interplay effects as a function of the target size for one patient with different CTVs.

### Material and Methods

A 4D XCAT chest CT was imported to RayStation 7. In addition to a set with typical clinical CT-numbers for treatment planning, a copy with image-values representing organ IDs was imported. The segmentation tools thereby allowed to perfectly map organs in all 4D CT

phases. The structures guided the deformable image registration (DIR). Five spherical liver tumours of radius  $R=1-5$  cm were manually delineated as CTVs in the end-exhale phase and mapped to other phases by DIR. A dose of 63 Gy<sub>RBE</sub> was prescribed to the CTVs in 15 fractions. The magnitude of interplay effects was analysed based on an experimentally validated 4D dose calculation routine including DIR and 50 interplay scenarios per plan with varying field delivery time structures [1]. The homogeneity index ( $HI=(D_5-D_{95})/D_{prescribed}$ ) and the percentage over- and underdosage ( $V_{107/95}=V_{107}+100-V_{95}$ ) of the CTV served as evaluation criteria.

### Results

All workflow steps from data import to interplay simulations were successfully completed for the v4D CT. The simulated CT data enabled fast, threshold-based segmentation of 48 anatomical structures in all 4D CT phases. Thus, 4D studies could be performed with perfect contouring, minimal DIR uncertainties and realistic image quality without the influence of CT artefacts. Fig. 1 shows exemplarily two 4D dose distributions. While the HI increased with growing target volume from  $11.5\% \pm 3.0\%$  (average value  $\pm$  standard deviation of all scenarios) for  $R=1$  cm to  $22.3\% \pm 2.4\%$  for  $R=5$  cm,  $V_{107/95}$  did not reproduce this trend.  $V_{107/95}$  was maximal for the largest CTV (39.9%  $\pm$  5.4%), but the smallest value was observed for  $R=3$  cm ( $22.3\% \pm 7.6\%$ ).

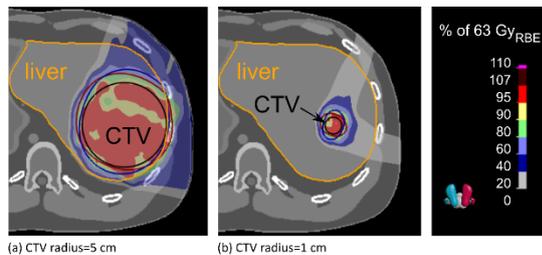

Figure 1: 4D dynamically accumulated dose distribution (overlayed as colour wash) of a random interplay scenario for the smallest and the largest CTV (transverse view): The beam-specific PTV margins are coloured dark blue and dark red.

### Conclusion

The results demonstrate the feasibility of 4D CT simulation based on XCAT phantoms for interplay evaluations. The manifestation of investigated interplay effects exhibited complexity, without clear correlation between the interplay level and the target size. Studies on larger scale must show whether a categorisation to influencing factors such as tumour motion or size into different treatment groups is possible and whether it can replace time consuming, individual interplay evaluations. The application of v4D CTs can facilitate these studies and furthermore allows investigation of mitigation strategies in a systematic approach.

EP-1975 Intra-fraction robustness evaluation of deep inspiration breath hold radiotherapy for lung cancer K. Håkansson<sup>1</sup>, M. Josipovic<sup>1</sup>, I.R. Vogelius<sup>1,2</sup>, G. Persson<sup>2,3</sup>, C. Behrens<sup>3</sup>

<sup>1</sup>Rigshospitalet- Copenhagen University Hospital, Department of Oncology- Section of Radiotherapy, Copenhagen, Denmark ; <sup>2</sup>Faculty of Health Science- University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark ; <sup>3</sup>Herlev Hospital- Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark

### Purpose or Objective

Deep inspiration breath hold (DIBH) for radiotherapy (RT) of lung cancer has recently been shown to be feasible and can reduce dose to the heart and lungs. Robustness may be an issue, however, and built in tools in the treatment planning systems typically do not account for anatomical

changes between subsequent DIBHs. It is of clinical interest to be able to identify the patients where variations in anatomy between DIBHs would result in a sub-optimal treatment. The purpose of the current study was to develop a method for evaluating the intra-fraction robustness of DIBH-RT treatment plans. Two treatment plans were evaluated as a proof of principle.

### Material and Methods

We chose two example patients from a previous DIBH study, where three repeated DIBH scans were acquired before treatment. Patient 1 had good agreement between scans and was treated in DIBH, whereas patient 2 was treated in free breathing because of large variation in tumor position between scans. The DIBH plans (2 Gy x 33, volumetric modulated arc therapy with two partial arcs) were divided into four sub-arcs, each of duration of one DIBH (~20 s), using the Eclipse Scripting Application Programming Interface (ESAPI) version 15.5 (Varian). The three DIBH scans were assigned randomly to the four sub-arcs in a simulation of all 33 fractions, to evaluate the impact of intra-fraction variation throughout the treatment course. Subsequently, a plan with corresponding field weights was created for each DIBH scan, followed by deformable registration and dose summation in Velocity version 4.0. The resulting simulated sum dose was compared to the planned dose. The workflow is illustrated in Figure 1.

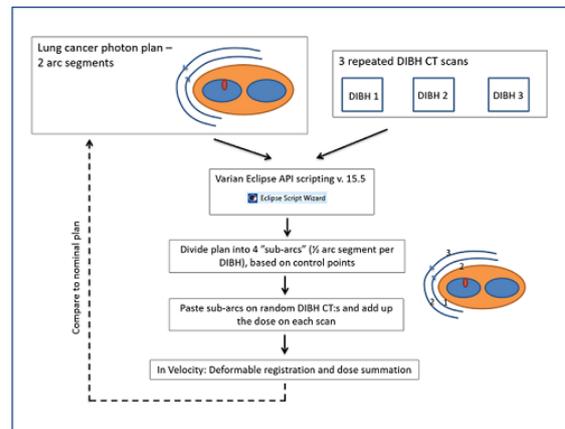

Figure 1. Workflow for the intra-fraction robustness evaluation of DIBH treatments

### Results

The ESAPI script could successfully divide a treatment plan into four sub-arcs. The robustness evaluation method showed small differences in target and organs at risk (OAR) doses between the original plan and the Velocity sum for patient 1. For patient 2, the dose differences were similar for OARs but large for the target. The difference was most pronounced for the coverage of the T-site lesion - V95% was 97.1% for PTV-T in the original plan but only 71.2% in the Velocity sum plan (Table 1).

Table 1. Dose metrics for comparison between original plan and Velocity sum, where the difference between three repeated DIBH scans have been applied in an intra-fraction robustness analysis. Patient 1 and 2 are example patients - patient 1 with small differences between DIBH scans and patient 2 with large differences.

		Patient 1		Patient 2	
		Original Plan	Velocity sum	Original Plan	Velocity sum
PTV-T	V95%	98.4 %	97.4 %	97.0 %	91.6 %
PTV-NI	V95%	97.7 %	97.1 %	97.1 %	71.2 %
Medulla	Dmax	43.7 Gy	44.0 Gy	28.5 Gy	28.3 Gy
Lungs - GTV	V20Gy	30.3 %	30.4 %	12.8 %	13.0 %
	Mean dose	17.2 Gy	17.2 Gy	7.8 Gy	7.9 Gy
Heart	V25Gy	0.3 %	0.1 %	24.8 %	23.5 %
Oesophagus	Dmax	69.3 Gy	67.9 Gy	68.8 Gy	66.8 Gy
Body	Dmax	73.2 Gy	72.3 Gy	71.1 Gy	72.3 Gy

### Conclusion

We demonstrated a method for dose-volume assessment of the impact of anatomical changes across consecutive DIBHs on a treatment plan. With the proposed method, a patient could be identified where the DIBH technique was sensitive to anatomical changes between repeated DIBHs

and could result in sub-optimal treatment. For a patient with small differences between DIBH scans, no concerning differences in dose due to intra-fraction uncertainty could be identified.

#### EP-1976 Clinical evaluation of two monitoring devices for prostate radiotherapy treatment

M. Biston<sup>1</sup>, L. Delcoudert<sup>1</sup>, T. Zaragori<sup>1</sup>, A. Munoz<sup>1</sup>, D. Sarrut<sup>2</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Léon Bérard Cancer Center, Radiotherapy, Lyon, France ; <sup>2</sup>Lyon university, Creatis, Lyon, France

#### Purpose or Objective

The objective of this work was to co-evaluate 2 in-beam monitoring devices for prostate radiotherapy: intra-prostatic electromagnetic transmitters (EM-T) (RayPilot®, Micropos Medical) and ultrasound imaging using transperineal probe (TP-US) (Clarity®, Elekta). We report the monitoring results obtained with the 2 devices used concomitantly on 9 patients.

#### Material and Methods

The accuracy of the 2 systems was first investigated in a phantom study. Then intra-fraction motions measured with the 2 devices used simultaneously were analyzed for 9 intermediate risk prostate cancer patients (155 sessions). They were implanted with the EM-T and 2 fiducial markers 8 days before the simulation CT. Pre-treatment positioning was performed with the TP-US and validated by a Cone Beam CT (CBCT) imaging (+ fiducial markers)/CT registration. During CBCT imaging the 2 devices monitoring mode were started. Irradiation was stopped and patient positioning adjusted for shifts above a threshold of 3mm for at least 15s for both devices. Each time threshold was exceeded a CBCT was performed to confirm the obtained shifts. The percent time the differences between TP-US and EM-T were >1, >1.5, >2, >2.5, >3 and 5mm, was scored for each direction and each patient.

	Left-Right (mm)	Supero-inferior (mm)	Antero-Posterior (mm)
Patient 1	0,16 ± 0,29	-0,11 ± 0,54	-0,02 ± 0,69
Patient 2	0,09 ± 0,38	0,55 ± 0,77	0,13 ± 0,69
Patient 3	0,05 ± 0,43	0,09 ± 0,56	0,04 ± 0,69
Patient 4	0,01 ± 0,50	-0,03 ± 0,33	0,05 ± 0,62
Patient 5	-0,04 ± 0,33	-0,09 ± 1,45	0,24 ± 0,74
Patient 6	0,41 ± 1,41	-1,77 ± 5,73	1,24 ± 3,51
Patient 7	0,11 ± 0,42	-0,53 ± 0,50	0,30 ± 0,43
Patient 8	0 ± 0,42	-0,19 ± 0,34	0,17 ± 0,45
Patient 9	0,02 ± 0,25	-0,10 ± 0,34	-0,33 ± 0,75

Table 1: Mean differences between displacements observed with EM-T and TP-US during all the treatment sessions.

#### Results

Experiments on phantom confirmed the lack of interference between the 2 systems, and showed deviations of less than 0.5mm when translations were applied progressively. In presence of rotations (5 to 15° around left-right (LR) and antero-posterior (AP) axis), each system compensated with systematic shifts up to 6.9 mm for the TP-US and up to 3.8 mm for the EM-T. Mean differences between displacements observed on patients with EM-T and TP-US were ≤0.55mm in all directions except for patient 6 (Table 1). A strong correlation was found in LR direction: differences >2mm were monitored only less than 0.22% of the time for all patients and differences >2.5 mm never exceeded 3s, except for patient 6 (>2.5 mm 9.3% of the time). More important differences were observed in supero-inferior (SI) and AP directions, where more intrafraction displacements occurred. In AP direction they were >2mm less than 3.8% of the time for all patients but patient 6 (26% of the time). They were >2mm less than 1% of the time for 6 patients

and more than 7% of the time (up to 19% (patient6)) for the 3 others. When intrafraction CBCT was performed, a strong correlation was observed with TP-US. While punctual differences could be explained by the differences in latency between the 2 systems, large prostate rotations, the presence of gas and EM-T location in the prostate are likely to explain more important differences.

#### Conclusion

TP-US is a promising option since it is non-invasive and enables visualization of the target and organs at risk. However the accuracy needs to be evaluated in presence of rotations. EM-T is a reliable technique for monitoring prostate. However location in the prostate volume is of important to be more accurate.

#### EP-1977 Intrafraction motion in CNS radiotherapy with an open mask system using an optical surface imaging

D. Reitz<sup>1</sup>, S. Schönecker<sup>1</sup>, M. Pazos<sup>1</sup>, P. Freislederer<sup>1</sup>, M. Reiner<sup>1</sup>, M. Niyazi<sup>1</sup>, U. Ganswindt<sup>2</sup>, C. Belka<sup>1</sup>, S. Corradini<sup>1</sup>

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, München, Germany ; <sup>2</sup>University of Innsbruck, Department of Radiation Therapy, Innsbruck, Austria

#### Purpose or Objective

Intrafraction motion control is of special interest in modern radiotherapy. Open masks allow for a continuous patient monitoring, reduce claustrophobia and anxiety and improve patient's compliance compared to closed masks. In this prospective study we evaluated the magnitude of intrafraction motion in patients receiving radiotherapy for CNS tumors with an open mask system.

#### Material and Methods

Data of 114 fractions in 10 patients that underwent non-stereotactic radiotherapy for CNS tumors (primary or secondary) were analyzed. During each treatment session patients were monitored using the Catalyst™ optical surface scanner (C-RAD AB, Sweden). Three-dimensional deviations and relative position differences during the whole treatment fraction were calculated and analyzed statistically.

#### Results

Overall, the maximum magnitude of the mean deviation vector was 0.62 mm ± 0.62 mm (standard deviation) (95%-CI: [0.07 - 2.2] mm) and a median of 0.35 mm during dose application (beam-on time only).

Along the lateral (-0.12 ± 0.61 mm; 95%-CI: [-1.73 - 0.99] mm) and longitudinal (-0.07 ± 0.56 mm; 95%-CI: [-1.38 - 1.09] mm) axis changes were quite similar, while for the vertical axis deviation was tendentially lower (-0.03 ± 0.25 mm; 95%-CI: [-0.46 - 0.53] mm). 99% of the whole beam-on time the magnitude of the deviation vector was < 2.55 mm. The median net beam-on time of radiation therapy was 92 seconds.

According to Friedman's test differences in the distributions between the three possible directions (lateral, longitudinal and vertical) were significant (p<0.01), in Post-Hoc-analysis a dissimilarity between lateral and vertical as well as longitudinal and vertical direction could be verified (p<0.01) whereas between lateral and longitudinal direction a dissimilarity could not be verified (p=1.0).

#### Conclusion

Real-time intrafraction motion was < 2.5 millimeters in all directions and open masks can therefore be considered a suitable and reliable treatment option in clinical practice.

#### EP-1978 Surface guided coplanar and non-coplanar stereotactic radiotherapy with open masks - a phantom study

E. Konradsson<sup>1,2</sup>, M. Kügele<sup>1,2</sup>, K. Petersson<sup>2</sup>, L. Berg<sup>2</sup>, M. Gebre-Medhin<sup>2</sup>, S. Ceberg<sup>1</sup>

<sup>1</sup>Medical Radiation Physics, Department of Clinical Science- Lund University, Lund, Sweden ; <sup>2</sup>Department of Hematology- Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden

#### Purpose or Objective

For most on-board imaging techniques in radiotherapy, such as Cone-Beam Computed Tomography (CBCT), verification of patient position is only possible with the couch at an angle of 0°. Furthermore, patient position is often only verified before, and not during, treatment. The purpose of this study was to investigate if an optical surface scanning (OSS) system with a novel surface algorithm for stereotactic radiotherapy (SRT), in combination with open masks, provide sufficient accuracy for positioning and real-time monitoring of coplanar and non-coplanar SRT treatments.

#### Material and Methods

The study was performed using an Alderson RANDO phantom and a costume-made three-point open mask (Orfit Industries, Wijnegem, Belgium) on a TrueBeam system (Varian, Palo Alto, California, USA) with an OSS three camera Catalyst™ system with the novel SRT solution (C-RAD Positioning AB, Uppsala, Sweden). For coplanar treatments the agreement between the isocenter shift calculated by the OSS system and the isocenter shift suggested after image-verification with CBCT was evaluated. A total of 40 measurements were carried out, after positioning the phantom using the OSS system's auto-couch function

For non-coplanar treatments the accuracy of positioning and real-time monitoring was evaluated by separating any potential couch rotation offsets from the uncertainties in the OSS system's calculation of the isocenter shift. This was done by placing a high-Z marker on top of the phantom in line with the isocenter point in longitudinal and lateral direction and acquiring megavoltage (MV) images at different couch angles. By comparing the MV images acquired at each couch angle (45°, 90°, 270° and 315°) with images acquired at the standard position (0°), the couch rotation offset could be identified and thus the accuracy of the OSS system's calculation of the isocenter position could be determined.

#### Results

For coplanar treatments the median agreement in the isocenter shift calculation between the OSS system and the CBCT was 0.1/-0.2/0.0 mm (range: -0.2 to 0.3/-0.5 to 0.1/-0.3 to 0.2 mm) in the vertical/longitudinal/lateral direction, respectively. For all rotational directions the agreement was within 0.9°. For non-coplanar treatments the accuracy of the OSS system's calculation of the isocenter position was within 0.5 mm, with a median of -0.3 and -0.4 mm (range: -0.4 to 0.4/-0.5 to 0.4 mm) in the longitudinal and lateral direction, respectively.

#### Conclusion

The OSS system with its novel surface algorithm for SRT in combination with open masks show excellent agreement with the CBCT system and has the ability to validate the position of a phantom with 0.5 mm accuracy regardless of couch angle. The results of the study show that the system could be very useful as a complementary tool for verification and real-time monitoring of coplanar and non-coplanar stereotactic radiotherapy treatments.

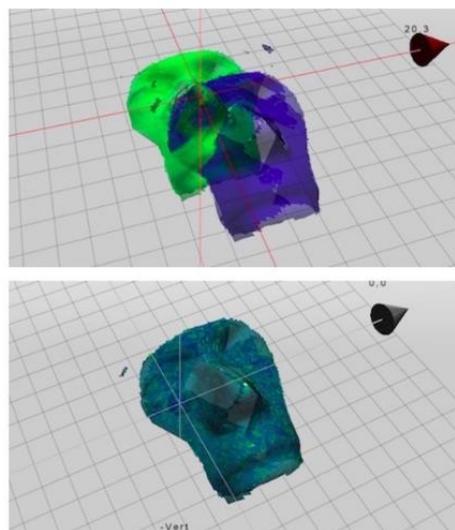

Figure 1: The live phantom surface (green) and the reference surface (blue) are displayed. The upper figure show a mismatch in position between the two surfaces and the lower figure show a perfect alignment.

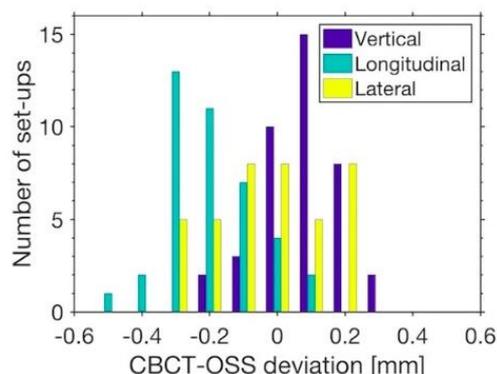

Figure 2: Translational deviations between the isocenter shift calculated by the OSS system and the isocenter shift suggested after image-verification with CBCT.

#### EP-1979 Intrafraction stability of 8526 deep inspiration breath holds in left-sided breast cancer

D. Reitz<sup>1</sup>, S. Schönecker<sup>1</sup>, M. Pazos<sup>1</sup>, P. Freislederer<sup>1</sup>, M. Reiner<sup>1</sup>, M. Niyazi<sup>1</sup>, U. Ganswindt<sup>2</sup>, C. Belka<sup>1</sup>, S. Corradini<sup>1</sup>

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, München, Germany ; <sup>2</sup>University of Innsbruck, Department of Radiation Therapy, Innsbruck, Austria

#### Purpose or Objective

Patients with left-sided breast cancer often receive deep inspiration breath hold (DIBH) radiotherapy to reduce the risk of cardiac side effects. Data of a large study cohort receiving radiotherapy with DIBH were analyzed regarding intrafraction breath-hold stability.

#### Material and Methods

105 patients that underwent left-sided breast cancer radiotherapy with DIBH using the Catalyst™ optical surface scanner (C-RAD AB, Sweden) were analyzed. During each treatment session the vertical motion of the patient was continuously measured by the optical system and gating control (beam on/off) was performed by an audio-visual patient feedback system. The Catalyst™ system works through an optical surface scanning with LED light and

reprojection captured by a CCD camera, which provide target position control during treatment delivery. Dose delivery is automatically enabled when the tracking point is within a predefined gating window.

### Results

8526 breath-holds were analyzed. The mean amplitude of the gating window referred to the baseline breathing curve was 16.36 mm (SD 6.57 mm) (95%-confidence interval: [7.81 - 31.11] mm). The mean standard deviation of breath-hold inside the gating window was 0.42 mm (95%-CI: [0.05 - 0.94] mm). The gating window height had a mean value of 3.24 mm (95%-CI: [0 - 5] mm).

### Conclusion

The use of the Catalyst™ optical surface scanner enables stable and reliable breath-holds during radiotherapy for left-sided breast cancer the clinical routine.

### EP-1980 Randomised trial investigating breathing regularity: Audiovisual biofeedback vs free breathing

E. Steiner<sup>1</sup>, K. Makhija<sup>1</sup>, R. O'Brien<sup>1</sup>, J. Wolf<sup>2</sup>, J. Ludbrook<sup>2</sup>, P. Greer<sup>2</sup>, P. Keall<sup>1</sup>

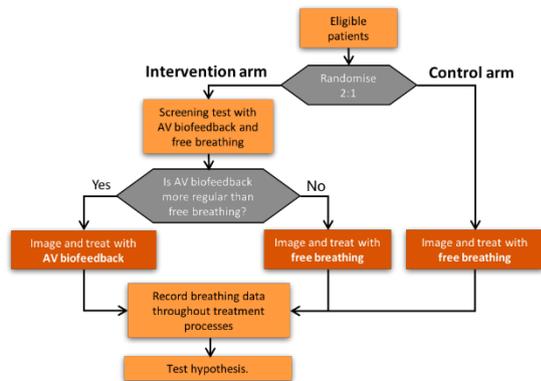

<sup>1</sup>The University of Sydney, Central Clinical School- ACRF Image X Institute, The University of Sydney, Australia ; <sup>2</sup>Calvary Mater Newcastle, Radiation Oncology, Newcastle, Australia

### Purpose or Objective

Irregular breathing leads to artefacts in 4DCT imaging and uncertainties during radiotherapy delivery. We present the early results of the first multi-institutional, randomised trial to investigate if breathing regularity improves with audiovisual biofeedback (AVBF) breathing guidance for lung cancer patients.

### Material and Methods

We report the data from the first eleven lung cancer patients recruited to the ethics-approved trial. Patients were randomised 2:1 to the intervention arm with AVBF screening or the free breathing (FB) control arm (Figure 1).

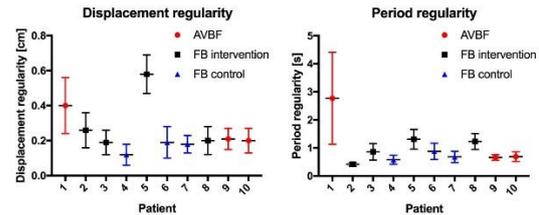

Breathing motion was measured with the Real-time Position Management (RPM) system (Varian Medical Systems). An in-house developed AVBF system provided breathing guidance to patients. Patients with AVBF screening were treated with AVBF if the AVBF-guided breathing was more regular during the screening session, or FB otherwise. Breathing regularity was quantified by the displacement regularity and the period regularity (as defined in Venkat *et al.* 2008) between the average breathing motion during the CT simulation session and the breathing motion during each treatment fraction. We tested the hypothesis that AVBF improves breathing displacement regularity and period regularity compared to FB using a one-sided t-test.

### Results

8 patients were recruited into the intervention arm, 3 patients into the control arm. In the intervention arm 3 patients were screened to be treated with AVBF, 5

patients were screened to be treated with FB. One patient treated with FB was excluded for analysis because the breathing traces could not be recorded for the treatment fractions. For the patients treated with AVBF and with FB the displacement regularity was  $0.27 \pm 0.09$  cm and  $0.25 \pm 0.14$  cm and the period regularity was  $1.4 \pm 1.0$  s and  $0.9 \pm 0.3$  s, respectively (Figure 2).

### Breathing regularity for all patients

Overall the FB arm had lower regularity values indicative of more regular breathing, but no significant difference between AVBF and FB could be shown (displacement regularity:  $p=0.41$ , period regularity:  $p=0.15$ ). Thus, our null hypothesis is not supported. Patient 1 treated with AVBF showed large variations in displacement and period regularity for different treatment fractions resulting from large changes in the daily performance. Patient 5's large displacement regularity values resulted from a different breathing pattern during CT simulation compared to the treatment fractions.

### Conclusion

At this stage, no difference in breathing regularity between AVBF and FB could be shown. Further investigations will be performed.

### EP-1981 Intrafractional baseline drift in SBRT of lung tumors

J. García Ruiz-Zorrilla<sup>1</sup>, M.A. De la Casa de Julián<sup>1</sup>, O. Hernando Requejo<sup>2</sup>, P. García de Acilu Laa<sup>1</sup>, C. Rubio Rodríguez<sup>2</sup>, J. Martí Asenjo<sup>1</sup>, P. Fernández Letón<sup>1</sup>, D. Zucca Aparicio<sup>1</sup>, J.M. Pérez Moreno<sup>1</sup>, X. Chen<sup>2</sup>

<sup>1</sup>Hospital Universitario HM Sanchinarro, Radiofísica, Madrid, Spain ; <sup>2</sup>Hospital Universitario HM Sanchinarro, Oncología Radioterápica, Madrid, Spain

### Purpose or Objective

To investigate the frequency and amplitude of baseline or drift of lung tumors treated with stereotactic body radiation therapy (SBRT) and ExacTrac Adaptive Gating® with intra-fractional IGRT. Methods and materials

### Material and Methods

Forty one fractions of 12 patients with lung tumors were treated with SBRT using ExacTrac Adaptive Gating® in a Novalis® linac. This system uses external markers to monitor the respiratory cycle and internal fiducial markers to set up the patient and measure the movement of the tumor. The tumor position is measured intermittently during the treatment via stereoscopic x-ray images to compensate the baseline drift. Therefore, the accumulative changes in the couch position correspond to the baseline drift in the tumor motion.

### Results

The average change in position of the treatment couch during the treatment time was  $-0.1 \pm 0.8$  mm (mean  $\pm$  standard deviation),  $-0.1 \pm 1.2$  mm, and  $0.2 \pm 1.9$  mm in the left-right (LR), antero-posterior (AP) and cranio-caudal (CC), directions respectively. Overall the baseline shift/drift occurs toward the cranial directions. The incidence of a baseline drift exceeding 1 mm was 43%, for the CC direction, within 15 minutes of the start of treatment, and 63% within 25 minutes. On the other hand, the incidence of a baseline drift exceeding 3 mm was 4% for the CC direction, within 15 minutes of the start of treatment, and 25% within 25 minutes.

The intra-fractional uncertainties due to baseline drift of lung tumors are:

Direction	M (mm)	$\Sigma$ (mm)	$\sigma$ (mm)
LR	-0.1	0.1	0.4
AP	-0.1	0.3	0.6
SI	0.1	0.5	0.8

M: the overall mean or group systematic error,  $\Sigma$ : the standard deviation (SD) of the systematic error,  $\sigma$ : the SD of the random error.

In the absence of intra-fraction IGRT, the baseline drift uncertainties does not imply the use of increased standardized margins in any direction in SBRT for lung tumors when the rest of uncertainties are minimized. Nevertheless this uncertainty can be very important in some patients leading to the needance of increased margins.**Conclusion**

Real-time monitoring and frequent adjustments of the couch position are suggested to be necessary to compensate for possible underdosage in CC direction due to baseline drift in SBRT for lung tumors in some patients.

#### EP-1982 Pancoast tumours. A good candidate for proton spot scanning?

D. Sloth Møller<sup>1</sup>, L. Hoffmann<sup>1</sup>, M. Josipovic<sup>2</sup>, A.K. Berthelsen<sup>2</sup>, G. Persson<sup>3</sup>

<sup>1</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus C, Denmark ; <sup>2</sup>Copenhagen University Hospital Rigshospitalet, Department of Oncology, Copenhagen, Denmark ; <sup>3</sup>Copenhagen University Hospital Herlev, Department of Oncology, Copenhagen, Denmark

#### Purpose or Objective

Large anatomical changes and respiratory motion during radiotherapy for lung cancer patients challenge precise delivery of proton spot scanning, with high risk of target under dosage. Upper-lobe pancoast tumors are less influenced by respiration and may be good proton-candidates, but setup-errors and longitudinal anatomical changes may still deteriorate the dose distribution.

#### Material and Methods

Nine patients with stage III NSCLC Pancoast tumours, treated with photon volumetric arc therapy (VMAT) were retrospectively planned using three-field intensity modulated proton therapy (IMPT) and single field uniform dose (SFUD) with field directions avoiding distal fall off in front of the spinal cord. The brachial plexus (BP) overlapped with the target for all patients and was delineated by an experienced radiologist (Fig 1). Target coverage and dose to oesophagus, lungs, BP and spinal cord of the initial treatment plans were compared. To evaluate the dose deterioration due to setup errors, all treatment plans were shifted 3 mm in each of the six directions and recalculated. To evaluate the dose deterioration due to tumor shrinkage, the daily CBCT scans acquired for setup were used. The tumor shrinkage present at the CBCT of the last treatment day was delineated and each plan was recalculated on a CT, where the HU inside the delineated structure were set to lung density. For both scenarios, CTV receiving 95% of the prescribed dose ( $V95\%_{CTV}$ ) and the dose to the hottest 1 cm<sup>3</sup> of the spinal cord ( $D1cm^3_{spinal}$ ) was analyzed.

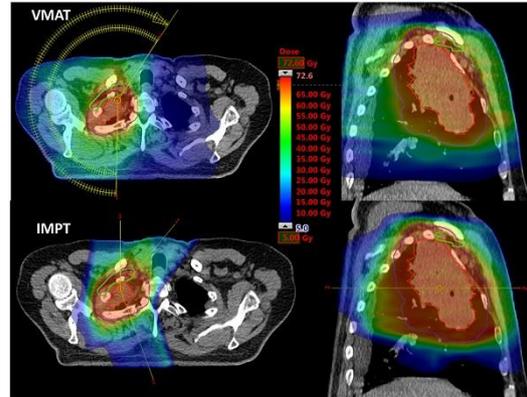

Figure 1: Patient example with GTV (red), PTV (blue) and Brachial Plexus (green) delineated. Dose color wash of doses above 5 Gy is shown for VMAT (upper panel) and IMPT (lower panel).

#### Results

Lung dose metrics (mean dose,  $V20Gy$  and  $V5Gy$ ) were significantly reduced (Fig 2), while no reduction was seen for the mean dose to oesophagus and BP (Fig 2) compared to VMAT. There were no significant differences in normal tissue dose between IMPT and SFUD. For target coverage, the  $V95\%_{PTV}$  differed between patients and planning strategies depending on target proximity to the spinal cord ( $D1cm^3_{spinal} < 45$  Gy for all plans). For SFUD  $V95\%_{PTV}$  was median[range] 93%[64-100], while IMPT and VMAT achieved 99%[97-100] and 94%[85-98]. Setup errors decreased target coverage of up to 3%, 4% and 10% and increased  $D1cm^3_{spinal}$  by 4Gy, 2 Gy and 6Gy for VMAT, SFUD and IMPT, respectively. Robustness towards tumor shrinkage was high for all SFUD/IMPT, where the field directions selected ensured  $<0.1$  Gy increase in  $D1cm^3_{spinal}$ . VMAT was less robust and  $D1cm^3_{spinal}$  increased 2-9 Gy, but low initial spinal cord doses prevented over dosage. All plans maintained initial target coverage regardless of tumor shrinkage.

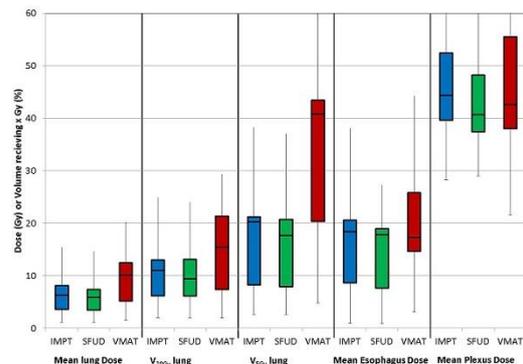

Figure 2: Difference in dose to organs at risk using IMPT, SFUD and VMAT presented as a boxplot. The box shows the range between 1<sup>st</sup> and 3<sup>rd</sup> inter quartile ranges, the vertical line in the middle indicates the median value and the whiskers range from minimum to maximum value. For both IMPT and SFUD the reduction in lung dose (mean,  $V_{20Gy}$  and  $V_{5Gy}$ ) compared to IMRT was statistically significant (Wilcoxon sign rank,  $p < 0.05$ ).

#### Conclusion

Pancoast tumours are candidates for proton spot scanning reducing lung dose significantly compared to VMAT. IMPT is preferred over SFUD due to superior target coverage. No sparing of the BP was seen due to large overlap with the target. For field directions avoiding distal fall off in front of the spinal cord, both IMPT and SFUD were highly robust towards tumor shrinkage, while setup errors posed a risk of target under dosage or spinal cord over dosage mainly for IMPT.

#### EP-1983 Inter and intra-fraction bowel motion during abdomino-pelvic stereotactic ablative radiotherapy

F. Slevin<sup>1</sup>, M. Beasley<sup>2</sup>, J. Lilley<sup>3</sup>, R. Speight<sup>3</sup>, L.J. Murray<sup>1</sup>, A.M. Henry<sup>1</sup>

<sup>1</sup>St James Institute of Oncology, Clinical Oncology, Leeds, United Kingdom ; <sup>2</sup>St James Institute of Oncology, Therapeutic radiography, Leeds, United Kingdom ; <sup>3</sup>St James Institute of Oncology, Medical physics, Leeds, United Kingdom

### Purpose or Objective

Abdomino-pelvic Stereotactic Ablative Radiotherapy (AP-SABR) is increasingly used to treat oligometastatic pelvic nodal disease. Bowel within or adjacent to the Planning Target Volume (PTV) is often the most significant organ at risk. Bowel motion is dynamic and unpredictable and could result in significantly different dose delivered than planned. This retrospective single centre study quantifies inter and intra-fractional changes in bowel using cone beam CT (CBCT) and calculates the impact on delivered bowel doses.

### Material and Methods

10 consecutive patients treated with AP-SABR delivered using flattening filter free (FFF) volumetric modulated arc therapy (VMAT) to a dose of 30Gy in 3 or 5 fractions were investigated (5 fractions used for re-irradiation cases). Delivery times are around 90 seconds. Median intra-fraction imaging time period was around 6 minutes. 84 CBCT images acquired immediately pre and post each SABR fraction were exported to Monaco Treatment Planning System and rigidly co-registered with the planning CT scan. Individual bowel loops within a 3cm expansion beyond the PTV were contoured on each CBCT (majority of dose fall off occurs within this region). Inter-fraction bowel changes were calculated by comparing the planning CT to each pre-treatment CBCT. Intra-fraction bowel changes were calculated by comparing each pre and post-treatment CBCT. Dosimetric consequences of changes in bowel volume and position were determined by superimposing the planned dose distribution onto each CBCT and generating dose volume histogram data. Bowel volume, maximum dose to 0.5cc (Dmax) and 5cc (D5cc) within 3cm of the PTV on planning CT and CBCT were compared using a Wilcoxon signed-rank test.

### Results

Significantly higher bowel volumes within a 3cm PTV expansion were consistently found on CBCT compared to planning images, resulting in greater delivered than planned bowel doses (Figures 1 and 2). Bowel volumes within 3cm of the PTV, Dmax and D5cc were greater on CBCT images compared to planning CT (all  $p < 0.0001$ ). Dmax of bowel on treatment CBCTs was greater than that planned in 37 of 42 (88.1%) pre-treatment CBCTs and 33 of 42 (78.6%) of post-treatment CBCTs. By summing the delivered Dmax per fraction for individual patients, the median net increase over the whole treatment course on pre and post-treatment CBCTs was 33.7% (range -18.5 to 133.1%) and 29.9% (range -23.8 to 135.9%) respectively. 5 of 10 (50%) patients had greater than 20% net increase in Dmax compared to planned doses. No significant difference was observed for intra-fraction variations in bowel volume, Dmax and D5cc within 3cm of the PTV.

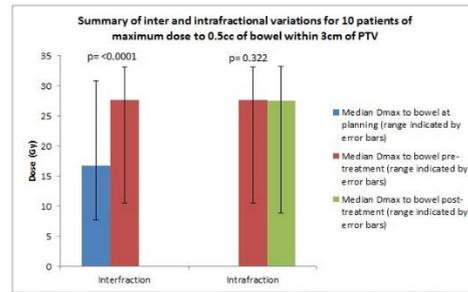

Figure 1: Bar chart showing median inter and intra-fraction maximum dose to 0.5cc of bowel (Dmax) within 3cm of the PTV for 10 patients with minimum and maximum ranges of Dmax indicated by error bars. Significantly greater inter-fraction variation in Dmax during treatment compared to planning was demonstrated ( $p < 0.0001$ ). Intra-fraction variation was non-significant.

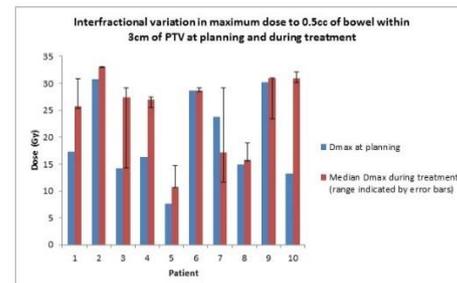

Figure 2: Bar chart showing inter-fractional variation in median maximum dose to 0.5cc of bowel (Dmax) for 10 patients with minimum and maximum ranges of Dmax indicated by error bars. Significantly greater median Dmax to bowel was observed during treatment compared to planning ( $p < 0.0001$ ).

### Conclusion

Significantly greater volume of bowel within a 3cm expansion of the PTV was observed during treatment than at planning, resulting in significantly higher than planned bowel doses. Little intra-fraction change in bowel was observed. Developing adaptive workflows that utilise plan-of-the-day or daily fast adaptive re-planning could compensate for inter-fraction bowel changes.

### EP-1984 Cone beam computed tomography (CBCT) interobserver variability in patient setup error evaluation

A. Delana<sup>1</sup>, V. Vanoni<sup>2</sup>, P. Ferrazza<sup>2</sup>, F. Coelli<sup>2</sup>, M. Maino<sup>2</sup>  
<sup>1</sup>S. Chiara Hospital- Trento, Dept. Medical Physics, trento, Italy ; <sup>2</sup>S. Chiara Hospital- Trento, Dept. of Radiation Oncology, trento, Italy

### Purpose or Objective

To evaluate the interobserver variability in registration of daily CBCT to treatment-planning-CT (TPCT) in patients treated in five different anatomical sites, with volumetric modulated arc therapy (VMAT).

### Material and Methods

In an off-line retrospective approach, 16 well-trained radiotherapy technicians/radiotherapists (RT) performed manual CBCT/TPCT registrations for five patients, treated with VMAT for head and neck, lung, breast, prostate and gastric tumors. An Elekta Synergy XVI linac was used for CBCT acquisition and CBCT/TPCT registration. Each RT quantified the patient setup error in all three axes, by manually matching CBCT and TPCT datasets after automatic pre-matching either based on a gray scale or bone algorithm. Matching results obtained by RTs were compared to those obtained by 1 board certified radiation oncologist with extensive experience in image guided radiotherapy: differences between technologists and radiation oncologist's results were quantified. A statistical analysis was performed to calculate the minimum threshold of agreement between the observers.

### Results

In total, 137 CBCT datasets were acquired and 2281 CBCT/TPCT registrations and setup error evaluations

performed. Table 1 summarizes the results obtained in terms of: number of CBCT acquired (#CBCT), number of CBCT/TPCT registrations (#REG) and threshold below which the agreement between the observers was 90% and 95% (Threshold\_mm95% and Threshold\_mm90%). The prostate patient had the largest threshold values, but always inferior to the planning target (PTV) margin and only 4% of the 713 differences evaluated were above the 5 mm or 7mm PTV margins used in the clinical routine for the respective VMAT treatment paradigms.

	#CBCT	#REG	Threshold_mm 95%			Threshold_mm 90%		
			AP mm	LL mm	CC mm	AP mm	LL mm	CC mm
Head&Neck	30	480	1.7	1.1	1.1	1	1	1
Lung	30	480	1.8	1.1	2	0.9	1.1	1.4
Prostate	39	713	4.2	5.4	2.8	3.2	2.5	1.5
Breast	12	192	1	2	2	0.9	1.6	1.1
Gastric	26	416	1.8	2	2.3	1	1.1	2

## Conclusion

Interobserver reproducibility between trained RTs and an expert radiation oncologist was very good. The largest variability was observed for prostate, probably as a consequence of the more difficult interpretation of the CBCT/TPCT fusion. The study will be extended to a larger number of patients and Radiation Oncologists to validate the results and provide a robust basis for the definition of IGRT protocols.

## EP-1985 Clinical feasibility of CBCT-based online plan adaptation for multiple lesion brain SRS

G. Wortel<sup>1</sup>, U. Stankovic<sup>1</sup>, J. Trinks<sup>1</sup>, G. Sotiropoulos<sup>1</sup>, S. Van Kranen<sup>1</sup>, S. Van de Water<sup>1</sup>, S. Van de Schoot<sup>1</sup>, L. Dewit<sup>1</sup>, E. Damen<sup>1</sup>, T. Janssen<sup>1</sup>, P. Remeijer<sup>1</sup>, J. Sonke<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

## Purpose or Objective

In the absence of a 6DoF couch, IGRT can correct for translation but is not able to manage more complex anatomical changes, including rotations. This study aims to develop and evaluate an online method to automatically adapt treatment plans to the anatomy of the day. As a first showcase, we apply the method to multiple lesion brain SRS.

## Material and Methods

All plans in this study are made with a GTV-PTV margin of 2 mm and a single isocentre, an approach we apply if the targets are < 4 cm apart.

The plan adaptation consists of 5 automated steps. 1) The CBCT is rigidly registered to the planning CT. A new CT, that represents the anatomy of the day, is created by applying the registration results to the original planning CT. 2) The treatment plan is transferred to the new CT in our TPS Pinnacle<sup>3</sup>. 3) A custom built script, based on Ahunbay et al. (2008), morphs the segment apertures to the new targets. 4) A segment weight optimization (SWO) is performed. 5) The plan is exported and checked. The method was evaluated by applying it 55 times (11 setup errors for 5 patients). 10 errors were randomly sampled from the typical setup error for this patient group ( $\sigma_{tx,ty,tz}=1.3\text{mm}, 1.6\text{mm}, 1.7\text{mm}, \sigma_{rx,ry,rz}=1.0^\circ, 1.1^\circ, 0.69^\circ$ ). A more challenging case ( $rx=10^\circ$ ) was also included. For comparison, the original plans were also recomputed on the new CTs, including table translations. The dose distributions were evaluated on the  $V_{100\%}$  to the PTVs and 5mm rings around the PTVs (conformity). We also recorded the duration of the process.

## Results

A DVH example for 1 setup error for 1 patient is shown in Fig. 1. The SWO results in an adapted plan that is more inhomogeneous (allowed for SRS) than the original and recomputed plan. An overview of all results is shown in Fig. 2. PTV coverage is slightly reduced, but acceptable, for most adapted (-1.9pp) and recomputed (-1.4pp) plans. Similarly, the plans are slightly less conformal, with the

recomputed plans performing 1.7pp better in ring  $V_{100\%}$  than the adapted. As can be seen in Fig. 2, the adaptation method is able to correct the large  $rx=10^\circ$  setup errors (with a plan quality similar to that for the small setup errors), whereas the table correction completely fails target coverage (average  $V_{100\%}$  of 65%). On average, the entire process from registration to plan export was completed within 14 (max 18) minutes.

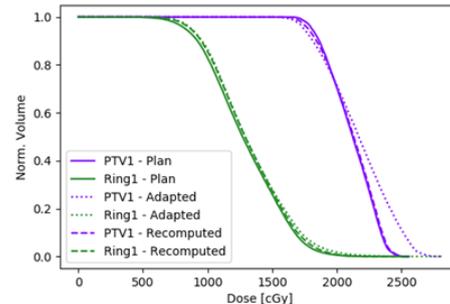

Fig. 1: DVHs for PTV and 5mm Ring (conformity) for one of the PTVs for the original, the adapted, and the recomputed plan.

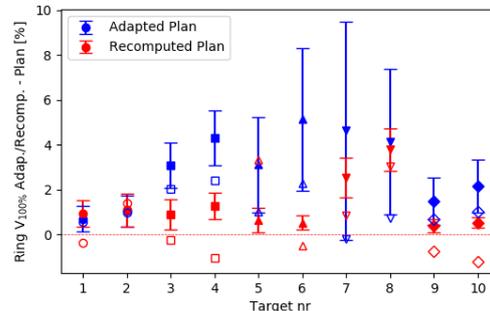

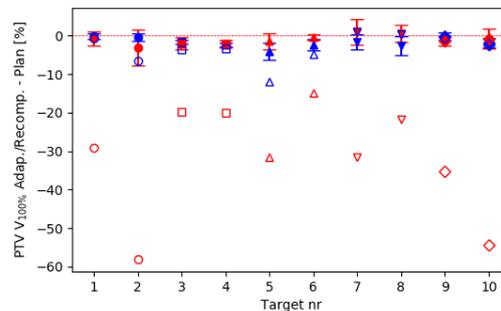

Fig. 2: The  $V_{100\%}$  (averaged over 10 realistic setup errors, with error bars representing  $\sigma$ , different symbols representing different patients) for the PTV (top) and 5mm Ring (bottom). The value of the  $V_{100\%}$  relative to the (original) Plan is plotted per target (2 targets for 5 patients). The open symbols represent a large setup error ( $rx=10^\circ$ ).

## Conclusion

We have successfully developed a method to adapt multiple lesion brain SRS plans online based on CBCT. Whereas this new method performs similar to a physical table correction for our current brain SRS protocol and setup errors, it greatly outperforms the table correction for larger geometrical differences. This ability to correct larger setup errors could allow a PTV margin reduction and extend the use of planning with a single isocentre. The introduced method is not limited to rigid corrections and can be applied to other tumor sites. Ultimately, we consider the development of this method an important step towards full online adaptive radiotherapy.

## EP-1986 Comparison of automatic OAR contour propagation from CT to MR lung images

M. Dubec<sup>1,2</sup>, S. Brown<sup>1</sup>, R. Chuter<sup>1</sup>, A. McWilliam<sup>1,3</sup>, D. Cobben<sup>1,3</sup>, C. Faivre-Flinn<sup>1,3</sup>, M. Van Herk<sup>1,3</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom ;

<sup>2</sup>University of Manchester, Quantitative Biomedical Imaging Laboratory, Manchester, United Kingdom ;

<sup>3</sup>University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom

### Purpose or Objective

For daily plan adaptation on the MR-Linac, fast and accurate methods of OAR contouring are required and it is envisaged that automatic contour propagation will play an important role.

MRI sequences differ in speed, with the DIXON VIBE being relatively quick, whilst acquiring multiple contrasts simultaneously. It is unknown whether contour propagation onto these images is as accurate as other slower sequences. The radial k-space stack-of-stars acquisition (STARVIBE) is commonly used in areas associated with motion, e.g. lungs, to reduce artefacts, while the DIXON sequence can be used as a basis for MR only planning.

This aim was thus to compare contour propagation from CT onto STARVIBE and DIXON images and to determine whether the fast DIXON would be a sufficient pre-treatment sequence.

### Material and Methods

5 NSCLC patients were imaged mid-treatment on a diagnostic 1.5T MR (MAGNETOM Aera, Siemens Healthcare, Erlangen, Germany) using non-triggered sequences: STARVIBE (time = 7:21, spokes = 1050, with fat sat) and DIXON VIBE (time = 1:51, averages = 4), both with matrix 1.25x1.25x3.5 mm<sup>3</sup>. Patients were scanned in the treatment position. The mean time between the two sequences was 25 mins. The DIXON water-only contrast was used for analysis.

MR images were first rigidly registered to the patients' CT planning scans in MONACO (Elekta AB, Stockholm, Sweden). Oesophagus, heart and spinal canal contours, drawn by radiation oncologist, were then propagated from the CT to each mid-treatment MR scan via deformable registration using ADMIRE (Elekta AB, Stockholm, Sweden). The resulting OAR contours were compared by volume, mean DTA and DICE index for both MR sequences.

### Results

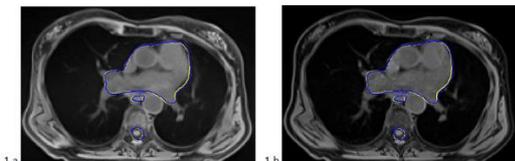

Figure 1. Oesophagus, heart and spinal canal contours overlaid on the STARVIBE (1.a, yellow contour) and DIXON (1.b, blue contour).

The average volume ratios (DIXON/STARVIBE) were 1.10, 1.01 and 1.00 for the oesophagus, heart and spinal canal respectively. Only the oesophagus volume was significant ( $p = 0.01$ ).

The mean DTAs  $\pm$  SD, were  $0.94 \pm 0.72$ ,  $1.23 \pm 1.00$  and  $1.24 \pm 1.70$  for the oesophagus, heart and spinal canal respectively. The mean DTAs for OARs across the 5 patients are shown in figure 2. All OARs were < 2 mm mean DTA except P1 heart (2.1 mm) and P5 spinal canal (2.2 mm). DICE indices of  $0.84 \pm 0.02$ ,  $0.96 \pm 0.02$  and  $0.87 \pm 0.05$  were obtained for the oesophagus, heart and spinal canal respectively.

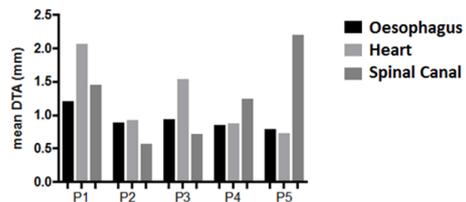

Figure 2. Mean DTA for oesophagus, heart and spinal canal contours on the STARVIBE and DIXON Images for the 5 patients.

### Conclusion

This work compared contours obtained via auto-contour propagation from CT to mid-treatment STARVIBE and DIXON VIBE images.

The mean volume difference for the oesophagus was significant. The mean DTA between the two MR scans was less than 2 mm in all but two instances. DICE was greater than 0.8 for all OARs. Differences could occur due to registration inaccuracies and also due to organ motion between scans.

The results indicate that the DIXON VIBE type sequence may be suitable for set up imaging on the MRL to reduce set-up times (DIXON <2 min, STARVIBE > 5 min). Auto-contour propagation must still be followed by clinician verification at this stage. Future work will compare OAR and GTV contours against clinician drawn contours in a larger sample.

### EP-1987 Dose accumulation assessing the validity of reduced PTV margins in head-and-neck radiotherapy

N. Lowther<sup>1</sup>, S. Marsh<sup>2</sup>, R. Louwe<sup>1</sup>

<sup>1</sup>Wellington Blood & Cancer Centre, Department of Radiation Oncology, Wellington, New Zealand ;

<sup>2</sup>University of Canterbury, Department of Medical Physics, Chirstchurch, New Zealand

### Purpose or Objective

**Purpose:** Emerging literature has reported reduced treatment toxicity while maintaining equivalent local-regional control rates after reducing planning target volume (PTV) margins from 5 to 3 mm for head-and-neck radiotherapy (HNRT). As we considered whether it was possible to implement reduced 3 mm PTV margins in our department, it was recognized that many aspects of HNRT including robustness of the planning solution for anatomical changes may influence treatment outcomes and should be considered when PTV margins are reduced. This retrospective study investigates the robustness of treatment plans using 3 or 5 mm PTV margins for anatomical changes. The results of this study can be used to develop strategies for treatment adaption based on objective criteria.

### Material and Methods

**Methods:** Volumetrically modulated arc therapy (VMAT) plans for 12 patients using 3 or 5 mm PTV margins (Prescribed dose 54 Gy and simultaneous integrated boost volumes to 60 and 66 Gy in 30 fractions) were optimized using the local planning protocol. The planning CT (pCT) was first registered to each daily cone beam CT using deformable image registration (DIR). Subsequently, the inverse registration was used to reconstruct and accumulate the delivered dose to target and organ-at-risk (OAR) structures in the pCT scan. For the initial analysis, the coverage of the PTVs, clinical target volumes (CTVs) and salivary glands were assessed using the  $D_{98\%}$ ,  $D_{99\%}$  and  $D_{mean}$  respectively. The uncertainty of the reconstructed dose was assessed using an *in silico* model based on clinically observed deformations to determine the 95% level of confidence.

## Results

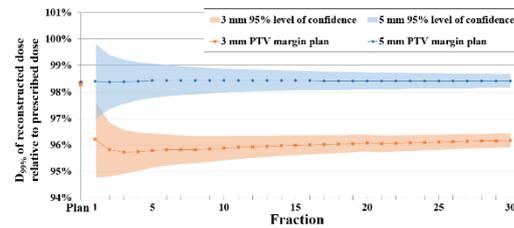

Fig. 1: Reconstructed dose relative to prescribed dose  $D_{99\%}$  for an individual patient's high-dose CTV.

**Results:** Preliminary results (4 patients) showed that for 4 out of 5 high-dose PTVs,  $D_{98\%}$  during treatment was at least 2% lower than planned in both margin plans. The high-dose CTVs'  $D_{99\%}$  generally changed less than 1% relative to the planned dose. However, for two 3 mm plans the high-dose CTV  $D_{99\%}$  was systematically 2% lower (Fig.1). For all high-dose CTVs, the  $D_{99\%}$  of the reconstructed dose at the end of treatment was always 96% of the prescribed dose or higher in both 3 and 5 mm margin plans. For the elective low-dose CTVs, the reconstructed  $D_{99\%}$  was at least 99% of the prescribed dose for all fractions in both plans. On average, the  $D_{\text{mean}}$  for the ipsilateral parotid glands was 4 Gy lower (range; 1 to 10 Gy) in 3 mm margin plans compared to the 5 mm plans. For submandibular glands, the average dose reduction was 2 Gy. The difference between reconstructed and planned  $D_{\text{mean}}$  of the parotid glands was not significantly different for the 3 mm (range; -1.2 to 1.1 Gy) and the 5 mm (range; -1.4 to 1.2 Gy) plans ( $p=0.67$ ).

### Conclusion

Changes in delivered dose due to anatomical changes can be accurately reconstructed using DIR. Initial results indicate that 3 mm PTV margins are robust for anatomical changes occurring during HNRT with CTV  $D_{99\%} \geq 96\%$  of the prescribed dose. PTV margin reduction resulted in increased OAR sparing.

### EP-1988 Statistical process control to monitor anatomical changes during head and neck radiotherapy

N. Lowther<sup>1</sup>, D. Hamilton<sup>1</sup>, H. Kim<sup>1</sup>, J. Evans<sup>1</sup>, S. Marsh<sup>2</sup>, R. Louwe<sup>1</sup>

<sup>1</sup>Wellington Blood & Cancer Centre, Department of Radiation Oncology, Wellington, New Zealand ;

<sup>2</sup>University of Canterbury, Department of Medical Physics, Christchurch, New Zealand

### Purpose or Objective

Reduced toxicity while maintaining loco-regional control rates have been reported after reducing planning target volume (PTV) margins for head-and-neck radiotherapy (HNRT). In this context, quantifying anatomical changes to monitor the patient during treatment is preferred. This retrospective feasibility study investigated the application of deformable image registration (DIR) and Exponentially Weighted Moving Average (EWMA) Statistical Process Control (SPC) charts for this purpose.

### Material and Methods

DIR was performed between the computed tomography for treatment planning (pCT) images of 12 patients and their daily on-treatment cone beam computed tomography (CBCT) images to quantify changes in patient pose and anatomy during treatment. EWMA charts were used to investigate trends in patient positioning reproducibility and soft tissue changes of various structures. The 90% confidence limits for both the EWMA trends and the SPC process limits were obtained using a comprehensive uncertainty analysis. These confidence limits were used to confirm whether a trend breached either an SPC limit or an *a priori* set clinical limit of 2 mm at a previous fraction or not.

### Results

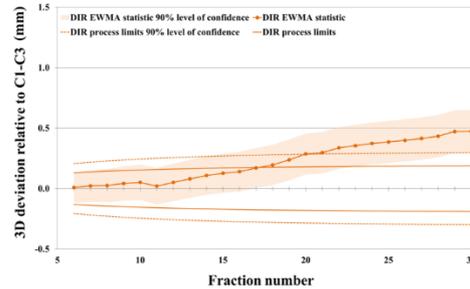

Figure 1: EWMA chart of the mandible deviation for patient 3 relative to week one of treatment

Trends in patient positioning reproducibility relative to the first week of treatment that were outside SPC process limits before the end of treatment week 4 occurred in 54% of cases. Only 24% of these cases could be confirmed at a 90% confidence level before the end of treatment. Using an *a priori* clinical limit of 2 mm, absolute changes in patient pose were detected in 39% of cases, of which 82% were confirmed. Soft tissue trends outside SPC process limits occurring before the end of treatment week 4 could be confirmed in 90% of cases.

### Conclusion

EWMA trends based on DIR data combined with structure specific action thresholds enabled detection of systematic changes in patient pose and anatomy during the first four weeks of treatment. This approach may facilitate timely treatment adaptation and provide a safety net for PTV margin reduction.

### EP-1989 Mesorectal variation and PTV margins for irradiation of rectal cancer patients using belly-board

M. Cox<sup>1</sup>, M. Wendling<sup>1</sup>, R. Van Leeuwen<sup>1</sup>, H. Rütten<sup>1</sup>, P. Braam<sup>1</sup>

<sup>1</sup>Radboud University Medical Centre, Radiation Oncology, Nijmegen, The Netherlands

### Purpose or Objective

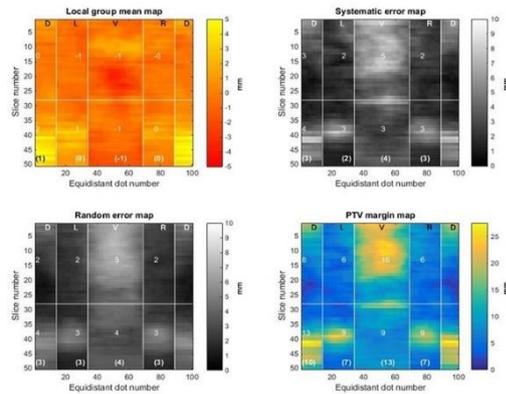

In our centre rectal cancer patients are currently treated with VMAT in a prone position, using a belly-board and full bladder protocol. Current PTV margins are 15 mm in anterior direction and 10 mm in other directions. These margins are based on studies in which patients were irradiated either in supine position or prone position without the use of a belly-board. In the mesorectal part of the CTV, shape variation is expected to be most substantial and heterogeneous. Therefore, the purpose of this study was to investigate the inter-fraction shape variation of the mesorectum and determine PTV margins in rectal cancer patients irradiated in prone position using a belly-board.

### Material and Methods

For 18 patients a planning CT (pCT) and five cone-beam CT (CBCT) scans were acquired in prone position using a belly-board (Pelvic Prone Board, MacroMedics, The Netherlands). The mesorectal part of the CTV was delineated on all scans. These delineations were interpolated on the craniocaudal axis to 50 slices, and 100 equidistant dots were placed and numbered on each slice, starting at the posterior side of the patient via left, anterior, right and back to posterior. The mesorectal shape variation was quantified for each patient by measuring the 1D distance between corresponding dots on the pCT- and the five CBCT delineations. For dots on the left/right side the distance was measured in lateral direction and for the anterior/posterior side in ventrodorsal direction. For each patient the mean and standard deviation (SD) were calculated for each dot and stored in 2D surface maps. Subsequently, local group mean (signed for inside/outside), systematic- and random error maps of the total group were calculated (figure 1). In

order to derive PTV margins, we adapted the margin recipe described by Nijkamp et al (Radiother Oncol 2012).  
**Results**

Systematic- and random errors were ranging from 2 mm SD in the upper-lateral region of the mesorectum up to 5 mm SD in the upper-anterior region (figure 1). Local group mean variation was relatively small, ranging between -1 mm in the anterior region and 2mm in the lower-posterior region. Derived PTV margins were smallest in the upper-lateral region (6 mm) and largest in the upper-anterior region (16 mm).

**Fig. 1.** Local group mean, systematic, random error and PTV margin for the total group of patients. The horizontal axis represents the 100 equidistant dots of each slice starting at posterior (P), via left (L), anterior (A), right (R) and back to posterior. The vertical axis represents the 50 slices ordered from cranial to caudal. The horizontal lines indicate the mean level of the apex of the os sacrum. The bold numbers in parentheses at the bottom represent the combined outcomes of the upper and lower mesorectum for each direction.

**Conclusion**

Even in rectal cancer patients irradiated in prone position and using a belly-board, mesorectal shape variation is heterogeneous and largest in the upper-anterior region. Derived PTV margins are less than described in literature, ranging from 7 mm in lateral direction up to 16 mm at the upper-anterior region of the mesorectum.

**EP-1990 Assessment of Inter-Sessional Positional Reproducibility in the HN Sub-Regions Using 1.5T MR-Sim**

Y. Zhou<sup>1</sup>, J. Yuan<sup>1</sup>, K.F. Cheng<sup>2</sup>, W.W.K. Fung<sup>2</sup>, O.L. Wong<sup>1</sup>, G. Chiu<sup>2</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China ; <sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China

**Purpose or Objective**

We hypothesize that head-and-neck (HN) sub-regions might show different inter-fractional positional characteristics due to the complicated HN anatomies and different sub-regional motion flexibilities. As such, we attempt to utilize the superior MRI soft tissue contrast to assess these inter-fractional positional characteristics in the HN sub-regions at 1.5T.

**Material and Methods**

14 healthy volunteers were recruited. Each subject was immobilized with a 5-point thermoplastic mask, and received 4 MRI scans using a T1-SPACE sequence (TR/TE = 420/7.2ms, isotropic voxel size = 1.05mm, scan time = 301s) on a 1.5T MR-sim to simulate RT fractions. Sub-regions of brain, nasopharynx (NP), oropharynx, and hypopharynx were manually drawn on the reference images acquired in the first MRI scan. Inter-fractional positional variations in translation and rotation were assessed by rigidly registering the overall HN images and each sub-region to the reference images. Correlations of sub-region positional shifts with that of overall HN were assessed using Pearson correlation. The mean and SD of positional shifts, systematic error ( $\Sigma$ ) and random error ( $\sigma$ ) of each sub-regional anatomy were calculated, and compared using paired Wilcoxon signed rank test.

**Results**

Mean and SD of positional shifts, systematic and random errors of overall HN and all sub-regions were mostly within 1mm and 1° (Table I), indicating the excellent positional reproducibility achieved on the MR-sim. Inter-fractional positional shifts in sub-regions were highly correlated with (highest in SI, lowest in roll) and insignificantly different from those in overall HN except for roll in hypopharynx, mainly attributed to the high motion flexibility in the neck even under immobilization ( $p=0.039$ ). Sub-regions did exhibit notably different, although insignificant, shift patterns from the overall HN, in particular in roll and yaw, as shown by the box-plot in Fig. 1. Overall HN mainly underestimated the inter-fractional shift magnitude, range and variability in sub-regions. In terms of margin setting, according to van Herk target margin recipe of  $2.5\Sigma+0.7\sigma$ , larger target margins might be needed in NP for positional compensation than in overall HN and other sub-regions.

Table I. Positional errors of the overall and four sub-regions and the statistical analysis of positional variation correlation in all translation and rotation directions.

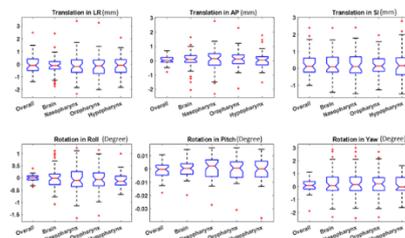

Fig. 1. Box-plot of sub-regions' translation and rotation displacements in every direction.

**Conclusion**

Sub-millimeter inter-fractional positional reproducibility could be achieved in HN sub-regionals on an MR-sim. HN sub-regions showed notably different inter-fractional positional characteristics and this should be taken into account for positional and motion compensation.

**EP-1991 PTV margin evaluation for pediatric craniospinal irradiation with 3D and 2D position verification**

E. Slooten<sup>1</sup>, N. Van Wieringen<sup>1</sup>, R. De Jong<sup>1</sup>, B. Balgobind<sup>1</sup>, S. Huijskens<sup>1</sup>, C. Windmeijer<sup>1</sup>, I. Van Dijk<sup>1</sup>, A. Bel<sup>1</sup>

<sup>1</sup>Academic Medical Center, Radiotherapie, Amsterdam, The Netherlands

### Purpose or Objective

Craniospinal axis irradiation (CSI) is important in specific brain tumors like medulloblastoma. This is a challenging tumor site due to the large size of the fields and complicated patient positioning. Little is known about these patients' inter and intrafraction motion, while these are important components of the PTV margin. The purpose of this study is to determine the magnitude of the inter and intrafraction motion for the thoracic and lumbar spine, and to compare these to the currently used PTV margins. Additionally, we investigate whether 2D kV/DRR position verification yields the same results as 3D CBCT/CT, as the 2D method would lead to lower imaging dose for the patients.

### Material and Methods

We retrospectively included 14 patients [median age 8.5y; range 5-14y] treated with CSI. The thoracic and lumbar CTVs were expanded with anisotropic margins of 0.8cm in LR direction, 1.0cm in caudal direction in the lumbar field and 1.0cm in AP direction for the thoracic and lumbar CTV.

All patients were treated in supine position on a thin mattress and knee support, immobilized with a 5 points mask. For clinical position verification, pre and post treatment CBCTs were acquired of the thoracic and lumbar CTV, using a hybrid offline/online protocol. Average time between the pre and post fractional CBCTs was 22min [range 17-33min]. In total 180 pre and 154 post fraction CBCTs were analyzed. Inter and intrafraction motion in LR, CC and AP directions were determined based on clinically used CBCT/CT automated matches of the bony anatomy. Distributions of systematic and random errors (standard deviations  $\Sigma$  and  $\sigma$ , respectively) were calculated. PTV margins were calculated using inter and intrafraction motion, without considering other sources of error.

We simulated 2D kV/DRR position verification by extracting two orthogonal radiographs from the CBCT series under angles with optimal visibility of the target. These were matched manually to the bony anatomy on DRRs of corresponding angles from the planning CT. The corrections resulting from these matches were compared to the corrections from the 3D CBCT/CT matches and Pearson correlation coefficients were calculated.

### Results

The systematic and random errors and resulting PTV margins for inter and intrafraction motion are shown in table 1 for the 3D CBCT/CT method. The clinically used PTV margins are sufficient for these uncertainties. In figure 1 the corrections from the 2D matches are plotted versus those from the 3D matches for all directions and linear regression lines are shown. A moderate to strong correlation was found as indicated by the Pearson correlation coefficients.

	Thoracic			Lumbar		
	LR	CC	AP	LR	CC	AP
$\Sigma_{interfraction}$ (cm)	0.14	0.20	0.13	0.13	0.28	0.19
$\sigma_{interfraction}$ (cm)	0.25	0.24	0.19	0.30	0.29	0.24
$\Sigma_{intrafraction}$ (cm)	0.15	0.09	0.07	0.13	0.11	0.19
$\sigma_{intrafraction}$ (cm)	0.26	0.20	0.18	0.24	0.18	0.23
PTV (cm)	0.8	0.8	0.6	0.8	1.0	0.9

Table 1:  $\Sigma$  and  $\sigma$  for the inter and intrafraction motion as found by CBCT.

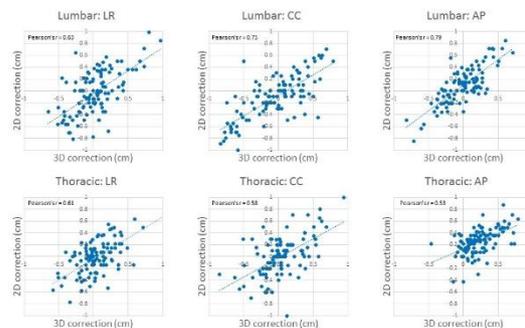

Figure 1: Correlation between corrections following from 2D position verification (i.e. 2D kV/DRR) and those following from 3D position verification (i.e. 3D CBCT/CT) for the lumbar and thoracic part of the target in all directions.

### Conclusion

The current PTV margins are sufficient to incorporate the inter and intrafraction motion measured on the CBCT for both the thoracic and lumbar CTV. The moderate to strong correlation between the 2D and 3D matches implies that larger margins may be needed when using 2D position verification to account for the additional uncertainty.

### EP-1992 Dose warping protocol for interfraction variation in Bladder filling in ano-rectal cancer patients

C. Fiandra<sup>1</sup>, E. Trino<sup>1</sup>, F. Arcadipane<sup>2</sup>, F. Olivero<sup>1</sup>, U. Ricardi<sup>1</sup>, P. Franco<sup>1</sup>

<sup>1</sup>University of Turin, Oncology, Turin, Italy ; <sup>2</sup>Città della Salute e della Scienza, Radiation Oncology, Turin, Italy

### Purpose or Objective

During pelvic radiotherapy (RT), bladder filling may randomly change during the course of treatment. The more reliable approach to account for this variation is represented by Plan of the Day approach; This relies on the robustness of deformable image registration (DIR) algorithms and software to match dissimilar volumes in different scansets. The main purpose of this work was to investigate a framework with 2 different algorithms to validate DIR performed between planning CT and each CBCT to explore the relationship between the "real" dose received by the Bladder and its volume change.

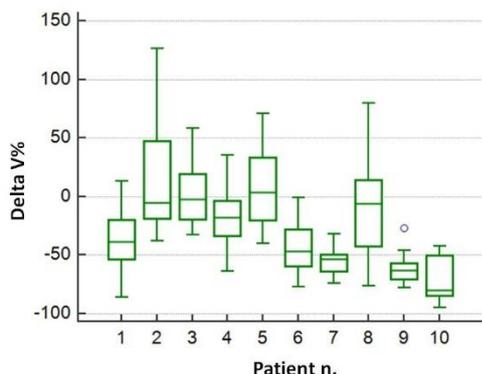

### Material and Methods

Ten patients were enrolled in the study; a total of 233 CBCTs were analyzed and contoured. Bladder, femoral heads and pubic symphysis were mapped from planning CT (pCT) to each CBCT and then verified by physicians. Each contour was then mapped back on the planning CT by means of specific deformable vector field (DVF) using both Hybrid and Biomechanical DIR algorithms. The goodness of the registration was double-checked first by visual inspection of each registration by physician and then by structures correspondence using Dice similarity coefficient (DSC) and Hausdorff distance (HD). The plan was then recalculated on each CBCT and dose warping was applied to accumulate dose on the planning CT with both algorithms, only in case of  $DSC \geq 0,8$  and  $HD \leq 3$ mm. Each re-calculated and deformed dose was used to evaluate the average dose (AD) and dose received by 2% volume ( $D_2$ ) of the Bladder for each treatment session and their correlation with percentage variation of volume of the Bladder (PVB) was investigated; Spearman's coefficient of rank correlation ( $r$ ) was calculated for both algorithms for AD and  $D_2$  in function of PVB

### Results

Percentage variation of Bladder volume compared to the pCT was  $-28.7 \pm 39\%$  showing a tendency for a smaller bladder volume during treatment than simulation CT. Figure 1 shows a box plot of the percentage variation of volume of bladder for each patient while Table 1 reports mean values and standard deviation of DSC and HD indexes for all structures for both algorithms;  $r$

values respectively of 0,171 and 0,140 for Hybrid algorithm were obtained for AD and for D<sub>2</sub>, while values of -0,164 and 0,041 were obtained for Biomechanical algorithm. Patient by patient analysis reveals higher correlation if volume of bladder has more limited variation like in the case of patient 3.

	DSC		HD (mm)	
	Hybrid	Biomechanical	Hybrid	Biomechanical
Bladder	0,929±0,135	0,951±0,025	0,967±1,261	0,776±1,111
Right femur	0,980±0,014	0,960±0,011	0,540±0,459	0,466±0,260
Left femur	0,976±0,020	0,967±0,01	0,560±0,497	0,572±1,902
Pubic symphysis	0,950±0,070	0,886±0,142	0,486±0,353	0,657±0,515

**Conclusion**

Dose warping protocol was applied for dose accumulation in the bladder during radiotherapy for pelvic cancers. Particular attention was addressed to the QA of the DIR involved for dose warping. Only deformable vector fields with a sufficient value of DSC or HD were considered, but random variations of Bladder volume shows poor or absent correlation with “real” dose received in terms of AD and D<sub>2</sub> compared to the original value of planning; an exception is represented by patients in which the volume variation of Bladder is more similar compared to the initial value on pCT.

**EP-1993 Evidence of CTV underdosing due to anatomical changes during breast Helical Tomotherapy**  
 P. Mangili<sup>1</sup>, M. Mori<sup>1</sup>, A. Fodor<sup>2</sup>, B. Longobardi<sup>1</sup>, P. Signorotto<sup>1</sup>, M. Pasetti<sup>2</sup>, F. Zerbetto<sup>2</sup>, N. Di Muzio<sup>2</sup>, R. Calandrino<sup>1</sup>, C. Fiorino<sup>1</sup>  
<sup>1</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Radiotherapy, Milan, Italy

**Purpose or Objective**

Several planning studies claimed Helical Tomotherapy (HT) as a valid technique to optimize breast cancer radiotherapy due to potential improvements in dose homogeneity within PTV and sparing of Organs at risk (OARs), especially in case of concave-shaped PTVs. However, no studies dealt with the robustness of the delivered dose. In current study we quantified the dosimetry effects of anatomical changes on the delivered dose to breast CTV during post-operative HT.

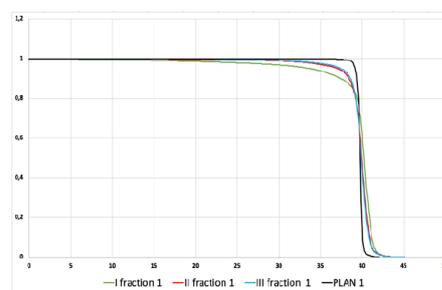

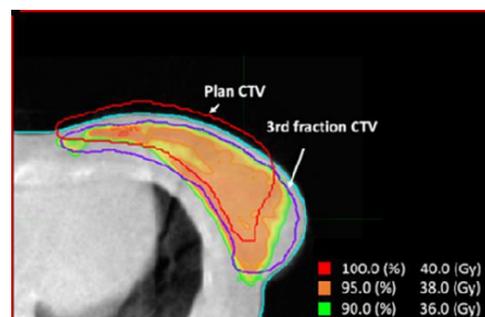

**Material and Methods**

Eleven patients (pts) previously treated with TomoDirect (TD) with post-operative radiotherapy to the whole breast were considered; HT treatment plans were optimized with the Tomotherapy planning station (Accuray Inc.) to deliver

a prescribed dose of 40Gy/15 fr. CTV and PTV were defined according to national guidelines (including a 5mm crop from body external contour); no additional PTV margins were added toward the body contour in order to avoid the inclusion of skin and the consequent delivery of high skin dose, expected in the HT mode. The changes of the dose distributions during treatment were weekly assessed in 3/15 fractions by dose-of-the-day recalculation on daily MVCT using the DQA TomoTherapy software. MVCTs were rigidly registered to the planning CT by matching chest bones position, according to our clinical procedure. CTV contours were then deformable registered from planning CT to the daily anatomy on MVCT, using a constrained-intensity-based algorithm (MIM software). Finally, after CTV fine-tuning manual correction, contours were cropped 5mm from MVCT body contour, consistently with the original definition. CTV DVHs during therapy were then obtained: for each patient, mean/min values of V32, V36, V38, V40, V43.2 over the three considered fractions were extracted (corresponding to 80%,90%,95%,100% and 105% of the prescribed dose) and compared against planning values.

**Results**

On average, the minimum values of V36 and V38 during therapy were 98.3% (92.8-99.9 %) and 97.1% (88.9-99.8 %) respectively against 100% at planning. For 3/11 pts (27%) there was an evidence of relevant local underdosing of CTV due to anatomical changes, with minimum values of V38 ranging between 95.4% and 88.9%. For two of these pts, local dose reduction >20% were visible: looking at V36, mean/min values for these pts were: 95.4/92.8 and 96.8/93.4 against planned values equal to 100%. The worst case is shown in Figure 1 (planning CTV in red, daily MVCT CTV in purple, dose delivered at fraction 4). The corresponding DVHs for the three fractions are compared against the planning DVH in Figure 2.

**Conclusion**

Although HT provides an optimal planned dose distribution, our results showed that breast HT is clinically associated to potentially dangerous underdosing of CTV during delivery, mostly due to relevant anatomical changes. Improved planning strategies need to be developed to improve delivery robustness and are actually under investigation.

### EP-1994 Lung Radiotherapy : Internal position reproducibility with spirometric DIBH

R. Garcia<sup>1</sup>, P. Mazars<sup>1</sup>, E. Jaegle<sup>1</sup>, V. Bodez<sup>1</sup>, C. Khamphan<sup>1</sup>, M.E. Alayrach<sup>1</sup>, A. Badey<sup>1</sup>, P. Martinez<sup>1</sup>  
<sup>1</sup>Institut Sainte Catherine, Physics, Avignon, France

#### Purpose or Objective

Deep Inspiration Breath Hold (DIBH) is an interesting method that provides a simple process with a single CT free from internal movements influences. The use of a spirometer has been the first way to implement a breathing control. With a calibrate system, the inspired air volume is well controlled but does not guaranty the internal organs positions. Lung radiotherapy benefit a lot from DIBH but IGRT is needed to evaluate the internal reproducibility.

#### Material and Methods

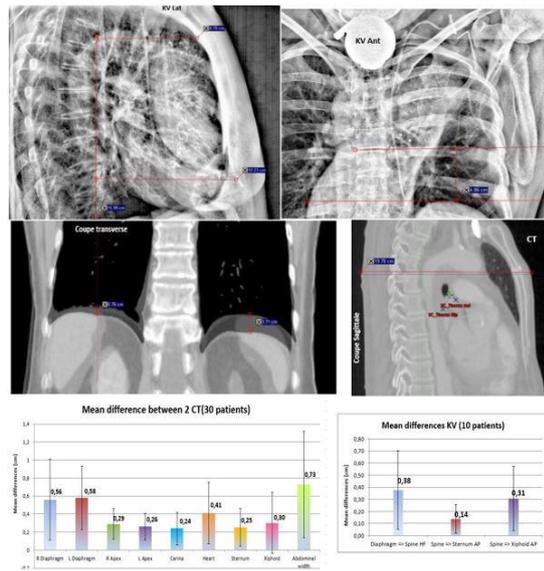

The lung radiotherapy is driven with the help of the SDX<sup>TM</sup> spirometer and video feed back assisting the patient to provide a deep inspiration breath hold during each imaging and delivery phase.

The anatomy position is evaluated with CT and KV images. The study is based on 30 patients who had a second CT during the course of treatment and 10 patients with KV images including the diaphragm.

Multiple distances were defined and measured on the whole set of data. They concern the diaphragm, the apex, the sternum, the xiphoid, the heart, the carina and the abdomen.

The lung volume, being and indicator of correlation with the dosimetry conditions, was measured and compared.

#### Results

The mean lung volume of the 30 cases studied is 5256 cm<sup>3</sup> ( $\pm$  928 cm<sup>3</sup>).

The mean lung volume difference between two CT acquisitions is 168 cm<sup>3</sup>  $\pm$  390 cm<sup>3</sup> (2 s), which represents a variation of 3.28% ( $\pm$ 3.81%).

The distances measurements carried out on CT images indicate a diaphragm mean displacement of 5.7 mm ( $\pm$  4 mm), the abdomen width (A-P) of 7,3mm (5,9mm), the apex (H-F) 2,8mm(1,6mm), the carina (R-L) 2,4mm(1,8mm), the sternum (A-P) 2,5mm (2,8mm), the xiphoid (A-P) 3mm (3,4mm) and the heart (perpendicular to the ribs 4,1mm (3,4mm).

The KV images measurements were obtained with the graphic rule on a stretched image area over the entire screen. The manual use of the graphic rule was evaluated

with a potential error of less than 2mm due to the mouse tool and the blurred edge of each anatomy image

The distances measurements carried out on KV images indicate a diaphragm mean displacement of 3.8 mm ( $\pm$  3.2 mm) in the cranio-caudal direction. The sternal position is pretty well reproducible with a mean variation of 1.4 mm ( $\pm$  1.2 mm). The xiphoid moves slightly more 3.1 mm ( $\pm$ 2.7 mm) in the anteroposterior direction.

#### Conclusion

The spirometric DIBH practice provides a reproducible lung volume which is important regarding the use of its DVH constraints. The distances measured on CT and KV images show an acceptable reproducibility and indicate the minimum PTV margins which have to be applied. Spirometric DIBH is safely used with high dose per session prescriptions often combined with VMAT and High Dose Rate FFF beams.

### EP-1995 Anisotropic definition of ITV-PTV margins according to the target position in lung SBRT with 4D-CBCT

S. Pini<sup>1</sup>, G. Della Gala<sup>2</sup>, S. Russo<sup>1</sup>, M. Esposito<sup>1</sup>, L. Paoletti<sup>3</sup>, P. Alpi<sup>3</sup>, R. Barca<sup>3</sup>, S. Fondelli<sup>3</sup>, F. Rossi<sup>3</sup>, P. Bastiani<sup>3</sup>

<sup>1</sup>Azienda USL Toscana Centro, S.C. Fisica Sanitaria di Firenze-Empoli, Firenze, Italy ; <sup>2</sup>Scuola di Specializzazione in Fisica Medica, Università degli Studi di Firenze, Firenze, Italy ; <sup>3</sup>Azienda USL Toscana Centro, S.O.C. Radioterapia, Firenze, Italy

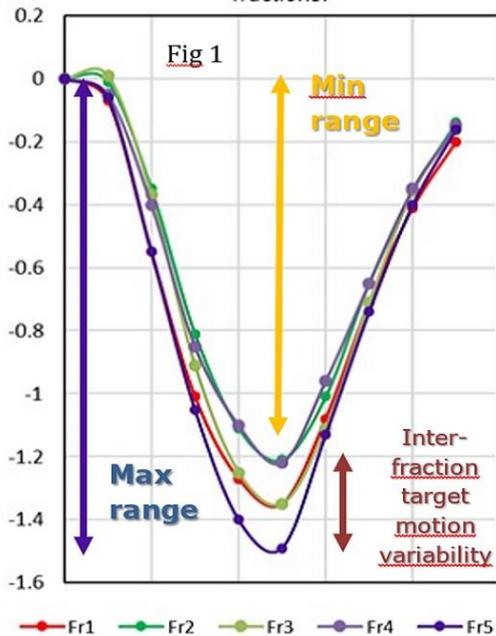

#### Purpose or Objective

4D-CBCT has been increasingly used to evaluate lung tumor position and to validate the PTV margins during SBRT treatments. The aim of this study was to estimate the inter-fraction variability of respiratory-induced motion of target volumes in lung SBRT treatments.

#### Material and Methods

This study is a retrospective analysis on 59 patients receiving lung SBRT (276 fractions in total). 4D-CT scans for planning were obtained on a GE 4D-CT scanner. For breath control a compression abdominal belt was used. GTV was contoured on each of the multi-phases reconstructed images to generate ITV and PTV (ITV plus 5mm). Prior to each fraction, in-room 4D-CBCT image scan was acquired and registered to the planning CT by the Symmetry XVI Elekta system using an automatic two steps image registration: first an anatomical landmarks-based clipbox was defined for setup correction and then a mask of 5mm around PTV was created for the soft tissue registration. Matching results were used to shift the table along the LL-SI-AP directions (respectively left-right, superior-inferior, and anterior-posterior) to correct daily patient setup and tumor baseline shifts. The dual registration results were always reviewed by the physician and manually adjusted if not correct. The baseline shifts were measured by subtracting the clipbox suggested correction from the applied table shift. Tumour motion was quantified for each fraction as the absolute range of the respiratory cycle. The inter-fraction variability of the target motion was then evaluated for each patient, first, by calculating the difference between the max and min range of the respiratory cycle for all treatment fractions and then extracting the value corresponding to the highest discrepancy (fig.1).

**Measure of the inter fraction target motion variability**  
 Example of respiratory cycles along SI for a patient treated with 10Gy in 5 fractions.

### Results

The inter-fraction target motion variability showed a distribution that ranges from zero to almost 1 cm in the worst case. SI direction was found to have the biggest discrepancy, followed by AP direction and LL. As expected, the variability was particularly significant for patients with a lesion in the lower lobe of the lung. For SI direction median values are respectively 0.9, 1.8 and 2.8 mm for upper, middle and lower lobe (fig.2). Target in the upper and medium lobe showed a stable motion along LL direction: for most of the patients the variability was less than 2 mm.

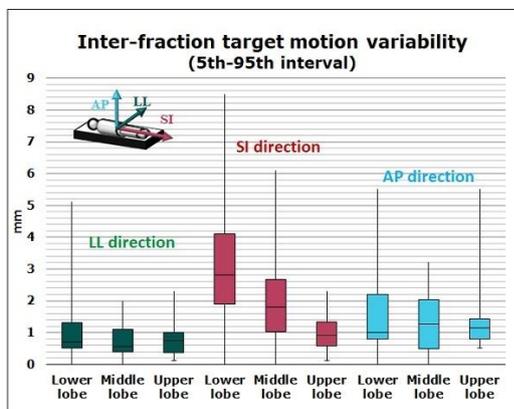

Fig.2: Box plot of the absolute inter-fraction target motion of the tumor along the three directions based on the position of the tumor in the lung. Higher ranges are visible for tumors positioned in the lower lobe of the lung and for SI direction.

### Conclusion

Targets in the lower lobe of the lung showed higher motion variability. SI direction, was found to have the biggest target motion discrepancy, followed respectively by AP and LL directions. Since the inter-fraction variability of the respiratory induced tumor motion contributes to the definition of the motion component of the PTV margin,

these results suggest the definition of anisotropic clinical ITV-to-PTV margins depending on target position: tighter margins for LL and AP directions and for lung tumors positioned in the upper lobe of the lung.

### EP-1996 Assessment of bulk-density CT accuracy for MR-guided proton therapy of prostate cancer

J. Handrack<sup>1,2</sup>, M. Bangert<sup>1,2</sup>, C. Möhler<sup>1,2</sup>, M. Ellerbrock<sup>2,3</sup>, S. Greilich<sup>1,2</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Department of Medical Physics in Radiation Oncology, Heidelberg, Germany; <sup>2</sup>National Center for Radiation Research in Oncology, Heidelberg Institute for Radiation Oncology, Heidelberg, Germany; <sup>3</sup>Heidelberg University Hospital, Heidelberg Ion-Beam Therapy Center HIT- Department of Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

Magnetic resonance (MR) imaging offers superior soft tissue contrast in comparison to computed tomography (CT) images and can be used to monitor anatomical changes in the patient during the treatment. Therefore, interest in MR guidance for proton therapy, which is highly susceptible to changes, is growing. However, the conversion of the MR image to so-called "synthetic CT (sCT)" images is necessary, since they lack stopping-power information. So far, mostly machine learning techniques have been applied to address this problem, but the required complexity of the sCT is still unknown. In this work, the influence of bulk density (BD) substitutes for different tissues was investigated for the male pelvis to identify the minimum number of BD classes necessary for accurate range prediction with a sCT.

### Material and Methods

The planning CT images from three prostate cancer patients irradiated with protons were retrospectively analysed by segmenting the CT into different tissue classes, which were replaced with mean BD values. Two types of BD-CTs were investigated: BD-CT1 contains four tissue classes, namely air, fat, non-fatty soft tissue and bone. For BD-CT2, the bone segment was further split into soft and hard bone. The clinical dose plans, consisting of two opposing beams, were re-calculated on the BD-CTs. The resulting dose distributions were compared to the original ones by means of gamma analysis (2mm/2%), dose volume metrics (DVMs), and proton range differences.

### Results

For BD-CT1, a mean absolute range difference ( $\pm$  mean s.d.) of (2.2 $\pm$ 2.7) mm was found. When splitting bone into soft and hard bone (BD-CT2), the mean absolute range difference was reduced to (1.4 $\pm$ 1.8) mm. Figure 1 shows this reduction exemplarily for the range shift maps of BD-CT1 and BD-CT2 for one patient. The mean gamma pass rates for the CTV and  $V_{>2\%presDose}$  (the volume where the dose was larger than 2% of the prescribed dose) were 99.6% and 98.8% for BD-CT1, and 99.9% and 99.6% for BD-CT2, respectively. For target volumes,  $D_2$ ,  $D_{50}$  and  $D_{98}$  were compared, which deviated less than 1.5% from the original plan for both BD-CT1 and BD-CT2, except for PTV- $D_{98}$  of one patient case, which deviated up to 2.9%. For the organs at risk,  $D_{50}$  and  $D_{15}$  were compared, which deviated up to 2.6%, however no RTOG dose constraints were exceeded.

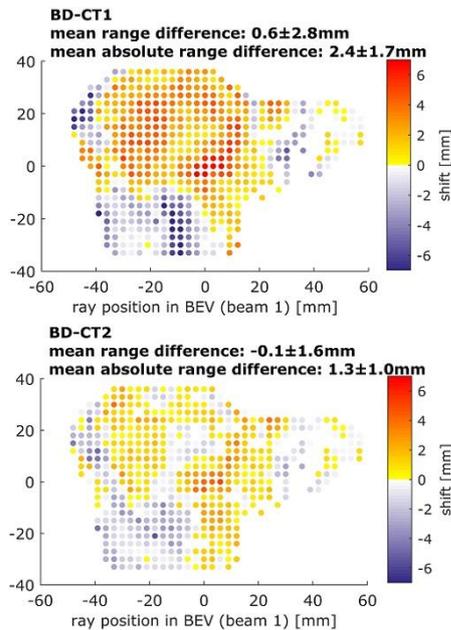

Figure 1: Proton range shift maps for one patient for BD-CT1 (top) and BD-CT2 (bottom). Each point represents one ray in the beam used during irradiation, the shift is color-coded.

## Conclusion

The deviations of the BD-CT dose distributions from the original dose distribution were small for the considered metrics in the three cases. It is necessary to include more patient cases to this work in progress for more significant results. However, our results indicate the applicability of a BD approach for sCT generation from MR for proton therapy. In a next step, we will identify MR sequences suited to identify respective tissue classes, transfer the gained knowledge to an MR-based workflow and compare the resulting predicted dose distribution to the calculation based on the planning CT.

## EP-1997 Daily adaptive proton therapy: A clear potential to reduce dose to healthy tissue and integral dose

L. Nenoff<sup>1,2</sup>, M. Matter<sup>1,2</sup>, J. Hedlund Lindmar<sup>1,2</sup>, T. Lomax<sup>1,2</sup>, D.C. Weber<sup>1,3,4</sup>, F. Albertini<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland ; <sup>2</sup>ETH Zurich, Department of Physics, Zurich, Switzerland ; <sup>3</sup>University Hospital Bern, Department of Radiation Oncology, Bern, Switzerland ; <sup>4</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

## Purpose or Objective

In some anatomical areas, for example the nasal cavities, anatomical changes can be observed on a daily base. This could lead to large dose distortions and is therefore covered by large target margins and a careful selection of field directions. However, this increases the dose to healthy tissue. With a daily 3D image in treatment position target coverage can be ensured by adapting on the daily geometry. Consequently, target margins can be reduced and alternative, less robust but more conformal field arrangements could be used. In this study we investigate the dosimetric effect of daily adaptive proton therapy (DAPT) combined with conformal field arrangements.

## Material and Methods

Planning CTs of 5 Patients with tumors involving parts of the nasal cavities were used to generate an anatomically robust “star” plan with the clinically used PTV margin and a “conformal” plan with a field specific PTV with covering 3% uncertainty in range and 1 mm in setup (60 GyRBE, 30 fx, figure 1) each. Also synthetic CTs with different nasal

cavity fillings were created by filling the nasal cavities onion layer wise from outside to inside. Each nasal cavity was filled separately ranging from empty to completely filled. Each artificial CT was combined with 5 random setup errors (1.57 mm  $\sigma$  for translation and 0.57°  $\sigma$  for rotation in all 3 directions), leading to between 180 and 625 clinical scenarios per patient and plan approach, depending on the size of the nasal cavities. Plans were recalculated and reoptimized for each scenario, simulating non-adapted and DAPT fractions, respectively. 100 times 30 randomly selected fractions were combined to treatment doses. Target coverage, dose to organs at risk (OARs) and integral dose were evaluated.

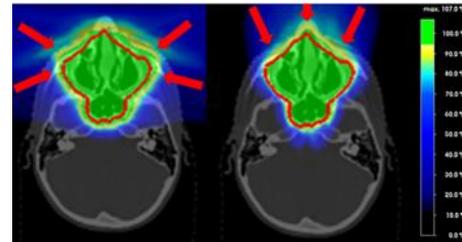

Figure 1: Example of planned “star” (left) and “conformal” (right) dose distribution.

## Results

By using conformal field directions the integral dose could be reduced by 43% on average (minimum reduction patient 4: 29%, maximum patient 2: 53%, figure 2a). Also OAR doses were reduced, if they were not directly attached or included in the target volume. In the non-adapted scenario the loss of target coverage is mainly patient dependent (V95 reduction of up to 34%, figure 2b) while the field direction has no systematic influence. DAPT can restore target coverage in all cases and in some cases even reduce the dose to OARs.

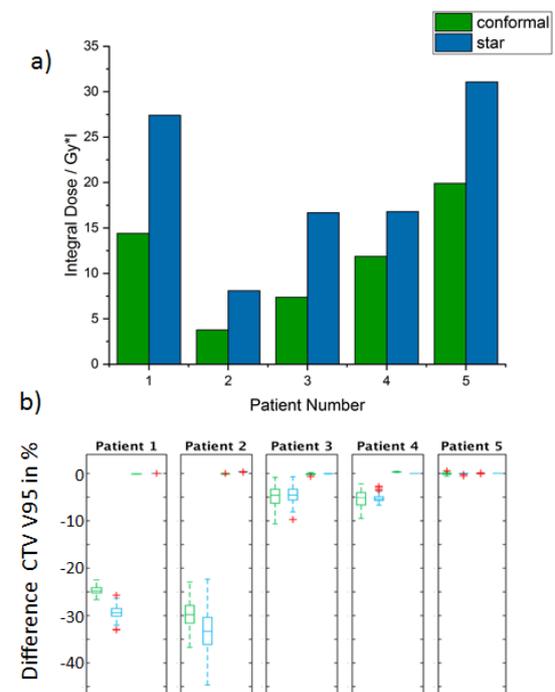

Figure 2: a) Integral dose of initial treatment plans. b) CTV V95 differences between treatment doses and initial treatment plan.

## Conclusion

DAPT combined with an adequate margin adaption and conformal field directions reduces the integral dose and

dose to OARs while ensuring robust target coverage. This will most likely translate to a clinical benefit for the patient.

#### EP-1998 Quality assurance criteria and anatomically plausible models for deformable image registration

C. Zachi<sup>1</sup>, B. Denis de Senneville<sup>2</sup>, B. Raaymakers<sup>1</sup>  
<sup>1</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands ; <sup>2</sup>Université de Bordeaux, Institut de Mathématiques de Bordeaux, Bordeaux, France

#### Purpose or Objective

Concepts in adaptive radiotherapy such as contour propagation and dose accumulation often rely on deformations provided by medical image registration algorithms. However, existing registration methods are often built upon elements originating from the computer graphics domain. Therefore, the anatomical plausibility of the estimated deformations may not be guaranteed. In this work we propose two quality assurance (QA) criteria, which assist in evaluating the anatomical plausibility of the deformations estimated by registration algorithms. In addition, a novel deformable image registration method is also proposed, specifically designed for biological soft tissue tracking.

#### Material and Methods

We propose assessing anatomical plausibility via two criteria: *the jacobian determinant* and *the curl magnitude* of the estimated deformations. Due to their high water content, most biological soft tissues are incompressible and therefore the jacobian determinant of their deformations is close to one. On the other hand, the local curl magnitude of the deformations should be close to zero, since local torsions inside most organs are unlikely to occur.

Two methods are evaluated against the proposed criteria: the state-of-the-art Evolution registration algorithm (EVO) and a novel method "Evolution Incompressible" (EVI) proposed here. The latter replaces the smoothness regularization of the former with a penalty on deviations from unity of the jacobian determinant of the deformations. By doing so, the new method constrains the estimated deformations to be incompressible.

The two methods were employed for the registration of five abdominal data batches, with each batch including five pairs of: (1) T1w MR - T1w MR, (2) CT - CT, (3) T1w MR - T2w MR, (4) CT - CBCT, (5) CT - MR images. The deformations estimated for the liver and kidneys were assessed both in terms the proposed QA criteria and the dice similarity coefficient (DSC). **Results** Table 1 reports the average DSC for the liver and kidneys before and after registration, with both methods leading to nearly identical improvements. However, a statistical analysis of the jacobian determinant of the deformations (see Fig. 1(a)) reveals high deviations from unity in the case of the EVO algorithm. A Mann-Whitney test indicates that this effect is significantly dampened by the EVI method at  $p = 0.05$ . Fig 1(b) illustrates an analysis of the vorticity of the deformations estimated by the two methods, with EVI providing overall lower values for the curl magnitude.

Data batch	Organ	Algorithm		
		None	EVO	EVI
T1w MR - T1w MR	Liver	0.91	0.96	0.96
	Kidneys	0.85	0.94	0.94
CT - CT	Liver	0.84	0.91	0.91
	Kidneys	0.83	0.92	0.92
T1w MR - T2e MR	Liver	0.89	0.94	0.94
	Kidneys	0.75	0.86	0.86
CT - CBCT	Liver	0.84	0.90	0.90
	Kidneys	0.83	0.90	0.90
CT - MR	Liver	-	-	-
	Kidneys	0.66	0.87	0.86

Table 1

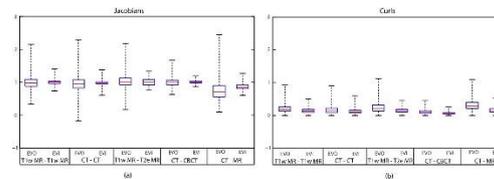

Figure 1

#### Conclusion

Both methods demonstrated a comparable performance for contour alignment. However, within the organ boundaries, the proposed method showcased an improved anatomical plausibility, with significantly lower compressions/expansions and vortices. This demonstrates both the importance of the proposed QA criteria for assessing the anatomical plausibility of deformations within the organ boundaries and that of adapting the registration model to the material properties of the observed tissues.

#### EP-1999 Robustness of IMPT plans towards anatomical variations for nasopharyngeal cancer

R. Argota Perez<sup>1</sup>, M.B. Sharma<sup>1</sup>, K. Jensen<sup>2</sup>, A. Vestergaard<sup>2</sup>, J.B.B. Petersen<sup>3</sup>, S. Korreman<sup>3</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus, Denmark ; <sup>3</sup>Aarhus University Hospital, Danish Center for Particle Therapy and Department of Oncology, Aarhus, Denmark

#### Purpose or Objective

Proton dose delivery is very sensitive to any variations during the treatment course. Setup uncertainties can be accounted for using robust optimization, whereas anatomical variations, e.g., changes in weight, tumour shrinkage, and filling or emptying of nasal cavities for head and neck cancer patients, are usually not accounted for. The present study evaluates the performance of a standard robust optimization technique towards anatomical variations.

#### Material and Methods

Proton treatment plans using simultaneous integrated boost (68/60/50 Gy) were optimized for five patients with nasopharyngeal cancer using the Eclipse TPS vs 13.7. Planning was performed using multiple-field optimization (MFO) with three beam directions, and robust optimization for the 68 Gy CTV (CTV1) with 5 mm perturbations in all directions. Anatomical changes were simulated by density overrides in the original CT scans. For weight gain and loss, 5 mm of water equivalent material (WEM) was added or subtracted to the body contour. Nasal cavity filling was simulated by overriding the entire cavity density with WEM. Setup errors were simulated using isocenter shifts of +/-5 mm in three orthogonal directions, separately and in combination with anatomical changes. The dose was recalculated with the original plans in each simulated situation, and plan robustness was evaluated comparing CTV1 coverage ( $V_{95}$ ) and OAR doses.

## Results

CTV1 coverage was not affected by the simulated isocenter shifts. For anatomical changes, weight gain and nasal cavity filling deteriorated CTV1 coverage, although  $V_{95}$  stayed above 95% in all cases (Fig. 1). When isocenter shifts and anatomical variations were combined, CTV1  $V_{95}$  dropped to unacceptable levels for a subset of patients. For weight gain combined with 5 mm setup errors, CTV1  $V_{95}$  dropped below 90% for 3/5 patients. For filling of the nasal cavity combined with 5 mm setup errors, CTV1  $V_{95}$  dropped below 95% for 2/5 patients. Weight loss did not affect CTV1 coverage even when combined with setup errors. The mean dose to the ipsilateral parotid gland was affected by all anatomic changes and setup errors, and the largest increases were seen for weight loss and filling of the cavities (Fig. 2). The maximum dose to the brainstem and the spinal cord had a similar behaviour for all the variations, but only for 1/5 patient the dose was above the clinical constraint.

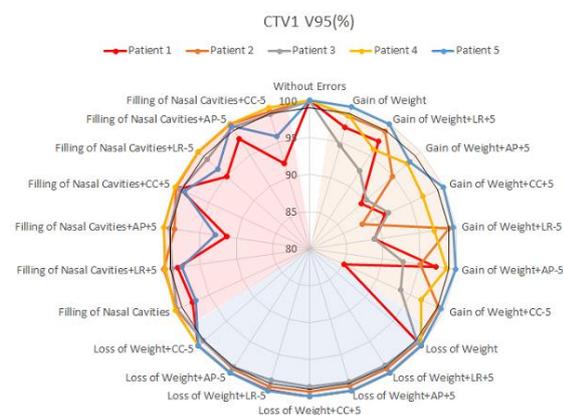

Figure 1. Spider plot of the dose coverage ( $V_{95\%}$ ) for CTV1. Doses are shown for the planned proton dose without errors (shown on top), for simulated weight gain, weight loss and cavity filling, separately and in combination with 5 mm setup errors. The black circle indicates the clinically acceptable level.

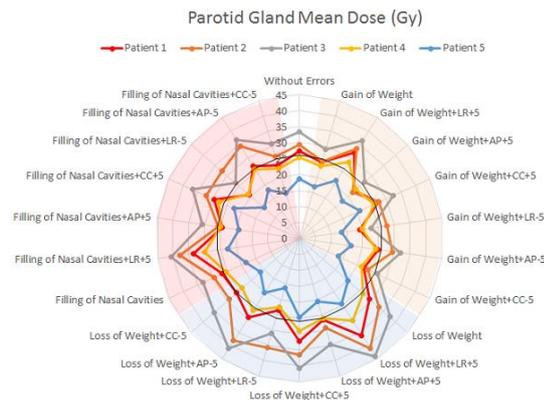

Figure 2. Mean dose to the ipsilateral parotid gland. Doses are shown for the planned proton dose without errors (shown on top), for simulated weight gain, weight loss and cavity filling, separately and in combination with 5 mm setup errors. The black circle indicates the opted clinical dose constraint.

## Conclusion

Target volume dose was not compromised by setup errors for robustly optimized proton plans in nasopharyngeal cancer patients. Weight gain and nasal cavity filling had detrimental effect on target doses, especially in combination with setup errors, reaching unacceptably low levels for several patients. Better robustness methods are needed to account for anatomical variations in order to minimize the need for plan adaptation.

## EP-2000 Dosimetric impact of setup errors and anatomical changes in breast cancer patients

E. Costa<sup>1</sup>, T. Bely<sup>1</sup>, M. Laurans<sup>1</sup>, S. Caneva Losa<sup>1</sup>, P. Poortmans<sup>1</sup>, Y.M. Kirova<sup>1</sup>

<sup>1</sup>Institut Curie Ensemble Hospitalier, Department of Radiation Oncology, Paris cedex 05, France

### Purpose or Objective

To evaluate the dosimetric impact of uncorrected setup errors and anatomical changes in stage I-III breast cancer (BC) patients during loco-regional radiation therapy (RT) with Helical Tomotherapy after adjuvant chemotherapy.

### Material and Methods

We studied the daily MVCT images acquired in patients treated to the breast or chest wall, internal mammary nodes (IMN), and axillary lymph nodes (levels II, III and IV). Setup corrections along the X, Y and Z directions and roll rotation were carried out after rigid registration of the bony anatomy and soft tissues between MVCT and planning CT. Pitch and yaw rotations were recorded only. Target volumes initially delineated on the planning CT were duplicated on every registered MVCT and adjusted by a physician in order to reflect the anatomical modifications of the day. Similarly, the external body contour was adapted to each MVCT and the volume of this structure was calculated. Using 1 MVCT/patient/week, we calculated the dose distribution on a total of 101 MVCT's. First, we analyzed the impact of the interval between chemotherapy and RT on the amplitude of anatomical changes. Subsequently, we quantified the changes in target volume coverage and we studied the correlation with the anatomical changes and with pitch and yaw uncorrected setup errors.

### Results

Dosimetric data of 19 patients with whole breast or chest wall RT were studied, of which 17 were treated to the regional lymph nodes as well. Spearman correlation analysis showed a significant correlation between the amplitude of the changes of the external body contour and the period between chemotherapy and RT ( $r_s=0.60$ ;  $p=0.01$ ).

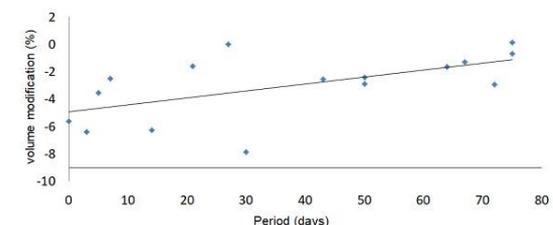

Figure 1. External body contour volume modification (%) vs. interval between completion of chemotherapy and start of radiation therapy.

The analysis of the calculated dose on the MVCT's showed that in 7% of studied fractions, the near maximum dose (D2%) increased by at least 2% in the breast, IMN and nodes level II and III. In 2% of studied fractions, the D2% increased by at least 5% in nodes level IV. In 5% of studied fractions, the D95% decreased by at least 5% in the breast, IMN and nodes level IV.

Pearson correlation analysis showed a significant correlation between the amplitude of external body contour changes and the influence on D2% in breast and IMN, D95% in nodes level IV and mean dose in breast. Pearson correlation analysis showed a significant correlation between pitch residual setup errors and modification of D2% in IMN and nodes level IV and the D95% in nodes level IV. We didn't note correlation between yaw residual setup errors and target coverage alteration ( $r<0.3$ ;  $p>0.01$ ).

		r (Pearson)	
		External body volume modification	Setup error for pitch rotation
Breast/chest wall	D2%	-0,51	
	Dmoy	-0,61	
IMN	D2%	-0,49	0,50
Lymph nodes level IV	D2%		0,51
	D95%	-0,52	0,51

**Table 1.** Pearson correlation coefficient between target coverage and setup errors or anatomical modifications ( $p < 0,01$ ).

### Conclusion

We demonstrated that, using our IGRT protocol with daily online corrections, anatomical changes, noted especially for patients with a shorter interval between chemotherapy and RT, affect target coverage in only a small proportion of the RT fractions. In addition, among the two uncorrected setup errors, pitch and yaw, only pitch is correlated to dose delivery changes. The clinical impact of these changes is likely negligible.

<sup>1</sup>Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Radiation Oncology -, Mumbai, India

### Purpose or Objective

Online adaptive correction in image-guided intensity-modulated radiotherapy appears to be a promising approach for precision radiation treatment in head and neck tumors. This study is to evaluate the effect of online cone beam computed tomography (CBCT) guidance in Intensity Modulated Radiotherapy of Head and Neck Cancers.

### Material and Methods

38 Head and Neck cancer cases treated at our institute were selected for this study from prospectively maintained data (May 2017 to May 2018). Most of the cases were of Ca hypopharynx (23 cases). The Varian NovalisTx system which integrates an On Board Imager (OBI), was used to deliver radiation treatment. Daily/alternate day CBCT images were acquired and registered to the planning CT for online and offline analysis and to correct the patient setup errors. The setup errors were noted after matching of CBCT with planning CT images. New plans were generated in each patient using the mean lateral, vertical and longitudinal shifts. This DVH was compared to the original planning DVH and doses delivered to the target and various critical structures were evaluated. and the difference in doses received were computed. Statistical analysis was done using paired t-test.

### Results

The mean setup errors in three directions were : 1.4mm longitudinal, 1.2mm vertical and 1mm lateral. Analysis of dosimetric change due to a translational isocenter shift, if no correction was applied showed : Mean PTV1 V95% coverage to be dropped to 94.95% from the original of 96.37%, if shifts weren't applied ( $p < 0.0001$  with standard error 0.007 and 95% CI -1.4331 to -1.406). Similarly PTV2 V95% coverage reduced by -1.06% (97.39% to 96.33%) with  $p < 0.0001$  (standard error of 0.006 and 95% CI -1.0724 to -1.0476). There was also considerable dosimetric changes to critical organs as follows : ipsilateral parotid mean doses were increased by 0.54 Gy (42.06Gy to 42.60 Gy ;  $p = 0.94$ ) ; Contralateral parotid mean doses were increased by 1.74Gy (28.12 to 29.96Gy ;

$p = 0.5$ ). Dmax to spinal cord was increased by 1.6Gy (40.3 Gy to 41.90Gy ;  $p = 0.2$ ).

### Conclusion

Online CBCT correction ensures better coverage of targets (PTV) while reducing doses to normal tissue. There was significant reduction in PTV coverage if translational shifts wouldn't have been applied during the course of radiotherapy. CBCT-based online correction also increased the accuracy of IMRT in Head and neck cancer patients and provides scope to reduce irradiated margins, by decreasing the setup errors.

### EP-2002 Prostate treatment planning for the MR-linac: effect of online performance on template development

R.A. Mitchell<sup>1</sup>, A. Dunlop<sup>1</sup>, A. Pathmanathan<sup>2</sup>, S. Nill<sup>1</sup>, A.C. Tree<sup>2</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom ; <sup>2</sup>The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, Clinical Oncology, London, United Kingdom

### Purpose or Objective

The MR-linac (Elekta AB, Stockholm) requires creation of an offline reference plan in Monaco 5.4 (Elekta) to enable propagation of planning parameters into an online workflow and adaptation of the existing plan. Consequently, the effect of parameters defined offline must be evaluated in the online setting during plan template development. We report on two areas for PRISM trial (NCT03658525) prostate planning: plan robustness with a-priori information and timing.

### Material and Methods

Monaco's constrained optimisation mode prioritises organs-at-risk (OAR) over target dose coverage; setting generic, effective OAR sparing IMRT objectives may adversely affect target coverage. Application of patient-specific objectives in Monaco, to lower OAR doses (Figure 1), is possible in our workflow using a-priori information derived from backup plans created upfront in RayStation 7.0 (RaySearch Laboratories, Stockholm). Two prostate patients, each with CT scan and four T2-weighted diagnostic MR scans, were used. CTVs (prostate and seminal vesicles), bladder and rectum were clinician-delineated, and RayStation and offline Monaco plans generated as per protocol. Monaco bladder and rectum IMRT objectives were set 5% higher than equivalent DVH values achieved by the backup plans. Online plans were generated on each MR image using an adapt-to-shape workflow (ATS); reference plans are adapted to each MR scan's anatomy. Further ATS plans were created using objective values at 10% above the backup plans to compare online plan robustness.

Planning time is affected by the number of shape changes during segment shape optimisation (SSO); more changes (SSO loops) may improve plan quality but with increased time, which is practical offline. Online, patients would be on-set for longer, with increased probability of intra-fraction motion. A reference plan was created for a prostate patient. Two ATS plans were generated on each of four MR scans, using our offline setting of ten SSO loops and then five to derive a suitable number for use online.

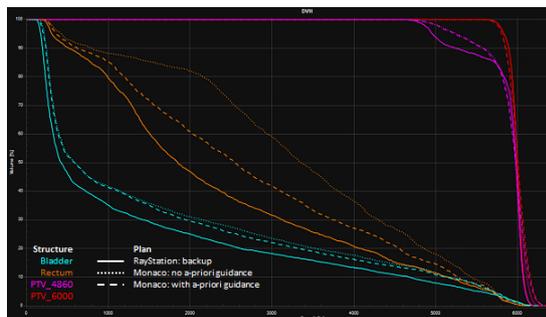

Fig. 1. Target and OAR DVHs comparison between: RayStation VMAT backup plan, Monaco IMRT plan without a-priori information and Monaco IMRT plan using a-priori guidance from the backup plan. All plans were prescribed to give 60Gy to the PTV\_6000 D<sub>50%</sub> in 20 fractions.

**Results**

Table 1 compares plans generated using differing a-priori information. For ATS plans, there were more PTV\_6000 coverage constraint violations (31% vs. 19%) when using more stringent objective values. All mandatory and optimal OAR constraints were satisfied except one optimal, which was likely due to randomness in Monaco's statistical-based optimisation.

Neither ten nor five SSO loops demonstrably changed the ATS plans in terms of distributions and DVH values. However, average planning time decreased by 40% (2.6 min) for five loops.

Table 1. Target and OAR results for reference plans and ATS plans generated with rectum and bladder optimisation objective values set to 5% and 10% above corresponding values achieved for backup plans. Results are averaged across plan types. Dose constraints are given as mandatory (optimal) where applicable.

Structure	Dose constraints	Plan						Units
		Reference		ATS @ 5%		ATS @ 10%		
		Average	SD	Average	SD	Average	SD	
Bladder	V6080cGy < 25 (3)	0.9	0.6	0.7	0.3	0.4	0.3	%
	V5676cGy < 35 (5)	5.5	0.9	3.7	1.3	3.4	0.9	%
	V5270cGy < 50	8.4	0.5	5.9	2.1	5.8	2.0	%
	V4870cGy < 25	10.9	0.3	7.7	2.8	7.6	2.7	%
	V4050cGy < 50	15.7	0.2	11.0	3.9	11.0	3.9	%
PTV_4860	D98% > 4617	5140	267	5030	189	5036	213	cGy
	D50% > 4860	5980	13	5968	17	5969	16	cGy
PTV_6000	D98% > 5700	5731	15	5685	31	5700	17	cGy
	D50% = 6000 ±60	6004	1	6005	2	6004	2	cGy
Rectum	V6080cGy < 5 (3)	0.7	0.6	0.8	0.6	1.2	0.8	%
	V5680cGy < 15	5.3	1.5	5.2	1.6	5.9	2.0	%
	V5270cGy < 30	9.5	1.7	9.2	2.5	10.3	2.8	%
	V4860cGy < 50 (35)	13.5	2.4	14.0	3.9	15.7	4.6	%
	V4050cGy < 60 (5)	23.1	3.2	23.4	5.1	26.9	6.9	%
	V3240cGy < 65	38.3	6.8	37.7	5.9	43.2	9.6	%
	V2440cGy < 80	55.6	9.1	56.0	5.8	61.7	7.4	%

**Conclusion**

MR-linac planning template development requires inclusion of IMRT objective flexibility to avoid the creation of highly optimised plans based on a particular geometry that will not exist online; more consistent target coverage requires allowances in OAR doses. On-set time reductions are also essential. It is possible to appreciably reduce online plan optimisation time by using five SSO loops without adversely affecting plan quality.

**EP-2003 Evaluation of three methods to calculate the dose on CBCT in case of IMRT for cervical cancer**

A. Barateau<sup>1</sup>, E. Trifard<sup>1</sup>, N. Perichon<sup>1</sup>, C. Hervé<sup>1</sup>, D. Guillaume<sup>1</sup>, J. Leseur<sup>1</sup>, A. Simon<sup>1</sup>, R. De Crevoisier<sup>1</sup>, C. Lafond<sup>1</sup>  
<sup>1</sup>Univ Rennes- CLCC Eugène Marquis- INSERM, Laboratoire Traitement du Signal et de l'Image - UMR 1099, Rennes, France

**Purpose or Objective**

To evaluate and compare the dose uncertainties of three methods to calculate the dose on CBCT in case of cervix carcinoma IMRT.

**Material and Methods**

A total of seven patients treated by IMRT for cervix carcinoma (45 Gy in 25 fractions) had 1 or 2 per-treatment couple(s) of CT and CBCT (corresponding to a total of 10 couples of images). The volumes of interests were delineated on CT. Reference dose distributions were calculated on the CTs, with Pinnacle TPS. CBCT images were first enlarged with assignment of water equivalent density to have the match with the corresponding CT body contour. Three methods of dose calculation on CBCT were compared: i) use of HU to density (HU-D) curve from phantom CBCT image, ii) density assignment method of three structures (air, soft tissues and bones) and iii) deformable image registration (DIR) method deforming the CT on CBCT, creating a deformed-CT (Admire research software, Elekta). As anatomy on CBCT can differ from CT, air pockets from reference CT were applied on CBCT of each method and contours (tumor volume, bladder and rectum) were rigidly registered from CT to CBCT. The dose distributions calculated on the CBCT by each method were compared to the reference CT dose calculation with DVH differences and 3D gamma analysis (local, 3%/3mm, 2%/2mm and 1%/1mm with a 10% dose threshold). The Wilcoxon test was used to compare the dosimetric endpoints.

**Results**

The figure shows the DVH differences for the tumor volume between dose calculation from CT and from CBCT using each of the methods. DVH differences were significantly lower when using the density assignment method or the DIR method, than when using the HU-D method.

The table shows the mean 3D gamma passrates (percentage of voxels with gamma <1) of each CBCT dose calculation method compared to the reference dose distribution on CT. Gamma passrates were significantly lower for the HU-D curve method than for the density assignment method or the DIR method.

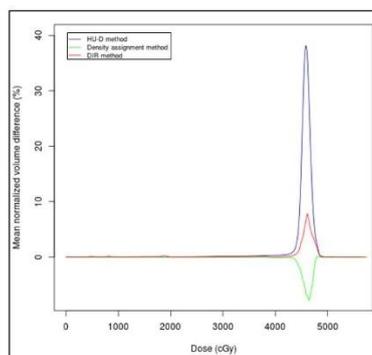

Figure. DVH differences of each CBCT dose calculation method compared to the reference CT for the tumor volume

Gamma criteria	HU-D method	Density assignment method	DIR method
1%/1mm	97 ± 2	100 ± 0.1	99.9 ± 0.1
2%/2mm	89 ± 5	99.3 ± 0.6	99.7 ± 0.3
3%/3mm	66 ± 11	94 ± 4	97 ± 2

Table. Mean 3D gamma passrates ± SD (in percentage) for each CBCT dose calculation method

**Conclusion**

The density assignment and DIR methods are the most accurate methods for CBCT-based dose calculation. Recently, more sophisticated methods based on deep learning lead to interesting results in MRI-based dose calculation. These methods could be evaluated with CBCT images to generate pseudo-CT. The next step is the dose accumulation to quantify the delivered dose during treatment (considering replanning or plan treatment library, if any) for comparison with the planned dose.

**EP-2004 Online rotation correction for MR-guided prostate radiotherapy**

W. Van den Wollenberg<sup>1</sup>, C. Carbaat<sup>1</sup>, P. De Ruiter<sup>1</sup>, P. Remeijer<sup>1</sup>, T. Janssen<sup>1</sup>, J. Sonke<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

The MR-Linac (Elekta Unity, Elekta AB, Stockholm, Sweden) integrates a 7MV linac with a 1.5T MRI scanner. Currently, translational target misalignment can be corrected for using plan adaptations but rotational errors cannot. The purpose of this work was to develop and evaluate a method to correct for inter-fractional target rotation in prostate cancer patients.

### Material and Methods

In this retrospective study, 4 prostate cancer patients with seminal vesicles (SV) invasion were included. Per patient, a planning CT scan, delineations of the prostate+SV (CTV), PTV (5mm margin), rectum, and anal sphincter, and a 9-beam step-and-shoot IMRT (20x3Gy) MR-linac treatment plan were available. The plans were created using the clinical version of Monaco 5.4.

For each patient, delineations were rigidly transformed to simulate prostate rotations around the LR axis (-15° to +15° in 1° steps). To avoid rotation into organs-at-risk (OARs) the rectum and anal sphincter were deformed by the same rotation that dampens with PTV distance (maximal within 5mm then drops off linearly over 1cm). Two adapt-to-shape (ATS) workflows available on the MR-linac were tested:

1.  $ATS_{seg}$  starts with the segments of the original plan but uses the rotated structure set. It then tries to satisfy the planning constraints as best as possible. Per structure, electron density is set to the median density on the planning CT.
2.  $ATS_{flu}$  works as  $ATS_{seg}$ , but starts from scratch with a fluence optimization.

We evaluated the anal sphincter and rectum  $D_{mean}$ , and the PTV  $D_{98\%}$  and  $D_{2\%}$ . In addition we expanded the CTV into a dose evaluation volume (DEV) with increasing margins accounting for residual uncertainties and calculated the DEV  $D_{99\%}$ . We compared these values to those obtained by the adapt-to-position (ATP) workflow, which does not correct for rotations.

### Results

Distributions of DVH parameters are shown in figure 1. Figure 2 shows the CTV (plus margins) coverage as a function of rotation angle. Unlike the ATP method, the ATS methods maintained CTV coverage ( $D_{99\%} > 95\%$ ) up to a margin of 3mm in all tested cases. CTV+4mm coverage was maintained in the large majority of cases. PTV coverage is lost incidentally for negative rotations, but often for positive ones ( $>5^\circ$ ); positive rotations wrap the rectum around the PTV hindering plan optimization. Median adaptation times were 4.0 min (ATP), 9.9 min ( $ATS_{seg}$ ) and 10.9 min ( $ATS_{flu}$ ). These were measured on a research computer and clinical times are expected to be faster.

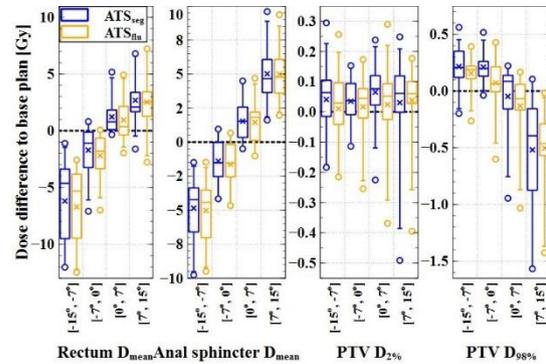

Figure 1 - Distribution of different DVH parameters for  $ATS_{seg}$  and  $ATS_{flu}$  in bins of rotation angle where all patients have been included. The whiskers denote the 2/98 percentile points. Note the different y-axis scales.

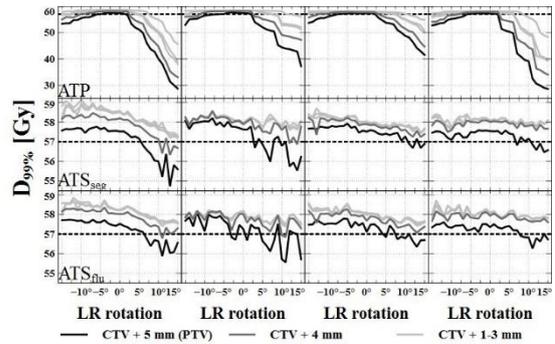

Figure 2 -  $D_{99\%}$  of the CTV expanded by various margins as a function of LR rotation angle for four patients (columns). Shown are ATP (top),  $ATS_{seg}$  (middle), and  $ATS_{flu}$  (bottom). The 5 mm expansion coincides with the PTV. The 57 Gy (95% of prescription dose) line is also shown (black dashed line). Note the different y-axis scales between ATP and ATS.

### Conclusion

The ATP method fails to adequately correct for larger prostate rotations, while ATS does account for such rotations.  $ATS_{seg}$  is faster than  $ATS_{flu}$ , but  $ATS_{flu}$  appears to be slightly better in terms of OAR sparing and target coverage. ATS is the preferred correction method for prostate rotations larger than a few degrees. The potential for PTV margin reduction following daily ATS is the subject of future studies.

### EP-2005 A novel method for rectal wall dose accumulation for prostate cancer patients

F. Kamp<sup>1</sup>, H. Liu<sup>1</sup>, L. Ermoschkin<sup>1,2</sup>, M. Di Biase<sup>1,3</sup>, C. Kurz<sup>1</sup>, G. Landry<sup>4</sup>, C. Belka<sup>1,5</sup>, M. Li<sup>1</sup>

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, München, Germany; <sup>2</sup>HELIOS Hospital Krefeld, Department of Radiation Oncology, Krefeld, Germany; <sup>3</sup>"G. D'Annunzio" University of Chieti-SS. Annunziata Hospital, Department of Radiation Oncology, Chieti, Italy; <sup>4</sup>Faculty of Physics- Ludwig-Maximilians-Universität München, Department of Medical Physics, Munich, Germany; <sup>5</sup>German Cancer Consortium DKTK, Munich, Munich, Germany

### Purpose or Objective

Due to inter-fractional changes in rectum and bladder filling, precise dose estimation for the rectal wall over all fractions of a prostate treatment remains a major challenge. We developed a novel dose accumulation workflow for rectal wall dose, explicitly accounting for the daily changing geometry as well as physiological properties of this elastic organ, without the need for deformable image registration (DIR).

### Material and Methods

In order to facilitate dose recalculations on the patient geometry of the day, the daily cone beam CT (CBCT) was intensity corrected using a previously published method. This method exploits the planning CT (pCT) as a prior to correct the projections yielding intensity corrected  $CBCT_{cor}$ . All necessary structures are contoured on  $CBCT_{cor}$ .

images. The dose of the day is calculated with the isocenter of the original treatment plan shifted according to the clinically applied IGRT table shift. The rectum wall dose is accumulated in several steps, partly illustrated in fig. 1.

- 1) The whole rectum is contoured. Axial rectum slices are numbered starting at the caudal end at the tuber ischiadicum going cranially.
- 2) The rectal wall in every slice is represented in polar coordinates (around the center of mass "CoM") and subdivided into equal angles (e.g. with a resolution of  $1^\circ$ ).
- 3) The dose is extracted in every axial slice for every arc length element and every daily fraction.
- 4) Dose accumulation is performed for every small arc length element and transferred back to the corresponding pCT rectum wall element.

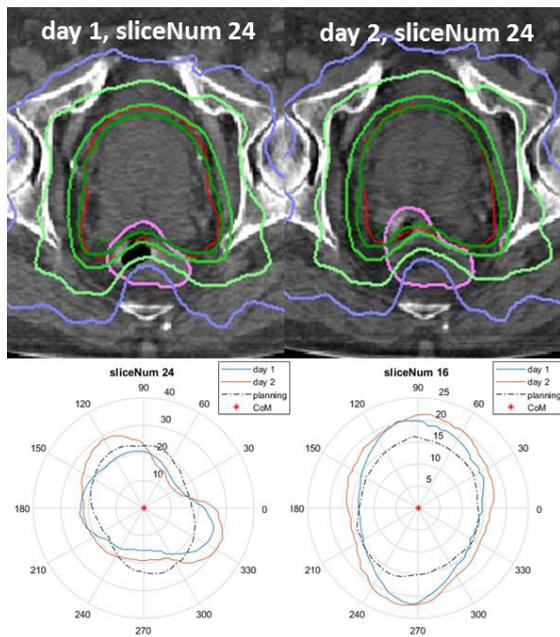

Fig.1: Axial slice through the CBCT<sub>cor</sub> of an exemplary patient. Isodoselines are shown together with the PTV (red) and rectum wall (pink). The second row depicts the corresponding rectum wall in polar coordinates around their center of mass (CoM) for two axial slices. Dose accumulation is performed in arc length elements with an angle resolution of  $1^\circ$  over all fractions and mapped back to rectum wall of the planning CT.

#### Results

In fig. 2 resulting dose-volume-histograms (DVH) are shown for an exemplary patient case irradiated with 37 fractions of 2 Gy. For this particular patient the dose to the rectum wall was higher in the planning CT than in the single fractions. Differences between the mean DVH over all fractions ("spatially not resolved accumulation") and the accumulated DVH in fig. 2 indicate the effect of the improved geometrical accuracy of the novel method. The developed dose accumulation approach is robust against changes in the angle resolution ( $0.1^\circ$ - $5^\circ$ ).

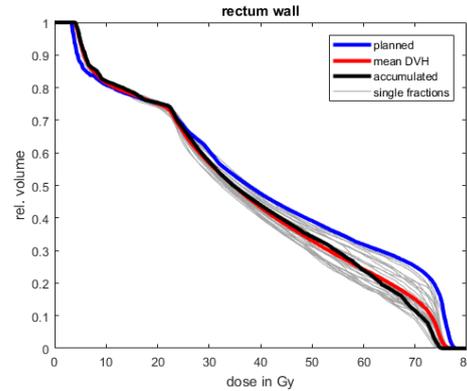

Fig.2: DVHs of the rectum wall. Doses are scaled to the treatment dose of 74 Gy.

#### Conclusion

The developed dose accumulation approach is a promising tool for dose estimations to the rectum wall, as it has a high geometrical precision and does not rely on potentially inaccurate DIR for dose accumulation. The method is applied to several patient cases which will be presented at the congress. A future goal is to validate the accumulated rectum wall doses by correlating them with patient reported side effects.

#### EP-2006 Dosimetric benefit of the first clinical SBRT of lymph node oligometastases on the 1.5T MR-linac

D. Winkel<sup>1</sup>, G.H. Bol<sup>1</sup>, A.M. Werensteijn-Honingh<sup>1</sup>, M.P.W. Intven<sup>1</sup>, W.S.C. Eppinga<sup>1</sup>, B. Van Asselen<sup>1</sup>, J. Hes<sup>1</sup>, B.W. Raaymakers<sup>1</sup>, I.M. Jürgenliemk-Schulz<sup>1</sup>, P.S. Kroon<sup>1</sup>

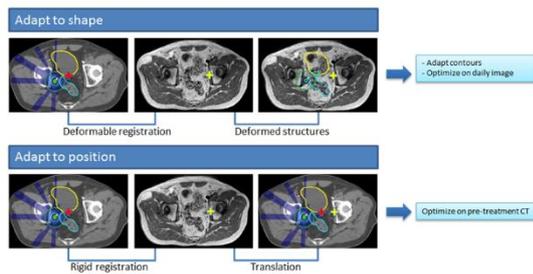

<sup>1</sup>UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

#### Purpose or Objective

The 1.5T MR-linac system (Unity, Elekta AB, Stockholm, Sweden) recently became available for clinical use in august 2018 and allows for MR-guided external beam radiotherapy. At our department, SBRT using the Unity has been initiated for patients with pelvic lymph node oligometastases. The purpose of this study was to compare the clinical dosimetric outcomes of online re-planning based on the new contours with an alternative online plan adaptation based on the online patient position with pre-treatment contours as well as with CBCT-linac VMAT back-up plans.

#### Material and Methods

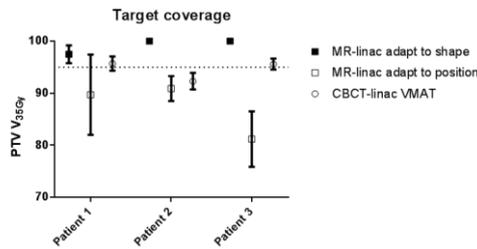

In August 2018 clinical treatment with the Unity commenced in our clinic. At this time three patients received SBRT of 5x7Gy prescribed to 95% of the PTV with a 3mm PTV margin. For each patient a 7-beam pre-treatment IMRT plan was created using Monaco TPS (Elekta AB, Stockholm, Sweden), taking into account the 1.5T magnetic field. Also, CBCT-linac VMAT back-up plans were created with the clinical PTV margin (8, 3 and 3 mm for patient 1, 2 and 3, respectively, based on target visibility). With online MR imaging as provided in the Unity, the pre-treatment plan can be adapted by either 1) taking the new target position into account (adapt to position) and optimizing on the pre-treatment CT and contours or 2) using the new patient anatomy (adapt to shape) and optimizing on the daily image and adapted contours (Figure 1). Optimization was done by optimizing both segment shapes and weights for both methods. We compared these clinical plans with adapt to position plans and with VMAT CBCT back-up plans, using the daily anatomy of all online MRIs. All plans were evaluated using clinical dose criteria: PTV V<sub>35Gy</sub> >95%, PTV D<sub>0.1cc</sub> <47.25Gy, ureter D<sub>max</sub> <40Gy and bladder, bowel bag, rectum and sigmoid V<sub>32Gy</sub> <0.5cc.

**Figure 1:** Schematic overview of the differences between the MR-linac Unity "adapt to shape" method in which online plan adaptation is performed on the new patient anatomy and optimized on the daily MRI and adapted contours, and the "adapt to position" method in which online plan adaptation is performed based on the new patient position and optimized on the pre-treatment CT and contours.

**Results**

The clinically delivered (adapt to shape) plans show the highest target coverage with an average PTV  $V_{35Gy}$  of  $99.2 \pm 1.5\%$  [range, 96-100%] (Figure 2). The clinical prescribed dose criteria were met for all fractions. The adapt to position strategy would result in the lowest PTV coverage with an average PTV  $V_{35Gy}$  of  $87.3 \pm 6.8\%$  [range, 72-99%], which is below dose criteria for three fractions for patient 1 and all fractions for patients 2 and 3. With the CBCT-linac back-up plans the PTV  $V_{35Gy}$  was on average  $94.5 \pm 2.1\%$  [range, 90-97%] which would be below criteria for 1, 5 and 2 fractions for patient 1, 2 and 3, respectively. For both the adapt to position and CBCT-linac back-up plans, small violations would have occurred for the ureter for patients 1 and 2, with a maximum  $D_{max}$  of 40.9Gy.

**Figure 2:** Target dose coverage (average and range) described as PTV  $V_{35Gy}$  in % evaluated on the daily anatomy for SBRT of lymph node oligometastases on the 1.5T MR-linac. Online plan optimization for the MR-linac plans was done through segment shape and weight optimization after segment aperture morphing. The 95% line depicts the minimum target coverage following the clinical dose constraints.

**Conclusion**

Evaluation of the first clinical SBRT treatments of pelvic lymph node oligometastases on the 1.5T MR-linac using the full re-planning approach yields beneficial DVH parameters compared to conventional treatment. The adapt to position option yields equal or worse DVH parameters compared to conventional treatment. This emphasizes the dosimetric benefit of online contour adaptation.

**EP-2007 Analysis of MRgRT treatment adaptation strategies with a high-field MR-Linac**

M. Nachbar<sup>1</sup>, D. Mönnich<sup>1,2,3</sup>, C. Marks<sup>2</sup>, A. Stolte<sup>2</sup>, O. Dohm<sup>2</sup>, D. Thorwarth<sup>1,3</sup>, D. Zips<sup>2,3</sup>, C. Gani<sup>2</sup>, S. Boeke<sup>1,3</sup>  
<sup>1</sup>University Hospital Tübingen, Section for Biomedical Physics- Department of Radiation Oncology, Tuebingen, Germany ; <sup>2</sup>Department of Radiation Oncology, University Hospital and Medical Faculty- Eberhard Karls University Tübingen, Tübingen, Germany ; <sup>3</sup>German Cancer Consortium DKTK, partner site Tübingen- and German Cancer Research Center DKFZ, Heidelberg, Germany

**Purpose or Objective**

MR-Linac systems are a promising technology with the capability of online plan adaptation. Here we evaluate the first treatment at our institution and compare

different adaptation workflows and their impact on target coverage and OAR sparing.

**Material and Methods**

A 55 year old patient with a single recurrent pararectal lymphnode metastasis of a prostate cancer was treated with the Unity 1.5 T MR-Linac (Elekta AB, Stockholm, Sweden) with 35/30 Gy to the GTV (10 mm<sup>3</sup>)/PTV in five fractions using eight step-and-shoot IMRT beams. The reference plan and all adapted plans were created with Monaco 5.4 (Elekta AB, Stockholm, Sweden). For daily online adaptation, the adapt-to-position (ATP) workflow was applied consisting of an isocenter shift for each segment followed by a segment weight optimization. Later, OARs were delineated offline on the daily pretreatment MR (T2w 3D). Retrospectively, the online adapt-to-shape (ATS) workflow was simulated, with a complete reoptimization starting from the fluence map based on the daily anatomy. In addition, a workflow consisting of using original segments (OS) only was simulated, in which the shift of the patient was not taken in account. The different workflows were compared with respect to the rectum  $D_{1.4ccm}$ , which corresponds to the  $D_{2\%}$  of the rectum in the reference plan, as well as PTV and GTV  $D_{98\%}$ . Plan conformity was evaluated based on  $V_{20Gy}$  of the total patient volume. To estimate the applied cumulative dose, the DVH parameters were averaged over all fractions.

**Results**

Table 1 shows the daily shift of the patient with respect to the PTV position in the reference plan. Table 2 shows the evaluated DVH parameters for each workflow. The rectum  $D_{1.4ccm}$  for the reference plan was slightly lower on the daily contoured and accumulated parameters (22.9 Gy) compared to the initial planning CT (23.5 Gy). The OS workflow shows a strong decrease of tumor coverage. Even for the minimal absolute shift (fx 5, 0.45 cm) the PTV  $D_{98\%}$  dropped from 29.2 Gy to 21.6 Gy. In the ATP workflow tumor coverage was maintained for all fractions, with minimal differences in the averaged PTV  $D_{98\%}$  of 29.2 Gy and 28.9 Gy for the reference plan and ATP, respectively, and equivalent OAR-sparing. The ATS workflow shows decreased rectum  $D_{1.4ccm}$ . with respect to the reference plan, equivalent tumor coverage with respect to PTV  $D_{98\%}$  (28.7 Gy) and GTV  $D_{98\%}$  (34.6 Gy) and the highest conformity ( $V_{20Gy} = 18.1$  Gy).

Fraction	Lateral	Cranial-caudal	Anterior-posterior	Absolute distance
1	0.63 cm	-0.01 cm	1.34 cm	1.481 cm
2	0.41 cm	-0.01 cm	0.47 cm	0.624 cm
3	0.62 cm	-0.03 cm	0.14 cm	0.636 cm
4	1.17 cm	0.30 cm	0.00 cm	1.208 cm
5	0.16 cm	0.12 cm	-0.40 cm	0.447 cm

**Table 1:** Changes in patient positioning per treatment fraction. The absolute distance is calculated based on the Euclidean distance.

**Table 2:** Analyzed DVH-parameters for the different workflows Original Segments (OS), Adapt-to-position (ATP) or Adapt-to-shape (ATS) for all treatment fractions.

**Conclusion**

Here we show with our initial experience that virtual couch shift with ATP is feasible to deliver high-precision MRgRT in a difficult-to-treat situation. Given the higher

complexity of ATS compared to ATP, further evaluation of the dosimetric and clinical benefit is ongoing.

### EP-2008 Positioning errors in free breathing and DIBH breast cancer radiotherapy: SGRT vs. skin markers

A.M. Acosta Roa<sup>1</sup>, S.G. Mikalsen<sup>1</sup>, T.P. Hellebust<sup>1</sup>  
<sup>1</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway

#### Purpose or Objective

The purpose of this study was twofold: 1) To compare positioning errors in patient alignment for surface guided radiotherapy (SGRT) and skin markers (SM), both for free-breathing (FB) and deep inspiration breath hold (DIBH) breast cancer radiotherapy (BCRT). 2) To calculate the required PTV margins due to setup uncertainties in the same patient groups, if no corrections are applied prior to treatment.

#### Material and Methods

Data from 83 whole breast or chest wall BCRT patients was retrospectively analyzed. Due to different equipment available at two different sites in our department the procedure for patient alignment and pre-treatment imaging is different: SGRT with cone beam CT (CBCT) or SM with extended no-action limit protocol (eNAL) from portal images. Thereby, four patient groups were identified: SM DIBH, SGRT DIBH, SM FB, and SGRT FB with 25, 14, 19, and 25 included patients, respectively. Varian's RPM system was used for DIBH at the SM site while AlignRT (VisionRT) was used at the SGRT site.

Mean positioning shifts (MPS) in the vertical (Vrt), longitudinal (Lng), and lateral (Lat) directions were found from the pre-treatment image registration (matched to planning CT following bony anatomy), and the vector length  $|r^2|$  of the shifts was calculated. Data from every treatment fraction was analyzed for patients undergoing the CBCT imaging protocol, whereas only the 3 first fractions were included for those following the eNAL protocol.

Minimum PTV margins for 95% dose coverage to the CTV in 90% of the patients were calculated using van Herk's equation.

#### Results

The MPS from initial setup in the Vrt, Lng, and Lat directions together with the mean displacement vector  $|r^2|$  for all patient groups are shown in Figure 1. A tendency towards larger positioning errors was observed in  $|r^2|$  for patients aligned with SGRT in comparison to SM, for both DIBH and FB (0.45 to 0.41 cm, and 0.49 to 0.45 cm, respectively). These differences are not statistically significant ( $p > 0.05$ ) according to a two-sample t-test assuming unequal variances.

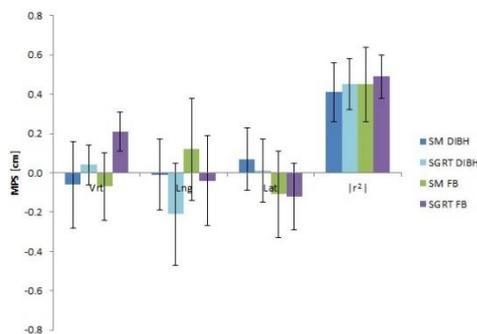

Figure 1. Mean positioning shifts in the four patient groups. Error bars correspond to one SD.

The results from calculation of the PTV margins for 95% dose coverage of the CTV in 90% of the patients are shown in Table 1. It can be observed that margins do not necessarily correlate to MPS, since margin calculation depend strongly on the size of the standard deviation (SD), and not on the average. SGRT yielded smaller margins in

the vertical direction for FB and DIBH, but larger for the longitudinal direction when used in combination with DIBH. Otherwise, margins agreed within 1 mm for both techniques.

Table 1. Mean positioning shifts ± SDs, and calculated PTV margins accounting for setup errors if no corrections are applied prior to treatment.

	MPS [cm]				PTV margin [cm]		
	Vrt	Lng	Lat	$ r^2 $	Vrt	Lng	Lat
SM DIBH	-0.06 ± 0.22	-0.01 ± 0.18	0.07 ± 0.16	0.41 ± 0.15	0.65	0.54	0.49
SGRT DIBH	0.04 ± 0.10	-0.21 ± 0.26	0.01 ± 0.16	0.45 ± 0.13	0.34	0.82	0.54
SM FB	-0.07 ± 0.17	0.12 ± 0.26	-0.11 ± 0.22	0.45 ± 0.19	0.57	0.77	0.68
SGRT FB	0.21 ± 0.10	-0.04 ± 0.23	-0.12 ± 0.17	0.49 ± 0.11	0.36	0.76	0.57

#### Conclusion

Patient alignment by SM seems to be generally more accurate but less precise than SGRT. Larger SDs in the MPS lead to increased PTV margins. A wider spread in SD was however expected for the SM patient group, as fewer image registrations could be included due to use of eNAL protocol. Calculated margins account only for setup uncertainties, and are required if no correction is effectuated prior to treatment.

### EP-2009 Inter-fractional Motion of Intact Cervical Cancer Treated On A MR-Guided Radiation Therapy System

D. Asher<sup>1</sup>, K. Padgett<sup>1</sup>, R. Llorente<sup>1</sup>, E. Mellon<sup>1</sup>, A. Wolfson<sup>1</sup>, B. Farnia<sup>1</sup>, G. Simpson<sup>1</sup>, N. Dogan<sup>1</sup>, L. Portelance<sup>1</sup>

<sup>1</sup>University of Miami, Radiation Oncology, Miami, USA

#### Purpose or Objective

Treatment verification has improved significantly over the past decade, with on-board MRI-guidance now available. MRI provides superior soft tissue contrast compared to CT-based imaging, allowing for identification of the tumor on daily imaging. Consensus contouring guidelines for IMRT of cervical cancer advise including the whole uterus in the target volume and adding large planning volume margins to account for motion. The primary objective of our analysis was to assess the inter-fractional GTV motion for those with an intact cervix using a MRI-guided-Radiation-Therapy (MRgRT) system and investigate the benefit of reducing the primary PTV to the GTV with a margin for microscopic disease and target motion.

#### Material and Methods

We analyzed 125 daily set-up MRIs from five patients with cervical cancer who received MRgRT. The GTV, bladder, uterus, and rectum were contoured on all 125 MRIs, then the positional and volume changes of the OARs were calculated to assess their effect upon the displacement of the tumor. Using these data, margin calculations were performed to account for the daily inter-fraction motion and compared to the consensus guidelines for margin expansions.

#### Results

The GTV decreased in size during the course of treatment for all patients, 34.0%-85.2%. The median GTV displacement range was 0.69cm-1.04cm. The margins calculated were: 0.78cm Left-Right, 1.31cm Anterior-Posterior and 1.38cm for the Superior-Inferior directions. The formalism presented here reduces the PTV by 36% compared to consensus guidelines sparing both the sigmoid and bowel.

#### Conclusion

Including the whole uterus in the target and adding large margin expansions, to account for inter-fractional motion, is the standard practice. However, by utilizing daily on-board MRI-guidance the GTV becomes readily visualized allowing for a reduction of margins and potentially excluding a portion of the uterine fundus from the PTV with the ultimate goal of decreasing treatment toxicity while maintaining tumor control.

**EP-2010 A QA method for evaluation of deformable image registration in head and neck adaptive radiotherapy**

E. Cagni<sup>1</sup>, A. Botti<sup>1</sup>, M. Orlandi<sup>1</sup>, M. Galaverni<sup>2</sup>, R. Sghedoni<sup>1</sup>, C. Iotti<sup>2</sup>, E. Spezi<sup>3</sup>, M. Iori<sup>1</sup>

<sup>1</sup>Azienda USL-IRCCS di Reggio Emilia, Medical Physics Unit, Reggio Emilia, Italy ; <sup>2</sup>Azienda USL-IRCCS di Reggio Emilia, Radiotherapy Department, Reggio Emilia, Italy ; <sup>3</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

**Purpose or Objective**

This study aimed to assess a method for evaluation of delivered VMAT dose based on multimodal deformable image registration (DIR) using for head and neck (HN) adaptive radiotherapy.

The main goal was to develop the proof-of-concept to be used as QA registration tool for adaptive radiotherapy.

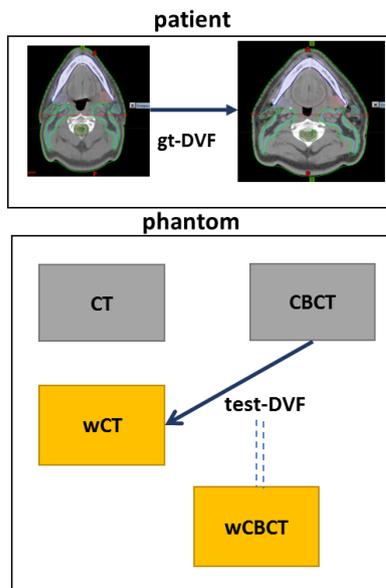

**Material and Methods**

The HN phantom, "ATOM Max TM Dental and Diagnostic Head Model-711"(CRS, Virginia) was scanned with CT and and cone-beam computed tomography (CBCT).

Firstly, CT images of the phantom were artificially deformed in a warped CT (wCT) by using 20 clinical representative deformable vector fields (DVF), considered the ground truth (gt-DVF). These DVFs were created by deformable registration between the planning CT (pCT) and two CBCTs of the 16<sup>th</sup> and 26<sup>th</sup> fraction of 10 HN patient treated in our Institute with VMAT plans. The CT-CBCT deformable registration was performed using Velocity AI (Varian Medical System, Palo Alto, CA) software, version 3.2.

Secondly, the phantom CBCT was registered with the wCT resulting in a test-DVF and generated a warped CBCT (wCBCT) (Figure1).

Quality of the registration was assessed as the ability of the test-DVF to recover the artificially induced gs-DVF..

**Figure1.** Workflow for validation of CT –CBCT DIR. The HN phantom was scanned with CT and CBCT devices. CT images were digitally warped using 20 realistic patient-based DVF, considered as ground truth ( gt-DVF) resulting in a warped CT (wCT). The CBCT was then registered with wCT generating a test-DVF. Test-DVF was compared with the gt-DVF to quantify the target registration error (TRE).

To assess dosimetric errors, adaptive-CT was created for each patient gs-DVFs to overcome the limitation related

to unconventional Hounsfield Unit (HU) numbers of CBCT, by reshaping the pCT into CBCT. VMAT treatment plans were recomputed on each adaptive-CT and back-projected to the pCT via both the gt-DVF (gs-dose) and test-DVF (test-dose), respectively. The differences between gs-dose and test-dose on pCT were evaluated. The following organs at risk (OARs) were considered in the analysis:

- spinal canal and mandible (inserted in the original phantom manufacture);
- oral cavity, left and right parotids (digitally created by post-processing CT and CBCT image sets with real patient HU contrast).

**Results**

DIR error statistics were quantified using the target registration error (TRE) between gt-DVF and test-DVF, on a voxel basis. In both fractions of all patients, we found a TRE (mean±std(max)) of 2.5±1.0(5.5) mm, 2.9±0.7(3.9) mm, 1.4±0.4(2.6) mm, 1.8±0.6(3.1) mm, 2.0±0.9(4.0) mm and 1.5±0.5(2.7) mm for body, spinal cord, mandible, left and right parotid and oral cavity respectively.

The difference between the two dose propagation methods (mean±std(max)) were 1.1±0.5(2.0) Gy, 0.9±0.3(1.6) Gy, 1.0±0.4(2.0) Gy, 1.6±0.7(3.7) Gy, 1.7±1.0(4.1) Gy and 1.1±0.5(2.6) Gy for body, spinal cord, mandible, left and right parotid and oral cavity respectively. Table 1 reports TRE and dose errors for all OARs, for each patient and in each fraction, in terms of mean±std calculated on a voxel basis.

<sup>1</sup>Fondazione Policlinico Universitario A.Gemelli IRCCS, U.O.C. Fisica Sanitaria- Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Roma, Italy ; <sup>2</sup>Università Cattolica del Sacro Cuore, Istituto di Radiologia, Roma, Italy ; <sup>3</sup>Fondazione Policlinico Universitario A.Gemelli IRCCS, U.O.C. Radioterapia- Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Roma, Italy

**Purpose or Objective**

The online MR-guided adaptive Radiotherapy (MRgART) workflow relies on the assignment of the water relative electron density (RED) map to the daily MR image (dMRI), to allow the dose calculation. The actual approach consists in co-registering the CT image acquired during the simulation procedure with the dMRI and then transferring the RED values obtained from the CT to the dMRI.

This approach can result misleading in clinical situations where the inter-fraction variability, the different organs filling and the changes in patient's anatomy (i.e. weight loss) can lead to considerable variations in RED map. A possible approach to overcome this variability consists in the daily generation of a synthetic CT (sCT) by segmenting the dMRI in 5 density levels (air, lung, fat, tissue and bone) and assigning a RED bulk value to each level according to ICRU 46 recommendations. Aim of this study is to evaluate the dose calculation accuracy of this approach in MRgART and to evaluate if assigning patient specific RED values can improve such accuracy.

#### Material and Methods

26 patients treated in the pelvic and abdominal sites were retrospectively enrolled.

For each patient, a planning CT (pCT) was acquired and segmented in 5 density levels, then median RED (mRED) values were calculated for fat, soft tissue and bone. Correlation between mREDs and clinical parameters (age, sex, body mass index) was investigated by using the Pearson Correlation Coefficient (PCC). Two sCTs were generated by assigning RED bulk values to the segmented levels on pCT: the sCT<sub>ICRU</sub> uses the RED values recommended by ICRU 46, the sCT<sub>tailor</sub> uses the median patient

specific RED values. The sCTs were generated from the CT image and not from MRI in order to avoid any potential bias due to the different MR and CT patient positioning. The same treatment plan was calculated on the sCTs and compared to those calculated on pCT in terms of 1%/1mm gamma analysis and dose volume histogram (DVH) parameters. The statistical significance of the difference between the sCTs was evaluated using Wilcoxon Mann Whitney test.

#### Results

A significant correlation between the clinical parameters and the mRED values was observed only between bone and age in women (PCC=-0.71), probably due to osteoporosis and menopausal status of the enrolled women (Figure 1).

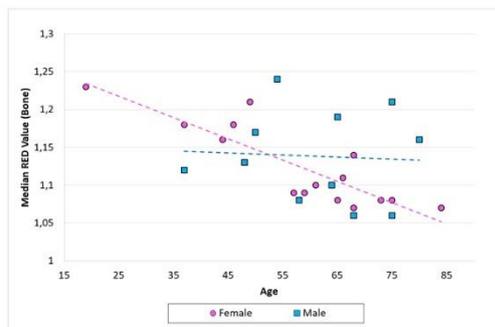

Figure 1 – Plot of the median RED values of the bone density for women and men in function of the age

For the dosimetric analysis, high agreement was found between dose calculated on sCTs and pCT:  $\gamma$  passing-rate was  $91.2\% \pm 6.9\%$  for sCT<sub>ICRU</sub> and  $93.7\% \pm 5.3\%$  for sCT<sub>tailor</sub>. A statistically significant gain in using sCT<sub>tailor</sub> respect to sCT<sub>ICRU46</sub> was found ( $p = 0.0013$ ). As shown in Figure 2, in 8 cases out of 26 the use of a personalised approach lead to an improvement in dosimetric accuracy higher than 4%.

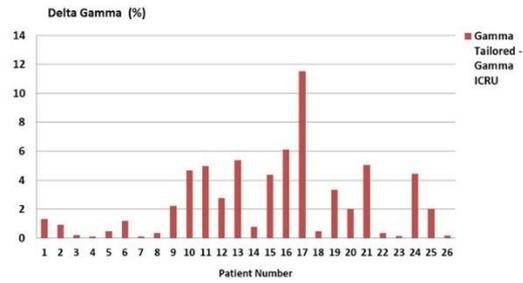

Figure 2 – Difference in gamma passing rates (1%/1mm) between the gamma analysis carried out between sCT<sub>tailor</sub> and pCT, and between sCT<sub>ICRU</sub> and pCT

#### Conclusion

The use of bulk synthetic CT achieves a high level of dose calculation accuracy, allowing its reliable use for online adaptive MR-guided Radiotherapy. In particular, assigning patient specific RED values to sCT allows to improve the accuracy of this approach.

#### EP-2012 MR-guided online adaptive radiotherapy for pancreatic cancer: where are we and where are we going?

<sup>1</sup>Fondazione Policlinico A. Gemelli IRCCS - Università Cattolica Sacro Cuore, Medical Physics, Rome, Italy ;

<sup>2</sup>Fondazione Policlinico A. Gemelli IRCCS - Università Cattolica Sacro Cuore, Radiation Oncology, Rome, Italy

#### Purpose or Objective

Magnetic Resonance guided -Radiotherapy (MRgRT) represents to date the most suitable IGRT technique for Online Adaptive (OA) RT, due to the superior soft tissue contrast and the real-time gating approaches achievable using cineMRI images. Aim of this study is to perform a process optimization analysis for the evaluation of the robustness and reliability of the OA workflow implemented in our institution for locally advanced pancreatic cancer (LAPC) patients (pts) undergoing low tesla MRgRT.

#### Material and Methods

Our OA workflow is characterised by different steps: for each fraction, OaR re-contouring is performed within a distance of 3 cm from the PTV surface on the daily acquired MR image scan. The dose distribution of the original plan is firstly calculated on the anatomy of the day and, if the dose constraints are not met, treatment plan is re-optimised. Online Quality Assurance (QA), based on an independent Monte Carlo (MC) calculation, is finally performed before delivery starts. Ten (pts) affected by LAPC were retrospectively enrolled after being treated with the OA workflow, for a total amount of 50 delivered fractions. Several parameters have been registered for the analysis: single fraction couch shifts after daily MRI registration, OaRs and target volumes variation, number of delivered OA fractions with a predicted or re-optimised dose, beam-on time for each adaptive fraction, online QA 3%/3mm gamma passing rate, DVH metrics (target coverage as PTV V95% and CTV V98%, and OaRs specific dose-volume constraint) and single fraction distance between CTV and duodenum/stomach centre of mass.

#### Results

Lateral, longitudinal and vertical single fraction couch shifts result in (mean $\pm$ SD (range min/max) for all patients, for all 50 fractions)  $-0.18\pm 0.58$ cm ( $-1.49/0.96$ cm),  $-0.11\pm 0.72$ cm ( $-2.81/1.38$ cm),  $-0.02\pm 0.31$ cm ( $-0.80/0.68$ cm) respectively. OaRs and targets volume variation are summarised in Figure 1. Out of a 50 fractions, 34 fractions were re-optimised and 16 delivered using the

original plan. Single fraction treatment time duration, including also the fraction with re-optimised dose distribution, was  $8.8 \pm 2.8$  min : 4.7/17.3min. When the plan underwent re-optimisation, a reduction of the beam-on time in comparison with the original plan has been detected in 44% of the cases (15 plans). Online QA 3%/3mm gamma passing rate was  $97.5 \pm 1.5\%$  (94.8/100.0%), comparable with the offline QA performed on a dedicated phantom ( $98.7 \pm 1.1\%$  (96.7/100.0%)). DVH metrics results are shown in Table 1 for a subgroup of 6 (pts) with same dose per fraction prescription (8 Gy). Maximum single fraction CTV to duodenum/stomach centre of mass distance was 2.4cm and 1.8cm respectively; SD of CTV to duodenum/stomach centre of mass distance for all the evaluated 50 fractions is 0.9cm and 0.8cm respectively.

Table 1 – Targets and OaRs DVH metrics in terms of minimum, maximum, mean and standard deviation (SD) of the difference between the planning DVH parameters and the daily registered one, after the online adaptation of the plan for a subgroup of 6 pts. d = duodenum, b = bowel, s = stomach, kr = right kidney, kl = left kidney, l = liver, PTV = planning target volume, CTV = clinical target volume

## Conclusion

The results of this evaluation emphasize that different parameters can affect the entire workflow. Most of them can be improved to optimise the current workflow in order to better perform the OA strategy.

## EP-2013 Lung tumor motion based on 4D-CBCT: baseline shift, interfraction amplitude and volume variation

F. Oger<sup>1</sup>, P. Dupuis<sup>1</sup>, E. Mesny<sup>1</sup>, T. Baudier<sup>2</sup>, S. Rit<sup>2</sup>, R. Tanguy<sup>1</sup>, M. Ayadi<sup>1</sup>

<sup>1</sup>Léon Bérard Cancer Center, Radiotherapy, Lyon, France ; <sup>2</sup>INSA-Lyon- Université Lyon 1, CREATIS- CNRS UMR5220- Inserm U1044, Lyon, France

## Purpose or Objective

4D-Cone Beam Computed Tomography (CBCT) allows the accurate positioning of moving targets and the study of tumor motion. In this work based on clinical data, we first compared the Internal Target Volume (ITV) volumes and motion amplitude between 4D-Computed Tomography (4D-CT) and 4D-CBCT. Secondly, we estimated the interfraction baseline shift and motion amplitude variations.

## Material and Methods

Patients with early non-small cell lung cancer treated with SBRT were included in the study. Patients were installed in a Bodyfix (Elekta) and underwent a 4D-CT scan (Big Bore, Philips). Treatment plans based on an ITV strategy were delivered on a Versa HD linac (Elekta). Before each fraction, a 4D-CBCT was acquired. A bone registration followed by an automatic region-of-interest (ROI) registration of the tumor were then computed with the

on-line reconstruction software Symmetry (Elekta). For each patient, baseline shifts were obtained by the difference between bone and ROI registrations. Mean tumor motion amplitudes were estimated from the 4D-CT by subtracting the 3D tumor centroid coordinates on extreme breathing phases, and automatically from 4D-CBCT images. A physician delineated the ITV on average images (4D-CT and 4D-CBCT) using a MonacoSim workstation (Elekta) to analyze the variations of the ITV volume.

## Results

A total of 280 4D-CBCT images from 58 tumors (52 patients) were retrospectively analyzed. The repartition of the tumors in the lungs was: 53% of tumors located in the upper lobe (UL), 9% in the middle lobe (ML) and 38% of tumors located in the inferior lobe (IL). The grand mean (GM) baseline shifts (SD) in the cranio caudal (CC) direction were 0.16 cm (0.12) for UL, 0.53 cm (0.26) for ML and 0.31 cm (0.28) for IL. In the other directions, GM baseline shifts were under 0.21 cm. 13% of UL tumors, 100% of ML tumors and 67% of IL tumors had a baseline shift above 0.30 cm in the CC direction. The mean [range] of amplitude differences between 4D-CT and 4D-CBCT was less than 0.10 cm [-0.93 cm; 1.70 cm] in all directions. 27% of UL tumors, 40% of ML tumors and 52% of IL tumors had amplitude differences larger than 0.30 cm in all directions. The median [range] of ITV volume deviation between 4D-CT and 4D-CBCT was -1.0% [-196.0%; +82.7%].

## Conclusion

The largest baseline shifts were observed for tumors located in the middle and inferior lobes. After a review of these cases, those tumors were mainly located on the fissure (ML), close to the chestwall, or in areas influenced by gastric filling (left IL). The same observation was found for amplitude variations. The variability of ITV volume between 4D-CT and 4D-CBCT was, in some cases, large and mainly due to delineation difficulties on average CBCT (image quality or atelectasis) or breathing artefacts (duplication) on the 4D-CT.

## EP-2014 Decision Support System for Checking Online Adaptive Treatments on the Elekta Unity

*This abstract is part of the media programme and will be released on the day of its presentation*

### Purpose or Objective

Reproducible patient positioning and image guidance are crucial aspects for effective particle therapy. Proper immobilization of patients with limb-extremities tumors can be challenging and existing guidelines on this topic are not univocal.

The aim of this study is to analyze positional interfraction reproducibility of limb-extremities when multiple combinations of immobilization devices are used in particle therapy.

### Material and Methods

Data of 12 patients treated at our institute between 2014 and 2017 were retrospectively recorded. Patient, treatment and setup data are enlisted in Table 1.

**Table 1. Patient characteristics, treatment data and details on patient setup and immobilization devices used. \*NA= not available**

Patient and Treatment data							Patient Setup				
Gender (M/F)	Weight (Kg)	Age (years)	Histology	Site	Particle	Decubitus	N° point tattoos	Thermoplastic mask	AccuForm™ cushions	Foot rest/ Additional supports	
P1	F	71.0	61	Chondrosarcoma	Femur	Carbon Ion	Prone	3	body	60x60 cm	-
P2	F	NA	62	Osteosarcoma	Hip	Carbon Ion	Prone	4	body	40x60 cm	Combitrill™
P3	M	82.5	57	Musfibrosarcoma	Thigh	Carbon Ion	Prone	3	body	60x60 cm	Combitrill™
P4	M	82.6	17	Ewing's sarcoma	Tibia	Proton	Supine	5	body	60x60 cm	-
P5	M	77.4	56	Liposarcoma	Knee	Carbon Ion	Supine	3	body	40x60 cm	-
P6	M	76.0	59	Liposarcoma	Thigh	Carbon Ion	Supine	4	body	60x60 cm	Feettrill™
P7	M	68.0	51	Rabdomiosarcoma	Thigh	Carbon Ion	Supine	6	body	60x60 cm	ankle support
P8	M	NA	75	Chondrosarcoma	Hand	Carbon Ion	Prone	4	head	20x25 cm	hand support
P9	F	80.0	80	Desmoplastico melanoma	Arm	Carbon Ion	Supine	5	body	40x60 cm	Combitrill™+ Wingstep
P10	F	63.8	44	Leiomiomasarcoma	Shoulder	Carbon Ion	Lateral	5	body	60x60 cm	-
P11	M	66.8	33	Sarcoma MPNIT	Brachial plexus	Proton	Lateral	6	body	60x60 cm	-
P12	F	77.6	68	Sarcoma MPNIT	Brachial plexus	Carbon Ion	Lateral	4	body	40x60 cm	head/rest+ cushions

All patients were immobilized using multiple combinations of immobilization devices: personalized AccuForm™ cushions, thermoplastic mask hooked on an indexed plate plus, when needed, either foot or ankle rest or head support. Tattoos setup points were drawn on patient skin to provide a reference for daily positioning. Before treatment, patients were first aligned according to the skin tattoos using localization laser. Daily orthogonal x-ray images were acquired prior irradiation and patient setup correction vectors were assessed by 2D-3D image registration. The correction of the set-up errors was performed using a 6-degree robotic positioning system. Sperman's correlation coefficient was used to investigate correlation between patient data and correction vector. Analysis of variance (ANOVA) was performed to investigate the 3D correction vector across patients and treatment site (lower and upper limbs).

### Results

A total of 156 treatment fractions were analyzed. The distribution of interfraction correction vectors is shown in Figure 1 for each patient (P1, P2, .., P12) and for the whole population. Median (interquartile range) correction vector over all patients was -0.6 (4.1) mm in latero-lateral direction, 1.2 (5.0) mm in cranio-caudal direction, -3.0 (4.8) mm in antero-posterior while rotations around the above mentioned axis were -0.2 (1.0)°, 0.0 (0.8)°, 0.0 (0.7)° respectively.

### EP-2015 Interfraction setup error using multiple immobilization devices for limb-extremity particle therapy

<sup>7</sup>Centro Nazionale di Adroterapia Oncologica CNAO, Clinical Department- Bioengineering Unit, Pavia, Italy ;

<sup>8</sup>Politecnico di Milano, Department of Electronics Information and Bioengineering, Milano, Italy

**Figure 1.** Distribution of correction vectors applied for each patient and over all patients (blue boxplot). According to clinical decision Patient 9 (P9) were positioned not applying rotations.

No correlation between the 3D translation correction vector and patient weight and age was found ( $r < 0.3$ ). No statistically significant difference between 3D correction vector in lower (P1-P7) and upper (P8-P12) limb was found ( $p$ -value=0.07) while it was significantly patient-dependent ( $p$ -value $<0.001$ ). **Conclusion**

The use of multiple combinations of immobilization devices for limb-extremities allowed for relatively small setup errors. This report might contribute to an Institutional standardization of limb-extremities positioning guidelines.

#### EP-2016 Evaluation of 4D cone beam CT-based dose calculation for SBRT lung cancer treatment

S. Bellefqih<sup>1</sup>, B. Benadon<sup>1</sup>, A. Roque<sup>1</sup>, N. Gaillot<sup>1</sup>, S. Servagi-Vernat<sup>1</sup>

<sup>1</sup>Institut Jean Godinot, Radiotherapy, Reims, France

#### Purpose or Objective

Stereotactic body radiation therapy (SBRT) has become a standard treatment for patients with medically inoperable early-stage non-small cell lung cancer (NSCLC). Daily image-guidance is crucial to ensure correct patient set-up prior to treatment delivery, with 3D-CBCT the conventional method used in image guidance. More recently, 4D-CBCT has been used to take into account tumor motion induced by respiration. Another potential use of 4D-CBCT is to determine the actual dose received by the tumor during treatment by using 4D-CBCT intra-fraction.

#### Material and Methods

This study included five patients treated with stereotactic body radiotherapy. Radiation treatments were delivered on an Elekta Versa HD linear accelerator. Prior to each radiotherapy treatment fraction, a 4D-CBCT was performed using XVI 4.5. Symmetry (from Elekta package of software solutions for IGRT). All translational errors were corrected prior to the treatment and then a 3D-CBCT was acquired to measure the residual error. Finally, a pre-treatment 4D-CBCT was acquired to verify intra-fraction motion. The intra fraction 4D-CBCT was used to delineate the GTV, and the ten GTV merged to form an ITV. A 5-mm margin was added to define a planning target volume (PTV). Finally, the initial plans were recomputed on the CBCT images using a patient specific stepwise curve (Hounsfield units to density). Internal target volumes (ITVs; D98%, D95%, D2%) were compared between simulation CT-derived treatment plans and 4D-CBCT-based plans.

#### Results

The ITV's volume was raised by an average of 26% [8.1%-44.6%]. The difference in ITV mean dose was 3.91% [0.2%-6.2%], D2% was 0.5% [0.2%-4.5%], D50% was 4.2% [1%-6.7%], D95% was 7.2% [3.3%-11.4%] and D98% was 8.3% [3.7%-12.1%]. Differences in dose distribution were less important for patients with less variation in volume of ITV

#### Conclusion

In this study 4D-CBCT based dose calculations was mainly affected by limited CBCT image quality. Improvement of CBCT image quality is necessary to accurate dose calculations.

#### EP-2017 GANs covert CBCT to CT for head-neck, lung and breast: paired vs unpaired; single-site vs generic

M. Maspero<sup>1</sup>, M.H.F. Savenije<sup>1</sup>, T.C.F. Van Heijst<sup>1</sup>, A.N.T.J. Kotte<sup>1</sup>, A.C. Houweling<sup>1</sup>, J.J.C. Verhoeff<sup>1</sup>, P.R. Seevinck<sup>1</sup>, C.A.T. Van den Berg<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands

#### Purpose or Objective

CBCT offers a representation of daily anatomy that may be used for online dose calculation and adaptation. However, dose calculations cannot be performed on CBCT due to lack of HU calibration, limited FOV and presence of image artefacts. This study investigates the use of generative adversarial networks (GANs) to convert CBCT into CT. Such networks allow very fast image conversion and thus facilitate online adaptation. However, CBCT to CT conversion using paired learning is problematic given the possible anatomical interscan differences breaking the "paired" (PA) assumption of data consistency. Here, we investigate the use of unpaired (UP) training, which obviates the need for consistent pairwise datasets (e.g. registered, anatomically matched) in the training. In this explorative study, we investigated the performance of PA vs UP learning and compared site-specific vs generic trained network.

#### Material and Methods

CBCTs of 88 patients diagnosed with head-neck (HN, 31), lung (29) and breast (28) cancer undergoing radiotherapy were rigidly registered according to the clinical procedure and resampled to the planning CT (XVI, Elekta). PA vs UP

To perform PA training, we used a conditional GAN (cGAN), while for UP training, we used a cycle-consistent GAN (cycleGAN). The two networks were trained in 2D transverse planes mapping CBCT to CT Hounsfield Units. For each anatomical site, the networks were trained on 15 patients (training set) and evaluated on the remaining patients (test set).

#### Single vs generic

To verify whether a single network could be used for all the patients independently of the anatomical site, we trained both the cGAN and the cycleGAN on the data of 45 patients.

Image comparison in terms of mean absolute error (MAE) and mean error (ME) in the FOV of the CBCT vs planning CT was performed on the test set for both the experiments.

#### Results

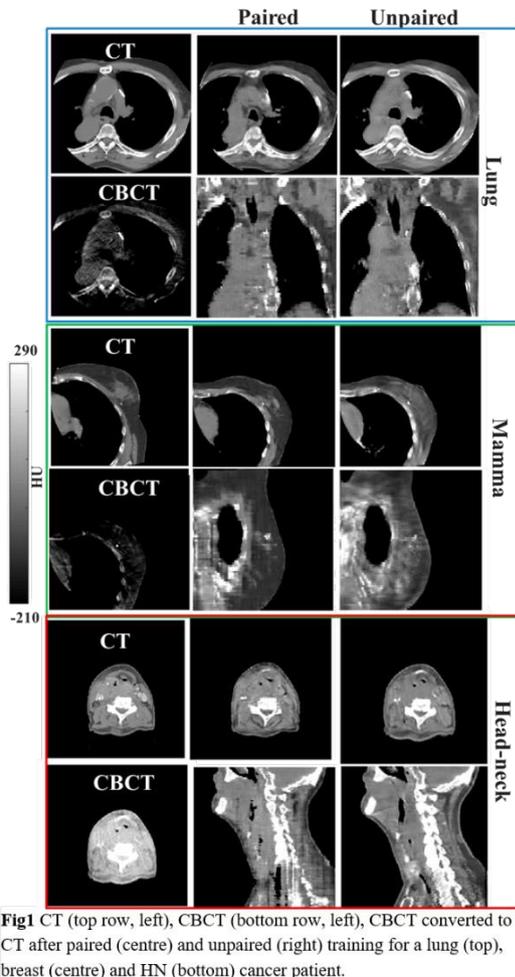

cGAN and cycleGAN training required about 1 and 5 days, respectively, on a GPU Tesla P100 (NVIDIA). Forward evaluation took about 20 s.

#### PA vs UP

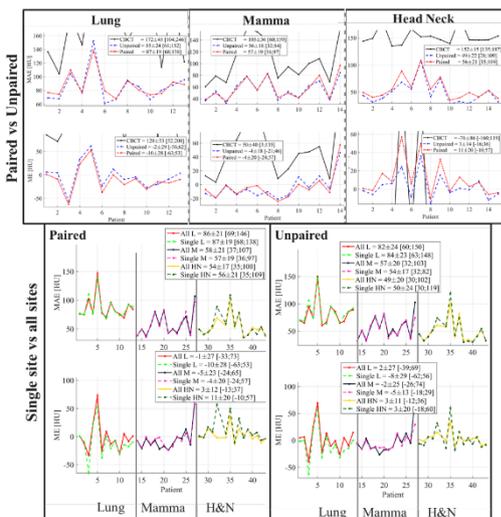

For all the three sites, discontinuities between 2D transverse slices were more visible after PA compared to UP training (Fig1). In the case of UP training, some residual image artefacts were present in the transverse plane, especially for the breast cases. Mean MAE and ME were for UP and PA are reported in Fig2.

#### Single vs generic

For all the anatomical sites, training with all the patients resulted in mean MAE and ME within  $1\sigma$  respect to training on patients of each site (Fig2).

**Fig1** CT (top row, left), CBCT (bottom row, left), CBCT converted to CT after paired (centre) and unpaired (right) training for a lung (top), breast (centre) and HN (bottom) cancer patient.

**Fig2** Top Mean absolute error (MAE, first row), and ME (mean error, second row) of original CBCT (black) paired wise translation of CBCT to CT (blue dashed), and unpaired conversion of CBCT to CT (red continuous). Bottom MAE (first row) and ME (second row) of the networks trained on all the sites (continuous lines) and single sites (dashed lines) for paired (left) and unpaired training (right) against CT. The insets display average  $\pm 1\sigma$  and range [min,max].

## Conclusion

Visually, UP training resulted in slightly better image quality although residual artifacts were present. Quantitatively PA and UP were comparable; however, a fundamental problem in the evaluation is the lack of a good reference considering that anatomical changes between CT and CBCT may have taken place. Investigations to verify the accuracy of dose calculations

is still needed to justify the use of GANs to enable CBCT-based dose calculations. In general, the use of a generic network for all the sites seems to be a viable option and the time necessary to convert CBCT into CT justifies the use of GANs for online ART.

**EP-2018 Actual delivered boost dose for gynecological cancer patients treated with image-guided IMRT**  
 S. Vieira<sup>1</sup>, M. Possanzini<sup>1</sup>, M. Silva<sup>1</sup>, J. Stroom<sup>1</sup>, C. Greco<sup>1</sup>  
<sup>1</sup>Fundação Champalimaud, Radiotherapy, Lisboa, Portugal

## Purpose or Objective

A phase I/II study of image-guided IMRT for intermediate and high risk endometrial cancer (EC) as brachytherapy replacement is ongoing in our department. The main rationale is to shape and deliver the high boost dose while overcoming the short range of brachytherapy sources without compromising normal tissue.

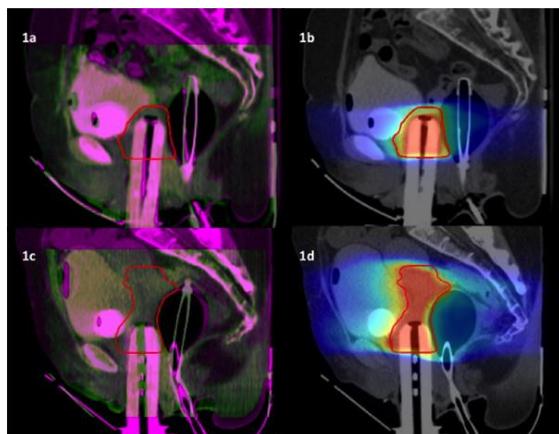

Our aim is to: (a) provide actual delivered dose for our endometrial and cervical cancer (CC) patients (pts) by non-rigidly deforming the planning CT (pCT) based on CBCT images acquired prior treatment delivery and (b) assess the applied CTV-PTV margins.

## Material and Methods

23 pts were included (14 EC and 9 CC). Patient set-up consisted of a rectal balloon, a vaginal cylinder and a full bladder (fig1). Intra-fraction motion was monitored by electromagnetic beacons (Calypso®) inserted in the vaginal cylinder (limiting beacon motion to <2mm). Operated pts received 3 fractions of 7.5-10.5Gy, non-operated 5 fractions of 4-5Gy after whole pelvis irradiation. For both schemes a CTV-PTV margin of 3mm was used. The 3 fraction scheme comprised of two dose levels: (1) 3x5-7Gy to PTV1 and (2) 3x7.5-10.5Gy to CTV2 (without PTV margin). VMAT boost treatment delivery included 4 arcs using 10MV FFF beams. Patient set-up was confirmed by CBCT on each fraction. The CBCT image acquired just prior to delivery of each treatment fraction served as reference for non-rigidly deforming the pCT using a structure guided multi-pass algorithm (Velocity® V3.2.0). Delineation of balloon, bladder, and vaginal cylinder on the CBCT improved deformation accuracy. Dose re-calculation (Eclipse™) was performed for each fraction on the reshaped pCT using the original plan parameters. The actual dose delivered was then obtained by inversely deforming dose map followed by a dose sum of all fractions. Fractions with obvious misfits after registration (bladder and rectal filling, cylinder placement) were rejected and replaced by worst-case fraction of the same patient. PTV coverage was evaluated for CTV-PTV margins review.

## Results

Planned and delivered doses are shown in Table1. Deformation acceptance rate was 93% and 73% for the 3 and 5 fractions scheme, respectively. Doses in the organs at risk (OAR) are within the constraints as defined in our protocol for both schemes, except for small bowel outliers due to poor CBCT image quality. All pts presented less PTV and CTV coverage than planned, as expected. For the 5 fraction scheme (cases without surgery), lower coverage was observed due to the OAR in the vicinity and larger tumor size ( $160 \pm 76cc$ ) as compared with the 3-fraction scheme ( $64 \pm 17cc$ ). Following the results shown for the 3-fraction scheme, a PTV margin of 3 mm was added to the CTV2 for new pts.

**Figure 1.** Sagittal view of two patients with a vaginal cylinder, rectal balloon and planning PTV (red). **1(a) and 1(c)** CBCT (green, without proper Hounsfield units) of one fraction overlaid on planning CT (purple), in treatment position. **1(b) and 1(d)** Measured dose map non-rigidly deformed overlaid on planning CT. **Upper images:** Patient 1 with CBCT-planning CT match leading to a CTV coverage difference between planned and measured of 0.5%; **Lower images:** Patient 2 with difficult patient set-up leading to a CTV coverage difference between planned and measured of 13.4%.

Table 1. Average dose planned and delivered for 23 patients. Delivered doses derived from CBCT anatomy for all fractions. Dose constraints as indicated in our clinical protocol. Data for the 3 and 5 fractions scheme is shown.

3 Fractions	Mean treatment	Mean planned	Dose volume constraints
D2cc Bladder wall (Gy)	15.7 ± 3.0	15.9 ± 3.0	V21.6 Gy/2cc
Dmax Small bowel (Gy)	5.5 ± 7.2	7.0 ± 10.0	Dmax = 80y (7.50y/fraction)
V PTV (%)	86.0 ± 6.3	99.8 ± 0.3	V15 or 21 Gy) ≥ 99%
V CTV1 (%)	96.8 ± 2.8	99.4 ± 2.2	V15 or 21 Gy) ≥ 99%
V CTV2 (%)	89.4 ± 10.8	99.6 ± 0.4	V22.5 or 31.5 Gy) ≥ 99%
D2cc Rectal wall (Gy)	16.2 ± 2.4	16.2 ± 2.6	V16.8 Gy < 2cc
5 Fractions	Mean treatment	Mean planned	Dose volume constraints
D2cc Bladder wall (Gy)	24.7 ± 1.6	24.9 ± 1.7	V25 Gy/2cc
Dmax Small bowel (Gy)	15.0 ± 6.5	7.5 ± 3.7	Dmax = 90Gy
V PTV (%)	58.8 ± 11.9	72.9 ± 11.0	V15 Gy) ≥ 99%
V CTV (%)	71.9 ± 14.2	82.0 ± 13.2	V15 Gy) ≥ 99%
D2cc Rectal wall (Gy)	19.6 ± 2.7	19.3 ± 1.2	V20.5Gy < 2cc

## Conclusion

Image-guided VMAT boost for gynecological cancer pts has been implemented. Patient set-up and CBCT image quality is a challenge for the low prognostic pts (5 fraction scheme). PTV margins used are adequate but evaluation of the added PTV margin to the 3 fraction scheme is needed.

## EP-2019 Does the use of an endorectal balloon improve seminal vesicle stability for prostate radiotherapy?

S. Chin<sup>1</sup>, A. McWilliam<sup>1,2</sup>, D. Brand<sup>1</sup>, S. Barton<sup>1</sup>, Y.P. Song<sup>1,2</sup>, M. Van Herk<sup>1,2</sup>, A. Choudhury<sup>1,2</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Department of Radiotherapy Related Research, Manchester, United Kingdom ; <sup>2</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom

## Purpose or Objective

Endorectal balloons have been used for prostate immobilisation and rectal wall sparing during radiotherapy for prostate cancer. However, inter-fraction motion of the seminal vesicles (SVs) is larger than for the prostate, and reducing their motion may lead to improved target volume coverage and/or decreased rectal dose when SVs are included in the clinical target volume. In this study, we assessed whether the use of an endorectal balloon (ERB) improved stability of the SVs.

## Material and Methods

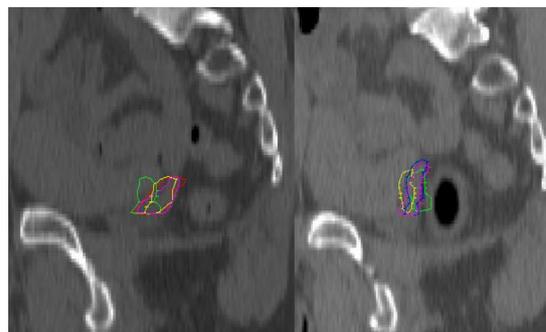

Ten patients undergoing radiotherapy for prostate cancer participated in a feasibility study of a RectalPro ERB filled with 100cc of air inserted at radiotherapy planning and 4 subsequent visits during treatment. SVs were contoured on the radiotherapy planning CT and subsequent cone

beam CTs (CBCT) with and without an ERB. SV stability was assessed by comparison of their displacement on CBCT compared to the radiotherapy planning CT by centre of mass, keeping the prostate aligned using soft tissue registration. Comparison of means and standard deviations were assessed using two-tailed unpaired t-tests and f-tests respectively.

## Results

34 and 37 CBCTs with and without ERB were assessed. Four patients were not able to complete all four pairs of cone beam CBCTs. Mean SV displacement without and with ERB for left-right direction was -0.6mm vs 0.6mm (p=0.070), superior-inferior -0.1mm vs -0.1mm (p=0.987) and anterior-posterior 0.7mm vs -0.3mm (p=0.476). Corresponding standard deviations of SV displacement without and with ERB were left-right 3.6mm vs 2.0mm (p=0.001), superior-inferior 2.8mm vs 2.0mm (p=0.132) and anterior-posterior 6.7mm vs 5.0mm (p=0.101). Seminal vesicles were more difficult to visualise on CBCT than radiotherapy planning CTs, especially with ERB in situ, and variation in ERB insertion angle affected positioning of pelvic soft tissue organs.

Seminal vesicle displacement	Endorectal balloon	Left-right	Superior-inferior	Anterior-posterior
Mean	Without	-0.6mm	-0.1mm	0.7mm
	With	0.6mm	-0.1mm	-0.3mm
Standard deviation	Without	3.6mm	2.8mm	6.7mm
	With	2.0mm	2.2mm	5.0mm

Left: Seminal vesicle positioning without endorectal balloon. Right: Seminal vesicle positioning with endorectal balloon.

## Conclusion

The insertion of an endorectal balloon for prostate radiotherapy improves stability of the seminal vesicles relative to the prostate. The largest seminal vesicle displacement is seen in the anterior-posterior direction. However, ERBs may impair soft tissue visualisation and alter soft tissue anatomy, so utilisation of daily image guided radiation therapy is recommended when ERBs are used.

## EP-2020 Assessment of treatment margins for breast radiotherapy evaluated using CBCT

S. Nørring Bekke<sup>1</sup>, C.F. Behrens<sup>1</sup>, F. Mahmood<sup>2</sup>

<sup>1</sup>Radiotherapy Research Unit, Department of Oncology-Herlev and Gentofte Hospital - University of Copenhagen, Herlev, Denmark ; <sup>2</sup>Research Unit for Oncology, Department of Clinical Research- University of Southern Denmark- Department of Oncology- Odense University Hospital, Odense, Denmark

## Purpose or Objective

In the clinical routine patients are often positioned based on planar x-ray images prior to irradiation in external beam breast radiotherapy. The objective of the present study was to find the treatment margins from a setup

based on planar kV-MV, in-room lasers or surface scans. The different setup techniques were evaluated using cone beam computed tomography (CBCT) as the ground truth.

#### Material and Methods

This prospective clinical trial included 39 patients, from which 102 treatment fractions were analysed. Patients were treated with deep inspiration breath-hold radiotherapy after breast conserving surgery, without lymph node involvement. The initial setup was based on in-room lasers and tattoo marks. A surface scan was acquired (Catalyst and Sentinel, from C-RAD Positioning AB, Uppsala, Sweden) followed by a CBCT scan. Lastly, the patient was moved to the planned treatment position based on anterior-posterior kV and tangential MV images (kV-MV), and treatment was delivered. In off-line analysis, the planned treatment position was found based on the acquired surface scans and on the acquired CBCTs scans (soft tissue, semi-automatic rigid registration in six degrees of freedom). The treatment position found from the CBCT scans were used as the ground truth. The CTV to PTV margins were calculated according to van Herk [1] using the systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors between the different setup techniques (kV-MV, in-room lasers and surface scans) and the CBCT.

#### Results

CTV to PTV margin required to ensure dose coverage of the CTV were largest in the vertical direction for all setup techniques (Table 1). Overall the margins were smaller for patient positioning based on kV-MV compared to in-room lasers and surface scans. The margins were smaller in the lateral and vertical direction using surface scans compared to in-room lasers. Of the 102 treatment fractions, the number of treatment fractions with a setup error above 1 cm in either direction was 6, 4 and 1 for in-room lasers, surface scans and kV-MV, respectively.

Table 1

	$\Sigma$ [mm]	$\sigma$ [mm]	CTV to PTV margin [mm] ( $2.5\Sigma + 0.7\sigma$ ) [1]
<b>Planar x-rays (kV-MV)</b>			
Lateral	1.8	2.3	6.2
Longitudinal	2.0	2.7	6.8
Vertical	2.7	2.4	8.5
<b>Tattoos and in-room lasers</b>			
Lateral	3.5	2.5	10.6
Longitudinal	3.0	3.1	9.8
Vertical	4.3	3.0	12.8
<b>Surface scans</b>			
Lateral	2.7	1.9	8.0
Longitudinal	3.3	2.9	10.3
Vertical	3.3	2.5	10.1

#### Conclusion

The study shows that the CTV to PTV margin is smallest for a kV-MV setup and suggests that a CTV to PTV margin of 6, 7 and 9 mm should be applied in the lateral, longitudinal and vertical directions, respectively. The margins from the initial setup based on in-room lasers can be reduced in the lateral and vertical direction using surface scans; in the longitudinal direction the margins are similar.

#### EP-2021 Commissioning and clinical implementation of dose accumulation and adaptive radiotherapy

K. Brock<sup>1</sup>, M. McCulloch<sup>1</sup>, G. Cazoulat<sup>1</sup>, A. Ohrt<sup>1</sup>, P. Balter<sup>1</sup>, H. Bahig<sup>1</sup>, S. Ping<sup>1</sup>, A. Mohamed<sup>1</sup>, H. Elhalawani<sup>1</sup>, B. Elgohari<sup>1</sup>, S. Frank<sup>1</sup>, J. Wang<sup>1</sup>, D. Rosenthal<sup>1</sup>, C. Fuller<sup>1</sup>  
<sup>1</sup>The University of Texas MD Anderson Cancer Center, Imaging Physics, Houston, USA

#### Purpose or Objective

Purpose/Objective: To commission a commercial deformable registration and dose accumulation system to

enable accurate and efficient adaptive radiotherapy for head and neck cancer patients.

#### Material and Methods

Material/methods: Patients treated on an IRB approved adaptive radiotherapy trial using weekly CT and MR and daily CBCT guidance were evaluated. The accuracy of a commercial deformable registration algorithm, using correlation coefficient and weighted Dirichlet energy, was evaluated for CT to CT and CT to CBCT DIR. For CT to CT DIR, 9 patients with mid-treatment repeat CT scans were obtained. Normal tissues were contoured on both images. The contours were propagated using DIR from the planning CT onto the mid-treatment CT and compared to the clinician drawn contours using the Dice similarity coefficient (DSC). The performance of the CT to CBCT DIR was evaluated relative to the CT to CT DIR, by rigidly registering the CBCT obtained the same day as the mid-treatment CT and copying the contours onto the CBCT. DIR was performed between the planning CT and the mid-treatment CBCT and the propagated contours were compared using DSC. The accuracy of dose calculation on the CBCT was evaluated by comparing the difference in the clinically relevant metrics between the dose calculated on the CT and the CBCT obtained on the same day. Dose accumulation was performed based on only weekly CTs and based on daily CBCTs. Differences in total accumulated dose over treatment was evaluated.

#### Results

Results: CT to CT DIR accuracy was evaluated for the brainstem, larynx, parotids submandibular glands, mandible and esophagus using DSC. The average DSC was 0.80 (SD 0.05), range: 0.73 (esophagus) to 0.91 (mandible). CT to CBCT registration accuracy was evaluated for 10 image pairs. The average DSC, relative to the CT to CT DIR, was 0.91 (SD 0.04), range: 0.89-0.94. Dose difference using CT or CBCT was evaluated for 10 image pairs based on the GTV, CTV, submandibular glands, larynx, mandible, and parotids. The average difference of clinical metrics was 0.6 cGy (SD 2.7 cGy) or 0.07% of the planned fraction dose (SD 2.7%). The maximum difference was 8 cGy, observed for a single image pair for the mean larynx dose. Based on daily CBCT dose accumulation, the average difference between the planned dose and the delivered dose for the targets was -170 cGy (SD: 51, range: -260 - -97) and for the normal tissues was -51 cGy (SD: 143 cGy, range: -277 - 181 cGy). For the target structures, the average difference between the dose accumulated using daily CBCT compared to weekly CT was 114 cGy (SD: 39 cGy, range: 55 - 180 cGy). For the normal tissues, the average difference between the dose accumulated using daily CBCT compared to weekly CT was 53 cGy (SD: 93 cGy, range: -101 - 175 cGy).

#### Conclusion

Conclusion: Dose accumulation is clinically feasible and can be used to guide adaptation to ensure target coverage and normal tissue sparing and to improve understanding of delivered dose and outcomes.

#### EP-2022 Dose-dependent changes in T2w-MRI texture of obturator muscles after prostate cancer radiotherapy

E. Scalco<sup>1</sup>, T. Rancati<sup>2</sup>, A. Mastropietro<sup>1</sup>, A. Cicchetti<sup>2</sup>, B. Avuzzi<sup>3</sup>, R. Valdagni<sup>2,3,4</sup>, G. Rizzo<sup>1</sup>

<sup>1</sup>Istituto di Bioimmagini e Fisiologia Molecolare, CNR, Segrate Milano, Italy; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milano, Italy; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milano, Italy; <sup>4</sup>Università degli Studi di Milano, Department of Oncology and Hemato-oncology, Milano, Italy

### Purpose or Objective

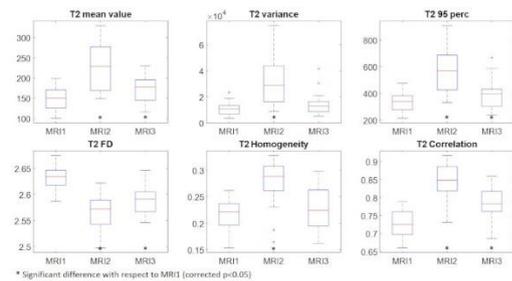

To investigate radiation-induced alterations in internal obturator muscles in prostate cancer patients treated with external-beam radiotherapy (RT), considering T2w-MRI images, acquired before treatment and at one and two years of follow-up.

### Material and Methods

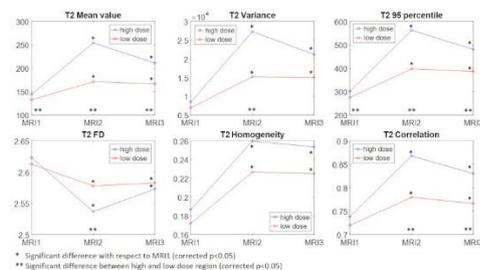

T2-weighted MRI were acquired in fourteen patients before RT (MRI1), about 12 months (MRI2) and 24 months (MRI3) of follow-up. Images were corrected for bias field inhomogeneities, normalized and spatially registered to automatically propagate obturators contours, which were manually delineated on MRI1. The following textural features were extracted: histogram-based indices (mean intensity, variance, 95<sup>th</sup> percentile, entropy, skewness, kurtosis), GLCM (Grey-Level Co-occurrence Matrix)-based indices (energy, correlation, homogeneity, entropy, contrast, dissimilarity), NGTDM (Neighborhood Grey-Tone Different Matrix)-based indices (coarseness, contrast, busyness, complexity, strength) and fractal dimension (FD). The dose map associated with the planning CT was deformed on each MRI and two regions were identified within the obturator: a high dose region (receiving >55 Gy) and a low dose region (receiving <55 Gy). To assess significant changes in internal obturator muscles, a comparison of the parameters extracted at each time point in the two regions was carried out by repeated-measure ANOVA and post-hoc t-test, with significant p-value < 0.05, after Bonferroni correction for multiple comparisons.

### Results

For several features (such as mean value, variance, 95<sup>th</sup> percentile, GLCM homogeneity and correlation, FD) it was found a significant increase or decrease at MRI2 and a gradual recovery at MRI3, in some cases still significantly different from MRI1 (see Figure 1).

Looking at regional results, different trends were found for the two regions. The high dose region presented highly different values at MRI2 with respect to MRI1 and a rapid but incomplete recovery at MRI3. The low dose region presented lower and less significant differences at MRI2, with respect to the high dose region, followed by a plateau at MRI3 (see Figure 2).

### Conclusion

In patients who underwent RT for prostate cancer treatment, a dose-dependent behaviour was observed regarding changes in T2w-MRI signal intensity and texture

of the internal obturator muscles. Specifically, the increased signal intensity and homogeneous pattern at MRI2, compatible with an inflammatory status, was more evident in the region receiving high dose. Two years after the end of RT, a relatively high recovery was observed in the high dose region, indicating a partial resolution of the inflammation; however, the plateau found in the low dose region may indicate that this altered status could not be completely recovered.

Other analyses at further time-points should be performed and correlations with genito-urinary toxicity scores should be investigated, considering the involvement of the pelvic floor muscles in the urinary dysfunctions.

### EP-2023 Predictive value of delta-radiomics features extracted from MR Images in image-guided liver SBRT

N. Dogan<sup>1</sup>, D. Asher<sup>1</sup>, B. Farnia<sup>1</sup>, C. Ford<sup>1</sup>, F. Yang<sup>1</sup>, L. Portelance<sup>1</sup>, G. Simpson<sup>1</sup>

<sup>1</sup>University of Miami- Sylvester Comprehensive Cancer Center, Department of Radiation Oncology, Miami-Florida, USA

### Purpose or Objective

With a projection of 600,000 deaths each year, liver cancer is a leading cause of cancer deaths worldwide and is very difficult to treat. A predictive model that could identify patients whose tumors are not responding to the treatment could be beneficial for improved personalized care. On-board MRI-guided radiotherapy which allows real-time tumor tracking presents a potential to utilize daily setup MR images to predict response and as well as safe dose escalation. The objective of this study was to determine the changes in image texture features (delta-radiomics) measured on daily low-field MR images and if delta-radiomics features could be used to assess treatment response and predict patient outcomes.

### Material and Methods

We conducted a retrospective analysis of ten patients with liver cancer treated with MR-guided SBRT (27 Gy to 50 Gy in 3 to 5 fractions). Radiomics features extracted from set-up images were acquired with an onboard 0.35 T MRI. The predictive capabilities of texture features extracted from daily set-up images for patients with liver lesions treated with SBRT were assessed using delta-radiomics which track changes in texture features through treatment. Five classes of texture features containing 42 features were extracted from the gross tumor volume (GTV). Gray-level Size Zone Matrix (GLSZM), Neighborhood Gray-level Difference Matrix (NGLDM), Gray-level Co-occurrence Matrix (GLCOM), and Gray-level Run Length Matrix (GRLRM) based features were selected. After extraction of texture features, the difference in feature value between first and last fraction set-up images was calculated. Patients were grouped into non-responders (three patients) who had local failure (disease progression) and responders (seven patients) who achieved local control. Patients were classified using follow-up PET images with modified RECIST criteria. The delta-radiomics features for each group were compared using Wilcoxon signed-rank test.

### Results

A univariate analysis identified three delta-radiomics texture features (*p*-value < 0.05) that were able to differentiate between responders and non-responders groups. The difference between dissimilarity (GLCOM), homogeneity (GLCOM), and busyness (GLNDM) features, was statically significant (*p*-value < 0.05) between the two groups. Entropy (GLCOM), complexity (GLNDM), and gray-level non-uniformity (GLSZM) features approached significance (*p* = 0.0874). No GRLRM or GLSZM features in the analysis were found to be significant.

### Conclusion

The ability to continually inform physician decisions during treatment would significantly advance the move towards personalized care. Delta-radiomics has the potential to

monitor patient response non-invasively during treatment, which could help inform physicians about whether a patient may require treatment adaption. This study demonstrated that three delta-radiomics texture features extracted from low-field MR images during SBRT in liver were able to differentiate between local disease control and local control failure.

**Table 1:** The table below displays the mean delta-radiomic texture features for each group of patients along with the standard deviation. Busyness, dissimilarity, and homogeneity were the only significant features selected, while entropy and complexity were trending towards significant.

Texture Feature	Responder (n=7)		Non-responder (n=3)		p-value
	Mean	STD	Mean	STD	
Busyness	0.05	0.09	-0.05	0.04	0.0167
Dissimilarity	1.25	2.01	-1.85	0.69	0.0304
Homogeneity	0.00	0.01	0.01	0.01	0.0167
Entropy	-0.09	0.22	0.62	0.74	0.0874
Complexity	-7933	36145	107588	141951	0.0874

### EP-2024 Assessment of ADC value when comparing two methods to reduce geometrical distortion in DWMRI

A. Lopez Medina<sup>1</sup>, A. Garcia<sup>1</sup>, C. Perez<sup>1</sup>, P. Montesinos<sup>2</sup>, I. Nieto<sup>3</sup>, A. Nieto<sup>4</sup>, V. Ochagavia<sup>3</sup>, M. Arias<sup>4</sup>, F.J. Salvador<sup>1</sup>, M. Salgado<sup>1</sup>, V.M. Muñoz<sup>3</sup>

<sup>1</sup>Hospital do Meixoeiro, Radiofisica y PR, Vigo Pontevedra, Spain ; <sup>2</sup>Philips Iberia, Healthcare, Madrid, Spain ; <sup>3</sup>Hospital do Meixoeiro, Radioterapia, Vigo Pontevedra, Spain ; <sup>4</sup>Complejo Hospitalario Universitario de Vigo, Diagnóstico por Imaxe, Vigo, Spain

#### Purpose or Objective

One of the most promising methods to determine tumor response during treatment using functional imaging is apparent diffusion coefficient (ADC), derived from diffusion-weighted imaging (DWI) in MRI. We investigate the use of reversed gradient (RG) algorithm in DWI for reduction in geometric distortion when using echo-planar imaging (EPI), and DWI using turbo spin echo (TSE) acquisition method, that reduces the distortion, but implies longer acquisition times. We compare the ADC values for water, ethanol and propanol using both methods and images for the phantom and for one patient from the HeNeBra project (continuation of ARTFIBio project).

#### Material and Methods

ADC was measured for RG corrected and original images of a specific phantom containing water, ethanol and propanol. The phantom (Fig. A) was scanned in a 3T Philips Ingenia magnet and for EPI images, b-values were set at 0, 50, 100, 200, 500 and 1000 s/mm<sup>2</sup>, reverting the phase encoding direction (AP: antero-posterior; PA: postero-anterior), while for TSE images, b values were: 0, 500, and 1000 s/mm<sup>2</sup>. Differences in b are because this protocol is being used in HeNeBra project to evaluate tumor response in radiotherapy patients during treatment (Fig. B) and compared results from ADC maps and PET/CT, and we wondered how acquisition method would influence in the obtained ADC. More b-values in TSE protocol are difficult to be considered, because its penalty in acquisition time.

#### Results

Figure shows how distortion is corrected by RG method in the phantom (Fig. A) and in the patient (Fig. B) and corrected RG images are similar to those obtained by TSE technique. Undistorted images (RG & TSE) from ADC maps and b=0 images can be compared with patient's PET/CT scan and the correspondence between the affected right node in all the image datasets is observed.

No significant difference in calculated ADC in water, ethanol and propanol for corrected and raw images of the phantom were observed, neither from EPI or TSE images. The table shows obtained mean values and one standard deviation from the images considering all the volumes. For low values of ADC, RG images have a greater variability

and associated standard deviation increases for ethanol and propanol. However, values from images are very close to expected values measured experimentally.

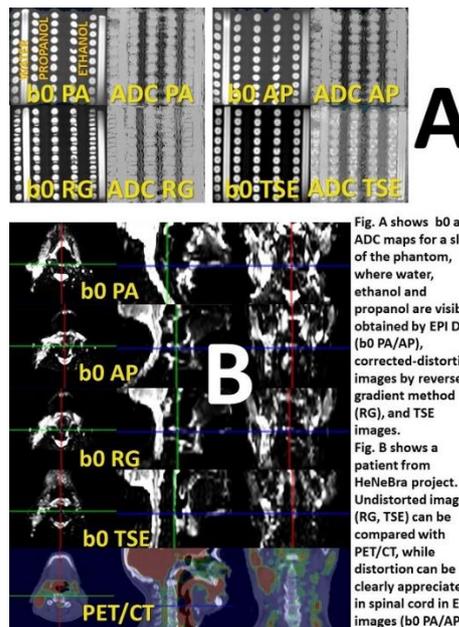

Fig. A shows b0 and ADC maps for a slice of the phantom, where water, ethanol and propanol are visible, obtained by EPI DWI (b0 PA/AP), corrected-distortion images by reversed gradient method (RG), and TSE images.

Fig. B shows a patient from HeNeBra project. Undistorted images (RG, TSE) can be compared with PET/CT, while distortion can be clearly appreciated in spinal cord in EPI images (b0 PA/AP).

	Water	Ethanol	Propanol
Measured diffusion Coefficient at 274,2 K (10 <sup>-9</sup> m <sup>2</sup> /s)	2,085	0,999	0,555
<small>Tofu, P. S. et al. 2000. Test liquids for quantitative MRI: measurements of self-diffusion coefficient in vivo. MR in Med 368-374.</small>			
<ADC> ± σ from DWI corrected by Reversed Gradients (10 <sup>-9</sup> m <sup>2</sup> /s)	2,20 ± 0,03	0,94 ± 0,28	0,56 ± 0,22
Difference respect to expected value	5,5%	-5,9%	0,9%
<ADC> ± σ from DWI corrected (Phase Encoding direction: AP) (10 <sup>-9</sup> m <sup>2</sup> /s)	2,21 ± 0,03	0,99 ± 0,19	0,56 ± 0,07
Difference respect to expected value	6,0%	-0,9%	0,9%
<ADC> ± σ from DWI corrected (Phase Encoding direction: PA) (10 <sup>-9</sup> m <sup>2</sup> /s)	2,18 ± 0,02	0,98 ± 0,10	0,56 ± 0,10
Difference respect to expected value	4,6%	-1,9%	0,9%
<ADC> ± σ from DWI obtained by TSE (10 <sup>-9</sup> m <sup>2</sup> /s)	2,15 ± 0,02	0,92 ± 0,09	0,51 ± 0,07
Difference respect to expected value	3,1%	-11,9%	0,9%

#### Conclusion

Both methods: RG from DWI-EPI and DWI-TSE can be used to evaluate ADC changes in the full range (0.555·10<sup>-9</sup> m<sup>2</sup>/s - 2.085·10<sup>-9</sup> m<sup>2</sup>/s) of the expected ADC changes of tumor during radiotherapy treatment and an important reduction of distortion can be observed in both cases, but the RG method introduces more noise in the final corrected image and can make more difficult to evaluate changes, especially in ADC range for tumors. Finally, we would like to highlight that if only ADC (not intravoxel incoherent motion) is used to evaluate tumor response and few values of b are required, TSE can be successfully used to measure the desired data.

### EP-2025 Predicting midtreatment FDG PET in head and neck cancer

Z. Gouw<sup>1</sup>, K. Lonning<sup>1</sup>, M.D. La Fontaine<sup>1</sup>, S. Van Kranen<sup>1</sup>, O. Hamming-Vrieze<sup>1</sup>, J. Van de Kamer<sup>1</sup>, A. Al-Mamgani<sup>1</sup>, J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

There are multiple ways to improve radiation therapy for head and neck cancer. One is by dose painting, using the baseline FDG PET. Another is adaptive response assessment, using a midtreatment FDG PET scan. Good predictability of the midtreatment PET is a reason to pursue baseline dose painting. Contrary, if the midtreatment PET does add substantial new information, adaptive response assessment would need further investigation. Therefore, we evaluated the predictability of the midtreatment PET scan, using pretreatment information.

### Material and Methods

We analyzed 39 patients with squamous cell cancer of the oropharynx, oral cavity and hypopharynx. Patients were treated with radiotherapy with curative intent, in combination with cisplatin or Cetuximab. Pretreatment imaging consisted of planning CT, MRI and FDG PET/CT. Patients received a second FDG PET and CT during treatment. All scans were deformable registered to the midtreatment CT. A neural network was formed for a voxel based prediction of the midtreatment FDG PET within the gross tumor volume. We used the mean square error as a loss function. The input were the imaging modalities, dose and the marked variables in table 1. A 6-fold cross-validation was used to create the artificial PET scans (example in figure 1). We compared the real and artificial midtreatment  $SUV_{max}$ ,  $SUV_{mean}$  and the area encompassed by 50% of the  $SUV_{max}$  ( $SUV_{50\%}$ ). The dice coefficient between the 2  $SUV_{50\%}$  segmentations was calculated. Last, we expanded the artificial  $SUV_{50\%}$  or lowered the segmentation threshold to encompass the entire real  $SUV_{50\%}$ .

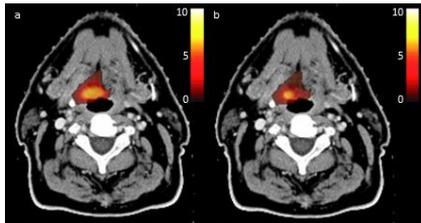

Figure 1. Patient with a cT4N2b base of tongue carcinoma. On the left is the planning CT with an overlay of the artificial midtreatment FDG PET. On the right an overlay of the real midtreatment PET. The colorbar represents range of SUV.

### Results

Patient and tumor characteristics are depicted in table 1. The artificial PET underestimated the real midtreatment  $SUV_{max}$ , the median difference was 3.4 points (interquartile range 4.1 points). The artificial PET underestimated the real  $SUV_{max}$  more when the real  $SUV_{max}$  increased (Pearson's  $r = 0.94$ ). The predicted  $SUV_{mean}$  was also lower, with a median difference of 2.2 points (interquartile range 2.7 points). The artificial  $SUV_{50\%}$  segmentations were larger, the median volume was 12.3 cc (interquartile range 15.1) vs 4.6 cc (interquartile range 4.7) for the real  $SUV_{50\%}$ . The median dice coefficient between the segmentations was 0.53 (interquartile range 0.18). To encompass the real  $SUV_{50\%}$ , the SUV threshold of the artificial scans had to be lowered till  $SUV_{38\%}$  (interquartile range of 15%) or a median expansion was needed of 3 mm (interquartile range 2 mm).

### Conclusion

This pilot study indicates that midtreatment PET scans can be partially predicted. Model improvements through increased sample size and modified loss functions are subject of further studies.

### EP-2026 Diffusion weighted textural differences between p16 positive and negative oropharyngeal carcinoma

S. Deschuymer<sup>1</sup>, V. Vandecaveye<sup>2</sup>, F. De Keyzer<sup>2</sup>, S. Nuyts<sup>1</sup>

<sup>1</sup>University Hospital Gasthuisberg, Radiotherapy, Leuven, Belgium ; <sup>2</sup>University Hospital Gasthuisberg, Radiology, Leuven, Belgium

### Purpose or Objective

To explore the feasibility and diagnostic performance of radiomic features (RF) based on diffusion weighted (DW) MRI in differentiating among p16 positive and negative oropharyngeal carcinoma (OPC).

### Material and Methods

Sixty-six patients with histologically proven OPC were prospectively analysed. OPC were considered p16 positive if more than 70% diffuse nuclear and cytoplasmic immunohistochemistry staining was present. 1.5 T MRI with echo-planar DW sequences at 6 b-values (0, 50, 100, 500, 750 and 1000 s/mm<sup>2</sup>) were acquired before treatment. The region of interest (ROI) encompassing the entire primary tumor volume was manually drawn on the apparent diffusion coefficient (ADC) map by an experienced head and neck radiologist.

One hundred and five RF (Table 1), including shape, size, first-order-histogram and textural analysis (TA), were extracted from the ROI with Pyradiomics software and were compared between p16 positive and p16 negative OPC with the two-tailed unpaired Student t-test. The significance threshold was set at a p-value of <0.05. In addition, receiver operating characteristic (ROC) curves were generated to determine the discrimination performance and the optimal cut-off value of the RF.

### Results

Fourteen (21%) tumors were p16 positive. A total of 34 RF were significantly different including volumetric parameters with smaller and more sphere shaped tumors

in the p16 positive group. There was no significant difference in ROI-based mean and minimum ADC value between p16 positive and p16 negative OPC (ADC<sub>mean</sub> = 1.11 ± 0.38 × 10<sup>-3</sup> mm<sup>2</sup>/s and 1.26 ± 0.57 × 10<sup>-3</sup> mm<sup>2</sup>/s, respectively, GLCM\_Joint\_Entropy, showed significant differences suggesting that p16 negative tumors are more heterogeneous than p16 positive tumors (Table 1\*). ROC curves of all significant RF were generated of which the volumetric parameters major\_axis and maximum\_3D\_diameter had the best AUC, both 0.80, followed by GLDM\_dependence\_non\_uniformity\_parameter (AUC=0.77). The optimal cut-off value of 6.78 mm 7.81 mm and 5.89 respectively, provided 80.3% accuracy for these three radiomic features.

Table 1: Seven different classes of radiomic features. Between brackets ( ) the number of displayed features and the total number of investigated features is shown. P-value was calculated with the two-tailed unpaired Student's t-test; significant values are in bold. The asterisk \* indicates significant values specifying tumor hetero/homogeneity. SD=standard deviation, NS = Not significant

**Conclusion**

Evaluating the global primary tumor volume, we could not establish a significant difference in ADC value between p16 positive and p16 negative OPC. However, analysing the ADC based TA features at DW-MRI, there was a significant difference with p16 positive OPC having a more uniform and homogeneous distribution. Future research should investigate if these TA differences have a prognostic and predictive value and if they can be used in a DW-MRI based individualized treatment strategy.

**EP-2027 FDG-PET/CT-based assessment of hematologic toxicity in anal cancer patients following chemoradiation**

J. Kalsnes<sup>1</sup>, E. Rusten<sup>1</sup>, A. Abravan<sup>2</sup>, B.L. Rekstad<sup>1</sup>, E. Hernes<sup>3</sup>, M.G. Guren<sup>4</sup>, E. Malinen<sup>5</sup>

<sup>1</sup>Oslo University Hospital, Department of Medical Physics, Oslo, Norway; <sup>2</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom; <sup>3</sup>Oslo University Hospital, Department of Radiology and Nuclear Medicine, Oslo, Norway; <sup>4</sup>Oslo University Hospital, Department of Oncology, Oslo, Norway; <sup>5</sup>University of Oslo, Department of Physics, Oslo, Norway

**Purpose or Objective**

The standard treatment of concurrent chemoradiotherapy (CRT) for anal cancer patients is known to cause high rates of severe haematologic toxicity (HT) such as lymphopenia. HT is associated with longer treatment times and/or reduction in chemotherapy dose, and may lead to

suboptimal treatment outcome. Previous studies have hypothesized that irradiation of active bone marrow (ABM), as defined by [<sup>18</sup>F]fluorodeoxyglucose (FDG)-PET, is the principal radiation-induced cause of HT, but the results have been inconclusive. This study tests the same hypothesis on a larger patient cohort than the previous studies.

**Material and Methods**

84 patients with anal squamous cell carcinoma were included. All patients underwent a FDG-PET scan prior to curative CRT. Lymphocyte counts were collected during and after treatment on a weekly to monthly basis. Lymphopenia was defined as lymphocytes nadir (LN) lower than 0.5 × 10<sup>9</sup> cells/L (≥ grade 3, CTCAE v5.0). The pelvic bones from the top of the iliac crest to 1-2 cm below the lesser trochanter of femur, as defined by CT, was used as a surrogate for total bone marrow (TBM). ABM<sub>x</sub> was defined as the subvolume of TBM that exhibited the X% highest FDG-uptake, respectively (Figure 1). Median dose to the volumes was calculated. Linear and logistic regression were used to assess the correlation between dose to BM and LN and lymphopenia, respectively. The bootstrap technique was used to generate 95% confidence intervals (CI) for model comparison.

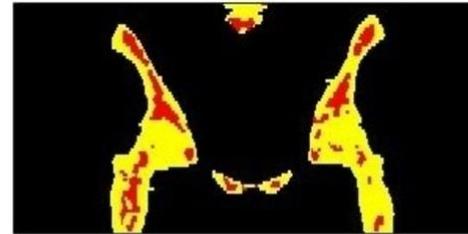

Figure 1: Delineation of ABM<sub>25</sub>. ABM<sub>25</sub> is the subvolume of TBM with the highest 25% FDG-uptake. Red = ABM<sub>25</sub>, yellow = TBM-ABM<sub>25</sub>. Abbreviations: ABM = active bone marrow, TBM = total bone marrow, FDG = [<sup>18</sup>F]fluorodeoxyglucose.

**Results**

Median lymphocytes nadir was 0.3 × 10<sup>9</sup> cells/L (range; 0.0 - 0.8 × 10<sup>9</sup> cells/L). Table 1 shows results from univariate linear regression analyses. All dose metrics were significantly associated with LN (p < 0.001). The model with the highest r<sup>2</sup> was that for ABM<sub>25</sub>, but 95% CIs for adjusted r<sup>2</sup> were [0.03, 0.28] and [0.07, 0.44] for TBM and ABM<sub>25</sub>, respectively, showing that the best ABM model was not superior to the TBM model. Lymphopenia occurred in 71 (85%) patients. The incidence of lymphopenia was associated with median dose to TBM, ABM<sub>75</sub>, ABM<sub>50</sub>, ABM<sub>25</sub> and ABM<sub>10</sub> (p < 0.05), with ABM<sub>75</sub> being the strongest predictor. Bootstrapping gave log-likelihood 95% CIs of [-36.6, -15.7] and [-35.0, -13.7] for TBM and ABM<sub>75</sub>, respectively, showing that the best ABM model did not significantly outperform the TBM model.

Table 1: Univariate linear regression with lymphocytes nadir (x10<sup>9</sup> cells/L) as response variable and median dose (Gy) to bone marrow volume as predictor variable.

Dosimetric parameter	β	95% CI	p value	Adjusted R <sup>2</sup>
TBM	-0.010	[-0.016, -4.5e-3]	5.9e-4	0.124
ABM <sub>75</sub>	-9.0e-3	[-0.013, -5.1e-3]	1.3e-5	0.199
ABM <sub>50</sub>	-8.1e-3	[-0.011, -4.8e-3]	4.7e-6	0.217
ABM <sub>25</sub>	-7.4e-3	[-0.010, -4.6e-3]	1.2e-6	0.242
ABM <sub>10</sub>	-6.0e-3	[-8.5e-3, -3.5e-3]	6.8e-6	0.210

Abbreviations: TBM = total bone marrow, ABM<sub>x</sub> = subvolume of TBM that exhibited the X% highest FDG-uptake, β = regression coefficient, CI = confidence interval, FDG = [<sup>18</sup>F]fluorodeoxyglucose.

**Conclusion**

Irradiation of pelvic bone marrow was associated with risk of developing lymphopenia following treatment. However, models using ABM, defined by FDG uptake, did not significantly improve model performance compared to models using TBM. One reason for this might be the strong

correlation between median dose to TBM and ABM (Pearson's  $r = 0.78$  between TBM and ABM<sub>25</sub>). In future works a clinical trial can be considered where one group is treated according to standard clinical practice and the other with an ABM sparing dose plan. This will reduce the correlation between TBM and ABM volumes, making it easier to evaluate the predictive power of FDG-PET-based models for HT.

**EP-2028 Pilot study: Textural features of mpMRI for response assessment in prostate cancer patients**

<sup>1</sup>Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria ; <sup>2</sup>Medical University of Vienna, Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Vienna, Austria ; <sup>3</sup>EBG MedAustron GmbH, Medical Physics, Wr. Neustadt, Austria ; <sup>4</sup>Umeå University, Department of Radiation Sciences, Umeå, Sweden ; <sup>5</sup>Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria

**Purpose or Objective**

Multiparametric (mp)MRI is a well-established tool for response assessment in radiation oncology. In view of the upcoming analytical methodology of radiomics, the potential of Haralick textural features (TF) in the context of response assessment has so far not been fully explored. The aim of this study is thus to investigate the added value of Haralick textural features for response assessment in prostate cancer (PCa) radiotherapy.

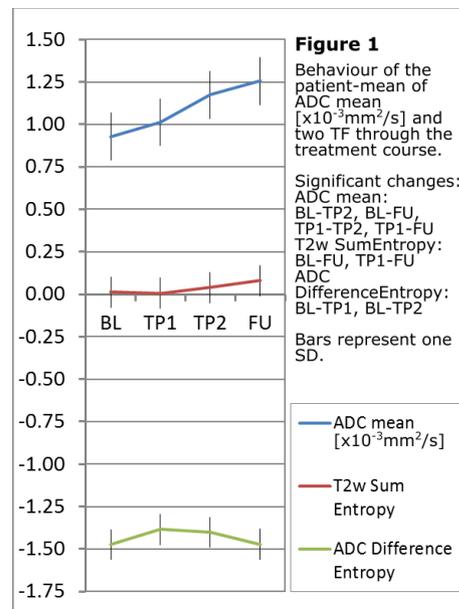

**Material and Methods**

21 PCa patients were enrolled in this longitudinal prospective IRB approved response assessment study, consisting of mpMRI at four time points (TP): at baseline (BL), in week 2 of treatment (TP1), in week 4 of treatment (TP2) and 3 months after end of EBRT as follow up (FU). Inclusion criteria were biopsy proven primary PCa, external beam radiotherapy (EBRT) and no contraindications to MRI. mpMRI was performed on a 3T scanner (MAGNETOM® Trio Tim, Siemens). For TF analysis T2-weighted (T2w) and apparent diffusion coefficient (ADC) MRI data were used.

Data collection of seven patients could be completed so far. The preliminary results are based on these 7 full datasets. The tumour lesion was delineated by an experienced radiologist on the BL T2w image dataset. The lesion was propagated to the other TP via rigid registration of the T2w images. Manual adaptations were performed on both T2w and ADC images in cases of tumour shrinkage, image distortions or artefacts caused by air in the rectum or movement. Both image datasets were normalized. Mean T2w and ADC values were extracted. After histogram equalization, 20 grey level invariant Haralick TF [1] were calculated for each modality. Data handling, visualization, image registration, pre-processing and feature extraction were carried out using MICE Toolkit® (© 2018 NONPI Medical AB). All features were tested for significant changes between TP with a Student's t test. **Results** Mean T2w grey level did not change significantly between TP. In total, for five T2w and 13 ADC TF significant changes could be identified during or after EBRT. Significance levels of the corresponding TF and the mean ADC for  $p < 0.05$  are presented in table 1 for each pair of TP. For better comparability, the behaviour of mean ADC, T2w SumEntropy and ADC DifferenceEntropy is plotted in figure 1.

T2w	BL	BL	BL	TP1	TP1	TP2
	TP1	TP2	FU	TP2	FU	FU
mean						
Entropy					0.05	
Correlation	None	None		None	0.001	None
SumEntropy			0.04		0.007	
InformationMeasureOfCorrelation1			0.02			
InformationMeasureOfCorrelation2			0.02			
ADC	BL	BL	BL	TP1	TP1	TP2
	TP1	TP2	FU	TP2	FU	FU
mean		0.01	0.01	0.04	0.02	
InverseDifference	0.01					
Entropy	0.02					
Energy	0.05					
DifferenceVariance	0.04	0.001				
DifferenceEntropy	0.02	0.005				
Contrast	0.02	0.005				
Homogeneity	0.02	0.007				None
Dissimilarity	0.01	0.04				
DifferenceAverage	0.01	0.04				
ClusterShade		0.03				
SumAverage			0.02			
Autocorrelation			0.03			
SumEntropy				0.05		

**Table 1** Significant changes of T2w and ADC TFs for each pair of time points. Non-significant TF are not listed.  $p < 0.01$  is highlighted as bold.

Nine ADC TF showed very early changes already in the second week of treatment (TP1). Three T2w features and two ADC features (SumAverage and Autocorrelation) differed significantly with respect to FU. Correlation to clinical outcome was not assessed in the scope of this preliminary analysis, but will be part of the final evaluation.

**Conclusion**

This pilot study demonstrated that T2w and ADC TF of PCa lesions change during EBRT. The results might suggest that some TF reflect very early response mechanisms while others could aid mid-term response assessment. These primary findings motivate further analysis of the remaining patient datasets.

**EP-2029 Principal component analysis for quantitative and robust analysis of dynamic PET/MR imaging data**

R. Winter<sup>1</sup>, S. Leibfarth<sup>1</sup>, S. Boeke<sup>1,2</sup>, P. Mena-Romano<sup>1</sup>, M. Krueger<sup>3</sup>, E. Cumhur Sezgin<sup>2</sup>, G. Bowden<sup>3</sup>, J. Cotton<sup>3</sup>, B. Pichler<sup>3,4</sup>, D. Zips<sup>2,4</sup>, D. Thorwarth<sup>1,4</sup>

<sup>1</sup>University Hospital Tübingen, Radiation Oncology-Section for Biomedical Physics, Tübingen, Germany ; <sup>2</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany ; <sup>3</sup>Werner Siemens Imaging Center, Preclinical Imaging and Radiopharmacy, Tübingen, Germany ; <sup>4</sup>German Cancer Consortium DKTK- partner

site Tübingen, and German Cancer Research Center DKFZ, Heidelberg, Germany

### Purpose or Objective

To investigate principal component analysis (PCA) as an alternative strategy to pharmacokinetic modelling for quantitative and more robust analysis of dynamic PET or contrast-enhanced (DCE) MRI data on a voxel level.

### Material and Methods

In 31 immuno-deficient nude mice, five different ectopic head and neck squamous cell carcinoma xenografts (subcutaneous, hind leg) were investigated with simultaneous PET/MRI (7T, Bruker Biospec). Tumor radiation sensitivity, i.e., tumor control dose 50% (TCD<sub>50</sub>) to clinically relevant irradiation with 30 fractions in 6 weeks have been previously published [1]. The imaging protocol included dynamic FMISO-PET over 90 min, T2-weighted (T2w) MRI and DCE T1-weighted MRI (750 s, 139 frames).

Tumor tissue was delineated on T2w MRI data. Necrotic tissue was excluded based on DCE-MRI information (low temporal median enhancement). The Brix model was fitted to the DCE-MRI tumor data on the voxel level. Standard deviations (SD) obtained from the fit covariance matrix were used to estimate the robustness of the fit parameters.

For PCA, DCE signal data  $S(t)$  was converted to relative signal increase  $RSI(t) = (S(t) - S_0) / S_0$ , where  $S_0$  represents the mean signal before contrast agent injection. PCA was then applied to the RSI data of the total set of tumor voxels of all animals.

Finally, parameter maps were calculated for both Brix and PCA. For each map, different thresholds were tested to identify volume fractions that would allow for stratification in terms of TCD<sub>50</sub>.

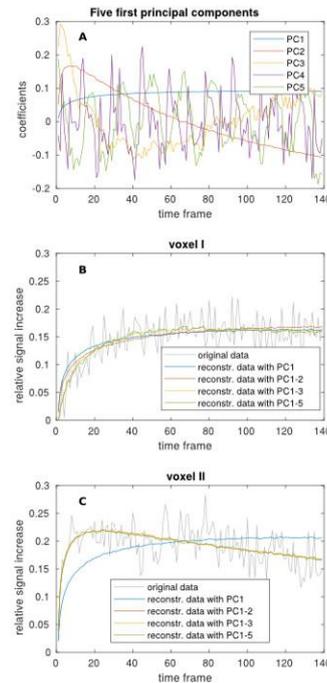

### Results

DCE-derived Brix parameters presented with highly varying SDs resulting in large fit inaccuracies on the voxel level.  $A_{Brix}$  was found to be more robust than  $K_{ep}$ . However,  $35 \pm 14\%$  of the voxels within a tumor (mean  $\pm$  SD over all tumors) showed a relative SD of  $A_{Brix}$  greater than 0.3. Both visual and mathematical examination of voxel curve data indicated that PCA allows for dimensionality and noise reduction in the recorded DCE data. Reconstructing the data with just the first two principle components reduced the number of variables extremely (139 time points) while most of the temporal information was still captured. Further principal components seem to rather depict noise (Figure 1). The percentage of the total variability expressed by the principal components PC1 to PC5 was 94.22, 1.95, 0.18, 0.11 and 0.10%, respectively. In a first analysis, similar results were found for PCA of dynamic FMISO-PET data.

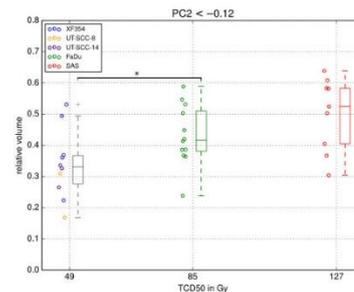

Threshold-based analysis of parameter maps indicated that the relative volume presenting with  $PC2 < -0.12$  correlates with TCD<sub>50</sub> (Figure 2). No such correlation was found for Brix parameters, other principal components, or any mean parameter values.

### Conclusion

PCA may be a more robust alternative to pharmacokinetic modelling for the analysis of functional image data on a voxel level and may reveal relevant information e.g. in terms of prediction of tumor response to therapy. Further investigation of PCA on patient data seems promising. [1] Yaromina et al., Radiother Oncol 96:116 (2010)

**Figure 1:** PCA on DCE RSI data. A: Five first principal components in descending order of component variance. B, C: The accuracy of data reconstruction with principal component coefficients is demonstrated for two different tumor voxels by successively increasing the number of principal components.

**Figure 2:** Relative volume of  $PC2 < -0.12$  seems to correlate with radiation sensitivity (TCD<sub>50</sub>) of the different tumor models. A Wilcoxon rank sum test was used for statistical analysis. Note that the one FaDu and one SAS tumors with volume fractions  $\leq 0.3$  were much smaller in size ( $< 600$  voxels) compared to the rest of the ensemble (mean  $\pm$  SD:  $1938 \pm 721$  voxels).

**Acknowledgements:** Research has received funding by the European Research Council (ERC).

### EP-2030 Multiparametric MRI and FMISO PET in HNSCC and its relation with outcome

<sup>1</sup>University of Freiburg, Department of Radiation Oncology- Medical Center University of Freiburg, Freiburg, Germany; <sup>2</sup>German Cancer Research Center DKFZ- German Cancer Consortiumion DKTK, Partner Site Freiburg, Heidelberg, Germany; <sup>3</sup>University of Freiburg, Department of Radiology- Medical Physics- Medical Center University of Freiburg, Freiburg, Germany; <sup>4</sup>University of Freiburg, Department of Nuclear Medicine- Medical Center University of Freiburg, Freiburg, Germany

### Purpose or Objective

Purpose of the current study was to assess the effect of radiochemotherapy (RCT) on tumour hypoxia assessed by <sup>18</sup>F-misonidazole PET/CT (FMISO PET) and on multiparametric (mp) MRI parameters in HNSCC at an early (week 2) and late (week 5) time point during treatment and to analyse the relation between mpMRI and PET parameters with local control.

### Material and Methods

Thirty-four patients with stage III to IVb HNSCC (UICC 7th edition) undergoing definitive RCT (total dose 70 Gy, 3 cycles of cisplatin administered over 7 weeks) were included in this study. Patients were prospectively imaged with <sup>18</sup>F-FDG PET/CT at baseline and with serial FMISO PET and serial 3 Tesla mpMRI for T1w-, T2w-TSE, dynamic contrast enhanced (DCE) perfusion measurements ( $k_{trans}$ ,  $v_e$ ) and diffusion weighted measurements (DWI) including apparent diffusion coefficient (ADC) maps in weeks 0, 2 and 5. Gross tumour volumes for tumour (GTV-T) and normal tissue (NT) were contoured. For MRI and FMISO PET analysis, mean values and SUVmax were obtained within GTV-T and NT. Patients were identified as responders or non-responders during follow-up. SUVmax FMISO PET and mean values for mpMRI parameters at weeks 0, 2, and 5 were compared between responders and non-responders with the t-test at a significance level of  $p \leq 0.05$ .

### Results

20 patients met inclusion criteria for image analysis by presenting a complete set of serial FMISO PET data and serial 3T MRI data. Mean follow-up time was 9.5 months. 11 patients were diagnosed with local recurrence. For GTV-T, responders showed less tumour hypoxia on FMISO PET than non-responders for weeks 0 and 2 (SUVmax=2.15±0.39 vs. 2.48±1.28 and 1.95±0.39 vs. 2.05±0.39,  $p > 0.05$ ). Baseline tumour volume was larger for non-responders than for responders (54.4±57.5ml vs. 31.0±15.1ml,  $p > 0.05$ ) and decreased at week 5 to 25.3±36.3 ml vs. 13.6±9.4 ml,  $p > 0.05$ . On mpMRI, tumour apparent diffusion coefficient ADC increased over time for both responders and non-responders from week 0 to 5. The increase was higher for responders than non-responders (51.1% vs. 5.7%,  $p = 0.094$ ). The volume transfer constant  $k_{trans}$  increased from week 0 to 5 for both responders and non-responders. The increase was higher for non-responders than responders (27.4% vs. 11.3%,  $p > 0.05$ ) and differed in pattern, as for non-responders the increase in  $k_{trans}$  reached a maximum at week 2 and then dropped, while for responders a steady increase in  $k_{trans}$  was found until week 5 (non-responders vs. responders (week 2 to 5:  $-0.107 \text{ min}^{-1}$  vs.  $+0.021 \text{ min}^{-1}$ ). Interstitial space volume fraction  $v_e$  was increased between week 0 and 5 by 37.8% for responders vs. 27.1% for non-responders,  $p > 0.05$ .

### Conclusion

Tumour volume and FMISO-PET-derived tumour hypoxia were higher among patients with local relapse as compared to locally controlled patients ( $p > 0.05$ ). DCE parameters  $k_{trans}$  and  $v_e$  and DW parameter ADC differed between relapsing and non-relapsing patients, however without reaching statistical significance in this cohort. Further studies are ongoing.

### EP-2031 <sup>18</sup>F-Choline-PET-CT to guide simultaneous integrated boost in prostate cancer

R. Pearson<sup>1</sup>, R. Samuel<sup>2</sup>, H. McCallum<sup>3</sup>, J. Frew<sup>3</sup>, E. Howell<sup>4</sup>, R. Maxwell<sup>4</sup>

<sup>1</sup>Newcastle University, Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom ; <sup>2</sup>Leeds Cancer Centre, Dept of Clinical Oncology, Leeds, United Kingdom ; <sup>3</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom ; <sup>4</sup>Newcastle University, Centre for In Vivo Imaging, Newcastle upon Tyne, United Kingdom

### Purpose or Objective

<sup>18</sup>F-fluorocholine positron emission tomography (PET-CT) has an established role in detecting recurrent prostatic carcinoma but is not routinely used to guide radiotherapy delineation in the UK. Radiotherapy dose escalation to a boost volume has potential to improve tumour control and is the focus of current research protocols using MRI. A suitable boost volume may be defined as <50% of the total prostate volume on MRI, however quantitative PET may

also hold utility in defining targetable boost regions. The aim of this study was to evaluate the feasibility of defining a deliverable simultaneous integrated boost (SIB) to a dominant intraprostatic lesion (DIL) in the context of intensity modulated radiotherapy using automated thresholding of <sup>18</sup>F-fluorocholine PET within a radiotherapy treatment planning system.

### Material and Methods

Five prostate cases were selected. All patients had high risk prostate cancer and were on androgen deprivation therapy. DILs were defined automatically by 60%, 70% and 80% of maximum prostatic uptake of <sup>18</sup>F-fluorocholine on PET-CT using the RayStation 7 Treatment Planning System. A comparison of prostate gross tumour volumes (GTV), planning target volumes (PTV) and SUVmetrics between DIL and prostate gland was undertaken. PTVprostate was defined on MRI/CT as whole prostate GTV plus 5mm, (posterior margin 3mm). PTV DIL was defined as GTV plus 3mm. Median values for PTVs with ranges are reported.

### Results

Median SUVmax of prostate gland was 8.5 (range 4.9 - 18.1). All patients had Gleason 9 disease. Median prostate GTV was 44.6 cm<sup>3</sup> (range 21.0 - 73.4 cm<sup>3</sup>). Median GTV for DIL defined by 60% SUVmax was 9.2 cm<sup>3</sup> (range 2.6 - 24.9 cm<sup>3</sup>) accounting for 16% of the prostatic GTV (range 6 - 33.9%). Median GTV for DIL defined by 70% SUVmax was 4.4 cm<sup>3</sup>, 8.2% of prostatic GTV (range 2.9 - 17.2). Median DIL defined by 80% SUVmax was 1.5 cm<sup>3</sup>, 2.7% of prostatic GTV (range 0.4 - 5.9%).

Region of Interest	Median volume cm <sup>3</sup> (range)	Median % prostate (range)	volume PTV
PTV prostate (manual)	83.2 (45.6 - 124.6)	-	-
60% SUVmax (automated PTV)	13 (8.6 - 46.2)	18.9 (8.5 - 37)	
70% SUVmax (automated PTV)	7.9 (4.7 - 31.1)	10.3 (5.4 - 24.9)	
80% SUVmax (automated PTV)	3.8 (1.2 - 15.6)	4.5 (2.6 - 16)	

### Conclusion

DIL defined using automated thresholding of 60% and 70% of SUVmax was technically feasible using readily available treatment planning software. 60% of SUVmax defined a suitable boost volume with DILs <50% of the total prostate volume. The impact of this metric on organ-at-risk constraints in the context of dose escalation is being studied in a larger cohort. Ongoing work is examining how these PET-derived boost volumes compare with MR lesions and how PET-MRI may have utility in this context.

### EP-2032 Automated Bone Scan Index (aBSI) as an Imaging Biomarker in Castration Sensitive Prostate Cancer

A. Alshehri<sup>1,2</sup>, J. O'Sullivan<sup>2,3</sup>, K. Prise<sup>2</sup>, S. Jain<sup>2,3</sup>, P. Turner<sup>3</sup>, C. Campfield<sup>1</sup>, S. Biggart<sup>1</sup>, C. Chatzigiannis<sup>1</sup>, A. Cole<sup>2,3</sup>

<sup>1</sup>Northern Ireland Cancer Centre- Belfast Health and Social Care Trust, Nuclear Medicine Department, Belfast, United Kingdom ; <sup>2</sup>Centre for Cancer Research and Cell Biology- Queen's University Belfast, Cancer Research and Cell Biology, Belfast, United Kingdom ; <sup>3</sup>Northern Ireland Cancer Centre- Belfast Health and Social Care Trust, Oncology, Belfast, United Kingdom

### Purpose or Objective

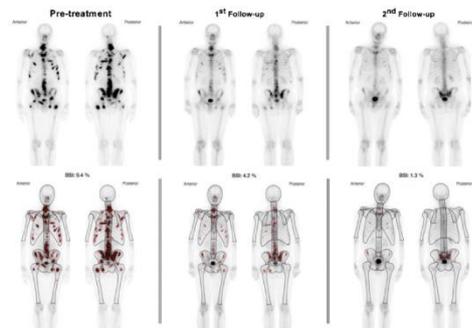

There is an unmet need for monitoring response to prostate cancer therapeutics in the management of bony metastases. A number of modalities including whole body MRI, PSMA-PET, CT scanning and Isotope Bone Scans (IBS) are used dependent on resources and centre preference.

Of these IBS is the most widely used in staging and initial management decisions. Often decisions regarding treatment are based on changes in ALP and PSA in the absence of radiological information. We present preliminary data from a Phase II trial exploring the use of Radium-223 (Ra-223) in combination with prostate and pelvic radiotherapy post docetaxel in a metastatic castration sensitive prostate cancer (mCSPC) (> 3 bone metastases, no lymph node or visceral disease T4N0/1M1b).

#### Material and Methods

Twenty-eight metastatic castration sensitive prostate cancer (mCSPC) patients were treated with monthly injections of radium-223 along with castration therapy and Volumetric Modulated Arc Therapy (VMAT) to the prostate and pelvic lymph nodes. Fifteen of the eligible mCSPC patients had baseline bone scans and treatment follow-up bone scans (during and post-treatment) available for automated aBSI analysis. The EXINI aBSI software programmed was used to retrospectively analyse the IBS and generate the aBSI value. Alkaline phosphatase (ALP) and Prostate Specific Antigen (PSA) values were collected. **Results**

Fifteen patients had at least 2 pre and post Ra-223 IBS available for analysis. All 15 patients had a reduction or stability in the aBSI reading. There was a median reduction of 71.5% (-350-88.9%) in the aBSI with a number of patients having almost complete resolution of quantifiable disease on bone scan as evidenced in Figure 1. All 15 patients included had a reduction in ALP from Cycle 1 to Cycle 6 with treatment, median reduction from cycle 1 90 (65-236) to cycle 6 59 (37-165). Over a median follow up period of 25.9 months the median overall survival and progression free survival have not yet been reached.

#### Conclusion

aBSI allows quantitative measurement of response to bone targeted therapies. It is more standardised, readily available and more economically sustainable than other modalities as a post therapeutic monitoring tool in bony metastatic setting. It's use in the castration sensitive prostate cancer setting with Ra-223 has not been previously documented, two-thirds of the patients in this study have prolonged reductions in aBSI in excess of 2 years post commencement of LHRHa. Further comparison with wbMRI in this study will allow comparison of response and prognostic information.

#### EP-2033 Impact of CBCT roll rotation artifact on adaptive online cranial SRS of multiple targets

J. Casals Farran<sup>1</sup>, J.F. Calvo-Ortega<sup>1</sup>, S. Moragues Femenia<sup>1</sup>, C. Laosa<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

#### Purpose or Objective

Roll artifacts up to 1° in CBCT scans have been described in the literature for the Varian OBI system [Phys Med Biol. 2013 Feb 21;58(4):1059-73]. Our aim is to investigate the dosimetric impact of this artifact on cranial SRS planning using an online adaptive procedure developed by our group [Med Dosim. 2013 Autumn;38(3):291-7].

#### Material and Methods

A Varian Clinac 2100 CD equipped with an OBI system was used. After placing a phantom (Easy Cube phantom, Scanditronix.....) on the treatment couch, 2 CBCT scans (CCW and CW directions) were acquired with the SRS protocol used for our CBCT-based SRS procedure. Proper leveling of the phantom was done before CBCT imaging by using a digital level with ± 0.1° accuracy (Smart Tool, M-D Building Products), and it was not moved between both scans. The differences between both CBCT scans were analyzed and the roll error observed in the axial reconstructed images was measured. Ten (10) independent measurements for each acquisition direction (CCW and CW) were performed to know the roll error inherent to the CBCT images (θ).

We randomly selected 10 cases of multiple brain metastases planned with a single isocenter. For each one, the CBCT scan acquired during patient setup (CBCTref) was corrected by applying a rotation of -θ° to the axial planes (CBCTcorr). A single-isocenter reference plan was calculated over the CBCTref (Plan\_ref), and then was also re-calculated over the generated CBCTcorr scan (Plan\_corr). Both plans were compared in order to know the dosimetric impact of these rotations in the target coverage (D99%) when the uncorrected CBCTref scan is used for adaptive SRS planning. Differences in D99% were given respect to the prescription dose (PD) of each target: [D99%@Plan\_corr - D99%@Plan\_ref]/PD. **Results**

Average roll errors of 0.3° (range: 0.1° to 0.4°) and 0.5° (range: 0.3° to 0.8°) were found for the CCW and CW-CBCT acquisitions, respectively. Target coverage differences (mean ± SD) of -1.0% ± 1.1% and -2.9% ± 2.1% were found for the CCW and CW-CBCT acquisitions, respectively.

#### Conclusion

Roll artifacts of less than 0.5° were detected in the CCW-CBCT direction acquisition. A negligible dosimetric impact (-1%) in the target coverage whether the CCW-CBCT scan is used for adaptive SRS planning. Only the CCW acquisition direction was selected for our SRS online procedure.

#### EP-2034 Evaluation of a web-based software for "Winston-Lutz" test analysis

J.F. Calvo Ortega<sup>1</sup>, M. Hermida-López<sup>2</sup>, S. Moragues Femenia<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain ; <sup>2</sup>Hospital Universitario Valle de Hebrón, Servicio de Física y Protección Radiológica, Barcelona, Spain

#### Purpose or Objective

The popular "Winston-Lutz (WL)" test is a well established procedure to check the congruency between the center of a target to be irradiated and the radiation linac isocenter.

In this work, we investigated the performance of a free web-based software to quantitatively analyze this test.

#### Material and Methods

A Varian Clinac 2100 CD equipped with the Millennium 120 MLC and the aSi-500 Portal Vision (EPID) was used (Varian Medical Systems, Palo Alto, CA). The EPID was placed with a source-detector-distance of 180 cm (0.4 mm/pixel at the isocenter plane). A tungsten ball (5 mm-diameter) was used as a target in the 2x2 cm<sup>2</sup> MLC-based WL test performed in our department.

One hundred fifty portal images (WL images) were retrieved from the Aria system to be analyzed using a web-based application ("Winston-Lutz-Automatic Analyzer", <http://winston-lutz.herokuapp.com/>), and also with a FDA (U.S. Food and Drug Administration) accredited software (DoseLab Pro v. 6.40, Mobius Medical Systems, LP, Houston, TX). DoseLab was used as reference.

Both softwares calculate on each portal image the distance between the centroid of the tungsten ball shadow and the radiation field center ("delta"). Different image processing tools and algorithms are implemented in each software. Delta values given by both softwares were compared, and agreement between both softwares was assessed using the Bland-Altman method.

#### Results

An average difference (bias) in "delta" metric of -0.01 mm (SD: 0.13 mm) was found. The 95% limits of agreement between both softwares were from -0.28 mm to 0.25 mm.

#### Conclusion

The 95% limits of agreement found were comparable to the pixel size of the portal images analyzed (0.4 mm). Therefore, the results given by Winston-Lutz-Automatic Analyzer are comparable to those reported by DoseLab Pro for WL test analysis.

#### EP-2035 Robust optimization of CT reconstruction and scanning parameters

S. Alani<sup>1</sup>, E. Gez<sup>1</sup>, J. Zidan<sup>1</sup>

<sup>1</sup>*ziv medical center, radiation oncology, zefad, Israel*

#### Purpose or Objective

CT simulation has become an integral component of modern RT planning and therefore needs to be continually optimized. We improved the detection of small and low-contrast regions in images obtained during CT simulation by optimization of CT reconstruction and scanning parameters. For potential applications involving detection of low-contrast tumor structures

#### Material and Methods

A CT phantom containing a contrast detail modulus for detection of low-contrast structures was used to optimize the CT protocol. The parameters (A) Pitch, (B) Reconstruction Filter, and (C) Rotation Time type were varied for assessment of image quality. Three factors, three levels, and nine experiments were identified. According to the Taguchi approach an L9 orthogonal array was selected. The reconstruction parameters of the CT scanner Toshiba aquilion Pitch, Reconstruction Filter type, and Rotation Time, were iteratively scanned according to the orthogonal array. A Catphan 604 CT phantom was used to characterize low-contrast resolution (CPT730 module). All CT scan images were analyzed by IMAGE-OWL software. The objective of the study was to identify parameters that maximize the low-contrast resolution of the images. The ANOVA and F-tests were used to analyze results using JMP 14.1.0 statistical software.

#### Results

The optimal settings and predicted optimal values for low-contrast resolution were determined. The ANOVA was used to determine the optimum combination of process parameters more accurately by investigating the relative importance of each process parameter. We determined that Pitch (61.3%) had the most significant influence on low contrast resolution, followed by the Reconstruction Filter type (31.3%). The optimal setting level is A1-B1-C3,

0.68 pitch, smooth filter, and gantry rotation time 1.5 sec, respectively. In the phantom model of this study, optimal Contrast Detail Values were determined to be: 1% contrast, 2mm; 0.5% contrast, 4mm; 0.3% contrast, 7mm. Additional measurements were made to confirm the prediction error model is justified and the results are validated.

#### Conclusion

Protocol was improved comparing to those using the standard clinic protocol. CT image quality can be improved with the protocol created in this study, to provide better soft tissue contrast, which would be beneficial for RT contouring for SBRT and stereotactic radiosurgery in which accurate delineation of small-sized, low-contrast regions are important.

#### EP-2036 Visualization of prostate fiducial markers using phase-cycled bSSFP MRI

Y. Shcherbakova<sup>1</sup>, S. Mandija<sup>1</sup>, L.W. Bartels<sup>1</sup>, L.G.W. Kerkmeijer<sup>2</sup>, J.R.N. Van der Voort van Zyp<sup>2</sup>, C.A.T. Van den Berg<sup>2</sup>

<sup>1</sup>*UMC Utrecht, Center for Image Sciences/Imaging Division, Utrecht, The Netherlands*; <sup>2</sup>*UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands*

#### Purpose or Objective

The existing manual techniques for visualization of gold fiducial markers (FMs) are mostly based on spoiled gradient-echo imaging (SPGR). FMs appear as signal voids in magnitude images, which makes it difficult to distinguish them from hemorrhages/calcifications. Being able to distinguish FMs in MR images is crucial for MR-only RT, where CT images are not available. Automatic FMs detection methods are available, but require special software which is not available at the MR console. Here we investigated a new method for distinctive FMs visualization in the prostate for MR-only RT which facilitates FMs detection at the MR console.

#### Material and Methods

A dynamic bSSFP scan is performed with RF phase cycling, where for each dynamic acquisition the phase of the RF excitation pulse is increased stepwise according to a certain incrementing scheme.

Complex phase-cycled bSSFP images were acquired on a phantom (agar phantom with 4 gold FMs GM1054 implanted) and on 8 patients at 3T: TR 9.2 ms, TE 4.6 ms, FA 20°, FOV (phantom) 200x200x80mm<sup>3</sup>, FOV (patients) 320x320x60 mm<sup>3</sup>, acquisition voxel size 2x2x2 mm<sup>3</sup>, reconstruction voxel size 1x1x1 mm<sup>3</sup> for both setups, 6 dynamics acquisitions with RF phase increment of , scan time 01:48 min (phantom) and 02:12 min (patients).

On each dynamic acquisition the manifestations of the magnetic field distortions around the FMs (the artifacts) are different due to different frequency offset related to the corresponding RF phase. Thus, the contrast from FMs in the images appears different for each dynamic acquisition.

CT scans of the phantom and patients were acquired. The distances between the centers of the markers were measured both on MRI and CT images by 1 observer. The accuracy of detecting FMs by was assessed by comparing the measured distances between FMs on MRI and CT images.

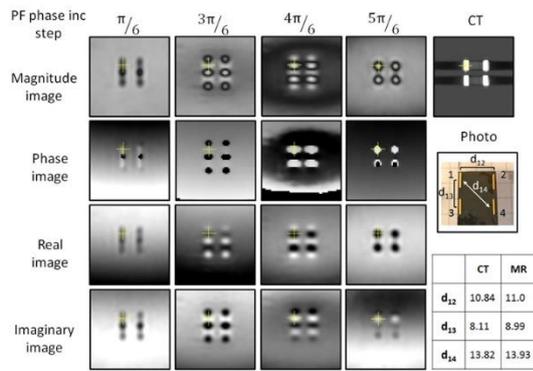

Figure 1. Experimental results in the phantom: MR images (Magnitude, Phase, Real, and Imaginary) acquired using 6 phase-cycled bSSFP, CT image for comparison for one coronal slice. The measured distances between the FMs using CT and MR images.

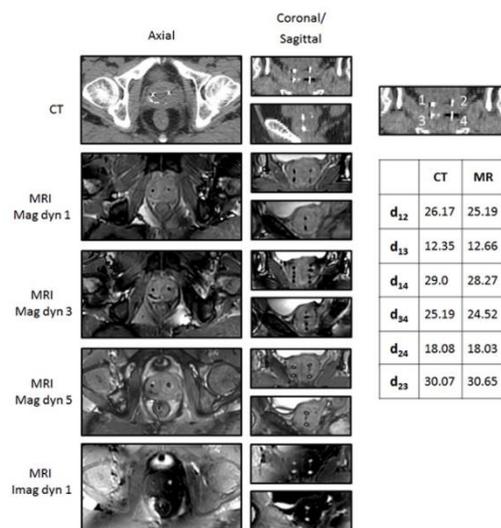

Figure 2. Experimental results in prostate: CT images and MR images acquired using 6 phase-cycled bSSFP (Magnitude Dynamics 1,3,5, Imaginary Dynamic 1) for axial, Coronal and sagittal planes. The measured distances between the FMs using CT and MR images.

## Results

The experimental results in the phantom are shown in Figure 1. Complex MR images are shown on one coronal slice for different dynamic acquisitions. These images show a distinct MR contrast given by the FMs for each dynamic. A CT image is shown as comparison. The differences between the distances between all FMs measured using MR and CT are within 1mm, proving correct FMs detection.

The CT and MR images of the prostate with implanted FMs are shown in Figure 2 for one patient. The same variable contrast of the FMs can be seen dependent on the RF phase increment used. FMs can be clearly seen on the acquired images. Similar results were observed in the other 7 patients. The < 1 mm differences in the distances between all FMs measured using MR and CT proves correct FMs detection.

## Conclusion

We have presented a method for direct FMs visualization at the MR console. The method is based on phase-cycled bSSFP imaging, providing different contrast of FMs dependent on RF phase increment used. This method does not require any additional post processing or software and can be easily done directly at the scanner. This is relevant especially for MR-only prostate RT.

## EP-2037 Digital phantom for evaluating the dosimetric impact of MRI Geometric inaccuracy in MR only based RT

T. Torfeh<sup>1</sup>, R. Hammoud<sup>1</sup>, S. Paloor<sup>1</sup>, S. Aouadi<sup>1</sup>, N. Al-Hammadi<sup>1</sup>

<sup>1</sup>National Center for Cancer Care & Research, Radiation Oncology, Doha, Qatar

### Purpose or Objective

Magnetic Resonance Imaging (MRI) is increasingly being used in radiotherapy applications for tumor delineation and tracking in the presence of respiratory motion. The purpose of this work is to investigate the impact of magnetic resonance distortions on dose distributions during respiratory motion.

### Material and Methods

An in-house motion platform and a control point based phantom were used to calculate an MR distortion map during motion for a Cine sequence which is the standard sequence for target delineation in liver cancer RT.

The calculated distortion map was used to distort original images generated from a 3D virtual phantom as shown in figure 1 which is composed of a C shape target of 5 and 7 mm of inner and outer diameters respectively. This C shape is surrounding a spherical target shape of 5 mm diameter. Another ellipsoidal organ shape with a width of 6 mm and a height of 5 mm is also included.

A dataset of 42 dicom images was finally generated with a resolution of 512X512 pixels, a 3 mm slice thickness, a 0 mm gap between slices and a pixel size of 0.97x0.97 mm.

Targets on the original and distorted datasets were automatically delineated. A treatment plan for liver cancer treatment was computed on EclipseTM TPS using the distorted dataset. This plan was then copied on the original dataset and the dose distribution was analysed. A highly conformal volumetric modulated arc therapy (VMAT) technique using multiple noncoplanar arcs was used. Dose Volume Histograms (DVH) including  $D_{95}$ ,  $D_{50}$ ,  $D_{min}$  and  $D_{mean}$  were benchmarked for accuracy measurements.

### Results

The mean magnitude of the geometric distortion was 0.5, 0.7 and 0.9mm for radial distances of 50, 100 and 150 mm respectively. Blurring was observed during motion causing an increase in the FWHM of  $\approx 30\%$ . Our results showed differences of less than 5% in the DVH parameters distorted and undistorted treatment plans. Results also showed that the difference in the DVH is sensitive to the size and position of the tumor. Higher differences were recorded as the distance to the isocentre increases and/or the tumor size decreases.

### Conclusion

The present work is a preliminary study aimed at putting in place an infrastructure allowing addressing the dosimetric impact of image deformation with any anatomy of interest.

Further investigations using more realistic shapes will be carried out with the idea of producing 3D patient specific models for SBRT evaluation.

## EP-2038 Use of deformable image registration for automatic outlining of the rectum

S. Hunt<sup>1</sup>, S. Thomas<sup>1</sup>, J. McClelland<sup>2</sup>, K. Harrison<sup>3</sup>, C. Rose<sup>1</sup>, J. Scaife<sup>4</sup>, M. Sutcliffe<sup>5</sup>, N. Burnet<sup>4</sup>, R. Jena<sup>6</sup>

<sup>1</sup>Cambridge University Hospitals NHS Foundation Trust, Medical Physics Box 152, Cambridge, United Kingdom ;

<sup>2</sup>University College London, Centre for Medical Image Computing, London, United Kingdom ;

<sup>3</sup>University of Cambridge, Department of Physics, Cambridge, United Kingdom ;

<sup>4</sup>University of Cambridge, Department of Oncology, Cambridge, United Kingdom ;

<sup>5</sup>University of Cambridge, Department of Engineering, Cambridge, United Kingdom ;

<sup>6</sup>Cambridge University Hospitals NHS Foundation Trust, Oncology, Cambridge, United Kingdom

## Purpose or Objective

We have evaluated deformable image registration (DIR) as a method of automatically outlining the rectum on pelvic megavoltage CT (MVCT) scans.

The rationale for this work is to retrospectively correlate the dose delivered to the rectum with the toxicity patients experience from external beam radiotherapy for prostate cancer. To calculate the dose delivered to the rectum, it must first be delineated on MVCT images acquired at the time of the patient's treatment. However, the study recruited 529 prostate patients who each received 20 or 37 treatment fractions; manual outlining for such a large number of images would clearly be impractical.

Our group currently uses a purpose-built automatic segmentation algorithm to outline the rectum on these images. However, DIR presents a potential alternative method of doing this, and we wished to investigate its performance for this purpose.

## Material and Methods

On six MVCT images from six different patients, the rectum was independently outlined by ten oncologists, according to our departmental protocols. They were also outlined using the automatic segmentation algorithm. The rectums on patients' original planning CT scans had been outlined by one oncologist at the time of treatment planning.

Three pieces of DIR-capable software were tested as part of this project:

- Prosoma (MedCom, Darmstadt, Germany)
- Pinnacle (Philips, Amsterdam, The Netherlands)
- RTx (Mirada, Oxford, United Kingdom)

Each piece of software was used to deformably register the patients' planning CT scans to their MVCT scans. The calculated deformations were then applied to the original rectum outline on the planning CT to propagate it to the MVCT dataset.

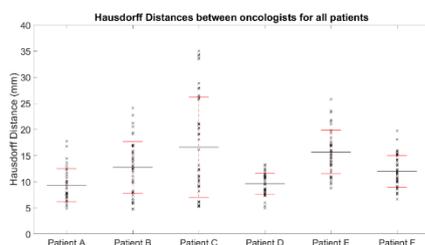

Contours were compared to one another using the Jaccard Index and Hausdorff Distance, to assess general volume overlap and gross spatial variation. Each oncologist's outline was compared to all others for each patient, to assess inter-observer variation in outlining. The outlines produced using DIR and automatic segmentation were then compared to each of the oncologists' outlines to assess the performance of the software.

## Results

The mean Jaccard Indices (JI) and Hausdorff Distances (HD) between the oncologists' outlines, and between outlines from each piece of software and each oncologist, are displayed in Table 1.

Table 1		Oncologists	Prosoma	Pinnacle	RTx	Auto. Seg.
Jaccard	Mean	0.68	0.62	0.60	0.62	0.58
Index	S.D.	0.06	0.09	0.07	0.08	0.10
Hausdorff	Mean	11.9	13.5	15.0	18.0	15.6
Dist. (mm)	S.D.	4.8	4.0	5.1	7.3	3.0

The figure below displays the variation in HD between each pair of oncologists for each of the six patients in this study. The central bar indicates the mean HD for that patient, while the smaller bars indicate the range of the mean  $\pm$  one standard deviation.

## Conclusion

The above results show that there is significant inter-observer variation in outlining of the rectum on MVCT images. In the context of this variation, DIR appears to produce outlines that are comparable to those of oncologists. These outlines may also be a superior alternative to the automatic segmentation algorithm currently used for this purpose.

## EP-2039 Validation Of The Direct Density™ Ct Image Reconstruction Algorithm

I. Peiro Riera<sup>1</sup>, E. Fernandez-Velilla Ceprià<sup>1</sup>, J. Quera Jordana<sup>1</sup>, O. Pera Cegarra<sup>1</sup>, N. Anton Comelles<sup>1</sup>, M. Prieto Carballo<sup>1</sup>, M. Algara López<sup>1</sup>

<sup>1</sup>Hospital del Mar, Radiotherapy Oncology, Barcelona, Spain

## Purpose or Objective

The standard kV setting for Simulation CT images in radiotherapy is 120kV. Planning Systems (TPS) use calibration curves at that energy for associating electron densities to Hounsfield units (HU). For contrast and radiation protection reasons, in some situations a different kV may be recommendable. This requires the commissioning of one calibration curve for each kV. In our work we analyze the Siemens reconstruction algorithm Direct Density™ (DD), which gives CT numbers proportional to relative electron densities (RED), independent of the kilo-voltage used. DD is evaluated and compared to the standard Filtered Back-Projection (FBP) in order to verify its accuracy to be introduced in the radiotherapy workflow.

## Material and Methods

A Siemens Somatom Confidence RT Plus CT system was used to acquire the images at 70, 80, 100, 120 and 140kV. Slice thickness and pitch were the same used in clinical protocols for pelvis and brain patients. mAs were adjusted at all kV in order to keep CTDI unchanged from the reference 120kV studies.

A Catphan CTP 604 phantom was scanned in order to evaluate image quality in terms of high and low contrast resolutions, uniformity and noise. Additionally, a Gammex 467 Tissue Characterization Phantom was scanned to obtain calibration curves and to confirm that they were kV independent when DD was applied. CTDI doses were verified with an RTI Piranha to assure they were unchanged. Finally, a comparison between 3D doses using FBP at 120kV and DD images was done by means of a Varian Eclipse v. 13.6 TPS in real patients, using both AAA and Acuros XB 13.7 algorithms.

## Results

The observed differences in calibration curves were maximal at 70kV for the cortical bone and the 50% CaCO<sub>3</sub> rods (highest densities). For the other values of kV, HU and electronic density showed the same linear relationship whatever the kV was.

Image quality was slightly better in FBP than in DD images (Table 1). Spatial resolution in high contrast showed a worsening from 0.71mm to 0.83mm, and in low contrast no circles of the Catphan module could be detected in DD images at energies over 70kV. A slight difference in uniformity was observed, always being FBP better than DD. Noise was significantly higher in the DD images, around 3 times higher.

As expected, DD does not result in significant differences in dose calculations in comparison with FBP. Using AAA, the maximum differences were 0.1% in pelvis and 0.7% in brain. For Acuros the same differences were found.

Pelvis	Filtered Back-Projection					DirectDensity™				
	70 kV	80 kV	100 kV	120 kV	140 kV	70 kV	80 kV	100 kV	120 kV	140 kV
Spatial Resolution in High Contrast (mm)	0.71					0.83				
Spatial Resolution in Low Contrast with a contrast level of 1.0 % ( $\pm 1$ mm)	4	5	6	2	4	7	>15	>15	>15	>15
Uniformity - Relative differences in HU from the central pixels (%)	0.022	0.028	0.032	0.037	0.052	0.039	0.044	0.045	0.042	0.055
Noise level (HU)	3.2	3.4	3.2	3.3	3.4	10.2	11.6	9.1	9.6	10.0
Brain	Filtered Back-Projection					DirectDensity™				
	70 kV	80 kV	100 kV	120 kV	140 kV	70 kV	80 kV	100 kV	120 kV	140 kV
Spatial Resolution in High Contrast (mm)	0.71					0.83				
Spatial Resolution in Low Contrast with a contrast level of 1.0 % ( $\pm 1$ mm)	4	2	2	2	2	>15	>15	>15	>15	9
Uniformity - Relative differences in HU from the central pixels (%)	0.014	0.026	0.038	0.020	0.043	0.053	0.036	0.049	0.041	0.048
Noise level (HU)	3.4	3.2	2.9	3.0	3.1	11.6	9.8	9.1	10.4	10.2

### Conclusion

DD allows the acquisition of CT images at different kV settings with only one calibration curve in the planning system, with a minimum impact in dose calculations. However it needs matching with the original FBP images for volume delineation due to the lower image quality. Consequently Direct Density™ is accurate enough to be introduced in clinical routine.

### EP-2040 IDose4 algorithm for radiotherapy planning process: how reduce the dose without image quality loss

A. Clivio<sup>1</sup>, E. Barletta<sup>2</sup>, C. Bonacini<sup>1</sup>, R. Graeter<sup>1</sup>  
<sup>1</sup>Zentrum für Radiotherapie Rüti, Radiotherapy, Rüti ZH, Switzerland ; <sup>2</sup>Zentrum für Radiotherapie Rüti / KSW Kantonsspital Winterthur, Radiotherapy, Rüti ZH / Winterthur, Switzerland

### Purpose or Objective

With the software upgrade on the Big Bore CT (Philips), we have the opportunity to use the iDose<sup>4</sup> Algorithm (iDA) to reduce the patient dose during the CT acquisition. The aim of our study is to verify that, applying this Algorithm, the CTs are compatible for the radiotherapy planning process in terms of image quality and physical aspects

### Material and Methods

We used three different phantoms. The Catphan CTP504 and CIRS O62M phantom to measure the parameters linked to the image quality analysis (as Hounsfield Unit (HU), Homogeneity, and Resolution). The anthropomorphic Alderson RANDO phantom (AP) to evaluate the image quality on a 'real' patient. Using the iDA we have to select one of the seven available strength levels. With the level one we have to reduce about 20% the nominal mAs and for each higher level the reduction is 10% more. We took into account 4 different iDose<sup>4</sup> level (1 to 3 and 6) and we tested those applying nominal mAs value from 100 to 500, with a step of 50 mAs for the first 2 phantom. For the AP phantom, we acquired CT in three regions (Head, Thorax, and Pelvis) with our standard internal protocol and with the above four iDose<sup>4</sup> levels. We evaluate qualitatively the resolution and the image quality and we calculate some standard plans on the AP scan to compare the dose distributions

### Results

For the HU analysis, we found very small differences in the inserts of the CatPhan Phantom between the values obtained with the standard scan and with the iDA. For the scans with 150 mAs or more, the maximal difference is 5.1 HU (for Teflon). When we applied iDose<sup>4</sup> level 3, we had as mean difference in terms of HU over all the inserts (in the square bracket the range),  $1.4 \pm 0.8$  [0.3;2.3] with

500mAs,  $1.7 \pm 0.9$  [0.5;3.3] for 250mAs and  $1.3 \pm 2.2$  [-1.5;5.1] for 150mAs. We noted the maximal difference about 10.1HU with the iDose<sup>4</sup> level 3 and 100mAs in one of the two air insert. We obtain the same results also for the CIRS phantom: maximal difference about 6.5 HU and for iDose<sup>4</sup> level 3  $-1.0 \pm 1.9$  [-4.8;1.2],  $0.4 \pm 2.1$  [-2.4;3.8] and  $1.2 \pm 3.6$  [-3.9;6.5] HU mean difference respectively with 500, 250 and 150mAs. About the resolution and the homogeneity in the Catphan no difference is visible if we apply more than 200 mAs. With high iDose<sup>4</sup> level and less than 200mAs we lost 2 low constants inserts, with level 6 we lost one more. The qualitative evaluation on the AP CT didn't show any relevant difference and the same result we had with the test plans calculation. We calculated also the CT dose sparing and for Head region we had -30% respect our standard protocol with the level 2, for Thorax -22% with level 3 and for Pelvis -29% with iDose<sup>4</sup> level 3

### Conclusion

With the iDA we have the possibility to reduce the dose for the planning CT keeping a good resolution and without significant difference in the HU numbers. For the region in which we don't need a very high resolution, for example for simple breast or prostate Patients, suggest to use iDose<sup>4</sup> level 3 and for the other level 1 or 2 are recommended

**EP-2041 A comparison between 120kv and virtual mixed images in dual energy CT for RT simulation**  
 E. Fernandez-Velilla Cepria<sup>1</sup>, J. Quera Jordana<sup>1</sup>, O. Pera Cegarra<sup>1</sup>, M. Prieto Carballo<sup>1</sup>, N. Anton Comelles<sup>1</sup>, M. Algara Lopez<sup>1</sup>

<sup>1</sup>Hospital del Mar, Radiotherapy Oncology, Barcelona, Spain

### Purpose or Objective

Dual Energy CT (DECT) is being introduced in RT simulation due to its special features. DECT combines low kV (typically 80kV) and high kV (140kV) in order to enhance iodine contrast detection. So far radiotherapists needed two acquisitions in the simulation process: one with contrast for delineation and one without it for calculation. DECT allows the creation of Virtual Non Contrast Images (VNC) at 120kV (standard kV used for simulation), eliminating the need of the non contrast acquisition. The accuracy of this approach depends on the ability of the algorithm to calculate virtual 120kV images from the real 80 and 140kV acquisitions. The so called 120Mixed images are obtained with a weighted formula which uses HU at both kV and a single weighting parameter. A first step in the verification of this formula is applying it to non contrast images to prove whether it works properly. The objective of this study is checking the reliability of that calculation in real patients without injected iodine.

### Material and Methods

CT Simulation images were acquired by means of a Siemens Confidence RT Plus CT. For each patient two series were imaged: the standard 120kV (used for simulation) and the DECT (composed of 2 consecutive series at 80 and 140kV). For the 120kV series, the acquisition protocol was the one used in clinical routine. For the DECT acquisition, parameters were modified in order to keep the same CTDI as that of the 120kV. Slice thickness was 2mm in all cases. No iodine contrast was used, in order to avoid changes in Hounsfield Units of soft tissues.

For each patient, 6 tissues of interest (TOI) were delineated: lung, fat, blood, muscle, liver and cortical bone. Mean HU and standard deviations were calculated for each TOI in the 120kV, 120 Mixed, 80 kV and 140kV series. Comparisons were done in the Contouring module of a Varian Eclipse 13.6 TPS.

### Results

Mean differences in HU between 120kV and 120Mixed series were less than 3 HU in all tissues except bone (see table). 120kV were the series with less noise, followed by

120Mixed and 140kV. The highest noise and deviations were observed in bone, where a mean difference of 52HU appears and the difference between maximum and minimum deviations is 129.5HU.

The analysis of all patients and tissues one by one shows that even Lung has a mean at 120kV (-763.6HU) only 2.4HU different to the 120Mixed, the extreme values are separated by 50.7HU, and the standard deviations are 84.6 and 94.3HU respectively.

Fat, blood, muscle and liver show very small differences and deviations between 120kV and 120Mixed images, always under 6HU.

	120kV		120kV Mixed		Dif (HU)	Difference 120MIX-120KV	
	Mean	StDev	Mean	StDev		Max	Min
Lung	-763,6	84,6	-761,1	93,0	2,4	17,8	-32,9
Fat	-104,5	10,0	-105,6	12,0	-1,1	3,2	-2,8
Blood	41,5	9,4	42,8	9,5	1,3	3,1	-0,6
Muscle	51,8	10,9	54,6	13,3	2,8	5,7	1,3
Liver	55,5	8,6	57,4	12,7	1,9	3,6	0,6
Bone	800,4	276,8	853,1	302,0	52,7	92,8	36,7

### Conclusion

The calculation of 120Mixed images from 80kV and 120kV DECT images is accurate enough for soft tissues. Deviations increase at high HU tissues as bone. A fixed weighting factor seems to have some limitations to calculate 120Mixed images in all the HU range. More studies are needed to find the impact of such a limitation in dose calculation, and to find the factor dependency on density and composition.

### EP-2042 A clinically applicable deep learning model for segmentation in the prostate region

M. Nakamura<sup>1</sup>, H. Enno<sup>2</sup>, T. Kabasawa<sup>2</sup>, Y. Shido<sup>2</sup>, Y. Okunishi<sup>2</sup>, K. Muguruma<sup>2</sup>, H. Hirashima<sup>3</sup>, T. Mizowaki<sup>3</sup>  
<sup>1</sup>Kyoto University, Department of Information Technology and Medical Engineering, Kyoto, Japan ;  
<sup>2</sup>Rist- Inc., Department of Research and Development, Tokyo, Japan ;  
<sup>3</sup>Kyoto University, Department of Radiation Oncology and Image-Applied Therapy, Kyoto, Japan

### Purpose or Objective

The purpose of this study was to evaluate the accuracy of a deep learning segmentation model using FusionNet architecture, to delineate the prostate, seminal vesicles, rectum, and bladder in pelvic CT images.

### Material and Methods

The clinical data used in this study were obtained from randomly chosen from 469 prostate cancer patients who underwent IMRT or VMAT in prone position between July 2007 and October 2016. Regions of interest (ROIs), including the prostate, seminal vesicles, rectum, and bladder, were manually drawn by radiation oncologists and medical physicists. All CT images were acquired with a 512x512 matrix and 2.5-mm slice thickness (voxel size, 1.07 mmx1.07 mmx2.5 mm). A total number of CT images of 14,301 and their corresponding structural images were randomly assigned to either training (60%), validation (20%) or testing (20%) sets. A deep neural network, FusionNet, was implemented as the segmentation model. The CT image data set for training was augmented by performing rotation and shear on the original images. The model was then trained using the CT image data set with corresponding ROIs label data set. The optimization algorithm called Adam (adaptive moment estimation optimizer, learning rate=2e-5) was used to train the network weights. The trained model was evaluated with

test data set to segment the final ROIs slice by slice. The segmentation was conducted on a workstation with Intel(R) Xeon(R) CPU E5-2686 v4 2.30GHz, the NVIDIA Tesla V100 GPU accelerator (64 GB GPU Memory), and 244 GB Main Memory.

### Results

Median (interquartile range) dice similarity coefficient was 0.95 (0.85-1.00), 1.00 (1.00-1.00), 1.00 (0.97-1.00), 0.94 (0.87-0.96) for the prostate, seminal vesicles, rectum, and bladder, respectively. An averaged computation time to complete segmentation was 0.12 s per slice.

### Conclusion

Our proposed method, which employs the FusionNet architecture, was highly accurate for automated ROI segmentation.

### EP-2043 Efficiency Boosting of HN Positional Verification Using Highly Accelerated 3D MR Imaging in MRgRT

Y. Zhou<sup>1</sup>, W.W.K. Fung<sup>2</sup>, K.F. Cheng<sup>2</sup>, J. Yuan<sup>1</sup>, O.L. Wong<sup>1</sup>, G. Chiu<sup>2</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China ;  
<sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China

### Purpose or Objective

We aim to evaluate the performance of highly accelerated 3D MRI scan for head and neck (HN) in MR-guided-radiotherapy (MRgRT) on efficiency enhancement and inter-fractional positional error measurement.

### Material and Methods

18 healthy volunteers immobilized with a customized 5-point thermoplastic mask received 183 scans on a 1.5T MR-sim to simulate MRgRT fractions. Each scan included a high-resolution (voxel-size=1.05x1.05x1.05mm<sup>3</sup>, duration=5min) and a highly-accelerated low-resolution (acceleration-factor=9, voxel-size=1.4x1.4x1.4mm<sup>3</sup>, duration=59s) T1w spin-echo sequence (TR/TE=420/7.2ms) (Fig.1). The high-resolution images of the first session were used as the reference to mimic planning MRI. Rigid image registration was used to pairwise register the following sessional high-resolution and low-resolution images to the reference using 3D-slicer, named HHR and LHR respectively. Disagreement of inter-sessional positional shift calculated from HHR and LHR were analyzed using Bland-Altman plot. Systematic and random errors were also compared.

### Results

In efficiency, accelerated MRI, although with artifacts and lower image quality, considerably reduced scan time from 5min to 1min. LHR also reduced the automated registration time on a personal computer from ~45s to ~15s. The calculated translation shifts (mm) were 0.00±0.76 (mean±SD), 0.23±0.33, -0.23±0.69 and 0.33±1.08 in LR, AP and SI from HHR, and correspondingly -0.01±0.78, 0.26±0.31 and -0.32±0.71 from LHR (Table 1). The calculated rotation shifts (°) were -0.04±0.14, 0.00±0.00, and 0.16±0.44 in roll, pitch and yaw from HHR, and correspondingly -0.07±0.15, 0.00±0.00, and 0.13±0.43 from LHR. Bland-Altman analysis showed the calculated shift difference from LHR to HHR was small, i.e. -0.01 95%CI: [-0.23, 0.21], 0.03 [-0.14, 0.19], and -0.09 [-0.36, 0.18] in LR, AP and SI translation (mm) respectively, and -0.03 [-0.14, 0.09], 0.03 [-0.003 to 0.003], and -0.02 [-0.26, 0.21] in roll, pitch and yaw (°). The calculated systematic error and random error from HHR and LHR were also highly consistent, showing negligible differences (Table 1).

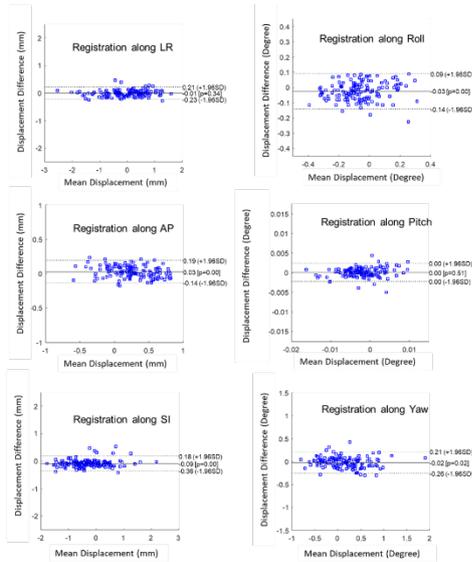

Fig 1. Altman-Bland plot of the positional shift difference in translation and rotation calculated from LHR to HHR

#### High-High Registration (HHR)

	3D Translation			3D Rotation		
	LR	AP	SI	Roll	Pitch	Yaw
Mean (mm)	0.00	0.23	-0.23	-0.04	0.00	0.16
SD (mm)	0.76	0.33	0.69	0.14	0.00	0.44
Group Systematic Error M (mm)	-0.16	0.14	-0.09	-0.01	0.00	0.05
SD of Systematic Error $\Sigma$ (mm)	0.64	0.25	0.43	0.14	0.00	0.31
RMS of Random Error $\sigma$ (mm)	0.63	0.27	0.73	0.11	0.00	0.25

#### Low-High Registration (LHR)

	3D Translation			3D Rotation		
	LR	AP	SI	Roll	Pitch	Yaw
Mean (mm)	-0.01	0.26	-0.32	-0.07	0.00	0.13
SD (mm)	0.78	0.31	0.71	0.15	0.00	0.43
Group Systematic Error M (mm)	-0.15	0.16	-0.16	-0.04	0.00	0.07
SD of Systematic Error $\Sigma$ (mm)	0.68	0.24	0.55	0.13	0.00	0.28
RMS of Random Error $\sigma$ (mm)	0.61	0.24	0.72	0.10	0.00	0.25

Table 1. The mean, standard deviation, systematic error and random error of translation and rotation shift calculated from HHR and LHR registrations.

## Conclusion

Highly-accelerated 3D-MRI could enhance positional verification efficiency in the HN MRgRT without compromising guidance accuracy.

## EP-2044 CT number estimation techniques for the stoichiometric method to predict proton stopping power

V. Taasti<sup>1</sup>

<sup>1</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA

### Purpose or Objective

The stoichiometric method is a well-established method, often used in proton therapy planning to estimate the stopping power ratio (SPR) of a patient's tissue. This method includes a CT scanner characterization and a subsequent CT number estimation for reference human data from the literature. The method originally proposed for these steps is based on a parametrization of the x-ray attenuation coefficient with fixed parameters for the target material dependency. However, other CT number estimation methods exist, which can equally well be used

for the stoichiometric method. This study investigated whether the SPR accuracy of the stoichiometric method could be improved by applying other CT number estimation methods.

### Material and Methods

Six published CT number estimation methods (Table 1) were investigated, including the method originally proposed for the stoichiometric method. All methods proposed a calibration method to characterize the x-ray energy spectrum based on CT scans of an electron density phantom, without the need for direct measurements of the x-ray spectrum. Therefore, these methods can all be used in the first steps of the stoichiometric method to estimate the CT numbers for reference human tissues, which in the last step is used to fit an empirical piecewise linear conversion curve from CT numbers to SPRs. CT scans of a tissue equivalent phantom (Cone-Beam Electron Density Phantom, Gammex, Middleton, WI, Fig. 1) were acquired at 120 kVp with a Flash scanner (Siemens Healthineers, Forchheim, Germany). The CT number estimation accuracy of the six methods was tested in a fully self-calibrated evaluation for the twelve insert materials used in the calibrations (measured vs estimated CT numbers), as well as theoretically for the reference human tissues (theoretical vs estimated CT numbers). Stoichiometric conversion curves were fitted based on each set of estimated CT numbers for the reference human tissues, applying the same curve fitting recipe for all six conversion curves (Fig. 2). The SPR accuracy was evaluated for published proton range measurements of organic beef and pork tissue samples, which had been scanned with the same CT scanner.

Table 1: Naming convention for the six methods, and references to the original publications. Parameters:  $\mu$  – x-ray attenuation coefficient;  $\sigma_e$  – electron cross section; Z – atomic number.

Name	Note	Reference
Method A	Parametrization of $\mu$	Schneider <i>et al.</i> , PMB, 41 (1996)
Method B	Parametrization of $\sigma_e$	Bourque <i>et al.</i> , PMB, 59 (2014)
Method C	Z-space	Lalonde and Bourchard, PMB, 61 (2016)
Method D	Effective energy	Han <i>et al.</i> , Med Phys, 43 (2016)
Method E	Effective energy	Taasti <i>et al.</i> , Med Phys, 43 (2016)
Method F	Two effective energies	Taasti <i>et al.</i> , Med Phys, 45 (2018)

Table 2: Results for the six CT number estimation methods. Column two and three are for the self-calibrated CT number ( $J_t$ ) estimation of the Gammex inserts, stated as the root-mean-square error (RMSE) and the mean error, both in percentage relative to the experimentally measured CT numbers for the twelve inserts. On the right in column four and five, the results for the stopping power estimation (SPR) of the fourteen pork and beef tissue samples are listed; the results are stated relative to the experimentally measured SPR values.

	RMSE $J_t$ (%)	Mean $J_t$ (%)	RMSE SPR (%)	Mean SPR (%)
Method A	3.1	-1.2	0.7	-0.2
Method B	2.9	-1.0	0.9	-0.3
Method C	2.1	-0.6	1.3	0.3
Method D	0.6	0.0	0.7	-0.3
Method E	0.5	0.0	0.6	-0.1
Method F	0.2	0.0	0.5	-0.1

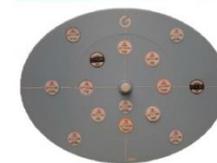

Figure 1: Gammex electron density phantom used in this study containing twelve tissue equivalent inserts. The measured CT numbers for the inserts were used to perform the CT scanner characteristic in each of the six methods, and in the self-calibrated CT number evaluation.

## Results

The CT number estimation method originally proposed for the stoichiometric method provided the least accurate CT number estimates with a root-mean-square error (RMSE) of 3.1% (Table 2). The lowest RMSE was 0.2%; this was obtained with a method based on two effective energies to characterize the CT scanner energy spectrum. In the theoretical evaluation, the deviations for the original method were found to increase with density for bone tissues (Fig. 3). The SPR accuracy for the organic tissues varied between the methods, with RMSEs between 1.3% and 0.5% (0.7% for the original method).

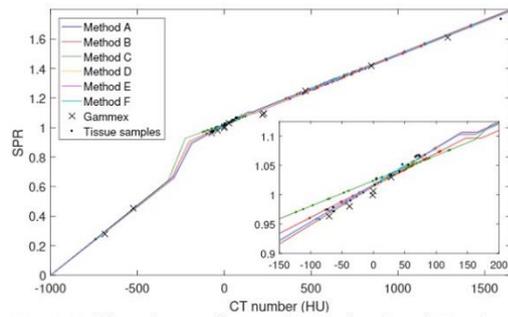

Figure 2: Stoichiometric conversion curves fitted on the estimated CT numbers for the reference human tissues for each of the six methods. The data points for the Gammex inserts and for the organic tissue samples are also shown.

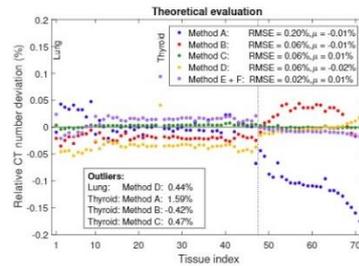

Figure 3: Relative deviations for the estimated CT numbers,  $\Delta H$ , for the reference human tissues in theoretical evaluation. The vertical dashed line separates soft and bone tissues. Data points for method E and F overlaps.

**Conclusion**

The accuracy of the SPR estimation in the stoichiometric method could be improved by changing the CT number estimation method. For the optimal method, the SPR accuracy (RMSE = 0.5%) was close to values obtained for dual energy CT.

**EP-2045 Tumor profile matching at the end of 8x7,5 Gy SBRT treatment: CBCT vs Untagged Image Reconstruction**

G. Pozo Rodriguez<sup>1</sup>, P. Garcia<sup>2</sup>, A. Ferrando<sup>1</sup>, M. Leonor<sup>1</sup>, A. Gaïtan<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de Octubre, Medical Physics Department, MADRID, Spain ; <sup>2</sup>Hospital Universitario de La Princesa, Medical Physics Department, Madrid, Spain

**Purpose or Objective**

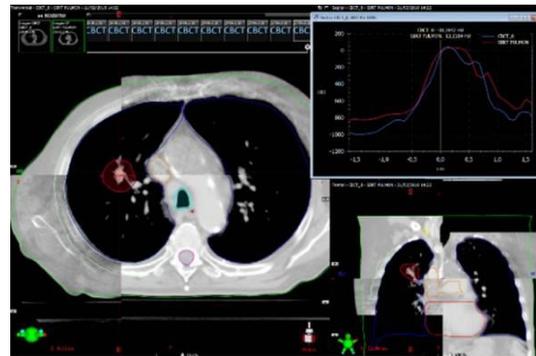

To assess and quantify correlation between tumor images by comparing Hounsfield Unit (HU) profiles of 4DCT acquisition and CBCT image acquired at last therapy fraction.

**Material and Methods**

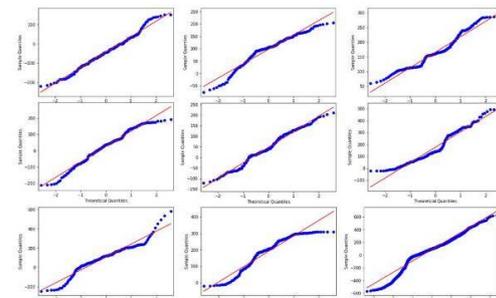

A cohort of 15 NSCLC patients treated with SBRT and dose administration delivered in 8 fractions of 7,5Gy (BED=105Gy) was selected for this study. SBRT treatments were performed on a Varian Clinac 2300 iX (Varian Medical Systems, Palo Alto.CA). This linear accelerator includes an On Board Imager (OBI) unit to perform planar or CBCT KV image, with a aSi digital panel detector model PaxScan 4030CB. In each fraction, 2 CBCT are acquired for patient positioning and intra-fraction movement tracking, with an average acquisition time (tacq) of 13,02s ( $\sigma=0.21s$ ). 4DCT was acquired with a Philips Brilliance Big Bore CT of 64 detector rows (Philips Healthcare, Amsterdam.The Netherlands), using a nominal slice thickness of 2mm. Respiratory cycle was binned into 10 phases and ITV was generated by means of merging 10 contoured GTV. This structure is expanded 5mm isotropically and determines PTV to be treated. CT utilized for planning is an averaged reconstruction called Untagged Series. Image analysis has been performed with Image Registration tool implemented in ARIA R&V System (Varian Medical Systems)

**Results**

Performing a rigid registration between CT image acquired with CBCT at the eighth fraction (last treatment's fraction) and CT Untagged, a HU Profile has been plotted referred to PTV's centroid of in both images as seen in Figure 1.

Since qualitative profile depicts analogous behaviour between both images, statistical analysis has been performance to quantify whether or not are correlated. Normality tests were performed to decide the best fit model. Attempt to correlate CBCT and Untag profiles was carried out by performing and ordinary least square (OLS) linearity model with Python 3.7. This analysis was done for each individual and also considering 'all in one' bulk data. R2 for individuals ranged from 0,736 to 0,980, yielding an average R2=0.872 for individuals ( $\sigma=0.074$ ) and R2=0.739 for bulk analysis. In fact, 75% of patients had an R2>0.850, showing a strong correlation that only fails in HU ranges linked to air and intrinsic variability of acquisition process as seen in Quantile Quantile Plot (Figure 2).

1) to 8) Examples of good linearity accordance, centered in high density area. Deviations are linked to lung tissue and extreme values.  
9) Bulk QQPlot Analysis

**Conclusion**

CBCT and planning Image matching in lung has been evaluated in terms of HU profile since acceptable contrast can be obtained. Focusing on target shape, in despite of apparent artifacts frequently seen in CBCT, profile analysis exhibits good correlation between initial and final image (R2=0.872). Apparently, HU topography of the tumor represented is not device-dependent as averaged target is displayed in both cases: Untagged CT and CBCT acquisition ( $t_{aq}=13,02s$  evolving several respiratory cycles), although inherent noise may be present (OAR proximity, respiration). Even when considering bulk data analysis, an R2 of almost 0,750 reveals a predictable model at least concerning to tumor surrounding.

**EP-2046 Patient setup verification using synthetic DRRs in an MR only workflow for head and neck cancer**

E. Palmér<sup>1</sup>, A. Karlsson<sup>1,2</sup>, F. Nordström<sup>1,2</sup>, K. Petruson<sup>3</sup>, M. Ljungberg<sup>1,2</sup>, M. Sohlín<sup>1,2</sup>

<sup>1</sup>University of Gothenburg, Department of Radiation Physics- Institute of Clinical Sciences- Sahlgrenska Academy, Gothenburg, Sweden ; <sup>2</sup>Sahlgrenska University Hospital, Department of Medical Physics and Biomedical

Engineering, Gothenburg, Sweden ; <sup>3</sup>University of Gothenburg, Department of Oncology and Radiotherapy- Institute of Clinical Sciences- Sahlgrenska Academy, Gothenburg, Sweden

### Purpose or Objective

The MR only radiotherapy workflow is based solely on MR data, hence there is no CT data available. Instead a synthetic CT (sCT) generated from the MR data is used as Hounsfield Unit (HU) map for dose calculation. Consequently, the Digital Reconstructed Radiograph (DRR) originating from CT data is replaced with synthetic DRR (sDRR) (Figure 1). The purpose of this observer study was to investigate the precision of patient positioning for head and neck cancer using sDRR, compared to the today clinical used DRR.

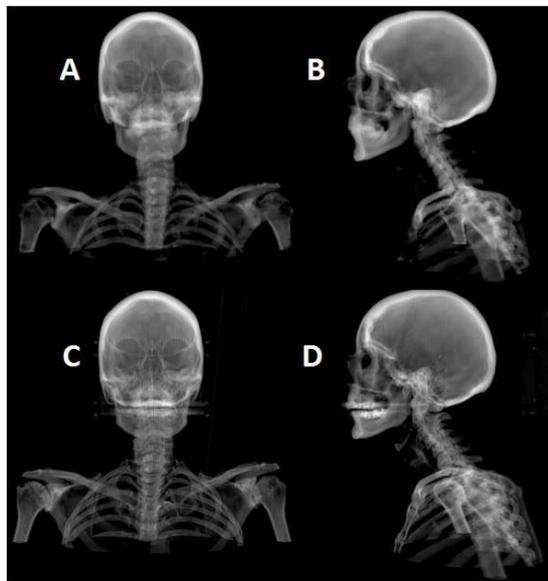

Figure 1. Illustration of synthetic DRR (A and B) and today clinical used DRR (C and D), in 0° and 90°.

### Material and Methods

Pre-treatment CT and MR from four patients, as well as kV-images (0° and 90°) from the linac mounted imaging device were used. sCT data was generated using MriPlanner (Spectronic Medical AB). A second CT data set was created by deformable registration of the CT to the MR using Velocity (Varian Medical Systems). The deformed CT data was used to mitigate anatomical differences between the pre-treatment imaging sessions. For each patient, orthogonal kV images from 4 fractions were retrospectively manually registered in five degrees of freedom against 3 different image sets (DRR, sDRR and deformed DRR (defDRR)) by 6 observers, resulting in a total of 288 registrations. None of the observers were informed about which type of DRR they worked with.

### Results

Differences between patient positioning with sDRR and the clinically used DRR, as well as differences between defDRR and DRR, in vertical (vrt), longitudinal (lng) and lateral (lat) directions, for all observers, are presented in Figure 2. The mean differences and the standard deviations between patient positioning with sDRR and DRR were  $-0.79 \pm 1.75$  mm,  $-0.59 \pm 0.79$  mm and  $0.96 \pm 1.20$  mm in vrt, lng and lat direction respectively. For pitch and rotation (rtn), a difference of  $-0.61 \pm 1.41^\circ$  [ $-4.0$  2.6] and  $-0.22 \pm 0.83^\circ$  [ $-2.7$  1.7] were noticed. The differences between defDRR and DRR concluded in a mean difference of  $-1.08 \pm 2.36$  mm,  $-0.53 \pm 1.08$  mm and  $0.53 \pm 1.26$  mm in vrt, lng and lat directions and in pitch and rtn of  $-0.68 \pm 1.33$  [ $-3.8$  2.4] and  $-0.31 \pm 0.87^\circ$  [ $-3.5$  1.6].

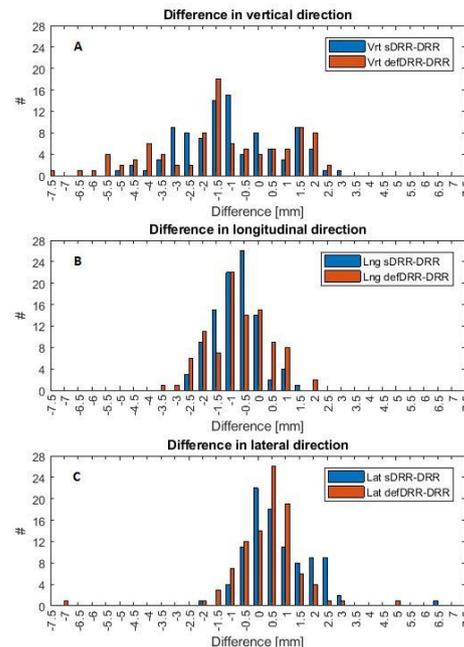

Figure 2. Histograms presenting differences between patient positioning with sDRR and DRR (blue) and with defDRR and DRR (red). Histogram A illustrates differences in vertical direction, histogram B differences in longitudinal direction and histogram C differences in lateral direction.

### Conclusion

Differences in all degrees of freedom for sDRR-DRR are found to be similar to the differences for defDRR-DRR, i.e. the generation of sCT is not introducing any large additional uncertainties or errors that propagates to the sDRR. The similarity indicates that the dominating factor contributing to the observed differences is repositioning between the CT and MR scan. Supplementary phantom measurements, enabling fixed coordinate systems, could be valuable.

### EP-2047 Investigating a new MR sequence combined with radiologist training for prostate delineation

J. Wyatt<sup>1</sup>, J. Frew<sup>1</sup>, A. Henry<sup>2,3</sup>, L. Murray<sup>2,3</sup>, R. Pearson<sup>1</sup>, A. McNeil<sup>4</sup>, E. Johnstone<sup>2</sup>, R. Speight<sup>3</sup>, H. McCallum<sup>1</sup>  
<sup>1</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom ; <sup>2</sup>University of Leeds, Leeds Institute of Cancer and Pathology, Leeds, United Kingdom ; <sup>3</sup>Leeds Teaching Hospitals NHS Trust, Leeds Cancer Centre, Leeds, United Kingdom ; <sup>4</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Radiology, Newcastle upon Tyne, United Kingdom

### Purpose or Objective

MR is increasingly being used for prostate delineation in radiotherapy due to its superior soft-tissue contrast. However the literature is scarce regarding the optimal sequence for prostate definition and many oncologists are unfamiliar with using MR images for delineation. This study aimed to investigate the variability of prostate delineation for two different MR acquisition sequences both prior to and after expert radiologist training.

### Material and Methods

CT and MRI scans for radiotherapy planning were acquired in the treatment planning position for 15 patients in two cohorts (5 and 10 respectively). Two MR sequences were acquired in the same scanning session, a 3D T2-weighted turbo spin echo sequence (SPACE) and a 2D T2-weighted combined multiple gradient echo sequence (MEDIC). Three consultant oncologists from two institutions delineated the prostate and seminal vesicles on each image set independently for the first cohort using the same treatment planning system. These delineations were then

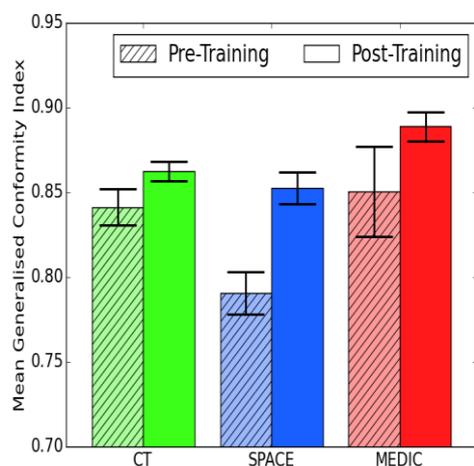

reviewed by an expert urology radiologist and discussed with the oncologists. The same oncologists subsequently delineated the second cohort.

The delineation variability was quantified using a generalised conformity index for each image and patient. This is the intersection volume divided by the union volume generalised to be independent of the number of observers. The delineation variability for each MR sequence was compared to the CT within each cohort using a paired t-test. The mean ratio of volumes delineated on each MR sequence to the volumes delineated on CT was calculated.

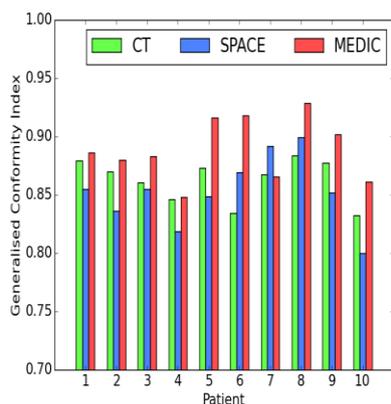

### Results

The radiologist training substantially improved the delineation variability for all three image data sets (see figure 1). Prior to radiologist training, the delineation on MEDIC sequence showed a similar variability to CT and the SPACE sequence significantly more ( $P = 0.05$ ). Post-training delineation on the MEDIC sequence showed a significantly reduced variability compared to CT ( $P = 0.01$ ) and the SPACE sequence similar to CT. The MEDIC sequence gave the least delineation variability in 9/10 post-training patients (figure 2) and was preferred by all delineators.

The volumes on both MR sequences were consistently smaller than on CT. Post-training the SPACE volume was  $87 \pm 2\%$  of the CT (mean  $\pm$  s.e.m.). The MEDIC volume was  $96 \pm 3\%$  of the CT. Further work will investigate the reason for differences in volume size between the two MR sequences.

**Figure 1** Mean conformity index pre and post radiologist training. 1 indicates perfect agreement. Error bars are one s.e.m.

**Figure 2** Conformity index for each post-training patient.

### Conclusion

Radiologist training reduced delineation variability on all sequences and particularly on the MR sequences. Post-training the MEDIC sequence had the least delineation variability, was preferred by all delineators and produced slightly smaller volumes compared to CT. This study suggests the MEDIC sequence in conjunction with radiologist training can reduce the variability in prostate delineation.

**EP-2048 Development and implementation of a cost-effective technique to improve CT scans for contouring**  
D. Nash<sup>1</sup>, A.T. Davis<sup>1</sup>, A.L. Palmer<sup>1</sup>

<sup>1</sup>Queen Alexandra Hospital, Medical Physics, Portsmouth, United Kingdom

### Purpose or Objective

Radiotherapy CT scans are generally of inferior image quality (IQ) to a diagnostic CT scan. However, for IMRT and VMAT, more intricate structures need to be visualised, thus needing superior IQ. This is particularly true considering that the clinician outlining can be the most significant uncertainty in radiotherapy. This work was to develop a method of enhancing IQ for contouring without impairing the dose calculation, introducing any motion error or any additional imaging dose.

### Material and Methods

The proposed method was to provide a second reconstruction of the planning CT raw data with alternative, optimised, parameters specifically to improve the image for contouring. The second scan was to be fused with the planning scan but never used for planning dose calculations.

The preferred parameters were determined, with an initial focus on head and neck (H&N) scans. These were determined qualitatively by two experienced physicists by reconstructing previous scans acquired on a Canon Aquilion LB CT scanner, with a particular focus on edge and contrast enhancement. Reconstruction of the same data set meant no induced error due to motion between two scans, nor any additional radiation dose. Parameters changed included the reconstruction kernel to a head-specific one from the standard body one (FC13) and reduction of the reconstruction FOV diameter. The scan was then fused onto the planning CT scan and guidance sought from two experienced radiation oncologists.

For the chosen parameters, the next 11 (6 with IV contrast) head and neck patients had this second scan reconstructed. Each oncologist was provided with a short questionnaire asking to qualitative opinions on the additional scan, whether there was any reduction in outlining time, their degree of confidence in images and how they compared to diagnostic scans stored for the patient on the PACS system. Comments were also requested.

### Results

The selected image parameters for the secondary reconstruction were to reduce the FOV to approximately 20cm, from the usual 55 or 80 cm, and changing the reconstruction kernel to a sharper head kernel (FC44). An example is shown in fig. 1.

For 9 of the 11 scans the Oncologists reported a reduction in outlining time, with no change for 2. For all scans the Oncologists had more confidence in their outlining. When compared against PACS, 9/11 were superior, 1/11 equivalent and 1 poorer (which was acquired at a different hospital). In terms of the comments given, all were positive. Based on these results the technique was adopted for all H&N patients and performed automatically with little workflow impact.

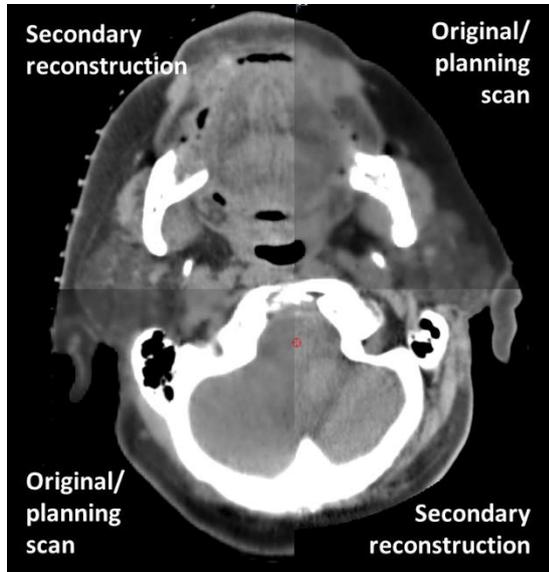

Fig. 1. Example image.

### Conclusion

A technique to provide enhanced IQ from a radiotherapy CT scanner has been developed and demonstrated qualitatively to be superior to conventional scans. Major benefits of the technique include no additional time required for the scan, no extra radiation dose and no motion effects introduced with use of the second scan. Further work including a contouring study is planned.

### EP-2049 Patient specific pixel-based weighting factor bone-only dual-energy x-ray imaging

S. Darvish-Molla<sup>1</sup>, M. Reno<sup>2</sup>, M. Sattarivand<sup>1,2,3</sup>

<sup>1</sup>Nova Scotia Health Authority, Radiation Oncology - Medical Physics, Halifax, Canada ; <sup>2</sup>Dalhousie University, Physics and Atmospheric Science, Halifax, Canada ; <sup>3</sup>Dalhousie University, Radiation Oncology, Halifax, Canada

### Purpose or Objective

Implement the novel pixel-based weighting factor dual energy (DE) algorithm for effective soft-tissue suppression throughout the image to enhance the bone-only image quality and to overcome the limitation of the conventional DE algorithm with constant weighting factor, which is restricted to regions with uniform patient thickness.

### Material and Methods

A step phantom was constructed consisting of slabs of solid water and average bone materials. Thicknesses of bone ranged from 0 to 6 cm in one direction, and solid water from 5 to 30 cm in the other direction, creating 7 by 7 regions of interest (ROIs). The slabs were stacked and placed on a custom-made plastic stand, angled at 42°, such that the central axis of the x-ray beam was perpendicular to the phantom surface. Using Brainlab's ExacTrac system, projection images of the step phantom were acquired at (60 kVp, 40 mAs) and (140 kVp and 12 mAs). Using an in-house Matlab code, the optimal pre-calculated weighting factors ( $\omega$ ) were found by varying values in the range 0-2 for each ROI such that the soft tissue contrast-to-noise ratio (CNR) reached zero. CT images of Rando phantom were acquired using thorax protocol. Ray tracing technique was used to calculate the bone and soft-tissue DRRs (digitally reconstructed radiographs) (Figure 1b,c). Weighting factors for different pixel locations on the DRRs were interpolated (or extrapolated) using the pre-calculated weighting factors and the  $\omega$  image for Rando phantom was generated. By applying the  $\omega$  image into the DE algorithm and utilizing noise suppression algorithm, the bone-only DE image was generated and compared to the clinical single energy x-

ray image and conventional DE image which uses a constant  $\omega$  throughout the image. Signal-to-noise ratio (SNR) of regions with different soft-tissue and bone thicknesses in step phantom was investigated for both DE techniques.

### Results

The optimal pre-calculated  $\omega$  values were found to be in a range [0.82, 1.19] depending on the region thickness in step phantom (Figure 1a). The  $\omega$  values that cancels 25 cm (ROI1) and 10 cm (ROI2) soft-tissue overlapped with 3 cm bone were calculated as 0.93 and 0.83, respectively. Figure 1d demonstrates the  $\omega$  image of Rando for the given projection view. Figure 2 demonstrates the effectiveness of the PP-DE algorithm compared to the clinical single energy x-ray image and conventional DE images (with  $\omega=0.93$  and  $\omega=0.83$ ). The SNR of DE image for ROI1 and ROI2 of the step phantom was 45 and 674 for PP-DE compared to 43 and 203 for conventional DE, respectively.

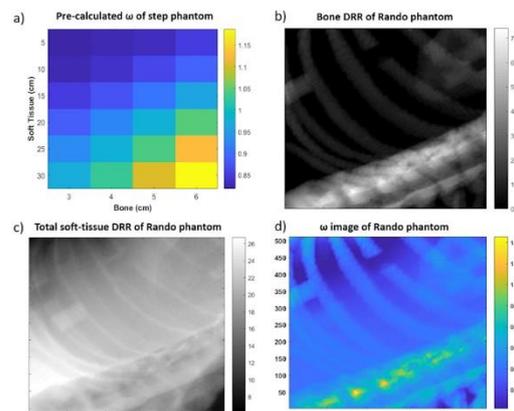

Figure 1. Generating pixel-based  $\omega$  image (d) from precalculated  $\omega$  values of step phantom (a) and Bone and soft-tissue DRRs (b,c)

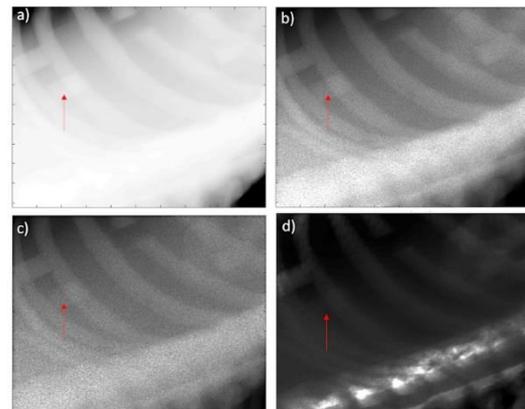

Figure 2. a) Single Energy clinical x-ray image, b) Conventional DE image with  $\omega=0.83$ , c) Conventional DE image with  $\omega=0.93$ , d) the novel pixel-based bone-only DE image that effectively suppresses different thicknesses of soft-tissue simultaneously. Note that the red arrow pointed to the solid water plug, inserted to the lung of Rando Phantom, which should not appear in the bone-only DE images.

### Conclusion

Bone-only patient specific pixel-based algorithm was successfully implemented, which could have clinical interests for image guidance for spine SBRT patients. Compared to the conventional DE, this novel technique creates images with improved bone contrast, specifically in soft tissue overlapping regions, improved SNR, thus enhanced image quality for precise tumor localization.

### EP-2050 Implementation of CT-based attenuation maps of RT positioning devices in PET/MRI - online vs offline

L. Taeuber<sup>1,2,3</sup>, A. Pfaffenberger<sup>1,3</sup>, Y. Berker<sup>4</sup>, B. Beuthien-Baumann<sup>5,6</sup>, A.L. Hoffmann<sup>7,8,9</sup>, E. Troost<sup>6,7,8,9,10</sup>, S.A. Koerber<sup>3,6,11</sup>, M. Kachelrieß<sup>4</sup>, C. Gillmann<sup>1,3</sup>

#### Purpose or Objective

Integrating PET/MR hybrid imaging into radiation treatment (RT) planning has great potential to improve tumor delineation and dose prescription. Since these scans must be acquired under treatment conditions, attenuation correction of RT positioning devices is necessary. Attenuation maps can be implemented either online (directly at the PET/MRI scanner) or offline (at another PC). In this study, we compare both methods and assess their impact on PET image quality using a CT-based user-generated attenuation map of an RT table overlay.

#### Material and Methods

CT images of an RT table overlay (in-house construction) were acquired on a stand-alone CT (Somatom Definition Flash, Siemens Healthineers, Erlangen, Germany) at 120 kV and 360 mAs. Based on the CT images, an attenuation map of the RT table overlay was calculated via the bilinear approach [1].

The RT table overlay was then mounted onto the patient table of the PET/MRI (Biograph mMR, Siemens Healthineers) and two sets of PET-measurements were taken using an active <sup>68</sup>Ge phantom (32 MBq, 10 min scan time). The phantom was scanned with the RT table overlay (RT scan), and without the RT table overlay (reference scan).

PET reconstructions of the phantom scans were performed online at the PET/MRI scanner and offline using the e7tools (Version VA20, Siemens Healthineers) with identical reconstruction parameters. For the PET-reconstructions of the RT scan, the attenuation map of the RT table overlay was implemented. Attenuation correction accuracy was evaluated by comparing PET activities between RT and reference scans in 10 ROIs placed every 10 slices along the phantom in longitudinal direction, both for the online and the offline reconstruction methods.

#### Results

The RT table overlay attenuation map was successfully added to the hardware attenuation maps produced online and offline. Table 1 compares measured PET activities. For the online reconstruction, a mean percentage difference of 0.7% was found between the reference and the RT scan. For the offline reconstruction, a mean percentage difference of 1.4% was found. A systematic difference of around 500 Bq/ml was found between the online and offline reconstructions.

#### Conclusion

For the integration of PET/MRI in RT planning, attenuation correction of RT positioning devices is viable. The online

reconstruction seems to be more accurate, but it has the disadvantage that the attenuation map must be removed from the system after every RT measurement to prevent an incorrect reconstruction of patient data that were not scanned in RT setup. Alternatively, offline reconstruction can be implemented at any PC via e7tools, and the reconstruction could be automated, thereby diminishing human error. The cause of the systematic signal difference in online and offline reconstruction needs to be investigated further.

[1] Carney et al. doi: 10.1118/1.2174132

**Table 1: Comparison of measured PET activities for online and offline reconstruction of the RT and the reference scans.**

Slice location	Online reconstruction			Offline reconstruction		
	RT scan [Bq/ml]	Reference scan [Bq/ml]	Difference [%]	RT scan [Bq/ml]	Reference scan [Bq/ml]	Difference [%]

<sup>1</sup>Politecnico di Milano, DEIB - Department of Electronics Information and Bioengineering, Milano, Italy ; <sup>2</sup>National Centre of Oncological Hadrontherapy CNAO, Clinical Bioengineering Unit, Pavia, Italy ; <sup>3</sup>National Centre of Oncological Hadrontherapy CNAO, Diagnostic Imaging Unit, Pavia, Italy ; <sup>4</sup>National Centre of Oncological Hadrontherapy CNAO, Medical Radiology Technicians Unit, Pavia, Italy ; <sup>5</sup>National Centre of Oncological Hadrontherapy CNAO, Radiation Oncology Unit, Pavia, Italy

#### Purpose or Objective

To compare typical normalization strategies applied to T1- and T2-weighted MR images in patients affected by meningioma for evaluating the MR signal intensity (SI) during proton therapy (PT).

#### Material and Methods

55 exams consisting of contrast-free T1w (VIBE, 3D GRE, TR=5.16 ms, TE=2.09 ms, flip angle=9°, resolution=1.02x1.02x1.02 mm) and T2w (TSE, 2D SE, TR=11.9-14.5 s; TE=104 ms, flip angle=80°, resolution=0.47x0.47x3 mm) MRI were acquired on a 3T scanner during PT for 17 patients. Gross tumour volumes (GTV) were manually delineated on T2w images, whereas white matter (WM) contours were obtained by an automatic algorithm, post-processed and visually checked. T1w images were rigidly registered on T2w images, to allow their evaluation on the same regions. Three normalization methods based on histogram matching (M1,[1]), WM-driven standardization (M2,[2]) and min-max (M3) were implemented. Two metrics computed in WM areas were considered for the evaluation: the Jeffreys' divergence between any combination of mode-aligned histograms (JD) and the ratio between interquartile range and median computed on the median SI values (npCV). Medians and percentiles (5<sup>th</sup>-95<sup>th</sup>) from WM and GTV regions were also compared.

#### Results

For T1w-images, JD (median[IQR]) was 0.029[0.023], 0.035[0.041] and 0.056[0.074] for M1, M2 and M3, with respect to 0.045[0.045] derived from raw ones. According to JD and npCV (Tab. 1), M1 was the best-performing

method. For T2w-images, JD was 0.182[0.496], 0.036[0.038] and 0.095[0.152] for M1, M2 and M3, with respect to 0.090[0.142] in raw images. M2 was found to outperform all the other methods according to JD, whereas the use of M1 was supported by npCV (Tab. 1). For both T1w- and T2w-images it was noticed that WM variability measured by npCV was lower than the GTV one, apart from M2 for which median values were close to zero. Differences in variability varied for different normalization methods, but all of them qualitatively kept the WM-GTV relation observed in raw images (Fig.1).

**Conclusion**

Overall, M1 showed better performance for T1w-images and both M1 and M2 for T2w-images. M3 is the simplest method but it does not seem to guarantee a comparison between MRI acquisitions. The evaluation of the performance of different MR normalization methods is not trivial but required for MRI analysis in longitudinal studies, as well as for applications in feature extraction for patient classification or stratification. Harmonized evaluation of such (and other) pre-processing method is therefore needed.

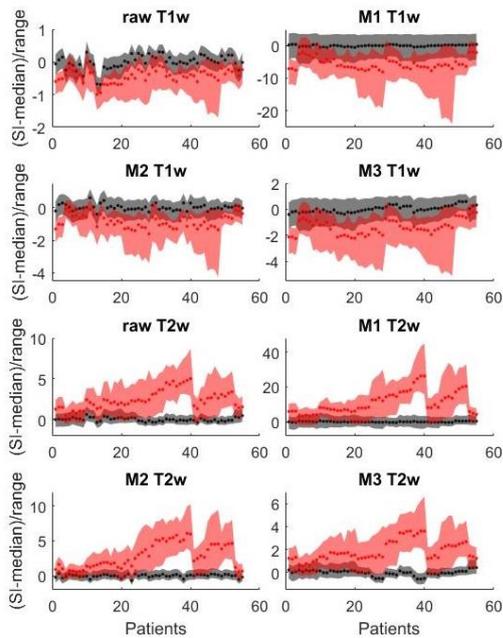

Figure 1 - Median distributions for T1w- (up) and T2w- (down) raw images and normalized by M1, M2 and M3, in WM (black) and GTV (red) regions.

npCV	WM	GTV	npCV	WM	GTV
T1w			T2w		
raw	0.077	0.107	raw	0.096	0.281
M1	0.016	0.108	M1	0.081	0.619
M2	1.790	-0.710	M2	2.359	1.291
M3	0.066	0.204	M3	0.109	0.342

Table 1 - Values of npCV for T1w- (left) and T2w- (right) raw images and normalized by M1, M2 and M3, in both WM and GTV (regions).

**EP-2052 Commissioning monoenergetic CT images for optimal proton dose calculations using TwinBeam scans**

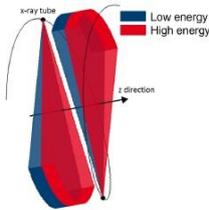

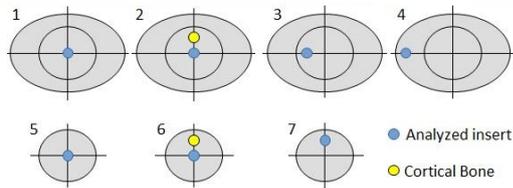

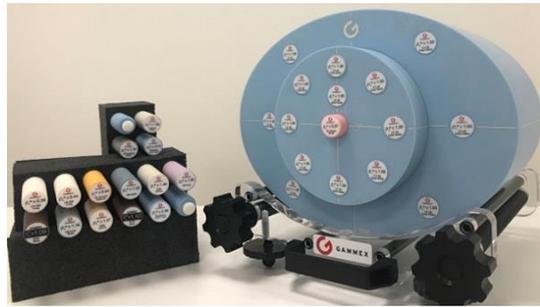

P. Randers<sup>1</sup>, M. Fuglsang<sup>1</sup>, V. Trier Taasti<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Danish Centre of Particle Therapy, Aarhus, Denmark

**Purpose or Objective**

Monoenergetic CT images derived from two CT images acquired at different kVps offer the potential of reducing the beam hardening (BH) effect compared to single energy CT (SECT) images. Commissioning monoenergetic CT images for proton dose calculations could therefore lead to a reduced range uncertainty. The first step is to determine the optimal energy leading to the lowest possible BH effect, and then to establish stoichiometric calibration curves from CT numbers to proton stopping power ratios (SPRs) and mass densities.

**Material and Methods**

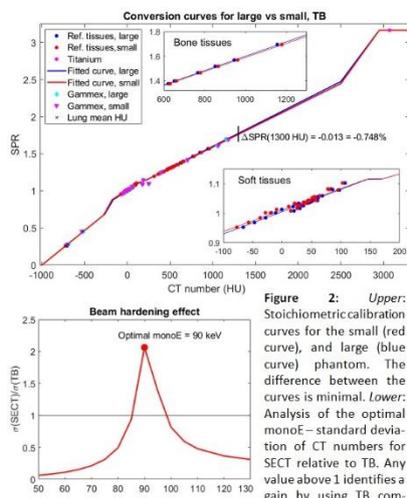

CT scans of a tissue equivalent electron density phantom (Gammex, Middleton, WI) were acquired with a SOMATOM Definition Edge dual energy CT (DECT) scanner (Siemens Healthineers, Forchheim, Germany). This is a single source scanner with a TwinBeam (TB) mode (Fig.1), which enables simultaneous dual energy acquisition, which reduces the risk of motion blurring. CT scans were acquired in both TB and SECT mode. Seven different clinically relevant configurations were used and fifteen different tissue equivalent inserts were scanned individually within each configuration (Fig 1). All remaining positions were filled with solid water inserts of the same composition as the bulk phantom, to avoid interference between the different inserts. Monoenergetic images were generated using the Siemens syngo.via software at different energies (monoEs). The size of the BH effect was quantified as the standard deviation of the monoenergetic CT numbers over the various configurations for a specific insert at a given monoE. The BH effect was analysed for all inserts together by summing over the inserts, as well as for each insert separately. The CT number differences for the SECT scans of the seven configurations were also extracted and used to investigate if the TB monoenergetic CT images decreased the BH compared to SECT. After obtaining the optimal monoE, stoichiometric calibration curves were fitted for the small and the large phantom, respectively.

**Figure 1:** *Upper:* Electron density calibration phantom, with fifteen tissue equivalent insert materials. The phantom consists of an inner head sized phantom, and an outer torso shaped phantom. *Middle:* The seven clinically realistic configurations used to investigate the beam hardening effect. *Bottom:* TwinBeam mode, the x-ray spectrum is split in two by different prefiltration materials to obtain DECT scans with two different energies.

**Results**

The CT number variance was very small for the low- to medium-density inserts and could be assumed to originate from CT noise rather than BH. In contrast, large differences were seen for the CT number of the high-density bone inserts. The lowest BH effect was found at slightly different monoEs for the four high-density bone inserts. The average optimal monoE was found at 90 keV. At this monoE, the BH was at least reduced by half compared to SECT. The resulting calibration curves for the small and large phantom differed only slightly at very high monoenergetic CT numbers, above the clinically relevant region (Fig. 2)

**Figure 2:** *Upper:* Stoichiometric calibration curves for the small (red curve), and large (blue curve) phantom. The difference between the curves is minimal. *Lower:* Analysis of the optimal monoE—standard deviation of CT numbers for SECT relative to TB. Any value above 1 identifies a gain by using TB compared to SECT, as TB then reduces the BH effect.

**Conclusion**

Using monoenergetic images at 90 keV derived from TB DECT scans, the BH effect can be markedly reduced compared to SECT. The difference between the calibration curves for the small and large phantom was minor, which would decrease the SPR deviation when

patients' sizes differ from the size of the calibration phantom used to generate the curves.

**EP-2053 Pelvic plan adaptation to manage systematic rotations without CT re-imaging**

A. Licup<sup>1</sup>, S. Van Kranen<sup>1</sup>, M. Buijs<sup>1</sup>, F. Koetsveld<sup>1</sup>, J. Sonke<sup>1</sup>, P. Remeijer<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

**Purpose or Objective**

In IGRT workflows for pelvic treatments, rotations often remain uncorrected. Especially for large target volumes (TVs), e.g. cervical tumors that include pelvic and para-aortic lymph nodes, large CTV to PTV margins are required to account for the residual errors. Replanning on a repeat CT (rCT) scan may correct for systematic rotations, however this increases clinical workload and patient imaging dose and may still fail to image the systematic rotational error. Therefore we propose to simulate an rCT scan based on the clinical (rigid) registrations of TVs in CBCT scans. To overcome large displacements outside the registered region, often seen as considerable displacements of the patient skin contour, we developed and validated a technique that restricts skin deformations while correcting for the observed systematic rotations in the pelvic area.

**Material and Methods**

To simulate an rCT scan, we propose to use compactly-supported radial basis functions (CSRBF) [1]. CSRBF is a method in which rigid registrations are confined in a local region, outside of which non-rigid deformations reduce smoothly to zero within a set RBF radius. Figure 1 illustrates this method for a cervical cancer patient model.

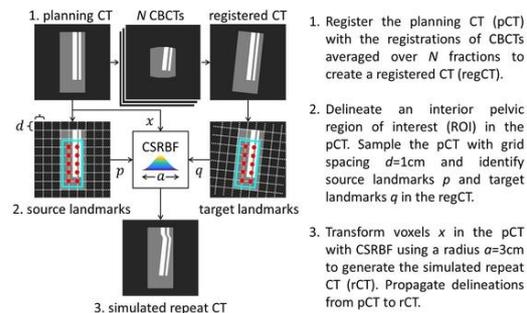

Figure 1. Schematic to simulate a repeat CT with CSRBF. The blue delineation encloses the interior pelvic region of interest (ROI) marked by source and target landmarks *p* and *q* (red grid points).

We validated the simulated rCT scan based on a single fraction (*N*=1) on the following aspects:

- (1) skin contour preservation,
- (2) interior pelvic anatomy rigid registration, and
- (3) delineation shape preservation.

**Results**

Offline simulation of the rCT took 6mins on a 64-bit 3.40GHz Intel® Xeon® PC. Figure 2A shows a translation-only registration between the planning CT (pCT) and a single CBCT with a large rotation, the effect of uncorrected rotations are clearly seen. Figure 2B shows an example where we simulate an rCT on the same CBCT. The patient outline is preserved while the internal anatomy rotations are corrected. Figure 2C is a grey level difference image between pCT and rCT registered on the skin. We evaluated the root mean squared differences (RMSD). An RMSD=0 suggests high similarity. Figure 2C shows minimal RMSD outside the ROI, validating (1). To validate (2), the entire rCT was rigidly registered back to the pCT (figure 2D), with minimal RMSD inside the ROI. Figure 2E summarizes the RMSD statistics. Finally, to

validate (3), We evaluated Dice's coefficient to verify shape similarity between pCT and rCT delineations (figure 2F). Values near 1 indicate shape preservation except for kidneys, as these intersect the ROI superior boundary where non-rigid transformations were applied.

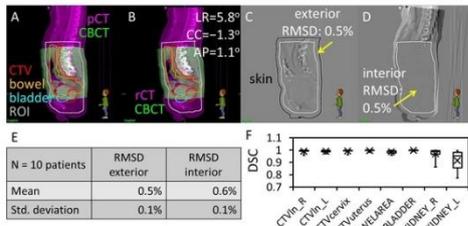

Figure 2. (A) Overlay of planning CT (pCT) with CBCT and (B) simulated rCT with CBCT. (C) Grey value differences between pCT and rCT, show minimal RMSD in the region exterior to the ROI. (D) Registration of rCT back to the pCT shows minimal RMSD within the ROI. (E) Summary RMSD statistics for 10 patients. (F) Dice similarity coefficient (DSC) close to 1 verifies shape similarity between pCT and rCT delineations.

**Conclusion**

Simulation of a repeat CT scan based on RBFs successfully corrects pelvic rotations, while maintaining minimal skin displacement and preserving tumor and OAR shapes. To manage systematic rotations, the simulated rCT should be based on the average registration of N CBCTs. The proposed method is a highly efficient alternative for repeat CT scanning to adapt pelvic treatment plans for systematic rotations.

**Purpose or Objective**

**Purpose/Objective:**

Dual-energy CT (DECT) is a more and more widespread technique based on the merging of two CT scans acquired at different tube potentials (80 and 140 kVp) to improve differentiation of materials and patient tissues. Images obtained through virtual monoenergetic reconstruction (MONO) can improve image quality compared with conventional single-energy CT scanning (SECT). The purpose of this study is to investigate potential applications of MONO reconstructions to improve soft-tissue contrast with no need of contrast medium injection, and consequent repercussions on target volume identification and delineation.

**Material and Methods**

The CIRS® Electron Density Phantom containing different tissue-equivalent inserts was imaged using two CT scanners: Siemens Somatom Confidence (sequential scanning at two tube voltages) and General Electric (GE) Revolution GSI (rapid switching of tube voltage). SECT and DECT acquisitions were performed maintaining a similar dose level and MONO images were then reconstructed at various energies levels (40, 50, 70, 100, 120, 140, 190 keV). In the first step of our analysis, both SECT and DECT images were reconstructed through a Filter Back Projection (FBP) algorithm. CT numbers and their standard deviations were measured within the CIRS® inserts to

evaluate different contrasts (breast-adipose, muscle-adipose, liver-adipose) of MONO reconstructions with respect to SECT images.

**Results**

In general, a soft-tissue signal enhancement was observed with the decrease of MONO images reconstruction energy. The greatest signal enhancement is observed at 40 and 50 keV compared to SECT for adipose and breast inserts for both scanners (Figure 1). Moreover, at 40 keV breast-adipose CT number contrast results in +48% and +45% for GE and Siemens respectively when compared to SECT data. At 50 keV this contrast enhancement is still observable (+19% and +14% for GE and Siemens respectively). As expected, higher energy MONO reconstructions show less contrast with respect to SECT data (Table1).

**Conclusion**

**Conclusion:**

Low energy (40-50 keV) DECT MONO reconstructions increase soft-tissue contrast, potentially allowing a better radiotherapy target volume identification and delineation, in particular when breast and pelvic anatomy are involved. The increased image noise associated with lower MONO energies could be at least partially compensated by using iterative reconstruction algorithms. Our results suggest that a great advantage might be achievable for example in the neoadjuvant radiotherapy of breast cancer, especially in the partial breast irradiation with ablative intent.

**EP-2055 Impact of patient-specific MRI distortion correction for stereotactic cranial target definition**

T. Gevaert<sup>1</sup>, B. Engels<sup>1</sup>, C. El Aisati<sup>1</sup>, M. De Ridder<sup>1</sup>

<sup>1</sup>Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

### Purpose or Objective

The accuracy of a stereotactic treatment is primarily limited by the least accurate process in the whole chain of events from patient scanning to patient treatment. The total error is accumulated through the processes of a) target localization and planning using medical imaging (computed tomography (CT) and magnetic resonance imaging (MRI), image fusion, dose planning, and b) dose delivery using image guidance patient positioning, immobilization devices and a radiation dose delivery system.

QA is often performed on the dose delivery and planning section rather than the localization. This targeting is primarily limited by the accuracy of the CT and MRI images. In theory CT scans are precise. In contrast, MRI datasets are subjected to distortions, due to nonlinearity of gradient fields, and may cause incorrect target definition.

This study aimed to analyze the impact of a patient-specific algorithm, Cranial distortion Elements (Brainlab, München, Germany), rather than a manufacture-specific, to correct spatial distortion in cranial magnetic resonance images.

### Material and Methods

Twelve trigeminal patients treated with a single dose of 90 Gy with a 4mm collimator were studied retrospectively. A radiosurgery target (gross target volume (GTV)) was defined on a 1.0mm T1 MPRAGE and T2 MRI corrected for distortion with a machine-specific algorithm.

For this study, the manufacture-specific corrected MRI was further corrected using a patient-specific distortion correction algorithm that references the treatment planning CT. The GTV were then mapped onto this newly created patient specific corrected MRI dataset. The original defined target and the corrected deformed object were mutually compared by means of several quantitative measures such as Dice, Jaccard, and Hausdorff indices. The average distance between the two centers of the two GTV was also calculated.

### Results

On average, a good agreement was found between both GTV resulting in a Dice index of 0.76 (SD 0.23) ranging between 0.13 and 0.92. The Jaccard index, which is an intersection over Union was similar ( $p > 0.1$ ) to the Dice with an average of 0.66 (SD 0.23) ranging between 0.09 and 0.86. The greatest of all the distances from a point in GTV to the closest point in the other GTV, called the Hausdorff distance, was 0.73 on average (range 0.50 - 1.80), reflecting good similarity between both GTVs. Average distance between both GTV was 0.43 mm (SD 0.26mm), with a minimum of 0.20 mm and a maximum of 1.10 mm. One out of the 12 patients met criteria of "geometric miss", which was not correlated with clinical outcome.

### Conclusion

Although MRI distortion is often corrected manufacture specific, distortion may persist due to patient specific conditions. Our study showed that the cranial distortion Elements correct all images even when manufacture-specific corrections fail. In order to avoid any geometrical miss, a patient specific distortion correction must be applied for all cranial indication.

### EP-2056 Feasibility of realistic Digitally Reconstructed Radiograph (DRR) rendering through shallow learning

J. Dhont<sup>1,2</sup>, J. Vandemeulebroucke<sup>1</sup>, I. Mollaert<sup>3</sup>, D. Verellen<sup>2,3</sup>

<sup>1</sup>Vrije Universiteit Brussel, Department of Electronics and Informatics ETRO, Brussels, Belgium ; <sup>2</sup>Vrije Universiteit Brussel, Faculty of Medicine and Pharmaceutical Sciences, Brussels, Belgium ; <sup>3</sup>GZA Ziekenhuizen Sint-Augustinus- Iridium

kankernetwerk, Department of Medical Physics, Antwerp, Belgium

### Purpose or Objective

Accurate DRRs with realistic soft-tissue contrast could aid markerless tumor tracking. Purpose of this study is to investigate the feasibility of accurate DRR rendering using a shallow neural network (NN) that models the CT-to-Xray intensity, including non-linear effects such as beam-hardening, omitting multiple phantom measurements and Xray source modeling.

### Material and Methods

To overcome the black box character of deep-learning (DL), this study was divided into several controlled steps. Initially, real-patient data was omitted to avoid object deformations, and input and output data was rendered using a static CIRS thorax phantom. One planning CT image (512\*512\*328, 1 mm slice thickness, 1.1x1.1 mm<sup>2</sup> in-plane res., Toshiba) and one full-fan CBCT image (TrueBeam STx, Varian) were acquired, of which only the anterior-posterior (AP) projection image (1024\*768 ppx, 0.39 x 0.39 mm<sup>2</sup> res.) was used.

To render input for the NN, a ray-tracing algorithm was developed in Matlab, see Figure 1. Taking into account the CBCT acquisition geometry, the nearest CT voxel was sampled every 1 mm on a straight line from the Xray source to each pixel in the AP projection image, resulting in 1024\*768 rays. Per ray, most surrounding was discarded, keeping 500 samples per ray centered around the phantom as input to the model.

Secondly, to determine the model topology and optimize the hyper-parameters while keeping other degrees of freedom to a minimum, the line integral over each ray was taken as the output target value for each ray, creating a raw DRR value. In total 1024\*768 input-output couples were generated, of which 24% were discarded to avoid imbalance. Of the remainder, 98% was used to determine model topology, for hyper-parameter optimization and for training, while 2% was used for validation, sampled randomly.

A shallow feed-forward regression network, see Figure 1, was created using TensorFlow, consisting of an input layer of 500 nodes, one single-node fully-connected hidden layer with rectified linear activation (ReLU) function, and a single-node output layer. Stochastic gradient descent was used to optimize the network weights and the loss function was minimized based on the mean squared error (MSE). The network accuracy was evaluated using student's t-test to determine the statistical significance of the difference between the predicted and ground-truth output values in the validation data-set.

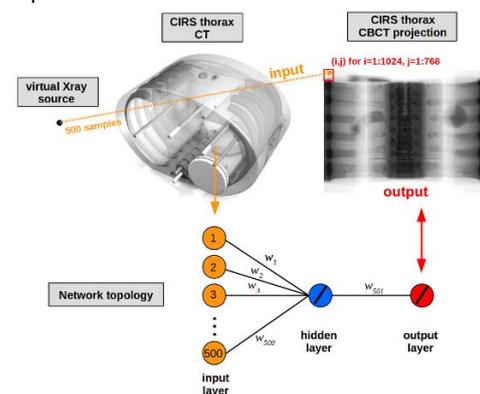

Figure 1: A ray-tracing algorithm was used to sample the CT image and generate 500 input samples per ray, for every pixel in the corresponding projection image, whose values will be used as targets in the illustrated network topology.

### Results

Student's t-test showed no significant difference between the predicted and ground-truth output values ( $p < 0.001$ ), with maximum intensity differences of 0.1%.

## Conclusion

The first steps in this feasibility study, implemented to avoid the black box nature of DL, allowed to render useful and sufficient training and validation data, and to construct an accurate NN with optimized hyper-parameters. In a next step, the pixel intensity in the projection image corresponding to each ray will be used as output target value, to include the non-linearities into the model and to render realistic DRRs.

## EP-2057 Influence of implanted metals in new CT reconstruction algorithm for radiotherapy treatment planning

T. Kamomae<sup>1</sup>, T. Nakaya<sup>2</sup>, F. Kawabata<sup>2</sup>, K. Okudaira<sup>2</sup>, M. Kumagai<sup>1</sup>, H. Oguchi<sup>3</sup>, Y. Itoh<sup>1</sup>, S. Naganawa<sup>1</sup>

<sup>1</sup>Nagoya University Graduate School of Medicine, Department of Radiology, Aichi, Japan ; <sup>2</sup>Nagoya University Hospital, Department of Radiological Technology, Aichi, Japan ; <sup>3</sup>Nagoya University Graduate School of Medicine, Department of Radiological and Medical Laboratory Sciences, Aichi, Japan

## Purpose or Objective

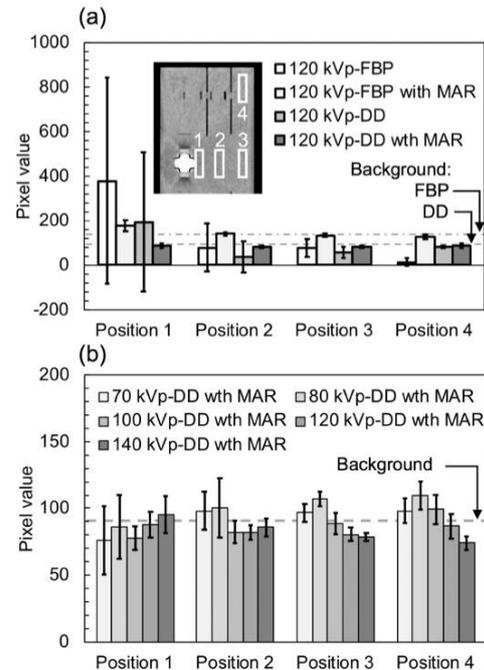

Computed tomography (CT) imaging is used to delineate organs and calculate the dose distributions for treatment planning. To calculate the dose distributions, the CT numbers are converted to relative electron density (RED) or mass density by using the conversion curve that depends on the X-ray tube voltage. A recently developed algorithm directly reconstructs the CT images constructed from the RED values, which are independent of the tube voltage. This algorithm offers the freedom to choose the tube voltage to obtain higher contrast images. We have recently clarified the feasibility of using this algorithm for accurate dose calculations in the low- to middle-density regions correspond to the human body tissues. In this work, we evaluate this algorithm in the regions containing high-density implanted metals, which lead to the metal artifacts.

## Material and Methods

Gammex phantom with various rods inserted was scanned to evaluate the CT number to RED conversion curves. These rods contained titanium and steel. All raw data were reconstructed with the standard filtered back-projection (FBP) and the novel DirectDensit™(DD) algorithms, and additionally, the metal artifact reduction (MAR) algorithm was applied. Furthermore, the CT images of the experimental oral phantom that contained a mock metal crown and tooth were obtained with various tube voltages to evaluate the impact of metal artifacts and dose perturbations.

## Results

For the rods correspond to the human body tissues (i.e., lungs, soft tissues, and bones), the mean differences in pixel values between the present and absent metal rods were  $-6 \pm 31$ ,  $2 \pm 8$ ,  $-2 \pm 25$ , and  $3 \pm 6$  for 120 kV-FBP, 120 kV-FBP with MAR, 120 kV-DD, and 120 kV-DD with MAR, respectively. The maximum pixel value became saturated at about 2500 at the region of titanium and steel for DD images. The artifact indices at 10 mm apart from the metal in the experimental oral phantom were 464, 23, 318, and 8 for 120 kV-FBP, 120 kV-FBP with MAR, 120 kV-DD, and 120 kV-DD with MAR, respectively. For varied tube voltages in DD with MAR images, the artifact indices were 25, 23, 0, 8, and 13 for 70 kV, 80 kV, 100 kV, 120 kV, and 140 kV, respectively. The calculated dose differences between the 120 kV-FBP with MAR and DD with MAR images were in general less than 1% when the density override corrections for the remaining metal artifacts were performed.

## Conclusion

The metal artifacts and dose calculation results of the DD images were the approximation of standard FBP images, and the MAR was also beneficial in the DD algorithm. The restriction of the maximum pixel value in the DD image and the remaining metal artifact that tended to appear in the lower tube voltage need to be considered carefully. The DD algorithm can be used for treatment planning in the regions containing the high-density implanted metals, and lead to the benefit of an optimization of the tube voltage individually in the treatment planning process.

## EP-2058 Measuring eye deformation between planning and proton beam therapy position

M. Jaarsma-Coes<sup>1</sup>, M.S. Schuurmans<sup>2</sup>, M.K.M.A. Hassan<sup>2</sup>, E. Astreindou<sup>3</sup>, M. Marinkovic<sup>4</sup>, F.P. Peters<sup>3</sup>, J.W.M. Beenakker<sup>1</sup>

<sup>1</sup>LUMC, Radiology & Ophthalmology, Leiden, The Netherlands ; <sup>2</sup>LUMC, Radiology, Leiden, The Netherlands ; <sup>3</sup>LUMC, Radiotherapy, Leiden, The Netherlands ; <sup>4</sup>LUMC, Ophthalmology, Leiden, The Netherlands

## Purpose or Objective

Uveal melanoma (UM) is the most common primary malignant intraocular tumour. Proton beam irradiation (PBT) is often the therapy of choice for large tumours. MRI is essential not only for diagnosis but also for the clinical target volume (CTV) definition (shape and extension of the tumour) and PBT treatment planning. However, while PBT is performed with the patient in sitting position, the acquisition of the MRI images are done with the patient in supine position. This change in gravity direction potentially changes the shape of the eye and tumour. As even small geometrical deformation can lead to over- or underdose to the tumour and surrounding healthy tissues, we used MRI to investigate and quantify the effect of different patient positions on the shape of the eye.

## Material and Methods

Seven volunteers and one UM patient were scanned with closed eyes in two positions on a 3T Philips MRI scanner with a 47mm surface coil after giving informed consent. One set of images was acquired in supine position, while a second set was acquired mimicking the patient sitting for PBT (flexed position, figure 1). Additionally, two volunteers were scanned twice in the supine position to assess the reproducibility of the segmentation method.

For the healthy subjects, the analyses were performed on 3D T2-weighted images (0.9mm isotropic) as these provide optimal contrast to differentiate the sclera, while for the UM patients a post-contrast T1 (1.0mm) was used to differentiate between UM and retinal detachment (RD). The analysis strategy is described in figure 1. For the UM patient only the tumour-vitreous border could be accurately compared, as the fast retinal wash-out of the contrast agent changed the appearance of the eye-wall between both acquisitions.

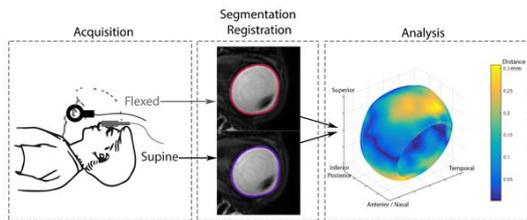

Figure 1. The image in flexed position is registered to the image in supine position and the sclera in both positions is segmented. Subsequently the distances between both segmented sclera meshes were calculated.

**Results**

In healthy controls the median difference between the supine and flexed scans was 0.1mm (95<sup>th</sup> percentile (P): 0.3mm), which is in the order of the reproducibility of the method (95<sup>th</sup> P: 0.3mm), figure 2-A. The slightly larger difference in eye-shapes of subjects 5 was caused by eye-motion artefacts. In the UM patient we found a median deformation of the tumour of 0.1mm (95<sup>th</sup> P: 0.4mm).

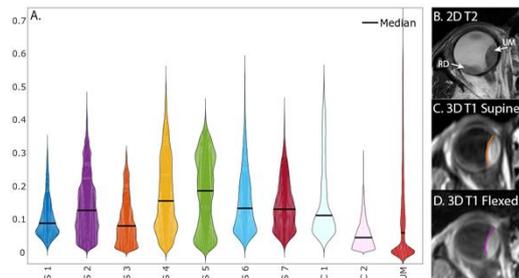

Figure 2: A. Violin plots of the measured distances. Controls (C1&C2) show a measurement reproducibility of 0.3mm. The subjects (S1-S7) and UM patient show similar distances as the controls. B. 2D T2 showing the UM and Retinal detachment (RD). C. 3D-T1 in supine position with segmented UM. D. Registered 3D-T1 in flexed position with segmented UM.

**Conclusion**

Changes in gravity direction produce no substantial changes in sclera and tumour shape. We are currently expanding the number of UM patients, but the results so far indicate that supinely acquired MR images can be used to accurately plan ocular PBT, which is performed in sitting position.

**EP-2059 Assessment of image quality in simulated low-dose paediatric cone beam CT**

J.W.H. Lindsay<sup>1</sup>, A. Bryce-Atkinson<sup>1</sup>, M. Van Herk<sup>1</sup>, M.C. Aznar<sup>1</sup>

<sup>1</sup>The University of Manchester, Faculty of Biology-Medicine and Health, Manchester, United Kingdom

**Purpose or Objective**

Reduction of dose to healthy tissue is imperative to limit the risk of secondary cancers in paediatric patients. Lower imaging dose would naturally reduce this risk and allow for more frequent imaging, which may reduce dose due to

positioning errors and (in proton therapy) range uncertainties. However, it is important to maintain sufficient image quality for position verification and visualisation of potential anatomical changes during the course of radiotherapy. In this work, we have evaluated the image quality for soft tissue visualisation of low-dose CBCT scans simulated for phantom and paediatric patient acquisitions.

**Material and Methods**

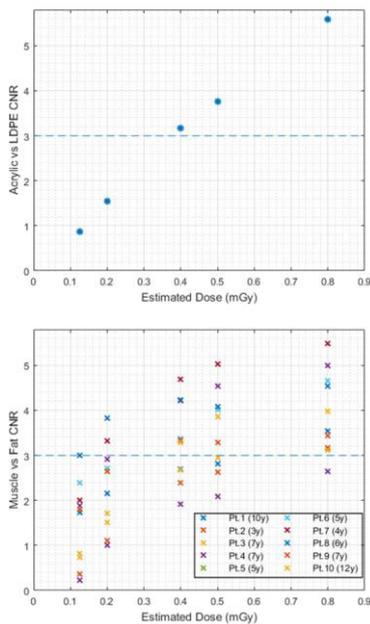

CBCT scans of a Catphan 503 phantom were acquired with Elekta XVI v5.02 using 16mA/10ms and 100 kV, 200 projection images. In addition, CBCT scans acquired as part of routine treatment were collected from 10 paediatric patients (aged 3 to 12 years) with tumours in the abdominal-pelvic region. All scans were acquired using the same exposure (16mA/10ms and 100 kV), small field of view, half rotation. Low-dose images were created by adding non-uniform Gaussian noise to the original projection images prior to reconstruction, accurately simulating exposures of 10mA/10ms, 10mA/8ms, and 5mA/5ms while keeping kV constant. In addition, the imaging dose was estimated as fraction of the CTDI for the acquisition dose (0.8 mGy). Contrast-to-noise ratio (CNR) was determined between subcutaneous fat and abdominal/pelvic muscle for the paediatric scans and between the acrylic and LDPE inserts (most similar to fat and muscle tissue, respectively) of the Catphan.

**Results**

Figure 1 shows an example of simulated low-dose (8mA/10ms and 5mA/5ms) scans compared to the original (16mA/10ms) image. Figure 2 shows the relationship between CNR and dose in paediatric scans and phantoms. Lower-dose simulations created images with more noise and artefacts than the original scans; however the muscle and subcutaneous fat could still be distinguished at all simulated exposures. CNR remained higher than 3 until around 0.5 mGy in paediatric simulations and above 0.4 mGy in the phantom images (sufficient for observation of the selected contrasts for small objects according to the Rose criterion) (Rose, 1974). There was considerable inter-patient variation in CNR for the same dose, which does not seem to correlate with patient age, suggesting these are related to image artefacts.

Figure 1: Original 0.8 mGy pelvic CBCT scan of patient 4 (top) compared to simulated 0.4 mGy (centre) and 0.2 mGy scans (bottom).

**Figure 2:** CNR in phantom (top) and paediatric CBCT simulations (bottom). The Rose criterion (CNR  $\geq 3$ ) is represented by a dashed line. Some patient CNRs are lower than the phantom, indicating the effect of artefacts.

### Conclusion

Simulations of low-dose paediatric CBCT scans show that a lower dose than is currently used clinically is sufficient for image evaluation in paediatric IGRT. As expected, a 50% reduction in dose leads to a 25% reduction in CNR. At 15% of clinically used doses CNR is reduced dramatically, but muscle and subcutaneous fat can still be distinguished. Investigation of the clinical impact of CNR reduction is planned.

### EP-2060 Feasibility of prostate rectum spacer in an MRI only radiotherapy workflow

M. Lerner<sup>1,2</sup>, E. Persson<sup>1,2</sup>, N. Eliasson<sup>1</sup>, M. Moreau<sup>1</sup>, H. Benedek<sup>1,3</sup>, C. Gustafsson<sup>1,2</sup>, P. Nilsson<sup>1</sup>, E. Kjellén<sup>1</sup>, L.E. Olsson<sup>1,2</sup>, A. Gunnlaugsson<sup>1</sup>

<sup>1</sup>Skåne University Hospital, Hematology- Oncology and Radiation Physics, Lund, Sweden ; <sup>2</sup>Lund University, Translational Sciences- Medical Radiation Physics, Malmö, Sweden ; <sup>3</sup>Lund University, Medical Radiation Physics, Lund, Sweden

### Purpose or Objective

A precondition for MRI only radiotherapy is the generation of a synthetic CT (sCT). Previous studies have successfully validated such methods for prostate radiotherapy. A prostate rectum spacer can reduce the dose to the main risk organs while maintaining high target dose. The aim of this clinical study was to validate the use of the spacer in an MRI only radiotherapy workflow by evaluating dose volume criteria and comparing Hounsfield Units (HU) within the spacer structure between the CT and sCT images. Since treatment planning is performed on the sCT, a validation of the spacer is required to ensure correct dose delivery.

### Material and Methods

This study was approved by the Ethical Review Board and informed consent was obtained from all patients. Study participation did not affect treatment prescription, and routine clinical workflow was followed. Eight patients with localized intermediate risk prostate cancer were included. A hydrogel prostate rectum spacer was injected during gold fiducial marker insertion, by an oncologist certified

by the spacer distributor. Besides a CT examination, dedicated MR examinations were performed on a GE Discovery 750w. A T2-weighted image, covering the full body contour, was added to the clinical protocol and was used for sCT generation.

A clinically approved VMAT treatment plan was created based on the CT and clinical local practice. For each patient, the generated sCT was resampled and rigidly registered to the CT. Structures were transferred to the sCT, including a structure delineating the spacer (see image for illustration). Separate body contours were generated based on the respective image. The CT based treatment plan was recalculated on the sCT, using the same number of MU. The dose distributions, based on sCT and CT, respectively, were compared based on the departments clinical DVH criteria. The mean HU value within the spacer structure was compared between the sCT and CT for all patients.

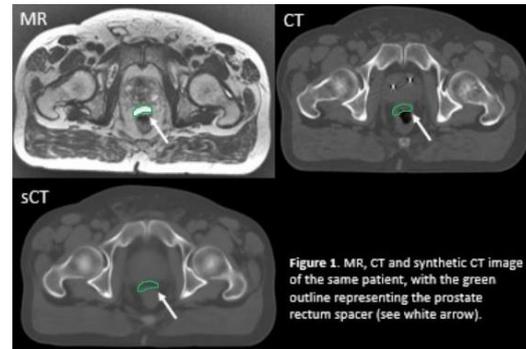

### Results

The median dose differences [95% CI] between sCT and CT for  $D_{mean,PTV}(\%)$  and  $D_{mean,CTV}(\%)$  were 0.45% [0.35, 0.80] and 0.48% [0.40, 0.90], respectively. The median [95% CI] difference between sCT and CT for the rectum dose-volume constraint  $D_{15\%}$  was 0.34% [0.26, 0.56]. Thus, the dose differences between sCT and CT plans for target structures and rectum were found to be small and not clinically significant.

The mean HU within the spacer structure was  $-11.8 \pm 26.7$  HU for sCT and  $7.6 \pm 32.0$  HU for CT.

### Conclusion

The use of a hydrogel prostate rectum spacer is a straightforward procedure which fits well into our MRI only radiotherapy workflow. Minimal differences were found between sCT and CT dose distributions for both target and rectum, comparable to previous studies evaluating the technique without a spacer. The small differences in dose and HU indicate that the use of a prostate rectum spacer in an MRI only workflow is feasible with no clinically significant effect on the dose calculations.

**Figure 1.** MR, CT and synthetic CT image of the same patient, with the green outline representing the prostate rectum spacer (see white arrow).

### EP-2061 Feasibility of MR-only planning in a commercial treatment planning system

H. McCallum<sup>1</sup>, N. Richmond<sup>1</sup>, C. Walker<sup>1</sup>, S. Andersson<sup>2</sup>, S. Svensson<sup>2</sup>

<sup>1</sup>The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom ; <sup>2</sup>RaySearch Laboratories, Research Department, Stockholm, Sweden

### Purpose or Objective

MR is of increasing interest in radiotherapy treatment planning due to its superior soft-tissue contrast compared to CT. An MR-only pathway improves delineation accuracy and removes uncertainty due to CT-MR fusion. This study aims to investigate the feasibility of an MR-only planning solution which relies on bulk-density assignment which is fully integrated within the commercial treatment planning system RayStation.

## Material and Methods

CT and MR images were acquired in the treatment position for five prostate cancer patients. The planning target and OARs were delineated according to the standard practice of the clinic. Conventional VMAT plans were generated for each patient based on the CT image. In order to create a tissue density map to calculate dose on the MR image, a bone ROI was created by a multi-atlas-based segmentation algorithm. To minimise the effect of anatomical differences between the CT and MR image, the external contour defined on the CT image was used for the MR image. The CT based plan was recalculated on the MR image by assigning bulk densities to the external contour and bone. The calculated dose for the CT based plan was compared to the recalculated dose based on the MR image.

In order to find the optimal bulk density assignments for soft tissue and bone, a range of soft-tissue and bone density pairs were evaluated for all patients. The soft-tissue density varied from 0.95-1.03 g/cm<sup>3</sup> in 0.01 increments and the bone density varied from 1.15 - 1.65 g/cm<sup>3</sup> in 0.05 increments. Dose differences between the CT and the bulk density based dose distributions were calculated for D1, D2, D50, D95, D98, D99 and average dose for the PTV, Rectum and Bladder. The density pair with the lowest dose difference between the CT and MR based calculations among all dose statistics and for all ROIs and patients was considered the best and used for the rest of the study. Further, the robustness of this bulk-density approach was investigated by looking at the average dose per ROI for all five patients. **Results**

With a mean absolute dose difference of 0.3% of the prescribed dose over all patients, ROIs and dose statistics, the best results were found with a density of 0.98 g/cm<sup>3</sup> for soft tissue and 1.25 g/cm<sup>3</sup> for bone. In Table 1 the average percentage dose difference of the prescribed dose is shown for each ROI and patient with these densities. The mean average dose was close to 0.0% and the standard deviation was 0.5% or less for all ROIs. Figure 1 shows the CT based dose distribution, MR based dose distribution and DVHs for PTV, Rectum and Bladder for Patient 1.

	PTV	BLADDER	RECTUM	Mean
Patient 1	-0.60	0.04	-0.01	-0.19
Patient 2	0.39	0.43	0.29	0.37
Patient 3	0.48	0.24	0.15	0.29
Patient 4	-0.50	0.01	-0.13	-0.21
Patient 5	0.14	0.14	0.16	0.15
<b>Mean</b>	<b>-0.02</b>	<b>0.17</b>	<b>0.09</b>	<b>0.08</b>
<b>MAE</b>	<b>0.42</b>	<b>0.17</b>	<b>0.15</b>	<b>0.24</b>
<b>SD</b>	<b>0.50</b>	<b>0.17</b>	<b>0.17</b>	<b>0.27</b>

Table 1: The average dose difference of the prescribed dose between the MR image and the CT image in percent.

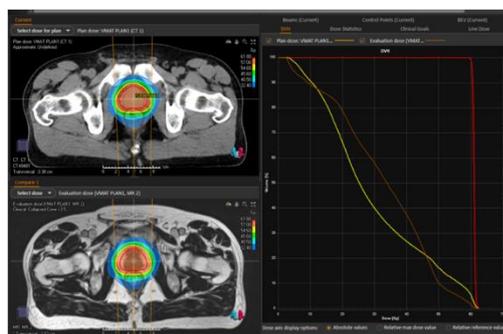

Figure 1: Top left - Dose distribution on CT. Bottom left - Dose distribution on MR. Right - DVH for PTV (red), bladder (yellow) and rectum (brown) CT based statistics solid lines, MRI statistics dashed lines.

## Conclusion

Using bulk-density assignment on MR images with dosimetrically optimized densities for bone and soft tissue results in small dose differences compared to dose calculated on the CT. This demonstrates that an integrated MR-only pathway utilizing a bulk density

assignment for two tissue types is a feasible approach for patients with prostate cancer.

## EP-2062 Feasibility of automatic detection of breast limits for auto-planning

J. Oliveira<sup>1</sup>, M.C. Aznar<sup>2</sup>, Y. Kirova<sup>3</sup>, A. Henry<sup>3</sup>, P. Aljabar<sup>1</sup>, M. Van Herk<sup>2</sup>, P. Poortmans<sup>3</sup>, M. Gooding<sup>1</sup>  
<sup>1</sup>Mirada Medical Ltd, Science department, Oxford, United Kingdom ; <sup>2</sup>University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom ; <sup>3</sup>Institut Curie, Radiation Oncology, Paris, France

## Purpose or Objective

The planning of tangential breast radiotherapy requires the detection of the limits of the breast on CT imaging. The purpose of this abstract is to assess the feasibility of automated methods for detecting those limits without resorting to any manual annotations or markers (e.g., wires) for the patient.

## Material and Methods

Three automated methods were evaluated in this work. The first used a convolutional neural network (CNN) to predict the slice coordinate in a reference volume given a single slice of a query volume (e.g., finding slice location in the superior-inferior axis). Once these normalized coordinates are computed for the query volume, the breast limits can be predicted by matching the normalized coordinates with manual annotations of the limits in the reference volume.

The second method used a CNN to predict the normalized distance to the selected limits given an input slice. This approach is more focused on the limits, nonetheless it has the downside of requiring manual annotations for all the volumes in the training set.

The ground truth for training the CNNs of these two approaches was derived from the deformable registration of the reference volume to the query volumes. The third method predicts the limits of breast clinical target volumes (CTVs) through atlas-based segmentation. This is a simpler approach that requires less parameter tuning, but it requires manually contouring the CTVs for the whole training set.

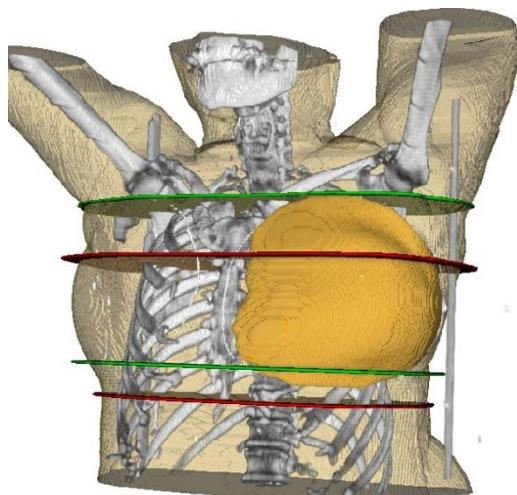

The methods were evaluated in a database of 56 CT scans from breast cancer patients, including manual delineations of breast CTVs contoured according to the ESTRO guidelines. The delineations were used to define the cranial and caudal limits of each CTV. One CT scan was defined as the reference, while the remaining database was divided into 5 folds, where 4 were used for training and 1 for testing. The methods were evaluated on the 55 CT scans by rotating the training and test sets across folds.

## Results

The results for detecting the cranial and caudal limits of breast CTVs are presented in Table 1. Method 2 outperformed method 1 (Figure 1), which may be justified with the former method being more focused on detecting the limits, allowing the CNN to learn a more direct mapping between image features and breast limits. Methods 2 and 3 achieved comparable results, with method 2 performing better for the caudal limit but worse for the cranial limit.

Table 1 - Results of the evaluated methods. The metric used evaluation was the absolute error in number of slices, which is presented in the table in the form of mean absolute error ± standard deviation (lowest values in bold).

Limits	Proposed (approach 1)	Proposed (approach 2)	Atlas-based segmentation
Cranial	11.58 ± 6.56	3.56 ± 3.50	<b>2.95 ± 2.54</b>
Caudal	6.82 ± 5.43	<b>3.89 ± 3.07</b>	4.53 ± 3.43

**Figure 1** – Visual representation of the results for a volume. The red and green planes represent the result of method 1 and 2, respectively. The volume corresponds to the manual delineation of the breast's CTV.

### Conclusion

The results demonstrate that CNN-based methods trained on a relatively small database of CT scans can detect the cranial and caudal limits of breast CTVs with an accuracy comparable to that of an atlas-based segmentation. Besides the accuracy level, a CNN-based method might be a better option than atlas-based segmentation for this application because it requires less manual effort for setup. In the future, methods 2 and 3 will be evaluated in larger datasets to observe how the accuracy and computation scale. Additionally, breast limits on other imaging planes will be considered.

### EP-2063 Treating prostate cancer with MRI-only radiotherapy

**E. Persson**<sup>1,2</sup>, **C. Gustafsson**<sup>1,2</sup>, **J. Nilsson**<sup>1</sup>, **S. Ceberg**<sup>3</sup>, **S. Engelholm**<sup>1</sup>, **S. Bäck**<sup>1</sup>, **L.E. Olsson**<sup>1,2</sup>, **A. Gunnlaugsson**<sup>1</sup>  
<sup>1</sup>Skåne University Hospital, Hematologi- Oncology and Radiation physics, Lund, Sweden ; <sup>2</sup>Lund University, Translational Sciences- Medical Radiation Physics, Malmö, Sweden ; <sup>3</sup>Lund University, Medical Radiation Physics, Lund, Sweden

### Purpose or Objective

The use of imaging has a crucial role in radiotherapy (RT), for localizing both tumours and organs at risk (OARs). Imaging is also an integral part of treatment planning, dose calculations and patient set-up. Magnetic resonance (MR) imaging provides excellent soft tissue contrast. A major argument for replacing CT with MR in the RT process (MRI-only technique) is the significantly improved spatial definition of the target and OARs. In addition, an MRI-only RT workflow may eliminate image registration uncertainties between MR and CT. Excluding CT will simplify the patient logistics process, reduce the number of appointments and may also decrease the workload and reduce costs. The purpose of the MR-PROTECT (The MR-only Prostate RadioTherapy Excluding CT) trial was to implement and prospectively study an MRI-only RT workflow for prostate cancer.

### Material and Methods

Preceding the clinical study and on different patient cohorts, the following tasks were performed: We validated and used the MRiPlanner (Spectronic Medical AB, Sweden) to generate syntheticCT (sCT) from T2w MR-sequence. Target delineation directly on the T2w image was compared to the traditional combined MR/CT delineation process. A dedicated gold fiducial detection tool for MR workflow was developed and tested. A QA method for using cone beam CT (CBCT) for quality control of the sCT was validated. For the clinical implementation study,

forty patients with localized prostate cancer were included for treatment according to an MRI-only workflow based on the validated methods. A CT was acquired after the MR examination, but only strictly used in the background for evaluation of the implementation process.

### Results

For the tasks preceding the clinical study, the following results were obtained: The validation study of the sCT confirmed that MRiPlanner can be used clinically with negligible differences between sCT and CT dose distributions for target and relevant organs at risk. The CTV using MRI-only for delineation was consistently smaller (18%) than using CTV for a combined CT/MR workflow. A dedicated multiecho gradient echo sequence was shown to be a feasible and reliable way for manual identification of fiducial markers (100%). CBCT was a clinically feasible QA procedure for MRI-only RT of prostate cancer patients. Thereby all the methods developed for the clinical study was working appropriately. In the clinical study, 39 of 40 patients completed their treatment with no major deviations. One patient was too large for the field of view of the MR-scanner.

### Conclusion

The results of this prospective clinical trial demonstrate that a successful MRI-only implementation can be achieved with a fine detailed work plan and thoroughly validated methods. One patient was excluded due to a large body contour, a problem that has been solved in a later process during our work. Our results confirm that the CT can successfully be entirely excluded. MRI-only RT enables a high precision RT technique with simplified logistics and less workload.

### EP-2064 A novel method for GTV generation for large-scale analysis of lung cancer patients planned with 4DCT

**A. Davey**<sup>1</sup>, **M. Van Herk**<sup>1</sup>, **C. Faivre-Finn**<sup>1</sup>, **S. Brown**<sup>2</sup>, **A. McWilliam**<sup>1</sup>

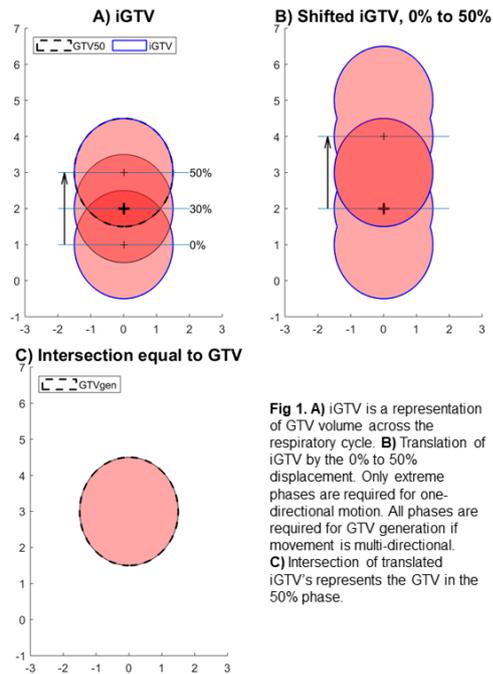

<sup>1</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

### Purpose or Objective

Lung cancer patients undergoing stereotactic ablative body radiotherapy receive 4DCT for treatment planning. Often, an internal gross target volume (iGTV) is directly delineated without defining a GTV. However, the GTV volume and shape are important parameters for prognostic and dose modelling. In this study, we demonstrate and validate a new method to automatically generate the GTV, on any phase, directly from the iGTV.

### Material and Methods

Eleven 4DCT data-sets and delineations were collected from an institutional archive; each plan had a contoured iGTV. The method assumes deformation of the GTV is small compared to its motion. Rigid registration was therefore performed to map the tumour across all 4D phases to a reference phase, e.g. 50%. Registration performance was assessed by the mean and standard deviation (SD) of the correlation ratio cost function. Figure 1 demonstrates the GTV generation method. The iGTV should encompass the GTV volume at all positions across the respiratory cycle (A). Therefore, inversely, if the iGTV is translated by the registration displacements of each phase to the reference (B), the intersection of all translated iGTVs will recreate a GTV volume in the reference coordinate frame, GTVgen (C).

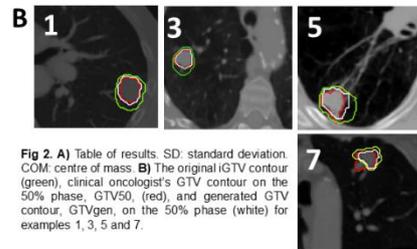

For validation, a radiation oncologist contoured the GTV on the 50% phase (GTV50). For comparison, surface distance to agreement (DTA) was calculated by extracting the absolute perpendicular distance from the surface of GTVgen to GTV50, with mean and SD recorded. For geometric comparison, the volume (V) and surface area (A) were extracted and ratios calculated. For shape, the ratio of sphericity,  $S = (\pi^{1/3}(6V)^{2/3})/A$ , was calculated. To assess position, the vector distance between centre of mass (COM) was extracted.

#### Results

Mean registration cost function was 0.95. The mean tumour motion amplitude calculated as vector of three directions was 7.47mm (range: 2.75-12.60mm). All tumours analysed were T-stage 1 or 2. Six patients had an upper lobe tumour and five had a lower lobe tumour.

Observer variation is reported as 1.2-1.8mm SD (Peulen et al., 2015). The distance variability, DTA SD, is within the range of observer variation (Fig. 2A). Pictorial examples (Fig. 2B) display good agreement. GTV shape was highly accurate. GTV volume was well estimated and a ratio change represents small volume difference.

A	GTV volume (cm <sup>3</sup> )	Volume ratio	Mean DTA (mm)	SD DTA (mm)	Sphericity ratio	COM distance (mm)
1	4.51	1.31	1.16	1.03	1.02	0.55
2	3.16	0.54	0.82	0.99	0.98	2.39
3	3.61	0.96	0.94	1.07	1.02	0.65
4	2.76	1.38	1.27	1.20	1.06	0.77
5	9.05	0.93	1.14	1.13	1.25	3.50
6	16.06	0.71	1.14	1.18	1.01	1.34
7	2.57	1.30	1.77	1.70	0.97	1.86
8	6.83	0.95	0.90	1.05	1.10	1.80
9	14.42	0.83	0.87	0.97	1.07	1.16
10	7.86	0.74	0.90	0.98	1.05	0.94
11	4.32	0.94	0.61	0.91	1.00	0.99

Patient 5 displayed worst results, with a 3.5mm COM deviation and largest sphericity ratio, however, the segmented volume is accurate. Patient 7 provides an example of higher DTA SD but this seems to be driven by observer disagreement, rather than issues with algorithm performance.

#### Conclusion

This study presents and validates a method for automatically generating the GTV from an iGTV. The technique provides a representation of the GTV that is accurate within observer variation. This method supports calculating delivered dose to the GTV without additional delineation and will facilitate large-scale retrospective analysis of patients treated in the routine setting.

#### EP-2065 Simulation PET-CT vs diagnostic PET-CT fusion in head and neck RT: volumetric and planning implications

S. Di Biase<sup>1</sup>, A. Ferretti<sup>2</sup>, E. Bellan<sup>2</sup>, F. Perrotti<sup>3</sup>, A. Augurio<sup>1</sup>, M. Nuzzo<sup>1</sup>, M. Trignani<sup>1</sup>, L. Caravatta<sup>1</sup>, D. Genovesi<sup>1</sup>, G. Mandoliti<sup>3</sup>

<sup>1</sup>SS. Annunziata Hospital, Department of Radiotherapy - G. D'annunzio University, Chieti, Italy; <sup>2</sup>Santa Maria della Misericordia Hospital, Medical Physics Unit, Rovigo, Italy; <sup>3</sup>Santa Maria della Misericordia Hospital, Radiotherapy Unit, Rovigo, Italy

#### Purpose or Objective

To evaluate the dosimetric impact of an automated threshold SUV based delineation method on simulation PET-CT (sPET-CT) compared to manual delineation target volumes on diagnostic PET-CT (dPET-CT) fused with simulation-CT in head and neck (H&N) radiotherapy.

#### Material and Methods

Ten consecutive H&N cancer patients underwent to sPET-CT in treatment radiotherapy set-up. A specific sPET-CT acquisition protocol was optimized by the medical physicist. All patients also underwent to whole body dPET-CT that was co-registered and fused with planning CT using a rigid algorithm (mutual information intensity-based metrics).

1. GTVs were delineated using an automated threshold method at 50% of the intra-lesion SUV max ( $t_{50\%GTV}$ ), both on sPET-CT and dPET-CT. GTVs differences were analyzed in terms of volumetric absolute values, Jaccard Index (JI) and distances from centroids, in order to evaluate shift errors. GTVs were manually

(mGTV) delineated both on sPET-CT and dPET-CT, too.

- CTV was obtained adding an isotropic margin of 9 mm respecting anatomical boundaries; a margin of 3 mm was added for PTV. Plans were then generated using IMRT or VMAT considering also elective nodal irradiation and different dose levels, in the following two steps:
  - First, plans were optimized on the PTVs generated from the manual delineation on dPET-CT; then the coverage of the PTVs deriving from  $t_{50\%}$ GTV on sPET-CT was assessed in terms of target coverage and conformity index (CI), without a plan re-optimization.
  - Secondarily, plans were optimized on PTVs deriving from  $t_{50\%}$ GTV on sPET-CT to evaluate organs at risk (OAR's) dose differences compared to dPET-CT plans.

#### Results

- The volumetric analysis showed a mean JI of 0.2 (0-0.5) between  $t_{50\%}$ GTV on sPET-CT vs  $t_{50\%}$ GTV on fused dPET-CT. Mean distance between centroid in these volumes was 1.05 cm (0.53-2.17cm). Comparing  $t_{50\%}$ GTV, in 6/10 cases the dPET-CT presented larger volumes respect to sPET-CT (mean: 3.7 vs 3.3 cc). Moreover, mGTV on dPET-CT were larger then  $t_{50\%}$ GTV on sPET-CT (mean: 13.2 vs 3.3 cc) in the totality of cases (table1).
- Planning evaluation:
  - In all cases a decrease of CI (mean reduction 18%, range 7%-35%) of PTVs deriving from  $t_{50\%}$ GTV on sPET-CT, introduced into the plans optimized on dPET-CT, was observed; although, in 7/10 cases a good coverage, defined as  $v_{95\%}>95\%$ , was obtained.
  - For plans optimized on sPET-CT, a slightly dose reduction, almost to one of OARs, was observed in all cases.

	Fusion with dPET-CT	sPET-CT
Mean $t_{50\%}$ GTV	3.7 cc	3.3 cc
Mean Jaccard Index	0.2	
Range Jaccard Index	0-0.5	
Mean centroid distance	1.05 cm	
Range centroid distance	0.53-2.17 cm	
Mean mGTV	13.2 cc	11.9 cc

Table 1. Volumetric analysis results

#### Conclusion

Shift errors, related to the image fusion process, negatively influenced concordance between target volumes obtained on sPET-CT and dPET-CT. An adequate coverage of sPET-CT volumes in plans optimized on dPET-CT volumes despite lower CI and a small reduction of dose to OAR's in sPET-CT plans were reported. Based on these preliminary evaluations, sPET-CT could be considered an optimization in RT workflow for H&N cancer management to reduce image fusion uncertainties and to standardize delineation.

#### EP-2066 Evaluation of ANACONDA performances varying the exploited subset of controlling ROIs (AIRC IG-14300)

C. Romano<sup>1,2</sup>, S. Trivellato<sup>1,2</sup>, P. De Marco<sup>1</sup>, S. Comi<sup>1</sup>, A. Bazani<sup>1</sup>, G. Marvaso<sup>3</sup>, D. Ciardo<sup>3</sup>, B.A. Jereczek-Fossa<sup>3,4</sup>, R. Orecchia<sup>5</sup>, F. Cattani<sup>1</sup>

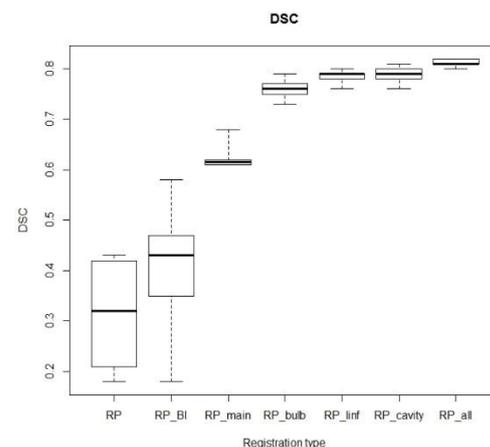

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Unit of Medical Physics, Milan, Italy; <sup>2</sup>University of Milan, Department of Physics, Milan, Italy; <sup>3</sup>IEO- European Institute of Oncology IRCCS, Division of Radiation Oncology, Milan, Italy; <sup>4</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy; <sup>5</sup>IEO- European Institute of Oncology IRCCS, Scientific Directorate, Milan, Italy

#### Purpose or Objective

To evaluate the influence of different controlling Regions Of Interest (ROIs) selection on Raystation ANatomically CONstrained Deformation Algorithm (ANACONDA) performances. This is an ancillary study for further investigations on deformable image registration (DIR) performances in assessing dose accumulation in mixed beam treatments (AIRC IG-14300).

#### Material and Methods

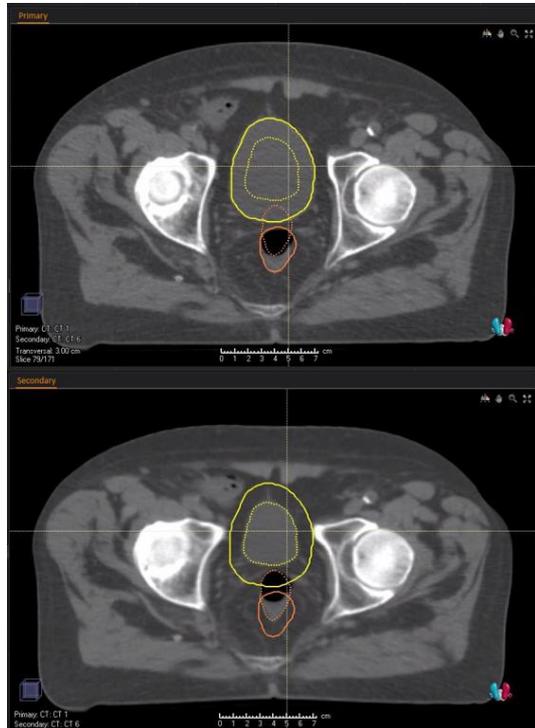

Two different deformed image datasets (target CTs) were computationally generated by applying proper Deformation Vector Fields (DVF) to an original synthetic man pelvis dataset and a real patient CT dataset (reference CTs). The target CTs were obtained by exploiting the ImSimQA package (Oncology System Limited, Shrewsbury, UK). These datasets were generated simulating different bladder filling levels. In both datasets, the bladder enlargement and shrinking were simulated preserving the femoral heads stiffness (figure 1). DIR performances were tested selecting different subset of controlling ROIs to guide the registration. The DIR deformed ROIs were mapped to the target CT and then compared to the ROIs returned from the ImSimQA software. A statistical test was performed to highlight DIR differences based on Correlations Coefficient (CC) and Dice Similarity Coefficient (DSC). This analysis was carried out on the global CC and DSC obtained for each bladder volume by multiplying the CC and DSC scored for all the contoured ROIs (body, bladder, prostate, rectum and femoral heads for the synthetic image case with the addition of penile bulb, peritoneal cavity, anal canal and lymph nodes for the real patient CT dataset).

#### Results

DIR performances improve increasing the number of controlling ROIs reaching a saturation level after the selection of bladder, rectum and prostate in the synthetic phantom case with the addition of the penile bulb in the real patient CT dataset (figure 2). The fluctuation of

bladder filling affects DIR performances only in the case where no controlling ROI is selected or when only the bladder is exploited as controlling ROI. The statistical test shows significant differences on the DSC results between the DIR obtained selecting as controlling ROIs all the available ROIs and the DIR obtained without controlling ROIs or only when a subset of controlling ROIs is selected (bladder or bladder, prostate and rectum). As far as the CC concern, significant differences were observed only between DIR computed exploiting as controlling ROIs all the delineated ROIs and DIR performed without the selection of controlling ROIs or, for the real patient CT case only, where the bladder was selected as controlling ROI.

### Conclusion

ANACONDA performances improve increasing the number of selected controlling ROIs approaching a saturation level after the selection of a defined ROIs subset. This would suggest to reduce the number of controlling ROIs delineated in clinical practice thus decreasing the time spent to contour each patient CT.

### EP-2067 Data driven region of interest respiratory surrogate signal extraction from CBCT data

A. Akintonde<sup>1,2</sup>, H. Grimes<sup>3</sup>, S. Moinuddin<sup>3</sup>, R.A. Sharma<sup>4</sup>, J. McClelland<sup>1</sup>, K. Thielemans<sup>2</sup>

<sup>1</sup>University College London, Centre for Medical Image Computing- Department of Medical Physics and Biomedical Engineering, London, United Kingdom ;

<sup>2</sup>University College London, Institute of Nuclear Medicine, London, United Kingdom ; <sup>3</sup>University College London Hospital, Department of Radiotherapy Physics, London, United Kingdom ; <sup>4</sup>University College London, Cancer Institute, London, United Kingdom

### Purpose or Objective

Cone-beam CT (CBCT) scans performed during a course of radiotherapy can be degraded by respiratory motion. 4D reconstruction or motion-compensated (MC) reconstruction can be used to visualise or compensate for the motion. Both techniques require a respiratory surrogate signal. Surrogate signals derived directly from the projection data are appealing as they require no extra

equipment and may have a stronger relationship to the internal motion than signals from external devices. In this study, we developed a novel method for extracting a surrogate signal directly from CBCT data, and we compared it to the Amsterdam Shroud technique.

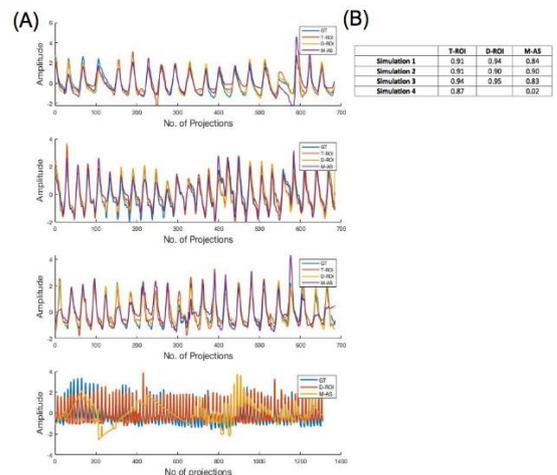

### Material and Methods

A region of interest (ROI) corresponding to either the tumour or diaphragm was selected, and the ROI in the projection data was enhanced by digitally removing the rest of the anatomy. PCA was applied to groups of adjacent projections using a sliding-window approach, and a novel technique used to combine the extracted signals from each window to generate a coherent respiratory signal from the entire data set.

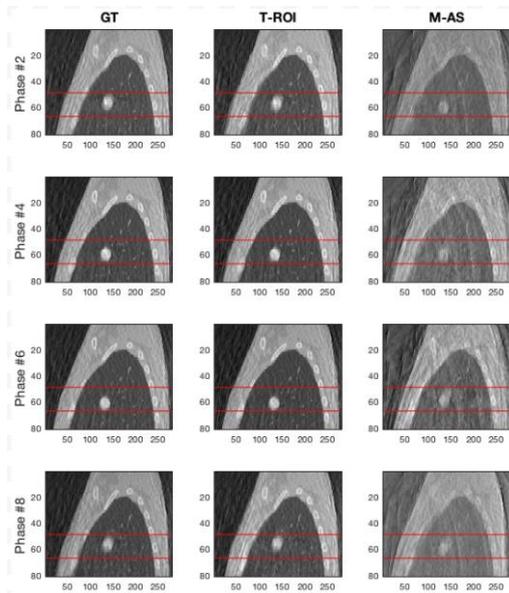

We evaluated our method using four simulated CBCT acquisitions (three standard, one extended) that emulate clinical conditions and were generated with the XCAT computer phantom and real patient respiratory traces as the ground truth (GT) signals. Simulations were performed using OpenRTK. We assessed the signals extracted from the tumour ROI (T-ROI) and the diaphragm ROI (D-ROI) by calculating the correlation coefficient (CC) with the GT signal. For comparison, we extracted a signal generated using a modified Amsterdam Shroud (M-AS) technique, which corrects for the drift that can be present in the original Amsterdam Shroud signal. Finally, phase sorted 4DCBCT images were reconstructed for the extended acquisition using the GT, T-ROI, and M-AS signals.

### Results

Figure 1 shows the different signals for the four simulated acquisitions, also shown are the corresponding CC obtained for each simulation. Figure 2 shows the 4DCBCT reconstructions generated using the different signals. It can be seen that the 4DCBCT images from the T-ROI signal closely resemble the images from the GT signal, whereas the images from the AS signal show clear motion artefacts.

**Figure 1.0.** (A) Respiratory signals obtained from 4 different simulations. The first 3 simulations were standard acquisition with the tumour and diaphragm region in the FOV of the projections, where the last simulation corresponds to an extended acquisition where the diaphragm was not in the FOV. Plots show the signals obtained using our method from 2 ROIs (D-ROI and T-ROI), the M-AS method and the GT. For the last simulation, D-ROI is not shown as not available. (B) Correlation coefficients between the extracted signals, M-AS, and the ground truth signals for the different simulations

**Figure 2.0.** Sagittal planes of the images reconstructed from respiratory sorted phase bins using the GT motion, our proposed method and the M-AS technique respectively. Each row corresponds to a particular phase bin, shown here are the 2<sup>nd</sup>, 4<sup>th</sup>, 6<sup>th</sup> and 8<sup>th</sup> bins (out of 8) respectively. These phases were chosen to highlight the extent of the tumour motion. The red horizontal lines are positioned to show the extent of the tumour motion.

## Conclusion

We have developed a novel method of extracting respiratory motion from CBCT projection data. The method allows selecting a ROI to target the respiratory motion of interest. We evaluated our method on XCAT simulations and compared it to the well-known Amsterdam Shroud technique, combined with a simple method for baseline-drift correction. High correlations were obtained between signals from our proposed method and the ground truth for all simulations, achieving better correlations than when using AS. The preliminary evaluation shows that the proposed technique is therefore a potential candidate for a robust basis for respiratory motion management without need for external equipment. In future, we plan to apply this method to patient data.

**EP-2068 Scatter-corrected CBCTs for online water-equivalent path length calculations in proton therapy**  
 A.G. Andersen<sup>1</sup>, U.V. Elstrøm<sup>2</sup>, B. Winey<sup>3</sup>, J.B.B. Petersen<sup>2</sup>, M. Falk<sup>1</sup>, P. Skyt<sup>1</sup>, O. Nørrevang<sup>1</sup>, C. Grau<sup>4</sup>, L.P. Muren<sup>1</sup>

<sup>1</sup>Danish Centre for Particle Therapy, Department of Medical Physics, Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark ; <sup>3</sup>Massachusetts General Hospital, Department of Medical Physics, Boston- MA, USA ; <sup>4</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

## Purpose or Objective

Releasing the full potential of proton therapy requires mitigation of proton range variations caused by density/anatomy changes during the course of treatment. Cone-beam CT (CBCT) scanners are becoming available at proton gantries, but scatter and other artefacts deteriorate the accuracy of the Hounsfield unit representation in the CBCTs, with implications for online proton range or dose calculations. *A priori* scatter correction algorithms have shown promising results for reducing CBCT artefacts. Proton range calculations based on scatter corrected CBCTs have not yet been compared directly to calculations on conventional CTs in patients. The aim of this study was therefore to do such a

comparison using mid-course CTs of head and neck cancer patients.

## Material and Methods

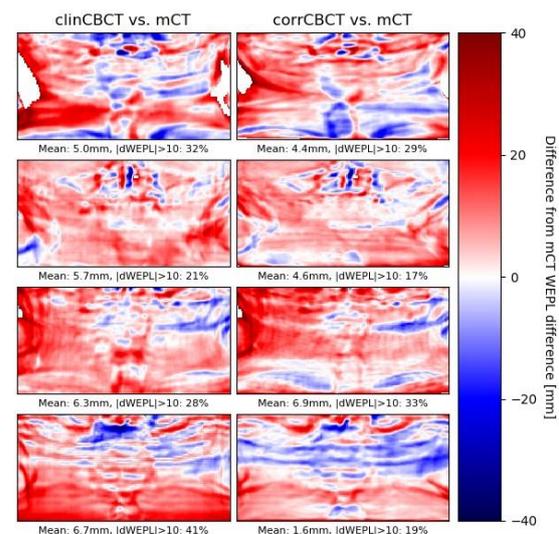

Our scatter correction algorithm initially used rigid and deformable registration of the planning CT (pCT) to a raw reconstruction of the CB projections (rawCBCT). The deformed CT was then forward projected onto the same geometry as that of the CB projections, from which the forward projections were subtracted. The differential projections were then smoothed with a low-pass gaussian filter, to create a scatter map which was then subtracted from the original CB projection before a final reconstruction (corrCBCT). For comparison we also used our clinical reconstruction of the CB projection (clinCBCT), which used the adaptive scatter kernel superposition method (Varian iTools). The pCT, a mid-course CT (mCT) and CB projections acquired the same day as the mCT from four head and neck patients previously treated with photon-based radiotherapy were analysed. Proton ranges, i.e. water-equivalent path lengths (WEPLs), were calculated in planar projections of all voxels in the patients, using the pCT as reference. WEPL maps for the mCT were subtracted from both the corrCBCTs and the clinCBCTs, under the assumption that the patient anatomy changes between the mCT and the CBCT were negligible.

## Results

In three of the four patients, the WEPL maps based on the corrCBCT deviated less from the WEPL maps based on the mCT compared to the clinCBCT (Fig 1). In one case the average across the subtracted WEPL map was reduced from 7 mm to 2 mm, with the fraction of the WEPL maps with deviations exceeding +/- 10 mm reduced from 41% with clinCBCT to 19% using the corrCBCT. In the fourth case the averages were within 0.5 mm.

## Conclusion

Scatter correction of CBCTs translates into clinically relevant improvements in CBCT-based WEPL calculations, opening a potential for online proton range verification/monitoring.

**Figure 1:**

The difference between the WEPL difference of the pCT and mCT, and the WEPL difference of the pCT and the two CBCT reconstructions, in units of mm WEPL. The corrCBCT reconstruction to the right and the clinCBCT to the left. Each row corresponds to one patient.

**EP-2069 Improved dose calculation on CBCT using polyenergetic quantitative (Polyquant) reconstruction**  
 J. Mason<sup>1</sup>, W. Nailon<sup>2</sup>, A. Perelli<sup>1</sup>, S. Andiappa<sup>2</sup>, M. Davies<sup>1</sup>

<sup>1</sup>The University of Edinburgh, School of Engineering, Edinburgh, United Kingdom ; <sup>2</sup>Edinburgh Cancer Centre-

Western General Hospital-, Department of Oncology Physics, Edinburgh, United Kingdom

### Purpose or Objective

The accuracy of radiotherapy dose calculation from cone beam computerised tomography (CBCT) depends on estimation of the electron density accounting for beam hardening, the effects of metal artefacts and inhomogeneous object scatter. However, this is made challenging by the inherent sampling deficit in CBCT and the desire to minimise patient dose. Several studies have considered this problem from the point of view of reconstruction, registration or a combination of the two. Here we present the enhanced electron density and dose planning accuracy made possible by a new direct quantitative reconstruction method called Polyquant.

### Material and Methods

The stereotactic end-to-end verification (STEEV) phantom patient, Model 038, was used for this study (CIRS, Norfolk, VA, USA). Using a 1 mm head protocol planning fan beam CT images were acquired on a Philips Brilliance Big Bore CT scanner fitted with a flat couch (Philips, Amsterdam, The Netherlands). Treatment plans were prepared using the Eclipse treatment planning system (Varian Medical Systems, Inc., Palo Alto, CA, USA) for a 200 MU 10x10 cm<sup>2</sup> field delivered at 9 gantry angles and the dose calculated at a predetermined reference point. The STEEV phantom was set up on a Varian Truebeam linear accelerator and CBCT images acquired using the on-board imager with the preset head acquisition protocol. Physical dose measurements were acquired using a Pinpoint ionization chamber (PTW, Freiburg, Germany) inserted into the dosimetry cavity of the STEEV phantom. Using the 'raw' CBCT projections standard Feldkamp, Davis and Kress (FDK) reconstruction was carried out. Quantitative reconstruction was also performed using our new Polyquant method. Dose calculation was carried out on the FDK-CBCT and the Polyquant-CBCT images on Eclipse and compared to the physical measurement.

### Results

Quantitative results from the physical measurements on the STEEV phantom compared to the calculated dose by Eclipse using the planning CT, FDK-CBCT and Polyquant-CBCT are shown in Table 1 and Figure 1. Not only is the error reduced from the FDK-CBCT result, but the Polyquant reconstruction significantly outperforms the planning CT accuracy with a 26.5% reduction in error. This may be a surprising result due to the usual superiority of fan-beam CT, from its heavily reduced scatter over CBCT, and the routine use of this modality in practice for planning. We would expect that if we had access to the raw data from the fan-beam CT also, the Polyquant applied to this would likely result in better accuracy still.

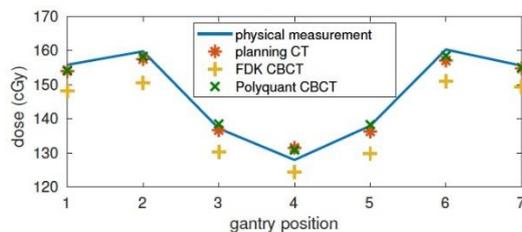

Figure 1: Graphical representation of dose results.

Gantry Angle (deg)	Dose (cGy) from			
	Measurement	Planning CT	FDK-CBCT	Polyquant-CBCT
270	155.84	154	148.2	154.2
300	159.78	157.5	150.6	158.3
330	137.18	136.7	130.4	138.5
0	127.98	131.5	124.4	130.9
30	137.98	136.3	129.9	138.3
60	160.31	157.1	151	158.5
90	155.58	154.8	149.3	155
RMSE	-	2.234	7.491	1.642

Table 1: Results from calculated and physical measurements.

### Conclusion

These preliminary results show that a significant increase in CBCT dose calculation accuracy is possible with the use of the new Polyquant method that we have developed. Further work is however required particularly on the utility of this approach on a range of different phantoms, with different dose calculation algorithms, and also in particle therapy.

### EP-2070 Comparison of multi-atlas based synthetic CT generation methods for radiotherapy for prostate cancer

C. Choi<sup>1</sup>, G. Sasso<sup>2</sup>, B. Pontre<sup>1</sup>

<sup>1</sup>The University of Auckland, Anatomy and Medical Imaging, Auckland, New Zealand ; <sup>2</sup>Auckland District Health Board, Radiation Oncology, Auckland, New Zealand

### Purpose or Objective

Magnetic resonance imaging (MRI) plays an important role in radiation therapy planning (RTP) due to its excellent soft tissue contrast. In recent years, there has been increasing interest in MR-only RTP to prevent registration errors between the MRI and computed tomography (CT) images, to minimise total radiation dose to patients, and to reduce the time and cost associated with planning and treatment. The goal of this study is to evaluate the performance of MRI-guided synthetic CT (sCT) workflows used in a commercial RTP software package.

### Material and Methods

A multi-atlas based sCT conversion workflow was developed using MIM's in-built deformable registration tools (MIM Software Inc., Cleveland, OH). MIM offers three types of deformable registration: one based on image intensities (intensity-based), one using contours of anatomical structures of interest (contour-based), and one using a combination of the intensity-based and contour-based methods (hybrid). The contours for contour-based and hybrid workflows (bladder, prostate, rectum and bone) were manually drawn with reference to axial, sagittal, coronal MR images and validated by a clinician.

The three workflows were tested on CT and T2 weighted MR atlases from six patients using a leave-one-out approach [1]. Once the atlas MR is registered to the target MR, sCTs were generated by applying the corresponding deformation vector field from the registration to atlas CTs, which were then fused to form a final sCT. Dice similarity coefficient (DSC) of the bone region and mean absolute error (MAE) of bone and tissue regions were computed in order to evaluate the performance of the three workflows.

### Results

The target planning CT and sCTs produced from the three workflows are shown in Figure 1. Among the three deformable registration methods, the hybrid deformable registration workflow produced the highest dice coefficient, followed by the intensity-based and contour-based workflows (Table 1). Furthermore, the lowest mean absolute error was also produced using the hybrid workflow. However, the results show a reduction in grey scale contrast due to fusion of multiple sCTs. More focus should be on examining techniques to address this issue.

	Intensity-based	Contour-based	Hybrid
DSC	0.73 ± 0.05	0.62 ± 0.02	0.75 ± 0.04
MAE (bone)	28.05 ± 5.90	37.90 ± 4.63	27.75 ± 4.85
MAE (tissue)	39.89 ± 3.27	44.34 ± 3.01	34.91 ± 2.66

Table 1: DSC and MAE computed between the sCTs and planning CT

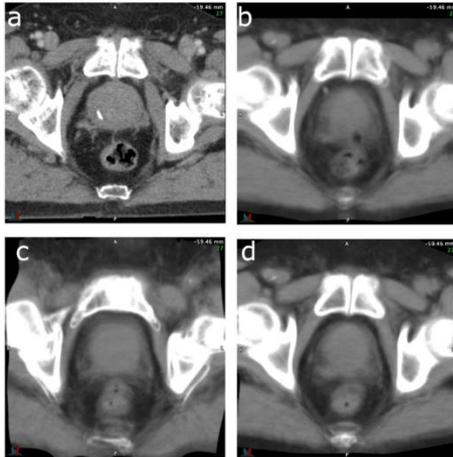

Figure 1: Typical example of a) planning CT b) intensity-based sCT c) contour-based sCT d) hybrid sCT

### Conclusion

In this project, we have tested multi-atlas based deformable registration workflows using commercially available RTP software. Our results indicate that hybrid of intensity- and contour-based deformable registration methods MIM provides the best solution for generating sCTs in the prostate region.

### EP-2071 Redefining the classical Winston-Lutz test for cranial radiosurgery in terms of dose

J.F. Calvo Ortega<sup>1</sup>, S. Moragues Femenia<sup>1</sup>, J. Casals<sup>1</sup>  
<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

#### Purpose or Objective

To analyze the dosimetric impact of the deviations (ball center-field center) revealed by the traditional Winston-Lutz (WL) test.

#### Material and Methods

A pointer-based WL plan containing 15 non-coplanar fields is routinely delivered in our department for SRS QA purpose (Pointer-WL test). The maximum deviation between the ball center and the radiation field center ( $d_{\text{ball-center,max}}$ ) over the 15 taken portal images gives the result of this test. Two acrylic phantoms able to support a radiochromic film in coronal and sagittal orientations, respectively, were home-made. Both phantoms were CT-scanned and transferred to the Eclipse treatment planning system (TPS).

The WL plan was recreated in the Eclipse TPS over each phantom to be delivered (Dose-WL test). This film-based

test was generated to investigate whether the deviations reported by the Pointer-WL test are actually reflecting the geometrical shift of the measured prescription isodose line respect to the target center ( $d_{80\%-\text{center}}$ ). In addition, the film dose distributions were compared with the theoretical distributions computed by the Eclipse, to evaluate the entire delivery accuracy (E2E test) in terms of isodose shifts ( $d_{\text{E2E}}$ ). The Pointer-WL, Dose-WL and E2E tests were performed in 10 different sessions using CBCT imaging. For each session, the  $d_{\text{ball-field,max}}$  value was compared to the three patient's anatomical components (Left-Right or L/R; Anterior-Posterior or A/P; and Superior-Inferior or S/I) of the  $d_{80\%-\text{center}}$  and  $d_{\text{E2E}}$  vectors.

#### Results

The deviations (mean ± SD) found for the Dose-WL (L/R:  $0.5 \pm 0.4$  mm; A/P:  $0.5 \pm 0.4$  mm; S/I:  $0.6 \pm 0.2$  mm) and the E2E tests (L/R:  $0.7 \pm 0.5$  mm; A/P:  $0.5 \pm 0.4$  mm; S/I:  $0.6 \pm 0.2$  mm) were in most cases less than 1 mm, and they were quite less than the maximum deviations registered with the traditional Pointer-WL tests ( $d_{\text{ball-field,max}}$ :  $1.8 \pm 0.3$  mm). On average,  $d_{\text{ball-field,max}}$  exceeded 1.2 mm (in R/L and S/I) and 1.3 mm (in A/P) the deviations reported by the 10 Dose-WL tests. Analogously, an average excess of 1.0 mm (in R/L), 1.3 mm (in A/P) and 1.1 mm (in S/I) were noted for the 10 E2E tests.

#### Conclusion

In this study we have proved that deviations greater than 1 mm as reported by the analysis of a traditional WL test do not necessarily imply shifts greater than 1 mm in the prescription isodose line respect to the target to be treated. According to the results of this work, it is advisable to move to a dose-based WL test by replacing the classical WL test involving a metallic ball that only provides information about geometric misalignments of the isocenter.

### EP-2072 Automatic analysis of patient specific QA measurements made with the Octavius verification device

P. Haering<sup>1</sup>, M. Splinter<sup>1</sup>, C. Lang<sup>1</sup>  
<sup>1</sup>DKFZ, e040, Heidelberg, Germany

#### Purpose or Objective

Patient specific 3D QA measurements with the PTW Octavius phantom are well accepted. A small drawback of the method is, that only the 3d dose distribution can be evaluated what makes it difficult to understand possible deviations found. We present a tool that compares the measurement file to the DICOM RT plan file and detects deviations automatically.

#### Material and Methods

The measurement of the PTW Octavius system results in a time sample structured file, based on the settings given for the system. This file includes the dose matrix together with gantry and time information. The tool presented detects the dose information and puts them together as dose groups by eliminating the beam off times. Calibration and correction factors are also applied. The DICOM RT plan file is searched for MU, MLC, Gantry information which will be sorted to fit the order of the measurement data. Knowing the geometry, RT-plan data are transferred to dose matrixes using a simple scatter model (Gaussian curve based). Measured values are given in the Octavius/array resolution needing an interpolation and correction of partial volume effects, which is also taken care of by a scatter model. The tool now analysis both data sets for dose and position errors which are indicated only if given limitations are exceeded and finally calculates a gamma pass rate per segment/gantry step. 12 patient cases from a Siemens Artiste have been analyzed so far with the IDL (RSI) written tool. Excel sheets then help to understand and display the generated data.

#### Results

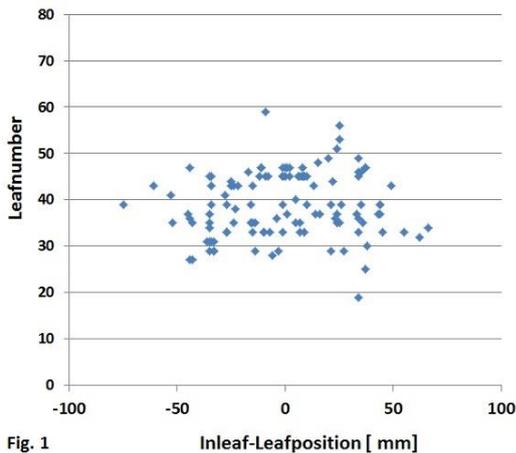

Fig. 1

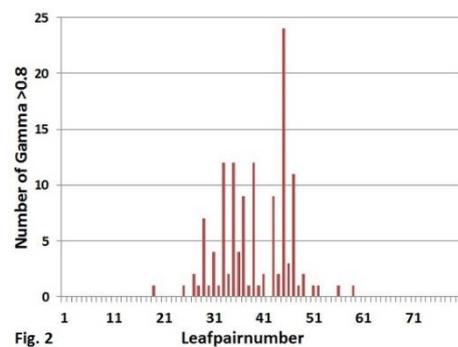

Fig. 2

The additional effort for the analyzation is quite low and just takes a few minutes for copying data and starting the tool. All results can be summarized in a printable report file or Excel sheets. The analyzation of the 12 cases with almost 1000 segmented fields resulted in a mean gamma value 0,549 while only 19 segment fields had a maximum gamma of more than 1, based on a 2mm/3% local criteria. Fig 1 shows positions of gamma values >0.8 in the dose. While here results are equally distributed the histogram of leaf pairs (Fig 2) indicates that the area of leaf pair 45 has highest number of >0.8 gamma values of the matrixes. Here it might be worth to look at the leaf calibration even though center leafs are more in use than others. Beside that, patient cases did show good results and thereby supported the positive 3d dose results. A manipulated test case (changed leaf positions and MU settings) was easily detected by gamma index and local dose error results.

#### Conclusion

The tool breaks up the complex 3D dose verification measurement to an understandable field based approach and automatically checks the dose delivery in a different way. This might have the potential to easier understand why some patient verification measurements might show higher or lower pass rates.

#### EP-2073 Reconstruction of the electron source distribution using in-air measurements and genetic algorithm

E. Borzov<sup>1</sup>, A. Nevelsky<sup>1</sup>, R. Bar-Deroma<sup>1</sup>, I. Orion<sup>2</sup>  
<sup>1</sup>Rambam Health Care Campus - Faculty of Medicine, Oncology, Haifa, Israel ; <sup>2</sup>Ben-Gurion University of the Negev, Nuclear Engineering, Beer Sheva, Israel

#### Purpose or Objective

The intensity distribution of a pre-target electron source in Monte Carlo accelerator model is needed for accurate reproducing of measured photon beam data. The purpose of this study is to develop an approach for the electron source reconstruction problem. The approach should

justify the selection of electron beam parameters in MC simulations aimed to model small fields and detector specific correction factors.

#### Material and Methods

Monte Carlo simulations were performed using the EGSnrc code system. The MC model for the Agility treatment head of the Elekta VersaHD linear accelerator was created and examined in our previous study. The IBA Stereotactic Field Diode was approximated as a silicon chip of relevant dimensions.

In the current study, the electron source was presented as a sum of square sub-sources. We divided the electron target area of 4.8 x 4.8 mm<sup>2</sup> into a number of squares of 0.2 x 0.2 mm<sup>2</sup> in the centre region and 0.4 x 0.4 mm<sup>2</sup> in the peripheral region. Then, each part was treated as an independent electron sub-source in (x,y) position on the target surface. The reconstruction of the source intensity distribution was based on a search of the best agreement between simulated and measured data. Measured data was obtained in the form of a 2D array where each value corresponds to an in-air measurement in a certain position of the SFD detector at SSD 100 cm.

The weights for each sub-source was optimized to minimize a least-square cost-function:

$$\text{CostFunction} = \sum_V (A_V^{\text{meas}} - A_V^{\text{MC}})^2$$

where  $A\{\text{meas},V\}$  is the measured dose at position V in the 2D array of measured doses;  $A\{\text{MC},V\}$  is the MC dose at position V in the 2D array of simulated doses. At position V in the plane of measurements,  $A\{\text{MC},V\}$  consists of a weighted sum of simulated dose  $A\{\text{MC},V\}(x,y)$  from each sub-source in the (x,y) position on the target surface:

$$A_V^{\text{MC}} = \sum_{(x,y)} \text{weight}(x,y) \cdot A_V^{\text{MC}}(x,y)$$

The search for weight factors was performed using a genetic algorithm optimization with rank scaling function and tournament selection function. For benchmarking the proposed technique, the whole procedure was applied in the case where the MC simulation data with the known electron source distribution was used instead of the measured data.

#### Results

The benchmark procedure demonstrated that the algorithm reconstructs the source dimensions with accuracy better than 0.01 cm. Using measured data, the matrix of electron intensity distribution was calculated. After a curve fitting procedure, the matrix was found to be elliptical in shape with Gaussian intensity distribution:  $\text{FWHM}_x = 0.08$  cm and  $\text{FWHM}_y = 0.17$  cm, where x and y correspond to inplane and crossplane directions. The found source dimensions with the current approach are similar to those found in our previous work using empirical method:  $\text{FWHM}_x = 0.10$  cm and  $\text{FWHM}_y = 0.20$  cm.

#### Conclusion

Our results demonstrate that the electron source of the Elekta Versa HD linear accelerator has Gaussian elliptical shape. The approach can be used for accurate parameter selection of the electron source when MC simulations are used for calculation of small field correction factors.

#### EP-2074 Can we use Effective Depth for deformable image registration QA alongside the AAPM recommendations?

M. Wilson<sup>1</sup>, J. Lui<sup>1</sup>, D. Noble<sup>2,3</sup>, G. Royle<sup>1</sup>, S. Holloway<sup>1,4</sup>

<sup>1</sup>University College London, Medical Physics and Biomedical Engineering, London, United Kingdom ;  
<sup>2</sup>Cambridge University Hospitals NHS Foundation Trust, Oncology, Cambridge, United Kingdom ;  
<sup>3</sup>University of Cambridge, Oncology, Cambridge, United Kingdom ;  
<sup>4</sup>NIHR University College London Hospitals Biomedical Research Centre, Medical Physics, London, United Kingdom

### Purpose or Objective

A common problem with the QA of deformable image registration (DIR) algorithms is the absence of ground truths with which to generate quantitative metrics for performance evaluation. It was hypothesised that Effective Depth (ED) calculations could be used as a surrogate ground truth for assessment of image warping using DIR for daily proton dose evaluations.

### Material and Methods

We compared two DIR algorithms, open-source software NiftyReg and commercial solution OnQ (Oncology Systems Ltd.), by deforming two head-and-neck CT scans to a repeated scan at the end of treatment for two different modalities: repeated CT (rCT) and image-guidance MVCT. Effective Depth (ED) Dose calculations were then performed using an in-house effective depth algorithm and stoichiometric calibration curves for the relevant modalities (MVCT and kVCT). The quality of the DIR performance was assessed according to APPM TG132 recommendations. By comparing the effective depth calculated, we can determine the range errors associated with the DIR that are relevant for dose calculations.

### Results

We performed ED calculations for an equally-spaced range of 32 coplanar and non-coplanar beam angles centred on the GTV centroid as shown in Figure 1.

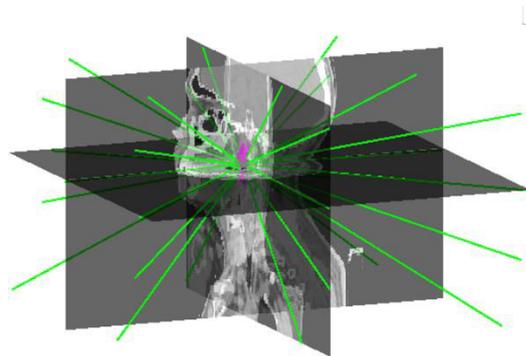

Figure 1: The selection of 32 beam angles used to calculate the Effective Depths. The isocentre was defined as the centroid of the gross tumour volume.

The EDs were calculated for the deformed CT and the ground truth rCT and MVCT for comparison of the percentage difference. For the standard DIR QA, we calculated the mean surface distance, dice similarity coefficient (DSC) and Hausdorff distance (95<sup>th</sup> percentile) for five organs at risk outlined on the CT, rCT and MVCT images: the parotid glands, submandibular glands and spinal cord.

The results are shown in Table 1.

Modality \ DIR Metric	Mean Surface Distance [mm]	DSC	Hausdorff Distance [mm]	Effective Depth MAE [%]
MVCT OnQ	1.92 (0.69)	0.75 (0.07)	5.63 (1.90)	4.00 (3.38)
MVCT NiftyReg	1.59 (0.66)	0.78 (0.07)	5.22 (2.14)	3.64 (3.06)
rCT OnQ	1.48 (0.48)	0.78 (0.05)	3.45 (0.96)	2.49 (3.65)
rCT NiftyReg	1.78 (0.31)	0.82 (0.02)	3.01 (0.62)	1.71 (2.09)
AAPM standards	~2-3mm	~0.80-0.90	N/A	N/A

Table 1: Results of the DIR evaluation metrics. For the contour-based metrics, the values are given as a mean over five organs at risk with the sample standard deviation in brackets. The ED is provided as a mean absolute error over 32 beam angles with the standard deviation in brackets.

The results show that when the DIR is within tolerance according to the APPM recommendations, the %ED error is also within 3%. When the DIR is just outside the tolerance, as observed for the MVCT, the mean %ED error is between 3-4%. NiftyReg performed better than OnQ for both standard QA metrics and ED error for both modalities. The large %ED errors (>3%) for both NiftyReg and OnQ occurred at similar beam angles for both MVCT and rCT. However, the ED difference for NiftyReg and OnQ was systematically greater than the ground truth for MVCT but with opposite signs with respect to the ground truth for rCT.

### Conclusion

This work highlights the potential for ED to be used as a QA measure for DIR for the purposes of proton dose calculations, which does not require labour-intensive manual contouring on the images involved. However, we also think this method would be useful for standard radiotherapy in centres using TomoTherapy with MVCT as daily IGRT. ED calculations could be used concurrently with contour propagation for QA of regular dose delivered assessments. Further work will be to implement this technique in a TomoTherapy centre and evaluating other commercial DIR software. A limiting factor to this work is that current proton centres use CBCT as their method of IGRT, which ED cannot be calculated on directly at present.

### EP-2075 mARC vs. IMRT prostate treatments: OAR dose distribution analysis stratified by PTV extent

R. Bermúdez Luna<sup>1</sup>

<sup>1</sup>Hospital Universitario de Fuenlabrada, Medical Physics, Fuenlabrada, Spain

### Purpose or Objective

mARC is the volumetric modulated arc therapy technique provided by Siemens. This technique was implemented in our centre during 2016.

Among the reported benefits of the volumetric modulated arc therapy plans is that they can yield dose distributions highly conformed to the target volumes with improved protection of the surrounding organs at risk (OAR).

The aim of this work has been to compare the dose distributions obtained with mARC plans with those corresponding to the IMRT technique in prostate cancer radiotherapy treatments. The analysis has been focused on the OARs and has been stratified according to seminal vesicle and pelvic lymph node involvement.

### Material and Methods

The dose-volume histograms (DVH) of 60 prostate cancer mARC plans have been analysed and compared to the

results corresponding to 60 seven-field step and shoot IMRT plans that had been previously delivered in our centre. Both samples were formed by 3 groups of 20 patients each, regarding the target volume extent: prostate (PR), prostate and seminal vesicles (PR+SV) and prostate, seminal vesicles and pelvic lymph nodes (PR+SV+PLN).

All treatments had a prescription dose to the prostate PTV of 70 Gy in 28 fractions (2.5 Gy/fraction). In case of seminal vesicle involvement, the corresponding PTV had a prescription dose of 56 Gy (2 Gy/fraction). If the pelvic lymph nodes were also considered for treatment, the prescribed dose to their PTV was 50.4 Gy (1.8 Gy/fraction). Plans were optimised to meet the dosimetric requirement of at least the 95% of each PTV receiving the 95% of its prescription dose, with the OARs being irradiated with the lowest dose as possible.

Several dosimetric quantities and the mean DVHs have been evaluated for the rectum, bladder and femoral heads.

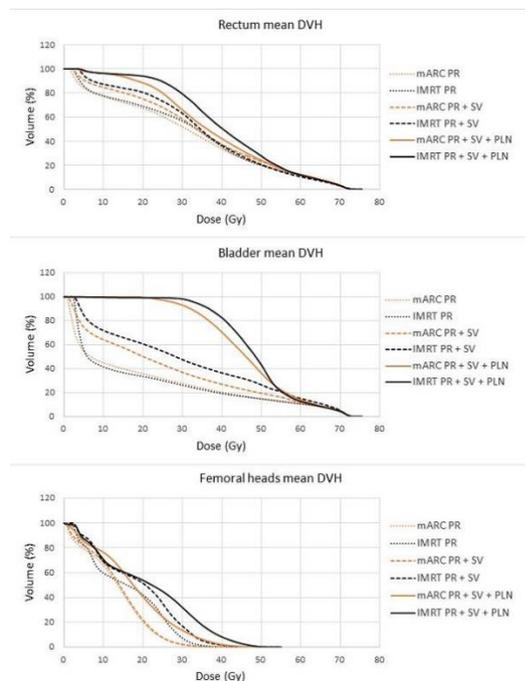

The unpaired t-test or the Mann-Whitney test have been conducted on the evaluated parameters to assess statistically significant differences among both techniques, with a 5% significance level.

### Results

Every plan was considered valid for treatment by the radiation oncologists.

The table lists the results of the analyses (mean values  $\pm$  standard deviations; n.s.: not significant). The mean DVHs are displayed in the figure.

Organ at risk	Plan parameter	Group	IMRT	mARC	p
Rectum	Mean dose (Gy)	PR	32.1 $\pm$ 3.7	31.4 $\pm$ 5.1	n.s.
		PR + SV	35.4 $\pm$ 3.8	34.5 $\pm$ 5.1	n.s.
		PR + SV + PLN	41.1 $\pm$ 2.7	38.1 $\pm$ 3.4	0.004
Bladder	Mean dose (Gy)	PR	19.1 $\pm$ 8.8	19.7 $\pm$ 8.6	n.s.
		PR + SV	32.4 $\pm$ 10.7	25.9 $\pm$ 5.7	0.043
		PR + SV + PLN	48.4 $\pm$ 3.3	46.6 $\pm$ 4.7	n.s.
Femoral heads	Mean dose (Gy)	PR	15.9 $\pm$ 3.1	13.3 $\pm$ 2.0	0.010
		PR + SV	19.1 $\pm$ 3.3	13.8 $\pm$ 1.9	< 0.001
	PR + SV + PLN	21.5 $\pm$ 3.4	18.0 $\pm$ 2.1	0.002	
	Maximum dose (Gy)	PR	41.0 $\pm$ 5.5	36.2 $\pm$ 6.6	0.016
		PR + SV	43.9 $\pm$ 7.4	35.5 $\pm$ 5.6	< 0.001
		PR + SV + PLN	50.9 $\pm$ 2.8	47.2 $\pm$ 4.4	0.007

### Conclusion

mARC prostate treatment plans have generated clinically acceptable dose distributions and have shown similar or better protection of the evaluated OARs.

Regarding the rectum, the greatest advantage of the mARC technique has been obtained in the PR+SV+PLN group, in which the mARC plans have yielded a statistically significant mean reduction in the mean dose of 3 Gy.

Considering the bladder, mARC plans have shown a systematic sparing over the entire dose range in the PR+SV group with a statistically significant mean reduction in the mean dose of 6.5 Gy.

With respect to the femoral heads, mARC dose distributions have yielded statistically significant reductions in the mean and maximum doses of every group, showing highly significant mean reductions of 5.3 Gy in the mean dose and 8.4 Gy in the maximum dose in the PR+SV group.

### EP-2076 Is there any advantage in using helium ions over protons for minibeam radiation therapy?

T. Schneider<sup>1</sup>, A. Patriarca<sup>2</sup>, Y. Prezado<sup>1</sup>

<sup>1</sup>Imagerie et Modélisation en Neurobiologie et Cancérologie IMNC, CNRS - Université Paris 11 - Université Paris 7, Orsay, France ; <sup>2</sup>Institut Curie - PSL Research University, Centre de Protonthérapie d'Orsay - Radiation Oncology Department, Paris, France

### Purpose or Objective

Hadron minibeam radiation therapy (hMBRT) is a novel concept combining the normal tissue sparing of submillimetric, spatially fractionated beams [1,2] with the improved dose deposition of ions. The increase of normal tissue tolerances may allow a safe dose escalation in the tumour. Along this line, proton minibeam radiation therapy [3] has already shown a widening of the therapeutic window for radioresistant tumours [4,5]. Next to protons, a possible choice for minibeam radiation therapy are helium ions. Their reduced multiple coulomb scattering compared to protons could lead to more favourable dose distributions, without the possible concerns related to nuclear fragmentation of heavier ions [6,7].

### Material and Methods

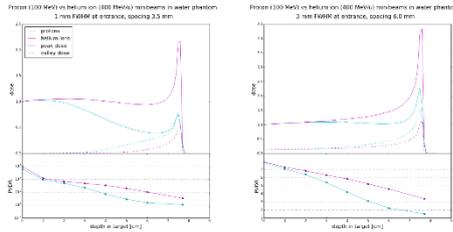

The dose distributions of protons and helium minibeam with the same range (7.7 cm) both in a water phantom and in the computer tomography images of an anonymized human patient (brain tumour) have been assessed by means of Monte Carlo simulations (GATE v.8.0 [7]). Two different full widths at half maximum (FWHM) at the entrance were considered: 1 and 3 mm. Different minibeam spacings and divergences were also evaluated. The peak-to-valley dose ratio (PVDR), entrance-to-Bragg peak dose ratio (EBDR) and lineal energy transfer (LET) were used as figures of merit.

### Results

It was found that the use of helium ions can significantly improve the EBDR yielding a two-fold increase for 3-mm beams and a more than three-fold increase for 1-mm beams, which favours tissue sparing. Due to their reduced lateral scattering, helium ions yield slightly larger PVDRs than proton minibeam, which ultimately might make it challenging to obtain a homogeneous lateral dose distribution at Bragg peak depth with only one array. However, in recent studies in pMBRT, tumour sterilization was achieved even in configurations leading to highly heterogeneous dose distributions [5]. Lastly, no significant difference was observed in terms of LET maps between protons and helium.

### Conclusion

Helium ions may be an optimum alternative for minibeam radiation therapy since they offer improved dose distributions with respect to protons without the possible drawbacks linked to nuclear fragmentations of heavier ions.

**EP-2077 De-intensification of radiotherapy dose to the elective neck in oropharyngeal squamous cell cancers**  
**R. Valentine<sup>1</sup>, A. Martin<sup>2</sup>, S. Currie<sup>1</sup>, C. Paterson<sup>2</sup>**  
<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy Physics Department, Glasgow, United Kingdom ; <sup>2</sup>Beatson West of Scotland Cancer Centre, Radiation Oncology Department, Glasgow, United Kingdom

**Purpose or Objective**

The incidence of oropharyngeal squamous cell cancer (OPSCC) is rising due to Human Papilloma Virus (HPV) infection. HPV-positive (HPV+) OPSCC has a good prognosis and is sensitive to treatment. Standard of care is high dose radiotherapy which is very effective but causes significant and permanent toxicity. There is a consensus that investigation into less toxic treatments for these patients is required. A retrospective planning study was carried out evaluating the effect of delivering a reduced radiotherapy dose to the elective neck, known as Planning Target Volume (PTV\_LR) on dose received by the organs at risk (OARs).

**Material and Methods**

Ten representative patients (HPV+, non-smokers, OPSCC) were re-planned retrospectively using Eclipse TPS v15.5 [Varian Medical Systems, Palo Alto, CA, USA], RapidPlan<sup>®</sup> and multi-criteria optimisation (MCO). All plans consisted of two VMAT fields with two full rotational arcs at 6 MV and 600 MU/min. In our centre, head & neck squamous cancers are typically prescribed 65Gy in 30 fractions to gross disease; High Risk Planning Target Volume (PTV\_HR) while the PTV\_LR is treated to 54Gy in 30 fractions (50Gy equivalent). The original clinical plans were re-optimised with a locally published RapidPlan<sup>®</sup> model and MCO to achieve optimal PTV coverage while maintaining OAR sparing consistent with our centre's specified dose constraints. Subsequently, all plans were similarly re-optimised only this time PTV\_LR was prescribed 42.1Gy in 30 Fractions [40Gy (EQD2Gy)] while retaining 65Gy to PTV\_HR. Finally, plan deliverability for all plans was assessed using the modulation factor (MF) and MLC average leaf pair opening (ALPO).

**Results**

Table 1 highlights the dose differences found between PTV\_HR, PTV\_LR and pertinent OARs when comparing between the 54Gy and 42.1Gy prescriptions to PTV\_LR. Acceptable and within protocol, PTV\_HR coverage was still achieved for 42.1Gy with only a small % reduction found in the D99% and D95% constraints. Comparing between the prescriptions, the dose constraints for PTV\_LR were clinically acceptable with each of the appointed OAR doses significantly reduced for 42.1Gy (p<0.05). On average, we found the MF to be 0.40 and 0.46 and the ALPO to be 2.9 and 3.0 for the 54Gy and 42.1Gy plans, respectively, suggesting highly deliverable plans.

PTV	Coverage/Constraint	Dose Prescribed to PTV_LR		Reduction (%)
		54Gy	42.1Gy	
		Dose (%)		
	D99% > 90%	93.4 ± 0.9	90.6 ± 0.5	-3.0
PTV_HR	D95% > 95%	96.1 ± 0.5	95.2 ± 0.3	-0.9
65Gy	D5% < 105%	103.8 ± 0.3	103.8 ± 0.4	0.0
	D2% < 107%	104.5 ± 0.4	104.7 ± 0.5	0.2
	D99% > 90%	93.0 ± 0.7	90.8 ± 0.7	-2.4
PTV_LR	D95% > 95%	96.2 ± 0.4	95.5 ± 0.5	-0.7
	D5%	109.1 ± 0.8	116.9 ± 3.8	7.1
	D2%	113.6 ± 1.2	129.7 ± 3.7	14.2
OARs		Dmean (Gy)		
Ipsilateral Parotid		32.5 ± 11.4	29.3 ± 11.8	-9.8
Contralateral Parotid		20.6 ± 3.7	15.6 ± 2.6	-24.3
Larynx		42.8 ± 5.9	39.3 ± 6.2	-8.2
Constrictor Muscles		57.2 ± 2.2	50.9 ± 2.7	-11.0

**Conclusion**

By reducing the dose from 54Gy to 42.1Gy to PTV\_LR, we found a significant reduction in OAR doses while maintaining acceptable doses to the PTV\_HR. Due to steep dose response curves seen in OARS, we anticipate that this reduction in radiotherapy dose will translate into potentially important toxicity gains for patients. This approach is likely to be safe due to maintained dose to gross disease yet with potential clinically relevant reductions in dose received by OARS. On the basis of these results a larger dosimetric study is in progress and will form the basis for the radiotherapy protocol and QA work for a clinical trial investigating this strategy.

**EP-2078 Comprehensive risk assessment for the clinical introduction of an MR-linac**

**J. Geuze<sup>1</sup>, R. Bouwman<sup>1</sup>, U.A. Van der Heide<sup>1</sup>, S. Ten Hoeve<sup>1</sup>, M.E. Nowee<sup>1</sup>, T.M. Janssen<sup>1</sup>**  
<sup>1</sup>Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

**Purpose or Objective**

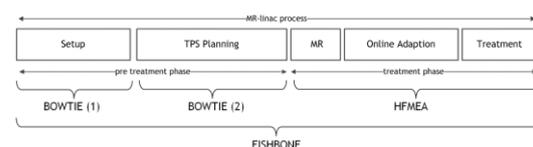

Bodies like Joint Commission International and Health & Safety Executive advise hospitals to use risk assessment methodologies like HFMEA (Healthcare Failure Mode Effect Analysis) to enhance patient safety and reduce unwanted incidents<sup>1</sup>.

A major event like the clinical introduction of the Unity MR-linac (Elekta AB, Stockholm, Sweden) has impact on the complete treatment chain. However, the scope and complexity of this process make a single HFMEA assessment inadequate for thorough identification of potential risks<sup>2</sup>. Alternatively, the execution of multiple HFMEA based risk assessments would be quite time consuming.

The aim of this work is to present a comprehensive risk assessment program, where multiple risk assessment methodologies are combined to ensure patients safety in a complex process like the introduction of an MR-linac.

**Material and Methods**

In the MR-linac treatment process 5 different sub processes are identified (fig. 1). Depending on whether a sub process was MR-linac specific or already clinically implemented, different risk assessment methodologies were chosen.

The sub processes of the pre-treatment phase are quite similar to those for a conventional linear accelerator. The

BOWTIE method is event based, which enables to focus on the distinctions. It is suitable to identify single hazards, root causes and measures that are MR-linac specific. The BOWTIE method has been used in the process of setup and planning.

The HFMEA method is process-based and more appropriate to identify potential failures and risks in the treatment phase. The steps of this process (MR acquisition, online plan adaptation and treatment) don't have an equivalent within the process of the conventional linac.

The final integral assessment is executed with the Fishbone method. By analyzing the 'process defects' based on 4 potential causes (treatment, technology, management/organization and environment) potential interface risks are included in the risk assessment.

### Results

The program resulted in 25 initiated outcome measures. (table 1a). The measures from the BOWTIES where more related with technology, materials, QA and SOP's, were the HFMEA and Fishbone resulted measures associated with task, responsibilities and authorizations.

The comprehensive risk assessment program was executed in five sessions with an average duration of 1h 40' with 19 different healthcare professionals (table 1b) over a period of 8 months (Oct'17 - Jun'18).

Process	Medical devices and supporting materials	Standard operation procedures	Quality Assurance	Training	Tasks, responsibilities and authorizations
Set-up	3	2	1	-	-
TPS Planning	1	2	3	-	1
Treatment	-	1	-	-	2
MR-linac (integral)	-	2	1	1	5
<b>Total</b>	<b>4</b>	<b>7</b>	<b>5</b>	<b>1</b>	<b>8</b>

Table 1a Overview of outcome measures

Process	Method	Involved people	Physician	Physicist	RTT	Session(s)	Total time
Set-up	BOWTIE	4	-	1	3	1	2h 00'
TPS Planning	BOWTIE	4	1	1	2	1	2h 00'
Treatment	HFMEA	5	1	1	3	2	3h 20'
MR-linac (integral)	FISHBONE	6	1	3	2	1	1h 00'
<b>Total</b>		<b>19</b>	<b>3</b>	<b>6</b>	<b>10</b>	<b>5</b>	<b>8h20'</b>

Table 1b Overview of risk assessments

### Conclusion

By tailoring the risk assessment methods for each sub process we able to thoroughly and efficiently identify root causes and potential risks relevant for the patient safety with respect to a complex chain process like MR-linac based radiotherapy. This avoids the need of multiple HFMEA assessments. The integral risk assessment, with the Fishbone method, ensured that overall logistics, interface and process based (potential) risks were identified. [1] Chatman I.J. (The Joint Commission, 2010) [2] Gould J, et al. (Health & Safety Laboratory, 2010)

### EP-2079 HyperArc™ RT for thyroid eye disease: a plan comparison with VMAT and parallel opposed techniques

R. Valentine<sup>1</sup>, S. Schipani<sup>2,3</sup>, P. Cauchi<sup>4</sup>, V. Chadha<sup>4</sup>, J. Connolly<sup>4</sup>, T. Mitchell<sup>2</sup>, D. Ritchie<sup>2</sup>, S. Currie<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy Physics Department, Glasgow, United Kingdom ; <sup>2</sup>Beatson West of Scotland Cancer Centre, Radiation Oncology Department, Glasgow, United Kingdom ; <sup>3</sup>University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom ; <sup>4</sup>Gartnavel General Hospital, Tennent Institute of Ophthalmology, Glasgow, United Kingdom

### Purpose or Objective

To compare HyperArc™ (HA) radiotherapy with 2-Field VMAT (2F-V) and 2-Field Parallel Opposed (2F-PO) technique for the treatment of Thyroid Eye Disease (TED).

### Material and Methods

Patients with high dose steroid refractory TED were selected. The patients were immobilized with a stereotactic radiosurgery (SRS) encompass shell. A non-contrast enhanced CT was acquired with 1mm slices for planning purposes. CT was fused with a baseline diagnostic MRI to better define the Organs at Risk (OARs). CTV was

defined as the bilateral retro-ocular soft tissues including the ocular muscles and the retro-bulbar fat and excluding the lacrimal glands with a 3mm margin. CTV was expanded to PTV with a 2mm margin. Lenses, optic chiasm, brain, lacrimal ducts, brainstem, hippocampus, pituitary, nasal cavity and lacrimal glands were defined as OARs. HA, 2F-V and 2F-PO plans were generated with Eclipse TPS v15.5 (Varian Medical Systems, Palo Alto, CA, USA). HA used up to 4 arc fields, 3 of which were non-coplanar, optimised collimator angles and a SRS normal tissue objective (NTO) feature for plan optimisation. 2F-V plans consisted of two full rotational arcs. HA and 2F-V plans were generated using high definition 2.5 mm leaf width MLCs along with a 1.25 mm optimisation resolution and grid size. 2F-PO plans were constructed with both anterior field edges placed posterior to the lenses and the posterior field edges covering the orbital apex. All plans were generated using a photon beam energy of 6MV, a dose rate of 600 MU/min, and a dose prescription of 2004 cGy in 12 fractions to the PTV. Dosimetric parameters for PTV and organs at risk (OARs) were evaluated.

### Results

Ten patients were included in the study. HA plans offered superior PTV coverage (p<0.05) at particular dose metrics compared to 2F-V (D99%, D98%) and 2F-PO (D99%, D98%, D95%, D50%). For the HA plans, Dmean to the brain, brainstem, hippocampus, pituitary and nasal cavity were reduced (p<0.05) compared to the 2F-V plans. For the 2F-PO plans, Dmax to optic chiasm, Dmean to lacrimal ducts, nasal cavity and lacrimal glands was higher (p<0.05), while Dmax to lenses, Dmean to brain, brainstem, hippocampus and pituitary was lower (p<0.05) compared to the HA and 2F-V plans. HA gave an increased Dmean to brain, brainstem, hippocampus and pituitary in the range of 0.8-2.4Gy compared to 2F-PO. The dosimetric results are reported in Table 1.

	Constraint	HyperArc (HA)	2F-VMAT	2F-PO
		Dose (%)		
PTV	D99%	91.6 ± 3.9	89.0 ± 6.3	6.3 ± 2.1
	D98%	94.0 ± 2.1	92.4 ± 3.1	8.2 ± 3.4
	D95%	96.2 ± 1.5	95.1 ± 2.5	16.0 ± 7.6
	D50%	101.8 ± 0.6	101.5 ± 1.5	99.6 ± 0.8
	D5%	105.8 ± 1.1	105.8 ± 2.1	103.2 ± 0.8
	D2%	106.9 ± 1.3	106.9 ± 2.2	104.1 ± 1.0
		Dose (Gy)		
OARs				
Optic Chiasm	Dmax	5.1 ± 1.4	6.5 ± 3.2	10.2 ± 6.9
Left Lens		5.7 ± 1.9	5.9 ± 1.1	2.3 ± 1.8
Right Lens		5.8 ± 1.9	5.8 ± 1.3	1.6 ± 0.8
Brain	Dmean	2.5 ± 0.2	2.6 ± 0.2	1.0 ± 0.2
Lacrimal Ducts		8.4 ± 3.4	9.5 ± 3.2	11.4 ± 6.9
Brainstem		2.5 ± 0.5	3.4 ± 1.4	0.2 ± 0.02
Hippocampus		2.6 ± 0.4	3.9 ± 1.3	0.2 ± 0.02
Pituitary		2.8 ± 0.6	4.2 ± 2.3	2.0 ± 1.4
Nasal Cavity		7.8 ± 1.7	11.5 ± 2.8	13.5 ± 1.5
L Lacrimal Gland		8.6 ± 4.2	9.5 ± 3.9	17.1 ± 2.3
R Lacrimal Gland		8.6 ± 4.0	9.4 ± 4.0	16.8 ± 2.9

### Conclusion

HA offers better compromise between PTV coverage and OARs sparing especially for lacrimal glands with possible advantage in TED symptom control and long term complications (ocular dryness). A prospective study will be carried out in our institution.

### EP-2080 MC simulations on the dose enhancement effect of antibody conjugated AuNPs in targeted radiotherapy

A. Klapproth<sup>1</sup>, W. Li<sup>2</sup>, S. Stangl<sup>1</sup>, C. Diederichs<sup>1</sup>, M. Shevtsov<sup>1</sup>, V. Ntziachristos<sup>3</sup>, G. Multhoff<sup>1</sup>

<sup>1</sup>Klinikum Rechts der Isar, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>Helmholtz Zentrum

München, Institute of Radiation Protection, Munich, Germany ; <sup>3</sup>Helmholtz Zentrum München, Institute of Biological and Medical Imaging, Munich, Germany

### Purpose or Objective

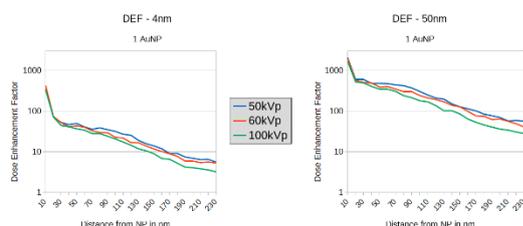

Different cell culture experiments and Monte Carlo simulations already showed that gold nanoparticles (AuNPs) can result in a dose enhancement of radiotherapy. Current *in vitro* results suggest an increased uptake of AuNPs into Hsp70-positive tumor cells after conjugation of AuNPs with cmHsp70.1 antibody. Before the start of *in vivo* investigation, the dose enhancement effect of functionalized cmHsp70.1 mAb AuNPs will be simulated.

### Material and Methods

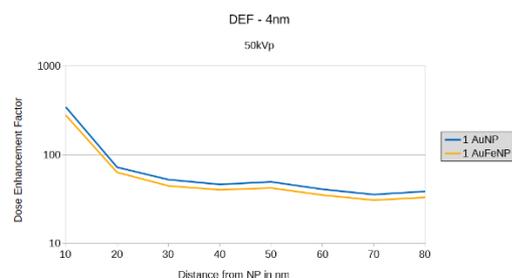

The Geant4-DNA toolkit was used to compute the dose enhancement effects of gold nanoparticles in different cellular compartments after x-ray irradiation. In particular, the amount of energy released by photon interactions will be analyzed after penetration of the x-ray beam through the cell. This energy is released by secondary electrons. Especially Auger-electrons contribute exceedingly to the dose enhancement effect for the tested energy spectra (50kVp, 60kVp, 100kVp). Different nanoparticle sizes (4nm, 10nm, 50nm, 100nm) and distribution patterns were used in the simulations. Simultaneously the same simulations are performed with the same geometry in water without AuNPs. The comparison provides the respective dose enhancement factor (DEF) in distinct areas within a cell. This work provides information about localization and energy deposition of the particle events and also the electron spectrum around the AuNPs.

To allow for tracking of the nanoparticles via MRI, we are planning to include an Fe<sub>3</sub>O<sub>4</sub> core at the center of the AuNPs used in experiments. Accordingly, we repeated the same set of simulations replacing the pure AuNPs with hybrid AuFeNPs.

### Results

The DEF is calculated by dividing the results from simulations containing AuNPs by results from respective simulations without AuNPs. Results of simulations with  $10^8$  photons shot directly at one AuNP are shown in the first figure. Due to the limited range of Auger-electrons, the DEF is at its maximum in immediate range to the AuNP and decreases with increasing range.

The second figure shows the comparison between the courses of the DEF for simulations with 1 AuNP and 1 AuFeNP respectively. A decrease in dose enhancement was expected, since iron-oxide is less likely to produce

secondary electrons under irradiation in comparison to a high-Z material like gold. Yet no decrease in functionality that would exclude the hybrid AuFeNPs from implementation could be found so far.

### Conclusion

The limited range of secondary electrons and fast decrease of the DEF with increasing range underlines the importance of developing techniques to deliver the AuNPs not only into the tumor cells but at best in close range to their nucleus to maximize the probability of cell death during irradiation.

The results of the simulations will be used to compute the overall dose in a phantom under irradiation. By this we determine optimal conditions for the subsequent *in vivo* experiments, where cmHsp70.1 conjugated GNPs will be tested in small animals treated with radiotherapy.

### EP-2081 Real time CyberKnife dosimetry using Radioluminescence imaging

A. Spinelli<sup>1</sup>, E. D'Agostino<sup>2</sup>, C. Fiorino<sup>3</sup>, S. Broggi<sup>3</sup>  
<sup>1</sup>San Raffaele Scientific Institute, Experimental Imaging Centre, Milano, Italy ; <sup>2</sup>DoseVue NV, Research and Development, Turnhout, Belgium ; <sup>3</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy

### Purpose or Objective

The main objective of this work was the development and the preliminary test of a novel real-time 2D dosimetry approach for CyberKnife quality assurance using radioluminescence imaging (RLI) with a commercial CMOS detector. In particular, the possibility to verify collimators field size was investigated. Radioluminescence light was generated by two flexible and thin scintillators film composed respectively of green-emitting and red emitting rare earth phosphors.

### Material and Methods

A CMOS detector was mounted on a photographic tripod and coupled with a F=1.4, 8 mm C-mount lens (Edmund Optics) facing the scintillator film placed on the patient bed, as shown in figure 1. The scintillator film was placed under a 1 cm slab of PMMA.

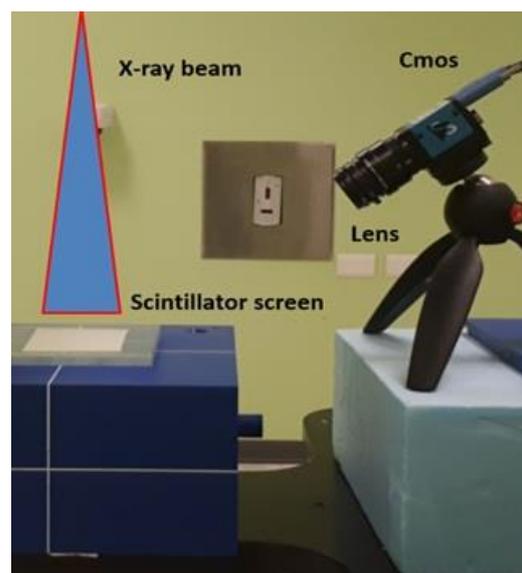

Figure 1 RLI acquisition setup in the CyberKnife treatment room. The CMOS is mounted on a tripod and coupled to a C-mount lens facing the film.

Dose measurements were performed using the CyberKnife system (Accuray) switching off the main treatment room light during RLI image acquisition; few led lights around the CyberKnife system were on. The CMOS setting was as follows: gain=22, brightness=50 and exposure time=1/100 sec. A sequence of 120 images was acquired every 1 sec

and summed using Fiji. RLI data were corrected for perspective distortion with a home-made program written using Matlab2018b. A perpendicular single beam (Source-Surface Distance = 80cm) was set with different field sizes. Two circular fields with diameter equal to 10 and 40 mm were tested.

Measured planar dose distributions and dose profiles were compared against radiochromic films (GC), including FWHM estimate. Measurement repeatability was tested on both beam by moving and repositioning the CMOS for three times.

### Results

The image correction procedure was confirmed to be able to reduce the perspective distortion at a negligible level and, at the same time, was reproducible. The agreement of the measured dose profiles and beam sizes is fairly good as shown in figure 2; light scattering due to the buildup slab slightly affected the flat region of the profile. The measured FWHM of the 40 mm beam obtained with RLI and CG were respectively equal to 42.4 mm and 42.7 mm.

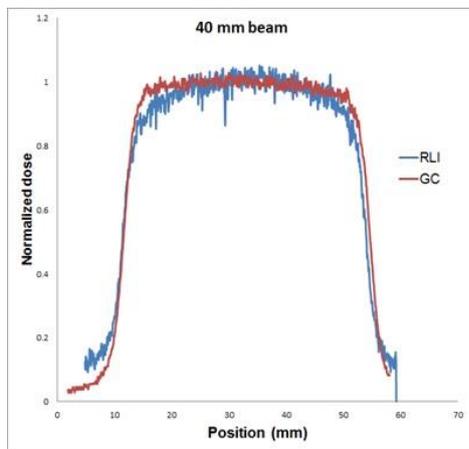

Figure 2 Comparison of normalized RLI and GC beams profiles.

The FWHM of the 10 mm beam were respectively equal to 10.9 mm and 11.3 mm: repeatability tests confirmed RLI values for FWHM within 0.3 mm. The RLI signal was detected in dimmed condition, showing the RLI dose measurements possible even when the lights in the treatment room cannot be totally removed.

### Conclusion

A novel RLI approach based on a thin scintillator screen and a CMOS detector was tested for CK dosimetry, in particular for periodic constancy checks, also allowing real time dose information. Preliminary results show a good agreement with GC dose measurements; the set-up of the measurement (positioning of the detector, fixation, PMMA slab optimization, light collection parameters) may likely be further improved and future investigation is warranted.

### EP-2082 An adapted use of the gamma index method for Monte Carlo dose distributions comparison

M. Cohilis<sup>1</sup>, S. Edmond<sup>1,2</sup>, L. John A.<sup>1</sup>, S. Kevin<sup>1</sup>

<sup>1</sup>Université Catholique de Louvain- Institute of Experimental & Clinical Research, Molecular Imaging- Radiotherapy and Oncology, Brussels, Belgium ;

<sup>2</sup>Katholieke Universiteit Leuven, Department of Oncology, Leuven, Belgium

### Purpose or Objective

In IMRT/IMPT, QA is essential. The quality of the treatment can be verified by comparing the TPS dose to measurements or to Monte Carlo (MC) simulations, which are slower and noisy due to their stochasticity, but more accurate. The most common method of dose comparison is the gamma test. However, this method is known to be

asymmetric and dependent on the noise level in dose distributions. When setting a noisy dose as reference (MCref) in the gamma test, the passing rate (PR) is underestimated, while setting a noisy dose as evaluated dose (MCEval) results in an overestimated PR. MC algorithms nowadays can be fast, but not enough to avoid substantial noise. This work proposes a method to correct the gamma test result when applied to MC doses, while keeping a tractable computation time.

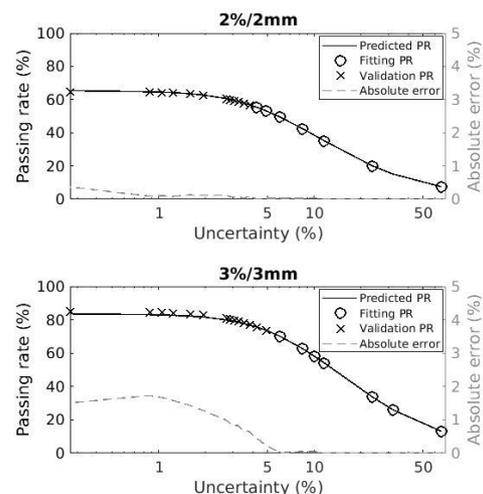

### Material and Methods

The method was derived thanks to the similarities observed between multiple patients. It consists of extrapolating the PR corresponding to a low noise MC dose from several PR computed for various high noise levels. We avoid this way a too costly MC computation. The fitting function has 7 parameters. This model being quite flexible, the optimization is performed with 50 random initial conditions uniformly distributed in a given interval, and the best solution is kept.

This method was applied to 5 PBS proton plans: prostate, lung, liver, brain, H&N. For each of them, using the fast code MCsquare, we computed 21 MC doses with different uncertainty levels: 7 for the fitting (high noise) and 14 for the validation (low noise). Gamma tests were performed between the MC and the TPS dose maps, for each available noise level and 4 different criteria. We then predicted the PR corresponding to the lowest MC uncertainty and compared our results with the actual PR previously calculated. Points used for the fitting corresponded to maximum 2E7 or 4E7 simulated protons in the MC calculation.

### Results

Only the results for MCref case are presented here, but MCEval case is similar. As the method is not deterministic, we applied it 60 times and report here the results as mean values with corresponding standard deviations (SD). Figure 1 illustrates the method for a brain case, showing the fit and the error in each point for two gamma criteria. Table 1 gives the results for all patients. The gain obtained with our method is defined as the difference between two errors: the error made by the classical gamma index for a MC dose calculated with uncertainty S, and the error made by our method when using a smallest fitting uncertainty S. We are thus comparing the methods at equal MC computation time. We see here that the error on the PR at the lowest uncertainty is most of the times between 1% and 3%, with a SD about 1%. The gain is between 0.5% and 12%.

Case		Mean error (%)	Mean gain (%)	SD (%)
Prostate	2%/2mm	1.86	2.38	1.27
	3%/3mm	0.47	5.14	0.74
	4%/4mm	0.94	2.58	0.69
	3%/1mm	1.42	3.17	0.11
Lung	2%/2mm	2.60	11.89	0.45
	3%/3mm	1.07	8.36	0.63
	4%/4mm	0.57	4.60	0.81
	3%/1mm	4.41	11.78	1.18

Table 1: MC<sub>ref</sub> case : summary of the results. The table gives the case, the criterion, the mean errors and gains obtained at the lowest uncertainty available ( $2 \times 10^{10}$  particles) and the standard deviation over these mean values.

### Conclusion

The gamma test can be very sensitive to the noise of MC dose distributions. We propose here a method to correct this bias. The test remains fast (< 7 minutes including MC computations) and provides a PR way more reliable than the conventional gamma test.

### EP-2083 Evaluation of Deformable Image Registration and Dose Accumulation in Prostate SBRT Patients

J. Swamidás<sup>1</sup>, R. Phurailatpam<sup>1</sup>, S. Panda<sup>1</sup>, V. Murthy<sup>1</sup>, K. Joshi<sup>1</sup>, D. Deshpande<sup>2</sup>

<sup>1</sup>ACTREC- Tata Memorial Centre, Radiation Oncology, Mumbai, India ; <sup>2</sup>Tata Memorial Hospital, Medical Physics, Mumbai, India

### Purpose or Objective

To quantify the difference between planned and the delivered dose using deformable image registration (DIR) and deformable dose accumulation (DDA) for patients treated with Stereotactic Body Radiotherapy (SBRT) for prostate cancer.

### Material and Methods

Ten prostate cancer patients previously treated with SBRT (35Gy in 5 fractions) were retrospectively analysed for this study. All patients were treated with Rapid Arc using 10MV FFF beams (Varian Eclipse TPS v13.5.37, True Beam v 2.1, Varian Medical Systems, Palo Alto). Daily cone beam CT (CBCT) was carried out as per the institutional protocol, which includes a bladder filling and a bowel protocol which reproduces the anatomy on the treatment day as compared to the planning day. Delivered dose was calculated by accumulating the doses using DIR and DDA in Velocity DIR software (v 3.2.1). Daily CBCTs were also imported and deformably registered to the planning CT (pCT) and generated a synthetic CT (sCT). RT plan was recalculated on sCTs. The dose calculated on sCTs were deformed back and accumulated onto pCT to estimate the total delivered dose-DDA. The planned and delivered doses were compared using various dose volume parameters for PTV, CTV and OARs (bladder and rectum). Target coverage was estimated by comparing the differences between the planned and accumulated doses of PTV and CTV in terms of V<sub>95%</sub>(%), D<sub>mean</sub>(Gy) and D<sub>max</sub>(Gy). For OARs, D<sub>max</sub>(Gy), D<sub>mean</sub>(Gy), volume receiving various dose levels such as 30, 20, 10 and 5Gy were evaluated. Registration accuracy were also evaluated

using Dice Similarity Co-efficient (DSC) and Hausdorff distances (Hf avg).

### Results

Mean (±sd) volume of PTV, CTV of pCT was 60(±12)cc and 27(±7)cc respectively. Mean (±sd) volume of bladder and rectum of pCT vs CBCT averaged over 5 fractions were 368(±88) vs 345(±104)cc and 50(±14) vs 53(±14)cc respectively. Mean (±sd) DSC of bladder and rectum were 0.88(±0.7) and 0.92(±0.06), while Hfavg bladder and rectum were 2.6(1.4) mm and 1.2(1.0) mm respectively. Mean (±sd) difference in V<sub>95%</sub> between the planned and the delivered dose for PTV was 4(±3)%. However, maximum variation in V<sub>95%</sub> between the delivered and the planned dose was found to be correlating with the variation in bladder volume (r=0.42). Variation in other dose volume parameters was found to be negligible including for CTV. Mean (sd) difference between the planned vs delivered dose for bladder was 1.4 (5.7)%. However, patient wise analysis showed a maximum variation of 19% when the bladder volume variation was 138cc (patient-1). Mean (sd) difference between the planned vs delivered dose for rectum was 1.7 (±3.0)%, patient wise analysis showed a maximum variation of 4.0%, when the volume variation was 22 cc, and no correlation with rectal volume was observed.

### Conclusion

The difference between the planned and the delivered dose to target volumes and OARs were quantified. Bladder volume variation was found to be correlating with dose to PTV, however, no correlation was found for rectum.

### EP-2084 Arms-down versus arms-up positioning for breast cancer patients receiving proton beam radiation.

E. Batin<sup>1</sup>, N. Depauw<sup>2</sup>, S. MacDonald<sup>2</sup>, R. Jimenez<sup>2</sup>  
<sup>1</sup>UMC Groningen Proton Therapy Center, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>Massachusetts General Hospital, Radiation Oncology, Boston, USA

### Purpose or Objective

Breast irradiation, with or without regional nodal involvement, is traditionally performed in an arms-up position. This is driven by the necessity to accommodate the photon treatment head while treating tangential fields in order to avoid collisions or treatment through the arms. This position can be uncomfortable for patients who, as a consequence of surgery, may have cording or contractures that limit arm mobility. Breast irradiation with proton therapy (PT) is performed using an enface approach, thus removing the treatment limitations of photons. This study evaluates the contouring, dosimetric, and practical challenges involved in performing PT breast irradiation in the arms-down position.

### Material and Methods

Ten breast patients underwent computed tomography (CT) simulation in both an arms-up and an arms-down position, following similar protocols for treatment. Contouring was performed on both arms up and arms down CT scans by two physicians with extensive proton breast treatment experience. Each set of contours was then verified by the non-contouring physician. Plans were generated with multi-criteria optimization and Pareto surface navigation using an in-house treatment planning system. Each treatment plan was generated using identical target coverage objectives, target constraints, and organs-at-risk (OAR) constraints, with each plan optimized by prioritizing target coverage within the confines of the a priori determined OAR constraints. No OAR objectives were used to avoid biasing the planning process. Two physicists was responsible for generating all plans. Each plan was then verified by the non-planning physicist.

## Results

At the time of CT simulation, all patients expressed a preference for the arms-down position in terms of comfort. Both physicians described a greater degree of difficulty when contouring the level I axilla in the arms-down position. Difficulty in plan generation between arms-up and arms-down cases was similar. Overall, the arms-down plans conferred a slightly lower target coverage, but within a clinically acceptable range. Treatment positioning using surface imaging presented equal challenges in either position.

## Conclusion

This study highlights the appropriateness of treating breast patients in an arms-down position when using proton therapy.

### EP-2085 PET/MR in GTV delineation in patients with carcinoma of the tongue

N. Samolyk-Kogaczewska<sup>1</sup>, E. Sierko<sup>2</sup>, K. Zuzda<sup>3</sup>, P. Gugnacki<sup>3</sup>, P. Szumowski<sup>4</sup>, M. Mojsak<sup>4</sup>, J. Burzyńska-Sliwowska<sup>5</sup>, T. Filipowski<sup>1</sup>, M.Z. Wojtukiewicz<sup>6</sup>, D. Jurgielewicz<sup>4</sup>

<sup>1</sup>Comprehensive Cancer Center of Białystok, Department of Radiotherapy, Białystok, Poland ; <sup>2</sup>Medical University of Białystok- Comprehensive Cancer Center, Department of Oncology- Department of Radiotherapy, Białystok, Poland ; <sup>3</sup>Medical University of Białystok, Scientific Student's Association affiliated with Department of Oncology, Białystok, Poland ; <sup>4</sup>Medical University of Białystok, Laboratory of Molecular Imaging- Nuclear Medicine Department, Białystok, Poland ;

<sup>5</sup>Comprehensive Cancer Center of Białystok, Department of Diagnostic Imaging, Białystok, Poland ; <sup>6</sup>Medical University of Białystok, Department of Oncology, Białystok, Poland

## Purpose or Objective

Evaluation of accuracy and usefulness of 18-fluor-labeled fluorodeoxyglucose (PET) and magnetic resonance (MR) hybrid in gross tumor volume (GTV) delineation during radiotherapy planning in patients with carcinoma of the tongue.

## Material and Methods

Computed tomography (CT) and PET/MR examination were made in group of 10 patients (pts) with squamous cell carcinoma (SCC) of the tongue. The GTV for primary tumor and lymph nodes (nGTV) were defined on CT (GTV-CT) and compared to GTVs obtained from PET (GTV-PET) and MR (GTV-MR) images. Two methods of GTV determination were used: visual interpretation of CT, PET (GTV-PET<sub>vis</sub>) and MR images and quantitative automatic method (Syngovia, Siemens) based on a chosen threshold value (20%, 30%, 40%, 50%) of SUV<sub>max</sub> from PET examination (GTV-PET<sub>20%</sub>, GTV-PET<sub>30%</sub>, etc.). Differences in GTV values obtained from CT, PET and MR studies were statistically analysed. The level of significance was considered as p<0.05. The GTV-CT was used as the reference.

## Results

The 80% of GTV-MR and 40% of GTV-PET<sub>vis</sub> were larger than GTV-CT. Respectively, 20% of GTV-MR and 60% of GTV-PET<sub>vis</sub> were smaller than GTV-CT. Taking into account all threshold measurements - 70% of volumes were smaller than GTV-CT. GTV-PET<sub>30%</sub> (p=0,2026) were the most closely related volumes to GTV-CT from all threshold method in 50% of patients. GTV-PET<sub>vis</sub> (p=0,5750) generated the most similar volumes in relation to GTV-CT from all PET measurements. Comparing to nGTV-CT - 70% of nGTV-MR and 20% of nGTV-PET<sub>vis</sub> were larger. Remaining nGTV-MR and nGTV-PET<sub>vis</sub> measurements were smaller than nGTV-CT. Measurements of all thresholds nGTVs were smaller than nGTV-CTV in 52,5% of cases. nGTV-PET<sub>20%</sub> were the most closely related volumes to nGTV-CT in 40% of the cases. Statistical analysis shown that nGTV-PET<sub>20%</sub> (p=0,0468), nGTV-PET<sub>vis</sub> (p=0,0166) and nGTV-PET<sub>50%</sub> (p=0,0166) diverge significantly from nGTV-CT results.

nGTV-MR (p=0,1141), nGTV-PET<sub>30%</sub> (p=0,2845) and nGTV-PET<sub>40%</sub> (p=0,5076) were the most significantly related with nGTV-CT.

## Conclusion

Combination of PET/MR provide better accuracy in GTV delineation in radiotherapy planning of pts with SCC of the tongue than other standard imaging methods. The most frequently matching threshold value in PET/MR was 30% of SUV<sub>max</sub> for primary tumor delineating and 30% and 40% of SUV<sub>max</sub> for nGTV estimation.

### EP-2086 Innovative hybrid 18FDG-PET/MR in GTV delineation in locally advanced oral cavity cancer patients

N. Samolyk-Kogaczewska<sup>1</sup>, E. Sierko<sup>2</sup>, D. Dziemiańczyk-Pakieta<sup>3</sup>, B. Nowaszewska<sup>3</sup>, K. Zuzda<sup>4</sup>, J. Burzyńska-Sliwowska<sup>5</sup>, P. <sup>1</sup>Comprehensive Cancer Center of Białystok, Department of Radiotherapy, Białystok, Poland ; <sup>2</sup>Medical University of Białystok- Comprehensive Cancer Center, Department of Oncology- Department of Radiotherapy, Białystok, Poland ; <sup>3</sup>Medical University of Białystok, Department of Maxillofacial and Plastic Surgery, Białystok, Poland ; <sup>4</sup>Medical University of Białystok, Scientific Student's Association affiliated with Department of Oncology, Białystok, Poland ; <sup>5</sup>Comprehensive Cancer Center of Białystok, Department of Diagnostic Imaging, Białystok, Poland ; <sup>6</sup>Medical University of Białystok, Laboratory of Molecular Imaging- Nuclear Medicine Department, Białystok, Poland ; <sup>7</sup>Medical University of Białystok, Department of Oncology, Białystok, Poland

## Purpose or Objective

The aim of the study was to assess possibilities offered by innovative hybrid of <sup>18</sup>FDG-PET/MR in GTV definition during RT planning in patients (pts) with locally advanced carcinoma of the oral cavity.

## Material and Methods

A group of 15 pts with squamous cell carcinoma of the oral cavity underwent contrast-enhanced CT (Aquilion ONE, Toshiba) and PET/MR (3T Siemens Biograph mMR) examination. Delineation of GTV was made using two methods: visual interpretation of CT (GTV-CT), PET (GTV-PET<sub>vis</sub>) and MR (GTV-MR) images, as well as quantitative automatic method (Syngovia, Siemens) based on a chosen threshold value (20%, 30%, 40%, 50%) of SUV<sub>max</sub> from PET examination (GTV-PET<sub>20%</sub>, GTV-PET<sub>30%</sub>, etc.). Obtained volumes of primary tumor were compared and differences were statistically analyzed. The level of significance was considered as p<0.05. The GTV-CT was used as the reference.

## Results

In 80% of cases of GTV-MR and 100% of GTV-PET<sub>vis</sub> volumes were larger than reference GTV-CT. Only in three patients GTV-MR was smaller than GTV-CT. The 40% of all PET automatic threshold measurements were larger than results based on CT images. Respectively - 60% of volumes from quantitative automatic method were smaller than GTV-CT. Statistical analysis shown that the most closely related results to GTV-CT were obtained from MR imaging (p=0,0796), GTV-PET<sub>30%</sub> (p=0,8927), GTV-PET<sub>40%</sub> (p=0,3452) and GTV-PET<sub>50%</sub> (p=0,0796). On the other hand GTV-PET<sub>vis</sub> (p=0,0431) and GTV-PET<sub>20%</sub> (p=0,0431) diverge significantly from volumes based on CT images.

## Conclusion

Quantitative automatic method based on a chosen threshold value combined with MR imaging seems to be better delineation method in cases of locally advanced cancer of oral cavity. Hybrid PET/MR supports the optimal determination of volumes for RT treatment. Although, further studies are needed.

### EP-2087 Probabilistic Modeling of Patient Setup Time in VMAT Treatments Based on Anatomical Regions

T.Y. Lee<sup>1</sup>, M.W.K. Law<sup>1</sup>, V.C.W. Cheung<sup>1</sup>, K.K. Tang<sup>1</sup>, S.W.K. Chow<sup>2</sup>, L.W.M. Lee<sup>2</sup>, M.M.S. Wong<sup>2</sup>, S.H. Yoo<sup>1</sup>, P.P.H. Nam<sup>1</sup>, J.W.Y. Lee<sup>2</sup>, B.S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics and Research Department, Happy Valley, Hong Kong SAR China ; <sup>2</sup>Hong Kong Sanatorium & Hospital, Department of Radiotherapy, Happy Valley, Hong Kong SAR China

**Purpose or Objective**

The patient setup time was analyzed to provide a statistical insight regarding the variation of setup time, including the most probable setup time and spread across treatments of different anatomical regions. The major benefit of the study is to facilitate treatment time slot allocation, so as to improve treatment machine throughput without increasing the patient waiting time.

**Material and Methods**

The statistics of 3069 fractions of 189 treatments, treated with 6MV photon-beam Volumetric-Modulated Arc Therapy (VMAT) by a linear accelerator (VersaHD, Elekta, Stockholm), were collected over a 25-month period. The setup time were inspected according to three treatment target regions: thorax (THX), breast (BRT) and head and neck (HN) as shown in Table 1. All first treatment fractions were excluded due to the high uncertainty in consultation and coaching time.

The Hypoexponential distribution (Eq.1.) was fitted to the setup time of each of the three concerned treatment regions based on maximum log likelihood.

**Results**

The observed setup time histograms were well-followed by the fitted distributions (Fig. 1). The probability distributions of the overall observed setup time were positively skewed with tails extending to longer setup time. BRT had a wider spread and appeared similar to a normal distribution, while HN was heavily skewed and asymmetrical. The distribution of THX was in between of the two. HN took the shortest time to setup, followed by THX then BRT, with medians of 4.18, 6.08 and 7.83 minutes respectively. The optimal value of K was empirically found to be 8 based on our data. The model parameters of the three studied regions were found dissimilar after fitting (Table 1).

$$pdf(t; \lambda_1, \lambda_2, \dots, \lambda_K) = \sum_{i=1}^K \lambda_i e^{-\lambda_i t} \left( \prod_{j=1, j \neq i}^K \frac{\lambda_j}{\lambda_j - \lambda_i} \right)$$

Eq. 1. The definition of Hypoexponential distribution of variable t, where  $\lambda_i$  is the model parameters to be found using maximum log-likelihood method.

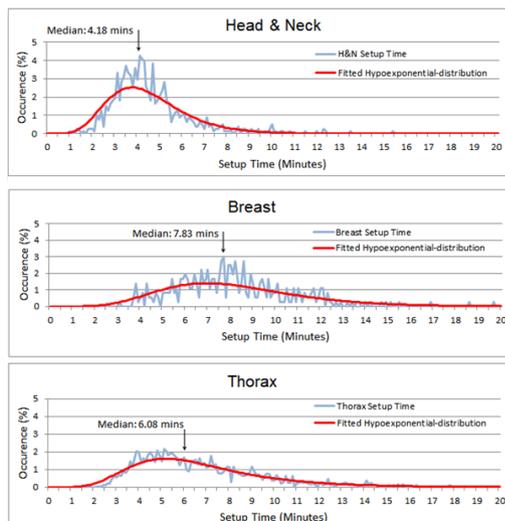

Fig. 1. The histograms of observed setup time for different treatment regions with the fitted Hypoexponential distributions.

The shaded area under the fitted Hypoexponential distributions (Fig.2) shows the most probable 68%

occurrence of setup time, mathematically the region of median  $\pm$  34%. Hypoexponential distribution (red area) offered a much closer agreement to the observed setup time range (purple area) in all cases, in contrast to the normal distribution (green area) which has a much wider spread.

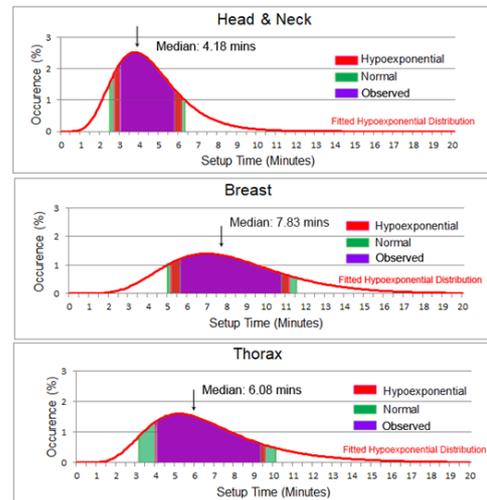

Fig. 2. The fitted Hypoexponential distributions with shaded regions showing the 68%-median samples in minutes for the three treatment regions respectively.

	Probability Density Function (pdf) with K=8								Median (mins)	Number of cases	Number of fractions
	$\lambda_1$	$\lambda_2$	$\lambda_3$	$\lambda_4$	$\lambda_5$	$\lambda_6$	$\lambda_7$	$\lambda_8$			
Head & Neck	0.80	1.65	2.01	2.20	2.29	2.32	2.30	2.25	4.18	40	786
Breast	0.48	0.98	1.14	1.22	1.23	1.20	1.14	1.06	7.83	27	364
Thorax	0.36	1.79	1.65	1.64	1.67	1.70	1.72	1.75	6.08	122	1919
Total Number of cases:										189	3069

Table 1. The fitted model parameters and details of studied treatments.

**Conclusion**

This study investigated the statistical distribution of the patients' setup time in 3069 fractions of VMAT treatments, categorized based on three anatomical regions. The setup time was shown to be effectively modeled by Hypoexponential distributions, a continuous probability model for describing the total finishing time of multiple sequential tasks such as queuing and logistic procedures. We have also shown the dissimilarity among the distributions of the three treatment regions, suggesting a treatment-region-based categorization scheme was essential for effective model fitting, so as to anticipate the patient setup time. In order to achieve a seamless and efficient treatment scheduling scheme, a representative probability model will help allocating treatment time slot based on treatment regions, thus achieving higher machine throughput while reducing patient waiting time simultaneously.

**EP-2088 Upright open-source cone beam CT imaging for radiotherapy**

J. Korte<sup>1</sup>, N. Hardcastle<sup>1,2</sup>, S. Everitt<sup>3,4,5</sup>, T. Kron<sup>1,4</sup>  
<sup>1</sup>Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia ; <sup>2</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia ; <sup>3</sup>Peter MacCallum Cancer Centre, Radiation Therapy Services, Melbourne, Australia ; <sup>4</sup>The University of Melbourne, Sir Peter MacCallum Department of Oncology, Melbourne, Australia ; <sup>5</sup>Monash University, Department of Medical Imaging & Radiation Sciences, Melbourne, Australia

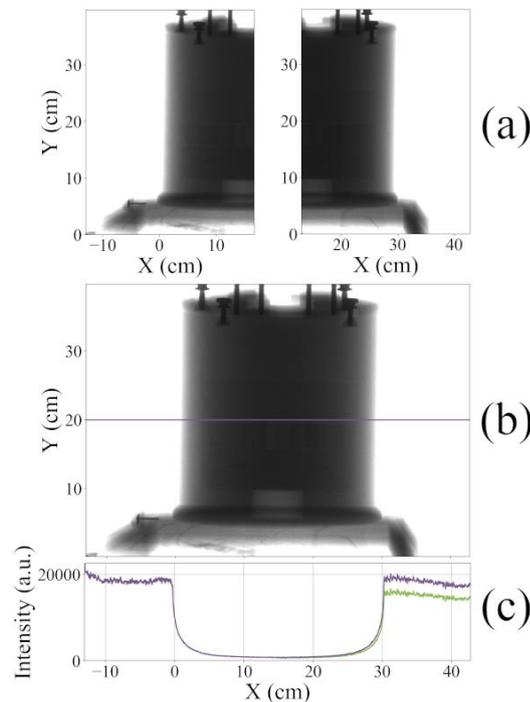

**Purpose or Objective**

Some patients receiving radiotherapy may benefit from treatment in the upright position due to inability to lay prone/supine and through improved tumour-organ at risk geometry. A major challenge of upright radiotherapy

however is the requirement of simulation volumetric imaging and image guidance imaging to be acquired in the upright position. In this work, we aim to acquire upright cone beam CT (CBCT) projections on a conventional digital linac and reconstruct images with an open-source toolkit.

#### Material and Methods

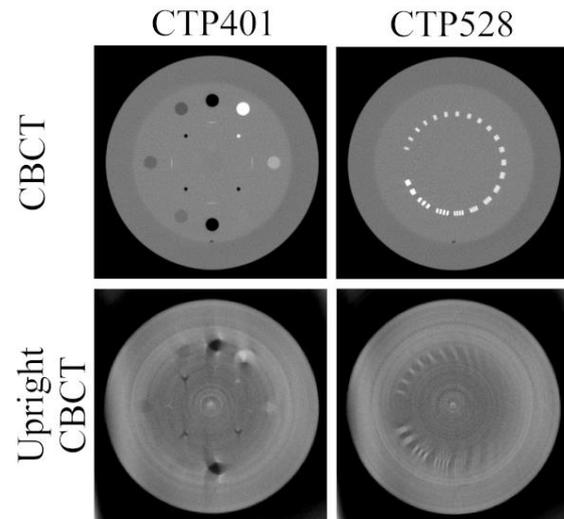

A phantom imaging study was conducted on a TrueBeam® linac (v2.5, Varian Medical Systems) in developer mode using a Catphan® 500 (The Phantom Laboratory). The kV imaging system was kept stationary at a gantry angle of 0° while the couch was rotated through a 180° arc. An extended field of view (FOV) was achieved by offsetting the kV detector in two half-rotation acquisitions (+13cm, -13cm) in continuous fluoroscopy mode (125kVp, 40mA, 11fps) with no bowtie filter. The 4cm wide region where the pair of offset projections overlaps was used for normalisation between image pairs, at each angle the mean intensity of a central patch was matched. A vertical shift correction was calculated by matching vertical line profiles in the overlap region. The corrected offset projections were combined into a single image frame (Fig.1) and header information modified using custom software. The combined projections were reconstructed with the Reconstruction Toolkit (RTK) using an alternating direction method of multipliers with total variation regularisation (ADMM-TV) algorithm. A standard CBCT of the Catphan® taken during routine quality assurance is included for comparison.

**Fig.1:** (a) offset projections (b) combined corrected projection (c) line profile of (green) uncorrected and (purple) corrected projection.

#### Results

Attenuation correction and vertical shift correction between the two offset projections improved the extended FOV projection (Figure 1c). A gradient from left to right is observed in regions of air and is attributed to anode heel effect and static flood field corrections. This will be addressed using a measured average flood field image in future experiments.

**Fig.2:** Comparison of CBCT and Upright CBCT images of a Catphan®

Reconstructed upright images (Fig.2) show a general agreement with the CBCT images. Expected intensity variations are observed in the spatial linearity module (CTP401) and some structures are visible in the high contrast resolution module (CTP528). The upright images suffer from ring artifact which may be reduced by median filtering or other methods. Further image improvements may arise from projection pre-processing methods and reconstruction options.

#### Conclusion

We have demonstrated upright CBCT can be acquired on a digital linear accelerator and reconstructed using an open source toolkit. Initial reconstruction results are promising, with future work to focus on improvement of image quality through projection space filtering.

#### EP-2089 Technical implementation of total marrow irradiation (TMI) using VMAT

J.M. Perez moreno<sup>1</sup>, C. Rubio Rodriguez<sup>2</sup>, J. Valero Albarrán<sup>2</sup>, P. Fernández Letón<sup>3</sup>

<sup>1</sup>Hospital HM Puerta del Sur, Radiofísica y Protección Radiológica, Mostoles, Spain ; <sup>2</sup>Hospital Universitario HM Sanchinarro, Radiation Oncology, Madrid, Spain ;

<sup>3</sup>Hospital Universitario HM Sanchinarro, Radiofísica y Protección Radiológica, Madrid, Spain

#### Purpose or Objective

To implement LINAC based total marrow irradiation (TMI) using VMAT in the first clinical case.

#### Material and Methods

Our first patient VMAT TMI case is reported. Treatment planning was performed on RayStation 7 using a VERSA HD LINAC.

Patient was immobilized using a head and neck mask and BodyFIX system. Two planning CT scans were performed to imaging whole target volume, head first and feet first supine (HFS and FFS). Target volume was defined in both scans and it included all bones in the body, whole brain, supraclavicular, axillary and paraaortic lymph nodes and spleen. A margin of 3 mm was used except in lower extremities and spleen, where 5 mm margin was used. Dose prescription was 12 Gy in 6 fractions twice a day.

Four factors were considered in plan design:

1. body and target geometry
2. encompass full target while limiting beam size to 27 cm in head-feet direction
3. force an overlap of 5-8 cm between beams of adjacent sectors
4. geometric viability of treatment

Patient's anatomy was split in 7 sectors: head, thorax, abdomen, pelvis and femoral using HFS patient orientation, and knee and tibial in FFS. One isocenter were used in each anatomic region except in abdomen and pelvis, where two coplanar isocenter were settled with a lateral shift between them. Two VMAT arcs were used in each anatomic area, except in tibial region where AP/PA field in field segmentation was performed.

Rigid and deformable registration between HFS and FFS scans were performed to map doses and calculate/optimize total dose in overlapping region of two CT studies.

QA was performed using with Octavius 4D system using 3%-2.5mm 3D gamma index analysis.

Patient setup was assured using one CBCT per isocenter with a 20 cm FOV in head-feet direction.

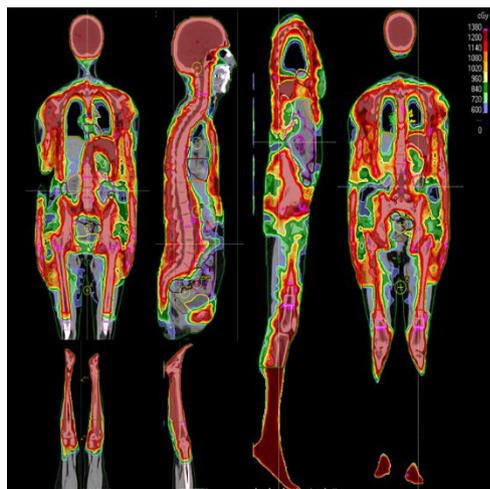

### Results

Total body volume of 55.8 litres and 43.8 cm body radius. Total PTV volume was 12.9 litres. This gives a ratio PTV/Body of 0.23. Plan was normalized to 95% of PTV be covered by 12 Gy. PTV Dmean, D98% and D2% were 12.8 Gy, 11.6 Gy and 14.1 Gy respectively.

Table 1 show dose statistics of main OARs.

Figure 1 shows dose distribution in coronal and sagittal planes of HFS, FFS and composite plans.

Total gamma <1 passing rates are 92.4%, 97.4%, 96.3%, 95.7%, 93.5% and 96.8% in head, thoracic, abdominal, pelvic, femoral and knees areas, respectively. In 3D gamma analysis was observed that total results were

dominated by 10%-20% dose areas, where passing rates were lower.

Mean setup error was 0.21, 0.27 and 0.39 cm in LAT, INF-SUP and AP directions, averaged over all isocenters.

First fraction delivery took 112 minutes, while remaining sessions had a duration between 90-100 minutes.

### Conclusion

Proposed TMI method allows achieve planning, delivery and patient setup accuracy similar to conventional radiotherapy, even managing large volumes where two CT scans in different patient orientation are needed.

OARs doses values are lower than in conventional TBI as was demonstrated by previous studies. Showed case values are slightly higher than in those studies, probably due to higher PTV volume.

### EP-2090 Helical tomography radiation therapy for multiple brain lesions: in-phantom accuracy assessment

M. Zani<sup>1</sup>, L. Marrazzo<sup>1</sup>, S. Calusi<sup>1</sup>, C. Talamonti<sup>1</sup>, S. Scoccianti<sup>2</sup>, D. Greto<sup>2</sup>, L. Livi<sup>2</sup>, S. Pallotta<sup>1</sup>

<sup>1</sup>University of Florence, Medical Physics Unit- Azienda Ospedaliera Universitaria Careggi, Firenze, Italy ;

<sup>2</sup>University of Florence, Radiotherapy Unit- Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

### Purpose or Objective

This study aimed to demonstrate the possibility of safely using helical tomography radiation therapy (HT) for the treatment of multiple brain metastases. Imaging and delivery accuracy of HT systems were investigated by performing End to End (E2E) tests on two different phantoms.

### Material and Methods

A two step analysis was followed in order to assess the reliability of the HT for the treatment of multiple brain metastasis. At first the imaging accuracy was tested. In HT systems target localization is provided by registering MegaVoltage CT (MVCT) and CT images and its precision depends on MVCT acquisition protocols as well as on image registration algorithms. These two aspects were investigated, for different registration options and MVCT slice thickness, by applying known misalignments to an ad-hoc developed phantom. The rotation detection of the imaging technique was also studied. E2E tests were then performed to assess the delivery accuracy in phantoms containing multiple targets by using radiochromic films. On the coronal plane 6 target were simulated on a phantom which consists of a PMMA plate 1cm thick with eight embedded glass spheres (GS-phantom) (fig.1a). On the axial plane 3 thin plastic sheets were cut thus to create 5 approximately circular holes, and then they were inserted and fixed between adjacent slices of an Alderson Rando phantom head (fig.1b): 5 targets in total, with the longest axis ranging from 4mm to 8mm (volumes ranging from 0.47cc to 1.79cc). Measured dose distribution centroids were compared with physical and calculated target positions. Moreover, along the axial plane, planned and measured dose maps were compared in terms of absolute values.

### Results

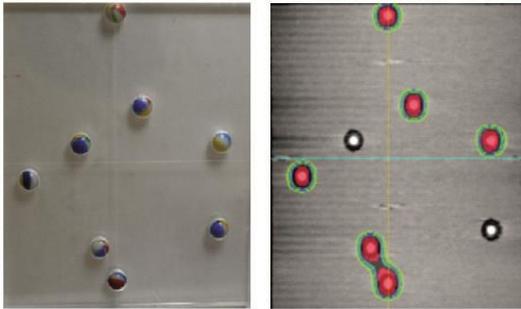

First Step: The algorithm focusing on bone and tissues with the fine MVCT reconstruction grid gave the best results among the automatic options. The most accurate registration modality resulted to be the manual one with a sub-voxel accuracy shifts and a capability in the detection of rotations within 0.3°.

Second Step: In fig.2a the results for the centroid shifts along the coronal plane (6 targets) are shown: the mean deviation between measured dose distribution centroids and physical barycenters is of 0.6 mm (range 0.1 mm-1.3 mm). Along the axial plane (5 targets), a mean deviation of 1.2 mm (range 0.7 mm-2.1 mm) was found for the centroid shifts. In fig.2b one dose profile is reported, corresponding to the dotted line in the EBT3 radiation

exposed map: calculated and measured values compare well. This is also reflected in the Gamma analysis: for each of the 3 films irradiated inside the Rando head phantom a passing rate higher than 97% (3%/2 mm, local) between planned and delivered dose distributions were measured.

Figure 1

a) Coronal Irradiation: 6 targets simulated in the GS-phantom

b) Axial Irradiation: 5 targets placed in 3 Rando Slices

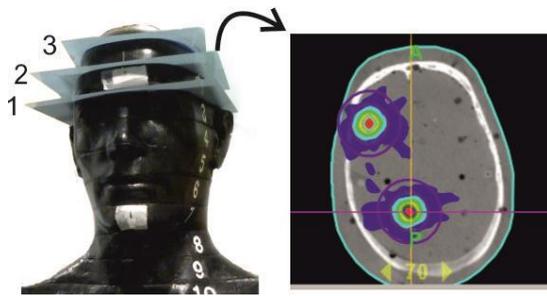

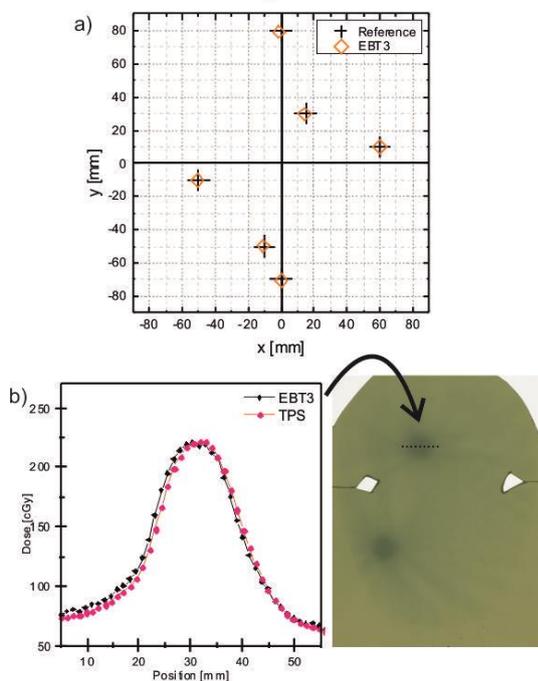

Figure 2

### Conclusion

These results give an in phantom demonstration that multiple brain lesions can be treated with the requested accuracy by HT. When treating real patients, contributions to the uncertainty in dose delivery such as intra-fraction motions have also to be taken into account.

### EP-2091 How to measure high dose in functional disorder treatment: an innovative silicon diode detector.

P. Gallo<sup>1</sup>, E. De Martin<sup>1</sup>, M.L. Fumagalli<sup>1</sup>, F. Ghielmetti<sup>1</sup>, M. Carrara<sup>2</sup>, S. Alhujaili<sup>3</sup>, M. Lerch<sup>3</sup>, A.B. Rosenfeld<sup>3</sup>, M. Marchetti<sup>1</sup>, L. Fariselli<sup>1</sup>, M. Petasecca<sup>3</sup>

<sup>1</sup>Fondazione IRCCS Istituto Neurologico Carlo Besta, Health Department, Milan, Italy; <sup>2</sup>Fondazione I.R.C.C.S. Istituto Nazionale dei Tumori di Milano, Health Department, Milan, Italy; <sup>3</sup>Centre for Medical Radiation Physics, University of Wollongong, Wollongong, Australia

### Purpose or Objective

**Purpose:** Stereotactic radiosurgery (SRS) of intra-cranial lesions is a treatment modality where a well defined target volume receives a high radiation dose in a short fractionation regimen. SRS is usually characterised by steep dose distributions achieved through the delivery of small radiation fields and therefore requires dosimetry performed with small active volume detectors. The purpose of this study is to validate the use of an innovative angular independent edgeless-diode detector, already characterised for standard Quality Assurance (QA) of Cyberknife, in stereotactic radiosurgery for brain functional disorders and trigeminal neuralgia.

### Material and Methods

**Methods and materials:** An anthropomorphic head phantom (RANDO, The Phantom Laboratory, Salem, NY) was CT imaged with three edgeless diodes inserted in central, 8 mm cranial and 26 mm caudal positions (Figure1) targeting the trigeminal nerve close to its root entry in the brainstem. The image set was transferred to the treatment planning system and a treatment volume was contoured by simulating a typical trigeminal target in correspondence of the central diode. In the framework of a dose escalation protocol, a radiosurgery plan (Rando) was optimized and delivered with the central diode receiving prescription doses respectively of 75, 100, 140 and 200 Gy in single fraction. Simultaneously to the 75 Gy - Rando delivery an EBT3 film, properly prepared and calibrated, was also arranged in correspondence with the caudal diode position, where a prescription dose of 12 Gy was delivered. The EBT3 reading was used to validate the corresponding diode's recorded value.

Quality-assurance (QA) verifications were also performed for three patient planes treated at different prescription doses. In this case the central diode was in correspondence with the contoured trigeminal target. Finally, the doses measured by the three diodes were compared to the planned ones.

### Results

The comparison between measured and planned doses is shown in the following table. The recorded values of the dose to the central diode (target) were within 3.6% of the plan for all the seven delivered plans (4 Rando plans and 3 patients). The difference between the EBT3 reading and the caudal diode's recorded value in the Rando-plan was smaller than 5%.

### Conclusion

**Conclusion:** The edgeless-diode detector was employed to measure the dose delivered by a full trigeminal stereotactic treatment. The obtained results combined with its mechanical and electrical characteristics make it a suitable choice for QA dosimetry of trigeminal neuralgia

functional treatments.

**Figure1:** the figure shows how the three diodes were inserted in Rando phantom in central, cranial and caudal position.

**Table:** the differences between planned and measures doses are reported for the three diodes.

	Prescribed Dose (Gy)	Plan Dose (Gy)			DIODE Dose (Gy)			Difference (%)		
		cranial	central	caudal	cranial	central	caudal	cranial	central	caudal
Rando plan	75	6.8	71.1	12.5	5.9	71.0	11.9	-13.1	-0.1	-4.7
	100	9.1	94.8	16.7	7.9	92.1	15.7	-12.7	-2.9	-5.5
	140	12.7	132.7	23.3	10.1	130.8	19.3	-20.7	-1.4	-17.2
	200	18.2	189.6	33.3	14.0	182.7	23.9	-22.7	-3.6	-28.2
QA- First Patient	90	4.9	85.6	3.6	4.6	83.3	3.5	-5.3	-2.0	-2.5
QA-Second Patient	90	11.1	92.4	3.0	11.3	94.9	2.6	1.9	2.6	-12.6
QA-Third Patient	100	9.8	74.6	2.3	9.5	71.3	2.1	-3.2	-1.7	-10.3

### EP-2092 Time-driven activity-based costing for competing treatments using different technology solutions

C.K. Torzsok<sup>1</sup>

<sup>1</sup>Foundation Arturo Lopez Perez, radiation therapy, santiago de chile, Chile

#### Purpose or Objective

##### Purpose

Adequate and equitable access to radiotherapy (RT) must be a reasonable health care goal worldwide. However, the provision of RT in low to middle income countries (LMIC) faces challenges such as lack of professionals, reimbursement schemes and public policies. Given that the costs of delivering state of the art RT care remain poorly described, this abstract reports results of time-driven activity-based costing (TDABC) for competing treatments using different technology solutions and opens the way for discussions on how to better account for and utilize resources.

#### Material and Methods

##### Methods

TDABC is an advanced cost calculation technique that iteratively allocates resource costs to products based on activity consumption weighed by treatment complexity factors. Process maps were developed for each phase of care from the initial visit to end of treatment through 2 years of clinical practice using Cyberknife Stereotactic body radiation therapy treatments (SBRT), Radiosurgery (SRS), Elekta Volumetric Arc therapy (VMAT), Tomotherapy (TOMO) and conformal RT (3D). The costs of materials, equipment, personnel, and space were calculated per unit of time and relative capacity used.

#### Results

##### Results

Substantial cost variation was observed over 2 years, with costs ranging from \$3,298 for TOMO, to \$10,565 for SBRT. TOMO was notably cheaper than VMAT \$4,648, and SRS \$3,665 was cheaper than VMAT, with the cost savings attributable to shorter procedure times and fewer fractions despite of higher initial capital costs. Both equipment costs and quality assurance contributed to the high cost of SBRT, where machine quality assurance (QA) and patient specific delivery quality assurance (DQA) costs range up to 54% when single fraction. 3D was only 20% cheaper than TOMO, largely because of workflow. RT costs are predominantly determined by personnel 38% and equipment cost 39%. Machine usage activities consume greatest proportion with treatment delivery 65%, QA 12% and DQA 8%.

#### Conclusion

##### Conclusions

The use of TDABC is feasible for cost estimation of RT and is converging with other studies when it comes to fractionation. It allows for analyzing cancer services and provides insights into cost-reduction tactics in an era focused on emphasizing value. By detailing all steps from diagnosis and treatment, this study demonstrates significant cost variation between competing treatments and highlights the impact of QA and DQA time on the actual cost structure. It impelled us to evaluate resource or practice changes in the 3 major cost drivers: fractionation, QA and DQA. Our aim is to develop a model that establishes a direct and transparent link between equipment, human resources, fractionation and quality assurance data and indications for RT to be used by LMIC when tackling the change of paradigm of using state of the art RT. Unlike published benchmarks for accelerator throughput to allow estimation of the number of Linacs per million people in each country, we vouch for considering the whole patient workflow.

### EP-2093 Heart sparing with deep inspiration breath hold (DIBH) in left breast treatment: a prospective study

V. Vanoni<sup>1</sup>, S. Mussari<sup>1</sup>, L. Bossi<sup>1</sup>, F. Coelli<sup>1</sup>, M. Maino<sup>1</sup>, A. Martignano<sup>2</sup>

<sup>1</sup>Ospedale Santa Chiara di Trento, Radiation Oncology, Trento, Italy ; <sup>2</sup>Ospedale Santa Chiara di Trento, Medical Physics, Trento, Italy

#### Purpose or Objective

The aim of the study was to prospectively assess the dosimetric benefit achievable with the use of the deep inspiration breath hold technique (DIBH) in left breast radiotherapy.

#### Material and Methods

101 patients with left-sided breast cancer underwent left breast irradiation with DIBH. Following an initial training period including the first 25 patients, the following 76 patients were included in the present study: patients were considered for DIBH if they were younger than 55 years or if the OAR-constraints (lung and heart) were unachievable with free breathing (FB). Both FB and DIBH simulation-CT were available for each patient and formed the basis of their dosimetric analysis. Mean heart dose (MHD), left ventricle V25Gy (V25V), V10Gy and V20Gy for ipsilateral lung (V10L, V20L), ipsilateral lung volume (LV) and minimum distance of the heart from the PTV (HDIST) were recorded and the differences ( $\Delta$ ) between FB and DIBH plans were calculated.

#### Results

The mean age of the enrolled patients was 50 years (range 31-66 y). 43.4% of the patients underwent VMAT radiotherapy and 55.3% 3D conformal radiotherapy; 1 patient was planned with a dMLC technique. In 39.5% of the patients, supraclavicular nodes were included in the treatment volume and 7.9% had supraclavicular and internal mammary lymph nodes involved. 72% of the patients enrolled in the study eventually underwent DIBH

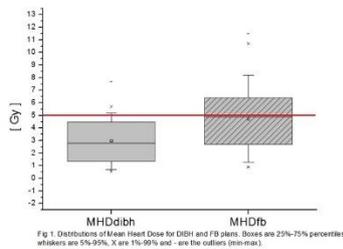

treatment. In the remaining patients the dosimetric benefit from DIBH was not considered sufficient to opt for this technique or (only 1 patient) they were not able to perform DIBH at the treatment sessions.

Mean DIBH inspiration threshold was 1.7 l (range 1.0-2.7 l). The results are reported in table 1. The percentage of plans with MHD inferior to the threshold of 5 Gy was 84.3 % for the DIBH technique, and 54.1 % for the FB plans.  $MHD_{DIBH}/MHD_{FB}$  and  $V25V_{DIBH}/V25V_{FB}$  distributions were significantly different ( $p < 0.001$ , paired T-test).

Table 1. Comparison of dose metrics in DIBH and FB plans.

Dose Metric	DIBH Mean [range]	FB Mean [range]	$\Delta$ of mean value of dose metric [range of $\Delta$ ] in DIBH and FB plans
MHD [Gy]	3.0 [0.5+7.7]	4.7 [0.9+11.5]	-1.9 [-6.9+0.1] $p < 0.001$
V25V [%]	1.3 [0+6.7]	4.3 [0+20.4]	-3.2 [-19.5+9.1] $p < 0.001$
V20L [%]	17.3 [1.2+37.8]	18.9 [0.1+59.4]	-2.6 [-29.6+6.7] $p = 0.009$
V10L [%]	26.3 [5.7+52.3]	27.1 [0.5+78.5]	-2.0 [-31.5+9.8] $p = 0.030$
HDIST [cm]	0.8 [0.0+3.0]	0.2 [0.0+1.4]	0.6 [-0.2+1.9] $p < 0.001$

MHD – mean heart dose, V25V – volume of left ventricle receiving 25 Gy, V20L – volume of ipsilateral lung receiving 20 Gy, DIBH – Deep Inspiration/Breath Hold, FB – Free Breathing, p – statistical significance (paired T-test).

## Conclusion

The use of DIBH in a routine clinical setting significantly reduced mean dose to the heart and the volume of the left ventricle that received 25 Gy, thus confirming that DIBH is an efficient technique that can be strongly recommended to lower the risk of ischemic heart disease after breast cancer radiotherapy.

## EP-2094 Machine QA Time Efficiency Savings with IBA Dolphin Detector

S. Loughlin<sup>1</sup>, R. Lally<sup>2</sup>, A. Reilly<sup>2</sup>

<sup>1</sup>NWCC, Department of Physics, derry, United Kingdom ;

<sup>2</sup>NWCC, Radiotherapy Physics, derry, United Kingdom

### Purpose or Objective

Machine availability is a precious commodity in a radiotherapy department when the burden of measurement based PS-QA and machine QA are considered, therefore vital that all links in the PS-QA and machine QA chains are streamline and accurate. Within our portfolio of dosimetry equipment, it was identified that further savings in time could be made by using the IBA Dolphin detector for measurement based PS-QA and machine QA.

### Material and Methods

Investigations were carried out on Varian TrueBeam linear accelerators (linacs) using the Dolphin detector and an appropriate chamber traceable to the National Physical Laboratory (NPL) in the UK. The Dolphin is a 2D detector array consisting of 1513 vented air ionisation chambers arranged across an area of 40 x 40 cm<sup>2</sup>. The spatial

resolution across the central area of the array (15 x 15 cm<sup>2</sup>) is 5 mm. Dose linearity was characterised between 1 MU and 500 MU under reference conditions (10 x 10 cm<sup>2</sup> field) at maximum dose-rate for all clinical MV photon energies (i.e. 6MV and 10MV in addition to flattening filter free 6FFF and 10FFF). Dose-rate response was characterised for all available dose-rates. The field size dependence of the array was assessed for all energies for square field sizes ranging from 1 x 1 cm<sup>2</sup> through to 25 x 25 cm<sup>2</sup>. Dose linearity and dose-rate response measurements were compared to that of a Farmer chamber whilst the field size dependence was compared to that of an IBA CC13 small volume ionisation chamber. PS-QA plan delivery time was compared to the SunNuclear ArcCheck solution. Deliberate errors (1.8%) were introduced by beam steering into the radial and transvers angles of the Varian linac to check if the array could detect an error.

## Results

The dolphin exhibited a linear response to dose. The dose-rate response of the Dolphin was comparable to that of the Farmer chamber (<1%) with the most significant dose rate dependence observed for the 6 MV delivery (0.87 ± 0.2%; mean ±2SD). Both the Dolphin and the CC13 exhibited field-size dependence below 5 x 5 cm<sup>2</sup> (i.e. a difference of 3% from the response at 10 x 10 cm<sup>2</sup>). The maximum difference between the response of the Dolphin and the CC13 was observed at 1 x 1 cm<sup>2</sup> for the 6FFF delivery (i.e. CC13 under responded by 21% in comparison to the 10 x 10 cm<sup>2</sup> field whilst the dolphin under responded by 43%). PS-QA time was reduced from 15 minutes on average for ArcCheck to 5 minutes on average for Dolphin. The Dolphin identified flatness and asymmetry in the beam for a 6 MV and 6 FFF delivery.

## Conclusion

The characteristics of this array make this detector suitable for PS-QA and machine QA, with the array demonstrating significant time savings.

## EP-2095 SBRT of prostate with integrated boost of Dominant Lesion. A crowd-knowledge based planning study

A. Savini<sup>1</sup>, S. Cilla<sup>1</sup>, M. Esposito<sup>1</sup>, E. Moretti<sup>1</sup>, E. Villaggi<sup>1</sup>, S. Russo<sup>1</sup>, M. Stasi<sup>1</sup>, P. Mancosu<sup>1</sup>

<sup>1</sup>SBRT Working Group, AIFM - Italian Association of Medical Physics, Italy, Italy

### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) with large dose per fraction has gained increasing popularity in treatment of prostate cancer due to its low  $\alpha/\beta$  ratio (e.g. 1.5 Gy). Furthermore, a dose escalation to the dominant intra-prostatic lesion (DIL) has the potential to increase biochemical control whilst avoiding the enhance in side effects associated with whole gland dose escalation. There is a lack of consensus on optimization strategies and appropriate plan quality metrics for SBRT plans delivered in simultaneous integrated boost (SIB). The aim of this study was to evaluate and ultimately reduce the variability of planning strategies. A crowd-knowledge approach was adopted, where teacher/student hierarchy is not defined a-priori, but hierarchy is dynamically determined by the results.

### Material and Methods

Four radiation oncology centers experienced in performing SBRT participated to this study. The case with pre-delineated volumes was distributed among participating centers using an ad-hoc web-platform. Two plans were optimized. A preliminary homogeneous plan with a prescribed dose to the target of 35 Gy in 5 fractions. A second plan with prescribed dose to the target of 35 Gy in 5 fractions and 50Gy integrated boost to the DIL. Constraints on target coverage and dose to nearby organs at risk were set a priori. Plans were collected in DICOM-RT format. A grouped analysis was performed using crowd-

based (CB) DVHs which were generated using a script developed in R language. CB-DVHs were reported on the web-platform in order to allow centers to confront their results in a fast and intuitive way.

### Results

The most relevant variations were observed for the dose to the PTVs and to the rectum (Fig.1 and 2). In particular, for the homogeneous plan, observed dose ranges were: PTV mean dose, 35.5-38.4 Gy; PTV max dose, 37.3-42.6 Gy; rectum mean dose, 15.8-22.3 Gy; rectum max dose, 35.9-39.8 Gy. For the inhomogeneous plan, dose ranges were: PTV mean dose, 36.1-37.9 Gy; PTV max dose, 51.1-54.1Gy; PTV-DIL mean dose, 46.9-50.2 Gy; PTV-DIL max dose, 51.1-54.1; rectum mean dose, 15.9 - 23.6 Gy; rectum max dose, 37.4 - 49.0 Gy.

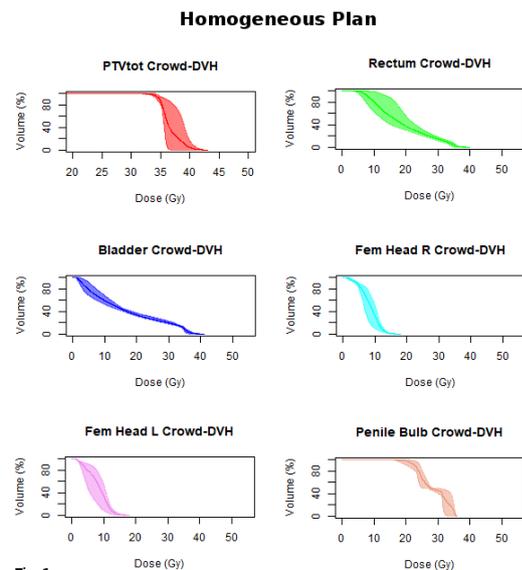

Fig.1

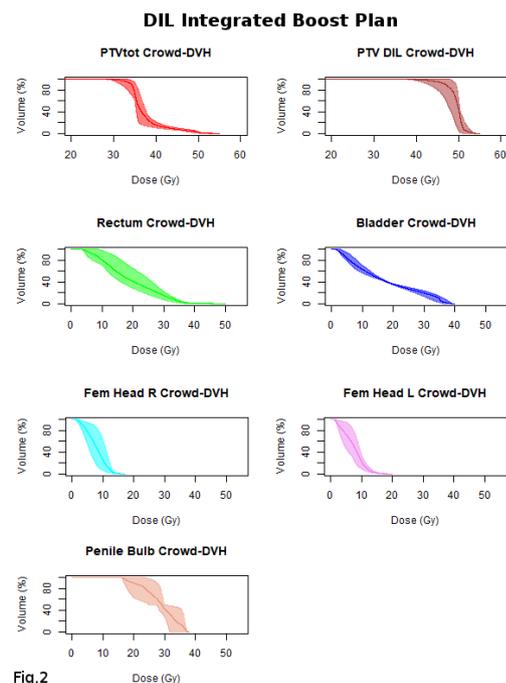

Fig.2

### Conclusion

A crowd-based method was applied for exploring different approaches in planning a novel treatment of prostate in SBRT. Variation of dose distributions for targets and organs at risk (especially rectum) showed the need of multicenter

comparison even among experienced centers. CB-DVHs could give a fast and intuitive overview of the variability of planning approaches. The analysis of CB-DVHs is propaedeutic for reviewing planning strategies of each center with the ultimate goal of uniforming treatment approaches in SBRT.

### EP-2096 Multi-institutional versus site-specific training data for a deep breast segmentation algorithm

J. Schreier<sup>1</sup>, H. Laaksonen<sup>1</sup>, F. Attanasi<sup>2</sup>  
<sup>1</sup>Varian Medical Systems Oy, Strategic Technologies, Helsinki, Finland ; <sup>2</sup>VMS International AG, Oncology Software Product Management, Steinhausen, Switzerland

### Purpose or Objective

Deep Learning techniques have demonstrated impressive performance in different medical image analysis applications, producing more accurate segmentation results and exhibiting significantly better generalization than traditional atlas or model-based approaches. In this study, we present results of training a deep neural network with a multi-institutional versus a site-specific dataset. This is done to evaluate the trade-off between generalizability versus specificity, meaning is it better for an institution to use a site-specific model or a multi-site one? For this, a deep neural network was developed that automatically contours organs-at-risk on CT images for breast cancer radiotherapy treatments.

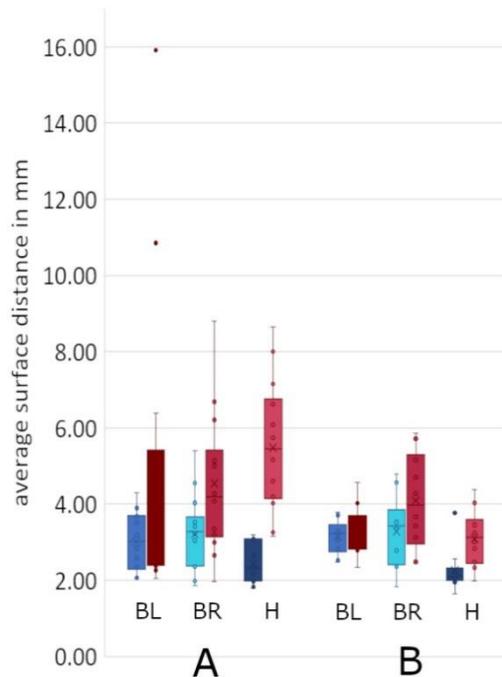

### Material and Methods

CT datasets from four institutions were selected, three from Europe (Clinic A, B and C) and one from the U.S. (Clinic D). The complete dataset consisted of 380 CT breast scans with heterogeneous characteristics to ensure balance with respect to diagnosis, age and body mass index. All patients were scanned in the supine position and immobilized either with breast boards or vacuum cushions. Patients from Clinic A, B and C were scanned with both arms up instead of the traditional one arm up used in Clinic D.

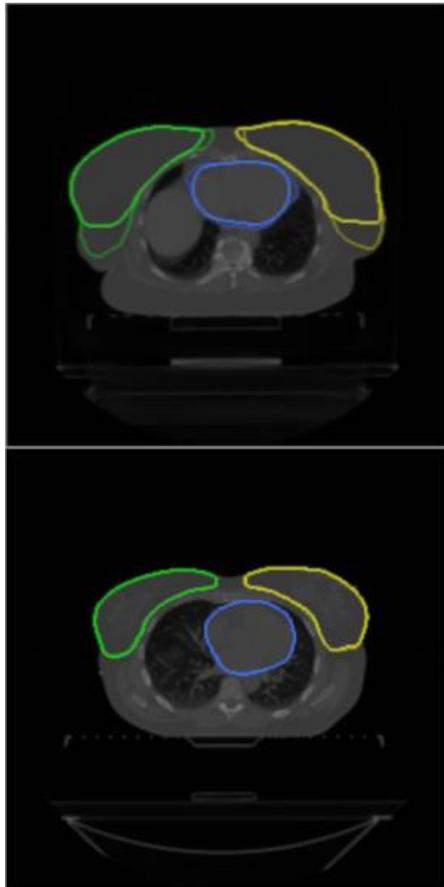

For each CT dataset, a team of experts reviewed the original contours and added missing structures to ensure both breasts and heart were delineated. Reviewed contours were used for representing the ground truth. Four site-specific models were trained. Additionally, one model was trained using data from all clinics. The models were evaluated using the average surface distance and the dice score on the test cases from the clinic trained on and compared to the multi-institutional model.

### Results

The average surface distance of the multi-institutional (blue) and the site-specific models (red) are shown for the two different clinics (A and B) for the left breast (BL), the right breast (BR) and the Heart (H). Preliminary results from model C are comparable.

The axial slices in Figure 2 show the comparison between the ground truth (solid) and the model-generated contours (faded) with the highest (upper) and lowest (lower) surface distance on the left breast among the test cases. The lowest average surface distance was produced by the multi-institutional model and the highest distance by a site-specific model.

**Conclusion**

A multi-site deep learning model for breasts and heart delineation was realized and compared against site-specific models showing that the multi-institutional model performs better than the site-specific model. Our results indicate that a deep learning model is able to generalize its output to apply to multi-site needs by using a broader training dataset. With deep learning, it is possible to overcome the current hurdles encountered in manual contouring and eliminate the need of creating site-specific deep learning-based models. Taken into use, this technology can have a huge impact on the workload of clinical staff and on the standardization of care.

#### EP-2097 Use of an a-Si EPID for routine QC of the Elekta Unity MR-Linac

J. Berresford<sup>1</sup>, J. Agnew<sup>1</sup>, T. Harriden<sup>1</sup>, G. Budgett<sup>1</sup>  
<sup>1</sup>The Christie NHS Foundation Trust, Christie Medical Physics & Engineering, Manchester, United Kingdom

#### Purpose or Objective

One challenge associated with the Elekta Unity MR-Linac is to develop a robust, time-efficient set of QC procedures. Accurate set-up of QC equipment and ion chambers takes longer than on conventional linacs and therefore making use of the onboard MV imager for QA purposes is attractive. This work investigates the use of the EPID panel for daily output checks, field size QC and a symmetry constancy check. Data was collected over six months of regular QC on the pre-clinical machine, with the intention of rolling out the checks on the final clinical version.

#### Material and Methods

Daily EPID images were acquired at the four cardinal gantry angles using a field size of 20x8cm. These four fields were always run immediately after a 1000 MU warm-up beam. A set of monthly images were also acquired at 4x4cm to provide a measure of field size scaling. For the daily images, code was written to extract the pixel factor from the log file and record the mean grayscale for the central square of 50x50 pixels (2x2cm at the level of the EPID). These output values were normalised against isocentric Farmer chamber measurements and the variation between the two investigated.

Symmetry was calculated on both axes discounting the penumbral region. A measure of flatness was also determined but, as the image is divided through by a flood field, this value is relative. The symmetry is also affected by this flood field but still gives a useful measure of constancy to complement periodic measurements with a beam profiler array.

Field size was calculated using both the 50% method and the point of maximum gradient.

#### Results

A comparison of normalised EPID output measurements at gantry angle (GA) 90° to those acquired with a Farmer chamber can be seen in Figure 1. The EPID results have a slightly larger variation (standard deviation of 0.6% vs 0.4% for the Farmer) but correspond with the low-level gradual trends measured using the Farmer.

The average symmetry value at GA0 was 101.9% (SD 0.1%) for the cross-plane axis and 100.8% (SD 0.2%) for the in-plane measurement.

The two techniques for measuring field size produced slightly different results with the averages at GA0 varying by up to 2mm for the in-plane field (8cm width). Both techniques however generated consistent results for a particular field size/orientation, with SD of <0.3mm for each set of measurements.

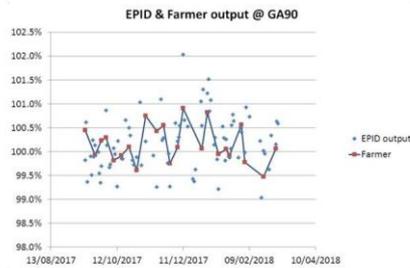

Figure 1: Normalised EPID output measurements at gantry angle 90° vs. those made using a Farmer chamber.

### Conclusion

The MV imager mounted on the Elekta Unity MR-Linac is a fast and reliable method of measuring daily output as a constancy check between weekly ion chamber measurements. The panel is also capable of performing field size QC for fields up to 20x8cm and generating values for beam symmetry. The Unity MR-Linac was found to be extremely stable for all QC parameters over a six-month period. For the clinical MR-Linac, the EPID will form a useful role in minimising time required for daily QC checks.

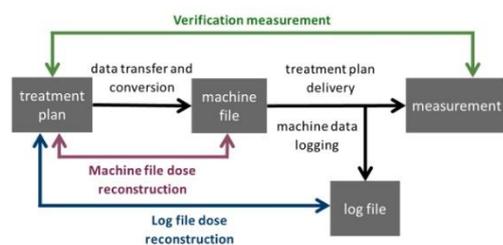

### EP-2098 Measurement free patient specific verification for PBS proton plans - a quantitative evaluation

M. Matter<sup>1,2</sup>, N. Fachouri<sup>1</sup>, L. Nenoff<sup>1,2</sup>, G. Meier<sup>1</sup>, A. Bolsi<sup>1</sup>, D.C. Weber<sup>1,3,4</sup>, A.J. Lomax<sup>1,2</sup>, F. Albertini<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen PSI, Switzerland ; <sup>2</sup>ETH Zurich, Department of Physics, Zurich, Switzerland ; <sup>3</sup>University Hospital Bern, Department of Radiation Oncology, Bern, Switzerland ; <sup>4</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

### Purpose or Objective

Large clinical efforts and substantial beam time are invested in patient specific verification (PSV) measurements for pencil beam scanning (PBS) proton therapy. Despite the big expenditure to conduct these measurements the added value to ensure the treatment integrity is not given without doubt. Hence, there is an urgent need to remove the PSV-bottleneck in the clinical work-flow, while upholding the high safety standards. Capabilities of current PSV methods to ensure the treatment integrity are investigated and compared to an alternative approach of reconstructing the dose directly from the machine control- or delivery log files with the help of an independent dose calculation (IDC) (Figure 1). The results from this investigation motivate the design and implementation of a clinical measurement free PSV protocol.

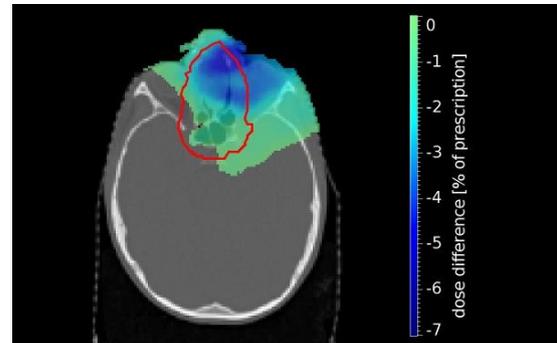

### Material and Methods

Six realistic delivery or work-flow failure scenarios based on in-depth assessment of the clinical procedures, were simulated on a varying range of patients and indications. Examples are patching miss alignment in a large head and

neck case or a simulation of imprecise spot positions during the delivery in a highly modulated IMPT plan surrounding the spinal cord. Investigating these scenarios is an important extension of the sensitivity analysis of the method on a single treatment field, conducted and published in prior. The failure simulations were realized by inclusion in the machine files. These altered machine files were delivered and measured with our clinical PSV measurement protocol. IDC machine- and log file checks were conducted and their sensitivity at detecting the errors was compared to the measurements. Further, a conclusive analysis of failure detection probability considering the whole clinical chain with measurements and with the alternative IDC checks was performed.

### Results

The PSV measurements showed a poor performance in detecting small, but clinically relevant alterations in the machine file. An example dose difference, which the PSV measurement was not able to detect, is displayed in Figure 2. The previously determined sensitivity of the IDC checks could be verified on the varying patient geometries and in combination the method was shown to out perform the measurements. The clinical PSV measurement protocol was able to correctly detect 2 out of 6 failure scenarios, while the IDC checks had a perfect detection record. The knowledge of the detection sensitivity and the failure detection probability highlighted the strengths and weaknesses of the investigated methods and enabled the definition of a new clinical measurement free PSV procedure.

### Conclusion

Machine- and log-file IDCs have been shown to represent a valuable and more sensitive addition to the QA procedure. The reported performance of the IDC yields a big potential for replacing PSV measurements, which would significantly streamline the quality assurance procedure. Currently in our clinic the defined measurement free PSV procedure is in the process of clinical implementation.

### EP-2099 The national approach to assign risk factors for failure modes and effects analysis in IMRT process

I. Koniarova<sup>1</sup>, V. Dufek<sup>1</sup>, I. Horakova<sup>1</sup>

<sup>1</sup>National Radiation Protection Institute, Department of Radiotherapy and X-Ray Laboratory, Praha, Czech Republic

### Purpose or Objective

It is mandatory with new legislation to perform risk analysis in the Czech Republic to prevent accidents or to minimize their occurrence in radiotherapy. The failure modes and effects analysis (FMEA) is a recommended tool to fulfil this requirement. The aim of this work was to estimate values of O (occurrence), S (severity), D (detectability), and RPN for possible failures in the IMRT process tree; and to describe systematic national approach to this problem.

### Material and Methods

The group of medical physics experts in radiation oncology in the Czech Republic is formed by representatives from hospitals, service companies, National Radiation Protection Institute (NRPI), and regulatory body. All members were asked to make the estimates for values of O (occurrence), S (severity), D (detectability), and RPN (risk priority number) used in the FMEA for IMRT process. Although there exist examples of these values published in literature, the analysis was performed to estimate independently the most appropriate and valid values corresponding to the national conditions, practices, and experience. Results from analysis of radiotherapy accidents was taken into account which NRPI performs on request of the regulatory body. The hospitals must report the most serious accidents to the regulatory body, but were asked to report also less serious accidents and near misses, which was voluntary based to cover accidents that happened in the Czech Republic in the period 2012 - 2017. The results from this analysis were used to modify and validate estimates of values for FMEA.

#### Results

Published values in AAPM TG 100 were confronted with the estimates based on experience of Czech physicists. The contribution shows differences in identification of the most hazardous steps on IMRT process tree. In total, more than 230 accidents in radiotherapy were evaluated. The most serious accidents in radiotherapy in the Czech Republic in previous years have been caused by software failures which was not included in 10 highest ranked failures by AAPM TG 100. The description of these most serious accidents caused mainly by data transfer and Record and Verify System failures will be included. The most frequent accidents in previous years were related to incorrect patient positioning, choice of incorrect treatment plan, and patient identification.

#### Conclusion

The contribution shows the results from performed analysis and helps local physicists to adopt legislative requirements. It also shows an effective way by grouping physicists to form an official body in the country to enable cooperation between professionals on the national level which is benefit especially in small countries where enough experts are not available to form different working groups. The results will be published in form of the national recommendation by the regulatory body and it is expected that particular departments will implement the method considering local conditions.

#### EP-2100 Quality in the implementation of stereotactic radiotherapy services on a national scale

T. Aland<sup>1</sup>, R. Fitzgerald<sup>2</sup>, M. Knesl<sup>1</sup>, A. Perkins<sup>3</sup>, D. Shannon<sup>1</sup>, L. Anderson<sup>1</sup>, M. Jones<sup>4</sup>, N. Bailey<sup>3</sup>, M. Foote<sup>1</sup>, M. Dally<sup>3</sup>

<sup>1</sup>Icon Group, Icon Cancer Centres, Brisbane, Australia ;

<sup>2</sup>Icon Group, Icon Cancer Centres - North Lakes,

Brisbane, Australia ; <sup>3</sup>Icon Group, Icon Cancer Centres - Richmond, Melbourne, Australia ; <sup>4</sup>Icon Group, Icon Plan, Brisbane, Australia

#### Purpose or Objective

Icon Group operates a network of 20 radiotherapy centres (Icon Cancer Centres) across Australia. A nationwide project was launched to implement a safe, high quality stereotactic radiotherapy programme, based on the extensive experience within our network already, for a variety of stereotactic radiotherapy (SRT) and stereotactic body radiotherapy (SBRT) treatment techniques including lung, liver, cranial, and oligo-metastases. The aim of this initiative was to provide these advanced treatments closer to patients in the community setting resulting in reduced travel time for treatment and associated financial and personal burden.

#### Material and Methods

Within the 20 Icon Cancer Centres, a mix of software and hardware exists including Varian, Elekta, Brainlab, and

RaySearch. Staffing across the network had varied levels of clinical and technical experience. Implementation was achieved using national multi-disciplinary project teams that developed a template for implementation to be used by other centres within our network. These project teams also developed draft clinical guidelines, which were then disseminated to wider staff groups for refinement. An endorsement program within a clinical governance structure was developed to facilitate implementation of a stereotactic service at a new Icon Cancer Centre. Endorsement for a centre to provide a specific stereotactic service involved the centre providing evidence of equipment commissioning, technique documentation (clinical and technical), staff training, and competency assessments.

The endorsement process is governed by national stereotactic "clinical streams", which are in-house physician led groups comprised of a mix of both senior and junior physicians, as well as key technical staff. To assist commencing junior physicians and to provide opportunities for learning and skill development, a mentorship program and national virtual stereotactic chart round was established and held weekly. To ensure quality control in treatment planning, a virtual treatment planning model was set up. This consisted of a mix of dedicated treatment planning staff, as well as remote planners, all operating within a virtual treatment planning room environment.

#### Results

To date, national clinical guidelines have been written for cranial metastases SRT, lung SBRT, liver SBRT, and bony/oligometastatic SBRT. To complement these guidelines, a series of national work instructions covering simulation, planning, and treatment processes have also been developed, and are based on what software / hardware is available on site. Stereotactic radiotherapy has been implemented in 13 of our centres. To date, 51 cases have been presented within our chart round.

#### Conclusion

Thus far, stereotactic radiotherapy services have been implemented at Icon Cancer Centres across Australia. Compliance with approved documents is monitored by the clinical streams via the endorsement programme and chart rounds, to ensure quality in stereotactic services on a national scale.

#### EP-2101 Evaluation of the feasibility of performing markerless tracking for lung SBRT patients

T. Gevaert<sup>1</sup>, A. Girardi<sup>1</sup>, C. El Aisati<sup>1</sup>, C. Collen<sup>1</sup>, B. Engels<sup>1</sup>, M. De Ridder<sup>1</sup>

<sup>1</sup>Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

#### Purpose or Objective

Tumor tracking based on fiducial markers using the VERO SBRT system uses a correlation model to estimate internal tumor position based on external surrogate motion. Previous studies in our department showed already the feasibility and accuracy of performing this marker-based tracking. The drawback of this technique is the implantation use of a marker as a surrogate for the tumor motion, as majority of patients are not eligible for marker implementation due to risk of pneumothorax in COPD patients and anatomical challenges. That is why we wanted to implement a less invasive technique eligible for a larger variety of patients using state of the art imaging. In this study, we want to report on the first simulation of a markerless real-time tumor tracking solution based on the Vero SBRT gimbaled Linac system for treatment of lung tumors.

#### Material and Methods

Twenty previously treated patients with a marker-based tracking were used to analyze the feasibility of markerless tracking. In these fluoroscopic images, the marker was erased in the image in order to analyze the markerless

environment of the ExacTrac v3.5 system (Brainlab, München, Germany). The density of the lesion was used as a surrogate for tracking. The accuracy of the target identification for a reference image pair, which is provided to the markerless tracking algorithm, was compared against the marker-based implants detection. The result gives an estimation of the manual target identification error. Additionally, the user-variability and the patient-variability of the manual target identification error were analyzed. Furthermore, 15 patients treated with internal target volume (ITV) were simulated for markerless tracking.

#### Results

Root mean square error between the markerless tracking and the marker-based tracking for all patients in LR, AP and SI directions were [0.1, 0.3] mm, [0.8, 0.9] mm and [1.2, 0.9] mm, respectively. This markerless tracking algorithm was able to track 87 % of all images. In the case of simulating real time patients treated with an ITV approach, 80% were eligible for markerless tracking.

#### Conclusion

In this study, we successfully implemented a markerless environment for dynamic tracking leading to a patient specific dose delivery.

#### EP-2102 Accurate software detection of light markers coincidence using a computed radiography system

M.A. Benito Bejarano<sup>1</sup>, A. Del Castillo Belmonte<sup>2</sup>

<sup>1</sup>Hospital Provincial de Zamora, Department of Radiation Physics, Zamora, Spain ; <sup>2</sup>Hospital Clínico Universitario, Department of Radiation Physics, Valladolid, Spain

#### Purpose or Objective

The current recommendations on quality assurance (QA) of medical accelerators set a monthly frequency for testing the coincidence of the light field crosshair projection and patient positioning lasers. Nowadays, the standard way of performing this test is by naked eye examination of the projection of those markers over graph paper. However, the accuracy of this method is compromised by interobserver variability. We propose a new method that allows a precision gain by means of a Computed Radiography (CR) system and an in-house developed analysis software.

#### Material and Methods

A Konica Regius model 140 CR System is used. The system has been previously tested to determine and correct geometric distortions. The CR cassette is irradiated with 16 MU in a 40x40 cm<sup>2</sup> 6MV field at isocenter distance to obtain a latent uniform background image. In our procedure, we use the sensitivity of the CR plate to visible light to acquire an impression of the optical indicators. The uncovered phosphor is directly exposed to the laser light for 20 s. The collimator is set to several angles, switching the light field on for 20 s in each one. The CR plate is put back inside the cassette and is read by the CR system. The result consists of a superposition of the image from the laser cross plus the image star from the different projections at each collimator position. An in-house software routine has been developed to analyse the images. It imports the image in RAW format and finds the laser crossing point. The lines of the star-shot pattern of the light crosshair are detected, and the minimum circle encompassing all the lines is determined. The software returns the radius as well as the distance of the circle centre to the laser cross point. The accuracy of this procedure has been tested by running it against synthetic images with intentional known shifts applied.

#### Results

Geometric distortions were found negligible, no image correction was needed. The coincidence of lasers with cross-hairs could be determined with an accuracy better than 0.2 mm with a 95% confidence interval. The image acquisition process takes less than 15 minutes, image processing less than 2 minutes.

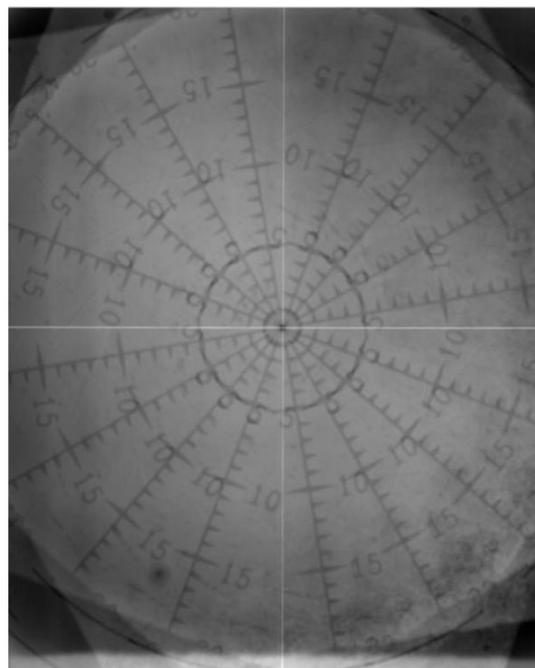

Figure1: Input image with laser marks in white, and crosshair star pattern in black

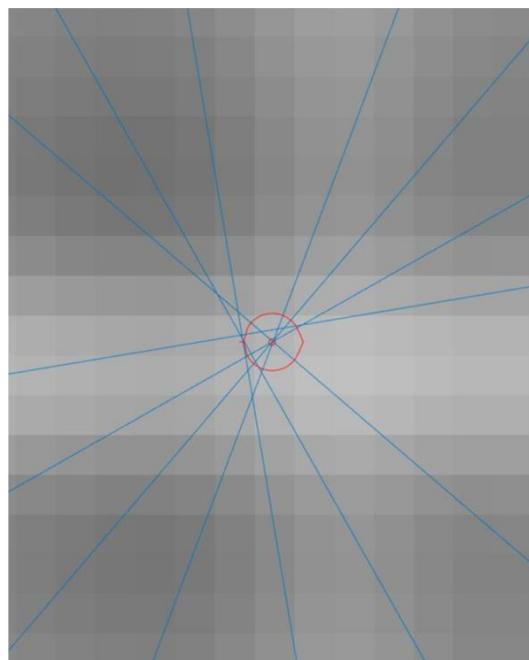

Figure2: Analysis results. Zoom of the area near the detected laser cross mark, showing the minimum encompassing circle and its centre.

#### Conclusion

This method allows the measurement of light crosshair and laser lines coincidence. The accuracy is improved, as it eliminates the inter-observer dependence. The resulting digital images can be archived after processing, for future reference. The materials involved are readily available in a modern hospital setting. The test is inexpensive as no consumables like film are used. This method has been proven useful when performing the light field crosshair to lasers coincidence test, mainly after a field service intervention in the linac, i.e. mirror or crosshair substitution.

**EP-2103 Development of a personalized, interactive patient decision aid for participation in clinical trials**  
 C. Offermann-Wulms<sup>1</sup>, C. Roumen<sup>1</sup>, A. Ankolekar<sup>1</sup>, J. Coenen<sup>1</sup>, I. Nijsten<sup>1</sup>, R. Fijten<sup>1</sup>, D. De Ruyscher<sup>1</sup>  
<sup>1</sup>*Maastrro Clinic, Department of Radiotherapy, Maastricht, The Netherlands*

#### Purpose or Objective

Performing clinical trials is a crucial step towards changing standard clinical practice.

Lack of statistical power is one of the major problems hampering clinical trials, thus ensuring that appropriate inclusion in trials takes place is crucial. However, cancer patients often do not make informed decisions regarding clinical trial participation. This is due to misconceptions and wrong beliefs that trial participants do not receive the best possible care, and due to the fact, that written or oral information about clinical trials is often incomplete, complex, unclear and confusing.

Therefore, patient-centered approaches in clinical trials call for support in the decision-making process, guiding patients to clarify their preferences and values, and helping patients make a well-informed decision about participation.

To this end, we developed a web-based patient decision aid for trial participation (tDAT).

#### Material and Methods

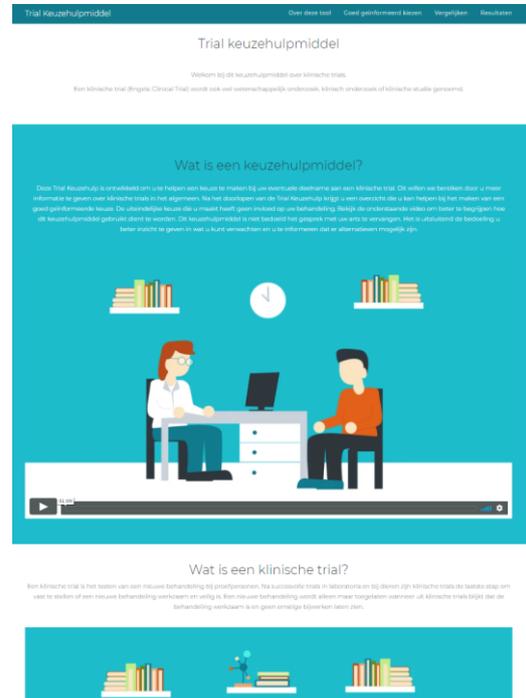

The tDAT was developed between April 2017 and April 2018 according to the international patient decision aid standard (IPDAS) guidelines. First, we identified views on decisional needs for trial participation of stakeholders (e.g. trial experienced patients, trial assistants, physicians) and verified these needs in scientific literature and by interviewing patients who were already participating in a clinical trial. Based on this evidence, a prototype was developed, which was subsequently tested by stakeholders using semi-structured interviews. This review by the stakeholders led to a redraft and redesign.

#### Results

The resulting tDAT displayed information about trial participation in an interactive manner and without medical jargon.

The general information on the definitions of clinical trials are given by using animations, videos and written text in which the trial participation process is explained. Additionally, a questionnaire is included that allows patients to test their gained knowledge. This is followed by multiple comparisons to determine what matters to them based on their personal preferences.

At the end, the patient receives an overview of their preferences which they can then discuss with the trial assistant and/or MD in order to make a founded and better-informed decision.

#### Conclusion

We have developed a tDAT that will enable us to test our hypothesis that well-informed patients are more likely to participate in a trial and less likely to drop-out of a trial. In the near future, we will be conducting a trial to evaluate the quality and effectiveness of our current web-based tDAT. This will be done after stakeholders tested the feasibility of the tool.

**EP-2104 Audit of the dosimetric impact of weight loss in head and neck patients to assess when a re-plan is required**

N. Lalli<sup>1</sup>, S. Khan<sup>2</sup>, L. Hong<sup>2</sup>, M. Daly<sup>2</sup>, D. Carnell<sup>2</sup>, R. Mendes<sup>2</sup>, A. Thompson<sup>2</sup>

<sup>1</sup>*University College London Hospital NHS Trust, Radiotherapy Physics, London, United Kingdom ;*

<sup>2</sup>*University College London Hospital NHS Trust, Radiotherapy, London, United Kingdom*

#### Purpose or Objective

Anatomical changes including weight loss can cause dosimetric changes over a course of VMAT radiotherapy for head and neck cancer, affecting target volume coverage or organ at risk dose. Adaptive re-planning can be used to mitigate these effects; however doing this can require additional time and resources. Repeat planning CTs can contribute concomitant radiation dose. Calculating the planned dose using on-treatment CBCT images helps quantify the dosimetric changes to OARs, facilitating decision-making when faced with weight loss during treatment.

At UCLH, when patient separation loss is observed on weekly CBCTs, a request is sent to the physics team to implement a dosimetric assessment. The planned patient external contour is amended to reflect the recent CBCT. The plan is re-calculated to document the changes in target coverage and OAR doses, and is reviewed by the clinician to determine if action is required. The purpose of this study was to audit the existing process and determine whether it could be streamlined within our department. Being able to identify patients where weight loss can have an undesired dosimetric impact and when and to take effective action was the endpoint of this study.

### Material and Methods

An institutional audit of head and neck patients undergoing radical arc radiotherapy was carried out for the period of April 2017 to March 2018. Specific time points during a patient's treatment were recorded including the date where dosimetric assessment query was raised to physics team and how long the evaluation took. The total number of dose re-calculations, and rescans were summarised and spinal cord doses were audited. The dosimetric impact of separation change was evaluated by recalculating the RT plans for a sample of 5 patients with irradiation of bilateral nodes, after reducing the external body contour on the TPS by 1cm in all directions. Using the typical fraction at which weight loss is seen a composite weight loss plan was created and spinal cord doses were evaluated.

### Results

Audit of Head and Neck patients in RT during April 2017 – Mar 2018	
Total no. of patients	99
No. of patients that required a plan recalculation, due to anatomical variations seen on CBCT	23
Average point of recal	17 fractions (out of 30)
No. that required a rescan/re-plan after recalculation	8
Average time between separation change CBCT and re-CT	5 days
Average time from re-CT to re-plan	5 days

The audit results are as shown in Table 1. In addition, it was found that patients requiring a re-scan were because of poor fitting shell, and thus variability of set-up, rather than the dosimetric impact.

### Conclusion

Where the planned cord PRV doses are within 0.5Gy of tolerance and with more than 50% treatment remaining, a rescan/re-plan should be actioned. This audit has shown that while the VMAT plan is robust to patient separation changes, if variability in set-up is seen a rescan pathway should be implemented immediately. IGRT is necessary to ensure accurate positioning throughout a course of treatment.

The results of this audit will help streamline local processes to implement an efficient adaptive pathway for head and neck patients. Further work is being carried out to implement deformable registration to facilitate this accurately and efficiently.

### EP-2105 Robustness comparison between 6- and 8-fields SIB proton plans on head and neck patients

N. Bizzocchi<sup>1</sup>, C. De Angelis<sup>1</sup>, J. Hrbacek<sup>1</sup>, A.J. Lomax<sup>1</sup>, D.C. Weber<sup>1</sup>, A. Bolsi<sup>1</sup>

<sup>1</sup>Paul Scherrer Institut, Center for Proton Therapy, Villigen, Switzerland

### Purpose or Objective

Pencil Beam Scanning (PBS) proton therapy, compared to conventional radiotherapy (CRT), can improve organs at risk (OAR) sparing in Head and Neck (H&N) patients, especially for median OARs like the spinal cord and brainstem. Nevertheless, plan robustness (PR) needs to be optimal and delivery time (DT) reasonable. For these reasons, bilateral H&N cases with involved lymph nodes chains could represent an issue due to the extension/complexity of the targets and the high number of OAR involved. The PSI standard approach for such cases uses an 8-field beam arrangement (BA) that was proven to satisfy PR specifications. However, with this approach the long delivery time (at least 30 minutes) still represents an issue for intra fractional setup. Therefore a new planning technique was studied to reduce fields number (and treatment time), without compromising the dose distribution. In this study, we report on a comparison of PR between the standard 8 field approach (8F) and a 6 field alternative (6F).

### Material and Methods

In H&N cases with lymph node involvement, a different BA is strongly advised between the cranial portion of the PTV and the PTV localized in the neck area. Different field directions are used to treat the different PTV portions, with overlapping junctions between the fields (8F, Figure 1). The 6F approach keeps also a different BA between head and neck regions, but the reduction in field numbers is reached by a different splitting of the PTV. In this way, 2 field directions are kept identical for both cranial and neck portions of PTV (6F, Figure 2). The 6F planning technique was studied for two H&N cases clinically treated at PSI using 8F BA and a Simultaneous Integrated Boost (SIB) fractionation of 3 dose levels (54, 60 and 69 Gy-RBE- at 1.8, 2 and 2.3 Gy-RBE- per fraction). 6F plans were designed to be clinically equivalent to the delivered 8F ones, and PR was computed for both 6F and 8F approaches (setup uncertainties for PSI patients positioned with mask:  $s_{85\%}=2.25$  mm) for PTVs, CTVs, spinal cord, brainstem, Parotids, chiasma and optic nerves. DT for 8F approach was over 35 minutes while for 6F between 25 and 30 minutes.

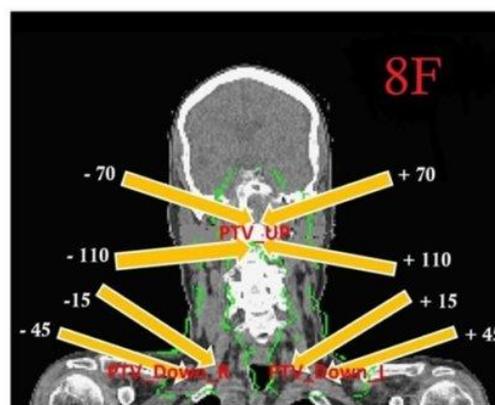

Figure 1: standard BA with 8 fields

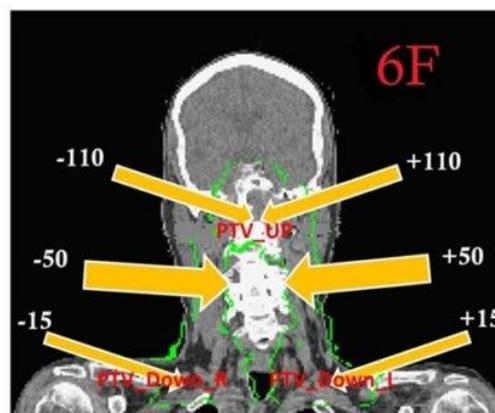

Figure 2: new BA with 6 fields

### Results

Table 1 shows the comparison between the 8F and 6F approaches. The values are for one of the 2 analyzed cases (also representative of the other). The fraction of PTV, CTV and OAR volumes (%) with dose errors over 5, 10 and 15% are reported. For OARs results are better for 6F for chiasma and brainstem while for the other VOIs there is no clear trend.

VOI	Brainstem			Chiasma			Spinal Cord

V15% (%)	0.31	0.48	-0.17	1.30	0.79	0.51	0.59	0.39	0.20

Table 1: robustness evaluation in % of set-up error over % of the target/OAR volume. In green the results where 6F is better (lower PR values) over 8F, while in orange the cases where 8F has better values as 6F.

**Conclusion**

In terms of robustness, the 6F approach could be considered similar to the 8F one. Nevertheless, 6F delivery time is reduced by 20% compared to the 8F technique. Indeed, for a comparable amount of spots, the couch movements between fields are reduced from 7(8F) to 5(6F), thus reducing intrafraction motion. 6F approach should therefore be preferred over the 8F one, even if other cases should be investigated to strengthen our conclusion.

**EP-2106 Statistical process control analysis of pre-treatment VMAT QA for different anatomical sites**  
 H. Omar Ghafour<sup>1</sup>, S. Russo<sup>2</sup>, M. Esposito<sup>2</sup>, S. Pini<sup>2</sup>, A. Ghirelli<sup>2</sup>, G. Zatelli<sup>2</sup>

<sup>1</sup>Ministry of Health KRG / Sulaymani directorate of health of Health/ Zhiyanawa Cancer Center, Zhiyanawa Cancer Center, Sulaymaniyha, Iraq ; <sup>2</sup>Azienda USL Toscana Centro, Medical Physics Unit- Azienda USL Toscana Centro- Sede di Firenze-, Firenze-, Italy

**Purpose or Objective**

Pre-treatment patients specific QA are used to validate the dosimetry of VMAT plans and to evaluate dosimetric performance over time of VMAT QA process. Discrepancy tolerance limits between calculated and delivered radiation doses are neither well defined nor consistently applied. The aim of this work is to determine the Tolerance limit and the Action Limit for the dose delivery process for different anatomical sites.

**Material and Methods**

QA measurements were performed by PTW Octavius 4D 729 in the PTW Octavius 4D phantom for 464 VMAT plan for six anatomical sites: Head and Neck, Lung, Breast, Prostate, post prostatectomy, Abdominal and Pelvic case. Measurements were compared with TPS Elekta Monaco 5.1 computed doses via 3D global gamma analysis 3%/3mm (global normalization point value >90% of maximum dose) by using PTW VeriSoft software 6.1. The Action limit and tolerance limit were established, by using the concept of Statistical control process (SPC), as suggested by AAPM Task Group 218:

$$\Delta A = B \times \text{SQRT}(\sigma^2 + (\bar{x} - T)^2) \quad \text{Eq(1)}$$

$$\text{Action limit} = (100 - \Delta A) / 2 \quad \text{Eq(2)}$$

$$\text{Tolerance limit (LCL)} = \bar{x} - 2.66 \times (\text{mean moving range}) \quad \text{Eq(3)}$$

$$\text{Mean moving range (MR)} = 1 / (n - 1) \times \sum |X_i - X_{i-1}| \quad \text{Eq(4)}$$

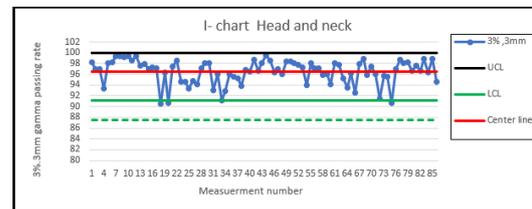

where ΔA is the difference between the upper and lower action limits (typically written as ± ΔA / 2); T is the process target value (100% for QA VMAT); σ<sup>2</sup> and  $\bar{x}$  are the process variance and process mean, respectively and B is a parameter whose suggested value is equal to 6. The moving range is absolute difference between two successive point data in the time ordered data and can be calculated according equation (4), where (X) is an

individual IMRTQA measurement. (n) is total number of measurements.

**Results**

The average pass rate of volumetric 3D gamma index for global normalization with criteria 3%,3mm, the specific tolerance limit and action limits for each anatomical site were shown in table 1. Gamma values resulted outside LCL only for about 6%, 2.5%, 4% of cases for Head and Neck, Prostate, post Prostatectomy and Pelvic case respectively. The chart control limit was constructed for each site based on the SCP. An example for Head and Neck patient is presented in

Site of patients	Patients	σ	( $\bar{x}$ ) of (γ) 3%,3mm	LCL	Action limit	Value over LCL
Head and neck	86	2.2	96.5	91.3	87.6	5
Lung	61	2.0	96.7	91.2	88.5	0
Breast	41	1.8	96.1	91.2	86.9	0
prostate	118	0.6	99.7	98.6	97.8	3
pelvic and abdominal	106	3.0	96.4	88.4	85.9	4
post prostatectomy	52	1.2	99.1	97.0	95.5	2

**Conclusion**

The action limits and tolerance limits for the specific couple of linac and measuring system used in this work were determined and stratified for different anatomical site. The Control chart limit approach indicates that the process is under control.

**EP-2107 DQA gamma Analysis evaluation criteria for prostate SBRT using MLC InCise 2 of a Cyberknife-M6**  
 A. Ruiz<sup>1</sup>, K. Torzsok<sup>1</sup>, M. Ribeiro<sup>1</sup>, H. Broqué<sup>1</sup>, J. Aponte<sup>1</sup>, F. Marangoni<sup>1</sup>

<sup>1</sup>Fundación Arturo López Pérez, Radiotherapy, Santiago de Chile, Chile

**Purpose or Objective**

A multileaf collimator (MLC) for radiosurgery on a robotic arm is new worldwide. The Cyberknife M6<sup>®</sup> shapes the beam in 3 ways, one through the MLC InCise2<sup>®</sup> consisting of 26 leaf pairs, each with a width of ≈ 2 mm. The maximum field size is 115 mm × 100.1 mm. Patient specific quality assurance evaluation criteria recommended internationally are scarce. The objective of this work is to determine tolerance criteria and gamma approval rates achievable for evaluation and validation of the gamma index and CC01 IBA<sup>®</sup> ionization chamber point dose measurements in prostate SBRT performed with the MLC InCise2<sup>®</sup> on a sample of 22 treated patients.

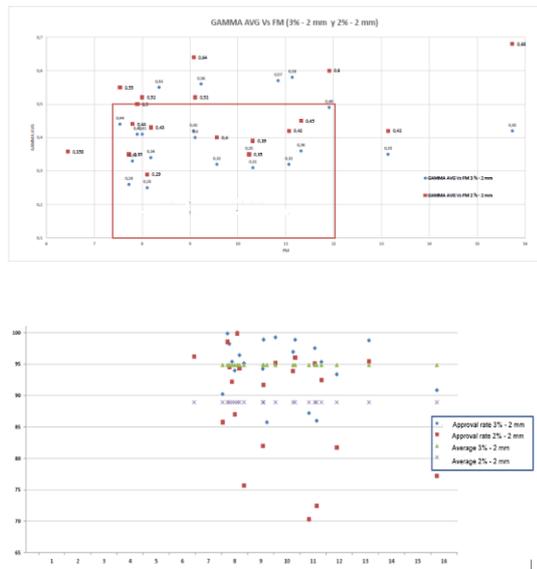

**Material and Methods**

A film dosimetry method was developed. A 24 hours calibration curve was made with EBT3 films and Omnipro software for evaluation of SBRT prostate plans, 2 dose planes and film background correction were used for each patient. Absolute and relative calculations were made, with different criteria to test approval rates ranges, as well as, the average gamma to obtain with this MLC with statistical parameters. Physics time investment per patient was ≈ 3.5 hours. The algorithm used by treatment planning system (TPS) is equivalent path length type A. MLC less collimation limits given by the manufacturer were evaluated, considering tests analogous to those proposed by James L Bedford et al.

**Results**

Different criteria of approval rate value, as well as modulation factor (MF) has not shown a defined trend

variation, with respect to the PTV volume. The values obtained from the point dose in a deviation range of  $\pm 3\%$  have corresponded to an approximate 8-13 range of the MF. The same range of MF is observed in figure 1, for those average gamma values that are less than 0.5, obtaining more points that fail as the criterion's rigor increases. When evaluating the approval rate with 2 different criteria, figure 2, the dispersion range of the points is much higher with the strictest criterion. It is not only that the approval rate is lower, which is not necessarily unfavourable, but points are more dispersed making it more difficult to establish an evaluation criterion based on a stable averaged behaviour. In addition, the values distribution of the approval rate was evaluated with Monte Carlo simulation. Minimum Gumbel type distribution was the best fit obtained.

## Conclusion

Regarding compliance of the objective, with the obtained data, it could be determined that most achievable criterion in DQA prostate SBRT with the use of this technology could be:  $\Delta D 2\%$  / DTA 3 mm in relative with an approval rate greater than 90% keeping an average Gamma of less than 0.5 and a point dose value in  $\pm 3\%$  between TPS calculated and ionization chamber measurement. Due to the high dispersion of the  $\Delta D 2\%$  / DTA 2 criterion, used with cones, it should not be used for the MLC, data shows that it is not possible to establish an evaluation criterion based on a stable behaviour averaging.

## EP-2108 Varian and Elekta quality assurance using artificial neural network based on portal imaging

F. Chatrie<sup>1</sup>, A. Vasseur<sup>2</sup>, A.R. Barbeiro<sup>3</sup>, F. Younan<sup>4</sup>, J. Mazurier<sup>4</sup>, M.V. Le Lann<sup>5</sup>, X. Franceries<sup>3</sup>

<sup>1</sup>CRCT- UMR 1037- INSERM- Université Toulouse III-Paul Sabatier- LAAS-CNRS, Disco, Toulouse, France ; <sup>2</sup>Institut de Cancérologie de Bourgogne, Physique Médicale, Auxerre, France ; <sup>3</sup>CRCT- UMR 1037- INSERM- Université Toulouse III-Paul Sabatier, Team 15, Toulouse, France ; <sup>4</sup>Atrium- Clinique Pasteur - Groupe Oncorad-Garonne, Service de Radiothérapie, Toulouse, France ; <sup>5</sup>Institut National des Sciences Appliquées- LAAS-CNRS, Disco, Toulouse, France

## Purpose or Objective

Artificial neural networks (ANN) applied to external beam radiation therapy, can be of great interest, especially for quality assurance (QA) based on electronic portal imaging device (EPID). As EPID images contain information about

the treatment delivery, they can be used to predict the delivered dose distribution, which can be compared to the planned one to ensure that the patient receives the correct treatment. Therefore, in this work we proposed the application of machine-learning algorithms to allow the reconstruction of 2D and further 3D absorbed dose maps based on EPID signal obtained from both, Varian and Elekta machines.

## Material and Methods

A supervised ANN algorithm consisting of a non-recurrent feed-forward multilayer model was employed, which works according to two phases - learning and recognition (like humans). In order to reconstruct 2D absorbed dose distribution from treatment delivery, during the learning phase, the creation of "neurons" was done by linking input and output data, taken from EPID images, and absorbed dose distributions from the TPS, respectively. Once the learning was over, new EPID signal (input data) was used to predict the delivered absorbed dose distribution (as output) in the recognition phase, to be compared to the TPS for treatment verification. The latter was done by means of global 2%/2mm gamma index (10% threshold). Although the learning phase was more time consuming while setting the ANN model, during the recognition phase, the model operated in an instantaneous way. Datasets from different EPID and TPS types were included, so that the developed model could be extended to Varian and Elekta machines. EPID images were taken from an aSi-1000 EPID on a Varian Clinac 23iX and an iViewGT on Elekta Synerg during 6MV treatment delivery, with a dose rate of 600 MU/min and 400 MU/min, respectively, while 2D dose distributions of IMRT plans were calculated in Eclipse<sup>TM</sup> and Pinnacle<sup>TM</sup>, at the maximum depth dose in a water phantom.

## Results

Learning was performed using 10 and 4 input/output datasets, respectively, from IMRT treatments. All of the used image datasets (both EPID inputs and absorbed dose distribution outputs) consisted of 384x512 and 1024x1024 pixels, respectively. In Figure 1 the result from one of the evaluated treatment plans is presented, showing the similarity between the absorbed dose distributions obtained by the implemented ANN and the originally planned. Gamma passing rates > 98% were obtained for the evaluated brain cases from Varian and Elekta instances, highlighting the ANN capability to predict the absorbed dose distribution based on EPIDs with different machines.

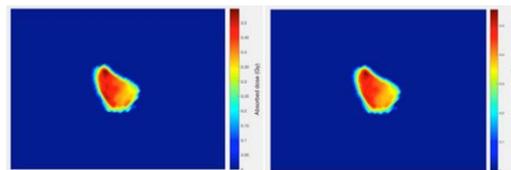

Figure 1: Comparison of 2D absorbed dose distributions calculated by ANN (left) and obtained from TPS (right) for a brain case of Varian instance.

## Conclusion

The ANN algorithm implemented in this work was able to perform IMRT treatment verification based on EPID, showing excellent gamma index results for the evaluated cases. Furthermore it was able to predict dose distributions with the same ANN model, depending of the training data, but regardless the machine type, which makes it extensible to Varian and Elekta QA.

EP-2109 Can we improve the dosimetric values with the experience? our results with vmat in lung cancer  
F.J. Luna Tirado<sup>1</sup>, M. Rincón<sup>1</sup>, D. Gonsalves<sup>1</sup>, L. Guzmán<sup>1</sup>, M. Montero<sup>1</sup>, J.M. Penedo<sup>1</sup>, A. Ilundain<sup>1</sup>, J. Olivera<sup>1</sup>, E. López<sup>1</sup>

<sup>1</sup>Capio-Fundación Jimenez Díaz, Radiation Oncology Department, Madrid, Spain

**Purpose or Objective**

RTOG 0617 trial established among other conclusions the advantages of IMRT/VMAT in locally advanced non small cell lung cancer (LA-NSCLC) mainly due to better dosimetric values comparing to 3DRT. Our objective is to determine if the better knowledge and experience in the development of VMAT in lung cancer is related with an improvement in dosimetric parameters.

**Material and Methods**

We started to employ VMAT for lung cancer in January 2014. Since then, 125 locally advanced non small cell lung cancer and limited disease small cell lung cancer have been treated with this technique.

All patients were treated following our protocol treatment. The simulation consisted in a 4D CT simulation (3mm slices) with an Elekta frame based immobilization system and free breathing. We delimited the planning target volume and organs at risk according to RTOG guidelines. For constraints, Quantitative Analyses of Normal Tissue Effects in the Clinic (QUANTEC) was used. The plan was designed using Volumetric Modulated Arc Therapy (VMAT) with one or two arcs and 6-10 MV photons. It was calculated by the Monaco treatment planning system (version 5.10).

The plan was delivered using Elekta Agility Linac with Precise treatment system (precise table) and Elekta XVI CBCT system for quality assurance.

We have analyzed and compared dosimetric values (lung V5-10-13-20 and mean lung dose; mean heart dose) between the first 20 patients treated with VMAT (group 1) and the last 20 patients treated with VMAT (group 2). To achieve an interpretable results a volume ratio have been employed to ensure homogeneous groups:  $V_{PTV} / V_{TOTAL}$  LUNG. Where  $V_{PTV}$  : Plannig target volume (cc) and  $V_{TOTAL}$  lung: Total lung volume (cc)

**Results**

Both groups were homogeneous with the same volume ratio: 0.16. Significant differences were registered between groups in all the dosimetric values analyzed, all of them in favour of group 2, mainly in mean heart dose, with a great difference of 28,6% for the group 2. Every lung dosimetric values were clearly better in group 2, especially Mean lung dose and V5 (see figure 1)

**Conclusion**

The implementation of every technical advance in radiation oncology requires a comprehensive formation and experience to achieve the best results.

In our experience, the dosimetric values in lung cancer have been clearly improved with the greater knowledge and use of VMAT technique.

**EP-2110 Developing a QA programme for the Elekta Unity MR-linac**

J. Chick<sup>1</sup>, I. Hanson<sup>1</sup>, S. Nill<sup>1</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>Royal Marsden Hospital NHS Trust and the Institute of Cancer Research, Joint Department of Physics, Sutton, United Kingdom

**Purpose or Objective**

In all modalities of treatment and diagnosis a well-structured Quality Assurance (QA) programme is necessary to ensure a high quality service and to minimise the risks to patients and staff. The Unity MR-linac (Elekta AB, Stockholm) has recently been brought into clinical service at the Royal Marsden Hospital (RMH), and requires a QA programme to include dosimetry, image quality and safety aspects. Here the RMH QA programme is outlined and initial results reported for the first month of clinical use.

**Material and Methods**

The QA programme is currently completed in daily 60-90 minute sessions before patient treatment, including daily mandatory tests (45minutes), and weekly and monthly tests on a rotating cycle. A summary of the programme is described in Table 1, detailing frequency and equipment used.

Many of the tests use a QA platform, which is a jig that fits onto the couch top, with set up marks to enable equipment to be set up reproducibly. The Syzygy phantom consists of spheres aligned along a plumb line and water level, to provide an absolute frame of reference (Hanson et al. ESTRO 37, QC-0079). The alignment of the MR and MV co-ordinate systems is measured daily using an Elekta Phantom which has 7 ZrO<sub>2</sub> spheres which are visible on MV, with corresponding signal voids on MR.

Further MR tests will be done quarterly, to include B0 homogeneity, B1 flip angle accuracy, dynamic stability, ghosting and spurious noise (Tijssen et al, ESTRO 36, QC-0257). Annual tests will include dose linearity, gantry angle attenuation, and MLC transmission/leakage.

FIGURE 1 (DOSIMETRIC VALUES VMAT LUNG CANCER)

	$V_{PTV} / V_{TOT}$	MEAN LUN G DOSE	LUNG V5	UNG V10	L LUN V13	LUN V20	HEART DOSE
GRO UP 1 (FIRST 20 PATIENTS)	0,24	16,24 Gy	74,67 %	55,29 %	45,17 %	28,91 %	15,09 Gy
GRO UP 2 (LAST 20 PATIENTS)	0,05	15,05 Gy	67,95 %	52,46 %	43,87 %	27,65 %	10,78 Gy
DIFFERENCE (%)	-7,3	9,0	5,1	2,9	3,3	4,28	28,6

**Table 1: RMH QA Programme for the MR-linac**

	Test	Equipment
DAILY	<b>Daily Radiation</b> (Consistency of output and field sizes)	EPID panel
	<b>MR-MV alignment</b> (Consistency of alignment of isocentres)	Elekta phantom
	<b>MR Image Quality</b> (SNR and scaling)	Philips PIQT
	<b>Safety</b> (e.g. interrupt/terminate buttons, patient communication)	n/a
WEEKLY	<b>Weekly Radiation</b> (Output, flatness and symmetry)	QA platform PTW StarCheck Maxi MR
	<b>MR Image Quality</b> (SNR, linearity, resolution, ghosting)	Philips PIQT ACR large phantom
	<b>Helium Level</b>	Philips Marlin
	<b>Weekly Safety</b> (Emergency Power Off buttons)	n/a
MONTHLY	<b>Monthly Radiation</b> (Absolute Output, TPR20/10, Output Factors)	QA platform PTW Watertank PTW Farmer 30013
	<b>Monthly Radiation with gantry angle</b> (Output, flatness and symmetry at cardinal gantry angles)	PTW Octavius 4D
	<b>MR Distortion</b>	Philips 3D Geometric Modus MRID phantom
	<b>System alignment</b> (Absolute gantry angle, EPID rotation, EPID iso-pixel, MLC/Jaw position & orientation)	QA platform Szyzyg phantom EPID panel
	<b>Radiation isocentre</b>	QA platform, StarShot film
	<b>Safety</b> (Interlocks, Emergency ventilation)	n/a
	<b>EPID</b> (image quality, image scaling)	QA platform, Las Vegas Phantom, Elekta Phantom
	<b>Couch</b> (level, slop and position)	QA platform, spirit level

**Results**

In the first month of clinical use, the daily output of the MR-linac, as measured by the EPID pixel factor, had a coefficient of variation (standard deviation/mean) of 0.22%. The mean RMS of the daily MR to MV alignment registration compared to the baseline registration was below 0.1mm. The results are summarised in Table 2, the MLC and Jaw positions reflected by the field size measurements were all within tolerance. All MR image quality tests passed Philips thresholds and were consistent. Further results will be reported including the weekly and monthly tests.

**Table 2: MR-linac Daily Tests (first 20 days of clinical use)**

	Mean (sd)
EPID pixel factor (a.u.)	0.01744 (0.00004)
MR to MV alignment (mm, RMS deviation)	0.08 (0.02)
Jaw defined field size @200 (mm)	199.68 (0.40)
Jaw defined field size @50 (mm)	49.47 (0.28)
MLC defined field size @80 (mm)	79.99 (0.39)
MLC defined field size @20 (mm)	20.04 (0.33)
MRI Signal to Noise Ratio (> 80)	122.43 (4.50)
MRI Scaling – axial (% , < 0.5)	0.09 (0.03)
MRI Scaling – coronal (% , < 0.5)	0.12 (0.03)

**Conclusion**

A comprehensive QA programme has been developed for the MR-linac, drawing on both Linear Accelerator and MRI methods. As more system data is collected, the programme will be optimised with respect to test frequency and methods, in order to reduce the overall time. The MR-linac performance in its first month of clinical use has been dosimetrically stable, geometrically stable with respect to the system alignment, with consistent MR image quality.

**EP-2111 Apex micromultileaf SRS Dynamic Conformal Arc treatment comparison with Agility multileaf collimator**

C. Ferrer<sup>1</sup>, C. Huertas<sup>1</sup>, R. Plaza<sup>1</sup>, R. Simón de Blas<sup>1</sup>, F. Sánchez<sup>1</sup>, E. Corredoirá<sup>1</sup>

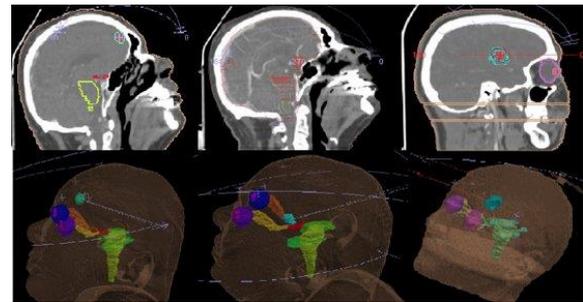

<sup>1</sup>Hospital universitaria La Paz, Radiofísica y Radioprotección, Madrid, Spain

**Purpose or Objective**

To evaluate the benefits of Apex micromultileaf collimator (mMLC) attached to the Agility multileaf collimator (MLC) against the same treatment without it attached when planning using Dynamic Conformal Arc (DCA) technique.

**Material and Methods**

Three brain metastases were prescribed to 18Gy, first one located in the central lobe, away from any critical structure. Second one located behind the optic nerves over the chiasm, and the third one in the right temporal lobe and showing irregular shape. The three locations are shown in Figure 1. Treatment was planned with Elekta Monaco treatment planning system (v. 5.11.02), and optimized using biological and physical based cost functions for isocentric DCA SRS treatment on an Elekta Synergy linear accelerator equipped with a 160-Agility MLC with of 5 mm nominal width leaves at the isocenter and an Elekta Apex mMLC attached, which has 56 pairs of tungsten alloy leaves with nominal width of 2.45 mm at the isocenter. Five non coplanar partial arcs were used, maintaining the same constraints when Apex was attached and when it wasn't. Additionally, a VMAT treatment was planned using only Agility MLC with another constraints, as with this technique a better modulation is possible. Conformation index (CI), conformation number (CN), Heterogeneity index (HI), Homogen

ity index (Hmi), Target coverage (TC), Monitor units MU, Modulation (UM/cGy) and Minimum Target Dose have been compared, as well as doses to organs at risk (OAR). Results Considering the TC, the Apex mMLC improves the treatment compared with the same DCA planning realized only with the Agility MLC, as it is shown in Table 1. Nevertheless VMAT planning achieves better TC at the cost of more MU. This better TC with Apex and DCA causes that some maximum doses are slightly higher, being the number of MU very similar. So as Apex is nearer to the patient, its penumbra is lower, and TC can be higher without increasing much the maximum doses to OAR. Conformation indexes are similar, being almost equal for Apex DCA and VMAT treatments.

INDEX	LESION 1		LESION 2		LESION 3		LESION 3	
	APEX	DCA	AGILITY	VMAT	APEX	DCA	AGILITY	VMAT
CI	1.42	0.94	1.00	1.56	1.22	1.72	1.08	1.08
CN (Padlock)	0.08	0.80	0.63	0.59	0.66	0.56	0.51	0.52
HI	1.05	1.08	1.04	1.07	1.14	1.07	1.09	1.12
TC (%)	98.80%	96.84%	100.00%	96.77%	89.83%	98.09%	97.82%	95.80%
MU	2407.69	2343.04	3017.72	2918.41	2927.27	4061.92	2384.86	3489.87
MODULATION (UM/cGy)	1.34	1.30	1.68	1.62	1.63	2.26	1.49	1.54
<b>ORGANS AT RISK</b>								
Minimum target dose (cGy)	0.98	0.92	1.01	0.95	0.89	1.02	0.94	0.89
Right optic lens (cGy)	52.70	40.60	54.80	40.50	83.50	66.80	11.30	22.80
Left optic lens (cGy)	70.80	84.20	90.60	20.20	81.00	25.50	8.00	5.00
Right optic nerve maximum dose (cGy)	87.90	62.80	92.90	1323.40	1382.50	1501.20	32.00	38.70
Left optic nerve maximum dose (cGy)	135.80	158.70	209.40	1516.50	1511.00	1641.50	19.80	16.20
Chiasm (cGy)	49.10	11.00	49.5	1811.60	1659.80	1748.20	69.40	51.40
Brain Stem (cGy)	29.20	8.80	37.00	284.00	193.20	143.20	90.20	73.50

**Conclusion**

The results achieved with Apex attached in SRS DCA treatments are superior then the same treatments are planned only with Agility. However VMAT treatments attain better results, at the cost of more MU. We will have to wait to be able to perform treatments with VMAT and APEX to have a full comparison.

**EP-2112 Automation of consistency and integrity checks in external radiotherapy plans**

M.A. Benito Bejarano<sup>1</sup>, F. Saez Beltran<sup>1</sup>  
<sup>1</sup>Hospital Provincial de Zamora, Department of Radiation Physics, Zamora, Spain

### Purpose or Objective

Modern external radiotherapy techniques rely on different computerised systems to design and deliver the treatments. Treatment plans are created in a Radiotherapy Planning System (RTPS), and upon approval they are sent to a Record and Verify System (R&V), where the plan data is stored for subsequent use in each treatment fraction. A quality assurance (QA) procedure must be applied to ensure that there have been no errors in the plan design, as well as inconsistencies or data corruption during the transmission or storage of the plan parameters. In the present, most QA procedures are based in manual and time-consuming verifications. We propose an automated system to check the plan integrity and validate its proper transmission to the R&V.

### Material and Methods

The plans were created in XiO RTPS. They were transmitted by means of DICOM RT PLAN protocol to the Mosaik R&V. A set of routines was developed in MATLAB. Those routines enable the extraction and analysis of data from DICOM files generated by the RTPS, as well from the OPENRTP text files exported by the R&V. The system works in a three stages sequence. In the first stage, the "verifydicomrt" routine analyses the DICOM file from the RTPS, to seek inconsistencies or plan errors. In the second stage, "dicomprocess" extracts data from the DICOM file to be used in our in-house secondary monitor unit (MU) verification spreadsheet. In the third stage, the "rtpdicomrtcomp" routine compares selected parameters from the RTPS-generated DICOM file with those in the OPENRTP file from the R&V. In any of those stages, when an issue is detected a warning message is displayed. DICOM and OPENRTP files with intentional errors were created to test the system.

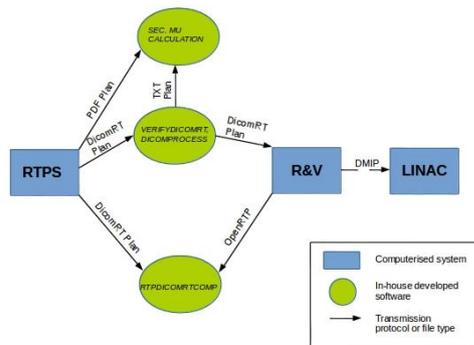

Figure 1: Plan transmission and automated QA procedures workflow

### Results

"verifydicomrt" was able to catch common planning errors in parameters related to the couch, collimator, gantry, MU, or others (see table 1). This allowed the early detection and correction of those errors before the plan was transmitted to the R&V. "dicomprocess" enabled the automatic extraction of the data needed for independent MU calculation, minimising the possibility of manual data input mistakes. "rtpdicomrtcomp" was able to compare the data generated by the RTPS with the actual parameters stored in the R&V database. This permitted tracking down any transmission errors, data corruption in the RTPS or R&V databases, or any mistakenly manual modification of parameters. "rtpdicomrtcomp" can be run in a weekly basis to keep track of unintended changes in the plans stored in the R&V database.

Table 1: Parameters processed by each routine

### Conclusion

The usage of this checking system enabled the automation of plan QA verification in a quick and reliable way. Errors could be detected during the treatment plan design, transmission and storage stages. The system could also detect data modifications in the R&V database.

### EP-2113 Congruence of mechanical, radiation, and imaging isocentres of two types of Elekta linacs

C. Mekala<sup>1</sup>, A. Naga<sup>1</sup>, N. Babu<sup>1</sup>, S. Kumar<sup>1</sup>, N. Khater<sup>1</sup>, C. Birch<sup>1</sup>

<sup>1</sup>Southampton University Hospital NHS Trust, Radiotherapy Physics, Southampton, United Kingdom

### Purpose or Objective

In this study we quantify the congruence of mechanical, radiation and imaging isocentres of two Elekta linear accelerator linacs as it is crucial for cranial hypofractionated stereotactic radiosurgery and radiotherapy deliveries where lesions of small volumes are treated with high-dose per fraction of 5 to 21 Gy.

### Material and Methods

Winston Lutz test was performed as a part of stereotactic pre-treatment linac quality control checks using a metal ball bearing phantom of diameter 5 mm which was set on the couch using in-room lasers which were originally calibrated to the MV isocentre. 2D planar MV images were acquired at 4 cardinal gantry angles and 4 couch angles with gantry set to 0° for a field size of 2.4x2.4 cm<sup>2</sup> on an Elekta Beam Modulator linac and 3x3 cm<sup>2</sup> using a recently commissioned 6MVFFF beam on Elekta Agility. The images were analysed using Pipspro software and the ball bearing was moved to match with the centre of the radiation isocentre based on optimal shifts calculated by the software. A cone beam computed tomography (CBCT) image and exactrac image of the ball bearing phantom were also acquired and the congruence of all the isocentres was evaluated based on the optimal 3D shifts of the centre of the ball bearing phantom to that of the MV isocentre. The data was acquired on both the linacs on 25 stereotactic treatment days over a period of six months.

### Results

Maximum systematic total deviation of 1.2 mm (0.6 mm radius) and 1.5 mm (0.75 mm radius) was found in the in

the Gun/Target (GT) direction for the MV isocentre for Elekta beam modulator and Elekta Agility linear accelerators respectively. The lateral and vertical errors were relatively smaller both under 0.8 mm diameter. The mechanical deviation of the couch was within 1.5 mm diameter on both the linacs. There were some outliers which were due to suboptimal beam steering and couch isocentric rotation setup which were picked up during this procedure and were corrected by our in-house engineers. The CBCT imaging isocentre was within 0.7 mm on the beam modulator linac whereas both the CBCT and exactrac isocentres were within 0.5 mm on the agility linac in comparison to the MV isocentres on each machine.

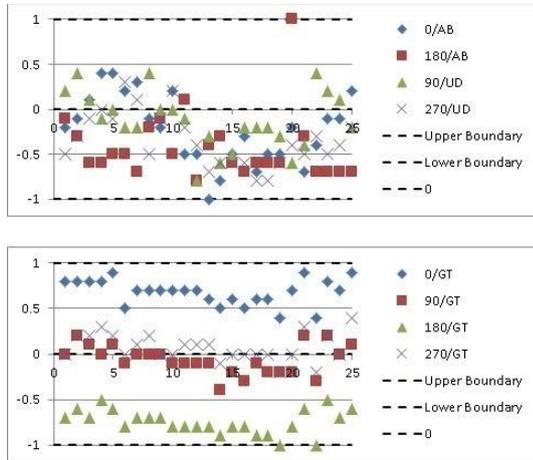

Fig.1. Gun/Target, Lateral and Vertical errors of position of the centre of the ball bearing to the central of the MV radiation isocentre for Elekta Agility linac (No. of fractions along x-axis and error in mm along y-axis)

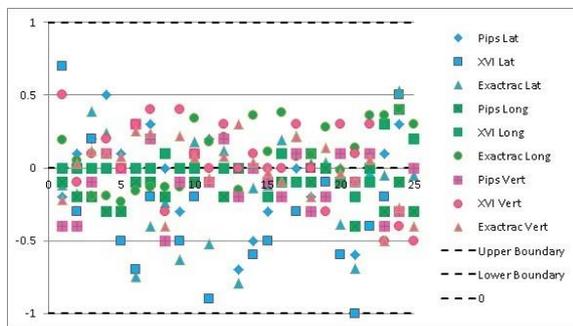

Fig.2. Lateral, longitudinal and vertical deviation between the centre of the ball bearing phantom and centre of MV, kV CBCT, and exactrac systems

**Conclusion**

Congruence of mechanical, radiation and imaging isocentres of two types of Elekta linear accelerator heads were quantified to ensure safe treatment of stereotactic patients and to assess if the planning target margins used are sufficient for target coverage.

**EP-2114 Predicting inaccuracy of overmodulated RapidArc plans using Machine Learning model**

A. Botti<sup>1</sup>, E. Cagni<sup>1</sup>, M. Orlandi<sup>1</sup>, R. Sghedoni<sup>1</sup>, D. Lambertini<sup>1</sup>, A. Barani<sup>1</sup>, V. Bertolini<sup>1</sup>, M. Iori<sup>1</sup>

<sup>1</sup>Azienda USL - IRCCS di Reggio Emilia, Medical Physics Unit, Reggio Emilia, Italy

**Purpose or Objective**

Significant differences between measured and calculated doses of RapidArc plans with very small PTV volume or overmodulated MLC pattern were observed [Fog et al - Phys. Med. Biol. 2011]. The aim of the study was to train a Machine Learning (ML) model to predict the calculated

dose inaccuracy for plan potentially affected by overmodulation issue.

**Material and Methods**

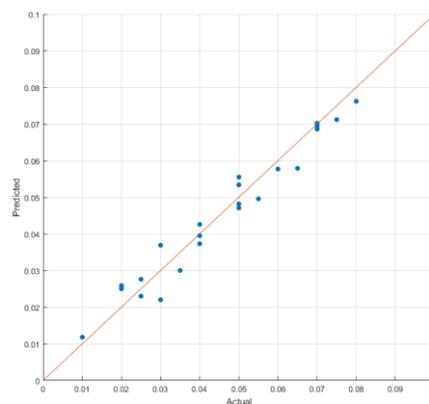

70 stereotactic RapidArc plans were planned in Eclipse v. 13.7 (Varian Medical System) and delivered on TrueBeam stx. Delivery Quality Assurances (DQA) of all plans were performed: delivered doses were measured with PTW SRS1000 chamber array combined with PTW Octavius 4D and compared with calculated dose using PTW Verisoft v.6.1. Each plan was characterized by 14 features extracted from RP-Dicom files describing different aspects of their complexity that could lead to dosimetric disagreements [Carlson et al - Phys Med Biol. 2016]. A subset of 45 plans (training set) was used to train a gaussian process regression model using the features as predictor inputs and the measured dose differences as response output. Training model was achieved with 5 fold cross validation and PCA for predictors reduction. Further open-loop validation was performed with the remaining 25 plans not belonged the training set (validation set). Features extraction, training process and validation analysis were performed using in-house Matlab ( the Mathworks) scripts. To evaluate an application of the model, a dose-painting plan was optimized in several steps with different plan complexity solutions, achieved by using different Max MU objective constraints, then DQA results were compared with prediction model.

**Results**

The cross validation analysis on the training set showed a Root Mean Square Error (RMSE) equal to 0.01 and R<sup>2</sup> equal to 0.92. The open loop-validation resulted in a RMSE equal to 0.003 and R<sup>2</sup> equal to 0.96, that indicate a good model generality. With PCA analysis the model was trained only by 3 principal components with an explained variance set to 95%.

The Figure 1 shows, for the evaluation set, a correlation plot of the predicted versus actual dose differences normalized to the maximum dose.

The dose-painting plan was optimized 3 times before to achieve a predicted dose difference within 3% of the maximum dose. In the Table1 prediction and actual values for each dose-painting plan are reported.

# Plans	total MU	predicted delta dose (%)	measured delta dose (%)	difference (%)
1	3596	5,3%	6,0%	-0,7%
2	2294	3,1%	3,5%	-0,4%
3	2091	2,8%	3,0%	-0,2%

**Conclusion**

The results indicate both a good accuracy and good generality of the trained model. ML model seems to be able to predict when a plan solution is deliverable during the planning processes, reducing the number of DQA failures, the re-optimizations due to failing DQA and the number of plans being rejected during the physics plan check because of overmodulation issue.

#### EP-2115 Semi-automated quality assurance of deformable registration in CT radiotherapy data

T. Mcgrath<sup>1</sup>, Z. Lawrence<sup>1</sup>, R. Farhad Salih<sup>1</sup>, Y. Peters<sup>1</sup>, J. Rawling<sup>1</sup>, M. Wilson<sup>2</sup>, C. Piazzese<sup>3</sup>, S. Holloway<sup>2</sup>

<sup>1</sup>The University of Manchester, School of Physics and Astronomy, Manchester, United Kingdom ; <sup>2</sup>University College London, Department of Medical Physics & Biomedical Engineering, London, United Kingdom ; <sup>3</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom

#### Purpose or Objective

A common issue in many medical physics studies is the lack of data available in order to successfully train machine learning algorithms to be able to validate registrations where ground truths are not available. Usually large datasets are required, especially for inference on more intricate structures. The aim of this work was to establish the viability of performing quality assurance on Deformable Image Registration (DIR) through the use of Convolutional Neural Networks (CNNs) in CT images.

#### Material and Methods

A total of 94 head and neck cancer patients' 2D planning CT images converted to 3D Nifty images from The Cancer Imaging Archive (TCIA) were used in this study. Pairwise affine and deformable registrations were performed on this dataset using the open source NiftyReg software package, and the contours of the brain stem, spinal cord, and left & right parotid glands were propagated. A brief grid search was carried out to optimise the bending energy, a penalty term in the optimisation algorithm to avoid overfitting, and control point spacing of the registrations, to ensure a reasonable quality of the registrations. The results were evaluated with commonly used overlap and surface based similarity metrics that measure how well the propagated contour has been transformed compared to the ground truth. Examples of these metrics include the DICE score and the 95th percentile surface distance. Furthermore, a brief viability study was conducted using pre-existing architectures within NiftyNet, by segmenting structures within a 3D CT scan of a patient.

#### Results

Using NiftyReg, 2753 out of a possible 8742 registrations were obtained. The average values of the DICE scores between the ground truth segmentation of the reference image and the propagated contours of the executed registrations were in the range of 0.5 - 0.6. However, there were a significant number of outliers, revealing the abundance of poor registrations and further highlighting the necessity of quality assurance in DIR. For the viability study, the method that provided the best metric values involved training 2D U-Net on 2D slices of the image and for a segmentation of the spinal cord to be generated for each one. The concatenated 3D segmentation was compared to a ground truth contour provided by a clinician by means of the metrics mentioned previously, obtaining a DICE score of 0.92 and a 95th percentile distance of 1.12.

#### Conclusion

To develop the project, the 2D U-Net method could be tested on the other structures to determine the difference in segmentation quality between them. Ideally, a 3D segmentation method would be successfully employed, as the field of medical physics is progressing in that direction. Combined with the registration dataset produced, our research lays the groundwork for continued development of this project.

#### EP-2116 End-to-end dosimetry audits of Stereotactic Ablative Radiotherapy

M. Shaw<sup>1,2</sup>, A. Alves<sup>1</sup>, C. Davey<sup>1</sup>, M. Geso<sup>2</sup>, F. Kadeer<sup>1</sup>, J. Lehmann<sup>3,4</sup>, J. Supple<sup>1</sup>, J. Lye<sup>1</sup>

<sup>1</sup>ARPANSA, Australian Clinical Dosimetry Service, Yallambie, Australia ; <sup>2</sup>RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia ; <sup>3</sup>Calvary Mater Hospital, Radiation Oncology, Melbourne, Australia ; <sup>4</sup>RMIT University, School of Science, Melbourne, Australia

#### Purpose or Objective

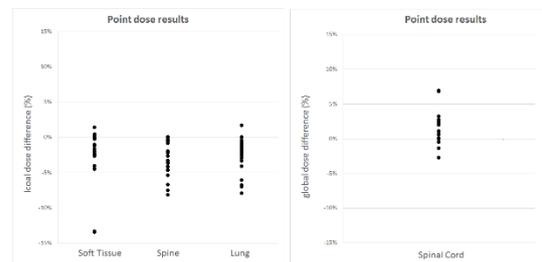

Stereotactic Ablative Radiotherapy (SABR) refers to radiotherapy treatment deliveries which give a high dose of radiation to an extra-cranial tumour, with high geometric precision (1). The risk to patients is increased with SABR techniques due to the increased dose per fraction, and as such specialised planning, treatment and QA practices are needed to ensure patient safety (1). Independent on-site audits are recommended by current SABR guidelines (1-3).

#### Material and Methods

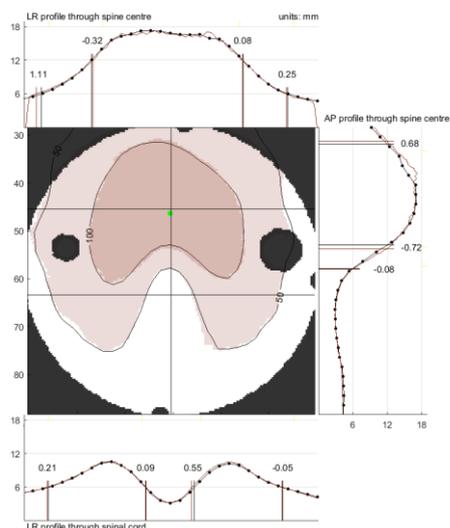

The Australian Clinical Dosimetry Service (ACDS) began SABR audits in March 2018. An end-to-end dosimetry audit was developed using a customised CIRS® humanoid thorax phantom. The audit planning cases include lung, spine and soft tissue targets, with delivery modality being at the discretion of the treating facility. Point dose measurements were taken at the centre of each target volume, and in the spinal cord using a PTW 60019 microDiamond. Gafchromic EBT3 Film measurements were taken and analysed with gamma criteria and distance-to-agreement between planned and measured dose profiles.

#### Results

To date, 59 SABR plans have been included in the audit. Figure 1 shows the local point dose variation for the target measurements and the global point dose variation for the spinal cord measurements. Large variations are seen in the vertebrae hard bone measurement point (average -3.6%, standard deviation 2.4%) and the lung measurement point (average -2.7%, standard deviation 2.4%). The measurements in the spine point in Figure 1 are with the detector calibrated in water. To account for measurement in bone, algorithm dependent Monte Carlo corrections are applied and the average improves to 0.0%, standard deviation 2.3%.

Film localisation accuracy within the phantom has been verified to <0.5 mm. The distance-to-agreement in the sagittal and coronal planes was analysed at the 50% isodose level. Figure 2 shows the results of a VMAT spine plan with maximum discrepancies of -0.08 mm (A-P) and 0.55 mm (L-R).

### Conclusion

The ACDS is developing a comprehensive audit for SABR treatments. Large discrepancies between calculated and measured dose in different medium such as bone are to be further explored.

### EP-2117 Novel kV CBCT Imager on Ring Gantry Radiotherapy Unit Permits High Inter-rater Contour Uniformity

L. Henke<sup>1</sup>, B. Cai<sup>1</sup>, S. Rudra<sup>1</sup>, B. Fischer-Valuck<sup>1</sup>, P. Gabani<sup>1</sup>, P. Samson<sup>1</sup>, A. Srivastava<sup>1</sup>, M. Roach<sup>1</sup>, E. Laugeman<sup>1</sup>, J. Luo<sup>1</sup>, S. Mutic<sup>1</sup>, G. Hugo<sup>1</sup>, H. Kim<sup>1</sup>  
<sup>1</sup>Washington University/Barnes Jewish Hospital, Radiation Oncology, Saint Louis- MO, USA

### Purpose or Objective

A novel kV imaging system coupled with a ring gantry radiation treatment system is now commercially available. Improved on-board kV CBCT acquisition time (17-40 seconds) and image quality using this device may allow online adaptive radiotherapy. The purpose of this work was to evaluate the image quality of the on-board kV CBCT as defined by inter-rater contour variability across a spectrum of anatomical structures.

### Material and Methods

Seven patients undergoing routine external beam radiation therapy were enrolled on an IRB-approved, prospective imaging study. Patients were imaged with the ring gantry kV CBCT system at breath hold and/or free breathing. Imaged sites included the head & neck, thorax, abdomen, and pelvis. Patient anatomy was independently contoured by 7 radiation oncology physicians on both the original simulation CT (diagnostic quality) and kV CBCT images. Sequence of contouring was randomized across raters to minimize bias and all kV CBCT images were contoured prior to diagnostic scans to mitigate physician learning of patient anatomy. Inter-rater contour variability was assessed by computing a consensus contour with STAPLE and computing DICE between each individual rater contour and the consensus contour. Inter-rater

uncertainty was computed as the mean DICE over all raters for each organ and patient. Statistical analysis included paired t-testing to evaluate differences between visualization of organs on the planning CT and corresponding kV CBCT images.

### Results

Eighteen organs-at-risk were evaluated across seven patients; a total of 52 kV CBCTs were acquired and contoured by each rater for comparison. The median DICE were 0.85 +/- 0.21 (planning CT), 0.82 +/- 0.11 (breath hold CBCT), and 0.84 +/- 0.11 (free breathing CBCT). Neither breath hold (p=0.14) nor free breathing kV CBCT (p=0.88) were statistically significantly different from planning CT for the inter-rater delineation variability across all organs-at-risk and patients. Limiting to a selection of abdominal organs only, the median DICE values were 0.93 +/- 0.07 (planning CT), 0.93 +/- 0.10 (breath hold CBCT, p=0.53), and 0.92 +/- 0.16 (free breath CBCT, p=0.15).

### Conclusion

Inter-rater ability to delineate organs-at-risk was not statistically different between images acquired on a novel ring gantry kV CBCT unit versus diagnostic quality simulation CT images. Prospective evaluation of the utility of kV CBCT imaging to enable online adaptation applications is.

### EP-2118 Effects of interfraction uncertainty with Strut Adjusted Volume Implant applicator

K. Miyaoura<sup>1</sup>, T. Fujii<sup>2</sup>, T. Kubo<sup>2</sup>, H. Shinjoh<sup>1</sup>, M. Kato<sup>1</sup>, K. Toyofuku<sup>1</sup>, A. Niiya<sup>1</sup>, R. Kobayashi<sup>1</sup>, Y. Ozawa<sup>1</sup>, K. Murakami<sup>1</sup>, M. Morota<sup>1</sup>, Y. Ito<sup>1</sup>, A. Imai<sup>1</sup>, Y. Kagami<sup>1</sup>  
<sup>1</sup>Showa University, Radiation oncology, Tokyo, Japan;  
<sup>2</sup>Showa University, Department of Radiological technology, Tokyo, Japan

### Purpose or Objective

We started accelerated partial breast irradiation (APBI) after breast conservation surgery using Strut Adjusted Volume Implant (SAVI) from March 2014. As the SAVI applicator does not displace after implantation, planning only at treatment start. However, slight displacement of the SAVI applicator and its influence on the DVH parameter may be considered. We examined changes in the interfraction uncertainty and DVH parameters of the SAVI applicator using daily CT.

### Material and Methods

In this study, we examined 50 patients. We use checking CT for each treatment to confirm that the SAVI applicator is not displaced. Therefore, after contouring the objects to CT, imprinting of the initial plan was performed, and the change of the DVH parameter due to the interfraction uncertainty of the applicator was calculated. The region of interest to be evaluated is a PTV = "PTV\_EVAL" for dose assessment excluding the SAVI catheter, adding 2 mm from the skin side and 0 mm from the chest wall, adding a 3-dimensional margin of 10 mm to the SAVI catheter, Skin = "SKIN", chest wall = "CHESTWALL".

### Results

The average coefficient of variation was "PTV\_EVAL" V 90%: 1.0%, V 150%: 7.2%, V 200%: 8.1%, "SKIN" D 1 cm<sup>3</sup>: 5.6%, "CHEST WALL" D 1 cm<sup>3</sup>: 4.1%. In "PTV\_EVAL", the variation of V90% is small, and the influence by interfraction uncertainty is considered to be small. However, the variation was increased at a higher dose region. "SKIN" was more variant than "CHESTWALL".

### Conclusion

From this study, it was revealed that a change in the dosimetric index of DVH occurs in the interfraction uncertainty of the SAVI applicator. In the future, it is suggested that it is necessary to consider the robustness of the plan from the interfraction change and the necessity of re-planning.

**EP-2119 HDR BRT boost in breast cancer: postoperative vs intraoperative procedure, long-term outcomes**

F. Piro<sup>1</sup>, D. Cosentino<sup>1</sup>, A. Martilotta<sup>1</sup>, A. Massenzo<sup>1</sup>, U. Piro<sup>1</sup>, G. Tocci<sup>1</sup>, L. Marafioti<sup>1</sup>

<sup>1</sup>*Ospedale Mariano Santo, Radiotherapy Center, Cosenza, Italy*

**Purpose or Objective**

To evaluate which is the best BRT technique, we studied the impact on survival and longterm outcomes of two HDRBRT procedure boost: postoperative (POST) vs intraoperative (INTRA).

**Material and Methods**

From January 2001 to February 2005, 75 pts. with breast cancer were treated with intraoperative (29) or postoperative (46) implant consisting of 3 fractions of 350 cGy each, 6 hour apart, before or after Whole Breast Radiotherapy (50 Gy/5 weeks). To provide coverage of tumor bed implant done with afterloading catheters at the time of quadrantectomy or after the external beam. All pts. underwent CT to evaluate the needles insertion according this criteria: 3 cm at least around surgical cavity (when surgical clips available) or 3 cm around surgical scar in case of postoperative. If intraoperative: clips to mark the walls of the excision cavity same treatment volume. All implants had markers at the extremities of each catheter plus other marker on the apex of the implant out of the breast (skin points). Implants planned with a semi-3-D technique aided by simulator, target volume determined by surgical clips and dose to the skin by the catheter markers. Survival comparison with Kaplan Meier method

**Results**

Median follow up: 8,2 years (1-16 years). Age: median 57 (26-77). Survival comparison median 10,24 years (POST) vs median 2.74 (INTRA) P=0.95 (not significant). In POST group 11/46 pts. (24%) had relapse or metastasis vs INTRA 8/29 (27%). The rate of relapse: 6.5 INTRA vs 6.8 POST. Lymph node status (guidelines of ABS not available at the time of treatment) for relapse or metastasis not significant. Ten years local relapse-free rate was 90 INTRA vs 89% POST.

**Conclusion**

Comparing these different boost techniques we did not find any difference in loco-regional recurrence, in metastasis-free and overall survival. Although it is preferable to perform intraoperative boost, these data show that postoperative mode, if properly performed according to the guidelines, is alternative to the first one. Also the treatment volumes should not be underestimated. INTRA is easier to carry out.

**EP-2120 Analysis of our Accelerated Partial Brachytherapy Irradiation (APBI) learning curve**

S. Pinto<sup>1</sup>, A. Pereira<sup>1</sup>, P. Fernandes<sup>2</sup>, L. Trigo<sup>2</sup>

<sup>1</sup>*Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Medical Physics, Porto, Portugal;* <sup>2</sup>*Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Brachytherapy, Porto, Portugal*

**Purpose or Objective**

To analyse our learning curve of APBI treatments with multi-catheter image-guided brachytherapy (BT), based on the experience obtained with the 60 initial applications.

**Material and Methods**

We changed the APBI treatment technique in November 2016 from an applicator-based planning (with a dosimetry based on isodose curves according to the Paris system without an imaged target volume - theoretical plan with rigid needles), to a volume-based planning (with target volume and OAR contouring, as well the reconstruction of plastic catheters in a CT image). Following GEC ESTRO<sup>(1)(2)</sup>, ABS<sup>(3)</sup> and ASTRO<sup>(4)</sup> recommendations for the implant technique and the AAPM TG43 formalism for the dosimetry, all plans were made with inverse planning (IPSA) and, when necessary, with graphical optimization, in Oncentra Brachy (version 4.5.3 - Elekta). Patients were treated with a high dose rate (HDR) modality (8 fractions, 2 per day, with 32Gy of prescribed dose) in a microSelectron from Elekta, with a difference of at least 6 hours between the fractions. To evaluate our learning curve, the patients were chronologically divided into three groups of 20. The following parameters were analysed: V<sub>PD</sub>, V<sub>1.5xPD</sub>, V<sub>PTV</sub>, V<sub>100</sub>, V<sub>150</sub>, V<sub>200</sub>, DHI, COIN, dose to the skin (0.2cm<sup>3</sup> and 1cm<sup>3</sup>, defined 5mm below the body contour), and the number of implanted tubes.

**Results**

The following table shows the analyzed dose-volume parameters and the recommended limits.

**Conclusion**

Regarding the parameters related to the target coverage (V<sub>100</sub> and COIN), a significant improvement was observed over time. Regarding the parameters related to the implant (V<sub>PD</sub>, V<sub>1.5xPD</sub> and DHI), a loss in homogeneity and the consequent appearance of high dose points (V<sub>200</sub>) was observed over time. Following recommendations, an improvement in the homogeneity of our implants and a better compromise between all parameters involved (target coverage, dose homogeneity, excessive dose volumes and dose in the OAR) should be achieved. It is noteworthy that the skin dosimetric values have always remained well below the recommended limits. Our dosimetric quality indices evolution shows that we are on the right track.

**EP-2121 Intraoperative radiotherapy in early breast cancer: short-term outcomes**

J.R. Oliver<sup>1</sup>, E. Hernando Almudi<sup>1</sup>, C. Casamayor Franco<sup>1</sup>, C. Vallejo<sup>1</sup>, G. Molina Osorio<sup>2</sup>, A. Miranda Burgos<sup>2</sup>, M. Lanzuela Valero<sup>2</sup>, R. Ibáñez Carreras<sup>2</sup>

<sup>1</sup>*Hospital Universitario Miguel Servet, General Surgery, Zaragoza, Spain;* <sup>2</sup>*Hospital Universitario Miguel Servet, Radiation Oncology, Zaragoza, Spain*

**Purpose or Objective**

The aim of this abstract is to evaluate the short-term outcomes of using Intraoperative radiotherapy (IORT) in early breast cancer in our center.

**Material and Methods**

A prospective review was performed. 233 cases of early breast cancer were treated with breast conserving surgery (BCS)/oncoplastic surgery and IORT from 13/05/2015 to 16/08/2017. A low energy X-rays system (Axxent Xofter device) administered a 20-Gy dose at the tumor bed.

All patients were evaluated by a multidisciplinary Tumor Board. Selection criteria for IORT as radiotherapy alone were: age ≥50 y.o., no BRCA mutations, clinical tumor size up to 3cm, none linfovacular invasion, ER +, not multicentric or multifocal tumors, histology of IDC, cN0 and no neoadjuvant therapy.

The rest of the patients who did not meet the criteria were finally treated with IORT as a boost.

Clinical and radiological evaluations (ultrasound and mammographic exams) were performed routinely. Complications reported are: dermatitis, hematoma, seroma, infection, pain, fibrosis / fat necrosis, ulcer and fistula (delayed healing of a small side of the surgical wound).

## Results

During the study period, 233 patients were treated with BCS/oncoplastic surgery and IORT: 218 (93.6%) patients as monotherapy, 12 (5.1%) patients as a boost, and 3 (1.3%) patients were treated out of protocol, accepted by the Tumor board because of comorbidities, elderly and social issues.

Patients: mean age 67 y.o. (48.2-88.9)

Histology: IDC 205 (88.0%), ILC 8 (3.4%), other subtypes of IDC 20 (8.6%). ER + 225 (91.0%). HER-2/neu 3+ or SISH+ 7 (3.0%). Ki 67 >15% 160 (68.7%).

Surgery: average IORT time 11.2 min (9.5-16.5), average operation time 150.5 min (65-315). BCS 219 (94.0%), oncoplastic surgery 14 (6.0%).

SLNB 224 (96.1%): positive (micrometastases or macrometastases) 64 (28.3%)

Reinterventions 20 (8.6%): rescission 6 (2.6%), MRM 1 (0.4%), ALND 5 (2.1%), complications 8 (3.5%).

Adjuvant therapy: chemotherapy 50 (21.5%), hormone-therapy 220 (94.4%), EBRT 65 (27.9%).

Oncologic outcomes: local recurrences 3 (1.3%). Metastases (liver, bone) 2 (0.9%).

Major complications: RTOG 3-4: 2 (1.0%), seroma that required >3 drainages 2 (0.9%), infection that required intravenous antibiotic or surgical drainage 4 (1.7%), hematoma that required surgical drainage 4 (1.7%), fistula that required surgical fixing 4 (1.7%), palpable fibrosis 14 (6.1%).

Median follow up: 857.5d (215-1210). Cancer related mortality: 0. Non cancer related mortality 7 (3.0%).

## Conclusion

IORT is a feasible technique with several benefits and good short-term outcomes in selected patients.

**EP-2122 Outcome of exclusive RT for BC in older women according to age and comorbidity: A retrospective study**  
W. Lorraine<sup>1</sup>, K. Cao<sup>1</sup>, M. Carton<sup>2</sup>, A. Fourquet<sup>1</sup>, Y. Kirova<sup>1</sup>

<sup>1</sup>Curie institute, Radiotherapy, Paris, France; <sup>2</sup>Curie Institute, Biostatistics, Paris, France

## Purpose or Objective

Older women with breast cancer (BC) are less likely to receive standard care. In specific circumstances when surgery is omitted as first step of treatment, RT seems to be an adequate local solution as a non-invasive option. The aim of this study was to assess the efficacy, tolerance and impact of comorbidities on outcomes in older women treated by exclusive radiation therapy (RT) for non-metastatic breast cancer (BC)

## Material and Methods

We studied retrospectively women aged  $\geq 70$  years at diagnosis who received exclusive conformational RT for their BC between 2003 and 2012 in our Department. We calculated the Charlson Comorbidity Index (CCI) for each patient. Conventionally fractionated or hypofractionated RT was prescribed at the physician's discretion in a case-by-case basis. We analysed overall survival (OS), progression free survival (PFS), and specific survival (SS). Acute and late toxicities were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) v3.0.

## Results

On sixty-six patients included, median age was 84.8 years [71.3-91.7]. Most patients had a CCI score  $\geq 1$  (n = 41, 62.1%). Nearly half (47%) had T1-2N0M0 BC (n = 31). Surgery was omitted in most cases because of patients' refusal (54.2%) and/or patients' comorbidities (41.7%). Most of them (87.9%) were treated by hypofractionated RT and received hormonal therapy for their HR+ HER2- BC (84.8%). With a median follow-up of 6.8 years [1.3-12.3], OS, SS and PFS at 5 years were 65.5% CI95%[54.1-79.3], 86.3% CI95% [77.2-96.4], and 58.4% CI95%[46.9-72.7], respectively. Five-year OS was statistically different according to age younger or older than 85 years: 72.9%

CI95% [58.4-91.1] and 57.1%, IC 95% [40.8-79.8], (p = 0.0026). Similar results were found for 5-year PFS: 64.5% CI95% [49.5-84.1] for patients aged from 70 to 85 years, and 51.6% CI95% [35.8-74.5] for patients over 85 years old, respectively (p = 0.014). The 5-year OS was also statistically different according to the CCI score: 70.8% CI95% [57.0-87.9] for a CCI of 0, and only 59.8% CI95% [42.4-84.3] for patients with a CCI Score  $\geq 1$  (p = 0.039). 10.6% of the patients had no toxicities; of those who experienced side effects, the most frequent were grade 1 and 2 radio dermatitis (59%). Late toxicities were observed in 39.4% of the patients, mostly of grade 1 and 2. No late toxicity of grade  $\geq 3$  was observed.

## Conclusion

Exclusive radiation therapy for non-metastatic BC in older women is feasible and well-tolerated when adapted techniques are used, but the prognostic is poor in comparison with younger patients as the outcome is strongly impacted by age and comorbidities.

**EP-2123 APBI with Interstitial Brachytherapy versus Whole-Breast Irradiation for Early-Stage Breast Cancer**

A. Figueiredo<sup>1</sup>, D. Delgado<sup>1</sup>, J. Santos<sup>1</sup>, A. Florindo<sup>1</sup>, V. Mendonça<sup>1</sup>, M. Jorge<sup>1</sup>, M. Filomena de Pina<sup>1</sup>

<sup>1</sup>Centro Hospitalar Lisboa Norte, Serviço de Radioterapia, Lisboa, Portugal

## Purpose or Objective

To report long-term outcomes of adjuvant accelerated partial breast irradiation (APBI) with multicatheter interstitial high dose rate brachytherapy (HDR BT) at our department and compare these results to adjuvant whole-breast irradiation (WBI) with 3D external beam radiotherapy (EBRT).

## Material and Methods

Between 2004 and 2017, 25 patients (pts) with early-stage breast cancer (pT1-2 ( $\leq 30$  mm) pN0) were treated with interstitial HDR BT after breast-conserving surgery. The characteristics of these pts are presented in table 1. The prescribed dose was 8 fractions of 4 Gy, twice a day, in all patients. A propensity-score matching approach was performed to compare the survival outcomes of APBI to WBI using a database of 260 pts treated with adjuvant WBI at our center.

DEMOGRAPHIC DATA	
Median age (range)	74 (51-81)
CLINICAL DATA	
Histology	
Invasive Carcinoma	20 (80 %)
G1	10 (40 %)

Involved	0 (0 %)
Not determined	7 (28 %)

*Table 1: demographic and clinical data of APBI group*

## Results

The median follow-up was 81 (3-167 months). There were no significant differences between the APBI and WBI groups in terms of age, stage, immunohistochemical analysis (hormone receptors, HER2, Ki-67), surgical margins, lymphovascular invasion and use of adjuvant hormone therapy. The 5-year recurrence-free survival and overall survival were 91.7 % and 100 %, respectively. No significant difference of recurrence-free ( $p=0.564$ ) and overall ( $p=0.113$ ) survival was found. The treatment with APBI was well tolerated with no late toxicity reported in 60 % of pts. Breast edema and fibrosis were the main

toxicities observed, but no grade 3 toxicity or higher was described.

## Conclusion

Several prospective trials demonstrated that the majority of local recurrences (69-90 %) arises at the vicinity (1-2 cm) of the tumor bed. Given that it seems rational the use of more conformational techniques with APBI. These techniques allow to spare organs at risk (heart, lung, chest wall and contralateral breast) without compromising the excellent survival outcomes in breast cancer, which is supported by recent results of randomized clinical trials. The interstitial HDR BT is the technique with the longest clinical experience and with strong evidences of non-inferiority in comparison with the standard WBI. These results are in line with our one-institutional analysis with the use of a propensity-score matching methodology. Careful selection of the pts who are most likely to benefit from such approach is crucial for the success of the treatment.

## Electronic Poster: Brachytherapy: Gynaecology

### EP-2124 Brachytherapy in the treatment of locally advanced cervical cancer: a single center study

J. Khalil<sup>1</sup>

<sup>1</sup>National Institute of Oncology Sidi Mohamed Ben Ab, Radiotherapy, Rabat, Morocco

#### Purpose or Objective

Concurrent chemoradiotherapy in combination with brachytherapy is the standard treatment of locally advanced cervical carcinoma. Brachytherapy has, in fact, become an integral component of cervical cancer treatment as it confers many dosimetric benefits insuring better local control and survival rates when compared to external beam radiation alone. Lately, a decline in brachytherapy use has been noticed either because of the lack of expertise or because of the radiation oncologist's trend to replace brachytherapy with the newest radiotherapy techniques. The aim of our study is to evaluate the role of brachytherapy as a boost technique in locally advanced cervical carcinoma.

#### Material and Methods

Our study is a retrospective one including 387 patients treated for locally advanced cervical carcinoma, between January 2007 and December 2007, in the national institute of oncology Morocco. 179 patients received external beam pelvic irradiation combined with brachytherapy, while 208 patients were treated with external beam radiotherapy alone (EBRTA).

#### Results

The mean age for the whole group was 47.7 (range 26-78 years), and the median age was 46 years, there was no significant difference between the two groups. The past medical history was also identical between the two groups. All patients received their treatment in our institution during the same time period, and by the same specialized gynecologic oncologists and radiotherapists. Differences between the two groups concerned tumor stage, tumor size, treatment doses and time duration. Local control rate at 5 years was of 80.7% in the brachytherapy group and 56.8% in the EBRTA arm (Pearson chi-square;  $p < 0.0001$ ). As to survival rates, there was a statistically highly significant difference in all of 5-year overall survival (73% and 57.3% for brachytherapy and EBRTA arms respectively,  $p < 0.001$ ), cancer-specific survival (63.5 % for the brachytherapy group and 47.6% in the EBRTA group,  $p=0.002$ ), and disease-free survival (log-rank test;  $p < 0.00001$ ). Patients in the brachytherapy arm showed less treatment related toxicities.

#### Conclusion

Our results are concordant with those previously reported in the literature and stating that brachytherapy should still

be considered as a standard of care in the treatment of locally advanced cervical carcinoma

#### EP-2125 High Dose Rate Brachytherapy in Brazil: Demand Estimation and Coverage in Public Healthcare System

G.H. Yoshinari<sup>1</sup>, M.P. Alvarenga<sup>1</sup>, H.H. Fernandes<sup>1</sup>, F. Nadur<sup>2</sup>, J. Domingues<sup>2</sup>, H.F. De Oliveira<sup>1</sup>  
<sup>1</sup>Hospital Marcio Cunha, Servico De Radioterapia, IPATINGA, Brazil; <sup>2</sup>Faculdade de Medicina de Itajuba, Graduação em medicina, Itajubá, Brazil

##### Purpose or Objective

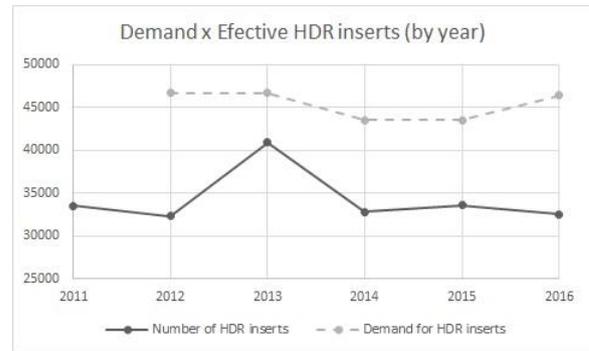

The Public Healthcare System (SUS) in Brazil allows high dose rate brachytherapy (HDR) for cervical and uterine cancers only. Objective: to characterize and compare the installed capacity and estimate the demand for HDR in the context of the public access.

##### Material and Methods

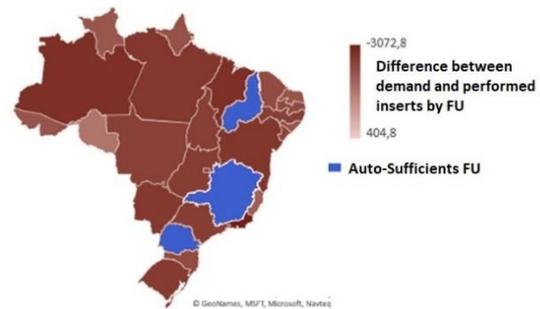

The number of services and HDR insertions is available in the SUS database. The official estimation of incidence for cervical and uterine malignancy by Federative Unit (FU) from 2011 to 2016 in a two-year basis was adjusted for the proportion of patients with HDR indication and the number of HDR insertions covered by SUS. We also compared the estimated demand for HDR inserts with the number of registered services from 2011 to 2016.

##### Results

In 2016, forty-five percent of all public radiotherapy services provided HDR, while four FUs did not offer HDR. There is a concentration in offer in the Southeast region (55%) which concentrates 38.6% of Brazil's population. For the year, the estimated demand for HDR insertions in the year was 46,400, but only 32,500 inserts were registered, generating a deficit of 13,900 inserts (coverage of 70%), even though 25% of the population afford private health insurance. Only three FUs met the estimated demand. We observe a tendency of decrease in the incidence of cervical cancer and a slight increase in the incidence of endometrial cancer, with an increment of services offering HDR in the past five years. Overall demand for HDR remained stable for the period. We detected a peak (superior to Median+2SD) of procedures registered in 2013 (40,939) for an expected need of 46,724 inserts, influenced by inserts carried out by only one FU (São Paulo). The cause of the peak of registered procedures carried out in São Paulo in 2013 should be investigated since it appears to be possible to increase the number of procedures without increasing the number of services providing HDR. There were no peaks detected in the estimated demand for HDR nor services offering the procedure in SUS.

Demand and Performed HDR inserts for 2016

##### Conclusion

Besides the consistent increase of services providing HDR in SUS the distribution of services along the country seems inadequate. There is a 30% deficit in the estimated demand coverage for HDR.

#### EP-2126 Cervix cancer treatments with electronic brachytherapy according to the EMBRACE protocol

S. Lozares<sup>1</sup>, A. Gandía<sup>1</sup>, J.A. Font-Gómez<sup>1</sup>, D. Villa<sup>1</sup>, A. Mendez<sup>2</sup>, A. Miranda-Burgos<sup>2</sup>, V. Alba-Escorihuela<sup>1</sup>, S. Jiménez-Puertas<sup>1</sup>  
<sup>1</sup>H.U. Miguel Servet, Física y Protección Radiológica, Zaragoza, Spain; <sup>2</sup>H.U. Miguel Servet, Oncología Radioterápica, Zaragoza, Spain

##### Purpose or Objective

In this study we present the first cervical cancer cases treated with interstitial electronic brachytherapy (eBT) in our hospital compared to plans made with high dose rate interstitial brachytherapy with Ir192.

##### Material and Methods

In our centre, 8 patients with cervical cancer have been treated with the Axxent (Xoft, Inc.) eBT equipment. The planning of all the patients has been carried out with MR image and CT image following the recommendations of the EMBRACE protocol. The dosimetric parameters of the recommended OAR for bladder, rectum and sigma have been evaluated: D2cc, D1cc, D0,1cc. In addition, the V150 and V200 of irradiated tissue are compared for each plan, both eBT and HDR-BT. The mean age of the patients was 59.8 years (27-70) with different tumor stages, all with good response to external radiotherapy and no parametrial involvement. All patients received IMRT with a regimen of 23 sessions of 2 Gy followed by 4 sessions of 7 Gy of eBT performed in two weeks (first two sessions and then another two a week later) following the EMBRACE recommendations.

##### Results

The doses in organs at risk for electronic brachytherapy plans were lower than for HDRBT plans. The dose in bladder with electronic brachytherapy was 62.8% of the prescribed dose for D2cc vs. 63.7% for HDRBT Ir 192, for D1cc was 69.7% vs. 70.1% and for D0.1cc was 85.4% vs. 84.9%. In rectum the D2cc was 27% vs. 34.3%, for D1cc was

32.9% vs. 39.5% and for D0.1cc was 52.4% vs. 46.7% and in sigmoid colon the D2cc was 49.5% vs. 53.6%, for D1cc was 57.7% vs. 61.5% and for D0.1cc was 78% vs. 81.9%. The results demonstrated lower doses to risk organs in all electronic brachytherapy plans. The acute toxicity for electronic brachytherapy in cases of mucositis was two cases with grade 1 toxicity and one case with grade 2 toxicity, without cases of rectal toxicity and one case with grade 1 urinary toxicity and no relapses have occurred to date.

#### Conclusion

The first results of treatment with the Axxent eBT unit for the 8 patients are very promising, as no recurrence has been observed and the toxicity of the treatment is very low. Despite the increase in V150 and V200 there has been no increase in the toxicity of the vaginal mucosa, and the doses in the OAR are lower than in the implemented plans of HDR-BT with Ir192. Electronic brachytherapy is a good alternative for treating cervical cancer in centers without the availability of conventional HDR. To date, there are few published studies reporting on the outcomes of patients treated with electronic brachytherapy, and none on patients treated for cervical cancer.

#### EP-2127 Hydrogel bladder and rectal spacer (TraceIT) for brachytherapy in locally advanced Cervical cancer

D. Najjari Jamal<sup>1</sup>, C. Gutiérrez<sup>1</sup>, L. Martí<sup>2</sup>, S. Marin<sup>1</sup>, A. Stocker<sup>1</sup>, G. Rodriguez<sup>1</sup>, S. Moreno<sup>3</sup>, M. Garcia<sup>1</sup>, F. Guedea<sup>1</sup>

<sup>1</sup>ICO Hospitalet, Radiation Oncology, Hospitalet de Llobregat, Spain; <sup>2</sup>Hospital de Bellvitge, Gynaecology, Hospitalet de Llobregat, Spain; <sup>3</sup>ICO Hospitalet, Physics, Hospitalet de Llobregat, Spain

#### Purpose or Objective

Treatment for locally advanced cervical cancer (LACC) comprises concomitant radiochemotherapy (RCHT) followed by brachytherapy (BT). Assessment of toxicity is important in radiotherapy, since is necessary to define therapeutic ratio and determine the specific benefit of a given treatment. The injection of an hydrogel to space the bladder and rectum from cervix may help to organ-at-risk (OaR) sparing during BT treatment and therefore reach higher doses to the D90 in the HR-CTV to improve local control. The aim of this study, therefore, is to place the hydrogel around cervix and evaluate the benefit on the plan dosimetry at time of BT. Appropriate approvals by local ethic committee was obtained.

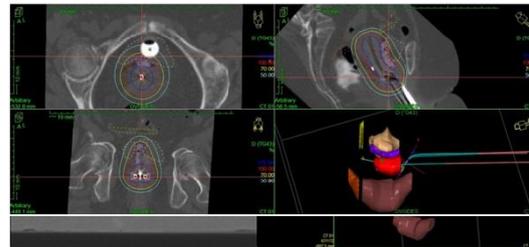

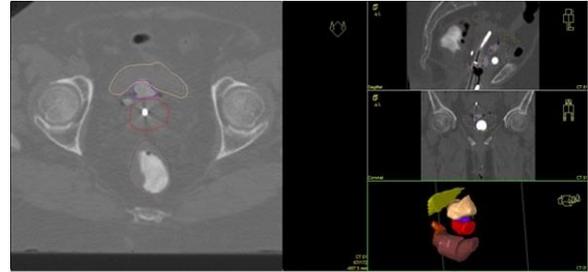

#### Material and Methods

The preliminary prospective study includes 3 patients diagnosed with LACC and treated with concomitant radio(chemo)therapy + IGABT. The radio-opaque hydrogel (TraceIT) is placed between rectum-cervix and bladder-cervix after conclude RCHT and at time of BT. We approached the technique using transrectal ultrasound (TRUS) and transvaginal injections. A stepper was used to stabilize the image and allow two hands to manipulate the needle and the speculum. A hydro-dissection technique with saline was used to open the space to advance the needle into this space 1cm at a time. Injection of 3-6ml of TraceIT created the space around cervix and bladder. The distance from cervix to OaR was measured before and after the hydrogel injection in CT-scan and (TRUS). At time of BT the distance was measured again in TRUS. A total nominal dose of 21Gy in 7Gy/fraction with HDR was prescribed. The D2cc for bladder and rectum and EQD2 (OaR alpha/beta=3 and tumor alpha/beta=10) HR-CTV D90 were calculated.

#### Results

TraceIT placement was performed in 2 of the 3 selected patients. The third patient was not a good candidate due to pouch of Douglas prolapse. The 2 performed cases were diagnosed with stage IIB cervical cancer. Before BT, the first patient had complete response and de second patient a partial response with more than >50%. At time of BT,

TraceIT was placed between cervix and bladder. A space of 8x20x38mm and 13x39x31mm (APxLLxCC), respectively, in each patient was created (Figure 1). The bladder D2cc were 6.20Gy and 5.11Gy, respectively, with a HR-CTV D90 >85Gy EQD2 in both cases (Figure 2).

#### Conclusion

TraceIT injection is easily reproducible in the 2 cases. In addition, the hydrogel can be easily identified in both MRI and CT-planning for BT. Compared to historical controls the rectum and bladder D2cc were lower without decreasing the HR-CTV D90 dose. Therefore, TraceIT can help to improve the dosimetry in IGABT for LACC and may help to raise the dose to D90 HR-CTV>85Gy without increasing the dose in bladder. No acute symptoms were described. Further investigations are needed to improve the technique and to perform rectum-cervix placement and furthermore to evaluate the benefit of TraceIT in dosimetry improvement at time of BT.

#### EP-2128 Rectal toxicity with MUPIT Interstitial Brachytherapy - Predictors, clinical and dosimetric outcomes

V. Pareek<sup>1</sup>, R. Bhalavat<sup>2</sup>, M. Chandra<sup>2</sup>, C. Bakshi<sup>3</sup>, N. Bhambhani<sup>4</sup>

<sup>1</sup>Jupiter Hospital, Radiation Oncology, Mumbai, India;

<sup>2</sup>Jupiter Hospital, Radiation Oncology, Thane, India;

<sup>3</sup>Jupiter Hospital, Medical Oncology, Thane, India;

<sup>4</sup>Jupiter Hospital, Surgical Oncology, Thane, India

#### Purpose or Objective

Late rectal toxicities are a concern associated with Interstitial Brachytherapy for various indications in pelvic malignancies. In this study we evaluate the rectal toxicities associated and look in to the clinical correlation with the predictive factors associated with such toxicities associated with high dose rate pelvic interstitial brachytherapy.

#### Material and Methods

From January 2010 to December 2016, 35 patients with residual or bulky cervical disease and vaginal vault recurrence were included in the study. Patients received

external radiation 50 Gy in 25 fractions over 5 weeks with weekly cisplatin. Rectum and rectal mucosa were delineated along with other organs at risk. The dose received by 0.1, 1, 2, 5 cc of rectum, RM, and sigmoid were assessed for dosimetric analysis. The 2Gy equivalent dose was evaluated for all the organs at risk. With assessment and grading of toxicities on the follow up, the predictive factors associated with rectal toxicities with brachytherapy were assessed using univariate analysis. The Coverage Index (CI), dose homogeneity index (DHI), overdose index (OI), dose non-uniformity ratio (DNR), external volume index (EI), conformity index (COIN) and dose volume parameters recommended by GEC-ESTRO were evaluated. The patients were followed up and toxicities were graded as per the RTOG scales and local control rates and disease-free survival were evaluated.

#### Results

The median follow-up of the patients was 30 months and grade II and grade III toxicities were seen in 5 (14.2%) and 1 (2.8%) patient respectively. The mean CTV volume was 154 cc. The median number of needles was 18 (Range 15 - 20). Median CI, DHI, V150, V200, DNR, OI, EI and COIN was 0.81 (range: 0.74 - 0.87), 0.7 (range: 0.59 - 0.79), 81cc, 29 cc, 0.42 (range: 0.25 - 0.47), 0.07 (range: 0.05 - 0.14), 0.12 (range: 0.06 - 0.16) and 0.81 (range: 0.69 - 0.89). On Univariate Analysis, D0.1-cc Rectal Mucosa dose >70 Gy ( $p = 0.02$ ), D1-cc Rectal Mucosa dose >67 Gy ( $p < 0.001$ ), D2-cc Rectal Mucosa dose and D5-cc Rectal Mucosa dose >60 Gy ( $p = 0.001$ ) correlated with Grade  $\geq$  II toxicity. The 2Gy equivalent dose for D2 cc rectum and rectal mucosa associated with 10 and 20% risk of rectal toxicity were found to be 56 and 67Gy and 54Gy and 64Gy respectively.

#### Conclusion

CT based planning using MUPIT for gynecological brachytherapy implants has good outcomes as assessed in our study. Plan evaluation and documentation using various indices and parameters recommended by GEC-ESTRO assist in objective evaluation and reproducibility and correlate with clinical outcomes in the disease. Limiting 2-cc RM and rectal doses within the proposed thresholds can minimize Grade  $\geq$  II toxicity for gynecological high-dose-rate interstitial brachytherapy.

#### EP-2129 A decision tool for interstitial needles implants in uterovaginal pulsed dose rate brachytherapy

M. Sandt<sup>1</sup>, F. Gassa<sup>1</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiothérapie, Lyon, France

#### Purpose or Objective

Implants of interstitial needles (IN) in uterovaginal brachytherapy treatments has proved its efficiency in case of parametrial invasion<sup>[1],[2]</sup>. The aim of the present study is to analyze patient anatomy and to determine cases where interstitial needles implants could help to cover the high-risk volume.

#### Material and Methods

Fifteen patient plans with interstitial needles were considered. On MRI or CT images post implantation, following dimensions were reported: the smallest distance between uterin probe and the nearest organ at risk in the anterior direction (frequently the bladder), and secondly the biggest lateral dimension between uterin probe and the edge of high-risk CTV. The ratio of these two values is called  $r$ . PDR dose plans were calculated and optimized on Oncentra® TPS using the same dosimetric method by a single operator, with and without needles activation. CTV coverage (D90 of CTVHR and CTVIR) and organ at risk near-maximum doses (D2cc for bladder, rectum and sigmoid) were reported and compared.

#### Results

Doses comparison of CTV coverage showed that  $r=2$  is a threshold. Wilcoxon test for paired samples reveals that

below this value, IN implant did not significantly improve CTV coverage. But for cervix uteri for which  $r$  is higher than 2, IN implant was a great help to increase CTV doses (D90 of CTVHR increases by an average of 16Gy, and D90 of CTVIR by an average of 9,2Gy -  $p=0.00195$ ), without significant variation of doses received by OARs ( $p>0,2$ ).

#### Conclusion

Interstitial needles implants can improve target volumes coverage when the high risk volume presents a  $r$  ratio higher than 2, with no change on organ at risk near-maximum doses.

#### EP-2130 Dose integration of intensity-modulated arc therapy and interstitial brachytherapy of cervix cancer

G. Fröhlich<sup>1</sup>, J. Vizkeleti<sup>1</sup>, N. Anhhong Nguyen<sup>1</sup>, T.

Major<sup>1</sup>, C. Polgár<sup>1</sup>

<sup>1</sup>National Institute of Oncology, Centre of Radiotherapy, Budapest, Hungary

#### Purpose or Objective

Comparative analysis of EQD2 total doses resulted with intensity-modulated arc therapy (IMAT) complemented with image-guided adaptive interstitial brachytherapy (ISBT) versus conventional treatment techniques in cervix cancer using a personalised biological dose integration method.

#### Material and Methods

21 locally advanced cervical cancer patients, treated with IMAT with 2 full arcs plus manual optimised ISBT, were selected. Additional plans were created: conformal teletherapy (TT) plans and inverse optimised interstitial (is.), optimised intracavitary (ic.), non-optimised ic. brachytherapy (BT) plans. Since neither the rigid nor the deformable image registration result appropriate fit of interested volumes in the proximity of the applicator, manual registration method is needed. As the critical organs receive the maximal total dose in the region where the dose maximum is in BT, the most exposed 2 cc volume (D2) of bladder, rectum and sigmoid in BT were identified manually on TT CT images individually for every patient. Biological total doses (EQD2) of these volumes were calculated and compared between each combination of TT and BT plans using 2-way ANOVA and Fisher-LSD post hoc test. This dose integration method was compared with the GEC-ESTRO recommended method, uniform dose conception (UDC) in IMAT and conformal TT plans with Wilcoxon-matched pairs test.

#### Results

The D90 of High-Risk CTV, D2 of bladder and sigmoid were different in BT techniques only:  $p=0.0149$ ,  $<0.001$ ,  $<0.001$ , respectively. The most advantageous values were obtained in the manual optimised ISBT plans, inverse optimised is. plans did not differ dosimetrically from these, while optimized ic. plans resulted in worse dose-volume parameters, and the worst of all were ic. plans without optimization. The D2 of rectum was significantly lower with IMAT than with conformal TT plans ( $p=0.037$ ) and showed the same trend in BT plans than the other parameters ( $p<0.001$ ) (Table). The UDC dose summation method overestimates D2 of the bladder with 12% and 8.5%, the rectum with 55% and 26.5% and the sigmoid with 17.2% and 12% in the case of IMAT and conformal TT plans, respectively ( $p<0.001$  for all).

Table:

EQD2		Manual	Inverse	Manual	Non-	p*	p* (BT)
		opt. is. BT	opt. is. BT	opt. ic. BT	optimised ic. BT		
D90 (HR-CTV) (Gy)	IMAT	84.6	84.3	82.2	88.7	0.9899	0.0149
	Conf. TT	84.6	84.3	82.2	88.7		
D <sub>2</sub> (bladder) (Gy)	IMAT	62.9	62.5	71.5	88.4	0.434	<0.001
	Conf. TT	64.9	64.6	73.6	90.5		
D <sub>2</sub> (rectum) (Gy)	IMAT	40.0	38.4	44.9	72.1	0.037	<0.001
	Conf. TT	49.0	47.3	53.8	81.1		
D <sub>2</sub> (sigmoid) (Gy)	IMAT	55.3	54.4	60.5	71.2	0.2794	<0.001
	Conf. TT	57.9	56.9	63.5	73.8		

Table. Mean EQD2 total doses of different combinations of BT and TT plans. IMAT:

intensity-modulated arc therapy, Conf. TT: conformal TT, is.: interstitial, ic.:

intracavitary BT plans. D90: the minimum dose delivered to 90% of HR-CTV,

D<sub>2</sub>(bladder), D<sub>2</sub>(rectum), D<sub>2</sub>(sigmoid): the minimal dose of the most exposed 2

ccm of bladder, rectum and sigmoid. \*2-way ANOVA and Fisher-LSD post-hoc

test.

## Conclusion

Although optimization improves the quality of intracavitary BT plans, interstitial plans yield in significantly higher dose coverage of HR-CTV and lower doses to OARs. IMAT plans decrease dose to the rectum. The impact of BT technique for summarised biological total dose of HR-CTV and critical organs is much higher than that of TT. Based on the personalised biological dose integration method, UDC overestimates OARs doses.

## EP-2131 Venezia: New Advanced Brachytherapy Gynecological Applicator in cervical cancer. Our preliminary data

G. Riva<sup>1</sup>, V. Andrea<sup>1</sup>, R. Spoto<sup>1</sup>, S. Durante<sup>1</sup>, D. Ciardo<sup>1</sup>, S. Comi<sup>2</sup>, F. Cattani<sup>2</sup>, R. Lazzari<sup>1</sup>, B.A. Jereczek-Fossa<sup>1</sup>  
<sup>1</sup>Istituto Europeo di Oncologia - IEO, Radiotherapy, Milan, Italy; <sup>2</sup>Istituto Europeo di Oncologia - IEO, Medical Physics, Milan, Italy

## Purpose or Objective

The purpose of this work is to report our recent and preliminary experience with Elekta's Advanced Gynecological Applicator, Venezia™, a new applicator system that allows clinicians to treat different stages of cervical cancer as a hybrid brachytherapy (BT) applicator, combining characteristics of both ring and ovoid devices, with the possibility to perform interstitial BT.

## Material and Methods

Clinical data, BT parameters and acute toxicity (Radiation Therapy Oncology Group RTOG toxicity scale) of consecutive women treated in our institute with Venezia™ were examined.

Pulsed-dose-rate (PDR) was the technique chosen for all the patients. Clinical Target Volume (CTV) coverage and mean dose (D<sub>2cm<sup>3</sup></sub>) to 2cm<sup>3</sup> of bladder, rectum and bowel were assessed. The dosimetric parameters of a series of 10 consecutive patients treated previously at our center with interstitial PDR BT employing other applicators (MUPIT and Utrecht, unpublished data) served as a dosimetry benchmark for the Venezia™ patients. Two-sided Wilcoxon rank sum test was performed for statistical comparison

## Results

Since January 2018 to May 2018, 8 women, median age 51 years (27.2-64.2) affected by cervical cancer were treated with Venezia™. All but one underwent interstitial BT. Median dose prescribed to CTV was 30 Gy (range 30-35) with a median dose rate of 0.6 Gy/h (range 0.5 - 0.6).

Coverage of CTV and dose to organ at risk (OAR) was reported in table 1, along with the dosimetric parameters of PDR BT employing other applicators.

Apart from manageable acute genitourinary and gastrointestinal toxicities (2 patients with RTOG grade 1), no complications grade 3-2 were reported.

	Venezia™ applicator	Benchmark cohort	p-value
	Median (range)	Median (range)	
CTV90(%)	100 (90-108)	114 (102-128)	0.015
D2cm <sup>3</sup> bladder (%)	73 (53-78)	82 (63-93)	<<0.01
D2cm <sup>3</sup> rectum (%)	33 (23-53)	78 (28-90)	0.013
D2cm <sup>3</sup> bowel (%)	66 (17-89)	59 (36-105)	0.9

## Conclusion

The initial experience revealed that BT treatment with Venezia™ was well-tolerated and allows for adequate tumor coverage while satisfying the dose constraints for OARs. It also appears user friendly in positioning and removal time. A larger cohort of patients will be required for additional conclusions related to the long-term clinical benefits and late toxicity.

## EP-2132 Verification of vaginal cylinder position using bony landmarks

M. Zahra<sup>1</sup>, P. Drewell<sup>1</sup>, W. Keough<sup>1</sup>

<sup>1</sup>Edinburgh Cancer Centre, Oncology, Edinburgh, United Kingdom

## Purpose or Objective

To allow rapid assessment at time of treatment of the correct positioning of the vaginal cylinder using bony landmarks

## Material and Methods

A cohort of patients who had planning CT scans for their adjuvant post-hysterectomy vaginal vault brachytherapy also had a verification scan to assess the position of the organs at risk. These scans were reviewed and the distances between the position of the tip of the cylinder and S1 vertebra, the most proximal surface of the pubic bones and left and right femoral heads were measured using the planning software. The bladder volumes, the amount of soft tissue cranial to the cylinder and the angle of the cylinder to the treatment couch were also measured for each scan. Descriptive statistics along with differences in the measurements between the 2 scans, using T-test for 2 samples (2-tailed testing with p ≤ 0.05 for significance) were assessed. Correlations between differences in the bladder volumes and cylinder angle with the differences in the measurements were studied using a Pearson correlation test (p ≤ 0.05).

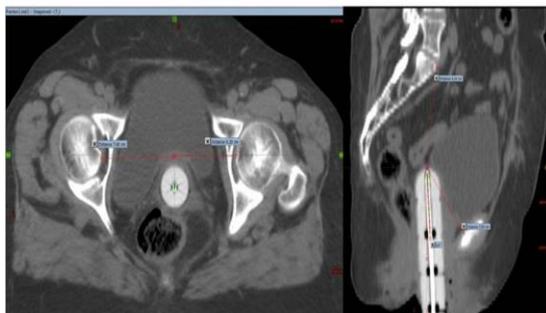

## Results

37 patients having had 2 CT scans were available for review.

	Planning CT	Verification CT	Difference between 2
	Median (range)± stdev.	Median (range)± stdev.	CT's Median (range)± stdev.
Tissue above cylinder (mm)	3(range: 0 to 9) ± 2.6	3(range: 0 to 9) ± 2.3	0 (range: -6 to 3) ± 1.48
Vaginal length (cm)	12 (range: 7-15.4) ± 1.8	11.8 (range: 7.6 to 16.8) ± 1.9	0 (range: -1.2 to 1.6) ± 0.65
S1 measurement (cm)	6.1 (range: 2 to 8.7) ± 1.48	6.5 (range: 2.5 to 8.9) ± 1.6	-0.3 (range: -1.9 to 1.2) ± 0.78
Pubic bone measurement (cm)	7.6 (range: 5.1 to 11.0) ± 1.3	7.4 (range: 5.3 to 10.2) ± 1.2	0.2 (range: -1.6 to 2.6) ± 0.78
Right measurement (cm)	6.8 (range: 4.5 to 7.5) ± 1.3	6.8 (range: 4.7 to 7.7) ± 0.7	-0.1 (range: -0.9 to 0.8) ± 0.4
Left measurement (cm)	6.6 (range: 4.3 to 7.7) ± 0.8	6.7 (range: 4.5 to 7.6) ± 0.7	0 (range: -0.6 to 0.9) ± 0.36
Angle of cylinder (degrees)	7 (range: -2.8 to 16.7) ± 4.8	4.5 (range: -3.2 to 13.7) ± 3.9	2.9 (range: -8.9 to 11.9) ± 5.6
Bladder volume (cc)	160 (range 40 to 891) ± 203	119 (range: 47 to 836) ± 202	3.1 (range: -184 to 277) ± 101

There was no significant difference between the 2 scans for the measurements done, T-test values for S1 -0.69 (p=0.48), pubic bone 1.05 (p=0.29), right -0.13 (p=0.89) and left -0.16 (p=0.87), showing a good degree of reproducibility in the cylinder insertions. There were 2

cases with a difference of >1.5cm in the S1 measurement and another 2 cases for the pubic bone measurement and in all cases there was no evidence of air gaps and no difference in the soft tissue measured above the cylinder. No correlation was identified between the bladder volume and the angle of the cylinder with any of the measurements or their differences.

### Conclusion

The use of verification imaging to assess the placement of vaginal cylinders using bony landmarks can provide a rapid confirmation of the correct position. From our cohort there was not much differences in the measurements used between the planning and the verification scans. Soft tissue evaluation showed that within the range of differences in the measurements using bony landmarks the cylinder remained correctly placed; these changes in measurements are likely due to elasticity of the vaginal walls.

### EP-2133 Interstitial brachytherapy for vaginal recurrence of pelvic gynecological cancers

A. Visy<sup>1</sup>, J. Charret<sup>1</sup>, F. Gassa<sup>1</sup>, A. Serre<sup>1</sup>, M. Sandt<sup>1</sup>, F. Lafay<sup>1</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Leon Berard, Radiotherapy, Lyon, France

### Purpose or Objective

To date, there are no standard therapy for vaginal recurrences of pelvic gynecological cancers. Local treatment with surgery, External Beam radiotherapy (EBRT) and/or brachytherapy (BT) may be proposed taking into account previous treatments and the extent of the recurrence. Compared to plesioBT, an interstitial implant may permit to deliver a more homogeneous and a higher dose to the tumor. The aim of this study is to evaluate the outcomes of interstitial BT with Iridium192 alone or in addition to surgery, EBRT and/or chemotherapy (CT).

### Material and Methods

From 2011 to 2018, 25 consecutive patients with isolated vaginal recurrences from endometrial (n=15), cervical (n=7), ovarian (n=2) or vaginal cancer (n=1) have been included. The primary treatment included surgery in all but one, EBRT and BT in 1 pt, EBRT in 1pt, and BT in 1 pt. The median time to relapse was 20 months. The site of the recurrence was central (vaginal vault) in 16; lateral in 6, both in 3 pts, with an upper-vaginal "parametrium" extension in 5. A surgery was performed in 6 pts. EBRT (with concomitant CT in 14) was delivered in all patient but one (previously irradiated). Two types of applicators were used according to the site of the recurrence (figure 1 and 2). BT technique was LDR (Iridium wires) in 8 pts treated before 2014 (median dose 19 Gy); PDR in 15 (median dose: 20Gy; 50Gy for exclusive BT) and HDR in 2 pts (12-15Gy in 3 fractions). The cumulative EBRT and BT median dose was: 64 Gy.

### Results

Only 1 grade 2 acute toxicity was observed with BT: a cutaneous abscess on the stitch after BT. Regarding late toxicities, 1 patient required a surgical resection for a

small intestine radio-necrosis. One patient experienced a vaginal necrosis with a bladder fistula, associated with a peritoneal and local tumor progression. In addition vaginal adhesions were reported in 2 and chronic diarrhea in 1 pt. With a 35 months median follow-up (4 - 85 months), 7 patients experienced a local failure (median delay of 22 months after BT, range 11 to 70 months) within the treated volume, isolated in 2 and associated to metastatic progression in 5. Distant metastases alone occurred in 3 pts.

### Conclusion

Interstitial brachytherapy associated with EBRT (+/- concomitant CT) is an effective treatment for locally recurrent gynecological cancers, with favorable clinical outcomes and an acceptable toxicity profile.

### EP-2134 Developing a IC+IS applicator for treatment of advanced cancer cervix by image based brachytherapy

S. Banerjee<sup>1</sup>, V. K<sup>1</sup>, D. Kamaraj<sup>1</sup>, D. Gupta<sup>1</sup>, S. Goyal<sup>1</sup>, S. Bisht<sup>1</sup>, K. Narang<sup>1</sup>, S. Mishra<sup>1</sup>, M. Pinto<sup>2</sup>, P. Manderna<sup>2</sup>, T. Kataria<sup>1</sup>

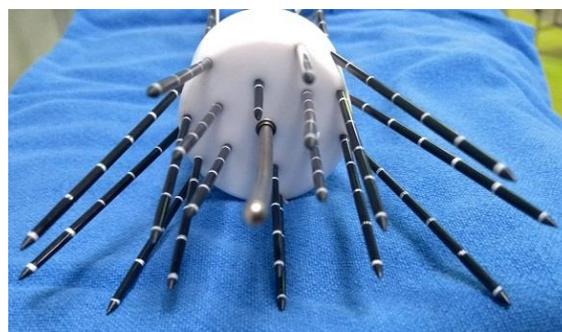

<sup>1</sup>Medanta The Medicity, Division of Radiation Oncology, Haryana, India; <sup>2</sup>Medanta The Medicity, Biomedical Engineering, Haryana, India

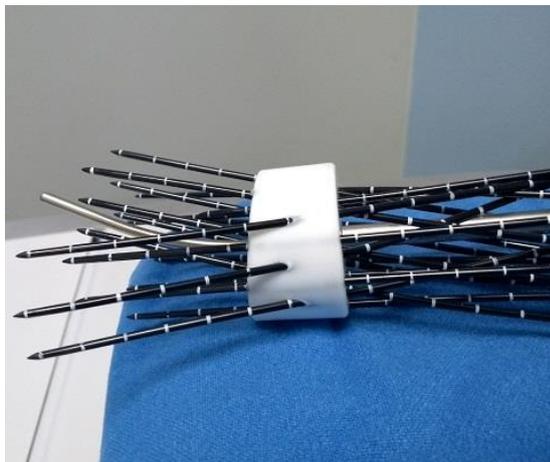

### Purpose or Objective

The GEC ESTRO initiatives have revolutionized the field of gynecological brachytherapy. Advanced applicators are capable of curative dose even to lateral parametria and allow modulation of dose to the critical organs. The outcomes are visible in terms of local control, and reduced toxicities. However in spite of all the advancements the practice of intracavitary + interstitial (IC+IS) is still restricted to select institutions. Due to limited resource and lack of training in IS techniques advanced applicators are not available where they are most needed. We have developed an IC+IS applicator that is easy to assemble and use.

### Material and Methods

A schematic planning diagram of the applicator was drawn on graphical paper. The size of the applicator, shape, position of the needles in the template (which also serves as fixed ovoid) was determined. First a virtual applicator was constructed in TPS and desired dose distributions were experimented keeping principles of IC + IS brachytherapy planning in mind. The applicator was constructed [Fig 1- End on view of the applicator with central tandem and needles, Fig 2- Lat view applicator with needles]. CT images of the applicator were acquired and the applicator was reconstructed in TPS. We selected 3 cases of interstitial brachytherapy treated in our institute and we contoured exact dimensions of HRCTV on the CT images of the applicator.

### Results

We have constructed a 3.5/ 4 cm cylindrical applicator with beveled surface (antero-posterior direction) to fit the plane of cervix, of length 2.5 cm with unique 6 Fr catheter insertion points at fixed distances within the applicator (acting both as template for needle inserting/guidance and ovoid for IC loading). Three needles in anterior oblique direction parallel and in same plane of the Central tandem and 3 needles in lateral oblique direction for distal parametria could be placed technically on each side. Other needles used were straight needles to achieve adequate coverage. The distance of the oblique catheters from central tandem is more than 3 cm at point A. We devised a loading pattern that can give IC + IS type of distribution.

Dummy plans was created to see coverage of HRCTV [Table 1].

volume	Max width (c.m)	Max Thickness (c.m)	Height (c.m)	Vol (c.c)	D90 (%)	V90 %
HRCTV A	5.6	3.9	5.3	45.5	114	98.2
HRCTV B	4.5	3.5	5.8	47.8	105.4	96.6
HRCTV C	5	4.5	5.1	25.3	127.3	98.4

### Conclusion

We have developed an IC+IS applicator capable of delivering dose up to > 3.5 cm from point A. A single cylinder functioning both as ovoid and template for interstitial needles makes the applicator easy to use. The needles used also do not need to be bent. The applicator will be clinically used after feedback from the scientific society.

### EP-2135 Exclusive brachytherapy in endometrial cancer: experience of an university hospital

C. Salas<sup>1</sup>, L. Gutiérrez Bayard<sup>1</sup>, M.J. Macias Lozano<sup>1</sup>, S. Garduño Sánchez<sup>1</sup>, R. Rodríguez Sanchez<sup>1</sup>, S. Sayago Gil<sup>1</sup>, V. Díaz Díaz<sup>1</sup>, E. Gonzalez Calvo<sup>1</sup>, I. Villanego Beltran<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M. Lorente Sanchez<sup>1</sup>, J. Jaén Olásolo<sup>1</sup>  
<sup>1</sup>Hospital Universitario Puerta del Mar, Comprehensive Care Department Cancer- Radiation Oncology Service- University Hospital Puerta del Mar, Cadiz, Spain

### Purpose or Objective

To analyze the impact of two different fractionation regimens of postoperative treatment through exclusive endovaginal High Dose Rate Brachytherapy (HDRBT) in women intervened for endometrial cancer, and find

differences of chronic toxicity (LT), local recurrence (LR), locoregional relapse (LRR) and survival free metastases (SFM).

### Material and Methods

102 patients who were diagnosed and intervened of endometrial adenocarcinoma Grade I (G), GII and localized G3, with IA and IIB stage, exclusively treated with endovaginal HDRBT, with cylinders, between 2008-2015 with a minimum follow up of 30 months, were included in this retrospective analysis. Fédération Internationale de Gynécologie Obstétrique Stage (FIGO): IAa:37, IB:63, IIA:2. Brachytherapy: Group (Gp) I: 30 patients who received 5-6 fractions (fx)/3,8-4 Gy at 0,5 cm. surface cylinders, and Group II: 72 patients, who received 3fx/7Gy 0,5 surface cylinder. The mean days overall treatment time (OTT) was 11 and 8 respectively in Group I and II. Previously they had undergone hysterectomy plus salpingo-oophorectomy abdominal or assisted by laparoscopy ± lymphadenectomy.

Toxicity vaginal, bladder and rectal was evaluated using Common Terminology Criteria for Adverse Events v4.03 (CTCAE). The equivalent dose at 2 Gy (EQD2) and bioequivalent dose (BED) study was performed in vaginal mucosa surface with  $\alpha/\beta:3$ . The results from these two groups were then compared and analysed with SPSS 18.

LT, LR, LRR, SFM and OS were compared in both groups and were analyzed with the SPSS 18. Survival (OS) was defined for Test Long Rank (Mantel-Cox).

### Results

Histology of adenocarcinoma in 94 (92%), serous-clear cell in 6,8%. Well differentiated 35%, moderated 60% and poorly 7%. Lymphovascular space invasion (LVSI) positive in 1 patient of Gp I. Grouped by risk group, low risk 34 (9GpI/25GpII), intermediate risk 40 (10/30), high-intermediate risk: 25 (10/15) and high risk: 3 (1/2).

The EQD2 on the vaginal surface of Gp I patients was 72,19 Gy and Gp II: 95,42 Gy. The BED on the vaginal surface of Gp I patients was 120,32 Gy and Gp II 159,04 Gy.

Late toxicity appeared in 14/102 (14%): vaginal 8 Grade 1, 3 Grade 2; bladder 2 Grade 2; rectal 1 Grade 1. With a mean and median follow-up of 69 and 72 months (range, 20-96), none patient had vaginal relapse. 5 of 102 patient had locoregional relapse, 2 in Gp I and 3 in Gp II. 6 patient had distant metastases, 2 in Gp I and 4 in Gp II. Of them, 2 dead in Gp1 and 3 in Gp II. No differences were found in relation to OTT, LR, SFM and OS in Groups I and II. No differences were found in LT to relation BED Groups I and II.

### Conclusion

Six fractions of 3,8-4 Gy in 11 days or three fractions of 7 Gy in 8 days in patients receiving exclusive HDRBT was a safe treatment in relation to late toxicity, local and locoregional control and survival free metastases, but the 3-fractions scheme increases the comfort of the medical team and the patient by reducing the number of times they go to the hospital.

### EP-2136 Brachytherapy study between patients treated with HDR Ir-192 and Xofigo 50kVp source for uterus cancer

K. Asiev<sup>1</sup>, S. Devic<sup>2</sup>, B. Bahoric<sup>3</sup>

<sup>1</sup>Jewish General Hospital, Radiation Oncology Department G18.123, Montreal, Canada; <sup>2</sup>Jewish General Hospital, Radiation Oncology Department G18.121, Montreal, Canada; <sup>3</sup>Jewish General Hospital, Radiation Oncology Department G.002, Montreal, Canada

### Purpose or Objective

To evaluate the possibility of treating patients with low-energy electronic 50kVp brachytherapy beam modality instead of present standard of care High-Dose-Rate Brachytherapy (HDRBT) Ir-192 source for patients with uterus cancer.

### Material and Methods

Five female patients with uterus cancer were treated with HDR Ir-192 source using intra-cavitary Miami applicator with 7 channels. Brachytherapy plans were generated using IPSA inverse planning module of MasterPlan Treatment Planning System (TPS). For the purpose of this study the same five patients were re-planned with HDR Ir-192 source but using only the central channel of Miami Applicator. Next step was to export all five patients (CT datasets and structure sets) to BrachyVision (Eclipse) TPS (Varian, Palo Alto, USA) and plan them with Xofig Axxent 50kVp electronic x-ray source. Due to the fact that same CT datasets and structure sets were used for re-planning process with BrachyVision TPS patient geometry and applicator geometry did not change. The best mimic of Miami applicator in BrachyVision TPS was Straight Tandem (1 channel) applicator overlaid with Miami applicator central channel. Re-planning was performed in such a way so that dosimetric coverage of the planning clinical target volume (Planning\_CTV) achieved for two comparative treatment modalities (single-Iridium and 50 kVp) was matched with the plan patient was treated with.

### Results

Comparison of doses to critical structures (small bowel, bladder and rectum) was performed and summarized in Table 1. Dose values of D (0.1 cc), D (1.0 cc) and D (2.0 cc) are averaged over 5 patients and given in Table 1, together alongside with range of doses and standard deviations. Average times for delivery of the plans were: 8.24 min. for HDR Ir-192 with Miami applicator with 7 channels, 5.38 min. for HDR Ir-192 with Miami applicator with 1 central channel and 6.23 min. for Xofig Axxent 50kVp electronic x-ray source with Straight Tandem 1 channel.

Table 1: Summarizes averaged (over 5 patients) doses to the organs at risk for the three plans per patient investigated.

	Small Bowel			Bladder			Rectum		
	D (0.1cc) Gy	D (1.0cc) Gy	D (2.0cc) Gy	D (0.1cc) Gy	D (1.0cc) Gy	D (2.0cc) Gy	D (0.1cc) Gy	D (1.0cc) Gy	D (2.0cc) Gy
HDR Ir-192 Miami applicator 7 channels

Range	4.03 - 16.45	3.12 - 8.78	2.72 - 7.11	7.51 - 8.35	6.09 - 7.14	5.42 - 6.58	8.61 - 12.00	7.36 - 9.31	6.27 - 8.05
SD	5.32	2.63	2.02	0.31	0.42	0.47	1.25	0.81	0.72

### Conclusion

Our results of retrospective dose comparison suggest that 50 kVp could potentially replace Ir-192 brachytherapy treatment modalities providing similar target coverage and similar maximum dose values to surrounding critical structures. Averaged treatment times are as well comparable between two treatment modalities. Further studies are needed however to investigate the impact of radio-biological effectiveness of 50 kVp photons when compared to Ir-192 emissions.

### EP-2137 Locally advanced cervical carcinoma treated with electronic brachytherapy: Our experience

A. Miranda Burgos<sup>1</sup>, A. Méndez Villamón<sup>1</sup>, R. Ibáñez Carreras<sup>1</sup>, M. Gascón Ferrer<sup>1</sup>, A. Campos Bonel<sup>1</sup>, B. García Gutierrez<sup>1</sup>, E. Muñoz Sanz<sup>1</sup>, S. Lozares Cordero<sup>2</sup>, J. José Gutiérrez<sup>3</sup>, I. Negro Quintana<sup>3</sup>, I. Escartín Martínez<sup>4</sup>, G. Riazuelo Fantova<sup>4</sup>, M. Tejedor Gutiérrez<sup>1</sup>  
<sup>1</sup>Hospital Universitario Miguel Servet, Radiation Oncology, Zaragoza, Spain; <sup>2</sup>Hospital Universitario Miguel Servet, Medical Physics and Radiation Protection, Zaragoza, Spain; <sup>3</sup>Hospital Universitario Miguel Servet, Gynecology, Zaragoza, Spain; <sup>4</sup>Hospital Universitario Miguel Servet, Radiology, Zaragoza, Spain

### Purpose or Objective

The standard treatment of locally advanced cervical carcinoma is radiochemotherapy, including concomitant external beam radiation (EBRT) with weekly Cisplatin and brachytherapy (BT). The electronic brachytherapy (XB) is a treatment option for breast, skin and gynaecological cancer.

Our objective is to present our experience using electronic brachytherapy for cervical cancer.

### Material and Methods

We present 8 patients with locally advanced cervical carcinoma. They were treated between May/2016 and August/2018 with EBRT, 46Gy in 200cGy fractions, using intensity-modulated radiation therapy (IMRT) and image-guided radiation therapy (IGRT) techniques concomitant with Cisplatin 40mg/m<sup>2</sup> followed by XB guided by magnetic resonance imaging (MRI). The total dose administered was 28Gy in 4 fractions given in two consecutive weeks (Thursday-Friday). We analysed the median dose in bladder, rectum and sigmoid D2cc with XB comparing the doses with Ir192. Toxicity was analysed according CTCAE 4.0 scale.

### Results

After EBRT, six of the patients presented a complete response and the other two a partial response with a residual tumour <3cm. The mean doses received were: CTV<sub>HR</sub> 90: 112,55%, CTV<sub>HR</sub> 98: 95,88%, CTV<sub>IR</sub> 90: 59,03%, CTV<sub>IR</sub>98: 63,67%. The mean V150 (cm<sup>3</sup>) with XB vs. Ir192 were: 23.4 vs. 20.7 and the V200 were: 13.8 vs. 11.8.

In organs at risk (OAR) the median dose in bladder with XB vs. Ir192 was: 2cc 60.4% vs. 60.7%. In rectum XB vs. Ir192 was: D 2cc 33.7% vs. 43.9. In sigmoid XB vs. Ir192 was: D 55.4% vs. 58.3%.

The mean following time is 13 months (range 2-29). Acute toxicity was observed: mucositis was observed in 4 patients (2 patients G1 and 2 G2); genitourinary (GU) toxicity was observed in 2 patients (G1) and gastrointestinal (GI) toxicity in 1 patient. At 3 months after treatment only 1 patient presents mucositis G1.

After the XB treatment 7 patients are in complete response and 1 patient died from systemic progression.

### Conclusion

The XB with tandem and ovoids is an appropriate technique on selected patients with residual tumour <3cm and without parametrial invasion. The dose received by the organs at risk with the XB is less compared to Ir192, with a good coverage of the PTV with excellent results as for toxicity.

### EP-2138 Rectal and urinary toxicity in patients with cervical carcinoma treated with brachytherapy

V. Garcia Jarabo<sup>1</sup>, S. Cordoba Largo<sup>1</sup>, M. Ramirez<sup>1</sup>, D. Martínez<sup>1</sup>, M. Gaztañaga Boronat<sup>1</sup>, C. De la Fuente<sup>2</sup>, G. Marquina<sup>1</sup>, A. Ortega<sup>1</sup>, R. Mendez<sup>1</sup>

<sup>1</sup>Hospital Clinico San Carlos, Radiation Oncology, Madrid, Spain; <sup>2</sup>Hospital Universitario Puerta de Hierro Majadahonda, Radiation Oncology, Madrid, Spain

### Purpose or Objective

To asses dosimetric factors predicting rectal and urinary morbidity and describe vaginal toxicity in patients treated with chemoradiation (CRT) and image-guide brachytherapy (IGBT-MRI) for locally advanced cervical cancer.

### Material and Methods

From November 2010 to February 2016 we treated 64 patients (p) with stages IB-III cervical carcinoma. Mean age: 54.6 years (30-88). TNM stage: I: 4p, II: 54p and III: 6p. Histology: epidermoid: 49p; adenocarcinoma: 15p. All patients were treated with CRT and 3D-based planning intracavitary/interstitial IGBT, using the GEC-ESTRO recommendations for defining high-risk clinical target volume (HR-CTV). Equieffective doses at 2 Gy (EQD2) were calculated, applying linear quadratic model. Statistical analysis: chi-square test for comparing

proportions and Kaplan Meier for survival analysis and log-rank for curve comparison. Toxicity was evaluated according to CTCAE v.4.0 criteria.

#### Results

After a median follow-up of 30 months, 3-year overall survival (OS), 3-year disease-free survival (DFS) and 3-year local relapse-free survival (LRFS) were 83.7%, 58% and 84.2%, respectively. The mean  $D_{2cc}$  in rectum and bladder were: 66.2Gy (47.8-87.9) and 76.3Gy (54.9-96), respectively. Rectal morbidity (diarrhea, proctitis and/or bleeding), was observed in 22p: G1: 13p (20%) and G2-3: 9p (14%). One patient presented with sigmoid perforation. Two-year G2-3 rectal toxicity-free survival (RTFS) and G2-3 rectal bleeding-free survival (RBFS) were 82.6% and 84.2%, respectively. In relation to dosimetric parameters, there were more rectal toxicity in patients with  $D_{2cc} > 65$ Gy, although differences were not significant (2y G2-3 RTFS of 65% vs 93%). A  $D_{2cc} > 65$ Gy was associated with more incidence of G2-3 proctitis (0% vs 100%,  $p = 0.05$ ). Urinary morbidity (urgency, incontinence, cystitis and/or hematuria) was observed in 17p (G2-3 cystitis: 2p and G2-3 hematuria: 6p). Two-year G2-3 hematuria-free survival was 91%. The probability of G2-3 hematuria was not related with  $D_{2cc} > 80$ Gy. G2-3 vaginal stenosis was observed in 25p (39.6%). Sacrum fracture was observed in 12p (19%). Two-year sacrum fracture-free survival was 84%.

#### Conclusion

Rectal complications remain as the main toxicity in modern brachytherapy. Efforts should be made to maintain rectal  $D_{2cc}$  below 65 Gy. Based in our results, early evaluation and intervention are recommended to detect and prevent sacral fractures.

#### EP-2139 Adjuvant brachytherapy for T1b1N0 cervical cancer: an alternative to postoperative EBRT

E. Bronsart<sup>1</sup>, C. Petit<sup>1</sup>, I. Fumagalli<sup>1</sup>, S. Gouy<sup>2</sup>, P. Morice<sup>2</sup>, C. Haie-Meder<sup>1</sup>, C. Chargari<sup>1</sup>

<sup>1</sup>Gustave Roussy, Radiation oncology, Paris, France;

<sup>2</sup>Gustave Roussy, Gynecologic Surgery, Paris, France

#### Purpose or Objective

Generally the treatment in early stage cervical cancer is upfront surgery. An adjuvant external beam radiation therapy (EBRT) is delivered according to histopathological risk factors (lymph node involvement, lymphovascular invasion, tumor > 4cm, deep stroma invasion, positive surgical margins, parametrial spread). In a Gynecologic Oncology Group (GOG) study, adjuvant EBRT was shown to reduce the risk of locoregional relapse by 46%, at the expense of an increase in severe morbidities.<sup>1</sup> We report our institutional experience of adjuvant vaginal wall brachytherapy as an alternative to EBRT in selected patient treated with upfront surgery for pT1b1N0 tumors.

#### Material and Methods

Medical records of consecutive patients treated for an early stage cervical by upfront radical colpohysterectomy and pelvic lymph node dissection for a pT1bN0 cervical cancer between 1991 and 2018 were examined. Patients were proposed adjuvant vaginal wall brachytherapy because of the following risk factors: tumor size  $\geq 2$ cm and/or lymphovascular involvement. Patients with parametrial spread, positive margins, or with nodal metastases were excluded and received adjuvant EBRT. Patients received a dose of 60 Gy and the dose was prescribed at 5 mm depth from the vaginal wall and the upper third of vagina was included in the target volume. The vaginal mould technique was used in all cases. Organ at risk point doses or dose/volume parameters followed ICRU dose constraints guidelines. Patients were followed clinically and toxicities were scored according to CTCAEv3.

#### Results

40 patients were included, mean age 50.3 years (range: 28.8-80.6 years). A total of 25 patients (62,5%) had a

squamous cell carcinoma and 15 (37.5%) had an adenocarcinoma. Eight patients (20%) had LVI, eight (20%) had a tumor size more than 3 cm and one (2.5%) had close resection margins (<2mm). Median follow-up time was 39.5 months. A total of four patients experienced tumor relapse (10%), all in the peritoneal cavity, associated with synchronous external iliac lymph node in one patient. No patient had vaginal relapse and no isolated pelvic nodal failure was reported. The median overall survival time was 42 months. The Kaplan-Meier estimated five-year probability of survival was 84% (CI95%:68%-100%). In univariate analysis, probability of relapse was significantly higher in patients with tumor size > 3cm ( $p=0.004$ ). Presence of LVI, margin distance, or histology (adenocarcinoma versus squamous cell) was not significant. No toxicity more than grade 1 was reported. During their follow-up, five patients (12.5%) presented telangiectasia grade 1, 2 (5%) had vaginal stenosis grade 1, 2 (5%) had vaginal bleeding grade 1, 1 (2.5%) had vaginal dryness grade 1. One patient had rectal bleeding and two had urinary toxicity. No bowel morbidity was reported.

#### Conclusion

This study suggests that adjuvant BT is an appropriate option for decreasing vaginal relapses in selected patients with pT1b pN0 cervical cancer with one or two of the following risk factors: size > 2cm and LVI.

#### EP-2140 HDR Brachytherapy in Reirradiation of Local Nasopharyngeal Recurrence

M. Ait Erraïsse<sup>1</sup>, W. Hassani<sup>1</sup>, T. Bouhafa<sup>1</sup>, K. Hassouni<sup>1</sup>

<sup>1</sup>CHU Hassan II, Radiothérapie, Fez, Morocco

#### Purpose or Objective

pharyngeal carcinoma (NPC) is a most cancer of head and neck in North Africa and South East Asia. Reirradiation of local recurrence is limited by the dose constraints. Brachytherapy alone or in combination with EBRT can be a good compromise. The aim of this study was to determine the role of brachytherapy in safety reirradiation of recurrent NPC.

#### Material and Methods

This is a retrospective study of 8 patients with nasopharyngeal cancer recurrence collected in the radiotherapy department of the University hospital Hassan II in Fez between January 2014 and December 2017.

#### Results

The average age of our patients is 42 years old. The average time to onset of relapse is 29 months. All patients received external radiation therapy at 70 Gy on macroscopic tumor volume (tumor and lymphadenopathy) during initial irradiation with or without chemotherapy. relapse was localized in 5 patients and associated with lymph node involvement in 3 patients. 2 patients received exclusive high-dose rate brachytherapy and 6 received external radiation radiotherapy followed by brachytherapy. The total radiation dose EQD2 was 60 to 66 Gy. With an average follow-up of 20 months, 37.5% of patients are alive and in complete remission.

#### Conclusion

Brachytherapy alone or after EBRT could play an important role in reirradiation of locally recurrent NPC with acceptable toxicity.

#### EP-2141 Recommendations for reporting the rectal dose during image guided HDR brachytherapy of prostate

M. Szlag<sup>1</sup>, A. Cholewka<sup>1</sup>, P. Wojcieszek<sup>2</sup>, S. Kellas-Ślęczka<sup>2</sup>, M. Stąpór-Fudzińska<sup>1</sup>, T. Krzysztofiak<sup>2</sup>, K. Ślosarek<sup>1</sup>

<sup>1</sup>Cancer Center and Institute of Oncology Gliwice Branch, Radiotherapy Planning Department, Gliwice, Poland;

<sup>2</sup>Cancer Center and Institute of Oncology Gliwice Branch, Brachytherapy Department, Gliwice, Poland

### Purpose or Objective

Imaging modalities, routinely used for 3D dose calculation for HDR prostate brachytherapy, are transrectal ultrasound (US) and computed tomography (CT). Depend on the imaging modalities, contours of the rectum contain: the whole rectum (when CT is used) or anterior rectal wall (for US based treatment plans). Contouring and rectum deformation by the transrectal probe modify the dose delivered to rectum. For different imaging types, the caution should be paid when using the same treatment plan evaluation protocol since some of the dosimetric parameters may be inconsistent. In this study we defined DVH regions where dosimetric parameters of the rectum and rectal wall differs significantly. The aim of this study was to specify dose-volume parameters for reporting the dose delivered to rectum and rectal wall during image guided brachytherapy of prostate and to indicate parameters which can be used for both imaging methods and these which should be used with caution. Clinical data are in relation to the set of physical dose parameters obtained from planning systems. Validation of dosimetric protocol is required to properly predict the clinical outcomes when new modalities are introduced to planning.

### Material and Methods

In our department prostate brachytherapy is performed in a real-time based on transrectal ultrasound (US) or computed tomography (CT). For the purpose of this study 33 randomly selected CT-based plans (OncentraBrachy ELEKTA) were compared with 33 US-based plans (OncentraProstate ELEKTA). Plans were calculated for patients treated with brachytherapy as a monotherapy with total dose of 26Gy delivered in two fractions. DVH parameters for prostate, rectum and rectal wall were selected for analysis (Table1). We evaluated statistically significant difference between mean values of dosimetric parameters for rectum and rectal wall.

Table 1. Mean DVH parameters for prostate, rectum and rectal wall

	V <sub>PTV</sub>	PTV <sub>100%</sub>	D <sub>90%</sub>	V <sub>rectum</sub>	D <sub>0.01ccm</sub>	D <sub>2ccm</sub>	D <sub>10%</sub>	D <sub>50%</sub>	D <sub>90%</sub>	V <sub>70%</sub>
CT	53.1ccm	95%	108%	55.3 ccm (whole rectum)	87%	63%	51%	25%	13%	3%
US	51.1ccm	95%	108%	23.9 ccm (rectal wall)	84%	67%	65%	34%	19%	7%
p value	0.59	0.76	0.13	<0.001	0.2	0.08	<0.001	<0.001	<0.001	<0.001

V<sub>PTV</sub> is the volume of the prostate gland, PTV<sub>100%</sub> is the volume of the prostate covered with 100% isodose, D<sub>90%</sub> is the dose that covers 90% of the organ (PTV, rectum or rectal wall), V<sub>rectum</sub> is the rectum or rectal wall volume (depend on the imaging used for treatment), D<sub>0.01ccm</sub> and D<sub>2ccm</sub> is the dose delivered to the 0.01 and 2 ccm of the rectum and rectal wall, D<sub>10%</sub> is the dose that covers 10% of the organ, D<sub>50%</sub> is the dose that covers 50% of the organ, V<sub>70%</sub> is the volume of the organ covered with 70% of the isodose. p value for t- test.

### Results

Table 1 presents dosimetry of prostate, rectum and rectal wall. Two groups of treatment plans were similar when comparing the PTV volume and PTV coverage, significant differences were observed for dose delivered to the 10%, 50% (intermediate-dose region) and 90% (low-dose region) of the rectum delineated based on CT and US. In the relative mode (Fig 1) rectal wall received higher dose in the low- and intermediate-dose regions but in absolute scale the dose delivered to the rectal wall covers larger volume when the whole rectum is delineated (Fig 1). The high dose regions for rectum and rectal wall (D<sub>0.01ccm</sub>, D<sub>2ccm</sub>) were comparable in US and CT plans and they

were consistent and independent on contouring methods.

### Conclusion

Dose delivered to rectal wall in the low- and intermediate-DVH region is underestimated in comparison to the dose delivered to the whole rectum. Only high dose region was comparable for both types of plan. CT and US plans should be evaluated with the use of different evaluation protocol for low and intermediate rectum doses.

### EP-2142 Analysis of dose distribution between TG-43 and TG-186 in lung cancer

M. Sawicki<sup>1</sup>, Ł. Jarosław<sup>2</sup>

<sup>1</sup>University of Rzeszów, Faculty of Medicine, Rzeszów, Poland; <sup>2</sup>Subcarpathian Cancer Center, Department of Brachytherapy, Brzozów, Poland

### Purpose or Objective

Standard treatment planning and dose calculation in brachytherapy HDR is based on water mass density. Human tissues has a different mass density than water. In the case of cancer located in the lung, the dose distribution is calculated mainly in the area of lung and critical organs (heart, esophagus, spinal cord). The OARs in lung, for example heart mass density is 1.05 which is very close to water density (1.0) and it seems correct to treat this area like a area of homogeneous water, but in case of lung there are such as areas like soft tissue and air. For lung (inflated) mass density is 0.2. in the area of lung cancer. The dose calculation algorithm should take into account the heterogeneity of the area, otherwise the calculated dose distribution will differ from the actual dose distribution in patient's body.

### Material and Methods

The material for this study included 15 patients with advanced inoperable non-small cell lung cancer treated with HDR Ir-192. The study group consisted 24 treatment plans with bronchial applicators (1-3 applicators). For each treatment fraction, two treatment plans were created. One for TG-43 and second one for TG-186. TP was created in the Oncentra MasterPlan Brachy 4.5.3 ® system. Dose distributions were compared in both treatment plans. First, the value of dose was compared at points at constant and same distance from the axis of the applicators (range 0.1-2.0 cm;). Then, the dose in the Target and critical organs (heart, oesophagus, spinal cord, healthy lung, lung) would have been evaluated. Parameters analysed for PTV are maximum and minimum value of median and V<sub>85</sub>, V<sub>100</sub> and V<sub>115</sub>. . In cases of the heart, spinal cord and oesophagus, the examined dosage equaled D<sub>0.1 cm<sup>3</sup></sub>, D<sub>1 cm<sup>3</sup></sub> and D<sub>2 cm<sup>3</sup></sub> for each of the structures.

Also, heart D20 was examined as well as D5 for the healthy lung

### Results

Comparison of both calculation methods presented differences in dose distribution in treatment plans. Were noted differences in dose points in distances from applicator axis as well as differences in dose distribution for PTV and OARs. Difference in value of median for the dose point in 1 cm distance from the applicator is 0,2%, maximal value was 41,78% and minimal value was 0,04%. For PVT V<sub>100</sub>, the difference was 2,6% and for the lung D5 was 3,6%.

### Conclusion

Differences in dose distribution in HDR brachytherapy for lung cancer between TG-43 and TG-186 prove that the we should consider the use of algorithms taking into account the tissue mass density.

### EP-2143 TRAK per unit reference dose as a QA tool is insensitive to finding cervix brachy planning errors

P. Gonzalez<sup>1</sup>, F. Koetsveld<sup>1</sup>, A. Mans<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiotherapy, Amsterdam, The Netherlands

### Purpose or Objective

To ensure the quality of a clinical treatment plan for HDR brachytherapy of the cervix, several checks can be made. Following the recommendations of the ICRU report 38, one of these checks is the calculation and reporting of the total reference air kerma (TRAK). This physical quantity, which is defined as the integral of the reference air kerma rate at 1 m distance from the source over the duration of treatment, is believed to be a reliable patient-specific QA tool in determining the treatment intensity. In our clinic the TRAK per unit reference dose, TRAK/D<sub>ref</sub>, as calculated from the TPS is compared to a predicted value. This predicted value is taken from a linear model relating the treatment volume (TV) to the TPS calculated TRAK/D<sub>ref</sub>. The TRAK check is passed if the predicted value does not differ more than 3% from the TPS calculated value. The purpose of this work is to test our hypothesis that the TRAK check is not sensitive enough in finding cervix brachy planning errors.

### Material and Methods

The linear model was determined by fitting TRAK/D<sub>ref</sub> to the treatment volume using a total of 51 clinical intra-cavitary/ interstitial plans. To determine the sensitivity of the TRAK check, several planning errors were introduced into a clinical plan using the Utrecht interstitial CT/MR applicator. All plans were made with the Oncentra treatment planning system. Planning errors were taken from an ASTRO white paper (Pract. Rad. Onc. (2014) 4, 65-70) and were complemented by several other error sources we check for in our institute. The errors included: wrongful addition of a dwell position, wrong dose optimization and wrong reference dose.

### Results

Table 1 shows the various types of errors introduced and the deviation of the predicted value of the TRAK per unit reference dose from the calculated value. Only 2 out of 13 planning errors were found using the TRAK check: using a wrong reference dose and wrongful positioning of a dwell position. The deviations in these cases were -15.5% and 4.7% respectively. All other deviations fall within 3% of the clinical no-error plan. In the first case it must be noted that this error will go undetected if the wrong reference dose is entered in *both* the planning and TRAK check, which is likely to occur in a clinical workflow. The second detected error was due to a misplaced dwell position. It was placed far outside of the high-dose region such that it contributed to the TRAK but not to the treatment volume. This planning error was only detected because we used a strict limit of 3%. We also placed additional dwell positions in the high-dose region. Evidently the treatment volume changed but the ratio TRAK/TV remained constant.

Introduced error	Treatment Volume [cc]	TRAK/D <sub>ref</sub>	Lin. Model	Deviation
No error plan	59.31	477.7	484.8	-1.5%
Wrong ref. dose in planning	59.31	409.6	484.8	-15.5%
Wrong isodose in planning	59.31	477.8	484.8	-1.5%
Additional dwell position in intra-uterine tube	66.54	518.6	518.0	0.1%
Additional dwell position in needle	67.66	518.6	523.2	-0.9%
Additional dwell position in needle	66.40	518.6	517.4	0.2%
Additional dwell position in needle	67.25	518.6	521.4	-0.5%
Additional dwell position in intra-uterine tube high	61.59	518.6	459.3	4.7%
Additional dwell position in intra-uterine tube low	66.40	518.6	517.4	0.2%
Accidentally displaced isodose line	92.07	645.6	635.5	1.6%
Accidentally displaced isodose line	130.9	828.1	814.1	1.7%
Offset intra-uterine tube -5 mm	59.28	477.8	484.7	-1.4%
Offset intra-uterine tube -15 mm	59.03	477.8	483.5	-1.2%
Offset needles +5 mm	59.23	477.8	484.5	-1.4%

Table 1. Calculated and predicted values of TRAK/D<sub>ref</sub> as a function of the treatment volume are shown. The last column shows the deviations of the predicted values from the TPS values after introducing several planning errors.

### Conclusion

We conclude that the TRAK check is not a sensitive QA tool since only two very specific planning errors were detected, one of which had a value just above the threshold, and the other could go undetected depending on the workflow.

### EP-2144 Feasibility of using Micro Silica Bead TLDs for 3D dosimetry in brachytherapy

S. Babaloui<sup>1</sup>, S. Jafari<sup>2</sup>, A. L. Palmer<sup>2</sup>, W. Polak<sup>2</sup>, M. W.J. Hubbard<sup>3</sup>, T. Skopidou<sup>3</sup>, A. Lohstroh<sup>3</sup>, R. Jaber<sup>4</sup>  
<sup>1</sup>Cancer Institute Tehran Univ. of Medical Science, Department of Medical Physics and Biomedical Engineering, Tehran, Iran Islamic Republic of;  
<sup>2</sup>Portsmouth Hospitals NHS Trust, Medical Physics Dept., Portsmouth, United Kingdom; <sup>3</sup>University of Surrey, Department of Physics, Guildford, United Kingdom;  
<sup>4</sup>Cancer Institute- Tehran University of Medical Sciences, Radiation Oncology Research Centre RORC, Tehran, Iran Islamic Republic of

### Purpose or Objective

Evaluation of the feasibility of using silica bead TLDs for 3D phantom dosimetry in brachytherapy (BT) for verification of treatment doses and routine quality control. Estimation of beam perturbation effect of TLDs and clinically relevant spatial resolution (SR) required for placing the beads at the organs' surface.

### Material and Methods

The TLDs were positioned with 2.5, 5 and 7.5mm spacing on the surface of a 5cc syringe (Fig1a) in a water tank of similar size to the pelvis of a medium patient. CT scans are taken and a 4field conformal radiotherapy (CRT) plan was created using 6MV beams. From the treatment planning system (TPS), 3dose planes were extracted at different depths, in the middle, bottom and below the syringe for every TLD's arrangement. By using a 2D-γ analysis, the TPS reports were compared with and without presence of the beads.

A novel anthropomorphic phantom was developed to position the TLDs. It consists of all pelvic organs which are relevant in gynaecology (GYN) BT. Organs were 3D printed using the CT scan datasets of handmade organs (Fig1 b & d). Acrylonitrile butadiene styrene (ABS) with 90% infill density was used with a CubePro printer (3D Systems Inc., U.S). Bones were made of PVC coated with clinical plaster. The phantom components were confirmed to have mass density and CT numbers similar to the relevant

tissues (solid water:  $CT\#=1012$ ,  $0.944 < \rho < 1.044$ ; Phantom organs:  $\rho=0.95$  and the  $CT\#=959$ ).

TLDs were threaded and placed on the organs' surface with 1cm resolution. Then whole assembly was placed inside the same water tank and irradiated with  $^{60}\text{Co}$  HDR source within a Vienna applicator (Eckert & Ziegler GmbH) to 7Gy prescribed to ICRU38 defined A-points. A TOLEDO TL system was used to readout the TLDs. Percentage difference of mean doses and dose surface histograms (DSH) of measured doses were compared against the TPS for the uterus as clinical target volume (CTV), bladder, rectum and sigmoid as organs at risk (OARs).

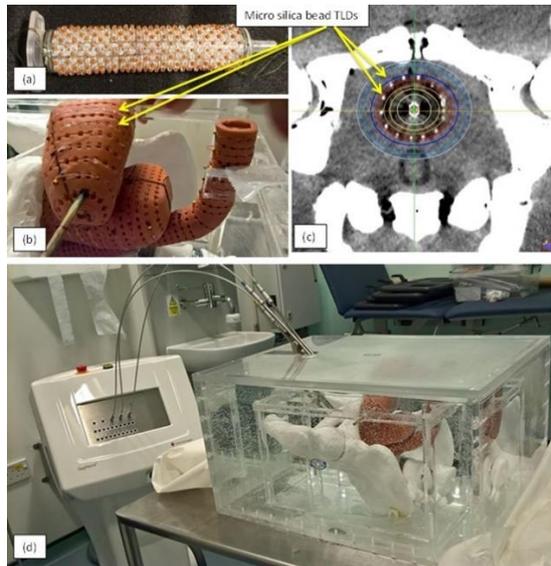

Fig1. (a) Syringe with a 2.5 mm spacing arrangement of silica bead TLDs. (b) 3D printed organs with placement of TLDs at the surface. (c) HDR plan on the CT scan of phantom; each TLD is clearly visible. (d) The anthropomorphic pelvis phantom in the water tank connected to the high dose rate (HDR) unit.

## Results

The 2D- $\gamma$  analysis on the syringe showed more than 99% points passed 3% and 3mm criteria at all source to plane distances which mean TLDs with different SR do not cause any perturbation effect.

Fig 2 shows the DSHs of measured doses with TLDs in comparison with those of the TPS dose calculation. By calculating the integral dose for the organs, % difference were found to be 3%, 4%, 10% and 45% for uterus, rectum, bladder and sigmoid respectively. Results showed, % difference of mean doses in the uterus is  $<1.4\%$  ( $SD=0.4$ ) for TLDs up to 4cm distance from the centre of ring vertically, 9% to 22% ( $SD=10.5$ ) above 6cm which is the low- dose region ( $<1\text{Gy}$ ).

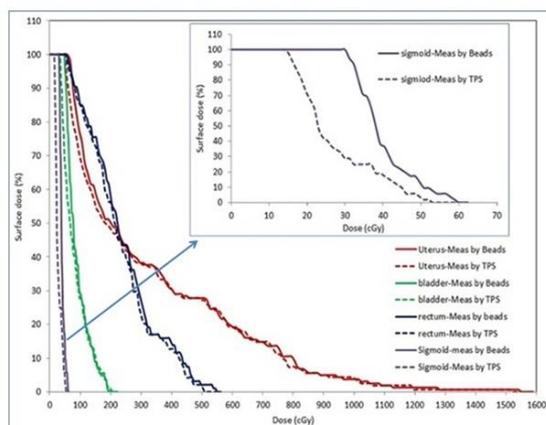

Fig2: Dose surface histograms obtained by TLDs readout and point doses calculations of TPS

## Conclusion

A customized anthropomorphic pelvis phantom was successfully built and clinically assessed to confirm properties similar to tissues. The small size of the TLDs together with negligible beam perturbation effect, suggest their further potential use as in-vivo dosimetry system which is the next step of this project. A careful calibration is needed, especially in the region of low doses.

## EP-2145 Biological comparison of $^{60}\text{Co}$ & $^{192}\text{Ir}$ brachytherapy sources: a possible need for correction factor

S. Abdollahi<sup>1</sup>, M. Dayyani<sup>2</sup>, H. Miri Hakimabad<sup>3</sup>, L. Rafat Motavalli<sup>3</sup>, E. Hoseinian Azghadi<sup>3</sup>

<sup>1</sup>Reza Radiotherapy and Oncology Center RROC, Medical Physics, Mashhad, Iran Islamic Republic of ; <sup>2</sup>Reza Radiotherapy and Oncology Center RROC, Radiation Oncology, Mashhad, Iran Islamic Republic of ; <sup>3</sup>Ferdowsi University of Mashhad, Physics, Mashhad, Iran Islamic Republic of

## Purpose or Objective

High Dose Rate Brachytherapy (HDR BT) has become a standard treatment as a boost or monotherapy for different tumors such as gynecological malignancies, prostate cancers, sarcomas, and breast cancers. In most of modern clinical studies in BT, one of the commercial Ir-192 sources was employed. Recently though, Co-60 HDR BT sources have been used worldwide. Co-60 with a lower dose rate (about one-half), can deliver the prescribed dose two times longer than Ir-192. Moreover, because of their different photon spectra, these two sources show some discrepancies in dose distributions. Before expanding the Iridium-based results to Cobalt-based clinical treatments, It may be questioned whether these differences can meaningfully influence the biologically effective dose (BED) distributions inside the tumor?

## Material and Methods

Dose rate distributions were estimated for Co-60 and Ir-192 sources (Eckert & Ziegler BEBIG) using TG-43 formalism for vaginal cylinder and Tandem-Ovoids used for gynecological tumors and interstitial needles for breast and prostate malignancies. The linear-quadratic (LQ) model was used to investigate probable biological differences made by dose and dose rate distributions of two sources. For the estimation of the incomplete recovery factor  $g$  in the LQ model which compares dose rate effects in one irradiation session, mono-exponential repair kinetics was assumed and the repair half-times ( $T_{1/2}$ ) were extracted from literature. BED distributions were then calculated considering site dependent  $\alpha/\beta$  values.

## Results

For all sites, DVH curves of clinical target volumes (CTVs) were in good agreement for two sources however dose distributions varied significantly in some dose points. Considering the physical dose, points on the vaginal cuff received higher dose up to about 40% from Co-60 as compared with Ir-192. In three other cases, discrepancies up to about  $\pm 10\%$  can be observed for some few points. For BED analysis,  $\alpha/\beta=10$  Gy and  $T_{1/2}=1$  h were selected for gynecological sites. However, several values of  $\alpha/\beta$  and repair time for prostate ( $\alpha/\beta=1.5$  and 3 Gy,  $T_{1/2}=16$  min) and breast tumors ( $\alpha/\beta=2, 3.5$ , and 5 Gy,  $T_{1/2}=0.1, 0.5$ , and 2 h) were examined. For gynecological sites, BED distribution patterns agreed with dose distributions except for the vaginal cuff in which Co-60 caused an increase from +10% to +90% in BEDs as compared with Ir-192. The patterns were different for prostate site because of the faster repair time and lower values of  $\alpha/\beta$ . BED values from Co-60 source showed -20% to -10% reduction in  $>70\%$  of CTV in comparison with Ir-192. For the breast site, the reduction to -10% can be observed only for  $T_{1/2}=0.1$ .

## Conclusion

The results were in agreement with the previous studies which clinically confirmed Co-60 as an HDR BT source for gynecological tumor management. However, one may be cautious for applying the Iridium-based prescribed dose into the Cobalt-based treatments in some cases such as prostate cancers which using a correction factor of about 1.2 might be reasonable.

#### EP-2146 Comparison of planning US HDR prostate on transversal or longitudinal ultrasound acquisitions

D. Aramburu<sup>1</sup>, V. Brennan<sup>2</sup>, G. Cohen<sup>1</sup>, A. Damato<sup>1</sup>  
<sup>1</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA; <sup>2</sup>Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA

##### Purpose or Objective

To investigate differences in planning using images acquired using different acquisition techniques in US-based HDR prostate brachytherapy.

##### Material and Methods

We analyzed the records of 20 patients who received real-time transrectal ultrasound (US) guided interstitial high-dose-rate brachytherapy at our institution. For each patient, two sets of US images were acquired with a digital stepper immediately after treatment: transUS using the transversal US transducer, acquired by retracting the TRUS probe during image acquisition; twistUS using the longitudinal US transducer, acquired by rotating the TRUS probe during image acquisition. For all patients, measurement from the template to the connector-end of each needle were recorded and used for relative confirmation of needle tip identification. The DICOM plans were analyzed using MATLAB routines to assess catheter shift (average distances between reciprocal dwell source positions at transUS and twistUS after rigid registration between all dwell positions is performed). Catheters were digitized on the transUS and the twistUS and the identified tip positions were verified against a reference needles using the measurement data. A subset of 13 patient records was recontoured; contours were rigidly registered based on implant geometry. Difference in target volume and kappa statistics were calculated.

##### Results

The average  $\pm 1$  standard deviation of the number of needle tip adjustments per patients performed due to discrepancies with measured data was  $4 \pm 2$  for transUS and  $3 \pm 3$  for twistUS. Average of the distance between reciprocal dwell source position between transverse transUS and twistUS were  $0.12 \pm 0.04$  cm with a range of  $(-0.03 - 0.03)$  cm. Difference in Target volumes between transUS and twistUS were  $-1.8 \pm 7.8$  cm<sup>3</sup>.

##### Conclusion

Based on the number of adjustment required to match the physical measurement, physical measurements are required for both twistUS and transUS to accurately identify the needle tips. On average, the digitization geometry was similar using the two imaging techniques, although differences up to 3mm were observed in some cases. This may be due to deformation of the anatomy and implant geometry occurring during retraction of the probe in transUS acquisitions. Further analysis will be performed on more patients and dose distributions to validate these results, which suggest similar dose delivered to the target using both acquisitions.

#### EP-2147 Commissioning of a novel brachytherapy device for diffusive alpha-particle radiation therapy

A. Damato<sup>1</sup>, B. Beattie<sup>1</sup>, G. Cohen<sup>1</sup>, B. Serencsits<sup>1</sup>, L. Dauer<sup>1</sup>, J. Humm<sup>1</sup>  
<sup>1</sup>Memorial Sloan Kettering Cancer Center, Medical Physics, New York, USA

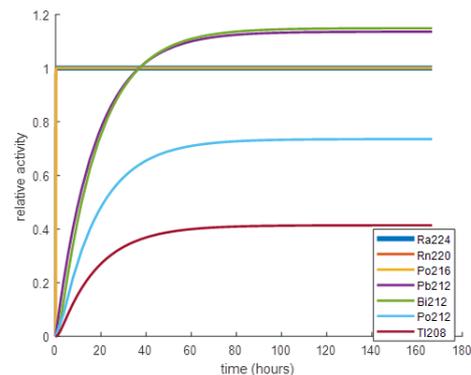

##### Purpose or Objective

To establish acceptance and commissioning of a novel brachytherapy device (DaRT, Alpha Tau Medical, Tel Aviv,

Israel) consisting of needles pre-loaded with stranded Ra224 sources. In the patient, each source delivers alpha radiation up to 3-6 millimeter in tissue through the diffusion of the daughter elements, emitted as a recoil from the source, and its progeny.

##### Material and Methods

Four devices were obtained, two "flex" (plastic catheters) devices, one with 3 sources and one with 6 sources; and two "needle" devices, one with 1 source and one with 3 sources. All sources were 1cm long. All devices were sealed against gas leaks at manufacturing and wrapped in sterile packages. The packages were tested upon arrival for contamination and leaks. A handheld Zinc Sulfide (ZnS(Ag)) detector and liquid scintillation counter, equipped with an alpha/beta discriminator, were used for the contamination survey. The gamma spectrum up to 2MeV of all devices were measured in their sterile packaging in a high purity Germanium detector (HPGe) and compared to the expected spectrum with equilibrium assumed (See Figure). Calibration of the HPGe was performed using a NIST calibrated Eu152 source with the same measurement geometry. Absolute calibration of the source activity was obtained from the 241 keV peak of Ra224, which was discriminated from the 238.6 keV peak of Pb212. Radiography of all devices was used to establish internal geometry and location of the active sources. Measurement of the devices in their sterile packaging in a well chamber was performed. The 1 source device was used to determine the sensitivity of the chamber (sweet spot), and correction factors were calculated based on the radiography measurements to account for geometry. Calibration factors were established using the HPGe absolute calibration.

##### Results

No contamination on the outer shipment packaging or inner shielding material was found. Preliminary measurements with an ionization chamber showed the external exposure rate on contact with the sealed sterile source packages to be 12.8 mR MBq<sup>-1</sup> hr<sup>-1</sup> for the metallic "needle" devices and 23.4 mR MBq<sup>-1</sup> hr<sup>-1</sup> for the plastic "flex" devices. Discrimination of the 238.6 keV and 241 keV peaks was possible using the HPGe. It was possible to visualize the sources inside the applicator and obtain a geometrical calibration factors for each type of device. Our measurements indicate that the use of a well chamber adds 1.8% uncertainty to source calibration when correction for geometry is used, and 2.5% otherwise.

##### Conclusion

Commissioning of this novel device is underway. A clinical protocol for routine source assay based in a standard well chamber has been established, using a HPGe measurements as reference. Absolute reference measurements will be performed at regular intervals.

**EP-2148 Brachytherapy on anal canal tumors**

C. Sousa<sup>1</sup>, M. Cruz<sup>1</sup>, K. Pereira<sup>1</sup>, A. Neto<sup>1</sup>, S. Gonçalves<sup>1</sup>, J. Brandão<sup>1</sup>, L. Khouri<sup>1</sup>, C. Alves<sup>2</sup>, P. Alves<sup>3</sup>

<sup>1</sup>Instituto Português de Oncologia de Coimbra, Radiotherapy, Coimbra, Portugal; <sup>2</sup>Instituto Português de Oncologia de Coimbra, Medical Physics, Coimbra, Portugal; <sup>3</sup>Instituto Português de Oncologia de Coimbra-Faculty of Medicine - University of Coimbra, Radiotherapy, Coimbra, Portugal

**Purpose or Objective**

Technological advancements in radiotherapy (RT) with improved volumetric conformation and accuracy of dose administration have resulted in better locoregional control (LCR) and lower toxicity. Brachytherapy (BT) is a technique that allows a greater dose escalation and can be used in combination with external RT to increase dosage in tumors of the anal canal, enabling the preservation of sphincter function and reducing the total treatment time. With this study, we intend to analyse the therapeutic approach and response to treatment of patients undergoing endorectal brachytherapy.

**Material and Methods**

Retrospective study of patients with anal canal tumors treated at our institution with endorectal high dose rate BT (HDR BT) with endocavitary applicator and Iridium-192 radioactive source, between 2008 and 2016. The toxicity evaluation was carried out according to the CTCAE4 and RTOG/EORTC scales. The response to therapy was assessed by clinical observation, imaging and histologically. Primary Endpoints: locoregional control (LCR), progression-free survival (PFS). Secondary Endpoint: overall survival (OS). Statistical analysis was performed using SPSS v20.

**Results**

We included 12 patients, all were female, with a median age of 67.5 (41-81) years; Histologically: 2 adenocarcinomas, 8 squamous carcinomas; As for the location of lesion and stage: 2 low rectal carcinomas, 1 stage I and 1 stage III; 10 anal canal carcinomas, 5 in stage I, 2 stage II, and 3 stage III; All patients had disease confined to  $\leq 50\%$  of the anal circumference, with 7  $\leq 25\%$ ; All tumors extension  $\leq 50$  mm, 9 with  $\leq 30$  mm and 1 with 50 mm; According to purpose of treatment, 9 patients under intensive, 2 patients in neoadjuvant and 1 in adjuvant intent; The main chosen chemotherapy regimen was MMC and 5-FU, concomitantly with external radiotherapy. 11 patients were subjected to external radiation, with the most frequent fractionation scheme 50.4Gy/28Fr/5.5weeks and dose increment by BT HDR endorectal, between 4.5 and 5Gy in a single fraction, on tumor volume; Concomitant treatment was well tolerated, with two major complications with need for treatment interruption: febrile neutropenia and herpetic lesions associated with G3 radiodermatitis; 10 patients obtained complete response and 2 partial response; The median follow-up time was 5.25 (1-9) years; 2 cases of disease progression have been reported, one in the liver, with a PFS of 47 months and 1 in a locoregional area with a PFS of 31 months. 3 colostomies were performed, 2 with abdominal-perineal amputation as treatment of rectal carcinoma and 1 in a palliative context due to locoregional recurrence. The median survival time was 8.7 years, with an overall survival of 77% at 5 years.

**Conclusion**

This type of malignant tumors with low incidence should be treated in centers with an experienced and differentiated team, allowing better results and control of the correlated morbidity. These results are in agreement with published literature. BT in association with external RT provides better LCR, allowing the preservation of sphincter function and better quality of life.

**Electronic Poster: Brachytherapy: Prostate****EP-2149 HDR brachytherapy as monotherapy for low and intermediate risk prostate cancer**

M. Gaudet<sup>1,2</sup>, M. Pharand-Charbonneau<sup>2</sup>, D. Wright<sup>2</sup>, M. Desrosiers<sup>2</sup>, A. Haddad<sup>1</sup>

<sup>1</sup>The Ottawa Hospital, Radiation Oncology, Ottawa, Canada; <sup>2</sup>Centre Intégré et de Services Sociaux de l'Outaouais, Radio-Oncologie, Gatineau- QC, Canada

**Purpose or Objective**

To determine biochemical disease-free survival, late toxicity and effect on health-related quality of life of a 2-fraction regimen of high dose-rate (HDR) brachytherapy for the treatment of prostate cancer.

**Material and Methods**

Patients with low or intermediate risk prostate cancer eligible for prostate brachytherapy were treated with HDR brachytherapy as monotherapy in 2 separate implants of 13.5 Gy spaced 7-14 days apart in a prospective REB-approved phase II clinical trial (NCT02077335). HDR brachytherapy was done with a CT-based planning with a template or freehand implant technique based on patient anatomy and prostate volume. Patients had evaluation with International Prostate Symptom Score (IPSS) and Expanded Prostate Index Composite (EPIC) questionnaires and serum PSA at 1,3,6, 9, 12, 16, 20, 24, 30, 36, 48 and 60 months post brachytherapy. Proportion of patients in each IPSS category (Mild=0-7, Moderate=8-18, Severe=19+) were evaluated at each of the intervals above. Paired t-tests with baseline values were done for IPSS and EPIC urinary, sexual, intestinal and hormonal domains. Biochemical disease-free survival was determined according to Phoenix criteria (Nadir + 2.0 ng/ml) and Kaplan-Meier method.

**Results**

30 patients were accrued to the study between June 2014 and February 2016. Median age was 66 (Range 54-82). Median PSA at diagnosis was 8,7 (Range 4.1-17.5). T stage was T1c=65%, T2a=21%, T2b=14%. 27% had Gleason 6 and 73% Gleason 7. Mean prostate volume at time of first implant was 45cc. IPSS categories at baseline, 6, 12 and 24, 36 and 48 months were respectively Mild(81%, 63%, 76%, 65%, 67%, 50%) Moderate (19%, 29%, 20%, 29%, 22%, 50%) and Severe (0%, 7%, 4%, 6%, 11%, 0%). There was a significant decrease in EPIC Sexual Summary Scores at 6 and 12 months with mean intra-patient differences of -18 points (p=0.02) and -17 points (p=0.01) respectively. Biochemical disease-free survival at 4 years was 94,7%. Median PSA (ng/ml) at 12, 24, 36 and 48 months were respectively 0.7, 0.3, 0.3 and 0.1. Overall survival at 4 years was 100%

**Conclusion**

This is the first report of biochemical disease-free survival in this cohort of patients treated with 2 fraction HDR monotherapy. This regimen shows rates of toxicity and health related quality of life that appear acceptable as compared to other treatment modalities. These results are also comparable with other reports with similar treatment regimens. Further study will be required to determine longer-term results of this cohort which can help guide determination of the optimal dose and fractionation for HDR prostate monotherapy.

**EP-2150 Re-salvage treatment for locally recurrent prostate cancer by HDR brachytherapy guided by MRI and US**

A. Garcia Perez<sup>1</sup>, P. Willisch Santamaria<sup>2</sup>, M. Martinez Agra<sup>2</sup>, A. Gonzalez Castro<sup>3</sup>, B. Andrade Alvarez<sup>1</sup>, E. Cespon Outeda<sup>1</sup>, A. Lopez Medina<sup>1</sup>, M. Salgado Fernandez<sup>1</sup>, V.M. Muñoz Garzon<sup>2</sup>

<sup>1</sup>Hospital Meixoeiro, Radiofísica y PR, VIGO, Spain;

<sup>2</sup>Hospital Meixoeiro, Radioterapia, Vigo, Spain; <sup>3</sup>Hospital

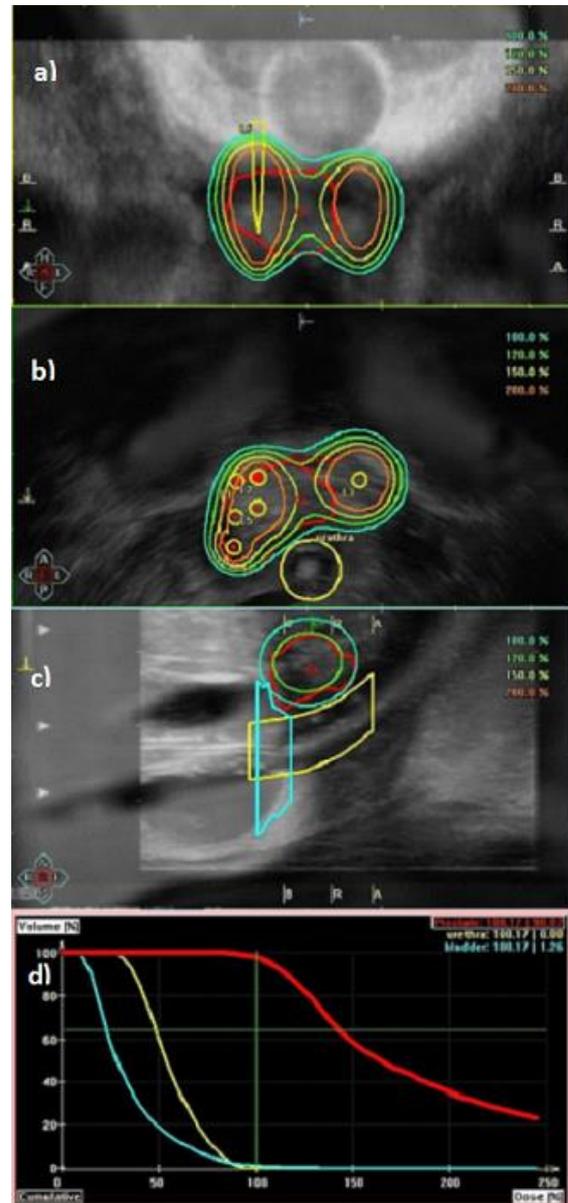

Universitario de Burgos, Radioterapia, Burgos, Spain;  
 4Hospital Meixoeiro, Urologia, Vigo, Spain

#### Purpose or Objective

Salvage IMRT is well established for recurrence of prostate cancer after radical prostatectomy. With the improvement in early diagnostics and the increase in survival it is possible to observe second local or distant recurrences, and hormonal therapy is the most common treatment in these cases. One challenge in patients with local recurrence is to delay the hormonal treatment and it can be achieved by re-salvage brachytherapy. In 2016 we started focal re-salvage high-dose-rate brachytherapy (HDR-BT) guided by MRI, registered with US [1,2], that is a novel treatment that minimizes side-effects. We describe the procedure carried out to our patients, evolution of the prostate specific antigen (PSA), and related toxicity.

#### Material and Methods

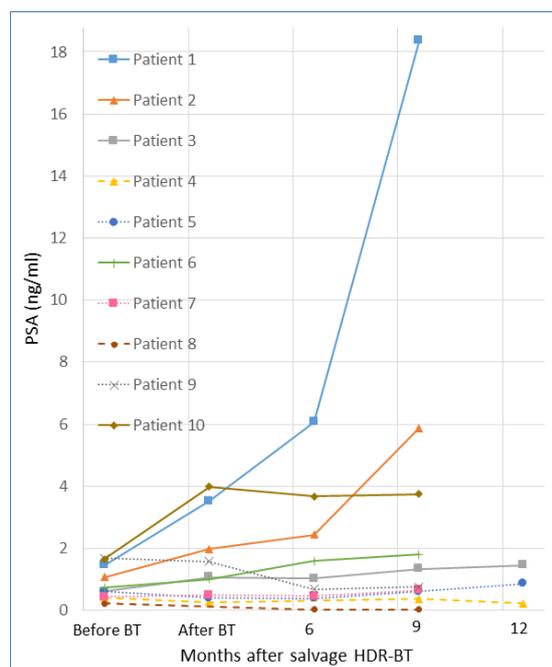

Ten patients were treated by focal HDR-BT because of a second local recurrence after undergoing radical prostatectomy and IMRT for primary recurrent prostate cancer. The mean age of the patients was 66,9 years (52-77). Dose prescription was 17 Gy for 6 patients and 20 Gy for 3 patients, given in two fractions. Delineation was performed using 1,5T MRI (T2-weighted) registered with US obtained by a transrectal probe. In order to reduce dose to rectum, hyaluronic acid was injected between rectum and target volume. Optimization (Figure 1) of the plan was performed by Oncentra Prostate® (Elekta) and based on the following constraints: CTV  $V_{100}$ : 95%,  $D_{90}$ : 100%,  $D_{min}$ : 80%; Urethra  $V_{120}$ : 0 cm<sup>3</sup>. Treatment was delivered by MicroSelectron HDR (Elekta). PSA was evaluated before and after treatment, and periodically every three months, and a follow-up consultation was carried out after each PSA evaluation.

**Figure 1.** a) Coronal plane, b) transverse plane and c) sagittal plane showing delineations of the PTV, urethra and bladder, the reconstructed catheters and the isodose curves on the MRI-US registered images. d) Cumulative DVH.

#### Results

Average dosimetric parameters after optimization were: CTV  $V_{100}$ : 98,0%,  $D_{90}$ : 118,1%,  $D_{min}$ : 84,5%; urethra  $V_{120}$ : 0 cm<sup>3</sup>;  $V_{100}$ : 2,53 cm<sup>3</sup>. With a follow-up of 12 months, 7 patients do not show any side effects, 2 patients have urethral stricture and one had haematuria. PSA values for all patients are shown in Figure 2. 3 patients had stable values of PSA and 2 patients showed PSA <0,2. PSA after treatment increased in 5 patients because of new local recurrences in other localizations (3 patients), or metastatic nodes (1 patient), or unknown cause (1 patient) and were treated with hormonal therapy (7-17 months delay).

**Figure 2.** Prostate-specific antigen values of all 10 patients. Solid line: patients with biochemical recurrence. Dotted line: patients with stable values of PSA. Dashed line: patients that show PSA<0.2.

### Conclusion

Re-salvage for locally recurrent prostate cancer by focal HDR-BT guided by MRI-US is feasible and can be offered to patients as low-toxicity local treatment. Even in those cases where it does not represent a definitive cure, it can delay hormonal therapy. Therefore, we consider this technique to be recommended especially in patients with a long life expectancy.

### EP-2151 Intermediate-risk prostate cancer with EBRT plus permanent 125-I seeds. Long term results

M. Peña<sup>1</sup>, J. Guinot<sup>1</sup>, R. Roncero<sup>1</sup>, B. Quiles<sup>1</sup>, P. Santamaria<sup>1</sup>, M.A. Santos<sup>1</sup>, C. Boso<sup>2</sup>, J.C. Sanchez-Relucio<sup>2</sup>, M.I. Tortajada<sup>1</sup>, L. Arribas<sup>1</sup>

<sup>1</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Oncology, Valencia, Spain;

<sup>2</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Physics, Valencia, Spain

### Purpose or Objective

To present long-term results in patients with intermediate-risk prostate carcinoma treated with combined treatment with external beam radiotherapy (EBRT) plus low dose brachytherapy with 125-I seeds.

### Material and Methods

From April 2008 to December 2010, 51 patients with intermediate risk prostate carcinoma according to EAU guidelines (T2b-c, Prostate Specific Antigen-PSA- between 10 and 20ng/ml or Gleason 7), underwent EBRT on prostate and seminal vesicles to a mean of 46Gy. In the next 3-4 weeks they received the permanent implantation of 125-I seeds, to a median dose of 108Gy, with real-time dosimetry planning and Bard ProLink™ system. Hormonal treatment (HT) was prescribed to 31% during 3-6 months.

Biochemical failure (BF) was considered according to Phoenix definition.

### Results

Mean age was 67, mean PSA was 9.34ng/ml (4.31-18.3) and Gleason score was 6 in 37.3% patients, 7 (3+4) in 45.1% and 7(4+3) in 17.6%. Clinical tumour stage was T1c in 51%, T2a in 27.5%, T2b in 11.7% and T2c in 9.8%. With a median follow-up of 99 months (range 24-124), 5 cases (9.8%) presented BF. Biochemical relapse free survival (bRFS) at 5 and 8 years was 98% and 89.3%. No differences according to Gleason (G), PSA, clinical T stage or HT. At 8 years, patients with Gleason 6 had bRFS of 94.7%, G7 (3+4) 89.5%, G7 (4+3) 75% (p=0.27). When we classify the risk of patients with Mount Sinai Criteria (intermediate or high), we appreciate differences in PSA control at 8 years, 94.3% vs 75% (p<0.06). Late genitourinary G1-G2 toxicity was observed in 9.8%, G3 in 5.8% (3 patients required Transurethral Resection (TURP). Late gastrointestinal G1-G2 toxicity was observed in 9.8%, G3 0%.

### Conclusion

Combined treatment in intermediate-risk prostate carcinoma offers good results on PSA control with low rates of late toxicity. The presence of several intermediate criteria marks a trend to worse results.

<sup>2</sup>Instituto de Cancerología - Clínica las Américas, Radiation Oncology, Medellín, Colombia; <sup>3</sup>Instituto Nacional del Cancer, Radiation Oncology, Santiago de Chile, Chile; <sup>4</sup>Oncosalud - AUNA, Statistics and Traslational Investigation, Lima, Peru

### Purpose or Objective

Our main goal is to describe a useful technique to decrease rectal dose during high dose rate (HDR) prostate brachytherapy given either as boost or monotherapy, Evaluated in a multicentric initial Latin American first experience from Peru, Chile and Colombia using a blood patch as OAR spacer, as an alternative procedure to improve rectal toxicity in developing countries with limited resources.

### Material and Methods

60 patients, underwent HDR prostate brachytherapy in multiple institutions. Under spinal anesthesia and sedation, approximately 16 mL of blood was extracted from the patient via antecubital venopuncture and mixed with 4 ml of iodine venous contrast as the technique firstly described in 2008 by Morancy from Boston For prostate LDR brachytherapy.

The perineum was prepared for a sterile procedure. Under ultrasound guidance, an 18 gauges spinal needle was placed to open the space below the denonvilliers fascia for hydro-dissection, after the volume of blood was then instilled within the peri-rectal space on each side, as the needle was withdrawn, using the sagittal ultrasound image for guidance as the technique described by Hatiboglu in 2012 in Heidelberg.

After creation of the blood patch, a standard needle insertion to the prostate is performed under US guidance, followed by CT Simulation and then MR fusion is performed for treatment planning. The prescribed dose to PTV in monotherapy is 20.5 Gy and as Boost to EBRT is 15 Gy.

### Results

Patients median age were 71, volume most of them between 20-60 cc, stage II and III intermediate and high risk, Blood Patch was successfully apply in 60 patients, the other 9 are controls without blood patch. It's remarkable that the use of in vivo dosimetry to compare the dose

calculated in the TPS and the dose measured in vivo with over 98% of correlation among them. The blood patch thickness will decrease in 50% in 10 to 15 days after the application. All the rectal dose parameters above the V20 - V80 were significantly improved by the blood patch, also the Dmax and it was correlated with the homogeneity of the blood patch application, V5-V10 weren't significant because these isodoses are 5 to 6 cm far from target. The average pre rectal space obtained was 0.83 cm. The dosimetric potential advantages with the blood patch are that, the mean dose to 0.1 cc of rectum was limited to 57.4% and mean dose to 2 cc of rectum was 40%, also parameters such as D90 and V100 were significantly improved.

#### Conclusion

The use of a blood patch can reduce the integral radiation dose to the rectum and may help to decrease the amount of possible acute and late rectal toxicities due to prostate HDR brachytherapy procedure, letting us to do a safe dose escalation treatment in order to improve outcomes. This technique could be particularly beneficial in patients with minimal peri-rectal fat, appearing to be a cost-effective way to improve outcomes in developing countries with limited resources.

#### EP-2153 Late toxicity after single dose HDR-BT and EBRT for prostate cancer: clinical-dosimetric predictors

D. Büchser<sup>1</sup>, F. Casquero<sup>1</sup>, J.M. Espinosa<sup>1</sup>, F. Perez<sup>1</sup>, P. Minguez<sup>1</sup>, L. Martinez-Indart<sup>2</sup>, F. Suarez<sup>1</sup>, A. Gonzalez<sup>1</sup>, J. Cacedo<sup>1</sup>, I. San Miguel<sup>1</sup>, P. Bilbao<sup>1</sup>, A. Gomez-Isturriaga<sup>1</sup>

<sup>1</sup>Hospital de Cruces, Radiation Oncology, Baracaldo-Vizcaya, Spain; <sup>2</sup>Hospital de Cruces, Bioinformatics and Statistics Department, Baracaldo-Vizcaya, Spain

#### Purpose or Objective

To describe the genitourinary (GU) and gastrointestinal (GI) late toxicity profile and to analyse the clinical and dosimetric predictive factors in a prospective trial of the combination of EBRT and high-dose-rate (HDR) prostate brachytherapy (BT) for localized prostate cancer.

#### Material and Methods

Between January 2012 and May 2017, 210 patients were included in a prospective protocol. Treatment consisted in HDR-BT (15Gy single fraction) and supplemental 3DCRT (37.5Gy/15 fractions) +/- androgen deprivation therapy according to risk stratification. Exclusion criteria included previous pelvic radiotherapy and pubic arch interference. Acute and late urinary complications were assessed using the CTCv4.0 definition.

A descriptive analysis was performed. Univariate and multivariate logistic regression was used to analyse the impact of these variables into late toxicity. All variables with a P value <0.15 in the univariate analysis were selected and included in the stepwise selection procedure of the multivariate analysis. In this last analysis, a P value <0.05 was considered statistically significant. A Hosmer-Lemeshow test and receiver-operating characteristic analysis was performed to calculate area under the receiver operator curve (ROC) (AUC) to compare strength of predictors.

#### Results

Median age was 71 (56-82), 12.4% of patients had low, 44.3% intermediate and 41% high-risk prostate cancer. Median prostate volume was 28.4cc. Median V100, V150, V200 were 98.2%, 27% and 7.4% respectively. Median urethra Dmax, rectum D1cc and D2cc, were 113.5%, 62.2% and 54.2% respectively.

After a median follow-up of 41 months (5-75) late G2 GU and GI late toxicity was observed in 14.8% and 5.2% of patients respectively. Late G3 GU and GI toxicity occurred in 0% and 1% of patients respectively. No grade 4 or 5 events were recorded.

Out of the 31 patients with G2 events, 21 had a resolution of their symptoms by the time the current analysis was

performed. Median time to the development of G2 GU toxicity was 13.5 month (3-63.6). The median duration of G2 events was 8.3 months (3.6-30.6).

Of the 13 patients presenting with G<sub>≥2</sub> GI toxicity, 10 were free of toxicity by the time of the current analysis. Median time to the development of G<sub>≥2</sub> GI toxicity was 11 months (3-44.2). The median duration of the events was 6 months (0.2-9.5).

In univariate analysis, no variable studied was associated with late G<sub>≥2</sub> GU toxicity, whereas previous cardiovascular disease (p=0.042), rectum D2cc (p=0.016) and rectum D1cc (p=0.017) were associated with G<sub>≥2</sub> GI toxicity. Multivariate analysis showed that rectum D1cc (HR11.56; 95%CI 1.4-92.1; p=0.021) and prior history of cardiovascular disease (HR3.6; 95%CI 1-12.9; p=0.045) remained independent predictors of G<sub>≥2</sub> GI toxicity.

#### Conclusion

Single fraction 15Gy HDR-BT and hypofractionated EBRT is well tolerated with low incidence and prevalence of late GU and GI toxicity. Lower rectal D1cc doses may reduce GI toxicity.

#### EP-2154 Efficacy of LHRH agonist-free cytoreduction prior to prostate seed brachytherapy

N. Wallace<sup>1</sup>, A.M. Peoples<sup>1</sup>, S.J. O'Brien<sup>1</sup>, P.J. Kelly<sup>1</sup>  
<sup>1</sup>Cork University Hospital, Radiotherapy Department, Cork, Ireland

#### Purpose or Objective

Our institutional practice for patients planned for prostate brachytherapy is to first perform a TRUS volume study to assess for technical feasibility. For patients who are unsuitable due to a large gland size or pubic arch interference (PAI), cytoreduction with androgen-deprivation therapy may convert patients to suitability for brachytherapy. In an effort to spare patients the known side effects of LHRH agonists, particularly erectile dysfunction, we have adopted bicalutamide 50mg once daily combined with dutasteride 0.5mg once daily for 12 weeks as described by Gaudet et al in Radiotherapy and Oncology in 2016.

The purpose of this retrospective review was to establish the efficacy of this regimen in converting patients to suitability for a prostate seed implant.

#### Material and Methods

We treated 36 patients who were deemed unsuitable for brachytherapy based on their large gland volume and/or the presence of pubic arch interference at the time of their pre-treatment TRUS assessment. Patients received a combination of dutasteride and bicalutamide for 12 weeks. We repeated the TRUS for each patient after 12 weeks of therapy to assess for the presence of PAI, gland volume and whether the patient had become suitable for treatment with brachytherapy.

The data was collected prospectively at the time of the volume studies and analysed retrospectively.

#### Results

The median pre-cytoreduction prostate gland volume was 53.5cc (IQR 47-60cc). The median prostate volume after 12 weeks of dual agent cytoreductive therapy was 38cc (IQR:35-42cc). The median reduction in gland size was 29.0% (IQR 25-36.2%).

33 out of 36 patients (91.7%) had PAI on initial TRUS. Of those individuals with initial PAI, 13/35 (37.1%) had persistent PAI post cytoreduction and one had an obstructive pattern on uroflow studies so was not a suitable candidate. Of the 13 patients with persistent PAI post cytoreduction 9 were felt unsuitable to proceed to implant.

Overall, 26/36 (72.2%) were suitable candidates for brachytherapy following 12 weeks of cytoreductive therapy

#### Conclusion

The percentage of our patients who converted to suitability for brachytherapy following LHRH-free

cytoreduction is similar to those described previously in the literature. It is also comparable to those who report conversion to suitability using LHRH agonists, albeit with a more favourable side effect profile.

#### EP-2155 Optimising HDR Prostate Implant, Planning and delivery. A new centre experience

R. Farrell<sup>1</sup>, S. Jain<sup>1</sup>, P. Shiels<sup>1</sup>, G. Workman<sup>1</sup>, K. Crowther<sup>1</sup>, D. Mitchell<sup>1</sup>

<sup>1</sup>Belfast Health and Social Care Trust- City Hospital, Radiotherapy Department, Belfast, United Kingdom

#### Purpose or Objective

High dose rate prostate Brachytherapy (HDR) is a well-established method of dose escalation in combination with external beam radiotherapy (EBRT) and research in its use as a monotherapy continues.

Having optimised our permanent seed prostate brachytherapy pathway over 500 cases, we wished to prospectively review the HDR pathway from its implementation at our centre. The goal was to minimize anaesthetic time, optimise ultrasound-based planning and improve patient throughput.

#### Material and Methods

Following formal training, mentoring and development of all departmental policies, procedures, work instructions and treatment pathways, 19 steps were identified on the pathway from patient admission to theatre to discharge from recovery. A supernumerary therapeutic radiographer prospectively documented the time for each task and following the initial 10 cases a multi-disciplinary meeting was held to identify potential areas where time could be saved. This process was repeated to the point where procedural times were consistent and no further significant time gains were identified.

#### Results

To date 66 patients have been treated with HDR brachytherapy for prostate, 55 combination cases with External beam radiotherapy and 11 salvage or monotherapy treatments.

At the Plan, Do, Study, Act, (PDSA) review of the initial 10 cases, several tasks including pre-implant contouring and planning catheter position were felt to be unnecessary duplication and a standardised 'template' coordinate implant was adopted. Subsequent cohorts clarified dose constraint objectives and defined methods of prioritising dose to target volumes. When required, second check verification was moved to be a parallel process at each task rather than serially.

By the 30<sup>th</sup> case our procedure time had reduced from 280mins to 175mins, reduction in overall treatment time of 37.5%. Adoption of identified changes in initial implant procedure resulted in 52% reduction in time, from the average of 69mins (1<sup>st</sup> 10 cases) to 33mins (11<sup>th</sup>-30<sup>th</sup> case), from probe insertion to grid locking and hence commencement of planning.

Additional reviews of time for catheter reconstruction (simplified to a maximum of 4 waypoints along catheter length) and reduction in the number of treatment checks by radiographers saw a further improvement in procedure time, a reduction of 29% was gained from these changes in the process between the grid locking and treatment start, average of 129mins in the 1<sup>st</sup> cohort compared to 92mins 2<sup>nd</sup>.

#### Conclusion

This time and motion study has reduced overall anaesthetic exposure and improved theatre capacity for our HDR cases. We continue to see a reduction in overall treatment time and frequent PDSA reviews highlight any further issues thus ensuring we improve the overall patient experience.

#### Electronic Poster: Brachytherapy: Miscellaneous

#### EP-2156 Assessment of Role of ILRT as palliative treatment in advanced esophageal cancer

V. Pareek<sup>1</sup>, R. Bhalavat<sup>1</sup>, M. Chandra<sup>1</sup>

<sup>1</sup>Jupiter Hospital, Radiation Oncology, Mumbai, India

#### Purpose or Objective

This study aims to assess the improvement in dysphagia, associated complications and overall and disease-free survival with intraluminal brachytherapy (ILRT) as palliative care in advanced esophageal cancer

#### Material and Methods

Thirty-four patients were treated with high dose rate ILRT with or without external radiation therapy from 2009 to 2017 at our institute. Patients were assessed for various parameters including disease stage, length of lesion, KPS and as per grade of dysphagia at presentation. The patients received median dose of 6Gy at 1 cm off axis for 2 fractions one week apart. Fourteen patients were treated radically and 20 patients post EBRT. Multivariate analysis was used to assess the predictors for dysphagia improvement. Remissions of dysphagia and other clinical and radiological factors were assessed in the first month post-treatment, and then in the third, sixth, and twelfth months. The survival rate was compared with some chosen clinical factors using a log-rank test and the Kaplan-Meier method.

#### Results

Patients were followed up as per standard institute protocol. Median dysphagia free survival was 12 months. Stricture was seen in 3 patients and ulceration noted in another 2 patients. However, no tracheoesophageal fistula or procedure related complications were noted. Complications were seen with the post EBRT group. The overall survival in the cohort was 12 months and was better post EBRT as compared to radical ILRT ( $p < 0.001$ ). On multivariate analysis, stage of disease ( $p = 0.02$ ), size of lesion ( $p = 0.018$ ) and grade of dysphagia ( $p = 0.023$ ) were found to be predictors for improved outcomes with use of ILRT in palliation.

#### Conclusion

Brachytherapy in the form of ILRT in advanced esophageal cancer provides good palliation with minimal complications and improved survival and quality of life to patients.

#### EP-2157 Needle-based stepping source electronic brachytherapy - a feasibility study

A.M. Ruder<sup>1</sup>, L. Inghelram<sup>1</sup>, F. Schneider<sup>1</sup>, Y. Abo-Madyan<sup>1</sup>, M. Ehmann<sup>1</sup>, J. Hesser<sup>1</sup>, F. Wenz<sup>1</sup>, F. Giordano<sup>1</sup>

<sup>1</sup>Universitaetsklinikum Mannheim, Klinik für Radioonkologie und Strahlentherapie, Mannheim, Germany

#### Purpose or Objective

Electronic needle-based kilovolt (kV) brachytherapy (eBT) may resemble an economic alternative to multi-catheter (HDR) and permanent seed implantation (PSI) brachytherapy. We have evaluated whether tumors treated with seed implants would have been suitable for electronic brachytherapy.

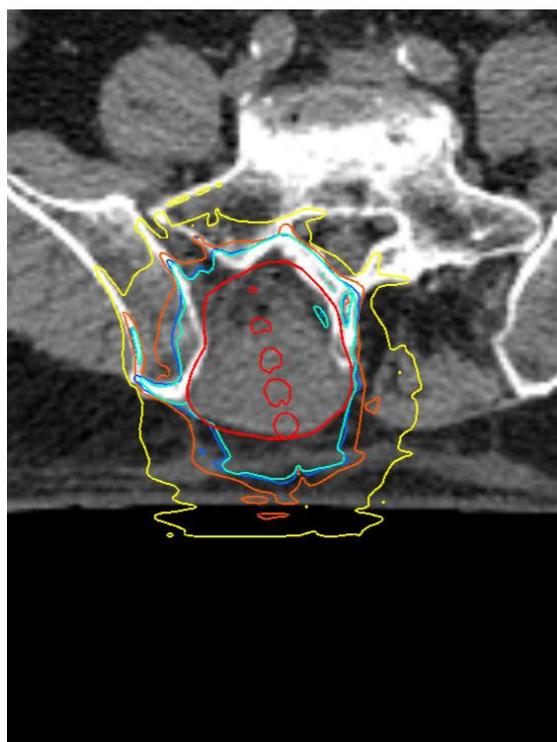

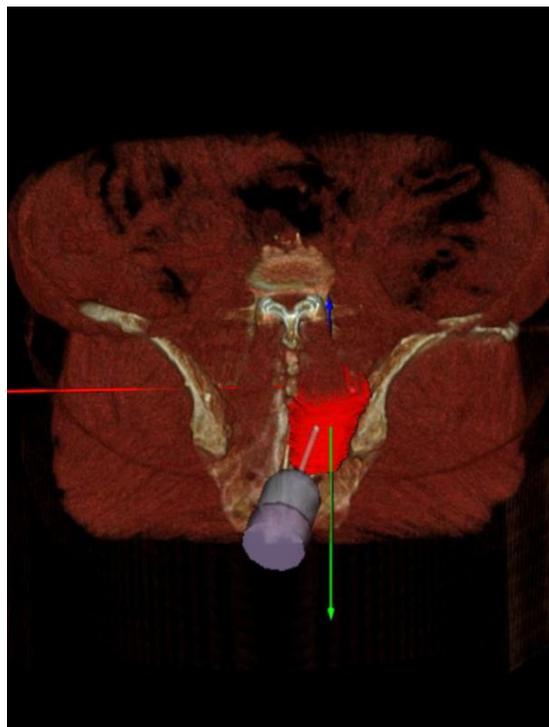

#### Material and Methods

N=5 post-interventional CT studies of patients who had received PSI with <sup>125</sup>I seeds in tumors were used as templates for planning. We then simulated treatment with a needle applicator (length = 94 mm) of a kilovoltage x-ray system (INTRABEAM, Carl Zeiss Meditec AG) using a dwell point stepping (DPS) approach. For planning the dwell points, an algorithm for kV-dose distribution in tissue of various density was used (Radiance®, GMV Innovating Solutions S.L., Madrid). For dose summation, Radiance dosimetry files were transformed and imported

into Velocity (Varian Medical Systems Inc., USA) for forward planning. DPS dose distributions achieved with eBT were then compared to those achieved with PSI.

#### Results

The total number of dwell points for eBT per patient ranged from 2 to 15. In all patients, dose coverages achieved with eBT were similar to the prescribed doses with those obtained in PSI. Dose constraints (e. g. D10, D1cc, Dmax) for organs at risk were met in all patients. The number of trajectories needed for adequate coverage was lower with eBT compared to PSI.

#### Conclusion

eBT with a DPS approach was feasible for tumors initially treated with PSI.

#### EP-2158 The Apoptosis Mechanism and Injury of Heavy Ion Beam and X-ray Radiation on Malignant Melanoma Cell

S. Li<sup>1</sup>, Q. Jin<sup>1</sup>, Z. Chao<sup>1</sup>, G. Dong-Wei<sup>2</sup>, L. Qiang<sup>3</sup>, Z. Hong<sup>4</sup>, J. Xiao-Dong<sup>3</sup>, L. Yang<sup>4</sup>

<sup>1</sup>Lanzhou General Hospital of PLA, Radiotherapy, Lanzhou, China; <sup>2</sup>Northwest Normal University, Biology, Lanzhou, China; <sup>3</sup>Modern Physics- Chinese Academy of Sciences, Medical Physics, Lanzhou, China; <sup>4</sup>Modern Physics- Chinese Academy of Sciences, Radiation Medicine, Lanzhou, China

#### Purpose or Objective

This study aims to investigate the influence of high LET heavy ion ( $^{12}\text{C}^{6+}$ ) and low LET X-ray radiation on apoptosis and related proteins of malignant melanoma on tumor-bearing mice under the same physical dosage.

#### Material and Methods

C57BL/6J mice were burdened by tumors and randomized into three groups. These mice received heavy ion ( $^{12}\text{C}^{6+}$ ) and X-ray radiation under the same physical dosage, respectively; and their weights and tumor volumes were measured every three days post-radiation. After 30 days, these mice were sacrificed. Then, median survival time (MST) was calculated and tumors on mice were proliferated. In addition, immunohistochemistry was carried out for apoptosis-related proteins to reflect the expression level.

#### Results

After tumor-bearing mice were radiated by heavy ion, MST improved and tumor volume significantly decreased in conjunction with the upregulated expression of pro-apoptosis factors, Bax and Cytochrome C, and the downregulated expression of apoptosis-profilin (Bcl-2, Survivin) and proliferation-related proteins (PCNA). Results indicated that radiation can promote the apoptosis of malignant melanoma cells and inhibit their proliferation. This case was more suitable for heavy ion ( $^{12}\text{C}^{6+}$ ).

#### Conclusion

High LET heavy ion ( $^{12}\text{C}^{6+}$ ) radiation could significantly improve the killing ability for malignant melanoma cells by inducing apoptosis in tumor cells and inhibiting their proliferation. These results demonstrated that heavy ion ( $^{12}\text{C}^{6+}$ ) presented special advantages in terms of treating malignant melanoma.

#### EP-2159 Influence of L-Dopa pretreatment on cellular features in T98G cells

A. Facchetti<sup>1</sup>, C. Aprile<sup>2</sup>, M. Cavagnini<sup>1</sup>, M. Ciocca<sup>3</sup>, A. Iannalfi<sup>2</sup>, L. Lodola<sup>4</sup>, M. Marengo<sup>4</sup>, R. Nano<sup>5</sup>, F. Pasi<sup>6</sup>, M.G. Persico<sup>7</sup>, F. Valvo<sup>2</sup>, R. Orecchia<sup>8</sup>

<sup>1</sup>Fondazione CNAO, Radiobiology Unit, Pavia, Italy; <sup>2</sup>Fondazione CNAO, Radiation Oncology, Pavia, Italy; <sup>3</sup>Fondazione CNAO, Medical Physics Unit, Pavia, Italy; <sup>4</sup>Fondazione IRCCS Policlinico San Matteo, Struttura Complessa di Medicina Nucleare, Pavia, Italy; <sup>5</sup>Università degli Studi di Pavia, Dipartimento di Biologia e Biotecnologie "L. Spallanzani", Pavia, Italy; <sup>6</sup>Fondazione IRCCS Policlinico San Matteo, Struttura Complessa di Radioterapia, Pavia, Italy; <sup>7</sup>Università degli Studi di Pavia, Scuola Universitaria Superiore IUSS,

Pavia, Italy ; <sup>8</sup>Fondazione CNAO- Istituto Europeo di Oncologia, Radiation Oncology, Pavia- Milano, Italy

### Purpose or Objective

Recently, a role of L-Dopa for the diagnosis and treatment of glioblastoma has been hypothesized. Four hours pre-load with L-Dopa has been previously reported to increase incorporation of BPA (boron-phenyl-alanine) in tumors both in vivo and in vitro, likely activating the LAT system and thus increasing the efficacy of BNCT (Boron Neutron Capture Therapy). This approach looks very appealing because in theory it could be employed to increase the tumor accumulation of <sup>18</sup>F-DOPA in PET diagnostics or of the <sup>11</sup>B substrate in BPCT (Boron Proton Capture Therapy). In light of these experimental applications, the aim of this study was to assess the effects of pretreatment with L-Dopa on the biological behavior of human T98G cells, a chemo/radioresistant glioblastoma cell line.

### Material and Methods

Briefly, 4-hour pretreatment with 50 µg/mL or 100 µg/mL of L-Dopa can influence the morphology, the growth rate, the ability to form colonies, and the migratory capacity of T98G cell in exponential growth, in basal conditions and after carbon ion irradiation (2 and 4 GyRBE). Statistical analysis has been performed with ANOVA and paired t test.

### Results

After L-dopa pretreatment cells show a lower tendency to aggregate and a round-like pattern. Recovery of the scratched area was significantly faster and higher by T98G cells pretreated cells. Boyden Chamber test confirmed enhanced migration of the treated cells. Carbon ions irradiation increases the migratory efficiency either at 15 and 24 hours.

### Conclusion

The results show that L-Dopa induced significant changes in T98G cells behavior. These aspects have been never previously evaluated and open further questions about real utility of L-Dopa pre-load in BNCT and indicate a lack of experimental data for a possible application in PET with FDOPA and BPCT.

### Electronic Poster: Radiobiology track: Radiation-induced signalling pathways

#### EP-2160 Downregulation of Nrf2 promotes radiation-induced apoptosis in non-small cell lung cancer cells H. Zhang<sup>1</sup>

<sup>1</sup>Institute of Modern Physics- Chinese Academy of Sciences, Department of Radiation Medicine, Lanzhou, China

### Purpose or Objective

The nuclear factor erythroid-2-related factor 2 (Nrf2) is a crucial regulator of the cellular antioxidant system. Nrf2 is often constitutively activated in non-small cell lung cancer (NSCLC) cell lines, which promotes cytoprotection against oxidative stress and xenobiotics. Notch1 signaling is critically implicated in cell fate determination. It has been reported that Nrf2 strongly regulates Notch1 activity. However, the role of Nrf2 mediated Notch1 signaling in response to ionizing radiation (IR) remains elusive. We report that knockdown of Nrf2 promotes radiation-induced apoptosis through Nrf2 mediated Notch1 signaling in NSCLC cells.

### Material and Methods

The human lung cancer cells (A549, NCI-H1299 (H1299), NCI-H460 (H460)) were exposed to ionizing radiation at room temperature using Faxitron RX-650 X-rays (Faxitron Bioptics, LLC, USA). The dose rates were 0.765 Gy/min. siRNA against Nrf2, Notch1 and non-targeting negative control siRNA were purchased from Invitrogen (Invitrogen Life Technologies, Carlsbad, CA, USA).

Real-time fluorescent quantitative PCR assay the level of Nrf2 and Western blot to analyze the Nrf2, GCLC, HO-1, NQO1, Bax, Bcl-2. Cells were treated with siRNA-Nrf2 before X-irradiation (4 Gy) and incubated for 24 h. After staining with anti-Nrf2 antibody and Alexa Fluor 647-conjugated secondary antibody and were visualized under a fluorescence microscope. Immunofluorescence staining for Notch1 in A549 cells, Alexa Fluor 647-conjugated secondary antibody and nuclei were counterstained with DAPI.

### Results

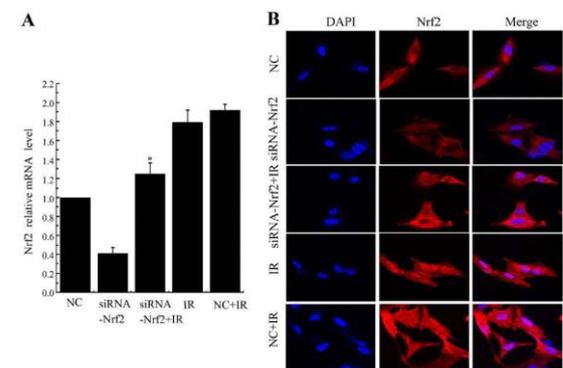

Figure 1. IR-induced nuclear translocation of Nrf2 is suppressed by siRNA-Nrf2 in A549 cells. (A) mRNA levels of Nrf2 at 24 h after 4 Gy of X-ray irradiation. (B) Cells were treated with siRNA-Nrf2 before X-irradiation (4 Gy) and incubated for 24 h. After staining with anti-Nrf2 antibody and Alexa Fluor 647-conjugated secondary antibody (red) and DAPI for nuclear staining (blue), cells were visualized under a fluorescence microscope. \* $p < 0.05$  versus NC+IR group.

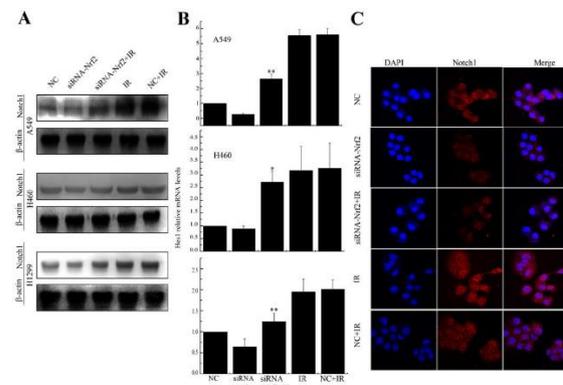

Figure 2. Expression of Notch1 and related gene in the knockdown of Nrf2 cells. (A) Quantification of protein expression. (B) Hes1 mRNA levels were measured by quantitative RT-PCR. (C) Immunofluorescence staining for Notch1 in A549 cells. \* $p < 0.05$  and \*\* $p < 0.01$  versus NC+IR group.

### Conclusion

- 1) Nrf2 is induced by ionizing radiation in A549 cells
- 2) Knockdown of Nrf2 decreases radiation-upregulated Nrf2 in A549 cells.
- 3) Knockdown of Nrf2 decreased Notch1 expression after IR

#### EP-2161 miR-454-3p regulates cellular radio-sensitivity by targeting to BTG1 in renal carcinoma cells J. Wang<sup>1</sup>

<sup>1</sup>Institute of Modern Physics- Chinese Academy of Sciences, Biophysics, Lanzhou, China

### Purpose or Objective

Our previous study showed that miR-454-3p decreased obviously after exposure of renal carcinoma 786-O cells to X-rays. miR-454-3p targeted to BTG1, which has long been recognized as a tumor suppressor gene, through a direct interaction with the 3'-UTR of BTG1 mRNA. Here, we try to explore the function and mechanisms of miR-454-3p in renal carcinoma cells responding to ionizing radiation and detect whether miR-454-3p contributes to the instability of genome after ionizing radiation exposure.

### Material and Methods

The human renal carcinoma 786-O cells were exposed to 2.5 Gy of X-rays. The mRNA levels and protein levels of BTG1 were analyzed by qRT-PCR and western blotting. The radio-sensitivity was quantified by assaying the number of micronuclei in binucleated cells with a fluorescence microscope after exposure.

### Results

We found that both the mRNA levels and protein levels of BTG1 were significantly increased at 4-8 hours in renal carcinoma 786-O cells exposed to 2.5 Gy of X-rays. The number of micronuclei increased significantly in binucleated 786-O cells at 36 hours when BTG1 were down-regulated by transfection of miR-454-3p mimics, implying that BTG1 contributed to maintain the genetic integrity after exposure of 786-O cells to ionizing radiation.

### Conclusion

Our results indicate that down-regulation of BTG1 renders tumor cells sensitive to radiation. These results support our previous report that miR-454-3p regulates cellular radio-sensitivity by targeting to BTG1. Our findings may shed light on the potential application of microRNA in tumor radiotherapy.

### EP-2162 Applying the Linear Quadratic Model to PC-3 cells irradiated under different O<sub>2</sub> conditions

T. McMullan<sup>1</sup>, J. Meehan<sup>2,3,4</sup>, S. Langdon<sup>2</sup>, D.B. McLaren<sup>3</sup>, S. McLaughlin<sup>5</sup>, W.H. Nailon<sup>1,6</sup>

<sup>1</sup>Edinburgh Cancer Centre, Oncology Physics, Edinburgh, United Kingdom; <sup>2</sup>University of Edinburgh, Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom; <sup>3</sup>Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom; <sup>4</sup>Heriot Watt University, Institute of Sensors- Signals and Systems., Edinburgh, United Kingdom; <sup>5</sup>Heriot Watt University, School of Engineering and Physical Sciences, Edinburgh, United Kingdom; <sup>6</sup>University of Edinburgh, School of Engineering, Edinburgh, United Kingdom

### Purpose or Objective

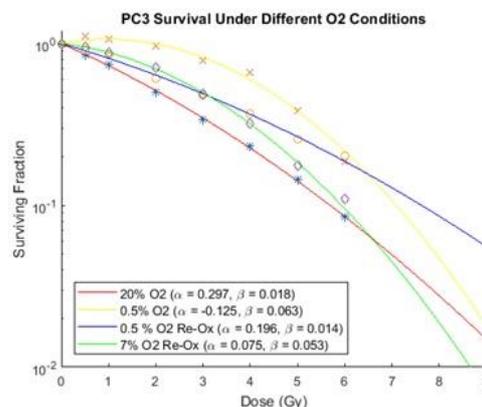

Prostate cancer outcome is compromised by areas of tumour hypoxia, which can be three times more radioresistant than well oxygenated areas. However, taking account of hypoxia when estimating the  $\alpha/\beta$  ratio and the resulting surviving fraction of cells as a function of dose is challenging. The aim of this study was to use the linear quadratic (LQ) model to fit to cell survival data obtained from PC-3 cells irradiated under a range of different O<sub>2</sub> conditions.

### Material and Methods

Human prostate cancer PC-3 cells, 100 cells in each well of a 96 well plate, were cultured and prepared under normoxic (20% O<sub>2</sub>), hypoxic (0.5% O<sub>2</sub>), and oxic conditions close to those in the human body (7% O<sub>2</sub>). Additionally, groups of 0.5% O<sub>2</sub> and 7% O<sub>2</sub> cells were transferred to 20% O<sub>2</sub> conditions after irradiation (Re-Ox). Irradiation was performed 24 hours after seeding in a Faxitron RX-650 cabinet X-ray device with doses in the range 0.5 - 6 Gy. The cells were left for at least 13 days before fixation and

cell response to irradiation was measured using SRB assays. The LQ model was fitted to the surviving fraction of cells at the different O<sub>2</sub> conditions and the  $\alpha$  and  $\beta$  values estimated.

### Results

**Figure 1:** The LQ fit to the surviving fraction of cells obtained under different O<sub>2</sub> conditions.

The LQ fits for the single dose data are shown in Figure 1. As expected, the 20% O<sub>2</sub> had the lowest survival fraction up to 6 Gy. The 7% Re-Ox cells, which are closer to those found in the body, had greater cell-kill at higher doses due to the larger  $\beta$  component. At 6 Gy the survival fraction for the hypoxic 0.5% O<sub>2</sub> cells (irradiated at 0.5% O<sub>2</sub> and kept at 0.5% O<sub>2</sub> until fixation) was essentially the same as the 0.5% Re-Ox cells (irradiated at 0.5% O<sub>2</sub> and transferred to 20% O<sub>2</sub> at fixation).

Interestingly, the hypoxic cells show increased resistance to irradiation at low doses up to 1 Gy with their populations increasing. However, the dose increments are not sufficient to show the *low dose hyper-radiosensitivity* found by other researchers. Beyond 6 Gy, the  $\beta$  effect of cell-kill dominates in a similar manner to the 7% O<sub>2</sub> curve. Overall, in the dose range studied, there is a decrease in surviving fraction with increasing O<sub>2</sub> conditions. The 20% O<sub>2</sub> has an almost linear response, which is reflected in the high  $\alpha$  value.

**Table 1:** Resulting alpha/beta ratios for the different O<sub>2</sub> conditions.

O <sub>2</sub> Condition	$\alpha/\beta$	Description
20%	16.5	Normoxic
0.5%	14	Hypoxic (with re-ox)
7%	1.4	Normal Prostate

### Conclusion

The data presented demonstrates that it is possible to obtain estimates of  $\alpha$  and  $\beta$  that accounts for different levels of O<sub>2</sub> in the tumour microenvironment. However, it is important to take account of the impact of fractionation before considering the probability of tumour control.

### Purpose or Objective

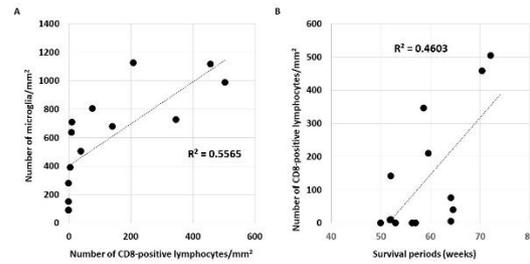

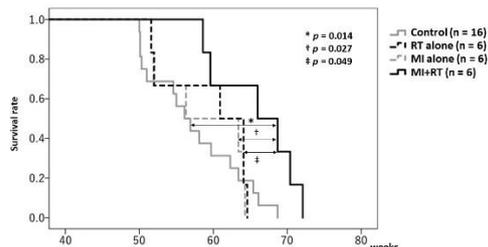

Glioblastoma multiforme (GBM) is the most common primary brain tumor in adults, accounting for approximately 70% of high-grade gliomas. The current standard of care is based on maximal safe surgical resection with concurrent chemoradiotherapy using temozolomide followed by 6 months of maintenance chemotherapy, resulting in median survival time of approximately just 15 months. Microglia are immune effector cells that play an important role in processes such as phagocytosis and antigen presentation in the CNS. The aim of this study was to investigate the efficacy of combination therapy with intravenously injected microglia (MI) and radiation therapy (RT) for malignant glioma in rats.

### Material and Methods

Transgenic rats expressing v-erbB and spontaneously developing malignant glioma were used. The rats were divided into 4 groups: control (n = 19), RT alone (n = 10), MI alone (n = 9), and combination MI and RT (MI + RT) (n = 10). Cranial x-ray irradiation (8 Gy per fraction; once per week) was performed at 50 and 51 weeks of age. Cultured rat microglial cells ( $5 \times 10^6$  cells/rat) were intravenously injected via the tail vein within 30 minutes after RT.

### Results

No evidence of side effects, including thrombosis or graft-versus-host disease, was noted. Rats treated with RT alone, MI alone, MI + RT, and control survived 60.9, 56.3, 66.0, and 56.1 weeks, respectively. The survival period of MI + RT was significantly longer than that of control (P = .014), MI alone (P = .027), and RT alone (P = .049). Immunohistochemical analysis showed a significantly higher number of tumor-infiltrated MI in the RT alone (P = .041) and MI + RT groups (P = .014) compared with the control. Significantly more CD8-positive lymphocytes were observed in the MI + RT group (P = .049) compared with the control. A positive correlation was found between the number of MI and CD8-positive lymphocytes ( $R^2 = 0.556$ ). A positive correlation was also found between CD8-positive lymphocytes and survival periods ( $R^2 = 0.460$ ).

### Conclusion

MI + RT increased infiltrated MI and CD8-positive T cells and prolonged survival in transgenic rats that spontaneously developed malignant glioma. Combined immunocellular therapy and RT may provide a novel treatment strategy for malignant glioma.

### EP-2164 Pilot Study: Systemic response after lung SBRT analyzing immune Cells phenotyping

A. Navarro-Martin<sup>1</sup>, I. Linares<sup>2</sup>, M.A. Berenguer<sup>2</sup>, R. Cañas<sup>3</sup>, F. Guedea<sup>4</sup>

<sup>1</sup>Instituto Catalan De Oncologia, Radiation Oncology Department, Hospitalet De Llobregat, Spain; <sup>2</sup>Instituto Catalan de Oncologia, Radiation Oncology Department, Barcelona, Spain; <sup>3</sup>ONCOBELL Program/IDIBELL, Radiation Oncology Department Barcelona, Barcelona, Spain; <sup>4</sup>Instituto Catalan de Oncologia, Radiation Oncology Department, Barcelona, Spain

### Purpose or Objective

To investigate changes of immune-phenotyping values in patients treated with Stereotactic Body Radiation Therapy (SBRT) over the lung in order to evaluate the immune response after radiation therapy.

### Material and Methods

From November 2016 to May 2018, 7 patients (p) with 7 lung lesions were enrolled in a translational sub-study. All of them underwent SBRT treatment.

Peripheral blood samples prior to the treatment for each patient (1month, 3 months and 6 months) were collected and analyzed. Peripheral mononuclear cells (PBMCs) were isolated from a heparinized venous blood sample by density gradient centrifugation. After centrifugation, PBMCs were collected from the plasma-Ficoll interphase and used for flow cytometry.

Three panels were used:

- Lymphocyte Phenotyping DuracloneTM, Beckman Coulter: CD16 Ab, CD56 Ab, CD19 Ab, CD14 Ab, CD4 Ab, CD8 Ab, CD3 Ab, CD45 Ab

- Regulatory T cells DuracloneTM, BeckmanCoulter: CD45RA Ab, CD25 Ab, CD39 Ab, CD4 Ab, Intracellular FOXP3 Ab, CD3 Ab, Helios Ab, CD45 Ab

- Myeloid Derived Suppressor Cells (MDSC) DuracloneTM, BeckmanCoulter: CD45, HLA-DR, CD14, CD33, CD11b.

Cell surface and intracellular staining were performed according to the manufacturer's protocols. Cell phenotypes were evaluated using the FACS Navios system (BeckmanCoulter).

### Results

Median age was 73r (65-80). 5 Males and 2 females. Primary lung tumor 5 cases, 1 CRC and 1 breast primary. None were a candidate to undergo surgery after evaluation in a multidisciplinary tumor board. Locations were: 2p right upper lobe, 3p right inferior lobe and 2p right medium lobe. Following the clinical protocol doses delivered were 60Gy (7.5Gy x 8fr) in 3p y 50Gy (12.5Gy x 4 fr) in 4 p. Mean follow up of 16 months r(2-20), 1p incomplete response, 2p in partial response and 4 in stable .

Lymphocyte Phenotyping showed that Natural Killer cells defined as CD56+high CD16+, increased among the follow up with initial values of 0.95% to 1.38% at 6 months. Statistical analysis using Friedman Test ( $p=0.18$ ) and Wilcoxon test don't showed significant differences.

Regulatory T cells activated defined as (CD4+-CD25+Foxp3+CD45RA) showed stable values during the follow up (baseline values 4.97% vs. 4.46% at 6 months). No statistical differences were detected.

Myeloid-derived suppressor cells (MDSC) CD33+CD11b+CD14-, showed a tendency to lower values during the follow up (basal 62.6% vs 66.1%). No statistical significance was detected.

#### Conclusion

High doses of radiation therapy over the lung can provide a systemic effect detected in peripheral blood samples. Even the small sample size, our study shows an increase of stimulatory immune populations with stability or decreasing suppressive populations.

#### EP-2165 m6A RNA modification by METTL3 regulates chemo- and radioresistance in pancreatic cancer cells

S. Tatekawa<sup>1,2,3</sup>, M. Konno<sup>2,3</sup>, A. Asai<sup>2,3</sup>, J. Koseki<sup>2</sup>, K. Taketo<sup>1</sup>, H. Ishii<sup>2,3</sup>, K. Ogawa<sup>1</sup>

<sup>1</sup>Osaka University Graduate School of Medicine, Department of Radiation Oncology, Osaka, Japan; <sup>2</sup>Osaka University Graduate School of Medicine, Medical Data Science, Osaka, Japan; <sup>3</sup>Osaka University Graduate School of Medicine, Cancer Frontier Science, Osaka, Japan

#### Purpose or Objective

N6-methyladenosine (m6A) is the most prevalent internal modification of messenger RNA (mRNA) and long noncoding RNA (lncRNA) in the majority of eukaryotes. The m6A modification in RNA can be catalyzed by methyltransferases, or removed by demethylases, which are termed m6A writers and erasers, respectively. m6A mRNA methylation is a gene regulatory mechanism affecting cell differentiation and proliferation through regulation of RNA stabilities, mRNA splicing, microRNA processing and mRNA translation. Especially in cancer, however, it has been mostly unclear what means m6A is dynamically regulated or written by enzymatic components represented by methyltransferase-like 3 (METTL3) and how m6A is significant for each of the numerous genes. We focused on METTL3 in pancreatic cancer, because the prognosis of which is not satisfactory despite the development of multidisciplinary therapies including radiation therapy.

#### Material and Methods

To study the roles of m6A mRNA methylation in chemo- and radioresistance, we established METTL3-knockdown pancreatic cancer cell line using short hairpin RNA. We performed proliferation assay, sphere formation assay, chemo- and radiosensitivity assay. For the purpose of searching target genes affected by METTL3, we conducted cDNA expression analysis and anti-m6A antibody methylated RNA immunoprecipitation sequencing (MeRIP-Seq).

#### Results

Although there was no difference in morphology and proliferation rate between control and METTL3-depleted cells, METTL3-depleted cells in sphere formation assay showed significantly lower ability than control cells to form spheres. Furthermore, METTL3-depleted cells showed higher sensitivity to anticancer reagents such as gemcitabine, 5-fluorouracil, cisplatin and irradiation through enhancing apoptotic response. Our data suggest

that METTL3 is a potent target for enhancing therapeutic efficacy in patients with pancreatic cancer. In addition, we performed cDNA expression analysis followed by gene ontology and protein-protein interaction analysis using the Database for Annotation, Visualization, and Integrated Discovery and Search Tool for the Retrieval of Interacting Genes/Proteins databases, respectively. The results demonstrated that METTL3 was associated with mitogen-activated protein kinase cascades, ubiquitin-dependent process and RNA splicing and regulation of cellular process, suggesting functional roles and targets of METTL3. Finally, we confirmed methylation statuses of those genes were changed by METTL3 using MeRIP-Seq.

#### Conclusion

The present study demonstrates that METTL3 is associated with chemo- and radioresistance and is a potential therapeutic target of pancreatic cancer. Additionally, our findings suggest several critical pathways, including MAPK cascades, ubiquitin-dependent process, RNA splicing and regulation of cellular process, as possible targets of METTL3.

#### EP-2166 Ro90-7501 is a novel radiosensitizer which inhibits ATM phosphorylation and DNA repair

K. Tamari<sup>1</sup>, Z. Li<sup>1</sup>, K. Otani<sup>1</sup>, Y. Takahashi<sup>1</sup>, K. Minami<sup>1</sup>, Y. Seo<sup>2</sup>, O. Suzuki<sup>1</sup>, F. Isohashi<sup>1</sup>, K. Ogawa<sup>1</sup>

<sup>1</sup>Osaka University Graduate School of Medicine, Radiation Oncology, Suita- Osaka, Japan; <sup>2</sup>Osaka University Graduate School of Medicine, Radiation Oncology, Suita-Osaka, Japan

#### Purpose or Objective

To explore new radiosensitizers, we have previously performed a cell-based high throughput screening by using 1280 compounds with irradiation, and found Ro90-7501 as a candidate for radiosensitizer. Ro90-7501 has been reported as an inhibitor of amyloid B42 fibril assembly which causes Alzheimer's disease. However, the radiosensitizing effect of Ro90-7501 was unknown. The purpose of this study was to validate the radiosensitizing mechanism of Ro90-7501.

#### Material and Methods

A human cervical cancer cell line, HeLa, was used for entire experiment. Radiosensitizing effect of Ro90-7501 were validated by clonogenic survival assay and tumor regression assay using female BALB/c nude mice. Flow cytometry was performed to evaluate the difference in apoptosis and cell cycle after irradiation with or without Ro90-7501. Western blot was performed to evaluate the expression of proteins, involved DNA damage response such as pATM, pH2AX, pChk1, and pChk2.

#### Results

Clonogenic survival assay showed significant radiosensitizing effects of Ro90-7501 not only in normoxia but also hypoxia. Tumor regression assay *in vivo* revealed that combination treatment group using radiotherapy with Ro90-7501 (RT+Ro) was significantly reduced tumor volume compared with no treatment group, Ro90-7501 group and radiotherapy group. Ro90-7501 did not induce apparent side effects. Apoptosis significantly increased in RT+Ro group compared with other groups. Cell cycle analysis showed that RT+Ro group increased G2/M arrest. Western blot analysis showed that Ro90-7501 suppressed phosphorylation of ATM, and also suppressed phosphorylation of several downstream proteins such as H2AX, Chk1, Chk2 after irradiation, indicating that DNA repair pathway was inhibited in Ro+RT group.

### Conclusion

Ro90-7501 was identified as a radiosensitizer, which represses ATM phosphorylation, inhibits DNA repair after irradiation, and then increases cell apoptosis.

### EP-2167 Radiosensitizing effect of eribulin mesylate in human cervical carcinoma cells in vitro

R. Benlloch Rodríguez<sup>1</sup>, J. Romero Fernández<sup>1</sup>, R. Castejón Díaz<sup>2</sup>, S. Rosado García<sup>3</sup>, P. Sánchez Rubio<sup>4</sup>, S. Sánchez García<sup>1</sup>, I. Martínez Montesinos<sup>1</sup>, I. Zapata Paz<sup>1</sup>, M. López Valcárcel<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta de Hierro, Radiation Oncology, Majadahonda - Madrid, Spain; <sup>2</sup>IDIPHIM, Internal Medicine, Majadahonda - Madrid, Spain; <sup>3</sup>IDIPHIM, Cellular Culture Unit, Majadahonda - Madrid, Spain; <sup>4</sup>Hospital Universitario Puerta de Hierro, Radiophysics, Majadahonda - Madrid, Spain

### Purpose or Objective

To determine the radiosensitizing properties of eribulin mesylate, a synthetic analogue of the marine natural compound halichondrin B, in human cervical carcinoma cells; and study the potential mechanisms of radiosensitization

### Material and Methods

Cell line: HeLa cells, derived from a human cervical carcinoma, were maintained in DMEM medium, supplemented with FCS and antibiotics. In vitro chemo- and radiosensitivity were assessed by the crystal violet method. To determine chemosensitivity, cells were treated with a 24 h. exposure time of eribulin at different concentrations and, after 10 days of incubation, a dose-response curve was constructed from which the IC10 and IC50 were calculated. Radiosensitivity was evaluated by irradiating the cells at different doses (1,2,4,6 and 8 Gy) in absence or presence of the drug at different concentrations. Survival data were adjusted to the LQ model by a least squares algorithm. Surviving fraction at 2 Gy (SF2) and 4 Gy (SF4) from each survival curve were calculated from the fitted data. Cell cycle changes for control and treated cells were assessed by propidium iodide (PI) staining and flow cytometry analysis. Apoptotic cells were detected by FITC-conjugated Annexin V labelling method using flow cytometry. The percentage of apoptotic cells was obtained from a bivariate histogram of Annexin V labelled-cells versus PI labeled cells for control, 1.5 nM and 3 nM eribulin exposure, irradiation (6 Gy) and combined eribulin-irradiation groups.

### Results

HeLa cells are sensitive to eribulin at nanomolar range. The IC10 and IC50 for 24 h eribulin exposure were 0.75 nM and 2.1 nM respectively. A dose-dependent radiosensitization was observed. The SF2 for control, eribulin 0.3 nM, 0.75 nM and 1.5 nM were 0.94; 0.96; 0.84; and 0.71, respectively. The corresponding figures for SF4 were 0.79; 0.85; 0.67; and 0.47, respectively. The dose enhancement factor (DEF) calculated at 2 and 4 Gy for 1.5 nM eribulin were 1.25 and 1.68, respectively. A G2M cell cycle arrest was induced by eribulin. In the time-course experiment, the percentage of cells in G2M phase for control and 8, 24 and 48 h after 24 h exposure to 1.5 nM eribulin were 11.6%, 20%, 26.3% and 74.7%. The cultures treated with 1.5 nM and 3 nM eribulin showed a percentage of apoptotic cells of 22.5 and 28.1%, respectively. The combined treatment of irradiation at 6 Gy with 3 nM eribulin produced a significant increase in the percentage of apoptosis up to 45% of cells.

### Conclusion

Eribulin mesylate confers radiosensitizing effect in HeLa cells in vitro. The potential mechanisms involved in this effect are an arrest in the most radiosensitive G2M cell cycle phase and an increase in apoptosis in combined radiation-drug treatment.

### EP-2168 Analysis of Chromosomal Aberrations by FISH in FaDu tumor cells after in vivo X-ray MRT irradiation

A. Porth<sup>1</sup>, A. Hunger<sup>1,2</sup>, T. Setzkorn<sup>2</sup>, N. Mehrabi<sup>1</sup>, K. Burger<sup>1,3,4</sup>, S.E. Combs<sup>1,2</sup>, T.E. Schmid<sup>1,2</sup>

<sup>1</sup>Technische Universität München, Klinik und Poliklinik für RadioOnkologie und Strahlentherapie, München, Germany; <sup>2</sup>Helmholtz Zentrum München, Institut für innovative Radiotherapie, Neuherberg, Germany; <sup>3</sup>Technische Universität München, Lehrstuhl für Biomedizinische Physik- Physik-Department, Garching, Germany; <sup>4</sup>Technische Universität München, Munich School of Bio Engineering, Garching, Germany

### Purpose or Objective

X-ray microbeam radiation therapy (MRT) is a new irradiation technique in which the dose is deposited spatially separated with high peak doses. Studies comparing this technique to conventional X-ray irradiation have shown reduced toxicity in normal tissue and a better tumor control. Requiring high dose rates and precise beam collimation, MRT studies are mainly performed at synchrotron radiation facilities. In contrast to these, more cost effective and compact novel X-ray sources like the Munich Compact Light Source, used in this study, overcome the main limitations for the transfer of MRT to a clinical setting. In this study fluorescence in situ hybridization (FISH) was performed to detect chromosomal aberrations in order to assess the cellular response to MRT.

### Material and Methods

The human head and neck cancer cell line (FaDu) was injected subcutaneously into the ear of immunocompromised NMRI nu/nu mice. Tumors were irradiated conventionally or with MRT at mean doses of 3 Gy or 5 Gy using 25 keV X-rays. Sham irradiated and unirradiated mice served as control group. When a tumor reached the 15-fold of its initial volume, the tumor cells were isolated and cultivated for further in vitro analysis. Applying standard protocols, metaphase chromosome spreads were prepared and then hybridized with probes staining chromosomes 2 and 4. For each cell line, 500 metaphases were counted manually under a fluorescence microscope and chromosome aberrations were evaluated, focusing on translocations and aneuploidy.

### Results

24 cell lines were successfully isolated and analyzed via FISH. Three to seven replicates constituted the control and experimental groups respectively. In the control group, 5 ±1% of the cells showed structural aberrations. In irradiated cells this portion was higher: 11 ±1% for cells treated conventionally with 3 Gy, 10 ±1% for cells treated conventionally with 5 Gy, 15 ±2% of the cells irradiated with 3 Gy MRT and 11 ±2% of those irradiated with 5 Gy MRT. Numerical aberrations were found in 4 ±3% of the cells in the control group, 1 ±2% in the group treated with 3 Gy conventional X-rays, 2 ±1% in the group treated conventionally with 5 Gy and 2 ±1% for both MRT irradiated groups.

### Conclusion

Our study demonstrated an overall higher percentage of stable chromosome aberrations in all irradiated groups, corresponding to the clastogenic effect of ionizing radiation. In respect to this effect, no difference was visible between conventional and microbeam X-ray irradiation. Aneuploidy rates were high, both in irradiated and non-irradiated cells, which is a typical finding for tumor cells. Interestingly, this rate was lower in conventionally irradiated groups but not in the MRT groups. This might indicate a different influence of conventional and MRT irradiation on genomic instability.

## E-posters RTT

#### EP-2169 Are treatment times with breast DIBH comparable to free breathing?

D. Ledsom<sup>1</sup>, V. Acton<sup>1</sup>, R. Biggar<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre, Department of Radiotherapy, Bebington- Wirral, United Kingdom

#### Purpose or Objective

The use of deep inspiration breath hold (DIBH) at the author's centre was extended to treat all breast cancer patients irrespective of laterality or nodal status in March 2017. This audit investigated the duration of treatment before and after implementation of the DIBH technique for all breast cancer patients to determine if the standard 15 minute appointment slot was still achievable.

#### Material and Methods

Varian Aria reports (v13.6) was used to identify treatment start and end time for all breast cancer patients treated March 2016 to February 2017 (left DIBH, right free breathing (FB)) and April 2017 to March 2018 (right and left DIBH). Data from March 2017 was excluded due to crossover of techniques.

#### Results

For all breast patients treated between March 2016-February 2017 (n=801, right sided FB, left sided DIBH) median treatment time was 12m:08s (SD 5:09) compared to 12m:47s (SD 5:22) when all patients were treated in DIBH (n=1288, April 2017-March 2018).

Data was stratified by laterality to compare FB and DIBH treatment times. For FB (n=418), median treatment time was 11m:50s (SD 5:01), versus DIBH (n=610) 12m:56s (SD 5:27). The difference was statistically significant (p<0.01). Outliers were excluded from data.

#### Conclusion

Median treatment time increased by 1 minute with DIBH; although this was statistically significant it was not clinically significant as there was no substantial increase in treatment time and the 15 minute appointment slot was achieved. DIBH treatment time therefore does not impact on capacity or extend appointment times.

#### EP-2170 Scheduling optimization to reduce patient waiting beam times in four-room proton therapy center

C.Y. Lin<sup>1</sup>  
<sup>1</sup>Chang Gung Memorial Hospital, Radiation Oncology, Taoyuan, Taiwan

#### Purpose or Objective

In proton therapy, patients are required to lie flat and wait on the treatment bed for the conversion of the beam before treatment. The displacement resulted from maintaining the posture with long time might lose the advantages of proton therapy. This study attempts to use the time difference to reduce wait time and provide the stability of the treatment posture.

#### Material and Methods

We recorded patients' waiting time from rooms 1 and 2 with the same wobbling system (Sumitomo Proton therapy System) and rooms 3 and 4 with the same pencil beam system. There were 27 working days for each time-dividing and non-time-dividing. For non-time-dividing, number of patients in room 1, 2, 3, and 4 are 262, 289, 219, and 231 and number of irradiation fields in room 1, 2, 3, and 4 are 528,584, 523, and 533, respectively. For time-dividing, number of patients in room 1, 2, 3, and 4 are 222, 210, 260, and 261 and number of irradiation fields in room 1, 2, 3, and 4 are 466,464, 682, and 621, respectively. The waiting time difference of time-dividing or not between

the treatment rooms was analyzed by using the independent T-test of SPSS Vision18 software.

#### Results

In rooms 1 and 2 with the wobbling system, the waiting time without and with time-dividing in one work day are 60.84±10.52 and 45.36± 0.17 minutes (p=0.173). In rooms 1 and 2 with the pencil beam system, the waiting time without and with time-dividing in one work day are 56.58±3.42 and 48.02±6.70 minutes (p=0.249). With all four treatment rooms simultaneous operation, the waiting time without and with time-dividing in one work day are 58.71±6.85 and 46.70±4.16 minutes (p=0.024). In rooms 1, 2, 3, and 4, the waiting time without and with time-dividing in one work day are 52.37±17.32 and 44.63±13.25 minutes (p<0.05), 66.67±19.86 and 45.00±12.95 minutes (p<0.05), 54.37±16.81, 45.26±10.42 minutes (p<0.05), and 57.04±22.89 and 43.70±12.64 minutes (p<0.05), respectively. The percentages of waiting time more than 60 minutes without and with time-dividing are 35.2% and 16.7%, respectively.

#### Conclusion

In proton therapy, the use time-dividing could reduce the patient's waiting time, decrease the discomfort of patients, minimize the random error of treatment, and improve the stability.

#### EP-2171 Optimizing individual customized neck rests for proton therapy of brain tumors

A. Schouboe<sup>1</sup>, M. Gioertz<sup>1</sup>, P. Randers<sup>1</sup>, A. Harboell<sup>1</sup>, C.R. Hansen<sup>1</sup>, A. Vestergaard<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus N, Denmark

#### Purpose or Objective

To study the reproducibility of individually customized neck rests for positioning patients with brain tumors undergoing irradiation in a Proton Centre. The Head and Neck board (HN board) is designed with an indentation for positioning the neck rest which has smooth sloping surfaces to ensure no steep gradients related to proton therapy. The system could potentially introduce an error in positioning of the individually customized neck rests. The purpose of this study was to evaluate the use of two neck rests with respect to displacement, ease of use and patient comfort.

#### Material and Methods

Individual customized neck rests from two different manufactures (A and B) were tested on 5 healthy volunteers. One individual customized neck rest from each manufacture was customized for each volunteer. The volunteer was positioned on the HN board with the head in neutral neck position.

In customizing individually neck rest we focused on comfortable and adequate support to the neck with no gaps underneath the head or neck. The aim was to create a neck rest as homogenous as possible in order to avoid large abrupt density variations, which for proton treatments can reduce plan robustness.

The volunteer was immobilized with a thermoplastic mask. A Beekly spot was placed underneath the HN-board and defined as reference. Two Beekly spots were placed in the same longitudinal plan as the reference and two on the cranial part of the neck rest (Fig 1). To evaluate the reproducibility of the positioning of the neck rests, the volunteer was re-positioned and a MRI scan was performed.

#### Results

A total of 10 MRI were evaluated. The mean longitudinal shifts were 1.4 mm (range 0.2-2.3 mm) and 1.3 mm (range 0.9-1.0 mm) for neck rest A and B, respectively. The cranial markers revealed no significant rotational error in positioning. The staff's main experience was to be extremely watchful when customizing the neck rest to make sure the material fitted in the indentation of the HN board to avoid the neck rests from being displaced. They

also subjectively experienced differences in handling the neck rests from the two manufactures. The staff found the material in neck rest A easier to handle because the amount of material was more appropriate. The amount of material in neck rest B resulted in too much spare material around the head which could contribute to steep gradients. The volunteers experienced neck rest A more comfortable and provided better support. Some of the volunteers observed smell from neck rest B in their clothes and hair for hours.

#### Conclusion

Challenges in customizing the individually neck rests for positioning brain tumor patients for proton therapy can be solved by being alert to the indentation on the HN board, when customizing the neck rest. The study showed no significant displacement using either of the neck rests. The staff found neck rest A was easiest to handle and without smell and most of the volunteers found neck rest A more comfortable.

#### EP-2172 Evaluation of the pitch functionality and setup accuracy of the Solstice SRS Immobilization System

C.L. Ong<sup>1</sup>, K. Hunnago<sup>1</sup>, F. Gescher<sup>1</sup>, J. Franssen<sup>1</sup>, E. Franken<sup>1</sup>

<sup>1</sup>Hagaziekenhuis, Radiotherapy, Den Haag, The Netherlands

#### Purpose or Objective

For stereotactic treatment of brain metastases, a good patient immobilization is crucial to ensure a highly accurate dose delivery with a limited PTV margin of 1-2 mm. Various commercial products offer great solutions for patient fixation and in combination with online daily imaging, translational and yaw-rotational setup errors can be corrected. Pitch-rotational setup errors correction is however only feasible with a 6D-couch, which is not commonly available in all institutes. The purpose of this study was to investigate the accuracy of the new Civo Solstice™ SRS immobilization system which allows manual correction of the pitch-rotational setup errors.

#### Material and Methods

The solstice mask comprised of a carbon fiber head support, customizable cushion, thermoplastic mask and a thermoplastic mouth-bite. A CT-scan of a Kyoto head phantom fixated with the Solstice mask was acquired (fig 1). Two spacers were position at the anterior and posterior side of neck area in order to allow a controlled pitch-rotational motion of the phantom within the mask. At the LINAC, CBCT's were acquired and registered to the CT in order to determine the accuracy of the mask. Subsequently several pitch-rotational setup errors were introduced within the mask and a CBCT was acquired. Based on the match value, the pitch setup error was manually corrected with the head support (fig 1) and a new verification CBCT was made. Furthermore, this mask was also applied on one patient receiving whole brain irradiation. This patient was also fixated using thermoplastic mask and the customized cushion and mouth bite. For this patient, two CBCT's were acquired before the treatment and one after. All scans were automatically registered on bony anatomy.

Figure 1 shows the setup of the Kyoto head phantom within the Solstice mask. The mask is secured to the head support, and the phantom is positioned within the mask. The setup is shown from a top-down perspective, highlighting the alignment of the mask and the phantom.

#### Results

The match values of CBCT with planning-CT with the phantom placed within the mask un-rotated were smaller than 0.1mm/° in all directions. After the phantom was rotated within the mask, CBCT match showed pitch-rotational errors of 1.7° and -3.7° (Fig. 2). After manual adjustment of the pitch-rotation on the head support, the verification match showed rotational setup error of  $\leq 0.1^\circ$  and translational setup error of  $\leq 0.2\text{mm}$  (Fig.2). The rotational match values of the CBCT are independent of the location of the correction reference point and correspond to the pitch-rotational axis of the head support. For the first patient, the pre-treatment and post-treatment verification CBCT showed translational setup errors of  $\leq 0.4\text{mm}$  and  $\leq 0.3\text{mm}$ , which is close to the accuracy of the couch motion accuracy of 0.2mm.

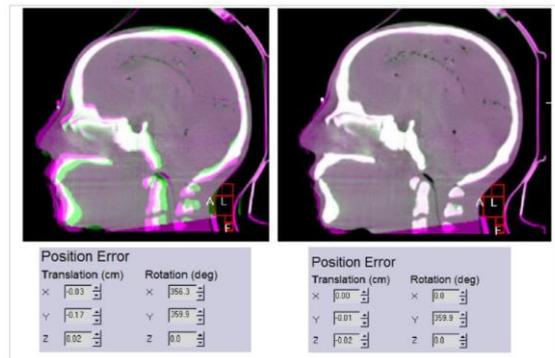

Fig 2. CBCT match to planning-CT (left) showed pitch-rotational setup error of 3.7°, the purple and green showed misalignment of the skull. After manual adjustment of the pitch rotation on the head support, CBCT match showed rotational setup error of  $\leq 0.1^\circ$  and translational setup error of  $\leq 0.2\text{mm}$  (right).

#### Conclusion

Manual adjustment of pitch-rotational setup error is feasible with the Solstice mask. This correction can be clinically importance for SRS treatment as it permits a more frequent use of single isocenter to treat patients with multiple brain metastases. The use of single isocenter has shorter treatment time and therefore is more patient friendly and reduce the risk of interfraction motion. These preliminary results warrant further investigation on more patients.

#### EP-2173 Bladder filling in patients undergoing prostate radiotherapy on the MR-linac

G. Adair Smith<sup>1</sup>, T. Herbert<sup>1</sup>, R. Lawes<sup>1</sup>, H. Creasey<sup>1</sup>, A. Dunlop<sup>2</sup>, A. Mitchell<sup>2</sup>, A. Pathmanathan<sup>1</sup>, L. Bower<sup>3</sup>, I. Hanson<sup>2</sup>, D. McQuaid<sup>2</sup>, R. Huddart<sup>1</sup>, U. Oelfke<sup>2</sup>, S. Nil<sup>2</sup>, A. Tree<sup>1</sup>, H. McNair<sup>1</sup>

<sup>1</sup>The Royal Marsden NHS Foundation Trust, Radiotherapy, Sutton, United Kingdom; <sup>2</sup>The Institute for Cancer Research, Medical Physics, Sutton, United Kingdom; <sup>3</sup>The Institute for Cancer Research, Radiotherapy and Imaging, Sutton, United Kingdom

#### Purpose or Objective

The first patient in the UK was treated for prostate cancer on the Elekta Unity (Elekta AB, Stockholm, Sweden) in September 2018. Due to the longer treatment times, departmental guidance for bladder filling was altered. An audit is being undertaken to evaluate if the bladder filling guidance is appropriate and reproducible; and to determine the rate of bladder filling and the effect on dose constraints across three time points during a treatment session.

#### Material and Methods

The first cohort of patients, under PRISM (Prostate Radiotherapy Integrated with Simultaneous MRI) trial

(NCT03658525), to be treated on the MR-linac will receive 60Gy in 20 fractions. These patients have been advised to drink 350ml of water 30 minutes before their MR-linac appointment time, to achieve a minimum bladder volume of 250ml during treatment (O'Doherty et al, 2006). The daily volume of water drunk, and time before treatment, was recorded.

A T2 weighted MR image was acquired at three time points: the start of each session, prior to treatment delivery and post treatment delivery. The bladder was retrospectively outlined for all three images. The volume of the bladder and time of MRI acquisition documented. The average rate of intrafraction filling was determined. The dose delivered to the re-outlined bladder at each timepoint was re-calculated and documented to assess if mandatory dose constraints were met with the initial bladder size and increased bladder size pre and post treatment. The effect on dose constraints will be investigated.

#### Results

The bladder filling guidelines were altered 11 times during the course of treatment. The patient drank 1 to 2 cups of water 25 to 35 minutes before treatment and had to partially empty his bladder 12 times prior to treatment. We will continue to assess the revised guidelines on future patients.

The median (range) percentage increase in bladder volume across 25 minutes from initial planning MRI to pre-treatment MRI was 62% (34% to 126%) and across 36 minutes from initial planning MRI to post treatment MRI was 89% (46% to 174%). The mean (SD) rate of bladder filling was 4.3cc per minute (1.5cc per minute) from initial planning MRI to post treatment MRI.

For the first fraction the mandatory bladder dose constraints were met for all three time points. Further fractions will be investigated.

#### Conclusion

Although the bladder filling guidelines were altered regularly, our initial analysis has indicated that the mandatory bladder dose constraints were achieved.

The rate of bladder filling during treatment delivery indicated the bladder volume was at recommended minimum for departmental guidance. The advantage of bladder filling displacing small bowel superiorly was noted across the course of treatment and will be investigated further.

#### EP-2174 Patients' experiences with whole body irradiation using Tomotherapy

P. Schon<sup>1</sup>, P. Lannerheim-Saure<sup>1</sup>, C. Hagstrom<sup>1</sup>, A. Löfgren<sup>1</sup>

<sup>1</sup>Skåne University Hospital, Department of Radiation Therapy, Lund, Sweden

#### Purpose or Objective

At our clinic, the traditional Total Body Irradiation treatment (TBI) using a linear accelerator has been replaced with Total Marrow Irradiation (TMI) with Tomotherapy, treating patients with leukaemia prior to stem cell transplantation. The reason to use TMI instead of TBI is to minimize dosage to healthy tissue. Total Skin Irradiation (TSI) is a similar treatment used for treating patients with severe mycosis fungoides. To be able to complete the treatment, the patient's well-being is crucial during the treatment. Therefore quality control that focus on the patient's experience is imperative. The purpose was to explore the patient's experience of full body irradiation, when treated with Tomotherapy.

#### Material and Methods

The oncology nurse perform the preparations, which includes giving information and support based on the patient's need prior to the start of the treatment. TMI- and TSI-treatments were similar to each other concerning immobilization and position of the patient. The patient was immobilized using a large vacuum cushion, from feet

to neck and a 5-point open-face thermoplastic mask. Fiducial markers and tattoos were used for positioning reference. In addition the patient receiving TSI was also wearing a wet suit for the bolus effect. It is important that the position is reproducible and comfortable to ensure the same position during 1,5-2 hours treatment time. A small break during change of position from head first to feet first is included. Four patients received a questionnaire with 37 questions after all radiotherapy sessions was finished, which included questions enquiring their experiences during their radiotherapy sessions. Five patients were also asked to rate their pain level and level of nausea using Visual Analog Scale after every session, and if so if they vomited. Their skin and mucous membrane were observed. They all received 12 Gy/6 sessions.

#### Results

All patients felt some level of pain and chafing during treatment (Fig 1). The TBI-patients felt more pain and nausea. The TSI-patient's skin improved during all sessions, but there were some bleeding. All patients felt safe, but the TBI-patients found the environment more frightening. The TSI-patient lacked information about side-effects and self-care, but found the overall information sufficient. None of the patients felt completely relaxed, but they all felt that the treatment sessions were manageable, though the treatment time was challenging.

#### Conclusion

The quality control revealed that the patient were lacking some information and support. The oncology nurses should focus on information and prevention to increase the patient's well-being. To minimize treatment time the nurse ought to develop skills handling the technology and treatment procedure. Based on the results, the patients' positioning was improved owing to some modifications, minimizing pressure and enhancing mobility of vulnerable parts of the body.

#### EP-2175 No more Lines - Omitting skin marks, safe to align with tattoo only for lung cancer patients?

L. Wiersema<sup>1</sup>, J. Stam<sup>1</sup>, T. Wiersma<sup>1</sup>, J. Belderbos<sup>1</sup>, A. Licup<sup>1</sup>, F. Koetsveld<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, radiotherapy, Amsterdam, The Netherlands

#### Purpose or Objective

In our department besides ink tattoos, skin marks are used for patient positioning treated within the thoracic area. The tattoos and skin marks are placed by RTT's during the Computed Tomography (CT) simulation. The added value of the skin marks is being questioned by physicians and RTT's. Patients are instructed to retrace the skin marks until the first day of treatment in case of fading, this introduces a risk of shifting the skin marks. Besides, there is also a degree of discomfort for the patients, because the skin marks might show from underneath their clothes, whereas some patients may also present with an allergic reactions to the ink. The purpose of this study was to see

whether omitting the skin marks and positioning based on tattoos only, would have an influence on the initial setup error within the context of image guided RT (IGRT). Within our department lung cancer patients will be treated according an online IGRT protocol, therefore the rotations are of most interest. In case an offline IGRT protocol is used in other departments, besides the rotations, the translations are also relevant when omitting skin marks.

#### Material and Methods

To analyze the results we selected 2 groups of lung cancer patients, treated with a fractionated radical dose prescription and a daily online IGRT protocol, aligned using 5 tattoos (3 anterior, 2 lateral) and positioned on a thorax support. Group A, the control group with skin marks, included 37 patients. Group B, a prospective cohort, included 30 patients irradiated without skin marks. For both groups, grand mean, systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors were calculated using the initial set up errors from 1388 Cone Beam Computed Tomography (CBCT) scans. This study was communicated to all RTT's within the department, but no additional set up instructions were given. The statistical significance for the systematic and random errors were tested using Levene's test and Mann-Whitney U-test, respectively.

#### Results

The mean for the translations in both groups are  $< 0.1$  cm. The Levene's test and Mann-Whitney U test showed no statistically significant difference between the group standard deviations.

Setup error	LR (cm)	CC (cm)	AP (cm)	roll (°)	pitch (°)	yaw (°)
<b>With skin marks - Group A</b>						
Mean	-0.07	0.07	-0.09	0.8	-0.1	0.2
Systematic Error	0.30	0.38	0.26	1.2	0.9	0.8
Random error	0.34	0.47	0.15	0.6	0.7	0.9
<b>Without skin marks - Group B</b>						
Mean	-0.03	0.02	0.02	0.5	-0.1	0.0
Systematic Error	0.23	0.42	0.20	0.7	1.0	0.9
Random error	0.35	0.41	0.14	0.6	0.7	0.9
P-value ( $\Sigma$ ) Levene's test	0.54	0.60	0.07	0.24	0.92	0.30
P-value ( $\sigma$ ) Mann-Whitney U test	0.47	0.48	0.41	0.27	0.19	0.44

#### Conclusion

Omitting skin marks for patients treated in the thoracic area results in an equivalent initial setup error for both translations and rotations. Patients might benefit, as there will be no risk of any allergic reactions from the ink and they do not have to retrace the skin marks.

#### EP-2176 Analysis of inter-fraction tumor position variability in lung SBRT

A. Coral<sup>1</sup>, N. Espinosa<sup>1</sup>, A. Latorre<sup>1</sup>, S. Bermejo<sup>2</sup>, X. Nolla<sup>1</sup>, G. De Segura<sup>1</sup>, C. Diaz<sup>1</sup>, M. Mancera<sup>1</sup>  
<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Servei de Radiofísica i Radioprotecció, Barcelona, Spain; <sup>2</sup>Hospital de la Santa Creu i Sant Pau, Servei d'Oncologia Radioteràpica, Barcelona, Spain

#### Purpose or Objective

The aim of our study was to compare the tumor position differences (*displacements*) between the simulation TC and the CBCT performed prior each treatment fraction. We also correlated the magnitude of the displacements and the tumor location (lobe) in the lung.

#### Material and Methods

We retrospectively analyzed 112 oligometastatic lung cancer patients between December 2013 and August 2018. The patients underwent a simulation 4D-TC with limited free breathing obtained by abdominal compression, using Respiratory Belt (CIVCO).

The positioning devices were a thorax support (Posirest-2, CIVCO) and vacuum mattress (Urethane MTVLPLV01, CIVCO). The positioning in the treatment unit was based on the simulation skin marks (tattoos) followed by the isocenter displacements as indicated by the treatment plan.

A CBCT was acquired before each treatment fraction to correct for inter-fraction positioning errors. We reported those position displacements for the three axes (AP, LR, SI). We finally correlated the magnitude of the displacements with the tumor localization (upper-, medium-, or low lung lobe).

#### Results

Figure 1 shows that the largest displacement was observed along the vertical direction.

The medium lung lobe was the localization with the lowest dispersion of the displacements. The largest range of displacements (in vertical direction between -1.8 cm and 0.3 cm and in lateral direction between -0.6 cm and 1.2 cm) was observed in the lower lobe.

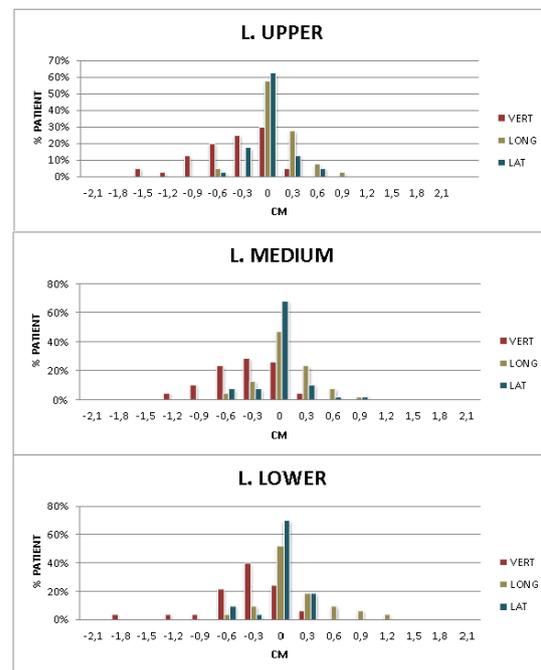

Figure 1. Distribution of displacements along the three axes for upper, medium and lower lung lobes.

#### Conclusion

Tumors located in the lower lobe have important mobility in all directions. We suggest performing a stronger diaphragmatic compression or other respiratory control strategies with the objective to reduce this movement. The largest displacements in all lung locations (upper-, medium-, lower lobe) were observed in the vertical axis. To reduce the displacement of the upper lobe, attributable to the positioning of the arms, implementation of the new systems of immobilization, as a thermoplastic mesh, or surface recognition systems are recommended. IGRT techniques are essential to ensure a good reproducibility of the treatment.

#### EP-2177 4D CBCT based determination of tumor amplitude variation in lung cancer SBRT

J. Papp<sup>1,2</sup>, M. Simon<sup>1,2</sup>, E. Csiki<sup>1</sup>, E. Csobán<sup>1</sup>, A. Molnár<sup>1</sup>, P. Árkosy<sup>3</sup>, Á. Kovács<sup>1,2</sup>

<sup>1</sup>University of Debrecen Med. and Health Science Centre-Clinic of Oncology, Department of Radiotherapy, Debrecen, Hungary; <sup>2</sup>University of Pécs Faculty of Health Sciences, Doctoral School of Health Sciences, Pécs, Hungary; <sup>3</sup>University of Debrecen Med. and Health Science Centre-Clinic of Oncology, Department of Oncology, Debrecen, Hungary

#### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) is often performed with complex immobilization systems paired

with four-dimensional information to assess tumor motion in time. The aim of this study was to determine tumor amplitude variation based on 4D CBCT data.

#### Material and Methods

Between May 2015 and August 2018 a total of 46 patients received lung SBRT treatment in 359 fractions based on 4DCT data. Abdominal compression was used in 8 patients to reduce tumor motion at lower lobe tumors. GTV was defined during treatment planning at least in 3 breathing phases to generate an ITV. Translational position corrections were determined using pre-treatment 4D CBCT at each fraction. A second 4D CBCT data set had been acquired after the treatment fraction to assess intra-fractional motion. Amplitude values in three directions were recorded both pre- and post-fractional.

#### Results

Population mean values ( $\pm$ SD) for pre-treatment amplitudes were: 0.12( $\pm$ 0.09) cm, 0.44( $\pm$ 0.4) cm and 0.24( $\pm$ 0.17) cm in Superior-Inferior (SI), Left-Right (LR) and Anterior-Posterior (AP) directions respectively for the free breathing cohort. Patients with abdominal compression the values were: 0.18( $\pm$ 0.1) cm, 0.87( $\pm$ 0.13) cm, 0.25 ( $\pm$ 0.51) cm respectively. Post-fractional values were: 0.11( $\pm$ 0.09) cm, 0.4( $\pm$ 0.4) cm, 0.22( $\pm$ 0.15) cm for the free breathing and 0.18( $\pm$ 0.1) cm, 0.78( $\pm$ 0.12) cm, 0.24( $\pm$ 0.41) cm for the abdominal compression group.

#### Conclusion

Correlating pre- and post-treatment values in our patient cohort the complex immobilization systems combined with four-dimensional data are capable of handling tumor amplitude changes over a fraction and abdominal compression can mitigate tumor motion to a more manageable area which can lead to the reduction of the volume of ITV.

#### EP-2178 Evaluation of a user-guided deformable registration workflow for multi-modal prostate imaging

A. Lastrucci<sup>1</sup>, A. Barucci<sup>2</sup>, S. Pini<sup>1</sup>, S. Russo<sup>1</sup>, R. Barca<sup>1</sup>, M. Coppola<sup>1</sup>, S. Fondelli<sup>1</sup>, L. Paoletti<sup>1</sup>, F. Rossi<sup>1</sup>, P. Bastiani<sup>1</sup>, M. Esposito<sup>1</sup>

<sup>1</sup>USL Toscana Centro, Radiotherapy, Florence, Italy; <sup>2</sup>Ifac CNR, Medical Physics, Sesto Fiorentino, Italy

#### Purpose or Objective

Reg-refine is a tool that adds human knowledge to deformable image registration (DIR) process. In this study a CT-MRI deformable registration workflow for prostate cancer was evaluated.

#### Material and Methods

Deformable and rigid alignments of axial CT and axial T2 weighted MRI scans of 8 patients were evaluated using Mim Maestro 6.7.10 (Mim Software Inc.). DIR workflow consisted of three rigid alignments, in the upper, middle, and lower prostate part, defined by two users in consensus using Reg-refine and converted in local alignments by the DIR algorithm. Dice coefficient and Hausdorff distance were computed for evaluation of deformable and rigid alignments.

#### Results

Dice resulted (0.78  $\pm$ 0.12; max 0.9, min 0.58) for rigid registration vs (0.89 $\pm$ 0.05; max 0.94, min 0.82). Hausdorff distance resulted (11.7 mm  $\pm$  4.5 mm; max 17.1, min 5.4) for rigid registration vs (7.6 mm  $\pm$  4.1 mm; max 13.5 mm, min 3.5 mm). Box plots are reported in Figure 1.

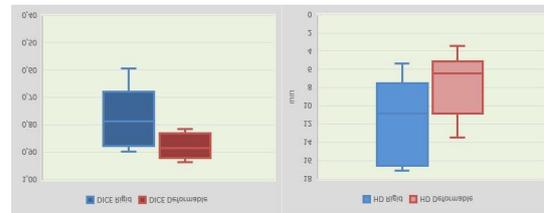

Figure 1: Box plot of Dice and Hausdorff distance (HD) for rigid and deformable CT-MRI alignments.

#### Conclusion

The DIR workflow evaluated in this study produced good results in all patients analyzed and was able to improve the registration accuracy of rigid alignments. Reg-refine based DIR of CT and MRI scans can be used for prostate contouring.

#### EP-2179 Estimation of intrafractional motion of intra-orbital optic nerve by MRI

S. Tsuruoka<sup>1</sup>, Y. Hamamoto<sup>1</sup>, Y. Kuribayashi<sup>2</sup>, H. Inata<sup>2</sup>, T. Matsuno<sup>2</sup>, T. Mochizuki<sup>1</sup>

<sup>1</sup>Graduate School of Medicine Ehime University, Radiology, Ehime, Japan; <sup>2</sup>Saiseikai Imabari Hospital, Radiology, Ehime, Japan

#### Purpose or Objective

Optic nerve is one of the most significant organs at risk in radiotherapy for the intra-and/or peri-orbital tumors. Although intra-orbital optic nerve is likely to move with eye-movement, intrafractional motion of the intra-orbital optic nerve has not been well documented. To determine the optimal planning organ at risk volume, intrafractional motion of the intra-orbital optic nerve was measured by magnetic resonance imaging (MRI).

#### Material and Methods

A total of five normal volunteers were underwent MRI around the orbit. (1) One of five volunteers was underwent MRI with maximally oriented in outward, inward, upward, and downward direction at the time of both opening and closing the eyes. The displacement in each direction at three points (the adhesive part of optic nerve and eyeball, 10 mm and 20 mm from the adhesive part) was measured. (2) For all volunteers, displacement in lateral direction of the intra-orbital optic nerve from the position when gazed at the front was measured by axial cine-MR imaging. The maximum displacement of the intra-orbital optic nerve was recorded.

#### Results

(1) At the time of opening the eyes, the average of maximal displacement in four directions (outward, inward, upward, and downward) at the adhesive part of optic nerve and eyeball, 10 mm and 20 mm from the attachment were 5.20 mm (standard deviations [SD]; 0.97), 3.23 mm (SD; 0.54), and 1.23 mm (SD; 0.55), respectively. At the time of closing eyes, those were 4.11 mm (SD; 1.31), 1.91 mm (SD; 0.82), and 0.53 mm (SD; 0.24), respectively. (2) For the right eye, the average of the maximal displacement inward and outward were 2.8 mm and 2.5 mm, respectively. For the left eye, the average of the maximal displacement inward and outward were 2.6 mm and 3.0 mm, respectively. The mean amounts displacement of right and left eye on cine-MR imaging were 2.65 mm (SD; 1.14) and 2.78 mm (SD; 1.62), respectively.

#### Conclusion

Based on our results, intrafractional margins of the intra-orbital optic nerve needed at least 3 mm in outward, inward, upward, and downward direction.

#### EP-2180 The effect of Rectal size and shape on Bladder deformation in Urinary Bladder Radiotherapy

N. Hutton<sup>1</sup>, J. Callender<sup>2</sup>, D. Hutton<sup>1</sup>, L. Williams<sup>1</sup>, S. Wong<sup>1</sup>, H. Wong<sup>1</sup>, I. Syndikus<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre, Radiotherapy, Bebington-Wirral, United Kingdom; <sup>2</sup>The University of Liverpool, School of Health Sciences, Liverpool, United Kingdom

**Purpose or Objective**

The urinary bladder is subject to variation in shape and size which, to some extent, be controlled using an empty bladder protocol for planning and treatment. Bladder can still be influenced by adjacent organs, notably the rectum.

Micro-enemas are used with a view to controlling the rectal volume. An earlier study, showed improve consistency in rectal diameter and content between planning and treatment with the use of a micro-enema. The aim of this study is to identify any significance in the relationship between rectal consistency and bladder deformation with a view to reconsidering appropriate treatment margins.

Utilising on treatment imaging technology for soft tissue visualisation enabled the variation in bladder and rectal volumes to be quantified.

**Material and Methods**

A control group consisted of patients asked to empty their bladder immediately before planning and treatment. No guidance was given on rectal state. An intervention group consisted of patients asked to use a micro-enema 20 mins prior to planning and each treatment and empty their bladder immediately before both.

Treatment CBCT images were analysed on-line using an automatic match algorithm to provide a rigid bone registration and a 3mm Action level and a CTV coverage check.

Retrospective analysis was carried out on 97 CBCT scans from 15 patients, control group (n = 41) and intervention group (n= 56). Volume and positional organ variations were determined from the rigid bone registration of CT and CBCT. Bladder and rectum volumes were manually contoured on planning CT and each CBCT using Varian Eclipse™ contouring module.

Centre of mass shifts for bladder and rectum were determined in the X,Y and Z axis and the magnitude of Centre of Mass shift calculated for the planning scan and all fractions. The Dice similarity coefficient was taken from the Eclipse planning system.

**Results**

Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	150
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	308
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.10
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.01
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02

Comparison test (z-test) of EYE/VA group

Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	81.7
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	13.1
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.03
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02
Rectum volume (cm <sup>3</sup> )	Bladder volume (cm <sup>3</sup> )	0.02

Comparison test (z-test) of CONTROL group

**Conclusion**

The introduction of a micro-enema shows significant worsening of bladder and rectum stability relevant to the control group. The significant result for correlation between rectum changes in the Y and Z directions and bladder centre of mass shift in the same direction suggest that the use of micro-enema may, in some cases, destabilise the rectum. It is acknowledged that the small study size may influence the results. Bladder radiotherapy may benefit from daily imaging with appropriate justification and optimization of imaging dose. The majority of target volumes in the pelvis are moving to daily online imaging acknowledging the physiological movements of organs.

**Electronic Poster: RTT track: Treatment planning and dose calculation / QC and QA**

**EP-2181 Use of treatment log-files for QA of cranial radiosurgery adaptive plans**

S. Moragues Femenia<sup>1</sup>, J.F. Calvo-Ortega<sup>1</sup>, M. Hermida-López<sup>2</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain; <sup>2</sup>Hospital Universitario Vall d'Hebron, Servicio de Física y Protección Radiológica, Barcelona, Spain

**Purpose or Objective**

To analyze the accuracy of delivered adaptive stereotactic radiosurgery (SRS) plans.

**Material and Methods**

Adaptive cranial SRS is performed in our department [Med Dosim. 2013 Autumn;38(3):291-7] as a strategy to compensate for the patient's roll and pitch rotational errors not supported by the 4D couch of the Varian 2100 CD linac used for treatment delivery. Our current adaptive SRS policy requires adapting the original treatment plan (Plan\_ref) when pitch and/or roll errors detected by CBCT imaging are ≥ 0.5 degrees. The beam fluences of the Plan\_ref are adapted to the actual patient's position such that an adaptive plan (Plan\_adapt) is created while patient is lying on the linac couch. Obviously, it is not possible to perform a fully patient-specific QA. In order to check the Plan\_adapt delivery, an off-line re-calculation of the Plan\_adapt is done using the Varian Dynalog files recorded by the linac during the delivery [J Appl Clin Med Phys. 2014 Mar 6;15(2):4665], such that a reconstructed plan is generated (Plan\_adapt\_Dyn). Dose calculations were done with the Analytical Anisotropic Algorithm (AAA) of the Eclipse v.13.6 treatment planning system using a 1 mm calculation grid size. The accuracy of this algorithm for SRS was previously investigated by our team [Med Dosim. 2014 Summer;39(2):129-33]. Plan\_adapt plans were computed with AAA modelled with the beam data (6 MV) of our linac, while the Plan\_adapt\_Dyn plans were calculated with the AAA modelled in an independent way with the Golden Beam Data (6 MV) supplied by Varian for our linac model. In order to assess the accuracy of the delivered dose, Plan\_adapt and Plan\_adapt\_Dyn plans were compared for 20 multitarget SRS cases using the 3D gamma tool of the Computational Environment for Radiotherapy Research (CERR) software. It was compiled from the source code available at <https://github.com/cerr/CERR> on July 8, 2018. 3D gamma calculations were focused on the planning target volumes (PTVs) and the OARs (brainstem, optic nerves and optic chiasma). Gamma passing rates were computed for several dose difference criteria (1%, 2% and 3% of the reference maximum dose), 1 mm distance-to-agreement-distance, and threshold of 10% of the reference maximum dose.

**Results**

Sixty PTVs were analyzed: average gamma passing rates were 87.4% (95% CI [81.9, 92.9]), 97.7% (95% CI [95.1, 100.0]) and 99.6% (95% CI [98.9, 100.0]) for 1%/1 mm, 2%/1 mm and 3%/1 mm criteria, resp. Minimum passing rate of 100% was reached for all 20 OARs of each type regardless of the gamma criteria used.

**Conclusion**

The proposed log-file-based method is a useful tool to assess the accuracy of the dose delivery when adaptive SRS is performed. A high agreement within 3% and 1 mm between the designed adaptive plans (Plan\_adapt) and the corresponding delivered ones (Plan\_adapt\_Dyn) was found for all cases.

**EP-2182 Skin dose calculation in breast cancer when the air surrounding the patient contour is considered**

I. Lorenzo<sup>1</sup>, J.F. Calvo-Ortega<sup>1</sup>, S. Moragues Femenia<sup>1</sup>, C. Laosa-Bello<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

#### **Purpose or Objective**

Skin dose calculations in plans of breast cancer have been performed with and without including the air surrounding the patient external contour.

#### **Material and Methods**

Wang et al have described the effect of considering the air surrounding the external patient contour ("body contour") in the accuracy of the calculated skin dose [J Appl Clin Med Phys. 2018 Mar;19(2):191-197]. They proved that an air extension of the body contour of at least 1 cm should be done in order to improve the skin dose calculation accuracy.

We have included 30 breast plans that were calculated for treatment without air extension of the body contour. Then, these plans were re-calculated for a 2 cm-extension towards the air of the body contour (Fig 1). The Eclipse v. 13.6 treatment planning system with the AAA dose calculation algorithm was used. Photons beams of 6 MV from a Varian Clinac 2100 CD with the Millennium 120 MLC were used. The skin structure was outlined in the axial slices where the PTV was present, and it consisted of a 5 mm thickness layer beneath the default body contour detected by the Eclipse (Fig 1). Skin dose is defined in this study as the mean dose registered in the skin structure as defined above. We compared the skin dose for the two type of plans computed with and without extension of the body contour.

#### **Results**

An average increase of 7% (range: 6% to 8.5%) in the skin dose was observed when a 2 cm-enlarged body contour was used.

#### **Conclusion**

The skin dose increase revealed by the 2 cm-enlarged body contour is considered during the dosimetric evaluation of the breast plans designed to patient treatments.

#### **EP-2183 Dosimetric impact of CBCT calibration curve on dose calculated by a radiotherapy TPS**

C. Laosa<sup>1</sup>, J.F. Calvo-Ortega<sup>1</sup>, S. Moragues Femenia<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

#### **Purpose or Objective**

A radiotherapy treatment planning system (TPS) requires a relationship between electron density and CT numbers (calibration curve) to account for tissue heterogeneities during dose calculations. In this work we investigated the dosimetric impact of variations of the calibration curve of a CBCT scanner used for online adaptive cranial radiosurgery.

#### **Material and Methods**

A Varian Clinac 2100 CD linac equipped with a kV-CBCT scanner was used. A half-fan protocol (655 projections, 125 kVp, 80 mA and 13 milisecc per projection, field of view of 260 mm, 384x384 matrix and 1 mm slice distance) is used in our department for adaptive cranial radiosurgery (Med Dosim. 2013 Autumn;38(3):291-7). A reference CBCT calibration curve was established in the Varian Eclipse TPS by using the CatPhan phantom containing seven inserts (air, PMP, LDPE, polystyrene, acrylic, Delrin and Teflon). After that, the CBCT calibration curve was monitored using the CatPhan phantom in a monthly-basis during a year. CBCT scanner was recalibrated when a variation greater than  $\pm 40$  HU was noted in any insert, according to the Varian recommendation. For each CBCT scan (obtained before re-calibration if needed), a box plan (6 MV) was planned and the mean dose and CT number were computed on each insert over an inner region of interest.

CT number and dose for each insert were compared to the values obtained for the reference CBCT scan.

#### **Results**

Maximum variations in the CT number and dose respect to the values of the reference CBCT scan were (CT#/dose): 3 HU/0.7%, 34 HU/0.7%, 32 HU/0.6%, 23 HU/0.5%, 34 HU/0.7%, 32 HU/0.6% and 96 HU/0.8% HU for air, PMP, LDPE, polystyrene, acrylic, Delrin and Teflon, respectively.

#### **Conclusion**

Small impact ( $< 1\%$ ) was observed in the dose quantity even for large absolute variations in the CT number ( $> 40$  HU). Some guidelines (TECDOC-1583; IAEA, Vienna 2008) recommend adjusting the calibration curve in the TPS or tuning the CT scanner when CT numbers vary by more than  $\pm 20$  HU. We propose to act when absolute dose differences greater than 1% are detected.

#### **EP-2184 A study on dose of the junction in radiotherapy of breast cancer including SCL**

W. Jung<sup>1</sup>

<sup>1</sup>Seoul National University Bundang Hospital, Department of Radiation Oncology, Seongnam-si, Korea Republic of

#### **Purpose or Objective**

In treatment planning with junction, heterogeneity is considered to be minimized, but if there are adjacent MLCs, dose distribution can be affected and heterogeneity can be increased. The aim of this study was to compare dose of junction between breast and SCL fields in radiation therapy by MLC located at the junction.

#### **Material and Methods**

With 6 MV of 21EX-S equipped with 120-leaf Millennium MLC, treatment plans were designed with 30 patients who underwent radiation therapy using tangential field technique. Plan 1 where the MLC was all used at the junction. In plan 2 and plan 3, MLC was retracted 5 mm from breast and SCL, respectively. Plan 4 with all of MLC retracted at the junction were designed. In all the plans, collimator angle for SCL field was divided into  $0^\circ$  and  $270^\circ$ . To verify junction dose, the dose at 3cm depth of junction was compared with average value by MapCHECK.

#### **Results**

In case of the SCL field with  $0^\circ$  collimator angle, average value of D3cm was 4131.1, 4215.9, 4351.4, and 4423.0 cGy. In case of the SCL field with  $270^\circ$  collimator angle, average value of D3cm was 4044.3, 4246.7, 4291.1, and 4441.2 cGy. In plan 1 and 3, change in average dose depending on collimator angle was changed more significantly than plan 2 and 4. Dose measured at 3cm depth of junction was similar to treatment plan.

#### **Conclusion**

As a result of the study, there was a difference of about 10% between the plan where all the MLC was applied to the junction and the retracted plan. In radiation therapy plan for breast cancer with SCL, retracting MLC from junction between breast and SCL fields will lead to reduce effect of dose of the junction.

#### **EP-2185 Study of the seroma volume changes in the patients who underwent Accelerated Partial Breast Irradiation**

D.H. Kim<sup>1</sup>, S.J. Son<sup>1</sup>, J.G. Mun<sup>1</sup>, S.J. Seo<sup>1</sup>, J.H. Lee<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, radiation oncology, Seoul, Korea Republic of

#### **Purpose or Objective**

By analyzing seroma volume changes in the patients who underwent Partial breast radiation therapy after breast conserving surgery, we try to contribute to the improvement of radiotherapy effect.

#### **Material and Methods**

Enrolled 20 patients who underwent partial breast radiation therapy by ViewRay MRIdian System were subject.

After seeking for the size of the removed sample in the patients during surgery and obtained seroma volume changes on a weekly basis. On the Basis of acquired volume, it was compared with age, term from start of the first treatment after surgery, BMI (body mass index) and the extracted sample size during surgery. And using the ViewRay MRIdian RTP System, the figure was analyzed by PTV(=seroma volume + margin) to obtain a specific volume of the Partial breast radiation therapy.

### Results

The changes of seroma volume from MR simulation to the first treatment (a week) is 0~5% in 8, 5~10% in 3, 10 to 15% in 2, and 20% or more in 5 people. Two patients (A, B patient) among subjects showed the biggest change. The A patient's 100% of the prescribed dose volume is 213.08 cc, PTV is 181.93 cc, seroma volume is 15.3 cc in initial plan. However, while seroma volume decreased 65.36% to 5.3 cc, 100% of the prescribed dose volume was reduced to 3.4% to 102.43 cc and PTV also did 43.6% to 102.54 cc. [Fig. 1] In the case of the B patient, seroma volume decreased 42.57% from 20.2 cc to 11.6 cc. Because of that, 100% of the prescribed dose volume decreased 8.1% and PTV also did to 40% [Table 1]

### Conclusion

As the period between the first therapy and surgery is shorter, the patient is elder and the size of sample is smaller than 100 cc, the change grow bigger. It is desirable to establish an adaptive plan according to each patient's changes of seroma volume through continuous observation. Because partial breast patients is more sensitive than WBRT patients about dose conformity in accordance with the volume change.

### EP-2186 Feasibility planning study for hypofractionated salvage prostate bed radiotherapy

L. Koopman<sup>1</sup>, S. Van der Neut<sup>1</sup>, C. Roos<sup>1</sup>, C. Hammer<sup>1</sup>, H. Vanhauten<sup>1</sup>, S. Bijmolt<sup>1</sup>, A. Van den Bergh<sup>1</sup>, J. Lagendijk<sup>1</sup>, S. Both<sup>1</sup>, C. Brouwer<sup>1</sup>, S. Al-Uwini<sup>1</sup>  
<sup>1</sup>UMCG University Medical Center Groningen, Radiotherapie, Groningen, The Netherlands

### Purpose or Objective

Salvage radiotherapy treatment (SRT) can provide long-term disease control for recurrent prostate cancer patients after radical prostatectomy. Introducing hypofractionation will decrease the overall treatment time and may improve effectiveness of radiotherapy. The aim of this study was to evaluate the feasibility of target coverage and organ at risk (OAR) constraints of our proposed hypofractionated regimen as an experimental arm of a phase III randomized controlled trial.

### Material and Methods

Planning CT-scans of 5 representative patients who received standard conventional SRT of 35 fractions of 2 Gy were used to virtually create hypofractionated (HF) (20x3Gy) and standard fractionated (SF) (35x2Gy) SRT plans. For both treatment regimens a predetermined list of OAR constraints (Table 1) was tested for its feasibility. Target coverage was evaluated on PTV coverage (D95%).

	Hypofractionated Regimen	Standard Regimen
Rectum Dmax	< 100 % PD	< 100 % PD
Rectum D, 2 cc	< 100 % PD	< 100 % PD
Rectum < 15%	V60	V70
Rectum < 10%	V55	V65
Rectum V50 < 80%	V25	V30
Rectum V50 < 60%	V38	V41
Rectum V50 < 35 %	V50	V60
Rectum V50 mean	< 25 Gy	< 30 Gy
Anal Canal Dmax	< 24 Gy	< 25 Gy
Anal V50 < 10%	V25	V30
Bladder Dmax	< 102 % PD	< 102 % PD
Bladder < 40%	V50	V60
Bladder < 20%	V60	V70
Uterus V50 < 10%	V45	V55

### Results

The average D95% of the low dose PTV (LD PTV) was 99,3% for the standard regimen and 99,5% for the hypofractionated regimen. For the high dose PTV (HD PTV) the average D95% for the standard regimen was 98,6% and 99,2% for the hypofractionated regimen. In only one case 50% of the constraints was not met for both HF and SF regimen. In two cases, all constraints were met for the hypofractionated regimen, while the constraints for rectum Dmax and bladder Dmax where not met for the standard regimen. In one of these two cases, the rectum V65 was not met neither for the standard regimen. For the other 2 cases, only the rectum volume receiving 55 Gy for HF and 65 Gy for SF was more than the intended 15%, with an average of 18,2% of the rectum volume receiving 55 Gy for the HF regimen versus 17,2% of the rectum volume receiving 65Gy for the SF. The median rectum volume (70 cc, range 62-119) did not influence the probability to meet rectum constraints.

### Conclusion

For both target coverage and OAR constraints the hypofractionated regimen appears feasible except for one constraint (rectum V55) which needs further research. A larger number of patients is needed to confirm this feasibility.

### EP-2187 Metal artifact correction improves dose calculation of intensity modulated radiation therapy

H. Moriwaki<sup>1</sup>, T. Ikeda<sup>1</sup>, T. Kiyomiya<sup>1</sup>, H. Tajima<sup>1</sup>, K. Shiraishi<sup>1</sup>, A. Sakumi<sup>2</sup>

<sup>1</sup>Mitsui Memorial Hospital, Radiation oncology, Tokyo, Japan; <sup>2</sup>NTT medical center Tokyo, Department of Radiology, Tokyo, Japan

### Purpose or Objective

We evaluated the dose errors of Intensity Modulated Radiation Therapy (IMRT) between the calculated dose from the planning CT with a commercial CT metal artifact reduction algorithm and the measured dose by ion chamber and radio-chromic film in a water phantom with a cylinder of Titanium alloy

### Material and Methods

A prostate cancer patient with a unilateral right hip prosthesis was selected for this study. IMRT plans were created by Pinnacle3 (Philips Ltd.) v.9.10 using Synergy MLCi (Elekta Ltd.) beam models. We compared among three plans: 1) Five beams step and shoot IMRT plan, 2). Volumetric Modulated Arc Therapy (VMAT) plans with split arc segments thereby avoiding direct beam deliveries to the prosthesis (hereinafter referred to as avoidance VMAT), and 3) a single full-arc beam.

A Titanium alloy (Ti-6Al-4V, density = 4.43 g/cm<sup>3</sup>) cylinder object with a diameter of 30 mm was placed in a water phantom imitating right femoral position. CT images were taken with a single energy metal artifact reduction (SEMAR) algorithm, installed on the CT system (Aquilion ONE, Canon Medical Corporation). The patient treatment

plan was recalculated on the phantom CT images with SEMAR algorithm. Dose calculation results were compared between CT numbers in metal regions replaced with that for the density of Titanium alloy and 2) no correction. An ion chamber was placed at the phantom center for dose comparison to TPS calculation. A film was placed inside a water phantom with a metal object and beams were delivered. Gamma analysis was performed between the film measurements and the TPS dose calculation.

### Results

The dose difference of the measured those and the calculation using SEMAR without no correction are shown in Table.1. The avoidance VMAT did not show the metal effects in all the plans. The density correction improves the dose calculation. Differences in dose distributions with and without the metal was mainly observed in low dose regions due to back scattering from the metal object.

	Table 1 Isocenter dose in each plan				
	Measured dose (phantom)	SEMAR without density correction	%Difference	With density correction	%Difference
Step and Shoot	179.6 cGy	177.7 cGy	-1.00%	178.3 cGy	-0.70%
Avoidance VMAT	189.5 cGy	192.1 cGy	1.35%	190.9 cGy	0.76%
Single arc VMAT	186.3 cGy	182.1 cGy	-2.26%	183.2 cGy	-1.68%

### Conclusion

We observed a significant impact of a metal object on dose distributions in VMAT when a single full arc beam was delivered. However VMAT beams with the avoidance angles did not suffer from the metal effect. The CT with metal artifact reduction improves the dose calculation in IMRT.

### EP-2188 The risk of CIEDs damage by photon beams, define by neutron activation products of CIED materials

W. Szyszka<sup>1</sup>, E. Konstanty<sup>2</sup>, K. Brudecki<sup>3</sup>

<sup>1</sup>Greater Poland Cancer Center, Department of Radiotherapy II, Poznań, Poland; <sup>2</sup>Greater Poland Cancer Center, Department of Medical Physics, Poznań, Poland; <sup>3</sup>Kraków, Poland

### Purpose or Objective

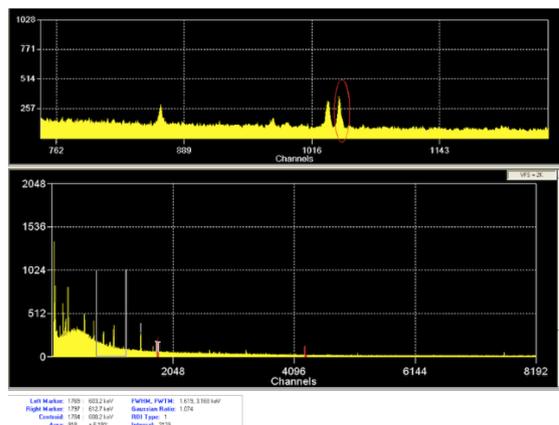

Epithermal or thermal neutron derived from photon beam radiation with energy above 10 MV could react with nuclei of the CIEDs materials. Threshold energies do not apply to (n;  $\gamma$ ) reactions. The study performance based on the risk of the pacemaker or cardioverter-defibrillator damage in a linear accelerator environment analyzing isotopes of elements of devices subjected to irradiation will depend only on the photon beam energy used during RT and the ensuing neutron contamination. The study is focused on understanding the mechanism causing devices malfunctions.

### Material and Methods

The study was performed based on the analysis of high-resolution gamma spectroscopy. Isotopes spectra allow establishing the occurrence of the reaction, and simultaneously determine the portion of emitted energy by detecting the type of the isotope and neutron contamination of the photon beam in linear medical accelerator environment. The study conducted for (i) 6 MV, (ii) 10MV, (iii) 15MV, (iv) 20 MV photon energy for 4 CIED distances relative to the radiation beam - 1) directly in the radiation beam, 2) 10 cm 3) 40 cm and 4) 100 cm from the edge of the radiation field. Each CIED received a dose of 2 Gy. The spectra of device material isotopes were detected using High Purity Germanium detector (HPGe).

### Results

For the samples of CIEDs, which has irradiated with high-energy photon beam (<15 MV) the different spectra of isotopes were observed. occurrence in samples spectra of long-lived isotopes on the energy of 350-360 keV confirmed neutron activation reaction.

### Conclusion

The CIEDs function in patients irradiated with above 10 MV photons should be avoided or if necessary closely monitored, especially in patients subject the increasing number of neutrons in high energies beams, the probability of malfunction increase with the energy of the beam, causing irreversible life-treating failures of the device. The appearance of long-lived isotopes explains the occurrence of CIEDs damages even after a long time from radiotherapy. Understanding the exact mechanism and all the factors of arising malfunctions of CIED is extremely important in consideration of the ever-increasing percentage of patients with CIEDs undergoing radiotherapy.

### EP-2189 Compare OARs dose in postoperative high-risk prostate cancer patients using IMRT and VMAT technique

Y. Chen<sup>1</sup>, L. Chou<sup>1</sup>, T. Wang<sup>2</sup>, Y. Liu<sup>1</sup>

<sup>1</sup>Taipei Veterans General Hospital, Department of Oncology, Taipei City, Taiwan; <sup>2</sup>China Medical University Hospital, Division of Radiation Oncology, Taichung City, Taiwan

### Purpose or Objective

For prostate cancer patients post radical prostatectomy with high risk features, post-operative radiotherapy improves biochemical progression-free survival at the cost of increased urinary and intestinal toxicities. Comparing to 3D conformal radiotherapy, step-and-shoot intensity-modulated radiotherapy (IMRT), volumetric modulated arc therapy (VMAT) both provide highly conformal dose distribution with good sparing of normal tissues in definitive setting. However, no comparison is done for the two techniques in post-operative radiotherapy setting.

### Material and Methods

Seventy-five consecutive post-operative prostate cancer patients were selected retrospectively for this dosimetric comparison study. nineteen patient received IMRT and 60 patient received VMAT radiotherapy using the Eclipse™ treatment planning system (Varian Medical Systems). Planning target coverage, monitor units (MU), dose to bladder and rectum were compared across techniques.

### Results

Overall, dose to the prostate bed, expressed as mean  $\pm$  standard deviation, was 74.7  $\pm$  1.1 (Gy). PTV coverage and total MU were 97.65  $\pm$  1.47 % and 1090.5  $\pm$  279.5 MUs for VMAT and 97.05  $\pm$  1.49 % and 913.3  $\pm$  441.1 MU for IMRT technique. For rectum, mean dose, V40, V45, V50, V55, V60, V65 were 46.2/46.75 Gy (p = 0.78), 35.4/35.6 % (p = 0.93), 27.2/26.9 (p = 0.92), 20.3/19.9 (p = 0.83), 14.2/13.4 (p = 0.68), 8.0/5.6 (p = 0.15), 1.4/1.7 (p = 0.77) % in VMAT and IMRT technique. For bladder, mean dose, V40, V45, V50, V55, V60, V65 were 63.1 /49.2 Gy (p = 0.04), 54.9/40.5 (p = 0.01), 45.9/32.6 (p = 0.02), 38.5/26.0 (p = 0.02), 32.0/20.5 (p = 0.02), 25.7/14.1 (p = 0.01), 7.4/4.2 (p = 0.17) % in VMAT and IMRT technique.

### Conclusion

Both techniques provided good target coverage and good organs-at-risk sparing. However, IMRT resulted in lower dose to the bladder.

### Electronic Poster: RTT track: Image guided radiotherapy and verification protocols

#### EP-2190 MVCT in pediatric craniospinal radiotherapy

F. Ferraro<sup>1</sup>, A. Lastrucci<sup>1</sup>, Y. Wandael<sup>2</sup>, C. Galeotti<sup>2</sup>, M. Vernaleone<sup>2</sup>, D. Greto<sup>2</sup>, G. Simontacchi<sup>2</sup>, P. Bonomo<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence, Department of biomedical-experimental and clinical sciences "Mario Serio", Florence, Italy; <sup>2</sup>A.O.U. Careggi, Radiotherapy, Florence, Italy

#### Purpose or Objective

This work reports the analysis of MVCT, system based on the image-guided radiation therapy (IGRT) in the tomography treatment, used for the initial setup verification in pediatric patients treated with craniospinal irradiation.

The duration of the MVCT scanning time on the entire craniospinal axis is high and anesthesia in pediatric patients is required during this period. For this reason, the reduction of the scanning time is a great interest. The final aim of this work is the comparison between the results obtained from the matching of MVCT and two different kind of patient centering on CT: one based on the scan of the entire craniospinal axis (case 1) and the other based on the acquisition average of the reduced volume at the end and at the beginning of the scanning (case 2).

#### Material and Methods

During this study 7 pediatric patients treated with craniospinal tomotherapy was investigated (total amount of 105 MVCT). Shifts (mm) along the three principal axes (X-lateral, Y-longitudinal and Z-vertical) were acquired for each single fraction associated to the different patients obtained during the matching. In the first case (matching between MVCT and CT scan of the entire craniospinal axis) the shifts were controlled by the operator and the results were acquired in the automatic mode; after the shifts were reset.

In the second case (matching between MVCT and the average CT scans of the reduced volume at the end and at the beginning of the scanning) the matching of MVCT and CT on two different parts was acquired. The analyzed sections were, respectively, the region from frontal sinus to the first thoracic vertebra and the region from the eleventh thoracic vertebra to the first lumbar vertebra. In this case the average of the scans at different positions was considered. The results obtained in the two different cases were compared. During the matching was only considered shifts of translations.

#### Results

The analysis confirms that there is only a slight difference between the two different methods, in some cases less than 1 mm, as reported in the table 1.

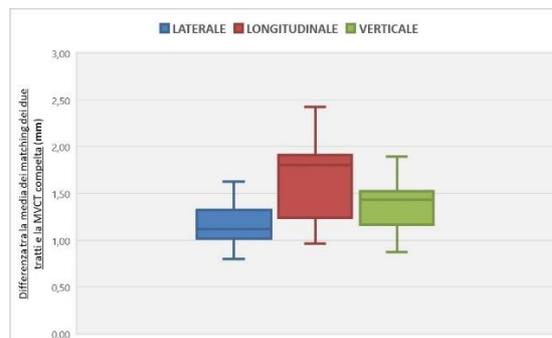

Table1

Box plot representation of the average values obtained from the two different matching on three different planes.

#### Conclusion

The good accordance of these data confirms the quality of the entire procedure, but other studies are necessary before the implementation of this procedure in the clinical protocols. In order to fulfill this goal the evaluation of the following parameters is mandatory:

*Accordance between the results obtained by two different operators:* evaluation of the matching of the data obtained by two different operators.

*Validation by third observer:* evaluation of the differences between the two kinds of MVCT obtained from the entire craniospinal axis and from the average of two reduced volumes (frontal sinus/ D1 and D11/L1).

#### EP-2191 Daily Image Guided Radiotherapy -the relevance for patients with metastatic spinal cord compression

L. Johansen<sup>1</sup>, D. Gasic<sup>1</sup>, V. Gram<sup>1</sup>

<sup>1</sup>The Finsen Center - Rigshospitalet, Radiation Oncology, Copenhagen, Denmark

#### Purpose or Objective

There are wide differences in pre-treatment verification for patients with metastatic spinal cord compression (MSCC). At our clinic, daily Image Guided Radiotherapy (IGRT) with cone beam computed tomography (CBCT) and volumetric modulated arc therapy has been standard practice for MSCC patients for almost a decade. It is seen as a great safety precaution that the treatment is delivered correctly. These patients often suffer from neurological and cancer related pain in various degrees, which can make precise positioning according to setup tattoos alone difficult. This setup uncertainty is compensated by daily setup correction in the form of a couch shift based on the pre-treatment CBCT scan.

For patients treated in the lumbar region of the vertebral column there are also added positional uncertainties as a result of the setup tattoos being placed on the side of the thorax wall, and therefore, far from the target. In addition, there are no fixations used for this anatomical site.

Daily IGRT with couch corrections for MSCC patients is not standard procedure for many radiotherapy clinics and the relevance of it is often discussed. Advantages of IGRT and couch corrections include the ability of reducing target volumes, as well as an added security in correct positioning-ensuring irradiation of the affected vertebra(s).

By looking at the setup corrections made for each fraction, it is possible to estimate the standard deviation and through this evaluate how far off mark a treatment would have been without the use of IGRT.

#### Material and Methods

A total of 30 consecutive patients from early 2018 with MSCC in the lumbar region (proximal thoracic vertebrae were sometimes included in the lumbar target) treated with 3 Gy X 10, 5 F/W were included. The CBCT based

couch shift for superior-inferior (SI), anterior-posterior (AP), medial-lateral (ML) and yaw (rotation around the AP-axis) for all fractions were examined and the mean, minimum, maximum shift and standard deviation (SD) of each parameter in each treatment course was calculated.

### Results

The mean couch shift following the 300 CBCT scans included (table 1) was 5.87 mm SI (Range: 0 - 30 mm, SD: 3.86), 3.96 mm AP (Range: 0 - 22 mm, SD 2.58), 6.51 mm ML (Range: 0 - 34 mm, SD 4.40) and 1.24° yaw (Range: 0 - 4.6°, SD .75). The greatest couch shifts and deviations were generally found in the ML direction.

**Table 1**

Table 1 shows the mean, minimum, maximum shift and standard deviation of each parameter of the 30 patients' treatment course. It should be noted that the couch corrections are not an expression of the direction the couch was moved, but an expression of the deviations corrected, regardless of direction.

### Conclusion

The CBCT based couch shifts showed, that IGRT is highly relevant and useful in ensuring correct treatment of patients with M SCC.

### EP-2192 A systematic approach aimed at reducing IGRT dose in paediatric patients

S. Stead<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre NHS Trust, Radiotherapy, Wirral, United Kingdom

### Purpose or Objective

Compared to adults, the higher survival rates and anticipated decades of longevity of paediatric patients heighten the concerns regarding late effects of radiotherapy and secondary malignancies. Much has changed in the way we plan and deliver radiotherapy and an understanding is required of the differences between adult and paediatric cancers and the consequences of treatment. With continual technological advances such as IMRT and VMAT the ability to optimise plans with sharp dose gradients has dramatically improved, reducing the amount of dose received by normal tissue. However, in order to minimise target volumes for these increasingly conformal techniques, there is a requirement for increased IGRT to ensure accurate tumour localisation and patient set up.

Over-utilization of RT verification systems and procedures could inflict a large amount of excessive radiation

exposure to our paediatric patients, who are already at greater risk of secondary malignancies. It is therefore essential to make sure that the dose delivered as part of any verification procedure is optimised such that the dose is high enough to produce a useable image, but no higher.

#### Material and Methods

A 1 year old patient was referred for RT with an upper lip rhabdomyosarcoma with metastatic neck nodes. The patient was anaesthetised for treatment with a nasogastric tube fitted and laryngeal mask. Daily CBCT was required as IMRT was to be used and also daily repositioning was difficult due to the position of the nasogastric tube and laryngeal mask.

A Varian TrueBeam linear accelerator with software version 2.0 was used for treatment. The CBCT mode editor was utilised and Varian default settings modified so that the gantry was forced to go under the couch, avoiding beam entry through radiosensitive structures such as the eyes. The mAs was reduced in steps to ensure image quality, such as homogeneity, contrast and noise were maintained in the reconstructed image. The geometry of a cone beam scan enables a large FOV to be viewed in one rotation. However this contributed to a large amount of scatter radiation. So in addition to a lower mAs, a smaller FOV was utilised to further reduce scatter radiation. Care was taken to not limit the total volume that could be reconstructed.

#### Results

CBCT images were reconstructed, evaluated, and compared. Visual comparison indicates that the image quality of CBCT(s) is comparable to that of the initial CBCT (#1-2). The results demonstrate that the scanning parameters can be manipulated to reduce the dose to the patient with minimal effect on the quality of the CBCT when comparing bony anatomy. This is done by employing lower mAs, less fps, smaller FOV, or by using 200° rotation below couch.

#### Conclusion

With optimal settings in use, the dose to the patient can be reduced by 95.5% when compared to the default setting with minimal impact on image quality. It is therefore safe and appropriate to use this optimised mode for all paediatric patients.

	kVp	mA	ms	Exposure time	Exposure	fps	Dag/se	Scan length	CTDIw ~mGy	% dose
#1-2 CCC Head	100	15	20	7350	14 6	15	6	185	3.0	100

#### EP-2193 Influence of rotational setup errors on dose in target and organs at risk in cranial radiotherapy

A.S. Gerhardt<sup>1,2</sup>, M.N. Duma<sup>1,3</sup>, M. Düsberg<sup>1</sup>, J.J.

Wilkens<sup>1</sup>, S.E. Combs<sup>1,3</sup>, M. Oechsner<sup>1</sup>

<sup>1</sup>Klinikum Rechts der Isar, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Technical University Munich, Faculty of Medicine, Munich, Germany;

<sup>3</sup>Helmholtz Zentrum München, Institut für Innovative Radiotherapie, Munich, Germany

#### Purpose or Objective

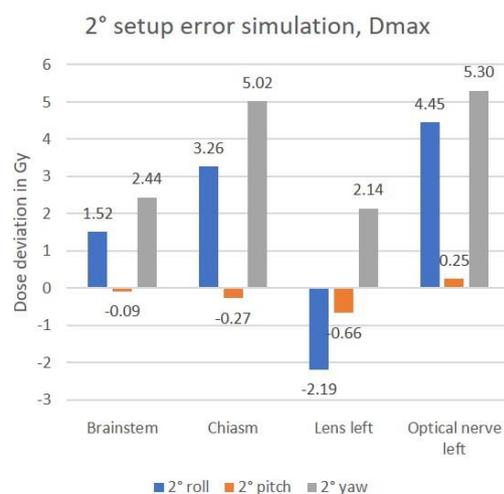

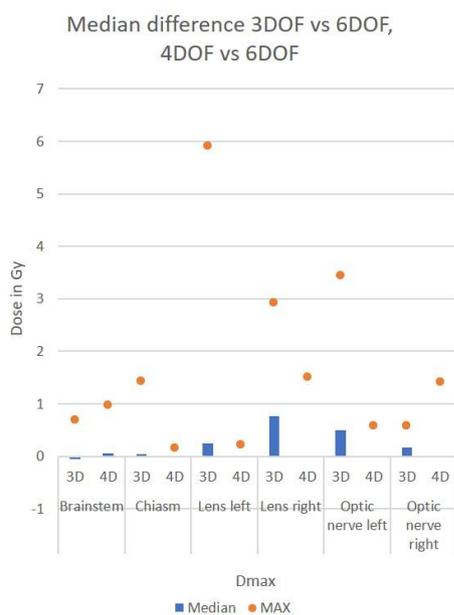

The aim of this study is to detect dose aberrations in cranial radiation therapy in the target volume and adjacent organs at risk (OARs) caused by insufficient rotational setup correction. 6 degrees of freedom (DOF) fusions were considered as the gold standard and compared to 4 DOF and 3 DOF registrations.

#### Material and Methods

Setup errors of 12 patients with cranial lesions undergoing radiotherapy and positioned with cone beam computed tomography (CBCT) were analyzed. The PTVs of the included patients were large and irregularly shaped and located near or overlapping cranial OARs such as brainstem, chiasm, optical nerves or lenses. A registration between planning CT and the first CBCT of the treatment course was performed using 6 DOF, 4 DOF and 3 DOF. Differences between the three registrations were implemented and the planning CT and associated structure set shifted and warped accordingly. To detect the DOF with the largest influence on the delivered dose a rotational error of 2°, 3° and 4° was simulated in one rotational dimension at a time. Using the original parameters, the treatment plan was copied and recalculated to the warped image set. Dmax and Dmean of the cranial OARs and D98 and D2 for the respective CTV and PTV were analyzed.

#### Results

Differences between 6 DOF and 4 or 3 DOF fusion ranged between -1.4° and 2° in pitch direction, -2.5° to 2° in yaw, and -4.4° to 4.2° in roll direction. Resulting median D98 in the PTV decreased by 0.7 Gy using only 3 DOF and increased by 0.08 Gy if 4 DOF were included. Maximum dose reduction of the PTV D98 was 2.96 Gy using 3 DOF and 0.39 Gy using 4 DOF. CTV dose decreased by 0.68 using only 3 DOF and by 0.03 Gy using 4 DOF. Resulting median dose effects in the OARs are displayed in Figure 1, with largest effects of additional 0.2 and 0.8 Gy for the left and right lenses, respectively. Doses for individual patients varied up to additional 6 Gy in the lenses and 3 Gy in the optic nerves. Effects on doses in the OARs and target volumes were generally larger with 3 DOF than with 4 DOF included, except for the brainstem with no visible difference. Pitch and roll setup errors had larger effects on the OARs compared to yaw setup deviations, as demonstrated in Figure 2. 2° roll setup errors caused more than 5 Gy dose effect on the ipsilateral optical nerve and chiasm, followed by 2° pitch errors resulting in over 3 Gy additional dose. The simulated 2° yaw error had an effect of under 1 Gy on dose delivery.

### Conclusion

For cases involving higher dose effects on the evaluated structures, 4DOF registration improved plan conformity compared to 3DOF. Clinically relevant dose deviations in the CTV were not found in this patient collective. While mean dose delivery to OARs increased only slightly, up to 6 Gy in additional dose occurred for individual patient cases in this collective because of rotational errors. Safety margins for OARs could be a solution to this matter.

### EP-2194 Do lower dose KV-CBCT protocols produce adequate quality images for head and neck cancer patients?

M. Forshaw<sup>1</sup>, A. Taylor<sup>2</sup>, S. Temple<sup>3</sup>, H. Wong<sup>4</sup>, A. Willet<sup>5</sup>, C. Rowbottom<sup>5</sup>

<sup>1</sup>The Clatterbridge Cancer Centre, Radiotherapy, Wirral, United Kingdom; <sup>2</sup>Sheffield Hallam University, Radiotherapy and Oncology, Sheffield, United Kingdom; <sup>3</sup>The Clatterbridge Cancer Centre, Physics, Wirral, United Kingdom; <sup>4</sup>The Clatterbridge Cancer Centre, Statistics, Merseyside, United Kingdom; <sup>5</sup>The Clatterbridge Cancer Centre, Physics, Merseyside, United Kingdom

### Purpose or Objective

Previous literature cites that patients treated with volumetric arc therapy (VMAT) for head and neck cancer necessitates Daily Cone Beam Computerised Tomography (CBCT) in order to ensure treatment accuracy. This is because throughout a course of radiotherapy for head and neck cancer anatomical changes occur within the patient due to the treatment delivered, resulting in geometric uncertainty. It is imperative the imaging dose is minimised in line with the Ionising Radiation (Medical Exposures) Regulations 2018 (IR(ME)R) and that images are fit for purpose.

Within the practice environment (PE) the imaging mode for KV CBCT is set by the manufacturer of the Linear Accelerators (Linac), Varian Medical Systems, Palo Alto, CA (Varian).

### Material and Methods

A service evaluation was undertaken to determine whether lower dose KV CBCT head imaging modes provided adequate imaging quality for the purpose of treatment verification, in comparison to the standard manufacturer settings. Optimization of images was completed via a reduction in the mAs. Two alternate settings were produced and tested on a phantom. The novel KV CBCT imaging protocols were then tested on patients who were receiving already justified for daily imaging. Daily KV CBCT scans were acquired and patients received one CBCT per week of a lower dose mode. Overall 304 KV CBCT images were scored independently using a graded scale by three independent multidisciplinary image observers. Qualitative analysis was used to evaluate the results of the study.

### Results

N=38 patients were included in the project. 304 KV CBCT scans were scored using a graded scale. Initial review of images allowed the grouping of image scores into good, moderate and poor categories based on the average image scores for all image reviewers. 56.57% of lower dose images were deemed good in quality in contrast to 1.31% were deemed poor in quality. 42.11% of the lower dose scans were grouped in the moderate quality category. This identified that poor quality images were infrequent. Statistical analysis was undertaken using parametric t-test analysis and provided comparison statistics between standard imaging and lower dose imaging for each individual score. Intra observer variability was also analysed using Kappa analysis. This identified that the physicist results were statistically different to the radiographer and clinician when scoring images.

### Conclusion

Findings identified that low dose imaging produce adequate quality imaging for the purpose that they are intended whilst benefiting the patient by minimising concomitant exposure. The very low dose imaging modes are not suitable for volumes that extend past cervical vertebrae seven, as this produces poor quality images with artefact and image distortion. Calculations were completed to obtain the effective dose that the patient would receive with the differing imaging modes throughout the course of radiotherapy and it was proven that the lower dose imaging reduced the dose received by the patient.

### EP-2195 Optimization of SABR lung CBCT verification

L. Turtle<sup>1</sup>, A. Willet<sup>2</sup>, C. Lee<sup>2</sup>, C. Fitzpatrick<sup>2</sup>, R. Biggar<sup>2</sup>  
<sup>1</sup>Clatterbridge Cancer Centre NHS Foundation Trust, Radiotherapy, Wirral, United Kingdom; <sup>2</sup>Clatterbridge Cancer Centre NHS Foundation Trust, Physics, Wirral, United Kingdom

### Purpose or Objective

CBCT verification is arguably more critical to ensure set-up accuracy in hypo-fractionated SABR regimens. At our clinic all SABR lung patients receive pre-treatment 4D-CBCT and post-treatment 3D-CBCT imaging. The current default is Varian TrueBeam 'thorax' mode (125kV, 15mA, 46cm FoV). This is a full trajectory scan, taking 60 seconds to acquire. To improve on-set efficiency and optimise imaging dose alternative 'spotlight' CBCT exposures were investigated. Spotlight offers a shorter 200° trajectory and the smaller 25cm FoV is sufficient for SABR lung PTV's. These modes were tested on the post-treatment imaging to determine if they are clinically suitable for verification.

### Material and Methods

Two thorax spotlight modes (A, B) were optimised using a CIRS lung phantom. Exposure parameters were reduced in both cases to 100kV and 10mA and 15mA for modes A and B, respectively. 5 patients were selected randomly for clinical testing (including gated and non-gated cases). For each patient, standard 'thorax' mode was replaced by 'spotlight' A or B, on subsequent fractions in no particular order. Treatment radiographers were blinded to which mode was of higher mA.

Images were reviewed and scored offline by 4 RTTs of various experience and 1 physicist. Scorers were blinded to which exposures had been used. The CBCTs were scored using an adapted 5-point scoring system, where 1 is the highest score. A score  $\leq 3$  was deemed clinically suitable. For each image, the highest and lowest scores were discarded.

### Results

CTDI<sub>w</sub> was established as 0.78 mGy (A) and 1.16 mGy (B). This represents a dose reduction of 71%-80% compared with the current standard 'thorax' mode (CTDI<sub>w</sub>=3.94mGy). This also corresponds to an effective dose of roughly 0.4mSv (A) and 0.6mSv (B) which is about a lifetime cancer risk of 1 in 42000 and 1 in 28000 respectively compared with the current standard 'thorax' mode which is 1 in 8000 (2.2mSv).

Spotlight A and B achieved an average scoring of 2.4 and 2.5 across all patients, respectively. Both would therefore be suitable for clinical use. With minimal scoring difference, the lower dose Spotlight A is preferable for its reduced dose.

CBCT delivery time was reduced from 60 seconds to 33 seconds.

### Conclusion

The use of spotlight mode for verification of lung SABR has been demonstrated. Imaging dose has been optimised as low as reasonably practicable whilst fulfilling the clinical requirement for verification. Delivery time has been reduced, improving patient experience and clinic throughput. The new mode will be introduced as the clinical standard.

#### EP-2196 Dosimetric impact of anatomical changes during IMRT for prostate cancer

L. Farhat<sup>1</sup>, W. Mnejja<sup>1</sup>, H. Daoud<sup>1</sup>, F. Dhoubi<sup>1</sup>, T. Sahnoun<sup>1</sup>, W. Siala<sup>1</sup>, J. Daoud<sup>1</sup>

<sup>1</sup>Hbib Bourguiba Hospital, Radiotherapy, Sfax, Tunisia

### Purpose or Objective

During the treatment of prostate cancer with intensity modulated radiotherapy (IMRT), we observe geometric (volumetric and positional) variations. We proposed in this work to evaluate the dosimetric impact of these variations on prostate and organs at risk: bladder and rectum.

### Material and Methods

Ten patients treated with IMRT for prostate cancer were included in this study. For each patient, 3 to 5 control scans (CTc) were made during the treatment period and fused with the initial scan (CTi). We manually delineated the prostate, the bladder and the rectum on the CTc. A comparative study of the different volumes was performed to determine the percentage of variation. We recorded the minimum dose (Dmin) in the prostate and the maximal dose (Dmax) in the rectum and bladder on the various CT made. Comparison of averages deviations was done using the Wilcoxon Signed Rank test for associated samples.

### Results

We found a significant average variation of volume for the different structures. It was about 20.67% [-89, 198%] for the rectum (p<0.001), 16.69% [-66, 86%] for the bladder (p<0.001) and 5.81% [-23, 18%] for the prostate (p<0.001). The Dmin in the prostate was decreased by 4.05%, the Dmax in the rectum and the bladder by 0.16 and 0.51%. Two patients had an important decrease of Dmin in the prostate. It was about 18 and 13.75%. For those patients, the increase in prostatic volume was about 6.97% and 16.04% and the decrease in rectal volume about 27.96% and 48.91%.

### Conclusion

The anatomical variations during IMRT in the target volume and the organs at risk were not correlated with a major dose variation. However, in two cases, the significant reduction in rectal volume was associated with a decrease in prostatic Dmin which could have an impact on the control of the disease. We insist, then, on the need to perform the dosimetric scanner with an empty rectum.

#### EP-2197 EEBH as a method of managing respiratory movement in treating abdominal structures with SABR

J. Barber<sup>1</sup>, B. Taylor<sup>2</sup>, A. Gaya<sup>2</sup>, A. Qureshi<sup>2</sup>, C. Thomas<sup>3</sup>, C. Hartill<sup>1</sup>, V. Staykova<sup>3</sup>, C. Sisodia<sup>3</sup>

<sup>1</sup>Guys and St Thomas', Radiotherapy, London, United Kingdom; <sup>2</sup>Guys and St Thomas', Oncology, London, United Kingdom; <sup>3</sup>Guys and St Thomas', Radiotherapy Physics, London, United Kingdom

### Purpose or Objective

When treating abdominal structures with SABR, accounting for respiratory movement is mandated by the CORE and SARON trials and SABR CtE. The most common methods are to apply an ITV, meaning the target volume stays within the high dose area, or using Abdominal Compression to physically restrict the movement of abdominal structures. Utilising EEBH for delivering treatment will enable complete eradication of target volume movement and therefore the ITV.

### Material and Methods

Following the implementation of EEBH in pre-treatment resulting in improved CT image quality, the potential impact of treating in EEBH rather than using an ITV was assessed by quantifying the reduction in target volume and the impact on OAR doses when an EEBH plan was created. This showed clear benefits to treating in EEBH, with volumes being as much as halved and OAR doses being dramatically reduced.

### Results

Treating in EEBH has reduced target volumes by an average of 31% (values ranging from 8% to 51% in the 8 patients analysed), consequently allowing higher doses to be used in more patients and increasing the overall number of patients suitable for treatment with SABR.

### Conclusion

There are challenges involved in treating patients in EEBH, including reproducing breath-holds and verifying the level of hold. Techniques used with DIBH techniques proved ineffective as a result of the EEBH position being within the normal range of respiratory motion, meaning AlignRT was unable to detect this as they would the significant

contour change of DIBH. Instead, RPM was used as this system normalises to a baseline of 0, determined by the End Expiration amplitude. This breath hold was then verified by acquiring a CBCT while in EEBH and comparing to the planning CT acquired in EEBH. Flattening Filter Free (FFF) was utilised at treatment to cut delivery time, allowing patients to be treated in an achievable number of breath-holds. Further work will be carried out to determine the dosimetric impact on OARs of this volume reduction.

##### EP-2198 Addressing treatment-related sexual side effects: Sub-optimal practice in radiation therapy

O. Lynch<sup>1</sup>, P. Murphy<sup>1</sup>, A. O'Donovan<sup>1</sup>

<sup>1</sup>Trinity College Dublin, Discipline of Radiation Therapy, Dublin, Ireland

#### Purpose or Objective

Sexual side effects of treatment are common among cancer patients receiving radiation therapy. Little attention has been given to the role of radiation therapists (RTs) in managing sexual issues. The current study sought to address this by assessing the provision of care for sexual issues by RTs in Ireland.

#### Material and Methods

Cross-sectional data were collected using an online questionnaire. Measures included: participant characteristics; sexuality-related practice, knowledge, awareness, and confidence in dealing with sexual issues; the sexual attitudes and beliefs survey; and opinions as to the 'ideal' management of sexual issues.

#### Results

Discussion of sexual issues with patients was rare, and most participants ( $N = 46$ ) did not feel these issues were addressed effectively in their departments. Barriers to the discussion of sexual issues included: low knowledge, awareness, and confidence, perceptions of professional role boundaries; and concerns about personal and patient discomfort. Nonetheless, participants indicated that RTs should ideally be equipped to discuss sexual side effects of treatment, as they would any other side effect.

#### Conclusion

This study has identified a sub-optimal provision of care for sexual issues by RTs. Training is needed if RTs are to effectively support the work of the multidisciplinary team in this area.

##### EP-2199 Attitudes of parents of female secondary school students towards the HPV vaccine

K. Lawless<sup>1</sup>, C. Poole<sup>1</sup>, P. Murphy<sup>1</sup>

<sup>1</sup>TCD Division of Radiation Therapy, Radiation Therapy, Dublin, Ireland

#### Purpose or Objective

Cervical Cancer is the seventh most common cancer worldwide. The HPV virus is responsible for 70% of invasive cervical cancers and the decision to vaccinate a child against HPV is made by their parents. Concerns over the safety of the vaccine has resulted in a decrease in the uptake of the HPV vaccine. The main purpose of this study was to identify the influences behind attitudes currently held by parents of Irish adolescent girls and the factors causing the drop-in uptake.

#### Material and Methods

An anonymous questionnaire was designed and circulated among the parents of first-year students in two all-girl secondary schools ( $n = 158$ ). The questionnaire included both quantitative and qualitative questions. Outcome

measures were HPV Knowledge, information sources and parental attitudes.

#### Results

The vaccine uptake according to this study was 63.4% ( $n=41$ ). The study showed that 68.3% of the parents had good knowledge of the HPV Virus/Vaccine. A strong trend towards significance in this study suggested that participants with lower knowledge were more likely to consent. Thematic analysis of the qualitative data revealed that parents wish to protect their child from cervical cancer and that worries about the vaccine safety were the main barrier to vaccination. Assumptions that more knowledge of HPV would lead to acceptability was not established in this study, instead it was suggested that those with lower knowledge were more likely to consent. Increased knowledge would indicate that the parents were more likely to do in-depth research and discover the well-publicised safety concerns.

#### Conclusion

Further efforts must be made to counteract the negative media available to parents to ensure they are fully informed in their decision making. Further research on the parents' knowledge of vaccine safety could be done to address this.

##### EP-2200 Understanding the impact of health literacy on self-efficacy in cancer patients undergoing treatment

R. Scanlon<sup>1</sup>, C. Gillham<sup>2</sup>, A. Craig<sup>1</sup>

<sup>1</sup>Trinity College Dublin, Discipline of Radiation Therapy, Dublin, Ireland; <sup>2</sup>St Luke's Radiation Oncology Network, Radiation Therapy, Dublin, Ireland

#### Purpose or Objective

Health literacy influences how cancer patients participate in self-care and disease management due to their level of knowledge in the area. As shown in other groups, greater levels of self-efficacy result in patients seeking information, thus improving levels of self-care. These factors are important to consider in cancer patients, who rely on disease management and self-care to improve quality of life.

The purpose was to investigate if a relationship exists between health literacy and self-efficacy in cancer patients undergoing radiotherapy and to identify if such a relationship can be affected by patients' sociodemographic factors.

#### Material and Methods

An anonymous survey combining sociodemographics with standardised instruments of health literacy and self-efficacy was distributed in a radiotherapy service. Quantitative analysis was used to determine if a relationship exists.

#### Results

From the 165 surveys distributed, 62 surveys were returned, yielding a 38% response rate. Health literacy moderately impacted on self-efficacy ( $r = 0.617, p < 0.001$ ), with the strongest correlation in participants asking questions and participating in treatment. Education ( $r = 0.39, p = 0.002$ ) and employment status ( $H(4) = 10.19, p = 0.04$ ) influenced health literacy. Of the sociodemographic data analysed, only employment status influenced self-efficacy ( $H(4) = 9.727, p = 0.045$ ).

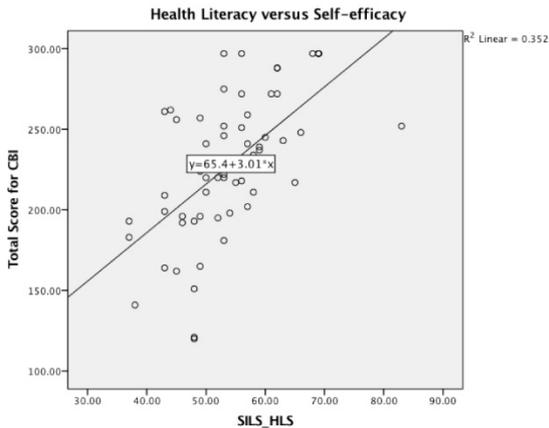

Figure 1. shows the moderate positive relationship between health literacy (SILS\_HLS) and self-efficacy (Total Score for CBI).

### Conclusion

Health literacy is related to self-efficacy in cancer patients. Education level positively impacts health literacy levels, highlighting the importance of tailoring patient information to patient education levels, in order to promote self-care and disease management.

### EP-2201 Auditing patient's radiotherapy medical file for improvement

S. Cucchiari<sup>1</sup>, M. Delgaudine<sup>2</sup>, P. Coucke<sup>1</sup>

<sup>1</sup>C.H.U. Sart Tilman, Radiotherapy Department, Liège, Belgium; <sup>2</sup>C.H.U. - Sart Tilman, STA Quality Department, Liège, Belgium

### Purpose or Objective

The patient's Radiation Therapy (RT) medical file is the place of collection and conservation of medical and paramedical information, recorded for any patient. The patient's record ensures the traceability of all actions performed. It is an important tool of communication, coordination and information between the multidisciplinary RT team. It makes it possible to follow and understand the patient's RT journey. This file must be complete and contain the information essential for the quality of the treatment. The purpose of this study is to draw up an objective inventory of the RT medical record and to propose improvement actions so that it is best documented as possible.

### Material and Methods

The methodology used is an internal audit of medical files. A grid was developed based on criteria used in the Quality Assurance Team for Radiation Oncology (QUATRO) reference, criteria recommended by Joint Commission International accreditation, and RT department-specific criteria derived from adverse event reporting for incomplete or erroneous patient records.

This grid (Figure 1) includes 19 observation items and one box for comments. The filling is simple and is carried out by "yes-no-partially-not applicable".

The analysis of files was carried out retrospectively by selecting patients treated by radiotherapy in the service between January and June 2018.

Figure 1: Assessment grid for chart review

Date:	Type	sheet 1	sheet 2	sheet 3	sheet 4	sheet 5	sheet 6	sheet 7	sheet 8	sheet 9	sheet 10
1	Is the pathology report included?										
2	Are Multidisciplinary Oncology Consultations (MOCs) decisions (taken)?										
3	Is the staging properly documented?										
4	Is the pathology clearly identified?										
5	Is the prescription evidence based?										
6	Are total dose, dose/fraction, and number of fraction stipulated?										
7	Was there any change during treatment?										
8	Are Chemos / surgery dates specified?										
9	Are the specific simulation features specified?										
10	Are the specific criteria of care completed? (allergy, pregnancy, sacral/prostate...)										
11	Is the irradiation technique as well as the laterality specified?										
12	Is performance status included?										
13	Is the first consultation completed?										
14	Are the follow up consultations completed?										
15	Is the end of treatment consultation completed?										
16	Is a geriatric assessment done?										
17	Is a pain assessment done?										
18	Is the patient's general consent stipulated?										
19	Is the information given to the patient and his family about his state of health, his examinations, his treatments (and possible changes) traced?										
	Comments										

### Results

10 patient files per doctor were randomly selected; there are 13 doctors in the department, so a total of 130 records were observed.

By analyzing the results obtained, it is noted that the files are quite complete, for example the pathology is clearly identified (100%), there is a trace of the first consultation (95%), the dose prescription is specified (99%). On the other hand, it is observed that in some cases important data for quality management care are missing, such as irradiation technique or tumor laterality are partially completed (65%), no systematic geriatric evaluation in patients over 75 (35%), no traceability of general consent (29%) and information given to the patient (39%). Various improvement actions were put in place following this analyze: setting up informed consent, check list to ensure that important issues are completed, use of a standard scale of pain identical to the one of the hospital. A half-yearly follow-up of these actions and a punctual audit during the year to verify the relevance of these actions will be realized.

### Conclusion

This RT patient chart review allows us to identify what is being done correctly and what needs improvement. Data contained within these files are extremely valuable for improving radiotherapy department efficiency and ensuring quality and safety of treatments. It is important that these files contain all the information necessary for good management.

Conducting internal audits such as medical records observation in the RT department is an effective tool for quality management in patient care.

### EP-2202 Iatrogenic sexual dysfunction following BRT. supportive therapy for better perception life quality

F. Piro<sup>1</sup>, D. Cosentino<sup>1</sup>, A. Martilotta<sup>1</sup>, A. Massenzo<sup>1</sup>, U. Piro<sup>1</sup>, G. Tocci<sup>1</sup>, L. Marafioti<sup>1</sup>

<sup>1</sup>Spedale Mariano Santo, Radiotherapy Center, Cosenza, Italy

### Purpose or Objective

BRT treatments can cause permanent sexual dysfunction due to shortening and vaginal shrinkage induced by fibrosis and post-treatment stenosis as a permanent toxic effect. We evaluated the introduction of supportive therapy (SuBRT) vs control group (CBRT).

### Material and Methods

From January 2010 to September 2017, 207 patients histologically proven endometrial carcinoma treated with BRT exclusively, with or without supportive therapy during treatment. BRT treatment involved a total dose of 30 Gy with a daily fraction of 6 Gy. Supportive therapy: daily endovaginal lavender with clorexidina and 12 hours after endovaginal ovules of hyaluronic acid low weight. We have formulated a psychological check-list for short interview to assess quality of life and impact on sexual activity after BRT, respecting privacy. We defined following areas: 1) social relationships and personal emotions, 2) intimacy of

couples and sexuality, 3) impact of treatment on sexuality, 4) relationship doctor-patient before BRT.

#### Results

Evaluable 199 pts.; median follow up 44 months (range 8-93); median age 62 years (40-88). Histological examination resulted 5 squamous and 194 adenocarcinoma; grading G1 for 15%, G2 for 65% and G3 for 20% of cases; all stage pT1B; lymph node status Negative in 149 (75%) and NX in other 50 (25%). Diameter of the cylinder used in 168 (84%) pts. it was 3-4 cm the remaining 31 (26%) diameter 1-2. Only 3 (1.5%) pts. disease progression. Psychological evaluation performed on 142 pts. (median age 61, range 44-71) the rest 57 not interested because not sexual active. Two groups: 69 CBRT vs 73 pts. SuBRT. First area the change of social activity recorded as "very, very much" was 33 of CBRT vs 22% of SuBRT, in the emotional state we found 42 of CBRT vs 29 % SuBRT. Second area: intimacy of couple; 71 vs 49% said they had undergone change; with repercussions on her relationship 49 vs 32 % and 81 vs 48 % of women reported decreased sexual desire.

Third area impact on sexuality: BRT changed your sex life? 46 vs 21% of SuBRT "very, very much". With sexual intercourse painful for 73 vs 48 % of the interviewees and to the question "Are sexual relations satisfactory?" 91 vs 60 % of respondents answered "NO".

Fourth area when we asked "Have you been informed that BRT could have an impact on sexuality?" 58 vs 80% of the patients answered "YES" while at the question "Did they advise you to have sex with your partner?" 71% vs 81 of the women received these indications. Unexpectedly, 13 vs 1 % SuBRT of patients explicitly requested psychological support.

#### Conclusion

Regardless of grading and lymph node depletion, BRT is effective in preventing disease recurrence. Although cylinders with larger diameter are used, the problem of post BRT toxicity management remains. Introduction of supportive therapy during treatment and best patient doctor relationship reduced the impact on quality of life of these patients.

#### EP-2203 DVH as predictor of acute skin toxicity, its clinical application in breast cancer radiotherapy

F. Piro<sup>1</sup>, D. Cosentino<sup>1</sup>, A. Martilotta<sup>1</sup>, A. Massenzo<sup>1</sup>, U. Piro<sup>1</sup>, G. Tocci<sup>1</sup>, L. Marafioti<sup>1</sup>

<sup>1</sup>Ospedale Mariano Santo, Radiotherapy Center, Cosenza, Italy

#### Purpose or Objective

The correlation between acute cutaneous toxicity and homogeneous dosimetry in breast cancer radiotherapy is now certain. For this reason, using the 3D conformational technique, we reviewed the dosimetry and DVH of each patient and recorded during the treatment the possible onset of acute cutaneous toxicity.

#### Material and Methods

from September 2017 to April 2018, 204 patients with breast cancer underwent 3D conformal radiotherapy on the breast. Tangential latero-medial technique, 6 MV photons, also using dynamic filters, two treatment schedules: single dose. 2.65 up to 42.40 Gy or single dose 2 to 50 Gy plus boost with electrons single dose 2.5 up to 10 Gy. So we evaluated the DVHs of each treated patient. Both during and after treatment, the onset, the location, and the degree of cutaneous toxicity were recorded.

#### Results

The evaluation of the DVH and of the dosimetry of each patient, regardless of the fractionation used, showed the presence of hot spots with respect to the prescribed dose for 51 of the 204 aforesaid patients even in the presence of normal dosimetrics for the remaining parameters that usually are considered. Reviewing the outlines made it was possible to highlight that the presence of such dose peaks may be due to various factors such as the size or shape of

the breast. 56 patients (27%) reported acute G2/G3 toxicity; 35 pts. in the ipsilateral axillary area and submammary line, 21 patients recorded (10% of total) G2 toxicity but affecting the whole breast. In any case, the presence of hot areas only in some points did not allow us to understand the onset of toxicity on the whole mammary area. From these data for this group of patients it was necessary to use a more aggressive topical therapy. No patient discontinued treatment. The post-treatment cosmetic result at a median follow-up of 8 months showed no permanent damage.

#### Conclusion

The possibility of having an instrument such as DVH to predict acute toxicity also allows to put in action for selected patients those actions useful to avoid the toxicity onset, first of all with the use of new treatment methods able to limit the number of hot spots. The combination of clinical and radiotherapy techniques knowledges allows the identification of new methodological approaches to avoid functional imperfections and limitations, limited to the duration of treatment. The 3D conformational technique used by us has allowed a decrease in toxicity compared to the data reported in the literature, but does not always allow homogeneity of the treatment. Even the continuous use of topical supportive therapy should not be underestimated.

#### EP-2204 The impact of breast irradiation using thermoplastic mask on quality of life

A. DINU<sup>1</sup>, T. Flonta<sup>1</sup>, L. Marcu<sup>2</sup>

<sup>1</sup>County Hospital "Gavril Curteanu", Radiotherapy, Oradea, Romania; <sup>2</sup>Faculty of Science- University of Oradea- Romania School of Physical Sciences- University of Adelaide- Australia, Medical Physics, Oradea- Adelaide, Romania

#### Purpose or Objective

The critical role of thermoplastic mask in patient immobilization during breast irradiation is well known. However, these immobilizing casts can have a buildup effect which augments the skin dose, thus leading to unwanted adverse events. The purpose of this study is to evaluate these adverse events and their impact on patient's quality of life (QoL).

#### Material and Methods

For patients with large and pendulous breasts the prone setup represents the ideal solution for an accurate immobilization, which can be achieved either with a designated board or using thermoplastic masks. The study included 42 patients, between the ages of 32-60, where 21 patients were irradiated with the mask, while the other 21 underwent breast irradiation without mask. Dose prescription for both groups was 50Gy in 25 fractions to the whole breast CTV and boost dose to the tumour bed of 60 Gy in 25 fractions. At the start of therapy all patients were informed about possible adverse events, particularly of radiodermatitis, as well as other risk factors (sun exposure, smoking, the use of inadequate ointments on the lesion). During the course of treatment, the radiation therapists used both verbal questioners and physical examination of the irradiated skin to be assured that the physicians' recommendations were followed. The main targeted aspects were: (1) the grade and time interval to radiodermatitis, (2) the impact of radiodermatitis on patient's quality of life. Radiodermatitis was visually evaluated using the RTOG criteria

#### Results

Without thermoplastic mask, skin erythema developed after 10-14 days from the start of treatment, all patients developing grade 1/2 radiodermatitis by the end of therapy. When irradiated with the thermoplastic mask, skin erythema was installed after the 7<sup>th</sup> day of treatment, grade 1 radiodermatitis after 26-30Gy, while by the 4<sup>th</sup> treatment week grade 2 radiodermatitis was present in all patients. By the end of treatment, 3 patients (14.3%)

developed grade 3 radiodermatitis. The QoL was directly proportional to the initiation of radiodermatitis. Local discomfort lead to insomnia, anguish and mild depression, with more pronounced depressive episodes in women aged 32-40 years. Five patients presented with skin telangiectasia. While irradiation-induced fatigue together with the above adverse events decreased their QoL on the short term, 6-month post-therapy radiodermatitis has cleared, leaving only a light depigmentation on the breast skin. All patients confirmed an increased QoL with the disappearance of dermatitis.

#### Conclusion

There is a clear dependence between radiodermatitis and breast cancer patients' QoL. The impact of adverse events on QoL can be diminished with the supportive care of the radiation therapists and physicians. The role of thermoplastic mask to reduce positioning errors and increase the therapeutic index outweighs the risk of adverse events and their impact on QoL.

#### EP-2205 Patient involvement in developing research-based patient information on proton therapy

A. Kristensen<sup>1</sup>, H. Hansen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Danish Centre for Particle Therapy, Aarhus N, Denmark

#### Purpose or Objective

No previous patient information material on proton therapy has been developed in a Danish setting.

A new centre for particle therapy is currently being established, and patient involvement is a fundamental value both during this process and will be in the future running of the centre.

The purpose of this project was:

- To test whether patient involvement as a method can be used in the development of research-based patient information.
- To identify possible differences in patient information aimed at children, adolescents and adults.

#### Material and Methods

Qualitative semi-structured interviews were conducted with seven adults (18-55 years) and eight families with children and adolescents (2-18 years). The adult interviewees and the children/adolescents had received proton treatment abroad within the last two years.

Qualitative content analysis inspired by Ricoeur was used to analyse the collected data. The emerging themes were discussed by the authors and consensus was reached.

To ensure compliance between interview data and the actual patient information material and to ensure the quality, a user panel consisting of some of the interviewees will be organised.

#### Results

The following main themes needed to be covered in the patient information:

- The difference between proton and photon therapy; what protons are and when protons are preferred.
- Illustrations of the equipment used in the treatment, making of the mask, how scans and treatment are performed as well as arguments for deliberately planning sometime between first visit and start of treatment.
- Knowledge about possible side effects and their effect on the patient's life during and after end of treatment.
- Information about practical issues (transportation and accommodation during course of treatment).

#### Conclusion

Patient involvement as a method is useful to ensure representation of the patient perspective when developing research-based patient information.

#### EP-2206 How long should men abstain from receiving anal sex following treatments for prostate cancer?

S. Ralph<sup>1</sup>, C. Richardson<sup>2</sup>

<sup>1</sup>NHS, The Clatterbridge Cancer Centre NHS Foundation Trust, Bebington, United Kingdom; <sup>2</sup>University of Manchester, Division of Nursing- Midwifery and Social Work, Manchester, United Kingdom

#### Purpose or Objective

To develop UK guidance on how long men should abstain from receiving anal sex before, during, and after investigations and treatments for prostate cancer.

#### Material and Methods

A modified Delphi technique utilising two question rounds was employed in order to generate consensus opinion from a panel of 15 clinical oncologists and 11 urological surgeons who specialise in the diagnosis and treatment of prostate cancer.

#### Results

The overwhelming consensus from panel members was yes men should abstain from receiving anal sex before, during, and after investigations and treatments for prostate cancer (table 1). The consensus and consensus level for how long should men abstain was: 1 week before a PSA test (n=15 / 58%); 2 weeks after a transrectal ultrasound guided biopsy (n=6 / 55%); 1 week after a transperineal biopsy (n=6 / 60%); 6 weeks after a radical prostatectomy (n=5 / 45%); yes during external beam radiotherapy (n=11 / 73%) and for 2 months after (n=4 / 40%); and 2 months after high-dose rate brachytherapy (n=3 / 60%). Panel members failed to reach consensus on how long men should abstain from receiving anal sex after the insertion of fiducial marker and permanent seed brachytherapy.

Table 1: Consensus summary table for should men abstain from receiving anal sex...?

Should men abstain from receiving anal sex:	Consensus (n / %)
Following a transrectal ultrasound guided biopsy?	Yes (10 / 90.9%)
Following a transperineal biopsy?	Yes (8 / 72.7%)
Following a radical prostatectomy?	Yes (10 / 90.9%)
After the insertion of fiducial markers?	Yes (9 / 60.0%)
Whilst undergoing a course of external beam radiotherapy?	Yes (11 / 73.3%)
After completing a course of external beam radiotherapy?	Yes (11 / 73.3%)
Following permanent seed brachytherapy?	Yes (4 / 100.0%)
Following high-dose rate brachytherapy?	Yes (5 / 100.0%)

#### Conclusion

Men should abstain from receiving anal sex before, during, and after investigations and treatment for prostate cancer in order to avoid receiving a false positive PSA test; manage their side effects appropriately; minimise radiation exposure to sexual partners; and to minimise the risk of developing post-intervention complications. The data from this study has been used by the charity Prostate Cancer UK to update their patient information publication 'Prostate cancer tests and treatment: A guide for gay and bisexual men'.

#### EP-2207 PROMS: Transperineal insertion of prostate markers - results from a prospective clinical trial

A. O'Neill<sup>1,2</sup>, K. Crowther<sup>1</sup>, D. Mitchell<sup>1</sup>, S. Jain<sup>1,2</sup>, A. Hounsell<sup>1,2</sup>, J. O'Sullivan<sup>1,2</sup>

<sup>1</sup>Belfast Health and Social Care Trust, Radiotherapy, Belfast, United Kingdom; <sup>2</sup>Queens University Belfast, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom

#### Purpose or Objective

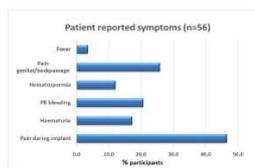

Surgical insertion of fiducial markers (FMs) is an important component of image guided radiotherapy for prostate cancer and has similar risks to that of prostate biopsy including pain, bleeding, and infection. The procedure is usually performed on an outpatient day case basis using a transurethral ultra-sound (TRUS). We report our experience of FM insertion and patient feedback on acute effects from a prospective clinical trial.

### Material and Methods

A prostate prospective clinical trial required all participants to have prostate FMs. All participants were invited to complete a simple questionnaire designed to capture their experience of FM insertion and any side effects they experienced within 1 week of implantation. FM insertion was performed trans-perineally under TRUS guidance using local anaesthetic and antibiotic prophylaxis.

### Results

58 participants were each implanted with three gold FMs, verified on CT planning scan. A total of 56 out of 58 (97%) questionnaires were returned. An overall summary of patient reported symptoms following FM implantation are given in Figure 1.

### Conclusion

In our centre, FM insertion is well tolerated. Acute side effects were mild to moderate and in general were transient, resolving within a few days. Grade >3 toxicity was rare and self-managed with the use of simple analgesics. Efforts to standardise patient preparation, implantation procedures and data collection to allow meaningful comparison and inform best practice are needed.

### EP-2208 Evaluating the efficacy of the Cancer Nurse Consultant Role for Radiotherapy Oncology inpatients

M. Rolfo<sup>1</sup>, T. Pearce<sup>2</sup>, J. Armstrong<sup>3</sup>, M. Guiney<sup>4</sup>, S. Ryan<sup>3</sup>  
<sup>1</sup>Genesiscare UK, Radiation Oncology, Berkshire, United Kingdom; <sup>2</sup>GenesisCareUnited Kingdom, Radiation Oncology Berkshire, United Kingdom; <sup>3</sup>GenesiCare Australia, Radiation Oncology, Melbourne, Australia; <sup>4</sup>GenesisCare Australia, Radiation Oncology, Melbourne, Australia

### Purpose or Objective

A pilot study to validate the implementation of a Cancer Nurse Consultant (CNC) role in a busy tertiary cancer centre in improving the patient experience, providing clinical expertise and coordinating all aspects in relation to the delivery of radiotherapy treatment to inpatients.

### Material and Methods

This pilot study was conducted in 2017 in a major tertiary hospital with over 800 inpatient beds and a comprehensive oncology program covering many tumour streams. In this evaluation, the CNC participated in the Multi-Disciplinary Team Meetings (MDTM) to initiate timely interventions and proactively manage the continuum of care for inpatients undergoing radiotherapy (RT). Participation of the CNC in MDTMs was postulated to enable better coordination and implementation of earlier interventions and create a efficient pathway for the patient to access care. Inpatients satisfaction termed a Net Promoter Score (NPS) metrics were taken

### Results

The evaluation demonstrated that the CNC was able to intervene earlier in the patient pathway and ensure that the time from MDT to treatment initiation was reduced by an average of 2 days. Findings included:

1. Collaborative model of care and engagement between Oncologists, CNC and the treating team to optimise patient outcomes.
  2. Patients were able to be identified earlier in the pathway, with a radiotherapy care plan initiated immediately post MDTM.
  3. Inpatient nursing reviews identified patient care needs which were incorporated into the treatment pathway.
  4. Toxicity management was assessed and initiated by the CNC who collaborated with inpatient clinicians, influencing earlier discharge.
  5. Coordination of multimodality treatment and providing education to patients, carers and MDT members and other relevant stakeholders.
  6. Minimising the administrative responsibility and burden on the Medical/Radiation Oncologists guides the appropriate skillset utilisation of all members of the MDT, and efficiently manages the process requirements associated with treatment initiation.
  7. Tumour specific initiatives such as a Head & Neck Allied Health MDTM were established to able the MDT to collaboratively manage toxicities and patient supportive measures.
- NPS improved from 67% to 100%.

### Conclusion

The study indicated that the RT CNC demonstrated significant efficiencies, in reducing diagnosis to treatment start time through a collaborative and coordinated approach. The results suggest that the CNC plays a key role in providing clinical expertise, establishing and embedding external relationships and integration within a large tertiary hospital. After the pilot evaluation the CNC role has been implemented at other affiliated institutions. Further investigation will continue evaluating metrics on all aspects of the inpatient oncology service.

### Electronic Poster: RTT track: Education and training/role development

### EP-2209 Non-medical prescribing for Therapeutic Radiographers - extending roles and advancing practice

H. Nisbet<sup>1</sup>  
<sup>1</sup>Oxford University Hospitals NHS Foundation Trust, Radiotherapy Department, Oxford, United Kingdom

### Purpose or Objective

Legislation has been in place in the UK to allow Therapeutic Radiographers to train as supplementary prescribers (SP) and the role has been successfully undertaken since 2005. Since March 2016 Therapeutic Radiographers can train as independent prescribers and this has been supported by the Royal College of Radiologists citing a positive patient experience, a more streamlined patient pathway and a sharing of the pressures of the clinical team's workload as just some of the very substantial benefits. One Advanced and two Consultant Therapeutic Radiographers at our Cancer Centre completed their qualification to become independent prescribers (IP) in June 2017. The objective of this poster is to outline the training pathway, scope of practice and clinical model for Therapeutic Radiographer non-medical prescribers (NMP) and to detail the advantages of this role.

### Material and Methods

The NMP must undergo an approved post-registration training programme that meets the prescribing standards set by the Health Professions Council before being annotated as an IP/SP on the register in order to be able to prescribe. As with most Trusts, the NMP must also be accepted into the role by the Trust's NMP lead for indemnity purposes. They may prescribe any licensed medicine for any condition within national and local

guidelines, the practitioner's area of expertise and competence, and the overarching framework of the treatment of cancer. NMPs within our cancer centre run independent clinics to review and treat patients who require the support and management of radiotherapy treatment related conditions and toxicities before, during and after their course of radiotherapy treatment. NMPs work in close liaison with other healthcare professionals to ensure safe and effective treatment is prescribed and administered to patients to manage common radiotherapy toxicities and complications such as skin reactions, oral mucositis, pain, diarrhoea, constipation and emesis.

#### Results

The introduction of NMPs supports the delivery of a seamless review service within this Cancer Centre. This benefits the patient by improving the patient pathway, reducing the need for repeated assessment and review, enhancing patient care, supporting the multi-disciplinary team and using the skills of the workforce more effectively. Since June 2017 NMP prescribing practice has averaged upwards of 10 prescriptions a week equating to a minimum saving of 3 hours of oncologist time otherwise spent in consultation and prescribing activity.

#### Conclusion

NMPs can provide a more holistic approach to patient care, a smoother patient pathway, provide improved accessibility to appropriately prescribed medication and release pressures on the oncologists' workload.

#### EP-2210 Building a respiratory synchronization model in the CK System during the RT session of liver metas

K. Szczepanik<sup>1</sup>, A. Grzadziel<sup>2</sup>, B. Jochymek<sup>1</sup>, D. Bodusz<sup>1</sup>, E. Telka<sup>1</sup>, M. Kijonka<sup>3</sup>

<sup>1</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy, Gliwice, Poland;

<sup>2</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Planning Radiotherapy and Brachytherapy, Gliwice, Poland; <sup>3</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Medical Physics, Gliwice, Poland

#### Purpose or Objective

The aim of this work is to show the building of a respiratory model used for radioablation of liver metastases using tracing of implanted markers using the Synchrony Respiratory Tracking System.

#### Material and Methods

The CyberKnife system (Accuray Inc., Sunnyvale, CA) enables irradiation of patients using the internal markers tracking method with respiratory synchronization.

The patients who are qualified for radioablation of liver metastases are implanted with 3 markers. After preparing the external stabilization, performing the CT (the patient should wear the Synchrony Tracking Vest) and performing the treatment plan in the MultiPlan system, and then can start irradiation. The process of preparing the patient for treatment includes the implementation of an individual external stabilizer and treatment planning based on the CT examination in the Synchrony Tracking Vest System. To build a respiratory model, it is necessary to put on the Synchrony Tracking Vest patient's vest and attach to it three external markers (Tracking Markers), whose movement, consistent with the patient's breathing movements, is recorded by means of X-ray lamps. After locating external and internal markers, it is possible to start building a breathing model. This is done using the Synchrony Respiratory Tracking System. The respiratory model is built on the basis of 6-8 verification imagines.

#### Results

Irradiation of metastases to respiratory organs (including the liver) using the Synchrony System enables precise treatment of the appropriate radiation dose with the saving of healthy tissues. Continuous control of the patient's position and correlation of the respiratory movements with the motion of the accelerator head are

the main advantages of the Synchrony Respiratory Tracking System of the CyberKnife System.

#### Conclusion

Irradiation of metastases to respiratory organs (including the liver) using the Synchrony System enables precise treatment of the appropriate radiation dose with the saving of healthy tissues. Continuous control of the patient's position and correlation of the respiratory movements with the motion of the accelerator head are the main advantages of the Synchrony Respiratory Tracking System of the CyberKnife System.

#### EP-2211 Impact of virtual learning environment on students' satisfaction, engagement, recall and retention

E. Ryan<sup>1\*</sup>, C. Poole<sup>1</sup>

<sup>1</sup>TCD Division of Radiation Therapy, Radiation Therapy, Dublin, Ireland

#### Purpose or Objective

Virtual Learning Environments (VLEs) were introduced to progress students from passive to active learners. Active learning promotes the critical thinking skills essential for the transfer/use of classroom-acquired knowledge into the clinical setting. Virtual reality forms an increasingly vital component of clinical skills development in a range of disciplines.

#### Material and Methods

A randomised control trial was conducted with students randomly attending one of two teaching sessions about radiation therapy. Both sessions were identical except a VLE was used in the second talk with the first being solely didactic. Anonymous questionnaires were distributed. Two weeks after the talks, participants were required to complete the same knowledge questionnaire to determine retention. Mann-Whitney, means, standard deviations and chi-squared tests were employed according to data characteristics. Qualitative data (open-ended questions) was analysed thematically.

#### Results

Virtual learning seemed to significantly improve students' satisfaction/engagement and recall (n40). The student group taught using the VLE had higher mean scores for retention compared to the didactic group however this was not statistically significant. Students' learning styles seemed to have no effect on their satisfaction/engagement and ease of learning. Three key themes emerged from the qualitative data, (1) the visuals were good/helpful, (2) the talk was informative, and (3) more detail/visuals were required.

#### Conclusion

Incorporating virtual learning into education suggests an enhanced student experience with increased levels of engagement, satisfaction and recall. This study adds to and supports current research which illustrates there is a role for VLEs in teaching. Future research is required to determine if VLEs produce a long-term impact on student's retention of knowledge.

#### EP-2212 Piloting an educational framework for the enhanced role of RTTs in MRI-guided adaptive radiotherapy

C. Eccles<sup>1</sup>, J. Webb<sup>1</sup>, A. Flynn<sup>1</sup>, A. McWilliam<sup>2</sup>, A.

Sanneh<sup>1</sup>, M. Van Herk<sup>2</sup>, A. Choudhury<sup>2</sup>, M. Aznar<sup>2</sup>

<sup>1</sup>The Christie, Radiotherapy, Manchester, United Kingdom; <sup>2</sup>University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom

#### Purpose or Objective

To develop and implement a framework to support the enhanced role RTTs delivering MRI-guided adaptive radiotherapy.

### Material and Methods

A team of MRI radiographers and RTTs was assembled to realise radiotherapy treatments on a hybrid MRI-linear accelerator (MR-Linac) and to pilot a program of learning, for safe, effective MR-Linac based research and treatment. We followed a scoping exercise to determine a framework of knowledge, skills and competence required for the enhanced role of RTTs working in MRI-guided adaptive radiotherapy. A gap analysis and survey of existing educational programs that could bridge gaps in knowledge were undertaken. Where no didactic or practical programs were available an in-house program was developed to fulfill the framework requirements. The program includes directed self-study, didactic and practical competency-based experiences.

### Results

From the scoping exercise it was determined the framework should include: a) MRI safety and screening, b) MR image formation/acquisition, c) MRI image interpretation, d) multi-modality image registration, e) radiotherapy specific imaging needs (e.g., geometric fidelity), f) MRI safe patient positioning, g) target and normal tissue segmentation and/or segment manipulation, and h) treatment plan evaluation. The survey of existing educational programs found a) several UK-based higher education institutions (HEIs) with suitable courses offering graduate level modules in MRI physics and clinical applications, that include basic MRI safety, with some including MRI-based anatomy, b) an international peer-to-peer MRinRT program and c) online MRI/multi-modality anatomical atlases that are suitable for inclusion in this framework of blended learning. All HEI programs included knowledge assessments, however, it was decided online-based learning and MRI screening should be appraised as competencies gained through practical experience. Formal programs in the specific imaging and positioning for radiotherapy were lacking, therefore tutorials and practical competencies will be developed to teach and assess this body of knowledge and skills. To date 12 tutorials are available, each with a question-based assessment, and competency profile to be included in each learner's portfolio of evidence. To embed competence in image registration, segmentation, and treatment plan assessment, practical tutorials and inter-observer variability studies supplemented by interdisciplinary discussions with clinicians and physicists experienced in treatment planning are planned.

### Conclusion

The safe, effective realisation of MRI-linear accelerator technologies requires an enhanced RTT portfolio, a formal framework for which does not yet exist in the UK. Using a scoping exercise and gap analysis, we have been able to define a preliminary framework for a blended learning experience that is currently being piloted in our institution. Following the pilot, a mixed method model will be used to evaluate its effectiveness and inform the program's evolution.

### EP-2213 An evaluation of radiotherapy students' perceptions of research and evidence-based practice

S. Ketterer<sup>1</sup>

<sup>1</sup>University of Liverpool, Department of Radiotherapy-School of Health Sciences, Liverpool, United Kingdom

### Purpose or Objective

Engagement with research is recognised as a pre-requisite for professional registration as a therapy radiographer. Educational programmes have an obligation to support and develop autonomous and reflective thinking, and evidence-based practice, as modern careers in radiotherapy require active engagement in research, and the generation of primary research data, in order to challenge the current evidence base and to optimise approaches to both treatment delivery and patient care. This study aims to evaluate how all three year groups

within a radiotherapy undergraduate degree course perceive the role of research within their future clinical practice, and looks to identify any changing attitudes of students to research as they progress through their undergraduate studies. A further objective is to examine if there are particular learning interventions that maximise student engagement with research.

### Material and Methods

A qualitative approach was adopted with students from all three years of an undergraduate BSc Radiotherapy programme invited to participate in individual year group focus group sessions. Each session was audio recorded, transcribed into an anonymous script, and subjected to thematic analysis.

### Results

A total of 17 students participated. Students recognised research as part of the role of a therapy radiographer, but did not always explicitly identify research activities within day-to-day work. Each year group had a strong focus on current academic research tasks, for example dissertation projects. Some could see the benefits of laying foundations in research methodology, although this was generally seen as an arduous process. Motivation and excitement around research had been observed in the clinical setting, but students felt this was largely amongst a minority of staff. There were multiple references to utilisation of practical, interactive, "real-world" examples in order to make research learning more relevant.

### Conclusion

The evidence-based nature of radiotherapy was welcomed, but only a minority of students appeared eager to accept active research involvement as part of their future roles. The challenge for educators, which emerged, is to inject excitement for research into the academic setting, so students feel ownership of and immersed in the topic, and can develop positive attitudes towards continuous questioning of practice to carry forward into the clinical environment.

### EP-2214 Assessing the evidence for proton therapy in prostate cancer

T. Chan<sup>1</sup>, P.W. Tan<sup>1</sup>, J.I. Tang<sup>1</sup>

<sup>1</sup>The National University Cancer Institute- Singapore NCIS, Radiation Oncology, Singapore, Singapore

### Purpose or Objective

Proton beam therapy (PBT) has evolved significantly with respect to its use in prostate cancer. Pencil beam scanning, an advanced technique of PBT is often used in many centers. Growing interest and controversy regarding its use has resulted in PBT being closely scrutinized. The plethora of evidence suggests that PBT is effective and safe for early stage prostate cancer. However, it is still unknown whether the theoretical dosimetric advantages of PBT translate into meaningful clinical improvements over routine intensity-modulated radiation therapy, which is commonly used for this patient group.

### Material and Methods

A systematic search using MEDLINE/PubMed and MeSH headings was used to identify articles addressing RT techniques with for early stage prostate cancer. The headings were prostate cancer, radiation therapy, proton therapy and intensity modulated radiation therapy. Eligible articles include articles about 1) prostate cancer RT; 2) RT associated toxicities; 3) advances in treatment delivery and 4) published in an English language peer-reviewed journal. Articles were excluded if they provided

pilot data, descriptions of a study design and articles on non-prostate cancer data.

**Results**

85 eligible articles were identified. Early trials on prostate cancer utilizing PBT demonstrated mixed results upon comparison with the routinely used IMRT. The systematic search highlighted the growing popularity and interest in PBT, demonstrated controversy on the efficacy of PBT, compared its clinical and cost-effectiveness and revealed advances in its delivery.

Table 1: Comparing treatment rates in Dose Escalation Randomized Controlled Trials

Study	Beam Modality	Planning Technique	Low dose Arms Gy	High dose Arms Gy	Median follow up (mo)	No of patients analyzed	Toxicity Scale	Grade 1-2 Toxicity, %		Grade 3-5 Toxicity, %

Backlund et al (2011) <sup>18</sup>	Protons	Conformal	70.0	80.0	5.1	306	RTDQ	1.9	6.9	2.6	1.9

RTDQ: Radiation therapy toxicity group; ORTC: European Organization for Research and Treatment of Cancer; LENTISSOM: Late Effects of Normal Tissue: Subjective, Objective, Management; RMI: Royal Marsden Hospital assessment score; UCLA PCI: University of California, Los Angeles Prostate Cancer Index; UCLA PCI score.

**Conclusion**

Literature demonstrated that the unique physical properties of protons allow dose escalation to the prostate while effectively sparing neighboring normal tissue structures. Theoretically, this allows for better disease control while minimizing toxicities and second malignancies. This allows a dosimetric advantage over photon IMRT. Existing literature consist of prospective Phase II trials and retrospective studies. These articles demonstrated favorable outcomes for early stage prostate cancer utilizing PBT. PBT is significantly expensive. This remains a barrier to its widespread use. To date, the cost-effectiveness of PBT remains conflicting. Its cost-effectiveness requires more study. More studies are needed for a better estimation. Ongoing trials directly comparing PBT with photon EBRT will hopefully elucidate the value of PBT for early stage prostate cancer. Unless there is overwhelming evidence for the clinical superiority of PBT over present advanced techniques, the case for PBT remains questionable.

# Radiotherapy & Oncology

Journal of the European Society for  
Radiotherapy and Oncology

## INFORMATION FOR AUTHORS

ARTICLES should deal with original research or reviews of topics defined in the aims of the journal. Radiotherapy and Oncology publishes original material only. It is therefore understood that the content of the paper has not previously been published in the same or a similar form and that it is not under consideration for publication elsewhere. The act of submitting a manuscript to the journal carries with it the right to publish that paper.

Radiotherapy and Oncology uses an online manuscript submission and peer review process.

Papers and correspondence should be submitted online at <http://www.ees.elsevier.com/ro> and the instructions on the site should be closely followed. Authors may submit manuscripts and track their progress to final decision. Reviewers can download manuscripts and submit their reports to the Editors electronically.

The full contact details for the Editorial Office are shown below:

**Professor Michael Baumann, Editor-in-Chief, Radiotherapy & Oncology Editorial Office, Deutsches Krebsforschungszentrum (DKFZ), Im Neuenheimer Feld 280, 69120, Heidelberg, Germany (E-mail: [RadioTherOncol@dkfz.de](mailto:RadioTherOncol@dkfz.de)).**

### TYPES OF PAPERS

#### 1. Full length original papers (max. 3000 words)

Describe original scientific work in the field of radiation oncology or related areas. The content of the paper should be sufficient to reach valid conclusions. Full papers should include a structured abstract and be divided into sections (Introduction; Materials and Methods; Results; Discussion; References; Tables; Figures) and should not normally exceed 6 printed pages, including references and a maximum of 6 tables/figures. Additional material can be submitted as supplementary files.

#### 2. Short communications and Technical notes (max. 2000 words)

Provide a brief but complete account of a particular piece of work, e.g. Phase I or II study, and should in total be no longer than 4 printed pages, normally including a maximum of 2 figures or tables. A summary of not more than 50 words should be included (not a structured abstract), but the manuscript can have fewer subheadings (e.g. short introduction; materials and methods; results and discussion). Authors are advised to see a recent issue of the journal for size and lay-out.

#### 3. First in Human – Translational innovations in radiation oncology (max. 3000 words)

These papers should follow the same format as for short communications or full length original research articles. The introduction must focus on the clinical translational need for further clinical studies and the preclinical translational history for the benefit of a general audience; recent papers illustrating the problems with the current clinical situation should underpin this. Materials and Methods may be brief. Only prospective trials that have undergone review by the appropriate review board or ethical committee and, if applicable by national or European law, will be considered. Statements indicating compliance with these laws need to be included in the materials and methods sections. Results may be brief but must show (with practical examples, photos, other appropriate illustrations) how this innovation is applied in the clinic. Discussion may be brief, does not need to discuss the limitation given by low patient numbers (as this applies to all papers in this section) but must end with a brief and very clear statement on "clinical translational relevance" also including an outlook on the necessary next steps. Please avoid terminology such as "pilot trial" – make clear that this is a significant innovation (and why).

#### 4. Review articles

Rigorous critical assessment of clinical and/or laboratory research in a field of interest to the journal and its subscribers. Reviews are normally solicited by the editors, and it is suggested that authors wishing to contribute a review article contact the editor-in-chief.

#### 5. Editorials and commentaries

Editorials and commentaries relate to articles in the journal or to issues of relevance for the readership. This type of communication is normally solicited by the editors.

#### 6. Letters to the Editor

On topics of current interest or comment upon material previously or simultaneously published in the journal. They should be limited to 500 words and may include 1 table or figure.

#### 7. Announcements

The inclusion of announcements, etc. is at the discretion of the Editors and the Publisher and subject to space availability. Request for inclusion of meeting announcement should be sent to the ESTRO secretariat (see address in journal).

### Author inquiries

For inquiries relating to the submission of articles (including electronic submission where available) please visit this journal's homepage at <http://www.elsevier.com/locate/radonc>. For detailed instructions on the preparation of electronic artwork, please visit <http://www.elsevier.com/artworkinstructions>. Contact details for questions arising after acceptance of an article, especially those relating to proofs, will be provided by the publisher. You can track accepted articles at <http://www.elsevier.com/trackarticle>. You can also check our Author FAQs at <http://www.elsevier.com/authorFAQ> and/or contact Customer Support via <http://service.elsevier.com>

**Language services.** Authors who require information about language editing and copyediting services pre- and post-submission please visit <http://webshop.elsevier.com/languageediting> or our customer support site at <http://service.elsevier.com>.

A full and complete Guide for Authors is available online at
