A feasibility study was carried out to evaluate the viability of this approach in the 1<sup>st</sup> 20 patients recruited.

Patients underwent DW- MRI immediately prior to #1 and #11. 3D target lesions were defined on each MRI by a clinical oncologist and radiologist. ADC measurements were obtained for each target lesion (primary and lymph nodes), and % change in ADC calculated. Disease status for each target lesion is noted at follow up at 6, 12, 18 and 24 months.

#### Results

71 patients have been recruited to date. The first 20 patients were recruited over a 10 month period, with a high recruitment up-take of approximately 62.5% of those screened.

Of the first 20 patients recruited 16 patients (80%) completed both MRI scans. One patient underwent MRI-1 and declined MRI-2 as they felt unable to tolerate the scan. Three of the patients were unable to undergo the 1<sup>st</sup> MRI therefore were withdrawn before being scanned (1-poor IV access for contrast, 1- unable to tolerate the scan, 1 - MRI unavailable).

All 16 scanned patients had at least one target lesion that was measurable on DW MRI baseline and repeat image for the purposes of recording ADC.

#### Conclusion

Feasibility work has demonstrated good patient compliance with scanning requirements and the ability to measure ADC in target lesions suggesting this is a viable approach to identifying the sub-group of non-responders during RT which may ultimately allow individualised and adaptive treatment intensification.

Establishing ADC thresholds that predict for local failure is an essential step towards using DW-MRI to improve the therapeutic ratio. The MeRInO study will help establish these thresholds in OPSCC

#### EP-1138 Non-invasive imaging of tumour hypoxia using EF5 and PET-CT in head and neck cancer: A pilot study.

E. Tran<sup>1</sup>, S. Hamilton<sup>1</sup>, D. Wilson<sup>2</sup>, F. Benard<sup>2</sup>, A. Tran<sup>2</sup>, F. Lacroix-Poisson<sup>2</sup>, E. Berthelet<sup>1</sup>, J. Wu<sup>1</sup>  
<sup>1</sup>BC Cancer Agency - Vancouver, Radiation Oncology, Vancouver, Canada ; <sup>2</sup>BC Cancer Agency - Vancouver, Functional Imaging, Vancouver, Canada

#### Purpose or Objective

Tumour hypoxia is an important factor in treatment failure following radiation therapy for locally advanced head and neck squamous cell carcinoma (HNSCC). This pilot study was performed to evaluate the feasibility of using

[18F]EF5 for clinical PET imaging of tumour hypoxia in HNSCC planned for radical radiotherapy.

#### Material and Methods

Fourteen patients with Stage III/IV HNSCC undergoing radical radiotherapy were enrolled between 2012 and 2016. Patients were imaged before and 2 weeks into radiation treatment with EF5-PET. All patients had an FDG-PET CT prior to treatment. On the FDG-PET CT, standardized uptake values (SUV) were calculated using a region of interest drawn around the target area images for suspicious primary and nodal disease separately where  $SUV = (\text{peak activity/mL in region of interest}) / (\text{injected activity/g of body weight})$ . These lesions were evaluated for corresponding EF5 uptake on the EF5-PET. After injection of 185 to 370 MBq of [18F]EF5, PET data was obtained in three-dimensional mode. EF5 uptake was evaluated by the tumour-to-muscle activity ratio (TMR) and a ratio of >1.5 was considered EF5 positive. Paired t-test was used to determine whether there is a significant difference between the TMR before and during treatment, based on the 2 EF5-PET scans.

#### Results

Median follow up was 26 months. All patients except one had 2 EF5-PET and 1 FDG-PET CT scan. One patient declined the second EF5-PET scan. No adverse pharmacological reactions were observed after administration of [18F]EF5. 13 patients had oropharyngeal cancer (all except 1 was p16+) and 1 had nasopharynx cancer. All patients were treated with 70Gy and 12 received concurrent chemotherapy.

38 lesions were identified on pre-treatment FDG-PET CT imaging. EF5 was positive in 22 lesions (8 primary and 14 nodal sites) before treatment. 6 lesions (3 primary and 3 nodal) remained EF5 positive during radiation, although 4 had borderline TMR ranging between 1.5-1.62. Mean TMR difference pre and during treatment was 0.30 for primary (p=0.003) and 0.53 for nodal disease (p=0.001). One patient with p16- oropharynx cancer had EF5+ persistence during treatment and subsequently had local recurrence. Two patients with p16+ oropharynx cancer died of metastatic relapse, one of which was EF5+ pre-treatment which did not persist during treatment.

#### Conclusion

PET imaging with [18F]EF5 was feasible, and adequate image quality was achieved. The single p16- oropharynx cancer patient who had no resolution of tumour hypoxia in lymph node and primary disease had locoregional recurrence requiring salvage therapy. In this study, EF5+ persistence was not predictive recurrence in p16+ oropharynx cancer, however, larger scale studies to further assess the impact of EF5-PET detected hypoxia prior and during radiation treatment is warranted to evaluate its ability to predict treatment outcomes.

#### EP-1139 Prognostic impact of hematological profile in oropharyngeal cancer treated with chemoradiotherapy

Maria degli Angeli, Division of

Otolaryngology, Pordenone, Italy ; <sup>8</sup>S. Martino Hospital, Division of Radiation Oncology, Belluno, Italy ; <sup>9</sup>IRCCS European Institute of Oncology, Scientific Directorate, Milano, Italy

#### Purpose or Objective

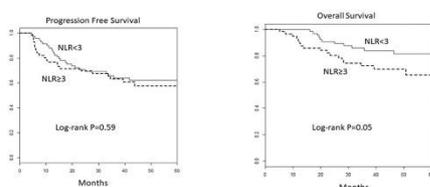

To evaluate the role of baseline neutrophil-to-lymphocyte ratio (NLR) and other haematological biomarkers and ratios such as neutrophil, lymphocyte, platelet and monocyte count, Lymphocyte to monocyte ratio (LMR) and Platelet to Lymphocyte ratio (PLR) as prognostic markers in locally advanced squamous cell carcinoma of the oropharynx (OPC) treated with definitive chemoradiotherapy (CxRT).

#### Material and Methods

A retrospective analysis of 125 patients, affected with locally advanced OPC and treated between 2010 and 2015 at two tertiary cancer centers in Northern Italy (European Institute of Oncology, Milan and Centro di Riferimento Oncologico, Aviano) was performed. Inclusion criteria were: age > 18 years, stage III or IV (TNM 7<sup>th</sup> ed.), definitive CxRT. Progression-free survival (PFS) and overall survival (OS) curves were evaluated using the Kaplan-Meier method. Multivariate Cox proportional hazard models were applied to obtain hazard ratios adjusted for other prognostic factors and confounders.

#### Results

Median age was 61 (42-77) years and 94 (75.2%) patients were male. HPV status was available in 102 (81.6%) patients and among them 77 (61.6%) pts had HPV/p16+ related OPC. Therapeutic choice consisted in sequential, concurrent and induction followed by concurrent CxRT schedule was delivered to 43 (34.4%), 71 (56.8%) and 11 (8.8%) pts, respectively. Median follow up was 50 months (range 5 - 95 months). A value of  $NLR \geq 3$  was associated with poorer OS with almost a triple increased risk of death: HR=2.7 (95%CI:1.2, 6.2; p=0.02, adjusted for age, gender, chemotherapy, HPV status and ECOG performance status). Two-years OS was 91% and 81% in pts with  $NLR < 3$  and  $\geq 3$ , respectively (figure 1). No correlation was found between other haematological parameters and prognosis. When restaged with TNM 8<sup>th</sup> edition, NLR confirmed prognostic role with increased significance (p=0.03).

#### Conclusion

In our cohort, a baseline  $NLR \geq 3$  at treatment initiation represented a negative prognostic marker for OPC treated with definitive CxRT. Our results are in line with literature data and confirmed after re-staging with last TNM. Therefore, this inexpensive and readily available marker could be considered for risk stratification of pts with locally advanced OPC.

#### EP-1140 Retropharyngeal Lymph Node Metastasis in Hypopharyngeal Carcinoma: Analysis from Multi-center Data

Z. Yin<sup>1</sup>, X. Zhang<sup>2</sup>, Y. Sun<sup>3</sup>, S. Miao<sup>4</sup>, C. An<sup>5</sup>

<sup>1</sup>Tianjin Medical University Cancer Institute & Hospital, Radiotherapy, tianjin, China ; <sup>2</sup>Cancer Institute Hospital-Chinese Academy of Medical Sciences- Peking Union Medical College, Head and Neck Surgery, Beijing, China ; <sup>3</sup>Sun Yat-sen University Cancer Center- State Key Laboratory of Oncology in South China, Department of

Radiation Oncology, Guangzhou, China ; <sup>4</sup>Harbin Medical University Cancer Hospital, Department of Radiation Oncology, Harbin, China ; <sup>5</sup>Cancer Institute Hospital-Chinese Academy of Medical Sciences- Peking Union Medical College, Department of Head and Neck Surgery, Beijing, China

#### Purpose or Objective

This study aimed to determine the prevalence, risk factors and prognostic significance of retropharyngeal lymph node (RPLN) in hypopharyngeal squamous cell carcinoma based on magnetic resonance image (MRI).

**Purpose** This study aimed to determine the prevalence, risk factors and prognostic significance of retropharyngeal lymph node (RPLN) in hypopharyngeal squamous cell carcinoma based on magnetic resonance image (MRI).

#### Material and Methods

A total of 259 patients diagnosed with hypopharyngeal carcinoma (HPC) from three cancer institutions in China were retrospectively analyzed. The MRIs of all patients were reviewed by two senior radiologists and the RPLNs were identified. 250 patients (96.5%) were male, with a median age of 57 years old (range: 36-85 years old). Most (85.7%) of them presented advanced diseases (stage III or IVa-b).

#### Results

RPLN metastasis was discovered in 44 patients (17%). Logistic analysis showed that primary tumor site located in posterior pharyngeal wall (PPW), PPW invasion, N2-3 stage, multiple LNs, and Level II/III LN involvement were identified as independent factors associated with RPLN metastasis in HPC. The rates of RPLN metastasis in patients with primary site located in posterior pharyngeal wall (PW), PW invasion and N2-3 were 37%, 30% and 31%, respectively, compared to those with primary disease located in pyriform sinus, T1-2 and N0-1 were 13%, 10% and 3%, individually. Patients with RPLN metastasis had a significant lower 5-year overall survival rate and 5-year disease-free survival rate than non-RPLN metastasis group (OS: 28% vs. 48%, p=0.001; DFS: 25% vs. 41%, p=0.040).

#### Conclusion

metastasis was not uncommon in hypopharyngeal carcinoma, with a prevalence of 17% in this study. Primary tumor located in PW, PW invasion, and cervical LN nodes are risk factors for RPLN metastasis. RPLN metastasis is a poor prognosticator for survival in hypopharyngeal carcinoma.

#### EP-1141 Marginal local failure in nasopharyngeal carcinoma in the era of intensity modulated radiotherapy

K. REN<sup>1</sup>, Z. Yin<sup>2</sup>

<sup>1</sup>Tianjin Medical University Cancer Hospital & Institute, Department of radiation oncology, Tianjin, China ; <sup>2</sup>Tianjin Medical University Cancer Hospital & Institute, Department of Radiation Oncology, Tianjin, China

#### Purpose or Objective

This study makes a detailed analysis of the initial irradiated dose of the recurrent site and local failure patterns after intensity-modulated radiation therapy (IMRT). Based on this analysis, further improvement of delineation recommendations may be made in order to reduce the local recurrence in nasopharyngeal carcinoma (NPC).

#### Material and Methods

In total, 253 newly diagnosed non-metastatic NPC patients between Jan. 2012 and Dec. 2014 were retrospectively enrolled. For patients with local failure, the location and extent of local failures were transferred to the pretreatment planning computed tomography (CT) for dosimetric analysis. The dose of radiation received by GTVr (gross tumor volume of recurrence) was calculated and analyzed with dose-volume histogram (DVH). Failures

were classified as: "in field" if 95% of GTVr was within the 95% isodose, "marginal" if 20%-95% of GTVr was within the 95% isodose, or "outside" if less than 20% of GTVr was inside the 95% isodose.

#### Results

With a median follow-up time of 61.3 months, the 5-year local control was 89%. 21 patients developed local recurrence. Dose conformity with IMRT was excellent, and the recurrence was mainly within 2 years after the first treatment. The dosimetric analysis showed that 14 failures were classified as "in-field", 1 out-field failure, and only 6 failures as "marginal" failure. Of these 6 marginal failures, two failures occurred in the site of sinus cavernosus, two presented failure in jugular foramina, one was nasal cavity and one in oropharynx wall.

#### Conclusion

In the era of intensity-modulated radiotherapy, in-field failures are still the main patterns for local recurrence. However, there were also 6 marginal recurrences, these recurrence patterns may help presenting us some data when delineation the target volume.

#### EP-1142 Death from aspiration after definitive radiotherapy for hypopharyngeal or supraglottic cancer

N. Kanayama<sup>1</sup>, T. Ikawa<sup>1</sup>, K. Wada<sup>1</sup>, T. Hirata<sup>1</sup>, M. Morimoto<sup>1</sup>, K. Hayashi<sup>1</sup>, K. Konishi<sup>1</sup>, T. Teshima<sup>1</sup>  
<sup>1</sup>Osaka International Cancer Institute, Radiation Oncology, Osaka, Japan

#### Purpose or Objective

The aim of this study is to identify predictors of death from aspiration after definitive radiotherapy for hypopharyngeal or supraglottic cancer, retrospectively.

#### Material and Methods

A total of 391 patients were identified from our institutional data base as started definitive radiotherapy for hypopharyngeal and supraglottic cancer between 2006 and 2014. Eighty one patients had a history of malignancy and 76 patients were diagnosed synchronous malignancy. Thirty six patients had a history of surgery for esophageal cancer and 16 patients received simultaneous radiotherapy for synchronous esophageal cancer. The primary site of tumor was hypopharynx in 277 patients and supraglottis in 114. Clinical stages were 0 in 4 patients, I in 28, II in 94, III in 92, IVA in 153, and IVB in 20. Treatment modality were RT alone in 157 patients, CCRT in 222, others in 12. Radiation modality were 3DCRT in 307 patients, IMRT or VMAT in 84. Median total dose was 70 Gy/35 fr. To explore the cause of death, cause of death was divided into 5 categories. "cancer under study", "other malignancy", "complication of treatment", "no data", and "others". "Others" include aspiration pneumonia and other comorbid illness. Clinical factors (age, performance status, tumor location, clinical T and N stage, treatment modality, radiation modality, history of malignancy, synchronous malignancy, history of surgery for esophageal cancer, simultaneous radiotherapy for synchronous esophageal cancer) were investigated for death from aspiration. Multivariate analysis (MA) was performed by using Cox proportional hazard model and  $p < 0.05$  was considered significant.

#### Results

Median follow up for survivors was 6.4 (range: 1.6-12.2) years. The 5-year overall survival and laryngectomy free survival rate were 61.1% and 53.9%. Fifty six patients received total laryngectomy in the follow up. The cause of total laryngectomy were severe dysphagia in 3 patients, laryngeal necrosis in 3, recurrence or second malignancy in 50. In the follow up time, 175 patients died. Eighty six patients (49%) died from "cancer under study", 46 (26%) from "other malignancy", 2 (1%) from "complication of treatment", 9 (5%) from "no data" and 32 (18%) from "others". Eleven patients died from aspiration. The median survival for patients who died from aspiration was

1.3 (range: 0.3-6.4) years. In MA, history of surgery for esophageal cancer (HR: 5.55, 95% confidence interval: 1.33-23.33;  $p = 0.019$ ) and simultaneous radiotherapy for synchronous esophageal cancer (HR: 8.07, 95% confidence interval: 1.93-33.78;  $p = 0.004$ ) was risk factor for death from aspiration.

#### Conclusion

History of surgery for esophageal cancer and simultaneous radiotherapy for synchronous esophageal cancer was predictor for death from aspiration after definitive radiotherapy for hypopharyngeal and supraglottic cancer.

#### EP-1143 Regional nodal failure after primary treatment for differentiated thyroid cancer.

Revelant<sup>1</sup>, S. Pisu<sup>1</sup>, A. Nappo<sup>1</sup>, E. Casanova Fuga<sup>5</sup>, M. Burello<sup>5</sup>, V. Giacomarra<sup>3</sup>, G. Franchin<sup>1</sup>, C. Gobitti<sup>1</sup>  
<sup>1</sup>IRCCS Centro di Riferimento Oncologico CRO National Cancer Institute, Division of Radiation Oncology, Aviano, Italy; <sup>2</sup>IRCCS Centro di Riferimento Oncologico CRO National Cancer Institute, Division of Nuclear Medicine, Aviano, Italy; <sup>3</sup>S. Maria degli Angeli Policlinic Hospital, Division of Otolaryngology, Pordenone, Italy; <sup>4</sup>S. Maria degli Angeli Policlinic Hospital, Unit of Endocrinology and Metabolic Diseases, Pordenone, Italy; <sup>5</sup>IRCCS Centro di Riferimento Oncologico CRO National Cancer Institute, Division of Medical Physics, Aviano, Italy

#### Purpose or Objective

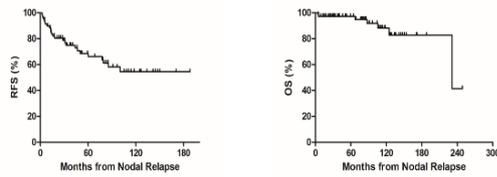

To evaluate the management and outcome of patients experiencing regional nodal relapse after primary treatment for differentiated thyroid cancer (DTC).

#### Material and Methods

Data of all consecutive patients treated at our Institution for DTIC were prospectively collected. All patients (at the time of first diagnosis) underwent surgery for non-metastatic DTC and received adjuvant radioiodine (I-131), if indicated. Regular follow up was performed with Thyroglobulin (Tg) and anti-Tg antibodies level and neck ultrasound (US). In case of suspicious nodes cytological proof of relapse was required and restaging was performed. Treatment of nodal failure was decided on the basis of clinic-radiological features and patient preference. After that, follow up examination with Tg and anti-Tg antibodies level as well as US was performed every 6 months for 5 years, then yearly. Restaging with Total body scan with radioiodine or 18FDG TC/PET was prescribed in case of raise of Tg level and/or positive US. Informed consent for use of anonymized data for scientific purpose was expressed.

#### Results

After primary treatment for DTC, 70 out of 1222 patients experienced a first locoregional nodal recurrence after a median time follow up of 21.6 months (range 3-334 months). Patients characteristics are shown in table 1. Treatment consisted of surgical (with or without adjuvant treatment) and non-surgical approach in 65 (93%) and 6 (7%) patients, respectively. Median follow up was 81.8 months (range 4.5-248.7 months) during which we observed a second relapse in 24 (34%) patients. Pattern of failure consisted in locoregional lymph nodes and distant sites in 19 (79%) and 5 (21%) patients, respectively. Five years-Relapse Free (RFS) and Overall Survival (OS) were 68.5% and 97.1%, respectively as shown in figure 1. At the last follow up 56 (80%), 7 (10%), 3 (4%) and 4 (6%) patients were alive with no evident disease, alive with disease, dead of disease and dead for other causes, respectively. Of the 6 patients treated with non-surgical approach (i.e. I-131 in 4 pts, external beam radiotherapy in 1 patient and TSH suppression in 1 case), only 1 patient had a second recurrence and is alive with disease at the last follow up. The remaining 5 patients are alive with no evident disease.

### Conclusion

Savage treatment of locoregional failure is effective in disease control for DTC with high percentage of RFS and OS. Surgical approach represents the treatment of choice. In patients ineligible for surgery, I-131 and external beam radiotherapy offered a valid option of cure.

### EP-1144 Is volumetric staging an alternative to TNM staging system in radiotherapy of tongue cancer?

M. MISZCZYK<sup>1</sup>, A. Napieralska<sup>2</sup>, B. Maciejewski<sup>2</sup>  
<sup>1</sup>Centrum Onkologii - Instytut im. Marii Skłodowskiej-Curie Oddział w Gliwicach, Zakład Planowania Radioterapii, Gliwice, Poland ; <sup>2</sup>Centrum Onkologii - Instytut im. Marii Skłodowskiej-Curie Oddział w Gliwicach, Zakład Radioterapii, Gliwice, Poland

### Purpose or Objective

The purpose of this study is to evaluate the prognostic value of GTV-based volumetric staging system (VS) in tongue cancer patients and compare it with the results based on the TNM staging system.

### Material and Methods

The clinical material consists of 99 consecutive patients with anterior or base of tongue cancers, aged 25-83 (median 58,2), treated with radical radiotherapy or chemoradiotherapy as a primary treatment between 2003 and 2014 in a single institution (Table I). The study excluded patients with prior surgical treatment. Total dose of 64-78 Gy was delivered to the primary site. Neoadjuvant chemotherapy was administered in 7 cases, concurrent in 15 cases and both in 8 cases. Efficacy of the irradiation was evaluated using 5-year overall survival (5yOS) and 3-year disease-free survival (3yDFS). The study group was retrospectively assessed using TNM classification (7<sup>th</sup> edition) and VS. The latter divided patients according to the gross tumor volume (GTV), that is combined total volume of the primary lesion and volume of metastatic lymph nodes. The cut-off values were 15 and 70 cubic centimeters (cc). The thresholds for volumetric staging system were adapted from works by Studer et al. based on retrospective analysis of the frequency of local failures in particular GTV ranges. The statistical analysis employed basic statistical tools and following tests: Shapiro-Wilk test, Kruskal-Wallis H test, Gehan-Wilcoxon test, logrank test, Chi-square test, Kaplan-Meier estimator and Cox proportional hazards model for single and multiple predictor analysis.

### Results

TNM stage groups correlated well with mean GTV ( $p=0.0001$ ) but the standard deviation of GTV overlapped between patients with TNM stage I-III, II-IVa and III-IVc. TNM stage groups did not correlate well with 5yOS ( $p=0.1$ ). At 5 years patients with TNM stage group III presented highest OS and patients with TNM stage IVa-IVc proved to have only marginally worse 5yOS than patients with TNM stage I-II disease.

The volumetric stage correlated well with 5yOS as presented in attached figure ( $p=0,001$ ). There was no statistically significant correlation between 3yDFS and TNM stage group ( $p=0,05$ ). On the other hand, VS correlated well with 3yDFS ( $p=0,0001$ ). The 3yDFS significantly decreased with increasing GTV and it was 69%

for patients with  $GTV < 15cc$ , 32% for patients with  $GTV$  between 15 and 70cc and 0% for patients with  $GTV > 70cc$ . In Cox regression model, both volumetric staging, addition of chemotherapy and BED reached statistically significant  $p$ -value of  $p=0.00006$  for VS,  $p=0.004$  for BED and  $p=0.017$  for addition of chemotherapy.

### Conclusion

Volumetric staging could be used as a prognostic tool in tongue cancer patients treated with radical radiotherapy and proved to be more accurate than TNM staging system at predicting 5-year overall survival and 3-year disease-free survival.

### EP-1145 Xerostomia and volume and CT number changes of parotid glands during IMRT for head and neck cancer

S. Ishikura<sup>1</sup>, T. Nakabayashi<sup>2</sup>, F. Kobayashi<sup>2</sup>, H. Fukuma<sup>3</sup>, Y. Shibamoto<sup>1</sup>

<sup>1</sup>Nagoya City University Graduate School of Medical Sciences, Department of Radiology, Nagoya, Japan ; <sup>2</sup>Accuray Japan K.K., Division of Tomotherapy Physics & Clinical Support, Tokyo, Japan ; <sup>3</sup>Nagoya City University Hospital, Department of Radiology, Nagoya, Japan

### Purpose or Objective

The purpose was to quantify and analyze the volume and CT number changes of the parotid glands during helical tomotherapy (HT) using daily MVCT images and to evaluate the correlation among these changes, xerostomia grades, and doses to the parotid glands.

### Material and Methods

Between September 2014 and February 2018, 34 patients (pts) with oropharyngeal squamous cell carcinoma were treated with HT at our institution. Patient characteristics were as follows: male/female, 28/6; median age, 68 years (range, 41-84); subsites anterior/lateral/posterior, 7/25/2; T1/2/3/4a, 4/17/8/5; N0/1/2a/2b/2c, 5/7/2/14/6; Stage II/III/IVA, 4/8/22. We used simultaneous integrated boost (n=18: 66 Gy/30 fr in 16; 70 Gy/35 fr in 2) and conventional cone-down boost (n=16: 70 Gy/35 fr in 13; others in 3). Therapies were induction chemotherapy (n=17: paclitaxel/cisplatin/fluorouracil, 15; others, 2) and concurrent biotherapy or chemotherapy (n=26: cetuximab, 20; cisplatin, 4; others, 2). During HT, pts underwent MVCT-guided radiotherapy at each session. We used an Accuray Precision™ research workstation with PreciseART™ Adaptive Radiation Therapy to analyze the volume and CT number changes of the parotid glands during HT. We examined correlations among the dose-volume histogram (DVH) values of the parotid glands, the volume and CT number changes for the first 20 fractions, and the grades of acute xerostomia (dry mouth, CTCAE version 4.0). For pts with a conventional cone-down boost, the DVH values of the initial plan were scaled to 70 Gy/35 fr. We analyzed the correlations of the xerostomia grades and the volume and CT number changes by box plots (significance level,  $p < 0.05$ ). We analyzed the correlations between the doses to the parotid glands and the volume and CT number changes by scatter plots and calculated correlation coefficients. This study was approved by our institutional review board.

### Results

The median follow-up was 1.2 years. The 2-year overall survival was 89%. Eight pts had acute grade 2 xerostomia; none had grade 3. Of these 8 pts, 7 had stage IV disease; 6 received induction chemotherapy, and 6 received concurrent biotherapy. The average of the median dose to the right and left parotid glands was 33.7 Gy (range, 10-63.6 Gy) and 26.2 Gy (7.6-56.9 Gy), respectively. There was no significant difference in the average of the median dose, the volume change, and CT number change between pts with grade 0-1 and 2 xerostomia. Weak-to-moderate correlations existed between the median dose to the parotid glands and both the volume change (Fig. 1,  $R =$

0.38) and CT number change (Fig. 2,  $R = 0.45$ ).

Fig. 1

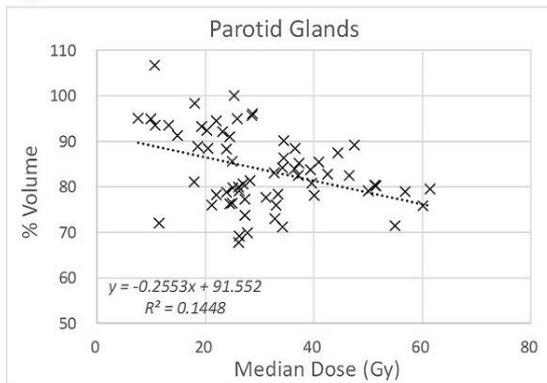

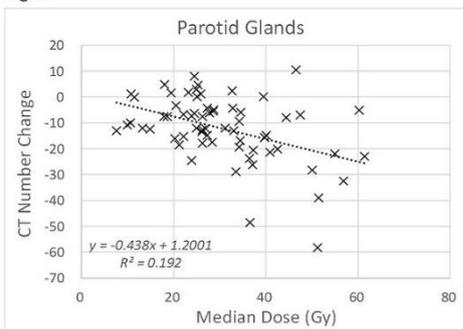

Fig. 2

### Conclusion

The volume and CT number of the parotid glands decreased as a function of the median dose to the parotid glands but were not significantly related to the grade of xerostomia. Further investigation is needed to determine if these changes would predict moderate-to-severe xerostomia and if adaptive radiotherapy could reduce acute and late toxicities.

### EP-1146 Prognostic Value of Hypoxia for Locally Advanced Hypopharynx Squamous Cell Carcinoma

F. Sert<sup>1</sup>, G. Serin<sup>2</sup>, A. Veral<sup>2</sup>, M. Esassolak<sup>1</sup>  
<sup>1</sup>Ege University Medical School&Hospital, Radiation Oncology, Izmir, Turkey; <sup>2</sup>Ege University Medical School&Hospital, Pathology, Izmir, Turkey

### Purpose or Objective

Head and neck squamous cell carcinoma (HNSCC) is the 6th common malignancy worldwide. As one of HNSCC, hypopharyngeal squamous cell carcinoma (HPSCC) only constitutes approximately 3-5% of HNSCC, but it is usually diagnosed in the advanced stage with poor treatment outcome. In the past decades, different treatment options, including surgery, chemotherapy (CT), radiotherapy (RT), and immunotherapy, have been developed and utilized for HPSCC, but any of those options could not achieve a promising results and the survival rate has not been improved significantly. We should both investigate and understand the resistance mechanisms of this group of patients in order to obtain more promising treatment outcomes. We aim to compare the relationship between the expression of hypoxia-associated marker HIF-1 $\alpha$  and proliferation with Ki-67 and clinical outcome after definitive CRT for locoregionally advanced p16 (-) HPSCC

### Material and Methods

Between January 2005 and December 2016, patients diagnosed with T3-4 HPSCC treated with curative intent by (chemo)radiation were identified using the radiation therapy. Clinicopathologic and outcomes data were

collected retrospectively. Pretreatment biopsy formalin-fixed paraffin-embedded tumor blocks were used for reevaluation in terms of related immune markers. Totally 44 patients were evaluated for this analysis. Pretreatment HIF-1 $\alpha$  and Ki-67 expressions, clinicopathologic data, and tumor volume were analyzed and compared with treatment outcomes.

### Results

Median age was 56 (range, 25-79), and 39% of them were female. Patient characteristics are shown in table 1. The median follow-up duration for all patients and surviving patients was 22.5 months (range, 4-213 months) and 93.0 months (range, 14-213 months), respectively. Ten patients (23%) developed distant metastases, and 15 (34%) had local/locoregional failure. At the time of the last follow-up, 11 patients (25%) were alive. Only 5 patients had p16 positivity, others had p16 (-) tumors. We could not find any significant effect of p16 status over treatment outcome. Median overall survival (OS), locoregional recurrence-free survival (LRFS), and metastasis-free survival (MFS) times were 24.5, 22, and 22.5 months, respectively. Two-years OS, LRFS, and MFS rates were 52%, 64%, and 75%, respectively. Ten of 44 tumor specimens were HIF-1 $\alpha$ -negative with a significantly better 5-year survival ( $92 \pm 8\%$ ) versus 34 patients who were HIF-1 $\alpha$ -positive ( $45 \pm 10\%$ ;  $p < 0.02$ ). patients with hemoglobin levels  $<12$  g/dl showed elevated HIF-1 $\alpha$  expression compared to patients with hemoglobin levels  $\geq 12$  g/dl ( $p=0.02$ ). Additionally, HIF-1 $\alpha$  correlated with Ki-67 proliferation marker ( $p = 0.01$ ).

### Conclusion

This is the first study to evaluate specifically at T3-4 HPSCC for a relationship between hypoxia-associated marker expression and clinical treatment outcomes. Pretreatment immunohistochemical HIF1 $\alpha$  and Ki67 expression are adverse prognostic factors for LRFS and OS, indicating HIF-1 $\alpha$  and Ki-67 expressions may show a more treatment resistant tumor type. However, we could not give p16 as a prognostic marker T3-4 HPSCC.

### EP-1147 Local control rate in patients with skull-base chondrosarcoma treated with particle therapy

E. D'ippolito<sup>1</sup>, A. Iannalfi<sup>1</sup>, B. Vischioni<sup>1</sup>, V. Vitolo<sup>1</sup>, M.R. Fiore<sup>1</sup>, S. Ronchi<sup>1</sup>, M. Bonora<sup>1</sup>, A. Barcellini<sup>1</sup>, R. Petrucci<sup>1</sup>, A. Mirandola<sup>1</sup>, A. Vai<sup>1</sup>, E. Mastella<sup>1</sup>, G. Viselner<sup>2</sup>, M. Ciocca<sup>1</sup>, L. Preda<sup>2</sup>, F. Valvo<sup>1</sup>, R. Orecchia<sup>1,3</sup>  
<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy; <sup>2</sup>National Center of Oncological Hadrontherapy, Diagnostic Image Unit, Pavia, Italy; <sup>3</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

### Purpose or Objective

Chondrosarcoma is a rare bone tumor that arise from the cartilage. Skull-base location is reported in about 6% of cases. The therapeutic approach to chondrosarcoma of the skull-base is still controversial and clinical experience is limited because of the relative rarity of this tumor. The aim of the study was to assess the local failure rate and overall survival (OS) of patients treated with particle therapy (Proton therapy -PT and Carbon Ion radiotherapy -CIRT) after maximal surgery or in the exclusive setting.

### Material and Methods

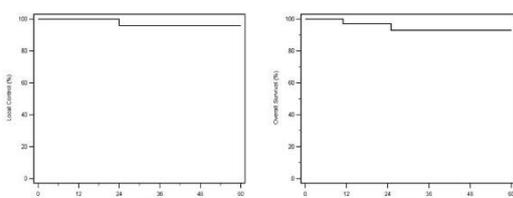

between September 2011 to May 2017 35 patients (pts) (17 male, 18 female) with a median age of 45 years (range, 13-78) with histologically proven skull-base chondrosarcoma were treated with PT or CIRT at National Center of Oncological Hadrontherapy (CNAO). 17 pts (49%) underwent previous surgery. A total of 13 pts had grade I (well differentiated), 20 pts had grade II (moderately differentiated) and 2 pts had grade III (poorly differentiated) chondrosarcoma. 6 pts had brainstem involvement, 1 pts optic pathway involvement. 17 pts were treated with CIRT, 18 pts with PT. Median gross tumor volume (GTV) was 16,4 cm<sup>3</sup> (range, 1,64 - 28,28).

Median prescribed total dose was 70,4 Gy RBE (range 66-70,4 Gy RBE) in 15-16 fractions (median 16 fractions) of 4,4 Gy RBE for CIRT, and 74 Gy RBE (range 70-74 Gy RBE) in 35-37 fractions (median 35 fractions) of 2 Gy RBE for PT. Clinical outcome (local control -LC- and overall survival -OS-) and toxicity profile (according to Common Terminology Criteria Adverse Events -CTCAE V4.03- scale) were evaluated

#### Results

The median follow-up was 34 months (range, 5-70 months). Only 1 patient had local progression 24 months after the end of the treatment. The LC rate was 97%. The 1-year, 3-year and 5-year LC rates were 100%, 96% and 96% respectively; the corresponding OS rates were 97%, 93% and 93% respectively (Fig 1). The toxicity profile was favorable. No pts developed late G4 treatment-related toxicity. G3 late toxicity occurred in 2 (5.7%) of pts: 1 case of hearing impairment and 1 case of ocular toxicity (sight reduction)

Fig.1 Local control and Overall Survival in pts with skull base chondrosarcoma treated with particle therapy

#### Conclusion

particle therapy is a safe and effective treatment in pts with chondrosarcoma of the skull-base

#### EP-1148 Long-term outcome of IMRT with simultaneous integrated boost in nasopharyngeal carcinoma

I. Linares<sup>1</sup>, M. Taberna<sup>2</sup>, J. Nogués<sup>3</sup>, R. Mesía<sup>2</sup>, D. Najjari<sup>1</sup>, J. Mases<sup>1</sup>, I. Guix<sup>1</sup>, M. Plana<sup>2</sup>, A. Lozano<sup>1</sup>  
<sup>1</sup>Institut Català d'Oncologia, Radiation Oncology, Barcelona, Spain ; <sup>2</sup>Institut Català d'Oncologia, Medical Oncology, Barcelona, Spain ; <sup>3</sup>Hospital Universitario de Bellvitge, Otorhinolaryngology, Barcelona, Spain

#### Purpose or Objective

To report the long-term clinical outcomes of nasopharynx cancer patients treated with IMRT-simultaneous integrated boost (SIB) in a non-endemic area.

#### Material and Methods

We retrospectively reviewed the data from 70 patients with non-metastatic nasopharyngeal carcinoma who received IMRT-SIB from January 2007 to December 2015. High-risk PTV was treated with a daily dose of 2.12 Gy and a total dose of 69.96Gy. Low-risk PTV was treated with a daily dose of 1.64 Gy and a total dose of 54.12 Gy. Patients received concurrent chemotherapy during the course of the RT with intravenous administration of 100 mg/m<sup>2</sup> cisplatin every 3 weeks or 30-40 mg/m<sup>2</sup> weekly. The induction chemotherapy regimen was TPF (docetaxel/cisplatin/5-fluorouracil) or PF every 3 weeks for 2-3 cycles. Post-radiation adjuvant chemotherapy with PF (two-three cycles) also was used as option treatment. We analyzed the survival outcome and late toxicity outcome (scale CTCAE v4.03).

#### Results

73% of all cases were men; median age was 51 years (range 15 - 79). Non-keratinizing carcinoma was the most common histological type (76.9%) and EBV was positive in 44 (62.9%). According to the AJCC 7<sup>th</sup> Edition staging system 94.3% of cases were locally advanced disease, stage III-IVB. Only 7 patients (10%) were treated exclusively with RT, while the rest received

chemotherapy, mainly concurrent (88.4%). 29 (41.5%) patients received induction chemotherapy. 25 (35.7%) patients received neoadjuvant and adjuvant chemotherapy. Response rate 8 weeks after ending radiotherapy were: complete response 65.7%, partial response 29.9%, stable disease 1.5% and progressive disease 2.9%. At a median follow-up of 62 months (range 4-136), 9 patients experienced local regional failure and distant metastasis occurred in 12 patients. 1-ys, 3-ys and 5- ys Disease Free Survival were 90%, 79% and 67%, respectively while 1-ys, 3-ys and 5- ys Overall Survival were 98%, 86% and 74% respectively. The most common late adverse effects were: xerostomia, dysphagia, and fibrosis. Grade 3 dental damage and xerostomia occurred in 1 case (16%) and 1 (2.1%) respectively. No case of grade IV toxicity was observed.

#### Conclusion

IMRT-SIB combined with concurrent chemotherapy or plus neoadjuvant or adjuvant chemotherapy resulted in promising rates of local regional control with acceptable rates of late side effects in patients with nasopharyngeal carcinoma.

#### EP-1149 Albumin-to-alkaline phosphatase ratio in nasopharyngeal cancer: a propensity score matching analysis

J.S. Kim<sup>1</sup>, B. Keam<sup>2</sup>, D.S. Heo<sup>2</sup>, D.H. Han<sup>3</sup>, C. Rhee<sup>3</sup>, J. Kim<sup>4</sup>, K.C. Jung<sup>5</sup>, H. Wu<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University Hospital, Department of Otorhinolaryngology, Seoul, Korea Republic of ; <sup>4</sup>Seoul National University Hospital, Department of Radiology, Seoul, Korea Republic of ; <sup>5</sup>Seoul National University Hospital, Department of Pathology, Seoul, Korea Republic of

#### Purpose or Objective

We first analyzed the prognostic power of albumin-to-alkaline phosphatase ratio (AAPR) before radical radiotherapy (RT) in non-metastatic nasopharyngeal cancer (NPC) patients.

#### Material and Methods

The records of 170 patients with biopsy-proven, non-metastatic NPC treated by radical RT between 1998 and 2016 at our institution were retrospectively reviewed. Median follow-up duration was 50.6 months. All patients received intensity-modulated RT and cisplatin based chemotherapy before, during, or after RT. The major treatment of patients were based on concurrent chemoradiotherapy (92.4%). The AAPR was calculated by the last value of both albumin and alkaline phosphatase within 1 month immediately preceding RT. The optimal cut-off level of AAPR was determined by using *Cutoff Finder*, a web-based system. Propensity score matching (PSM) analysis was performed.

#### Results

The optimal cut-off level of AAPR was 0.4876. After PSM analysis of whole cohort, an AAPR was not related to survival outcomes. In PSM analysis for patients with locoregionally advanced nasopharyngeal cancer (LA-NPC), an AAPR  $\geq 0.4876$  was related to better overall survival (OS), progression free survival (PFS) and locoregional relapse free survival (LRRFS) (OS, HR: 0.341, 95% CI: 0.144-0.805, p=0.014; PFS, HR: 0.416, 95% CI: 0.189-0.914, p=0.029; LRRFS, HR: 0.243, 95% CI: 0.077-0.769, p=0.016, respectively).

#### Conclusion

The AAPR, inexpensive and readily derived from a routine blood test, could be an independent prognostic factor for patients with LA-NPC. And it might help physicians determine treatment plans by identifying the patient's current status. Future prospective clinical trials to validate its prognostic value are needed.

**EP-1150 Dosimetric benefit on adaptive IMPT for patients with locally advanced nasopharyngeal carcinoma**

W.W. Lam<sup>1</sup>, H.F.V. Lee<sup>2</sup>, K.Y. Cheung<sup>1</sup>, S.K. Yu<sup>1</sup>

<sup>1</sup>Hong Kong Sanatorium & Hospital, Medical Physics & Research Department, Happy Valley, Hong Kong SAR China ; <sup>2</sup>The University of Hong Kong, Department of Clinical Oncology- Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong SAR China

**Purpose or Objective**

To evaluate the dosimetric impact and benefit on adaptive IMPT (APT) for locally advanced NPC patients due to anatomical changes.

**Material and Methods**

11 NPC patients (AJCC stage III & IV) were planned with IMPT using 3 beams with MFO and SIB technique in Eclipse proton TPS. PTVs (PTV<sub>70</sub> and PTV<sub>66</sub>) were aimed to achieve a V<sub>95%</sub> covered by 70 and 66 Gy(RBE), respectively. Patients were scanned by PETCT (ReCT) at 3<sup>rd</sup> week additionally to initial planning CT. DIR were performed between the two CT image sets and all deformed contours on ReCT were verified. To quantify the dosimetric impact due to anatomical changes, a non-adaptive IMPT plan was created by recalculating the initial IMPT plan on ReCT while an adaptive plan was created by reoptimizing on ReCT to evaluate the dosimetric benefit on APT. D<sub>99.5%</sub> and D<sub>95%</sub>, CN and HI of PTVs, D<sub>max</sub> and D<sub>2%</sub> of brainstem, spinal cord, optic chiasm, left and right optic nerves and D<sub>mean</sub> of left and right parotid glands were reported. gEUD and NTCP of OARs were calculated using LKB model. Wilcoxon signed-rank test was used for statistical analysis. A 2-tailed p<0.05 was considered significant.

**Results**

No statistically significant difference were found in D<sub>99.5%</sub>, D<sub>95%</sub>, CN and HI of all PTVs between adaptive and original plan although both PTVs were reduced by 11%(p=0.001) on ReCT. The mean D<sub>99.5%</sub>, D<sub>95%</sub>, CN and HI of PTV<sub>66</sub> were deteriorated by 9.8%(p=0.003), 3.1%(p=0.003), 23.0%(p=0.001) and 120.4%(p=0.001) in non-adaptive vs original plan. The mean CN and HI of PTV<sub>70</sub> were worsen by 50.9%(p=0.001) and 120.5%(p=0.001) in non-adaptive vs original plan. No significant difference were found in D<sub>max</sub>, D<sub>2%</sub>, gEUD and NTCP of brainstem, spinal cord, optic chiasm and optic nerves between adaptive and original plan. Significant increase in mean D<sub>max</sub>, D<sub>2%</sub>, gEUD of brainstem by 8.1%(p=0.019), 10.1%(p=0.014) and 10.7%(p=0.014) were found in non-adaptive vs original plan. The mean NTCP of brainstem was increased from 0.06 to 0.14% (p=0.01). Significant increase in mean D<sub>max</sub>, D<sub>2%</sub>, gEUD of spinal cord by 25.4%(p=0.001), 26.7%(p=0.001) and 26.2%(p=0.001) were found in non-adaptive plan. The mean NTCP of spinal cord was increased from 0.08 to 1.3%(p=0.001). Significant increase in mean D<sub>max</sub>, D<sub>2%</sub>, gEUD of optic chiasm by 5.1%(p=0.002), 5%(p=0.003) and 9.2%(p=0.032) were found in non-adaptive vs original plan. The mean NTCP of optic chiasm was increased from 1.4 to 9.4%(p=0.019). No statistically difference were found in D<sub>max</sub>, D<sub>2%</sub>, gEUD and NTCP of optic nerves in non-adaptive vs original plan. Significant increase in D<sub>mean</sub>, gEUD and NTCP of parotid glands were found in adaptive and non-adaptive vs original plan. D<sub>mean</sub>, gEUD and NTCP were significantly reduced by 5.4%, 5.8% and 5.5% for left parotid gland while 9.1%, 9.2% and 18.3% for right parotid gland in adaptive vs non-adaptive plan.

Table 1. Summary of dosimetric results for original, adaptive and non-adaptive IMPT plan

Target volume/ OARs	Parameters	Original Plan (mean ± SD)	Adaptive Plan (mean ± SD)	Non-Adaptive Plan (mean ± SD)	% Difference (%) (Original vs Adaptive)	P	% Difference (%) (Original vs Non-Adaptive)	P

\*Indicated as statistically significant

**Conclusion**

Anatomical changes had a significant dosimetric impact on IMPT plan quality and APT showed dosimetric benefits in both targets and OARs for locally advanced NPC patients.

**EP-1151 Effects of Continued Smoking in Head and Neck Cancer Patients: A Systematic Review and Meta-Analysis**

### EP-1152 Tumor volume as a prognostic factor in irradiated patient for locally advanced oral cavity cancer

N. Janmune<sup>1</sup>

<sup>1</sup>Songklanagarind hospital, Radiation Oncology, Hatyai, Thailand

#### Purpose or Objective

To determine the effect of the pretreatment tumor volume, in locally advanced oral cavity squamous cell carcinoma, on the survival in patients treated with concurrent chemoradiotherapy.

#### Material and Methods

Review of 74 patients, with histologically confirmed stage III-IV (AJCC 8<sup>th</sup> edition) squamous cell carcinoma of oral cavity, receiving treatment at a tertiary radiation oncology center between January 2009 and March 2016. The patients were treated with either primary radiation or concurrent chemoradiation therapy. This study excluded patients with lip cancer, metastatic disease, and those who diagnosed with other second primary cancer, except non-melanoma cancer of skin. Pretreatment computed tomography (CT) scans were reviewed by experienced neurological diagnostic radiologist for TNM staging. For tumor volume delineation process, the pretreatment CT was delineated by consensus of at least three researchers with Eclipse Planning System (version 10). For statistical analysis, the survival analysis was determined by a Kaplan-Meier estimator. The optimal cutoff tumor volume was evaluated by receiver-operating curve analysis. In the associations of predictor variables, univariate and multivariate analysis were performed with Cox proportional hazards regression models. A p-value of less than 0.05 was considered significant.

#### Results

From 74 patients, 67 patients who received treatment with concurrent chemotherapy were analyzed. The majority of the patient were male (82%), age 59±12.6 years with ECOG score 0-1 (89%). Almost all of them had T stage 3-4 and N stage 2-3. A half of primary tumors site were oral tongue. The median Total Tumor Volume (TTV) was 73.25 cm<sup>3</sup> (IQR 41.9, 132.3). The median survival was 1.04 years (95% CI 0.91 - 1.69). The optimal cutoff TTV that significantly affect the overall survival rate was ≥ 59.8 cm<sup>3</sup> (p < 0.001) (Figure 1). Multivariate analysis showed TTV ≥ 59.8 cm<sup>3</sup> (HR 3.19; 95% CI 1.59-6.4; P < 0.001) and IMRT/VMAT radiation technique (HR 3.5; 95% CI 1.38-9.08; P = 0.002) were considered to be the factors influencing the overall survival outcome.

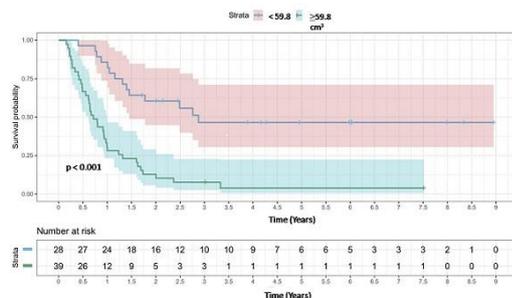

Figure 1. Kaplan-Meier of overall survival according to total tumor volume

#### Conclusion

TTV influenced on the overall survival of locally advanced oral cavity squamous cell carcinoma. In addition, TTV may be considered as a factor to select the appropriate treatment option for these patients.

### EP-1153 A retrospective single institutional analysis of 175 elderly head and neck squamous cell carcinoma

A.K. Gandhi<sup>1</sup>, M. Rastogi<sup>1</sup>, S.S. Nanda<sup>1</sup>, R. Khurana<sup>1</sup>, R. Hadi<sup>1</sup>, K. Sahni<sup>1</sup>, A. Srivastava<sup>1</sup>, A. Bharati<sup>1</sup>, S. Mishra<sup>1</sup>

<sup>1</sup>Dr Ram Manohar Lohia institute of Medical Sciences, Radiation Oncology, Lucknow, India

#### Purpose or Objective

We aimed to retrospectively analyze the demographics, clinical outcome and compliance to treatment of elderly (≥ 65 years) head and neck squamous cell carcinoma (HNSCC) at our institution

#### Material and Methods

Data of 175 consecutive patients of HNSCC presenting to the radiation oncology clinic from February 2013-June 2017 were retrieved and analyzed. Patients with primary in nasopharynx/ para-nasal sinuses, those with metastatic disease at presentation and patients who underwent surgery were excluded from analysis. Following patient details were retrieved from the medical charts: patient demographics, co-morbidities, primary site, stage (AJCC 7th edition), radiation dose parameter, compliance and disease free survival (DFS). DFS was calculated from the date of diagnosis till the time of recurrence. Statistical analysis was done using SPSS (version 21.0). Kaplan Meier method was used for survival analysis and p<0.05 was considered significant

#### Results

Patient characteristics are summarized in Table 1. 76% of patients were ≥ 70 years of age. After registration and initial evaluation, 11 patients (6.3%) defaulted before initiation of treatment. Of remaining 164 patients, 128 (78%) were planned for a radical and 36 (22%) for palliative intent of therapy. Of 128 patients planned for definitive radiotherapy (107 patients) /chemoradiotherapy (21patients); 97 patients (75%) received ≥ 60 Gray of radiation dose. Neo-adjuvant chemotherapy (NACT) was administered in 70/107 patients receiving definitive radiotherapy alone. Median number of NACT cycles was 2 (range 2-3). Median number of concurrent chemotherapy (CCT) cycles was 5 (range 3-6). Median radiotherapy dose was 60 Gray (range 20-70 Gray). Regimens used during NACT were mainly taxane/platinum/5-Fluorouracil based and during CCT was weekly cisplatin (35-40 mg/m<sup>2</sup>). Of 36(22%) patients planned for palliative intent therapy, palliative radiotherapy (median dose 20 Gray in 5 fractions) was delivered in 25 patients; palliative chemotherapy in 20 patients and 9 patients received both. Median follow up was 13 months (range 4-26 months). Median DFS for entire cohort was 17.9 months. Median DFS for patients treated with radical intent was 26.7 months versus 5.5 months for palliative intent (p<0.001). On univariate analysis, site of disease (p=0.10; Oral cavity primary worse), stage of disease (p<0.001; stage IV worse) and radiation dose ≥ 60 Gray (p<0.001; better outcome) were significant predictors of DFS. Karnofsky performance score, age and presence of co-morbidities did not impact DFS (p=NS).

Patient Characteristics

### Conclusion

Approximately, 3/4<sup>th</sup> of the patients of elderly HNSCC are offered radical intent therapy in our clinical setup. Of these, 75% of patients complete sufficient dose of radiation therapy ( $\geq 60$  Gray of radiation dose). Oral cavity primary and stage IV disease portend dismal outcome.

### EP-1154 Definitive RT and Postoperative RT of adenoid cystic carcinoma: a propensity score analysis

T.H. Lee<sup>1</sup>, B. Jang<sup>1</sup>, J.H. Kim<sup>1</sup>, H. Wu<sup>1</sup>, Y.S. Seo<sup>1</sup>, S.H. Oh<sup>2</sup>, D. Kim<sup>2</sup>, S.K. Kwon<sup>2</sup>, T. Won<sup>2</sup>, E. Chung<sup>2</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University Hospital, Department of Otorhinolaryngology, Seoul, Korea Republic of

### Purpose or Objective

The mainstay radical treatment of adenoid cystic carcinoma in the head and neck (HNACC) is surgery. The outcome of definitive radiotherapy (RT) and surgery combined with postoperative radiotherapy (PORT) has not been properly compared due to the rarity of disease and imbalances of characteristics between patients receiving either treatment. The present study aims to compare outcomes of definitive RT versus surgery + PORT for HNACC using adjustment with propensity scores (PS).

### Material and Methods

A retrospective review of medical records was performed in patients who underwent definitive RT (n=47) or surgery + PORT (n=145) for newly diagnosed nonmetastatic HNACC between January 1981 and December 2016. A median follow-up period was 4.9 years (range, 0.34 to 27.6 years). PS was estimated using factors including age, sex, T stage, N stage, radiotherapy techniques and primary sites. Propensity score (PS) matching and inverseprobability of treatment weighting (IPTW) were used to estimate and compare survival outcomes.

### Results

Five-year overall survival (OS), disease-free survival (DFS), locoregional control (LRC), distant metastasis-free survival (DMFS) of unmodified cohort were 75.7%, 31.4%, 66.3%, 34.2% (definitive RT) and 86.8%, 49.5%, 79.7%, 55.9% (surgery + PORT). These treatment outcomes were significantly different between two groups (p<0.05). In the PS-matched cohort, differences between the treatment outcomes were not significant. Five-year OS, DFS, LRC, DMFS of PS-matched cohort were 72.6%, 37.8%, 74.4%, 39.5% (definitive RT) and 89.3%, 48.2%, 79.0%, 52.1% (surgery + PORT). Also in the IPTW-adjusted cohort, the differences were not significant. Five-year OS, DFS, LRC,

DMFS of IPTW-adjusted cohort were 77.9%, 51.7%, 81.9%, 53.6% (definitive RT) and 86.8%, 48.9%, 79.9%, 53.7% (surgery + PORT).

### Conclusion

Two analyses using PS showed there were no differences in treatment outcomes after balancing patient characteristics. Definitive RT would actually give better treatment results than those reported in previous studies. These results ultimately need be explored in a randomized trial.

### EP-1155 Rare entities in head-and-neck cancer: A single institutional experience of carbon-ion reirradiation

T. Held<sup>1</sup>, P. Windisch<sup>1</sup>, S. Akbaba<sup>1</sup>, K. Lang<sup>1</sup>, D. Bernhardt<sup>1</sup>, P. Plinkert<sup>2</sup>, S. Kargus<sup>3</sup>, K. Freier<sup>3</sup>, S. Rieken<sup>1</sup>, K. Herfarth<sup>1</sup>, J. Debus<sup>1</sup>, S. Adeberg<sup>1</sup>

<sup>1</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>Heidelberg University Hospital, Department of Otorhinolaryngology-Head and Neck Surgery, Heidelberg, Germany ;

<sup>3</sup>Heidelberg University Hospital, Department of Oral and Maxillofacial Surgery, Heidelberg, Germany

### Purpose or Objective

The objective of this investigation was to evaluate outcome and toxicity of carbon-ion reirradiation (CIR) in patients with rare tumor entities of head-and-neck cancer. There are no guidelines for the treatment of these indications, therefore we want to increase the body of evidence.

### Material and Methods

Thirty-two consecutive patients with infrequent head-and-neck cancer entities treated at our clinic between 2010 and 2017 were retrospectively analyzed regarding progression free survival (PFS), overall survival (OS), patterns of failure and toxicity. Acute (initial 90 days after CIR) and late toxicity were assessed using NCI CTCAE v4.03.

### Results

The median age prior to CIR was 63 years (range 27 - 79 years) and the median time between initial irradiation and CIR was 5.2 years (range 0.6 - 46.5 years). On average, patients received 4 (range 1 - 6) tumor-specific treatments before CIR. 22% of primary tumors were mucoepidermoid carcinomas, 19% were acinar cell carcinomas, 16% were esthesioneuroblastomas, 13% were lymphoepithelial carcinomas and 9% myoepithelial carcinomas. Other entities included sinonasal undifferentiated carcinoma, salivary duct carcinoma and neuroendocrine carcinoma. Most common tumor sites were salivary glands (47%), nasopharynx (22%) and paranasal sinus (19%). 28 patients (87.5%) had T4-tumors and 4 patients (12.5%) had distant metastases prior to CIR. The median PTV and CTV of CIR were 137.1 ccm (range 23.1 - 714.89 ccm) and 98.3 ccm (range 13.3 - 550.6 ccm) respectively. Patients received a median dose of 51 Gy (RBE) (range 36 - 66 Gy (RBE)) in 3 Gy (RBE) fractions and the median cumulative applied dose after CIR was 128.6 BED 2Gy (range 105.8 - 146.5 BED 2Gy). 22% underwent surgical resection prior to CIR. Median overall survival after CIR was 24.1 months (95% CI 16.1 - 32.0 months). 11 patients (34%) survived at least 2 years after CIR. Local and distant control one year after CIR were 66% and 72% respectively. 92% of local recurrences after CIR were in-field. Patients with tumors infiltrating the skull base had a significantly worse OS compared to patients with salivary gland tumors (p=0.012). In addition, patients with two prior irradiation treatments compared to one prior course of radiation therapy had a significantly worse OS (p=0.001). No serious acute or late toxicity ( $\geq$  grade 3) after CIR was observed. Late toxicities of grade 2 included middle ear inflammation (n=3; 9.4%), dysgeusia (n=3; 9.4%), trismus (n=3; 9.4%) and impaired hearing (n=3; 9.4%). 18 months

after CIR, one patient developed a brain necrosis (grade 2) which was treated with bevacizumab.

#### Conclusion

In patients with rare tumor entities of locally advanced, recurrent head-and-neck cancer, CIR is an effective and safe treatment alternative to salvage surgery or palliative systemic therapy in carefully selected patients with good performance status. Further prospective studies are merited to confirm these findings.

#### EP-1156 Radical radio-chemotherapy in head and cancer: retrospective comparison between weekly and 3-weekly CDDP.

M. Buglione<sup>1</sup>, M. Gerardi<sup>2</sup>, D. Greco<sup>1</sup>, M. Maddalo<sup>1</sup>, A. Daniela<sup>2</sup>, M. Bonù<sup>1</sup>, M. Augugliaro<sup>3</sup>, A. Alghisi<sup>1</sup>, L. Pegurri<sup>1</sup>, A. Ferrari<sup>2</sup>, D. Tomasini<sup>1</sup>, G. Marvaso<sup>2</sup>, R. Orecchia<sup>4</sup>, B. Jereczek<sup>3</sup>, S.M. Magrini<sup>1</sup>  
<sup>1</sup>University and Spedali Civili - Brescia, Radiation Oncology Unit, Brescia, Italy ; <sup>2</sup>IEO- European Institute of Oncology IRCCS, Division of Radiation Oncology, Milano, Italy ; <sup>3</sup>IEO- European Institute of Oncology IRCCS and University of Milano, Division of Radiation Oncology and Oncology and Hemato-Oncology Department, Milano, Italy ; <sup>4</sup>IEO- European Institute of Oncology IRCCS, Scientific Direction, Milano, Italy

#### Purpose or Objective

Even if three weekly (3w) CDDP is considered the standard chemotherapy given concurrently with radiotherapy in the treatment of head and neck cancer, the alternative use of weekly (w) CDDP is widely adopted, because is thought to be less toxic and more manageable. This retrospective analysis aims to compare toxicity and survival of these two schedules.

#### Material and Methods

Patients eligible for the analysis had meso/hypopharyngeal or laryngeal locally advanced disease and were treated with radical radio-chemotherapy. Patient, disease and treatment characteristics were analysed and related with toxicity and survival, using  $\chi^2$ -test, log-rank test and propensity score (age, T, N, M) analysis (SPSS®).

#### Results

Between Jan 2010 and Jan 2017 166 patients were treated in two large reference Italian Centres, 52 pts with 3w (100mg/m<sup>2</sup>) and 114 pts with w-CDDP (40mg/m<sup>2</sup>). Patients treated with w-CDDP had a statistically significant older age (p=0.005), worse Karnofsky performance (p=0.000); higher smoking and alcohol consumption (p=0.000). Moreover, in this group there were less meso-pharyngeal (65% vs 90%; p=0.001) and N2-3 disease (71% vs 84.7% p=0.02) and more T3-4 disease (54% vs 38%; p=0.05). All patients were treated with equivalent RT doses. The CDDP cumulative doses were equivalent in both groups (p=0.10); the rate of RT interruption was higher in the w group. Clinical response was similar in the two groups (p=0.081 and p=0.984 in relation to N and T response, respectively). Local relapse rate is higher in w-group (17.65% vs 11.5%) while metastases occurrence is worse in 3w-group (4.4% vs 19.2%) (p=0.01).

Anaemia, leukopenia, renal toxicity, mucositis and dysphagia rates were similar in the two groups. Thrombocytopenia, nausea and vomiting were more frequent in the w-group (p=0.01 and 0,007 respectively). Overall survival was influenced by tumour site (better for meso-pharyngeal disease p=0.04), nodal stage (better for N0-1 p=0.01), and nodal response to treatment (better for CR p=0.004) but not by the CDDP schedule (p=0.433). Relapse free survival was influenced only by the nodal response to treatment (better for CR, p=0.015). All survival data were confirmed after propensity score analysis.

#### Conclusion

With the limits of a retrospective analysis the study showed the equivalence of the two CDDP schedules in

terms of survival outcomes. The higher rates of some toxicities and the higher rates of treatment interruptions in the w group could be explained by the worse patients and disease characteristics at baseline. A prospective randomised study comparing these two schedules is desirable to define the optimal chemotherapy association for patients treated with radical intent.

#### EP-1157 Elective nodal dose of 40 Gy is sufficient for locally advanced oropharyngeal carcinoma.

K. Asai<sup>1</sup>, S. Ohga<sup>1</sup>, S. Nomoto<sup>1</sup>, T. Yoshitake<sup>1</sup>, M. Shinoto<sup>1</sup>, K. Matsumoto<sup>1</sup>, H. Hirata<sup>1</sup>  
<sup>1</sup>Kyushu University, Clinical Radiology, Fukuoka, Japan

#### Purpose or Objective

To clarify the optimal dose of elective nodal irradiation for locally advanced oropharyngeal squamous cell carcinoma.

#### Material and Methods

We enrolled 119 locally advanced oropharyngeal carcinoma patients treated at our institution between April 2003 and October 2017. The inclusion criteria were followings: 1) over 6 months of follow-up period, 2) treated with definitive chemoradiotherapy or bioradiotherapy. In our institution, elective nodal regions were received 40 - 41.4 Gy with fraction size of 1.8 - 2 Gy. Gross lesions were prescribed with 65 - 70 Gy. We evaluate the pattern of failure, overall survival rate, and progression free survival rate. Incidence of regional failure within the elective nodal region is also evaluated.

#### Results

The median age of the patients was 63 years old, and the median follow up period was 44 months. Clinical Stage (according to AJCC 7th) was Stage III in 21, Stage IVa in 86, Stage IVb in 12. HPV status was p16 positive in 21, negative in 15, unknown in 83. Smoking status was  $\geq 10$  pack-years in 79, <10 pack-years in 35, unknown in 5. Treated with chemoradiotherapy in 115, bioradiotherapy in 4. Treatment method was 3D-CRT in 99, IMRT in 20. Recurrence was observed in 39 cases. The 5-year Overall survival rate and progression free survival rate was 76.6% and 63.2%, respectively. The pattern of failure was local in 21, regional in 17, distant in 11. Among the regional recurrence cases, nodal recurrence within the elective nodal regions was observed only in one case.

#### Conclusion

Dose of 40 Gy is sufficient for elective nodal region in locally advanced oropharyngeal cancer.

#### EP-1158 Impact of postoperative target volumes in management of head and neck carcinoma of unknown primary

F. Pondeur<sup>1</sup>, P. Pommier<sup>2</sup>, J. Ton Van<sup>3</sup>, E. Monchet<sup>3</sup>, D. Girodet<sup>1</sup>, M. Poupart<sup>1</sup>, P.E. Roux<sup>1</sup>, P. Zrounba<sup>1</sup>, M. Julieron<sup>3</sup>, S. Deneuve<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Head and Neck, LYON, France ;

<sup>2</sup>Centre Léon Bérard, Radiotherapy, Lyon, France ;

<sup>3</sup>Centre Oscar Lambret, Head and Neck, Lille, France

#### Purpose or Objective

We aimed to compare the outcomes of postoperative unilateral radiotherapy (UL-RT) versus bilateral radiotherapy plus total mucosal irradiation (COMP-RT) in management of head and neck carcinoma of unknown primary (HNCUP).

#### Material and Methods

Retrospectively, 69 patients with unilateral HNCUP treated in 2 cancer institutes between 2004 and 2014 were included. Diagnosis work-up included for all patients a positron emission tomography-computed tomography. The proportion of p16 positive HNCUP was similar in both centers. All patients were treated with curative intent by initial ipsilateral neck dissection. In one center, all 23 patients underwent UL-RT while in the other center, all 46

patients received a COMP-RT. The long-term quality of life (QOL) of the patient was evaluated using the Quality of Life Questionnaire for Head and Neck 35.

#### Results

After a median follow up of 6.3 years, primary tumour emerged in 3 (13%) patients in UL-RT group and in 4 (9%) patients in COMP RT group ( $p=0.68$ ). There were no differences ( $p=0.34$ ) in cervical node recurrence rate between UL-RT group (4%) and COMP-RT group (22%). The locoregional recurrence free survival rate at 5-years was 81% in UL-RT group and 68.6% in COMP-RT group ( $p=0.21$ ). When comparing it with COMP-RT, UL-RT had a trend to an improvement of the QOL related to teeth problems, swallowing, troubles with social contact and use of pain killers.

#### Conclusion

Unilateral postoperative radiotherapy provides similar outcomes as COMP-RT in unilateral HNCUP management. This radiotherapy modality seems to improve radiation morbidity and long term QOL of patients without compromising re-irradiation possibilities.

#### EP-1159 To compare outcome of Intensive nutritional support with standard practise in head and neck cancer.

T. Shahid<sup>1</sup>, N. Kalyani<sup>1</sup>, S. Modak Das<sup>2</sup>, M. Mukherjee<sup>1</sup>, J. Bhattacharya<sup>1</sup>, A. De<sup>1</sup>, R. Talukdar<sup>1</sup>, A. Samanta<sup>1</sup>, T. Ghosh<sup>1</sup>, D. Barman<sup>1</sup>, S. Sadhukhan<sup>1</sup>, P. Vijayaraghavan<sup>1</sup>, R. Rajan<sup>1</sup>

<sup>1</sup>Apollo Gleneagles Hospital, Radiotherapy, Kolkata, India ; <sup>2</sup>Apollo Gleneagles Hospital, Nutrition and Dietetics, Kolkata, India

#### Purpose or Objective

A randomized control study to evaluate the effect of Nutritional support following the American Dietetic Association Medical Nutrition Therapy (ADA MNT) protocol with standard practise (SP) for patients of head and neck cancer undergoing radiotherapy either alone or with chemotherapy. To determine the impact of nutritional intervention (NI) compared with standard practice (SP). Malnutrition related to persistent poor oral intake during radiation has significant adverse impact on clinical outcome and quality of life. Nothing much can be done in majority of our patients due to resource and financial crunch in our country. Henceforth, after radiotherapy, the nutritional status of the patients is poor and the curative effect is often unsatisfactory.

#### Material and Methods

60 patients, previously untreated and biopsy proven squamous cell carcinoma histology to be treated with either radical radiotherapy or radical concurrent chemo radiation with curative intent were included. (50 Male and 10 Female). Mean age being 51 years. Patients were randomized to receive either NI ( $n=31$ ) (nutrition counseling following the American Dietetic Association Medical Nutrition Therapy (ADA MNT) protocol for radiation oncology) or SP (general nutrition talk and booklet)( $n=29$ ). Main outcome measure was dietary intake (protein and kilocalorie) assessed at baseline, 4, 8 and 12 weeks after starting radiotherapy. Statistical analyses repeated measures ANOVA performed on an intention to treat basis.

#### Results

The NI group had a higher mean total kilocalorie ( $p=0.02$ ) and protein intake ( $p<0.001$ ) compared with the SP group. Mean intake per kilogram of body weight for the NI group ranged from 29 to 32 kcal/kg/day compared with 24 to 28 kcal/kg/day for the SP group ( $p=0.02$ ). The NI group had a higher mean protein intake (1.2-1.4g/kg/day) compared with the SP group (1.0-1.1g/kg/day) ( $p=0.001$ ). Treatment breaks were seen in 10 % of patients in NI group as compared to 30 % in SP group. Even the Health related Quality of Life (HRQOL) was better in the NI group. HRQOL was measured by the European Organization for Research

and Treatment for Cancer (EORTC) QLQ-C30 and EORTC HN35.

#### Conclusion

Intensive NI following the ADA MNT protocol results in improved dietary intake compared with SP and appears to beneficially impact on nutrition related outcome in patients receiving radiotherapy. All patients undergoing radiotherapy either alone or with concurrent chemotherapy should receive thorough nutrition assessment, adequate nutritional counselling and nutritional support for a meaningful clinical outcome.

#### EP-1160 Quantifying the impact of radiologic revision in head and neck cancer: monoinstitutional experience

D. Alterio<sup>1</sup>, L. Preda<sup>2</sup>, S. Volpe<sup>1,3</sup>, C. Giannitto<sup>2</sup>, G. Riva<sup>1,3</sup>, A.F. Pounou Kanga<sup>1,3</sup>, M. Atac<sup>4</sup>, G. Giugliano<sup>4</sup>, A. Ferrari<sup>1</sup>, G. Marvaso<sup>1</sup>, S. Durante<sup>1,3</sup>, S. Arculeo<sup>1,3</sup>, I. Turturici<sup>5</sup>, M. Cossu Rocca<sup>6</sup>, M. Ansarin<sup>4</sup>, M. Bellomi<sup>2</sup>, B.A. Jereczek-Fossa<sup>1,3</sup>, R. Orecchia<sup>7</sup>

<sup>1</sup>European Institute of Oncology IRCCS, Department of Radiation Oncology, Milan, Italy ; <sup>2</sup>European Institute of Oncology IRCCS, Department of Radiology, Milan, Italy ;

<sup>3</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy ; <sup>4</sup>European Institute of Oncology IRCCS, Department of Head and Neck Surgery, Milan, Italy ;

<sup>5</sup>University of Rome- Tor Vergata, Department of Radiation Oncology, Rome, Italy ;

<sup>6</sup>European Institute of Oncology IRCCS, Department of Head and Neck and Urogenital Medical Oncology, Milan, Italy ; <sup>7</sup>European Institute of Oncology IRCCS, Scientific Directorate, Milan, Italy

#### Purpose or Objective

Although the role of the radiologist as a core member of the multidisciplinary team (MDT) for Head and Neck (HN) cancer management has been increasingly advocated, a quantitative analysis on the impact of imaging revision is not available in currently published works. To address this unmet need, the current study provides a full report of MDT meetings held at a tertiary care cancer center at the presence of expert dedicated HN radiologists.

#### Material and Methods

Retrospective revision of cases discussed at MDT meetings from April 2014 to March 2017 for whom a radiologic revision was required. All cases were revised by two dedicated HN radiologists (LP and GC having 15 and 5 years experience in HN cancer imaging, respectively). Inclusion criteria were: 1) clinical and/or radiological suspicion or histologically-proven diagnosis of HN cancer, 2) availability of a written medical record of the MDT discussion and final radiological report 3) follow-up length of at least 12 months, 4) written informed consent for the use of personal data for educational and scientific purposes. Exclusion criteria were: adjuvant treatment (i.e. radiation treatment alone or in association with systemic therapies) and/or diagnosis of thyroid cancers. Both malignant and benign tumors were included. Only computed tomography (CT) and magnetic resonance (MR) imaging were considered. The following descriptors were used: 1) any changes of radiological staging (per Tumor Node Metastasis, TNM, staging system 7th ed.) 2) any changes in treatment strategy. The latter were categorized as either "major modifications" (i.e. MDT non indication to surgery in favor of radiotherapy± systemic therapy) or "minor modifications" (i.e. MDT indication to an alternative approach: open versus minimally-invasive surgery). Accuracy of MDT indication-to-treatment was verified through follow-up data (pathological specimens and/or subsequent imaging and/or clinical information).

#### Results

Five-hundred forty cases were retrieved, mainly at the time of tumor diagnosis (57%) and locally-advanced tumors (69%). The most represented HN subsite was the oropharynx (28%). MR-only was the most commonly reviewed type of imaging (46%), followed by CT-only

(43%). **Table 1** represents the clinical aim to radiologic imaging revision. Cases' stratification according to radiologic indication is represented in **Fig. 1**. Follow-up showed that radiology-driven MDT decision was correct in 117 of the 118 cases with available follow-up (99%), with 43 patients having a histological confirmation.

#### Conclusion

Data emerging from our work strongly support the inclusion an expert radiologist in the core of each institutional HN MDT. Further efforts of prospective nature are warranted in order to assess whether imaging revision translates into improved oncological outcomes in this clinical setting.

#### EP-1161 Clinical response and toxicity of VMAT low-dose RT with intravenous steroids for Graves' Orbitopathy

B. Salas<sup>1</sup>, R. Cabrera<sup>1</sup>, L. Ferrera<sup>1</sup>, M. Lloret<sup>1</sup>, M. Zajac<sup>1</sup>, J. Rutllan<sup>2</sup>, F. Medina-Rivero<sup>2</sup>, P.C. Lara<sup>3</sup>

<sup>1</sup>Hospital Universitario de Gran Canaria Doctor Negrin., Radiation Oncology, Las Palmas de Gran Canaria, Spain ;  
<sup>2</sup>Hospital Universitario de Gran Canaria Doctor Negrin., Ophthalmology, Las Palmas de Gran Canaria, Spain ;

<sup>3</sup>Hospital Universitario San Roque/Universidad Fernando Pessoa Canarias, Oncology, Las Palmas de Gran Canaria, Spain

#### Purpose or Objective

Radiotherapy has been considered an alternative to high doses glucocorticoids in progressing GO. Low doses (LD-RT) produce an anti-inflammatory effect and seemed to be equally effective than the old common fractionation protocol of 20 Gy, in 10 daily doses over a two-week period. Lower doses of 10 Gy fractionated in 1 Gy a week over 10 consecutive weeks, have been not studied under the new techniques as volumetric modulated arc therapy (VMAT) or Intensity-modulated radiation therapy (IMRT). Furthermore, there is no publications about the efficacy and toxicity of the combined use of LD-RT VMAT/IMRT and high doses glucocorticoids. The aim of this study is to analyze for the first time the clinical response and toxicity of a LD-RT VMAT/IMRT schedule plus high doses glucocorticoids in moderate to severe GO.

#### Material and Methods

33 patients (59 orbits) with diagnosis of moderate to severe Graves' ophthalmopathy (GO) according to EUGOGO were included in this prospective cohort study under our RT Quality Assurance programmed from March 2013 to February 2018. Treatment schedule consisted in retro-orbital LD-RT with VMAT or IMRT (Total Dose 10Gy, 1Gy/fraction/week) and concurrent high dose intravenous glucocorticoids therapy (Methylprednisolone 6 doses of 500mg/week, followed by 4 doses of 250 mg/week). The treatment response was evaluated by clinical activity score (CAS: Range 0-7), considering active GO CAS  $\geq 3$  and inactive GO CAS  $<3$ . Toxicity was scored by the CTC4.0 criteria. Clinical evaluation was jointly done by the ophthalmologist and the radiation oncologist at 3 months intervals. Follow-up was closed in October 1, 2018.

#### Results

All patients completed the irradiation and concurrent steroids therapy schedule. 29 orbits (49.2%) had active GO symptom score (CAS  $\geq 3$ ) before treatment and a mean pretreatment-CAS of 4,1. Three months after treatment all 59 orbits (100%) had inactive GO symptom score (CAS  $<3$ ). A marked reduction from mean pretreatment-CAS of 4,1 to posttreatment-CAS of 1,6 was observed ( $p=0.003$ ) (Figure 1). During follow-up 1 patient (1 orbit) required posterior decompression surgery, and 3 patients (4 orbits) required strabismus surgery due to reactivation and progression of GO symptoms. Three-year freedom from surgery was 81.5 $\pm$ 9.5% (Figure 2). Acute toxicity was very mild (only grade I): eye dryness: 18 orbits (30,5%) eye redness in 9 orbits (15,25%), and photophobia 1 orbit (1.69%). Toxicity from glucocorticoids therapy was G0. No

cataracts or other late toxicity was found.

Figure 1

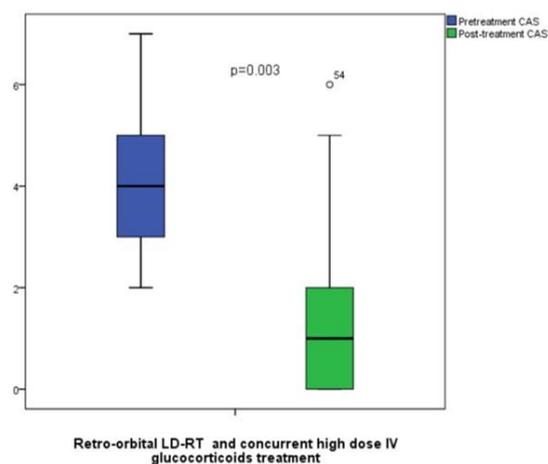

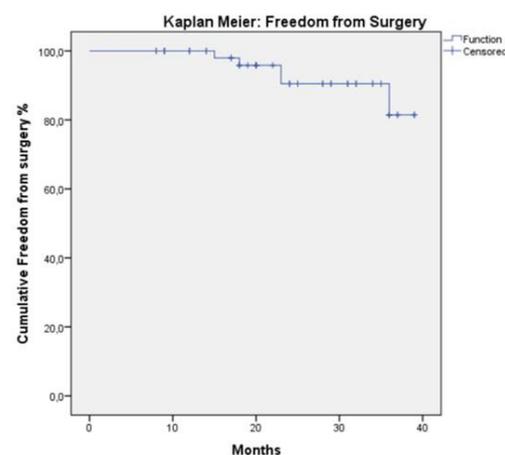

Figure 2

#### Conclusion

Highly-conformation techniques (VMAT/IMRT) retro-orbital LD-RT (10Gy, 1Gy/fraction/week) and concurrent high dose intravenous glucocorticoids is a very active treatment for Moderate to Severe Graves' Orbitopathy. Acute toxicity was very low and no cataracts appeared in the follow-up period. Rescuing surgery was needed in very few cases with a 3-year freedom from surgery of 81.5 $\pm$ 9.5%.

#### EP-1162 Post-radiotherapy sarcopenia: a new prognostic factor in oropharyngeal cancers?

C. Dupin<sup>1</sup>, R. Poncin<sup>1</sup>, A. Daste<sup>2</sup>, C. Majoufre<sup>3</sup>, V. Castetbon<sup>3</sup>, E. De-Mones<sup>3</sup>, R. Trouette<sup>1</sup>, V. Vendrely<sup>1</sup>  
<sup>1</sup>Bordeaux University Hospital, Radiation Oncology, Bordeaux, France ; <sup>2</sup>Bordeaux University Hospital, Medical Oncology, Bordeaux, France ; <sup>3</sup>Bordeaux University Hospital, Head Neck Surgery, Bordeaux, France

#### Purpose or Objective

Sarcopenia, or loss of muscle mass, is common in oncology, and is associated with survival in some retrospective studies. The objective of this study was to evaluate pre- and post-radiotherapy (RT) sarcopenia in patients treated for oropharyngeal cancer and its impact on survival.

#### Material and Methods

All consecutive patients treated for oropharyngeal cancer by irradiation without surgery with curative intent at

Bordeaux University Hospital, , with pre- and post-RT PET-scan were included. During RT, the variation in weight and the lumbar skeletal muscle index (SML) were studied according to oral nutrition, or use of feeding tube with preventive or curative intent. Sarcopenia was evaluated by SML calculated as the ratio of (L3 muscle surface) / (size)<sup>2</sup>, on pre- and post-RT PET scans. Overall and progression free survival have been estimated by the Kaplan-Meier method and evaluated according to pre- and post-RT sarcopenia and type of nutrition.

### Results

From 2011 to 2017, 124 patients were irradiated for oropharyngeal cancer and 116 (93%) had chemoradiotherapy. Median follow-up was 18.2 months [1.7-71.6]. At diagnosis, 55 patients (44%) were sarcopenic compared to 80 patients (65%) 3 months after RT ( $p < 10^{-6}$ ). Patients were less sarcopenic before treatment with p16+ oropharynx cancer than when with p16- oropharynx cancer: 28% vs 63% ( $p < 0.001$ ). Overall Survival was not significantly associated with pre-RT sarcopenia, [Hazard Ratio = 1.6; 95% CI = 0.77-3.2;  $p = 0.12$ ], as well as PFS [HR = 0.57; 0.32-1.03;  $p = 0.052$ ]. Patients lost less weight during RT with preventive feeding tube (mean weight loss :1.6 kg) compared to curative feeding tube (5.6 kg) or exclusive oral nutrition (4.2 kg) ( $p = 0.003$ ). The SML decreased significantly less in the case of preventive feeding tube (-4%) versus curative feeding tube (-12%) or exclusive oral nutrition (-8%) ( $p < 0.001$ ). Finally, OS [HR = 0.38; 0.18-0.81;  $p = 0.03$ ] and PFS [HR = 0.45; 0.26-0.82;  $p = 0.02$ ] were significantly associated with post-RT sarcopenia. At 2 years overall survival was 85% in non-sarcopenic patients after radiotherapy compared with 69% in sarcopenic patients after radiotherapy.

### Conclusion

Evaluation of sarcopenia is relevant in oropharyngeal cancers. Preventive enteral nutrition, associated with decreased muscle mass or post-RT sarcopenia, is predictive of OS and PFS.

### EP-1163 Hypo vs conventional radiotherapy for T1 glottic cancer: A prospective cohort study

B. Salas<sup>1</sup>, D.J. Domínguez Nuez<sup>2</sup>, R. Cabrera<sup>1</sup>, L. Ferrera<sup>1</sup>, M. Lloret<sup>1</sup>, P.C. Lara<sup>3</sup>

<sup>1</sup>Hospital Universitario de Gran Canaria Doctor Negrín., Radiation Oncology, Las Palmas de Gran Canaria, Spain ;

<sup>2</sup>Universidad de Las Palmas de Gran Canaria, Medicine School. Radiation Oncology, Las Palmas de Gran Canaria, Spain ; <sup>3</sup>Hospital Universitario San Roque/ Universidad Fernando Pessoa Canarias, Oncology Department, Las Palmas de Gran Canaria, Spain

### Purpose or Objective

The aim of the present study is to evaluate the clinical outcomes and toxicity rates of a series of prospectively followed patients suffering from squamous T1N0M0 glottic cancers treated either with conventional or hypofractionated radiotherapy schedules.

### Material and Methods

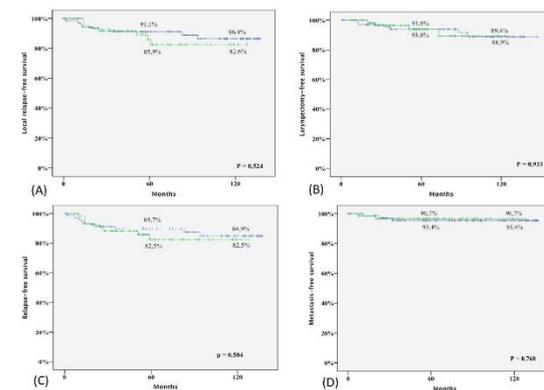

From Jan 1<sup>st</sup>, 2005 to August 1<sup>st</sup>, 2017, T1N0M0 squamous glottic cancers treated by exclusive curative radiotherapy were included in this study. Patients were followed prospectively under our programme for Radiotherapy Quality Assurance. Curative radiotherapy was administered daily, 5/fr/week, either as a conventional fractionation schedule, with doses ranging from 1,8 to 2Gy per day, total dose of 70,2/70 Gy in 7 weeks or hypofractionated schedule with a dose from 2,2 to 2,25Gy per day, total dose 63,8/63Gy in 5,5 weeks. Fractionation schedule was chosen by the treating physician, according to his/her best knowledge. Stratification for fractionation schedule (conventional or hypofractionated) was predetermined in the study. Follow-up was performed by the referring otorhinolaryngologist and the treating

radiation oncologist by clinical examination and laryngoscopy. CT-scan was used when needed.

### Results

One hundred thirty-eight (138) patients were included in this prospective cohort study from January 2005 to August 2017. Follow-up was closed in April 2018 (mean follow-up 78,11 ± 39,85 months, range 7 to 137 months, median 77 months). No one of the patients included were lost of follow-up until last visit or death. Seventy-one patients were treated by conventional schedules and sixty-seven by hypofractionated schedules. Patients characteristics for age, sex, alcohol and tobacco consumption were similar in both cohorts. All patients showed a complete clinical response after radiotherapy according to RECIST criteria. No differences were found for local relapse free survival ( $p=0,524$ )(Fig 1A), larynx preservation rate ( $p=0,933$ )(Fig 1B), disease recurrence ( $p=0,584$ )(Fig 1C) metastases ( $p=0,768$ )(Fig 1D) second primary tumours ( $p=0,895$ ) or Overall Survival rates ( $p=0,70$ ) between the two cohorts. Acute laryngopharyngeal toxicity was higher in the hypofractionation group ( $p = 0,004$ ), mainly due to an increase in mild and moderate toxicity. Severe late laryngeal toxicity (oedema) was similar in both cohorts ( $p=0,714$ ).

Figure 1

### Conclusion

In the present study, the hypofractionated schedule seems to be a feasible treatment option that have similar results than conventional fractionation treatment. Total treatment time saved (1.5w) at a cost of a moderate increase in mild toxicity is convenient for the patient and families.

### EP-1164 Estimated benefit of proton therapy and dose de-escalation in HPV p16-positive oropharyngeal cancer

P. Brodin<sup>1</sup>, R. Kabarriti<sup>2</sup>, V. Gondi<sup>3</sup>, M. Pankuch<sup>3</sup>, M. Garg<sup>2</sup>, W. Tomé<sup>2</sup>

<sup>1</sup>Montefiore Medical Center/Albert Einstein College of Medicine, Radiation Oncology, Bronx, USA ; <sup>2</sup>Montefiore Medical Center, Radiation Oncology, Bronx, USA ;

<sup>3</sup>Northwestern Medicine Chicago Proton Center, Radiation Oncology, Warrenville, USA

### Purpose or Objective

Dose de-escalation strategies are being explored for oropharyngeal cancer (OPC) patients with good prognoses through human papilloma virus (HPV) p16-positive tumor biopsies. Here, we estimate the quality of life (QoL) benefit of proton therapy (PT) for different dose de-escalation levels for OPC, using a data-driven approach for estimating the QoL burden from normal tissue complications.

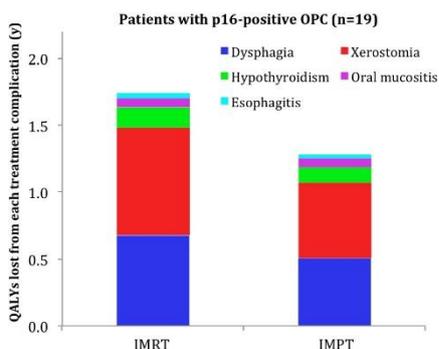

### Material and Methods

The most recent normal tissue complication probability (NTCP) models for dysphagia, xerostomia, esophagitis,

oral mucositis and hypothyroidism were identified through a systematic literature review. The NTCP for these endpoints was estimated in a cohort of 33 OPC patients, of which 19 had HPV p16-positive tumors. NTCP estimates were based on delivered photon intensity-modulated radiation therapy (IMRT) plans, and comparative intensity-modulated PT (IMPT) plans generated from clinical protocols in a collaborating PT center. Equal target coverage and robustness optimization was used in PT plans to account for setup uncertainty. Latencies and durations of complications were modeled based on NTCP estimates while accounting for OPC-specific age-, sex-, and smoking status-adjusted conditional survival probability. The quality-adjusted life years (QALYs) lost attributable to each treatment complication were then calculated by assigning quality-adjustment factors based on severity of complications. Monte Carlo sampling 10,000 times for each patient case was done to account for the uncertainty in underlying modeling parameters and quality-adjustment factors.

### Results

Mean age was 61y, 73% were male, 61% had stage IV disease and 70% had >10 pack-year smoking history. For all patients the average QALYs lost from all modeled complications were 1.52 with IMRT and 1.15 with IMPT, with average 0.37 QALYs spared with PT. The estimated QALYs spared varied considerably between patients and was significantly greater for patients with p16-positive tumors (0.45 vs. 0.25 QALYs,  $p=0.004$ ). Estimated QALYs lost from each complication are shown in the figure for patients with p16-positive tumors, illustrating how long-term complications dysphagia and xerostomia dominate the QoL burden. The table shows estimated QALYs spared with PT for different levels of dose de-escalation to the primary disease for p16-positive tumors, assuming that treatment efficacy remains at the lower dose levels. The combination of dose de-escalation and IMPT results in the lowest estimated QALYs lost.

De-escalation dose level	Average QALYs lost from IMRT	Average QALYs lost from IMPT	Average QALYs spared with proton therapy	Range in QALYs spared with proton therapy among patients
Planned dose	1.73	1.29	0.45	0.18 – 0.81
60 Gy	1.51	1.12	0.40	0.16 – 0.81
50 Gy	1.21	0.91	0.30	0.13 – 0.61
40 Gy	0.95	0.74	0.22	0.09 – 0.41

### Conclusion

The estimated QALYs spared with PT varies greatly even among p16-positive oropharyngeal cancer patients and identifying those who would benefit most using this data-driven approach could improve resource allocation and patient selection for PT. Since PT delivered with dose de-escalation protocols is estimated to have the least QoL burden it is imperative that this be tested prospectively, especially in regards to treatment efficacy.

### EP-1165 Failure Patterns of Cervical Lymph Nodes in Metastases of Unknown Primary according to Target Volume

D.Y. Kim<sup>1</sup>, D.S. Heo<sup>2</sup>, B. Keam<sup>2</sup>, S. Ahn<sup>3</sup>, J. Kim<sup>4</sup>, K.C. Jung<sup>5</sup>, J.H. Kim<sup>1,6,7</sup>, H. Wu<sup>1,6,7</sup>

<sup>1</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University College of Medicine, Internal Medicine, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University College of Medicine, Otorhinolaryngology, Seoul, Korea Republic of ; <sup>4</sup>Seoul National University College of Medicine, Radiology, Seoul, Korea Republic of ; <sup>5</sup>Seoul National University College of Medicine, Pathology, Seoul, Korea Republic of ; <sup>6</sup>Seoul National University, Cancer Research Institute, Seoul, Korea Republic of ; <sup>7</sup>Seoul National University, Institute of Radiation Medicine- Medical Research Center, Seoul, Korea Republic of

### Purpose or Objective

To analyze the clinical outcomes in patients with metastatic carcinoma of cervical lymph nodes from an unknown primary (MUO) according to the radiation target volume, and suggest an optimal radiation field

### Material and Methods

A total of 62 patients with MUO at Seoul National University Hospital between 1998 and 2016 were reviewed. We compared the overall survival (OS), locoregional recurrence (LRR) and primary site failure depending on radiation target volume. The target volume was classified according to whether the head and neck mucosal sites were included and whether the neck node was treated unilaterally or bilaterally.

### Results

Median follow-up time was 44.1 months. 37.1% (n=23) of patients received mucosa RT and 62.9% (n=39) didn't. Mucosa RT showed no significant effect on OS and LRR. Though mucosa RT had borderline significance with primary site failure, only 4 patients (10.3%) who had not treated mucosa developed a subsequent mucosal head and neck carcinoma. Moreover, the location of primary site failure was found to be unpredictable and 75% of recurred patients received successful salvage therapies. When analyzing the unilateral (n=35) or bilateral neck irradiation (n=21), there were no significant differences in OS and LRR between the two radiation fields. When treated bilaterally, there were 2 patients who recurred at ipsilateral in-field and 1 patient found out recurrence at contralateral neck. In case of the unilateral irradiation, there were 4 recurrences at ipsilateral in-field and 2 cases at ipsilateral out-field, especially neck node level I. In addition, when treated both neck, more mucositis occurred significantly.

### Conclusion

We found that there were no benefits in OS and LRR in patients with MUO when treating head and neck mucosal sites and bilateral neck node in radiation target volume. Primary site failure was hard to predict and salvage therapy could be performed in case of incidence of subsequent mucosal carcinoma.

### EP-1166 Optimal timing for salvage surgery after definitive radiotherapy in hypopharyngeal cancer.

S. Chun<sup>1</sup>, B. Keam<sup>2</sup>, D.S. Heo<sup>2</sup>, K.H. Kim<sup>3</sup>, M. Sung<sup>4</sup>, E. Chung<sup>4</sup>, J. Kim<sup>5</sup>, K.C. Jung<sup>6</sup>, J.H. Kim<sup>1</sup>, H. Wu<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea Republic of ; <sup>3</sup>Bundang Jesaeng Hospital, Department of Otorhinolaryngology, Seongnam, Korea Republic of ; <sup>4</sup>Seoul National University Hospital, Department of Otorhinolaryngology, Seoul, Korea Republic of ; <sup>5</sup>Seoul National University Hospital, Department of Radiology, Seoul, Korea Republic of ; <sup>6</sup>Seoul National University Hospital, Department of Pathology, Seoul, Korea Republic of

**Purpose or Objective**

Use of radiotherapy combined with chemotherapy is increasing in hypopharyngeal cancer. However, many show residual tumor after radiotherapy. Timing for treatment evaluation and salvage therapy is essential. However, optimal timing for salvage surgery has not been suggested. In this study, we tried to evaluate optimal timing for tumor response assessment.

**Material and Methods**

Patients who were diagnosed with hypopharyngeal squamous cell carcinoma between 2006 and 2015 were retrospectively analyzed. All patients received definitive radiotherapy with or without chemotherapy. Response of all treated patients were analyzed at 1, 3, and 6 months after radiotherapy. Any patients with progression before 6 months were excluded.

**Results**

A total of 54 patients were analyzed. Complete remission (CR) rates at 1 month (CR1), 3 months (CR3) and 6 months (CR6) were 66.7%, 81.5% and 90.7%, respectively. Non-CR at 1 month (NCR1), 3 months (NCR3), and 6 months (NCR6) showed poor locoregional recurrence-free survival rates (1-year rates of 63.7%, 66.7% and 0.0%, respectively) compared to CR1, CR3 and CR6 (1-year rates 94.3%, 88.0% and 91.5%, respectively). Particularly significant differences were seen between CR6 and NCR6 ( $p < 0.001$ ). Of 10 patients with NCR3, 5 showed CR at 6 months (NCR3/CR6). There was no statistical difference in locoregional recurrence-free survival between CR3 and NCR3/CR6 group ( $p = 0.990$ ).

**Conclusion**

Our data suggest half of patients who did not show CR at 3 months eventually achieved CR at 6 months. Waiting until 6 months after radiotherapy may be appropriate for avoiding additional salvage therapy.

**EP-1167 Sparing of high retropharyngeal lymph node irradiation in patients with oropharyngeal carcinoma**

B. Kang<sup>1</sup>, J.H. Kim<sup>1</sup>, H. Wu<sup>1</sup>, I.A. Kim<sup>2</sup>, K. Eom<sup>2</sup>

<sup>1</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University College of Medicine- Seoul National University Bundang Hospital, Radiation Oncology, Seongnam, Korea Republic of

**Purpose or Objective**

In radiotherapy for head and neck cancer, it is very important to define the appropriate treatment volumes that determine the treatment outcome and toxicity. We examined the feasibility of omitting elective retropharyngeal (RP) nodal irradiation in oropharyngeal cancer.

**Material and Methods**

We performed a retrospective review from 2009 to 2016; 197 patients with oropharyngeal squamous cell carcinomas were treated with definitive or postoperative radiation therapy at the Seoul National University Hospital or Seoul National University Bundang Hospital. Of these patients, 151 patients (76.6%) were treated ipsilateral RP nodal areas up to the upper edge of C1 vertebral body, while the other 46 patients (23.4%) were not. We reviewed patterns of failures, disease free survival, and patient-reported chronic xerostomia status in each patient group.

**Results**

During follow-up period, two patients developed RP nodal recurrences (4-108 months, median =46 months). There was no RP nodal recurrences in patients with a distance >1cm from gross tumor volume (GTV) to high RP nodal areas. There was no significant between-group difference in disease free survival, with a rate of 80.7% in the high RP nodal-irradiation group and 87.2% in the RP nodal spared group ( $P=0.22$ ). Patients in the high RP nodal-irradiation group had higher mean ipsilateral parotid gland dose (mean 28.7Gy vs 21.3Gy,  $P<0.001$ ) and higher rates of chronic xerostomia (72.2% vs. 58.7%,  $P=0.03$ ).

**Conclusion**

Omission of ipsilateral high RP irradiation in oropharyngeal squamous cell carcinoma patients seems safe and improves the patients' quality of life, especially for xerostomia.

**EP-1168 Early radiation induced changes in salivary glands in nasopharyngeal cancer patients after IMRT**

W.V. Wu<sup>1</sup>, M.T. Ying<sup>2</sup>, D.L. Kwong<sup>3</sup>, G.K. Wong<sup>4</sup>, P. Khong<sup>5</sup>

<sup>1</sup>Hong Kong Polytechnic University, HTI, Kowloon- Hong Kong- SAR, China ; <sup>2</sup>Hong Kong Polytechnic University, Health Technology & Informatics, Hong Kong, Hong Kong SAR China ; <sup>3</sup>University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>4</sup>Queen Mary Hospital, Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>5</sup>University of Hong Kong, Diagnostic Radiooogy, Hong Kong, Hong Kong SAR China

**Purpose or Objective**

Parotid and submandibular glands are the main source of saliva. Both glands are irradiated to high dose by radical external beam radiotherapy (EBRT) in nasopharyngeal cancer (NPC) patients. Xerostomia is one of the common radiation induced complications in NPC patients caused by damaged of parotid and submandibular glands after RT. Persistent xerostomia causes difficulties in mastication and swallowing and enhances the risks of dental problems. The aims of this study were to assess the changes of the salivary glands after 6 months of post-RT using magnetic resonance imaging (MRI), ultrasonography (US), saliva flow rate and contents.

**Material and Methods**

25 NPC patients with stage I to III (UICC) treated by routine EBRT using 6 MV 9-field intensity modulated radiotherapy and with no previous history of salivary glands disorder were recruited. Each subject underwent US and MRI examinations, saliva test before the start of radiotherapy (RT) and at 6 months after RT. The US assessment was conducted by the same operator in which the haemodynamics including the blood flow velocity and vascular resistance of the salivary glands were measured. The MRI, which was performed using T1 and T2 axial and sagittal scans with slice thickness of 3 mm, provided the salivary glands' morphological information. The saliva test included the measurement of mean saliva flow rate (SFR) and the main contents of the saliva including alpha-amylase and immunoglobulin A (IgA). The mean values of each measured parameters were calculated and paired t-test was conducted to assess their differences between the two time intervals.

**Results**

The mean volumes of parotid and submandibular glands were significantly reduced by about 30% at 6-month after RT ( $p < 0.001$ ). The two glands also demonstrated lower vascular velocity, resistive and pulsatility indices ( $p < 0.05$ ) when compared to the pre-RT condition. This indicated that the blood flow in the post-RT glands was slower and the blood vessels experienced lower pressure than those of the pre-RT. In addition, the post-RT mean SFR was reduced by more than 9 times when compared with that in pre-RT ( $p < 0.001$ ). The levels of the salivary alpha amylase and IgA were also significantly reduced at the 6-month post-RT interval.

**Conclusion**

Our study demonstrated that there were substantive impacts on the physiological and morphological aspects of the salivary glands after radical EBRT in NPC patients. The side effects were relatively early in which most measured parameters demonstrated significant changes at 6-month post-RT interval.

### EP-1169 Evaluation of swallowing function with PSSHN scale for head and neck cancer patients undergoing IMRT

S. Agarwal<sup>1</sup>, P. Mukherjee<sup>1</sup>, M. Roy<sup>1</sup>, S. Kommineni<sup>1</sup>, N. Kalyani<sup>1</sup>

<sup>1</sup>Jaslok Hospital and Research Centre, Radiation Oncology, Mumbai, India

#### Purpose or Objective

Head neck radiotherapy is associated with significant swallowing and speech dysfunction. Intensity modulated radiotherapy may allow us to reduce the doses to swallowing structures and decrease associated morbidity. Aim of present study is to prospectively assess change in swallowing function using PSSHN questionnaire.

#### Material and Methods

This is a prospective; ethics approved protocol for assessment of change in swallowing functions for head neck carcinoma patients undergoing curative intent radiotherapy with or without concurrent chemotherapy. Patients were asked to fill up PSSHN questionnaire at baseline, at conclusion of radiation and at 3 months post radiation. Change in PSSHN scores were evaluated for all patients. CTRI Registration No is CTRI/2017/11/010378.

#### Results

Between August 2017 to April 2018, 61 patients were enrolled in the study and written informed consent was obtained. Primary sites were: Buccal mucosa 21, Oral Tongue 12, Oropharynx 10, Hypopharynx 5, Larynx 5 and Naopharynx 4. All patients were treated with IMRT with median RT dose of 60 Gy. Thirty seven patients received concurrent chemotherapy. Three patients were excluded from analysis (One died, two withdrew consent). The mean weight loss was 5 kg (range: 3-12 kg). Seventeen patients needed nasogastric tube / PEG tube during radiation. At 3 month follow up, 1 patients had persistent nasogastric tube. Mean PSSHN score at baseline was 228. The mean score at completion of RT was 142 with mean decline in score was 86 (Range 10-225). The mean score at 3 months post RT was 225. Normacy of diet was worst affected domain in PSSHN at completion of RT. There was no significant correlation between ipsilateral or bilateral nodal irradiation and decline in PSSHN scores. Buccal mucosa primary site had less decline in scores as compared to other sites however difference was not significant.

#### Conclusion

There is significant decline in PSSHN score at completion of radiation with normalcy of diet being worst affected domain. There was almost recovery of PSSHN scores after 3 months post completion of radiation.

### EP-1170 Predictive factors of chemoradiation induced oral mucositis in head and neck cancer patients.

F. Arcadipane<sup>1</sup>, E. Olimpo<sup>2</sup>, R. Ragona<sup>2</sup>, G.C. Iorio<sup>2</sup>, S. Martini<sup>2</sup>, E. Gallio<sup>1</sup>, P. Franco<sup>2</sup>, U. Ricardi<sup>2</sup>

<sup>1</sup>Città della Salute e della Scienza, Department of Oncology- Radiation Oncology, Torino, Italy; <sup>2</sup>University of Turin, Department of Oncology- Radiation Oncology, Torino, Italy

#### Purpose or Objective

Radiation-induced oral mucositis (OM) is a major dose-limiting toxicity in head and neck cancer (HNC) patients. It is a normal tissue injury caused by chemotherapy (CT) and/or radiotherapy (RT), which has marked adverse effects on patient quality of life and cancer therapy continuity. We prospectively evaluated a cohort of patient affected with HNC and treated with CT/RT in order to identify dosimetric parameters and clinical characteristics predictive for OM occurrence

#### Material and Methods

We proposed a series of questionnaires, concerning pain (VAS score), quality of life and functional endpoints (OMWQ-HN, FACT-HN) to a total of 41 HNC patients. To define OM, both WHO and OMAS scores were used. Patient

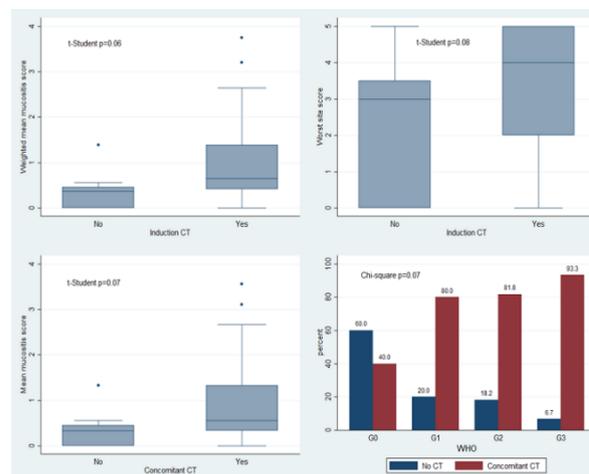

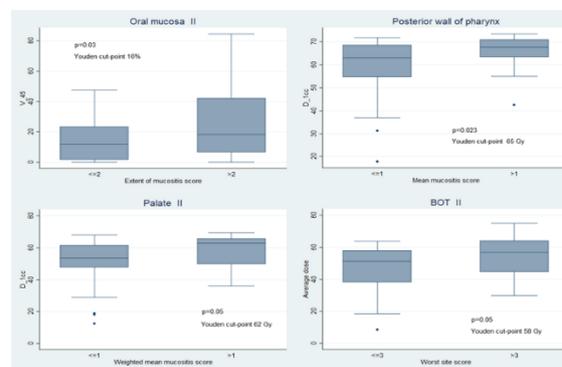

and treatment characteristics were considered. The whole oral mucosa was divided in 4 subsites: palate, base of tongue (BOT), oral cavity (OC) and posterior wall of pharynx (PWP). Planning target volumes were subtracted from the whole oral mucosa and from each subsite and dose-volume histogram (DVH) data were extracted.

DOSIMETRIC PARAMETERS	PALATE	BOT	OC	PWP	ORAL MUCOSA
Average dose	37,72 [15,62]	53,87 [15,28]	42,50 [13,69]	53,28 [14,86]	43,90 [12,57]
D 1cc	56,43 [16,40]	61,54 [12,86]	61,45 [13,36]	60,63 [12,25]	65,90 [10,87]
V20	78,65 [30,95]	94,23 [20,15]	87,70 [21,64]	90,73 [19,43]	87,56 [20,67]
V30	64,70 [33,03]	89,96 [24,27]	72,77 [26,44]	86,00 [24,22]	75,30 [23,78]
V45	37,04 [30,09]	75,74 [35,47]	45,96 [30,03]	77,14 [33,16]	50,69 [25,75]
V50	28,63 [27,92]	69,71 [37,38]	38,53 [29,79]	72,37 [35,22]	42,97 [25,50]

Table 1 Dosimetric Parameters; [Standard Deviation]

#### Results

A similar trend during treatment and follow-up was found both for the OMAS and PRO scores. In our analysis patient's age ( $p=0,02$ ), V30 ( $p=0,02$ ) and V45 ( $p=0,03$ ) of the oral mucosa, resulted to be significantly related to OM. The maximum dose (Dmax) received from PWP was related to Mean Mucositis Score (MMS) ( $p=0,023$ ), Weighted Mean Mucositis Score (WMMS) ( $p=0,022$ ) and Extent of Mucositis Score (EMS) ( $p=0,05$ ). Palate Dmax was related to MMS ( $p=0,05$ ), WMMS ( $p=0,05$ ). For BOT, the average dose was correlated to Worst Site Score (WSS) ( $p=0,05$ ). (Fig.1) OM was found to be significantly related to induction CT (WMMS  $p=0,06$  and WSS  $p=0,08$ ) and concomitant CT (MMS  $p=0,07$ ). Among patients with G3 OM, 93,3% were given concomitant CT while 6,7% underwent exclusive RT ( $p=0,07$ ). (Fig.2)

### Conclusion

In our prospective cohort, we observed a correlation between acute toxicity and pain, impairment in global health status and general QoL. DVH analysis of oral mucosa and its subsites accurately predicts acute oral mucosa toxicity. We were also able to assess the predictive value of clinical parameters for OM. Further studies will be needed to understand clinical relevance, implement daily practice and improve results.

### EP-1171 Toxicity profile of locally advanced head and neck cancer patients treated in 30 or 33 fractions RT

C. Franzese<sup>1</sup>, A. Fogliati<sup>1</sup>, D. Franceschini<sup>1</sup>, F. De Rose<sup>1</sup>, T. Comito<sup>1</sup>, P. Navarria<sup>1</sup>, L. Cozzi<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

### Purpose or Objective

Shortening the overall treatment time without increasing acute reactions is one of the major aims in radiotherapy for locally advanced head and neck cancer (LAHNC). Volumetric modulated arc therapy (VMAT) with Simultaneous Integrated Boost (SIB) showed improvements in the outcome and pattern of toxicity. Aim of this work is to evaluate the toxicity of patients presenting LAHNC, after VMAT-SIB treatment in two fractionation schemes of 30 and 33 fractions.

### Material and Methods

Two groups of LCHNC patients were selected: the first, named 33fx, of 98 patients who received 69.96 and 54.45 Gy in SIB in 33 fractions, between April 2009 and November 2015; the second, named 30fx, of 48 patients who received 66.0 and 54.0 Gy in SIB in 30 fractions, between March 2016 and January 2018. All the patients were treated with VMAT-SIB. Target volumes were delineated as CTV adding 1 cm margin to GTV for primary tumour, and according to the international guidelines for nodal regions; a CTV to PTV 5 mm isotropic margin was added for the 33fx group, and 3 mm margin for the 30fx group. Acute toxicity was graded according to CTCAE 3 for skin, salivary, mucosal, dysphagia. Doses from DVHs for each patient were recorded and analysed to determine possible correlations between dose to critical structures (parotids, oral cavity, submandibular glands and constrictor muscles) and toxicity grade.

### Results

The dosimetric results showed a significant reduction of the mean doses to the main critical structures when reducing the number of fraction (and the total dose) as well as the CTV to PTV margin. To the parotids, the mean doses were assessed as 28.0±0.7 and 21.8±0.9 Gy for 33fx and 30fx groups, respectively; to the oral cavity they were 46.3±0.9 and 40.9±1.4 Gy; for the constrictor muscles 59.5±0.5 and 52.1±0.9 Gy. Errors are the standard error of the mean.

Acute mucosal toxicity was reported as G1 in 28.6/27.1% (33fx/30fx) of the cases, G2 in 45.9/41.7%, G3 in 8.2/4.2%. Acute dysphagia was recorded as G1 in 22.4/18.8% of the patients in the 33fx/30fx groups, G2 in 25.5/56.3%, and G3 in 7.1/4.2%. Acute salivary toxicity was G1 in 25.5/8.3% of the cases, G2 in 3.1/6.3%, and G3 in 1.0/0.0%. The toxicity profile, in favour of the 30fx group, was significant only for dysphagia (p<0.01, test t). The highly significant difference in the mean doses was not translating to the same high degree of significance in the toxicity profile.

### Conclusion

Treatment of LAHNC with 30 fractions radiotherapy and 3 mm of margin seems to be advantageous for the decreased mean doses to the major organs at risk. However, significant toxicity benefit was only demonstrated in the reduction of dysphagia.

### EP-1172 Microstructural and physiological changes of parotid glands after RT for head and neck cancer

M. Bruvo<sup>1</sup>, C. Behrens<sup>2</sup>, R. Hvass<sup>3</sup>, H. Hjorth Johannesen<sup>3</sup>, A.M. Lynge Pedersen<sup>4</sup>, C. Maare<sup>2</sup>, E. Samsøe<sup>2</sup>, F. Mahmood<sup>5</sup>

<sup>1</sup>University College Copenhagen, Radiography, Copenhagen N, Denmark ; <sup>2</sup>Herlev Hospital, Radiotherapy Research Unit, Herlev, Denmark ; <sup>3</sup>Herlev Hospital, Department of Radiology, Herlev, Denmark ; <sup>4</sup>University of Copenhagen- School of Dentistry, Department of Odontology, Copenhagen N, Denmark ; <sup>5</sup>Odense University Hospital, Department of Oncology, Odense C, Denmark

### Purpose or Objective

Salivary gland hypofunction and xerostomia are prominent complications of conventional radiotherapy (RT) of head and neck cancer (HNC), having considerable negative impact on the patients' quality of life. It is therefore important to assess the salivary gland function in these patients for diagnostic and management purposes.

The aim of this study is to investigate use of diffusion-weighted magnetic resonance imaging (DWI) in the assessment of radiation-induced microstructural changes of the parotid glands in terms of apparent diffusion coefficients values (ADC), compared to physiological changes in terms of measurements of whole salivary flow rates. It is hypothesized that use of combined methods for assessment of parotid gland function, provides further insight into the factors that can predict xerostomia.

### Material and Methods

Five patients with HNC who have completed their RT course were assessed in this pilot study. The patients were examined before the first RT fraction (scan 1), after completion of the RT course (scan 2) and one year after completion of the RT course (scan 3). Unstimulated (at rest) and gustatory-stimulated DWI examinations were performed on a 1T MRI system using the DWIBS sequence. Whole-volume region of interest (ROI) method was used for delineation of parotid glands. To suppress perfusion and salivary flow effects high b-values (400, 600 and 800 s/mm<sup>2</sup>) were used for ADC calculation using a mono exponential fit. Unstimulated and chewing-stimulated whole saliva were collected and the flow rates were calculated. The degree of xerostomia was evaluated using the Radiation Therapy Oncology Group/European Organization for Research and Treatment of Cancer (RTOG/EORTC) morbidity score. Mean radiation dose (Gy) was registered for both contra- and ipsilateral parotid glands.

### Results

Mean ADC (ADC<sub>Mean</sub>) values and salivary flow rates were higher in the stimulated than in the unstimulated state (Figure 1a). An increase in ADC<sub>Mean</sub> from scan 1 to scan 3 both in unstimulated and gustatory-stimulated state is observed. Further, the unstimulated salivary flow tended to decrease, while chewing-stimulated salivary flow decreased between scan 1 and 2 and increased from scan 2 to scan 3. The ADC<sub>Mean</sub> tended to increase (R<sup>2</sup> = 0.29-0.37), and the salivary flow rates to decrease (R<sup>2</sup> = 0.01-0.12), with increasing mean radiation dose to the glands (Figures 1b). Mean radiation dose to the ipsilateral parotid gland was used for the correlation between saliva flow rates and mean dose. Figure 1c shows a strong correlation between both ADC<sub>Mean</sub> and saliva flow, and the degree of xerostomia (R<sup>2</sup> = 0.66-0.97).

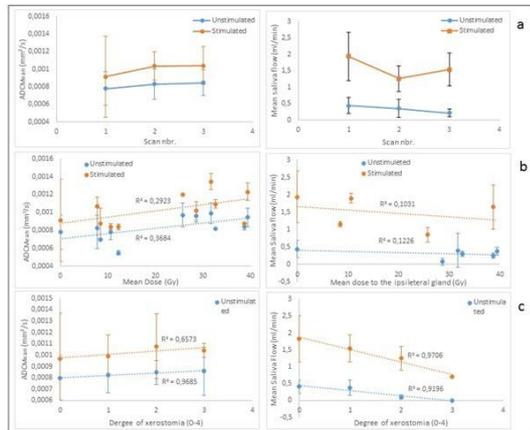

Figure 1. a) Mean ADC (Mean) values and mean salivary flow rates changes from scan 1 to scan 3 both in unstimulated and stimulated state; b) Correlation (R<sup>2</sup>) between mean ADC (Mean) values and mean radiation dose as well as correlation (R<sup>2</sup>) between mean salivary flow rates and mean dose to the ipsilateral parotid gland; c) Correlation (R<sup>2</sup>) between mean ADC (Mean) values and mean salivary flow rates and the degree of xerostomia; d) Unstimulated and stimulated state; e) Correlation (R<sup>2</sup>) between mean ADC (Mean) values and mean salivary flow rates and the degree of xerostomia; f) Unstimulated and stimulated state.

### Conclusion

The results of this pilot study indicate that the severity of microstructural and physiological changes of the parotid glands after RT is dependent on the mean radiation dose to the glands. It also suggests that DWI and salivary flow measurements can be used for assessing parotid gland function after RT and are associated with degree of xerostomia.

### EP-1173 Changes in blood pressure in patients undergoing radiotherapy for head and neck cancers

A. Nachankar<sup>1</sup>, P. Dandekar<sup>1</sup>

<sup>1</sup>Sir H N Reliance Foundation Hospital and Research Center, Radiation Oncology, Mumbai, India

### Purpose or Objective

Head and neck cancer patients undergoing radiotherapy often complain of fatigue, generalized weakness, light headedness associated with poor nutrition, weight loss, dehydration and vasomotor changes. Various theories are proposed for vasomotor imbalance including neurochemical causes, direct damage to carotid body due to radiation or effect on vasomotor centers in brainstem, effect of chemotherapy. Hence, we studied pattern of blood pressure (BP) changes in head and radiotherapy patients.

### Material and Methods

Patients with head and neck cancer, with ECOG 0-1 receiving radiotherapy to head and neck region to a dose of 60-70 Gy over period of 6-7 weeks from December 2016 to Feb 2018. We recorded blood pressure of patients, pre-radiotherapy, weekly during radiotherapy and postradiotherapy at 3-6 monthly interval. Patient symptoms were documented at the same time. We also contoured carotid body region to see document doses.

### Results

We analyzed 60 patients of head and neck cancers receiving radiotherapy to head and neck region, 34 patients received concurrent chemotherapy. Thirty-two patients received radiotherapy to bilateral neck. Twenty four out of 60 patients were hypertensive at baseline and were on antihypertensive medications and all patients continued their antihypertensive treatment. Only one patient had history of hypotension in the past. Average weight loss during radiotherapy was 4.1%. We found that there was statistically significant decline in blood pressure from 3<sup>rd</sup> to 6<sup>th</sup> week of radiotherapy in both systolic and diastolic blood pressure. Maximum average BP decline till 5<sup>th</sup> week of radiotherapy from baseline 132 +/-13 / 78 +/-7 mm of Hg to 115 +/-16 / 71 +/-9 mm of Hg (P<0.05). Compared baseline there was significant decline in blood pressure from 132 +/-13 / 78 +/-7 mm of Hg to 121 +/-14 / 75 +/-7 at 3 to 6 months post radiotherapy (P<0.05). Very

few patients complained of orthostatic hypotension. Mean doses to carotid body region were 62.45 +/- 4 Gy.

### Conclusion

There is a significant decline in BP recorded during in patient undergoing head and neck radiotherapy the effect of which was persistent upto 6 months after radiotherapy. Maximum decline observed upto 5<sup>th</sup> week of treatment. Hence, it is worthwhile to monitor BP during and after treatment and appropriate intervention to be taken.

### EP-1174 Assessment of nausea and dysgeusia in head and neck cancer patients undergoing radiotherapy

C.G. Iorio<sup>1</sup>, S. Martini<sup>1</sup>, F. Arcadipane<sup>2</sup>, E. Olimpio<sup>1</sup>, P. Franco<sup>1</sup>, U. Ricardi<sup>1</sup>

<sup>1</sup>University of Torino, Department of Oncology- Radiation Oncology, Torino, Italy ; <sup>2</sup>Città della Salute e della Scienza, Department of Oncology- Radiation Oncology, Turin, Italy

### Purpose or Objective

Nausea (N) and dysgeusia (Dg) are common side effects occurring during treatment in HN cancer patients, in case of either exclusive radiotherapy (RT) or combined modality treatment (CMT). Patients' daily living can be significantly affected by N/Dg, with a subsequent worsening of treatment compliance. We prospectively scored nausea and we employed an 18-item CiTAS (chemotherapy (CT)- induced taste alteration scale) questionnaire to evaluate 4 taste dimensions identified through factor analysis: decline in basic taste, discomfort, phantogeusia-parageusia, and general alterations.

### Material and Methods

Between 2016 and 2018, 31 patients were treated with Volumetric Modulated Arc Therapy (VMAT) in the HN region within a definitive or adjuvant setting (RT or CMT, 6 or 7 weeks overall treatment time). All patients were given 'Naumix/Naugin' (GAMfarma, Milan, Italy) a spray, containing ginger, anise and vitamin B6 as a prophylactic approach to prevent N/Dg. CiTAS scale was evaluated at baseline (Bs), every week of treatment and during follow-up at 2 adjunctive time-points (1 week and 1 month after RT end).

### Results

Patients were aged 64 (range 34-83) with mostly male sex (61.3%). Most represented tumor subsite was oropharynx (25.9%). Most common histology was SCC (77.4%). Patients were mainly staged as T1-T2 disease (58%); N0(19%), N1-3(71%). RT was delivered as definitive (38.7%) or adjuvant (61.3%) treatment with prescribed doses ranging from 54 to 70 Gy. Acute toxicities were generally mild. Grade 1 nausea was reported by 6.5% of patients at Bs, reaching the maximum value during the VI week (38.7%). No patient referred ≥ G2 nausea at Bs, while this endpoint peaked up at III week (13% of patients) with an optimal recovery in most of the patients with antiemetic drugs (Tab.1).

Tab 1- Worst events (Nause)- Note: Frequencies (Percentages) - Scale (1-3)

Grade	Baseline (n=31)	I week (n=31)	II week (n=31)	III week (n=31)	IV week (n=31)	V week (n=31)	VI week (n=31)	VII week (n=20)	I week post (n=31)	I month post (n=31)
1	2 (6.45)	6 (19.35)	10 (32.26)	6 (19.35)	10 (32.26)	8 (25.81)	12 (38.71)	5 (25.00)	5 (16.13)	2 (6.45)
2	0	1 (3.23)	0	4 (12.90)	1 (3.23)	1 (3.23)	2 (6.45)	0	1 (3.23)	0

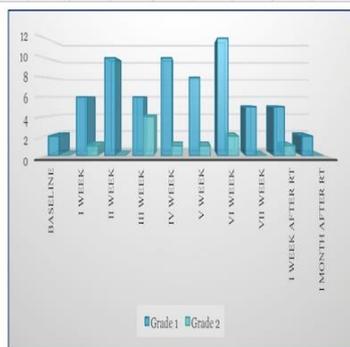

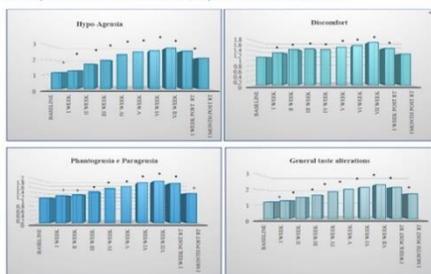

TABLE 1

For detailed CiTAS score results see Tab.2. Mean Hypo-Ageusia score was 1.14(±0.4) at Bs progressively increasing during RT and reaching the maximum values during the VII week at 2.82(±1.4) and decreasing after RT down to 2.13(±1.23) at 1 month from the end of treatment. The same could be observed for discomfort score which was 1.14(±0.47) at Bs, increased up to 1,74(±0.98) at week VII and decreased at 1.27(±0.45)1 month after treatment. The phantogeusia/parageusia score, which was 1.16(±0.60) at Bs, increased to 1.92(±1.08) at week VII and decreased to 1.36(±0.7) at week I after RT. A similar pattern was observed for general taste alterations score: 0.17(±0.43) at Bs, 2.35(±1.04) at week VII of RT and 1.73(±0.87) after 1 month from RT end.

TABLE 2

Scale trend

Note: the symbol \* indicates a difference at the level of 5%, the symbol † indicates a difference inferior to 1%.

Mean values and standard deviation CiTAS Scale

Note: only 20 patients of the overall study population (n=31) have attended a treatment schedule including a seventh week of treatment, according to the adjusted or definitive treatment setting.

Scale	Baseline	I week	II week	III week	IV week	V week	VI week	VII week	I week post	I month post
Hypo-Ageusia	1.14 (0.40)	1.26 (0.52)	1.73 (0.86)	1.99 (0.93)	2.38 (1.18)	2.57 (1.33)	2.64 (1.37)	2.82 (1.40)	2.62 (1.37)	2.13 (1.23)
Discomfort	1.14 (0.47)	1.32 (0.67)	1.45 (0.70)	1.48 (0.72)	1.45 (0.66)	1.55 (0.75)	1.61 (0.86)	1.74 (0.98)	1.50 (0.63)	1.27 (0.45)
Phantogeusia and Parageusia	1.16 (0.60)	1.27 (0.69)	1.31 (0.50)	1.45 (0.59)	1.60 (0.72)	1.68 (0.92)	1.85 (1.04)	1.92 (1.08)	1.82 (1.04)	1.36 (0.70)
General taste alterations	1.17 (0.43)	1.28 (0.50)	1.49 (0.66)	1.64 (0.69)	1.88 (0.74)	2.05 (0.99)	2.17 (1.03)	2.15 (1.04)	2.17 (1.03)	1.73 (0.87)

Conclusion

In conclusion our prospective clinical data point out the N/Dg trend during RT or CMT in HN cancer patients. We provided a quantitative and qualitative assessment of N/Dg, potentially useful for future comparison.

EP-1175 Use of different RBE-models in carbon ion RT - saving OAR constraints from being lost in translation

J.E. Dale<sup>1,2</sup>, S. Molinelli<sup>3</sup>, V. Vitolo<sup>3</sup>, B. Vischioni<sup>3</sup>, M. Bonora<sup>3</sup>, G. Magro<sup>3</sup>, A. Mairani<sup>3,4</sup>, A. Hasegawa<sup>5</sup>, O. Dahl<sup>2</sup>, F. Valvo<sup>3</sup>, P. Fossati<sup>3,6</sup>

<sup>1</sup>Haukeland University Hospital, Department of Oncology, Bergen, Norway ; <sup>2</sup>University of Bergen, Department of Clinical Science- Faculty of Medicine, Bergen, Norway ; <sup>3</sup>National Center for Oncological Hadrontherapy, Clinical department, Pavia, Italy ; <sup>4</sup>Heidelberg Ion-Beam Therapy Center, Medical physics unit, Heidelberg, Germany ; <sup>5</sup>Osaka Heavy Ion Therapy Center, Clinical department, Osaka, Japan ; <sup>6</sup>MedAustron, Carbon ion radiotherapy unit, Wiener Neustad, Austria

Purpose or Objective

In order to optimize carbon ion radiotherapy (CIRT) there is a need to validate dose constraints for important organs at risk. For the optic nerve (ON), constraints have been validated by the National Institute of Radiobiological Sciences (NIRS), Japan, in which the Relative Biological Effectiveness (RBE) of the CIRT has been predicted by the mixed beam model (RBE<sub>NIRS</sub>). These constraints are not immediately useful for centers where the Local effect model (RBE<sub>LEM</sub>) is used, because comparative studies show that RBE<sub>LEM</sub> can predict a 60% higher RBE in the entrance region of the beam, and 5-15% higher RBE in the spread-out Bragg peak, relative to RBE<sub>NIRS</sub>. At the National Center for Oncological Hadrontherapy (CNAO), Italy, current dose constraints for ONs comply with the NIRS constraints: D1% < 40 Gy(RBE) and D20% < 28Gy(RBE), although RBE<sub>LEM</sub> is used in treatment plan optimization. This is a conservative approach, possibly resulting in excessive underdosage to tumors close to the optic pathways. The aim of this work is to improve CNAO's ON dose constraints by analyzing institutional toxicity and by relating the results to RBE<sub>NIRS</sub>.

Material and Methods

A total of 65 optic nerves from 38 patients treated at CNAO with CIRT to the head and neck region in the period 2013-14 were analyzed. The physical dose of the patients' treatment plans was reproduced. Subsequently, both the RBE<sub>LEM</sub> and RBE<sub>NIRS</sub> was applied as RBE model, thus relating CNAO clinical toxicity to the NIRS constraints in RBE<sub>NIRS</sub>-weighted dose. Prediction of doses to selected volumes of the ONs giving x% probability of toxicity (TDx%) was derived using logistic regression.

Results

Median follow-up time was 47 (26-67) months. No toxicity occurred in the 56 ONs in which the current constraints were obeyed. Three ONs developed visual decline at doses D1%≥71 Gy(RBE<sub>LEM</sub>)/68 Gy(RBE<sub>NIRS</sub>) and D20%≥68 Gy(RBE<sub>LEM</sub>)/62 Gy(RBE<sub>NIRS</sub>). Table 1 presents patient characteristics and results of NTCP modelling. TD50 was comparable to the NIRS publication, while TD5 was substantially higher in our results, probably due to a scarcity of ONs receiving mid- to high doses relative to the ONs in NIRS publication. Figure 1 presents DVHs of all ONs in both RBE<sub>LEM</sub>- and RBE<sub>NIRS</sub>-weighted doses and demonstrates that potential new CNAO D1% and D20% constraints should be maximum 49 and 40 Gy(RBE<sub>LEM</sub>), substantially lower than the predicted TD5 doses, in order to comply with the respective NIRS constraints of 40 and 28 Gy(RBE<sub>NIRS</sub>).

n.s.= not specified. \*=approximated from NTCP curves<sup>1</sup>

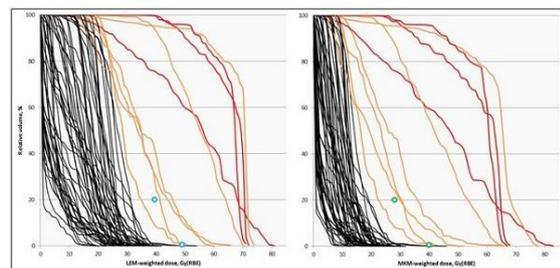

Figure 1: Cumulative DVHs of 65 ONs in RBE<sub>LEM</sub>-weighted dose (left panel) and RBE<sub>NIRS</sub>-weighted dose (right panel), showing the 3 ONs that developed visual decline (red), the DVHs that did (orange and red) or did not (black) breach NIRS D1% and/or D20% constraints (green circles) in RBE<sub>LEM</sub>-weighted dose. Blue circles illustrate possible new RBE<sub>LEM</sub>-weighted dose constraints that would comply with RBE<sub>NIRS</sub>-weighted dose constraints.

### Conclusion

This analysis confirms that the current constraints used at CNAO are safe, but suggest that the D1% and D20% constraints could be increased to about 49 and 40 Gy(RBE<sub>LEM</sub>), respectively. However, due to uncertainties in the recalculation method applied, and differences in the physical beam model of original NIRS and CNAO treatment planning system, only a partial and step-wise escalation of dose constraints should be done within protocols providing careful observation and revalidation.

### EP-1176 Comparison of patient and physician reported acute toxicities during head and neck cancer radiotherapy

J. Bhattacharya<sup>1</sup>, A. Jawade<sup>1</sup>, P. Vijayaraghavan<sup>1</sup>, T. Shahid<sup>1</sup>, M. Mukherjee<sup>1</sup>, R. Talukder<sup>1</sup>, A. Samanta<sup>1</sup>, C. Saikia<sup>1</sup>, A. De<sup>1</sup>, D. Barman<sup>1</sup>, T. Ghosh<sup>1</sup>, S. Sadhukhan<sup>1</sup>  
<sup>1</sup>Apollo Gleneagles Hospital- Kolkata, Radiation Oncology- Cancer Block- 1st Floor, Kolkata, India

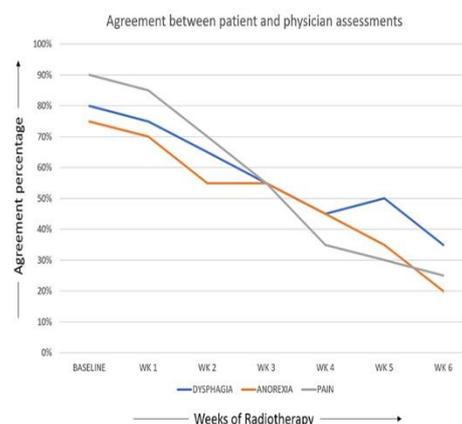

### Purpose or Objective

The purpose of our study was to prospectively assess and compare acute toxicities reported by radiation oncologists and patient reported outcome measures (PROM) during concurrent chemoradiation for locally advanced squamous cell carcinoma of head and neck. The aim was to find discordance between subjective and objective assessments and its characteristics.

### Material and Methods

Twenty patients of locally advanced head and neck squamous cell carcinoma on radical concurrent chemoradiation were included. Acute toxicities were assessed at baseline, weekly and at the end of treatment by the radiation oncologists and patients themselves independently. National Cancer Institute's Common Terminology Criteria for Adverse Events (CTCAE version 5.0) for 12 domains was used by the radiation oncologists while PROM for the same were recorded using PRO-CTCAE. At each point of assessment, the toxicity grades were compared in terms of agreement or disagreement between patients and physicians. The incidence, pattern and degree of disagreement between patients and physicians were analysed statistically. The relation between severity of toxicity and degree of disagreement were studied and plotted with Bland Altman Analysis.

### Results

20 male patients with mean age of 59 years with locally advanced carcinoma of oral cavity, oropharynx, hypopharynx and larynx were assessed. 6 (30%) and 12 (60%) patients presented with T4 disease and Node positive disease respectively. All patients were treated with cisplatin based chemoradiation. 3DCRT or IMRT were used. 30-35% patients developed grade 3 acute toxicity in terms of dysphagia, mucositis or dermatitis as per CTCAE. No grade 4 or above toxicity was noted. Some degree of disagreement existed at baseline for symptoms like pain (10%), dysphagia (20%), anxiety (25%) and depression (20%). The agreement between physician assessments and PROM demonstrated a decreasing trend from 80-100% at baseline to 20-35% at week 6 of treatment for all domains. Maximum disagreement was observed with pain (80%) and Anorexia (20%) at 6<sup>th</sup> week. The degree of disagreement (by one or two points) was found to be increasing with severity of toxicity grades (mean toxicity grade). The patient reported toxicity grades always remained higher across all domains towards the end of treatment. 3 patients required hospitalisation for toxicity management and treatment was interrupted for 4 patients.

### Conclusion

The study found that a significant amount of disagreement exists between physician and patients and the gap increases with the severity of toxicity. The result evokes the thought that there is a possibility of under-assessment by the physician or over-assessment of acute toxicities by the patients which may ultimately affect the final clinical outcome. These two scales can be used as complementary tools to assess acute toxicities more accurately so that an early intervention can be done. This is an ongoing prospective study in our department.

### EP-1177 Comparative study assessing QoL in HNSCC patients treated with Radical Radiation with IMRT vs 3DCRT

M. Mukherjee<sup>1</sup>, J. Bhattacharya<sup>1</sup>, T. Shahid<sup>1</sup>, A. Samanta<sup>1</sup>, L.N. Biswas<sup>1</sup>, A. Jawade<sup>1</sup>, A. De<sup>1</sup>, D. Barman<sup>1</sup>, T. Ghosh<sup>1</sup>, S. Sadhukhan<sup>1</sup>, P. Vijayaraghavan<sup>1</sup>, R. Talukdar<sup>1</sup>, C. Saikia<sup>1</sup>, R. Rajan<sup>1</sup>, R. Raj<sup>1</sup>  
<sup>1</sup>Apollo Gleneagles Hospital, RADIATION ONCOLOGY, Kolkata, India

#### Purpose or Objective

The purpose of the study is to assess and compare health-related quality of life (HRQOL) in patients with HNSCC, treated with radical radiotherapy with IMRT versus 3D-CRT.

#### Material and Methods

From January 2018 to May 2018, 40 patients of squamous cell carcinoma of oropharynx, larynx and hypopharynx (cT1-3 N0-2b except cT1N0 glottic cancer) undergoing radical radiotherapy either alone or with concurrent chemotherapy were included in this study. Patients were treated with radical doses with conventional fractionation using either IMRT or 3DCRT. EORTC QLQ-C30 and HN35 were used to study the HRQOL and assessed for each patients at baseline i.e. before the commencement of radiation, at 3<sup>rd</sup> week of RT, after completion of treatment, at 1 month and at 3 months of follow up. Radiation induced acute toxicities were assessed by RTOG acute toxicity criteria, every week during radiotherapy. For comparison, QOL data collected at different point of time were analyzed using unpaired 't' test and for acute radiation induced toxicities chi-square test was used.

#### Results

40 patients were evaluated in the study. The mean age of the sample population was 60 years with predominant male population (90%). Larynx was the commonest site (18 patients, 45%). 13 patients (32.5%) had T3 disease and 10 (25%) patients had node positive disease. 14 (35%) patients received cisplatin based concurrent chemotherapy. The number of patients treated with 3DCRT and IMRT were 19 and 21 respectively. HRQOL scores of various components deteriorated during and after treatment in both the arms. HRQOL scores of fatigue (24 vs 17, p=0.041), appetite loss (73 vs 44, p<0.001) and sense problems (31 vs 15, p<0.001) were significantly worse in IMRT group during and after completion of treatment. However, these differences were not evident at 3 months of follow up. Dryness of mouth and sticky saliva were significantly more in 3D-CRT group (HR-QoL score for dryness of mouth 60 vs 0, p<0.001 and for sticky saliva 9.52 vs 0, p=0.24) during radiation and 3 months after completion of treatment. Insomnia and ill feeling were found to be significantly more in 3DCRT arm. Other parameters like global health, physical, emotional and social functions, speech and swallowing, nutritional parameters remained comparable in both arms. There was no grade 4 or above acute toxicities. No significant difference was observed in acute toxicities e.g. mucositis, dysphagia, skin toxicities between IMRT and 3DCRT arm during RT.

#### Conclusion

Our study shows that technique of radiation (3D-CRT and IMRT) affects QoL in HNSCC, treated radically. Though there was no difference in terms of acute toxicity in between groups but IMRT did significantly better considering dryness of mouth and sticky saliva, not only during treatment but at 3 months after completion of treatment. More number of patients and long term follow up is required to validate these findings. This is an ongoing study in our department.

### EP-1178 Prognostic role of FDG-PET/CT during radiotherapy in patients with hypopharyngeal carcinoma

T. Mase<sup>1</sup>, Y. Toyomasu<sup>1</sup>, Y. Watanabe<sup>1</sup>, T. Kawamura<sup>1</sup>, A. Takada<sup>1</sup>, S. Ochiai<sup>2</sup>, Y. Yamashita<sup>3</sup>, N. Ii<sup>4</sup>, H. Sakuma<sup>1</sup>, Y. Nomoto<sup>1</sup>

<sup>1</sup>Mie University Hospital, Department of Radiology, Tsu, Japan ; <sup>2</sup>Saiseikai Matsusaka General Hospital, Department of Radiation Oncology, Matsusaka, Japan ; <sup>3</sup>Matsusaka Central Hospital, Department of Radiation Oncology, Matsusaka, Japan ; <sup>4</sup>Ise Red Cross Hospital, Department of Radiation Oncology, Ise, Japan

#### Purpose or Objective

Our study aimed to investigate the prognostic effects of <sup>18</sup>fluoro-2-deoxy-D-glucose positron emission tomography/computed tomography (PET/CT) during definitive radiotherapy (RT) in patients with hypopharyngeal squamous cell carcinoma.

#### Material and Methods

The pretreatment and interim PET/CT images of 38 patients with hypopharyngeal squamous cell carcinoma, receiving definitive RT between February 2014 and June 2018, were evaluated prospectively. RT was delivered 5 days a week using a single daily fraction of 1.8 Gy, to a total dose of 70.2 Gy. The interim PET/CT images were taken at a cumulative RT dose ranging from 36.0 to 45.0 Gy. The maximum standardized uptake value (SUV<sub>m</sub>) of primary tumor both pretreatment PET/CT and interim PET/CT and the reduction ratio of the SUV<sub>m</sub> (SRR) between the two images were measured. Progression-free survival (PFS) was calculated using the Kaplan-Meier method. Univariate and multivariate analyses were performed to evaluate the prognostic value of pretreatment SUV<sub>m</sub>, interim SUV<sub>m</sub>, SRR, age, sex, primary tumor site, T classification, and stage for prediction of PFS.

#### Results

The median follow-up time was 18 months (range, 6-55 months). The 1-year and 2-year PFS rates were 75.6% and 68.6 %, respectively. Eleven (29%) of 38 patients experienced disease recurrence (n=10, 26%) or death (n=4, 11%). In univariate analysis, a higher interim SUV<sub>m</sub> and a lower SRR were associated with the inferior PFS (Figure 1, Figure 2). Conducting a multivariate analysis revealed that an interim SUV<sub>m</sub> of primary tumor was an independent prognostic factor for PFS (Hazard ratio (95% CI), 12.5(1.59-98.21); p=0.016).

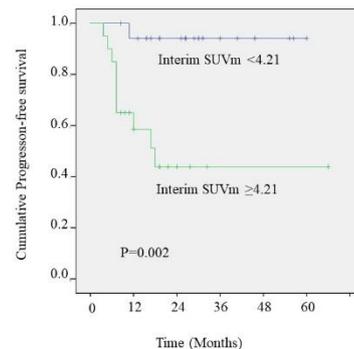

Figure.1 Progression-free survival according to interim SUV<sub>m</sub>. SUV<sub>m</sub>=maximum standardized uptake value.

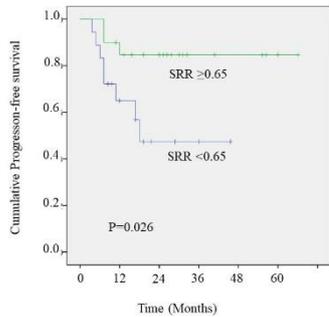

Figure 2 Progression-free survival according to SRR.  
SRR=reduction ratio of the maximum standardized uptake value of primary tumor.

### Conclusion

A higher interium SUVm of primary tumor was founded to be the prognostic indicator of oncological outcome.

### EP-1179 Primary concurrent chemoradiotherapy for locally advanced laryngeal squamous cell carcinoma

D. Adjogate<sup>1</sup>, F. De Felice<sup>1,2</sup>, Y. Suh<sup>1</sup>, J. Jeannon<sup>3</sup>, R. Oakley<sup>3</sup>, R. Simo<sup>3</sup>, M. Lei<sup>1</sup>, T. Guerrero Urbano<sup>1</sup>

<sup>1</sup>Guy's and St Thomas' NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom ;

<sup>2</sup>Policlinico Umberto I "Sapienza" University of Rome, Department of Radiotherapy, Rome, Italy ; <sup>3</sup>Guy's and St Thomas' NHS Foundation Trust, Head and Neck Unit, London, United Kingdom

### Purpose or Objective

Treating locally advanced laryngeal squamous cell carcinoma (SCC) with primary chemoradiotherapy (CRT) can preserve the larynx without compromising survival. However, whether this is associated with good functional outcomes remains up for debate. The aim of this study was to evaluate survival and functional outcomes in patients with locally advanced laryngeal SCC treated with primary CRT, with a focus on T3 disease.

### Material and Methods

We retrospectively analysed data from all consecutive patients with stage III-IV (M0) disease treated with primary CRT in our centre between January 2007 and December 2016.

Study endpoints were overall survival (OS), disease free survival (DFS), laryngectomy free survival (LFS), laryngo-oesophageal dysfunction free survival rate (LEDFS) and functional preservation rates (defined by freedom from tracheostomy or feeding tube at 2 years). Prognostic factors were assessed by univariate and multivariate analysis.

### Results

76 patients who underwent primary radical CRT were analysed. 25 patients received induction chemotherapy prior to CRT. 64 patients (89%) received concomitant platinum-based chemotherapy, and 8 (11%) concomitant Cetuximab. 74% of patients were treated with IMRT. All patients received elective nodal irradiation. The median follow-up was 42 months (range 3-109).

Median OS was 62 months. OS rates were 73.6% and 51.5% at 2- and 5 years, respectively. The 2- and 5-year DFS rates were 68.3% and 62.8%. For patients with T3 disease, the 2-year OS rate was 79.5% and DFS rate was 70.2%. Patients with positive nodal status, N2b or above disease, stage IV disease and age greater than 60 years demonstrated poor OS on univariate analysis. Older age (HR 3.13; 95% CI 1.39-6.98, p=0.005) and positive nodal status (HR 3.81; 95% CI 1.15-12.62, p=0.029) remained poor prognostic factors for survival on multivariate analysis.

Functional preservation was 67.3% at 2 years in all patients alive (64.8% in T3 patients). 70% of patients treated with IMRT had a preserved larynx at 2 years versus 58.3% for 3D-conformal RT. The 2-year LEDFS rate was 47.4%. The

2-year LFS rate was 85.8% for all patients and 89.9% for T3 patients. Salvage laryngectomies were performed in 11 patients; of which 10 were performed within 2 years of CRT. Use of induction chemotherapy had no effect on LFS or OS. There was also no demonstrated difference in LFS rate between RT technique (IMRT vs. 3D-conformal), primary tumour localization (Supraglottic vs. Glottic) or T3 subgroup (fixed vs. mobile larynx or cartilage invasion vs. no cartilage invasion).

### Conclusion

Our study illustrates high rates of OS, DFS and LFS. Functional preservation was highest in patients treated with IMRT. LEDFS rate was moderately low due to the inclusion of all-cause deaths, as per international consensus. The survival rates suggest that carefully selected patients with locally advanced laryngeal carcinoma can successfully be treated with larynx-preserving primary CRT without compromise on survival.

### EP-1180 Re-radiation in head and neck malignancies: experience from a tertiary care centre in eastern india

J. Bhattacharya<sup>1</sup>, M. Mukherjee<sup>1</sup>, V. Kumar K<sup>1</sup>, R. Rajan<sup>1</sup>, T. Shahid<sup>1</sup>, S. Goswami<sup>1</sup>, L. Naha Biswas<sup>1</sup>, P. Chatterjee<sup>1</sup>, S. Saha<sup>1</sup>

<sup>1</sup>Apollo Gleneagles Hospital- Kolkata, Radiation Oncology- Cancer Block- 1st Floor, Kolkata, India

### Purpose or Objective

Recurrent and second primary (RSP) of head-and-neck squamous cell carcinomas (HNSCC) arising within or close to previously irradiated areas are of significant clinical challenge. Salvage surgical resection is the standard of care, but reirradiation is often needed as an adjunct treatment and also needed when surgery is not feasible. The therapeutic ratio of reirradiation for RSP of HNSCC may be improved in the intensity modulated radiation therapy (IMRT) era. However, patient selection for reirradiation remains challenging. The aim of the study is to investigate outcomes after IMRT based reirradiation and to assess toxicity and median survival after re-irradiation in recurrent head and neck cancer patients treated at our institution since January 2013 till December 2017.

### Material and Methods

All patients were treated after confirming prior radiation dose, treatment portal and treatment technique or by assuming patients got a full radical dose of prior radiation. Minimum gap of 6 months after prior radiation, PS ECOG 1-2, Age < 75 years, no prior grade 4 late toxicity were taken as the inclusion criteria.

### Results

43 patients were included of which 37 were male and 6 were female. Recurrent disease was local in 70% and second primary in 30%. Minimum and maximum radiation free interval was 6 months and 196 months respectively with a mean interval being 58 months. 44% were treated radically and 56% treated post-operatively. All the patients were treated with IMRT/VMAT with conventional fractionation. Target volumes in 30 patients included nodal volumes only and in 13 patients primary disease was the target. (Depending on the recurrence pattern). Mean dose to PTV was 58.6 Gy with a minimum dose of 36 Gy and maximum 66 Gy was prescribed according to the clinical scenario and disease free interval. 6 patients received concurrent chemotherapy. The rates of grade 3 and grade 4 acute toxicities were 18% and 4.2% respectively. Median survival was 33 months, with 61% of the 43 patients alive at the time of this analysis. Poor nutritional status, weight loss, speech and swallowing difficulty was the other toxicity seen almost in every patient.

### Conclusion

Outcomes of our study reflect an efficient way of utilizing technology in combination with stringent patient selection criteria. IMRT technique must be applied with high priority to the limited target volume to reduce acute and late

morbidities and to reduce inevitable radiation related complications such as dysphagia, speech issue and neurological damage. In spite of all, the prognosis remains uncertain.

### EP-1181 Structure delineation using a deformable image registration-based contour propagation in HNC

B. Ng-Cheng-Hin<sup>1</sup>, D. McQuaid<sup>2</sup>, A. Dunlop<sup>2</sup>, S. Court<sup>2</sup>, I. Petkar<sup>1</sup>, C. Nutting<sup>1</sup>, K. Harrington<sup>1</sup>, S. Bhide<sup>1</sup>, K. Newbold<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and Royal Marsden NHS Trust, Head and Neck Radiotherapy and Imaging, Sutton, United Kingdom ; <sup>2</sup>The Institute of Cancer Research and Royal Marsden NHS Trust, Joint Department of Physics, Sutton, United Kingdom

#### Purpose or Objective

Delineation of head and neck structures and target volumes on planning CT is an essential but time-consuming process for the radiation oncologist (RO). Repeat delineation as part of adaptive radiotherapy substantially increases clinical workload, therefore there is interest in facilitating this process in a safe and efficient manner.

The aim of this study is to assess the benefit of the contour propagation component of a commercial adaptive planning workflow and the potential to save RO delineation time.

#### Material and Methods

5 head and neck cancer patients underwent a pre-treatment and repeat planning CT during treatment as part of the INSIGHT trial (CCR3926). The organs at risk (OARs) and target volume were delineated on the pre-treatment and repeat CT using RayStation 7.0 (RaySearch Laboratories, Stockholm, Sweden). The delineated structures from the pre-treatment scan were propagated to the repeat CT using an intensity-based Deformable Image Registration (DIR). This involved an initial rigid registration followed by DIR of the pre-treatment CT onto the repeat CT. The propagated structures were independently reviewed, modified and compared to the RO-delineated structures on the repeat scan. All contours were delineated by a single RO and reviewed by 2 experienced RO.

RO delineation was compared to the DIR propagated group using time factors and qualitative analysis using Dice similarity coefficient (DSC) and mean distance to agreement (MDA). **Results**

The mean time taken by the RO to delineate on the repeat CT was 87.34 minutes (SD 13.32). The mean time to propagate and amend the contours was significantly reduced (Paired t-test,  $p = 0.0039$ ) to 34.46 minutes (SD 7.02).

Compared to RO delineation, the mean MDA were 1.10 mm (SD 1.10) and 0.77 mm (SD 0.38) for unmodified and modified contours respectively. The mean DSC were 0.76 (SD 0.17) and 0.82 (SD 0.13) for the unmodified and modified contours respectively.

DSC for the unmodified structures were  $<0.8$  for the GTV and small OARs such as the lens, optic nerves and chiasm. All DSC either improved or remained unchanged following RO amendment.

Table 1. DICE and MDA scores reflecting the volumetric overlap and mean surface distance between 2 contours on registered images respectively. These scores compare clinician recontoured structures to clinician modified or unmodified propagated structures. A DSC tolerance of 0.8 to 0.9 and MDA between 2 to 3 mm were used tolerance as suggested by the AAPM Radiation Therapy Committee Task Group 132.

		DSC		MDA	
		Mean	Standard Deviation	Mean (mm)	Standard Deviation (mm)
GTV Node	RO Modified	0.82	0.06	0.62	0.29
	Unmodified	0.63	0.12	1.89	1.50
GTV Primary	RO Modified	0.73	0.07	1.23	0.29
	Unmodified	0.52	0.27	3.56	2.84
Right Parotid	RO Modified	0.89	0.03	0.91	0.25
	Unmodified	0.87	0.03	1.03	0.29
Left Parotid	RO Modified	0.89	0.02	0.78	0.17
	Unmodified	0.87	0.03	0.90	0.17
Spinal Cord	RO Modified	0.86	0.03	0.62	0.16
	Unmodified	0.85	0.03	0.63	0.14
Brain Stem	RO Modified	0.87	0.02	1.15	0.17
	Unmodified	0.86	0.01	1.21	0.16
Chiasm	RO Modified	0.55	0.21	0.88	0.47
	Unmodified	0.50	0.15	1.24	0.50
Right Optic Nerve	RO Modified	0.80	0.02	0.50	0.17
	Unmodified	0.72	0.12	0.62	0.33
Left Optic Nerve	RO Modified	0.77	0.02	0.59	0.29
	Unmodified	0.67	0.07	0.83	0.32
Right Lens	RO Modified	0.74	0.09	0.28	0.11
	Unmodified	0.73	0.08	0.33	0.12
Left Lens	RO Modified	0.70	0.19	0.50	0.37
	Unmodified	0.64	0.17	0.56	0.34
Right Globe	RO Modified	0.92	0.03	0.55	0.33
	Unmodified	0.92	0.03	0.61	0.35
Left Globe	RO Modified	0.93	0.01	0.52	0.13
	Unmodified	0.92	0.03	0.59	0.24
High dose CTV	RO Modified	0.91	0.03	1.1	0.31
	Unmodified	0.91	0.03	1.1	0.33
Prophylactic CTV	RO Modified	0.84	0.01	1.28	0.23
	Unmodified	0.81	0.05	1.45	0.42

#### Conclusion

Contour propagation using DIR significantly reduces RO delineation time. Although volumetric overlap did not perform well for small organs and the GTV, the mean MDA for each structure showed a high level of agreement for all structures apart from the unmodified GTV. This suggests that DSC overestimates the errors for small structures. RO modifications led to an improvement in volumetric overlap of the majority of the organs and target volume, but did not match perfectly. This may be accounted for by intra-observer variability or a bias towards making minimal changes to the propagated structures. A larger patient database is required to confirm the findings of this study and further work on the dosimetry impact of RO modification versus no modifications should be made.

### EP-1182 Selective neck irradiation for oropharynx cancer in relation with human papilloma virus status

S. Park<sup>1,4</sup>, D. Oh<sup>1</sup>, J.M. Noh<sup>1</sup>, Y.C. Ahn<sup>1</sup>, Y.H. Ko<sup>2</sup>, M.K. Chung<sup>3</sup>, H.S. Jeong<sup>3</sup>, Y.I. Son<sup>3</sup>, C. Baek<sup>3</sup>

<sup>1</sup>Samsung Medical Center, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Samsung Medical Center, Pathology, Seoul, Korea Republic of ; <sup>3</sup>Samsung Medical Center, Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea Republic of ; <sup>4</sup>Keimyung University Dongsan Medical Center, Radiation Oncology, Daegu, Korea Republic of.

#### Purpose or Objective

To evaluate the feasibility of selective neck irradiation (SNI) policy during definitive radiation therapy (dRT), in relation with human papilloma virus (HPV) status, for oropharyngeal cancer (OPC).

#### Material and Methods

From January 2008 to December 2017, 214 OPC patients received dRT, mainly by Helical Tomotherapy. HPV status was known in 150 patients (HPV+ in 115 and HPV- in 35), and the majority (138/150, 92.0%) received concurrent systemic therapy. Between HPV+ and HPV- patients, there

was no difference in the characteristics of demography, tumor burden (according to the 7th edition AJCC stage), and treatment. The same dose schedule, according to our SNI policy, was applied regardless of HPV status: 66-68.4 Gy in 30 fractions to the gross tumor volume (GTV); 60 Gy in 30 fractions to the high-risk clinical target volume (HR-CTV) that included immediately adjacent lymphatic level; and 36 Gy in 18 fractions to the low-risk CTV (LR-CTV) that included 1 additional lymphatic level, respectively.

#### Results

The median follow-up period was 35 (3-120) months. Grade  $\geq 3$  mucositis, dermatitis, weight loss, and soft tissue necrosis developed in 35 (16.4%), 7 (3.3%), 14 (6.5%), and 11 patients (5.1%), respectively, with no difference according to HPV status. The 3-year rates of locoregional control (LRC), distant control (DC), and overall survival (OS) of all patients were 91.7%, 89.6%, and 89.1%, respectively. HPV+ patients achieved significantly better LRC (93.3% vs. 78.6%,  $p=0.013$ ), but no difference was apparent in DC (89.1% vs. 85.8%,  $p=0.542$ ) and OS (90.6% vs. 81.6%,  $p=0.110$ ), respectively. Among 14 patients who developed regional failure, the failure sites in relation to the target volume were inside the GTV/HR-CTV in 11 (78.6%), both inside and outside the GTV/HR-CTV in two (14.3%), and outside the GTV/HR-CTV in one (7.1%), respectively.

#### Conclusion

Based on favorable LRC in HPV+ patients with the equivalent acute side effect profile, coupled with infrequent outside the GTV/HR-CTV failure, the current SNI policy seems successful, both in HPV+ and HPV- patients, and additional effort to improve LRC in HPV- patients may be necessary.

#### EP-1183 Proton therapy boost in locally advanced head and neck cancer: toxicity and clinical outcome

<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ; <sup>2</sup>European Institute of Oncology, Division of Radiation Therapy, Milan, Italy ; <sup>3</sup>National Center of Oncological Hadrontherapy, Radiation therapy Unit, Pavia, Italy ; <sup>4</sup>National Center of Oncological Hadrontherapy, Diagnostic Imaging Unit, Pavia, Italy ; <sup>5</sup>University Hospital- Novara, Division of Radiation Oncology, Novara, Italy ; <sup>6</sup>ICS Maugeri Pavia, Unit of Radiation Oncology, Pavia, Italy ; <sup>7</sup>University of Turin, Department of Oncology- Radiation Oncology, Turin, Italy ; <sup>8</sup>Niguarda Ca' Granda Hospital, Unit of Radiotherapy, Milan, Italy ; <sup>9</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

#### Purpose or Objective

evaluation of feasibility, acute toxicity and early clinical outcome in patients (pts) with locally advanced head and neck cancer (LAHNC) treated with exclusive sequential mixed beam (MB) approach: intensity modulated radiation therapy (IMRT) followed by proton therapy (PT) boost on high risk areas.

#### Material and Methods

between July 2012 to January 2018, 41 pts (29 male, 12 female), median age 51 years (range, 18-74), with histologically proven LAHNC (stage III and IV) were treated using a MB approach: IMRT of the neck and macroscopic disease, followed by PT boost on the pre-treatment macroscopic disease. Tumor sites were: nasopharynx 28 pts (69%), oropharynx 5 pts (12%), larynx 1 patient (2%), sinonasal 4 pts (10%) and oral cavity 3 pts (7%). The histology was: squamous cell carcinoma for 11 pts (28%), neuroendocrine tumor for 2 pts (5%);

nasopharynx tumor were classified according to World Health Organization (WHO) classification (2005): I type 4 pts (10%), II type 19 pts (47%) and III type 4 pts (10%). IMRT prescription dose was 54-60 Gy (elective irradiation of the neck and macroscopic disease), PT prescription dose was 10-20 Gy Relative Biological Effectiveness (RBE), for a total dose up to 70-74 Gy RBE. Local control (LC) and toxicity profile (according to Common Terminology Criteria Adverse Events -CTCAE V4.03- scale) were evaluated

#### Results

Twenty-three pts (56%) received platinum based induction chemotherapy, 39 pts (95%) received concurrent chemoradiation therapy. The median follow-up was 12 months, (range, 4-57). Treatment was well tolerated, 11 (27%) pts developed grade 3 acute radiation-related toxicity: 2 pts (5%) mucositis, 1 patient (2%) skin reaction and 5 pts (12%) dysphagia. No pts had high grade (grade 3-4) late toxicity. Grade 2 late toxicity was xerostomia found in 12 (29%) pts. Two pts (5%) developed G1 brain radionecrosis at 14 and 16 months after the end of the treatment, respectively, in both cases it was resolved at least follow-up. LC was 83%. Four pts had local recurrence at 12, 11, 8 and 8 months after treatment, respectively. Three pts developed distant metastases at 6, 18 and 25 months after the end of the treatment. Three pts died for tumor specific-causes.

#### Conclusion

for pts with LANHC a MB approach was feasible and our results showed good short-term outcome and limited radiation-related side effects. Preliminary results are encouraging but a longer follow-up and large patient accrual are required.

#### EP-1184 Target volume delineation for adaptive treatment in HNSCC is highly variable among experts

#### Purpose or Objective

Inter-observer variability (IOV) in target volume delineation is a well-documented phenomenon and a major source of uncertainty in radiation treatment (RT) planning. The increasing adoption of adaptive RT adds a dynamic component to IOV, which is largely unknown. We analysed IOV in the pre- and mid-treatment (PT and MT) setting using expert primary gross tumour volume (GTV)

and clinical target volume (CTV) delineations in locally advanced HNSCC.

#### Material and Methods

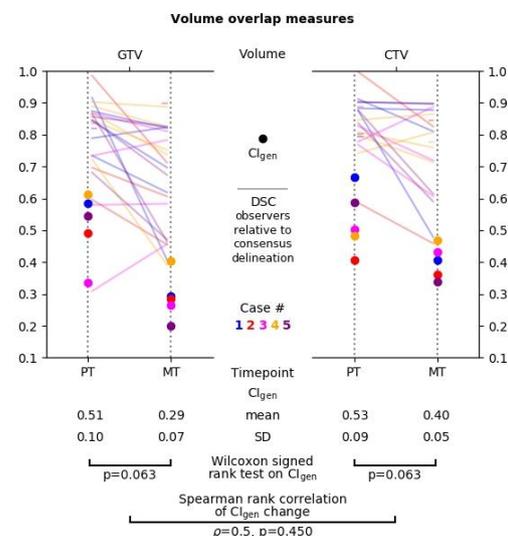

Five patients from routine clinical practice, who underwent repeat imaging, were selected such that a variety of features likely to prompt adaptation were included. Brief case reports and CT imaging data were sent to five observers, the latter supplemented with pre-therapeutic FDG-PET in four cases. Observers received PT and MT imaging data at least one week apart and were asked to delineate the GTV and CTV in their own treatment planning system and to comment on their delineation process, i.e. on how GTV to CTV expansion and adaptation were performed. Delineations were rasterised on a 1mm<sup>3</sup> grid and their compatibility assessed with the Generalised Conformity Index (Cl<sub>gen</sub>). Differences in IOV between PT and MT were probed with Wilcoxon signed-rank tests and the correlation between GTV and CTV IOV evolution with Spearman rank correlation. While it is respectively impossible and very difficult for these tests to show two-sided  $\alpha=0.05$  significance at  $n=5$ , more powerful parametric alternatives cannot credibly be employed. Delineations were processed with ITK and statistical analyses performed in R.

#### Results

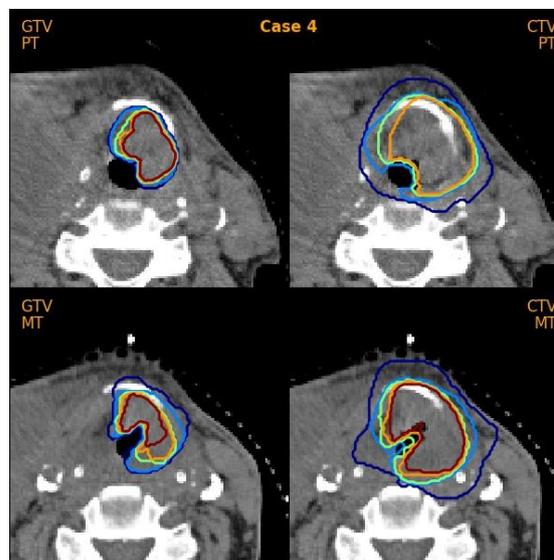

A total of 82/100 delineations were received and analysed. Figure 1 shows an overview of IOV in terms of volume overlap. All cases and volumes suffered a reduction of Cl<sub>gen</sub> when transitioning from PT to MT ( $p=0.063$  for both CTVs and GTVs). There was generally better agreement in CTV than GTV delineations at individual time points, and the correlation between GTV and CTV Cl<sub>gen</sub> changes was very weak ( $p=0.5$ ,  $p=0.45$ ). This comparative robustness of CTV delineations might stem from GTV to CTV expansion practices, which overwhelmingly employed sizeable isotropic margins (mean: 7.6 mm) and additional editing for anatomical boundaries at both time points. Figure 2 shows a case in which Cl<sub>gen</sub> for CTVs remains stable despite deteriorating IOV in the primary GTV. MT GTV delineations were often based on PT delineations after image registration (14/24 analysed observers and cases), the remainder contoured *de novo*. Post-transfer adaptation to changed anatomy was performed by two observers and inclusion of the PT GTV in the MT CTV by one. Shortcomings of this contouring challenge are a lack of MRI and contrast-enhanced CT at both time points.

#### Conclusion

IOV in target volume delineation increases during treatment, where a disparity in institutional adaptation practices adds to the static causes of IOV. Consensus guidelines are urgently needed and should recommend scope, frequency, and quality of MT imaging alongside adaptation strategies.

**Fig. 1:** Statistical overview of delineation overlap metrics. The Generalised Conformity Index (Cl<sub>gen</sub>) is shown for each case and time point for Gross Tumour Volume (GTV) and Clinical Target Volume (CTV) delineations. Its summary statistics are printed below, alongside the results of 1) hypothesis tests for a non-zero change in Cl<sub>gen</sub> when transitioning from pre- to mid-treatment time points (PT to MT), and 2) the correlation of those Cl<sub>gen</sub> changes between GTV and CTV delineations. The changes in Dice Similarity Coefficients (DSC) for each observer relative to a median consensus delineation (i.e. the collection of voxels delineated by at least half the observers) are depicted for comparison. Only a stub at either PT or MT is shown for observers who did not provide delineations for both.

**Fig. 2:** Illustration of inter-observer variability in target volume delineation for a case of cT3N2cM0 laryngeal carcinoma. Central axial slices are superimposed with contours representing the fraction of observers who included the contained voxels in their delineation (from the exterior inwards: dark blue: 1/5 observers, maroon: 5/5 observers). Despite a reduction of agreement in GTV delineation (left column), CTV variability remains relatively stable (right column).

**Abbreviations:** PT, pre-treatment; MT, mid-treatment.

**Note:** only 4 PT CTV delineations received for this case.

#### EP-1185 QOL for HPV+ SCC of the oropharynx treated with transoral laser microsurgery and postoperative IMRT

T. DeWees<sup>1</sup>, J. Rwigema<sup>2</sup>, L. McGee<sup>2</sup>, T. Nagel<sup>3</sup>, M. Golafshar<sup>4</sup>, S. Patel<sup>2</sup>

<sup>1</sup>Mayo Clinic Arizona, Biomedical Statistics and Informatics, Scottsdale, USA ; <sup>2</sup>Mayo Clinic Arizona, Radiation Oncology, Phoenix, USA ; <sup>3</sup>Mayo Clinic Arizona, Otorhinolaryngology ENT/Head and Neck Surgery, Phoenix, USA ; <sup>4</sup>Mayo Clinic Arizona, Health Sciences Research, Scottsdale, USA

#### Purpose or Objective

Upfront surgical management of oropharyngeal tumors with adjuvant radiation therapy is becoming a more common treatment paradigm. Low morbidity has been

reported in head and neck cancer patients treated with transoral laser microsurgery (TLM) rather than open procedures. We sought to characterize patient reported quality of life outcomes in patients treated with TLM and adjuvant radiotherapy.

#### Material and Methods

HPV positive oropharyngeal squamous cell carcinoma patients treated at a single institution from February 2013 through March 2015 were included in the study. The patients prospectively completed the University of Washington Head and Neck Quality of Life Surveys (UW-QOL) at baseline and every 3 months after therapy. The UW-QOL survey evaluated QOL in 12 domains specific to head and neck cancer and 3 domains of global health status, assigning scores on 0-100 scale.

Initial analysis was conducted utilizing repeated measures mixed models, with underlying unstructured covariance, utilizing all survey data to determine if significant differences existed in QOL over time for each of the 15 scored questions. Comparisons between paired time-points was conducted via T-tests utilizing Tukey's adjustment for multiple comparisons. Similarly, univariate mixed models were fit utilizing clinical and demographic variables in order to determine their association with QOL outcomes with statistical significance considered for  $p < 0.05$ . Kaplan-Meier methods estimated Locoregional control, distant control and overall survival. **Results**

Of the 26 patients participating, 25 of the patients completed at least two of the assigned surveys and are included in this analysis. Forty-four percent received concurrent chemotherapy. Median follow up was 44 months, with the respective 1-year and 2-year LRC, DC, and OS of 100%/100%, 100%/87%, and 96%/96%. Within 9 months after IMRT, 100% of patients QOL scores were not significantly worse than pre-treatment for all QOL questions. Saliva quantity and consistency was the only question in which QOL was significantly lower than baseline at any time-point, however, within 9 months patients had recovered to within a non-significant statistical and clinical difference. The average measures of Pain, Recreation, Mood, Anxiety, health-related QOL, and overall QOL were all significantly higher for all patients at 12 months than baseline, with Mood and Anxiety achieving significant improvement at 6 and 9 months, respectively. Mixed Modelling identified worse QOL associated with primary base of tongue treatment, bilateral neck surgery, advanced pathological T Stage, no PNI, higher dose, and a distant recurrence needing salvage treatment ( $p < 0.05$ ).

#### Conclusion

QOL for HPV positive oropharyngeal carcinoma after TLM and IMRT returns to pre-RT levels within 9 months of treatment, with most patients achieving a clinically significant increase in QOL within 12 months of treatment. This treatment approach appears to provide excellent disease control while preserving their quality of life.

#### Purpose or Objective

To investigate whether Volumetric Modulated Arc Therapy (VMAT) maintains its superiority on 3D-conformal-radiotherapy (3DCRT) in reducing dose to carotid arteries (CA) and carotid bulbs (CB) using a target sparing contouring approach in cT1 glottic cancer (GC).

#### Material and Methods

CTV of 10 cT1a0 GC patients were retrospectively contoured according to the new contouring recommendations proposed by Gregoire and colleagues. The CAs were separately outlined along their extracranial course. Since CB is the most critical structure involved in atherosclerosis, it was also outlined including two cm superior and inferior to carotid bifurcation according to Framingham Heart study. A 1 mm isotropic margin was applied to account for anatomical changes during cardiac cycle. 3DCRT and VMAT plans specifically optimized for carotid sparing were generated. The prescribed dose was 63 Gy in 28 fractions. In all plans at least 95% of the PTV was requested to receive  $\geq 95\%$  of the prescription dose and a spinal cord maximum dose of 25 Gy was allowed. Ipsilateral and contralateral CB and CA Dmax, Dmean, V35, V50 were determined. The two techniques were also compared for OAR doses and plan quality indices (V95, V107, D2, D98, Conformity index and Heterogeneity Index). T test for paired data with logarithmic transformation for continuous variables was used to compare dosimetric parameters. Mean and confidence interval of 95% were used to summarize continuous variables. A Two-sided  $\alpha$  error of 5% was used as significance threshold.

#### Results

Mean ipsilateral CB and CA Dmax significantly decreased from 51,8 Gy to 32,8 Gy ( $p < 0.0001$ ) and from 54 Gy to 44 Gy ( $p = 0,0005$ ) for 3DCRT and VMAT, respectively. VMAT significantly lowered ipsilateral CB Dmean ( $p = 0,0001$ ) and V35 ( $p = 0,0052$ ) and ipsilateral CA V35 ( $p = 0,0002$ ). Similarly, contralateral CB ( $p < 0,0001$ ) and CA Dmax ( $p < 0,0001$ ) were lower in VMAT than in 3DCRT. Moreover, contralateral CB ( $p = 0,0002$ ) and CA Dmean ( $p < 0,0001$ ) and contralateral CB ( $p = 0,02$ ) and CA V35 ( $p = 0,0052$ ) were higher with 3DCRT. VMAT significantly reduced the dose to pharyngeal constrictor muscles, thyroid gland and supraglottic larynx. Spinal cord Dmax was lower in 3DCRT plans (Table 1). No significant difference was found in terms of plan quality indices except for the better Conformity Index of VMAT plans (0,7 vs 0,6 of 3DCRT,  $p = 0,0197$ ). As regards hot-spots volumes, no sensitive structures out of target volumes such as contralateral arytoids were involved. For both VMAT and 3DCRT hot-spots fell inside the PTV. In particular, ipsilateral arytoid was involved in the 30% of 3DCRT and in 40% of VMAT plans, while ipsilateral supraglottic space in the 20% of 3DCRT and in 20% of VMAT plans.

Table 1: Dosimetric data for OAR in 3DCRT and VMAT.

OAR	3DCRT MEAN (CI 95%) (Gy)	VMAT MEAN (CI 95%) (Gy)	Mean difference (Gy)	P value
Spine (Dmax)	19,6 (18,9 to 20,2)	21,5 (20,9 to 22,1)	1,9	<0,0001
Spine PRV (Dmax)	19,2 (16,5 to 21,8)	18,8 (10,6 to 26,8)	0,4	0,92
Medium PCM (Dmean)	7,8 (5,4 to 11,2)	3,6 (2,1 to 6,0)	4,2	0,0006
Inferior PCM (Dmean)	51,9 (47,3 to 57,0)	42,4 (38,6 to 46,5)	9,6	0,0048
Supraglottic larynx (Dmean)	37,9 (33,0 to 43,5)	27,2 (22,1 to 33,5)	10,3	0,0012
Cricopharyngeal inlet (Dmean)	40,7 (33,4 to 49,6)	28,8 (23,8 to 34,8)	12,3	0,0026
Cervical oesophagus (Dmean)	2,1 (1,1 to 4,1)	1,4 (0,5 to 3,6)	0,7	0,6526
Thyroid gland (Dmean)	16,2 (11 to 23,9)	7,4 (4,3 to 12,8)	9,0	0,0003

OAR: organ at risk; 3DCRT: 3-Dimensional Conformal Radiotherapy; VMAT: Volumetric Modulated Arc Therapy; CI 95%: confidence interval of 95%; PRV: planned risk volume; PCM: pharyngo-constrictor muscle.

## Conclusion

Even with the new target delineation method, VMAT provides dosimetric advantages in carotids, bulbs and in the most of OARs sparing respect to 3DCRT in T1 GC.

## EP-1187 Different carotid contouring results in dosimetric variability and significant anatomical missing

## Purpose or Objective

Carotid Artery (CA) sparing approach is a field of increasing interest owing to long life expectancy of patients with early glottic cancer (EGC). A CA delineation consensus lacks with no internationally recognized dose constraints for this structure. Here we compare, in terms of anatomical and dosimetric variability, three of the most common CA delineation methods found in literature.

## Material and Methods

CA of 10 cT1a N0 EGC patients were outlined using 3 different approaches: 1) the whole CA from its origin up to the internal carotid entry into skull base (Contour 1); 2) the tract of CA from its origin up to at least 2.5 cm above the hyoid bone (Contour 2); 3) the tract of CA 1 cm superior and inferior to PTV (Contour 3). The carotid bulb (CB) was contoured 2 cm inferiorly and superiorly to carotid bifurcation according Framingham Heart definition due to its role in the radio-induced atherosclerosis. A 1 mm isotropic carotid and bulb margin was added to compensate the changes during cardiac cycle. Thirty VMAT carotid sparing plans were generated and CA Dmax, Dmean, V35 and V50 were compared across the different contouring approaches. T-test for paired data with logarithmic transformation was used to compare dosimetric parameters. A two-sided p-value < 0.05 was the significance threshold

## Results

In terms of carotid structures missing, Contour 3 did not include the entire bulb in 100% of contoured carotids while Contour 1 and 2 always included it entirely. A significant variability in ipsilateral and contralateral CA Dmean and ipsilateral CA V35 were found among the three contouring approaches with the lowest, intermediate and highest mean values found for Contour 1, Contour 2 and Contour 3, respectively (Table 1). No consistent variability was found for bilateral CA Dmax and V50 and for contralateral CA V35 across the three contouring approaches (Table 1).

Table 1: Dosimetric comparison of three different carotid artery delineation approaches in VMAT planning.

Dosimetric parameter	Contour 1 Mean (95% CI)	Contour 2 Mean (95% CI)	Contour 3 Mean (95% CI)	P value		
				Contour 1 vs 2	Contour 1 vs 3	Contour 2 vs 3
<b>Ipsilateral carotid</b>						
Dmax (Gy)	40,2(36,7 to 44,2)	39,6(35,8 to 43,7)	39,6(35,8 to 43,7)	1	1	1
Dmean (Gy)	8,5 (7,0 to 10,3)	10,5 (8,6 to 12,8)	20,9(18,2 to 23,9)	<0,0001	<0,0001	<0,0001
V35 Gy (%)	1,9 (0,1 to 3,6)	2,3 (0,1 to 4,5)	4,6 (0,1 to 9,2)	0,0545	0,0603	0,0568
V50 Gy (%)	0	0	0	NA	NA	NA
<b>Contralateral carotid</b>						
Dmax (Gy)	17,4(14,3 to 21,1)	17,4(14,3 to 21,1)	17,4(14,3 to 21,1)	0,5667	0,5449	0,3434
Dmean (Gy)	3,8 (3,1 to 4,6)	4,6 (3,7 to 5,7)	8,4 (6,4 to 10,9)	<0,0001	<0,0001	<0,0001
V35 Gy (%)	0	0	0	NA	NA	NA
V50 Gy (%)	0	0	0	NA	NA	NA

Contour 1: whole carotid from its origin to skull base entry; Contour 2: from carotid origin to at least 2.5 cm above hyoid bone; Contour 3: 1 cm superiorly and inferiorly to PTV; V35: volume percentage receiving  $\geq$  35 Gy; V50: volume percentage receiving  $\geq$  50 Gy; NA: not assessable.

## Conclusion

Here we document the need for a standardized CA delineation since a relevant dosimetric variability and a significant missing of important structures has been documented among the three most frequent used contouring approaches. Based on our Institutional preference, we suggest to delineate the whole bulb and whole CA from its origin up to the skull base entry to decrease interobserver variability among clinicians.

## EP-1188 Carbon ion radiotherapy for recurrent pleomorphic adenoma at CNAO: preliminary results.

<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ; <sup>2</sup>Osaka Heavy Ion Therapy Center, Radiation therapy Unit, Osaka, Japan ; <sup>3</sup>National Center of Oncological Hadrontherapy, Diagnostic Imaging Unit, Pavia, Italy ; <sup>4</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

## Purpose or Objective

To evaluate response and toxicity of carbon ion radiotherapy (CIRT) for recurrent pleomorphic adenoma patients (pts).

## Material and Methods

Inclusion criteria based on the CNAO phase II clinical protocol CNAOS10/2012/C were: (1) prior histological diagnosis of pleomorphic adenoma; (2) relapse after at least one previous surgical approach; (3) further surgery excluded (due to high risk of facial nerve damage/medical contraindications/refusal of the patient); (4) no previous radiotherapy. CIRT prescription dose was 65.6 Gy[RBE] in 16 fractions (4.1 Gy[RBE]/fraction). Local response and toxicity (tox) were respectively evaluated using RECIST and CTCAE v.4.0 criteria. MRI was performed after treatment every 3-4 months (mo.) in the first 2 years, every 6 mo. in the third year, then once a year.

## Results

Between November 2012 and May 2017, 24 pts were treated. Median age was 47 years (range 20-68). Median time from first diagnosis to CIRT was 17.4 years (range 1-33.5). Median number of previous surgeries was 3 (range 1-6). Median time from last surgery to CIRT was 16.8 mo. (range 9.8-274.4). Two and 22 pts were treated for unimodular and plurimodular recurrence, respectively. Mean GTV was 19.8 cc (range 1.1-91.1). Mean CTV was 83.5 cc (range 25.6-148.6). Median follow-up (FU) time was 23.3 mo.(range 7.8-64.4). Radiological response at first FU was partial response and stabilization in 2 and 22 pts, respectively. At last FU, all pts were alive with local control maintained. Only 1 patient treated for plurimodular tumor had out-field recurrence at 4.5 years after CIRT. Tox during/at the end of treatment was G0, G1, G2 for 3 (12.5%), 9 (37.5%), and 12 (50%) pts, respectively. Acute tox within 3 months was G0, G1, G2 for 10 (41.7%), 11 (45.8%), and 3 (12.5%) pts, respectively.

Maximum late tox was G0, G1, G2 for 3 (12.5%), 13 (54.2%), and 8 (33.3%) pts, respectively. No G3-G4 late tox was observed. Among pts with late tox, 11 (45.8%) had peripheral neuropathy (G1 and G2 in 8 (33.3%) and 3 (12.5%) pts, respectively). No patient experienced facial nerve damage as treatment-related tox.

#### Conclusion

In our experience, CIRT in recurrent pleomorphic adenoma pts has shown excellent local control and good toxicity profile. It might be a good alternative to invasive surgery especially when the latter is judged to be at high risk of facial nerve damage. However, a larger series of patients and a longer follow-up are needed to better investigate outcomes, especially in terms of late toxicity.

#### EP-1189 Adenoid Cystic Carcinoma Of The Head And Neck Treated With Carbon Ion Radiotherapy At CNAO

Facoetti<sup>1</sup>, M. Ciocca<sup>1</sup>, L. Preda<sup>4</sup>, F. Valvo<sup>1</sup>, R. Orecchia<sup>1,5</sup>

<sup>1</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ; <sup>2</sup>University of Turin, Department of Oncology- Radiation Oncology, Turin, Italy ; <sup>3</sup>Osaka Heavy Ion Therapy Center, Radiation therapy Unit, Osaka, Japan ; <sup>4</sup>National Center of Oncological Hadrontherapy, Diagnostic Imaging Unit, Pavia, Italy ; <sup>5</sup>European Institute of Oncology, Radiation therapy Unit, Milan, Italy

#### Purpose or Objective

To evaluate preliminary results of carbon ion radiotherapy (RT) in patients (pts) with adenoid cystic carcinoma (ACC) of the head and neck (H&N) region treated with curative intent

at the National Center for Oncological Hadrontherapy (CNAO) according to the phase II clinical study CNAO S9/2012/C.

#### Material and Methods

Between March 2013 and September 2016, 135 patients (M/F = 61/74) with ACC of the H&N were treated with active scanning carbon ion RT. Pts average age was 54 (range 19 -

82). Tumour site was minor salivary gland in 90 (67%) and major salivary gland in 45 (33%) pts. In 20 pts (15%) treatment was at disease recurrence, 115 (85%) pts were treated after first

diagnosis. Before carbon ion RT, 83 (62%) pts received surgery, of these 60 (45%) pts had positive margins (R1), 13 (10%) pts had no status of margins on histological report, and 9 (7%)

pts received debulking surgery (R2). No pts received previous RT. In all the cases prescribed total dose was of 68.8 Gy(RBE) in 16 fractions, 4 fractions/week. Toxicity was

evaluated according to the CTCAE v.4.0. Pts were followed up every three months after RT with clinical evaluation and MRI. For all patients C11 methionine PET-TC was used for target delineation.

#### Results

Median follow-up time was 23 months (range: 1 - 51 months). Local Control was reached in 101 out of 135 (75%) patients, with 12 and 24-months local control rates of 91% and

81% respectively. The Progression-Free Survival at 12 and 24 months was 81% and 67%, respectively. The Distant Metastasis Free Survival at 12 and 24 months was 86% and 81%,

respectively. Median overall survival (OS) time was 24 months and the rates of OS were 95% and 85% at 12 and 24 months respectively. At the end of treatment toxicity was G0 in 2%, G1 in

20%, G2 in 52% and G3 in 26% of the patients. At 3 months toxicity was G0 in 36%, G1 in 43%, G2 in 19% and G3 in 2% of the patients. Acute G3 was always mucositis, in the long FU the late

maximum toxicity was G3 for 20 (15%) pts and G4 for 2 (1%) pts. There were no G5 events. **Conclusion** CNAO preliminary data show encouraging outcome results and acceptable toxicities but longer follow-up is needed.

#### EP-1190 Preliminary evaluation of salivary cytokines in patients treated with IMRT for head and neck cancer

#### Purpose or Objective

The role of salivary inflammatory markers and their early variation in predicting increased risk radiation-induced acute toxicities in head and neck cancer (HNC) patients (pts) is under investigation within a prospective observational clinical trial. Preliminary evaluation is here reported.

#### Material and Methods

A series of HNC pts curatively treated with intensity modulated RT (prescribed dose  $\geq 66$  and  $\geq 54$  Gy for definitive and post-operative setting, respectively; 2-2.12 Gy/fraction; 5 fractions/week) with or without chemotherapy was considered.

Saliva samples for inflammatory marker levels evaluation were collected before RT (T0) and in the third week (T1), i.e. between the 10<sup>th</sup> and 15<sup>th</sup> RT fraction. The concentration (pg/ml) of IL-1B and IL-6 cytokines was measured using ELISA assays.

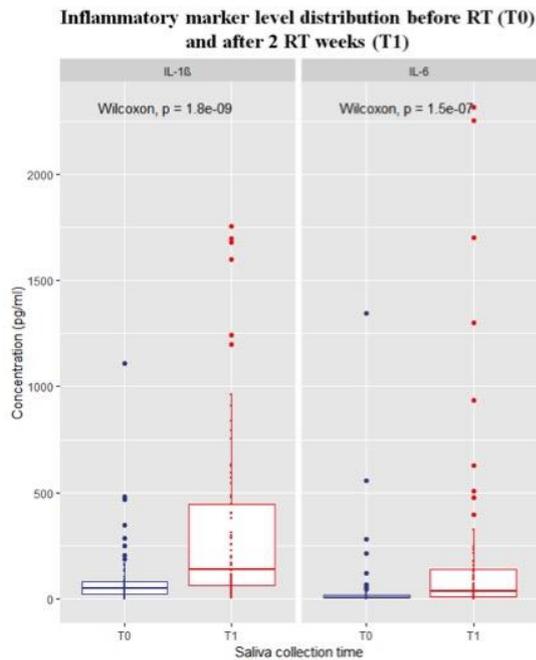

Acute toxicity profiles were assessed according to CTCAE v4.0 at baseline and weekly during RT. The following endpoints were considered: maximum oral mucositis (OM) grade (G) $\geq 3$ , mean OM G $\geq 1.5$  during RT, maximum dysphagia G3 and maximum dry mouth G $\geq 2$ . Early cytokines variation and its possible association with toxicity were evaluated with Wilcoxon signed-rank and Mann-Whitney tests, respectively.

#### Results

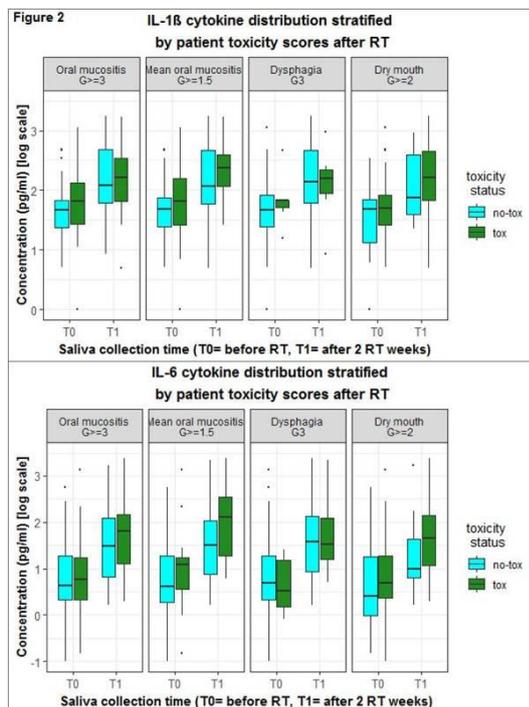

81 pts were available for this analysis; only 73/81 had saliva samples collected for both time points. Collection of saliva at T1 was difficult in many cases, due to an already present salivary flow alteration in the third week of RT.

OM G $\geq 3$  was reported in 27 pts (37%), mean OM G $\geq 1.5$  in 14 pts (19%), dysphagia G3 in 7 (10%) and dry mouth G $\geq 2$  in 60 pts (82%).

Salivary levels of both cytokines significantly varied between T0 and T1 (p<0.001). Figure 1 reports marker level distributions and early changes after 2 weeks of RT. The variation in IL-1B and IL-6 concentration was: <0 pg/ml (i.e. decrease in concentration) for 12 and 13 pts, in the range 0-300 pg/ml (i.e. mild to moderate increase) for 42 and 52 pts, higher than 300 pg/ml (i.e. large increase) for 19 and 8 pts, respectively.

No significant association was found between inflammatory marker levels and the selected toxicity endpoints ( $p > 0.05$  in all cases). Figure 2 shows the distribution of cytokine levels at both time points stratified by pts who showed (label “tox”) or did not show (label “no-tox”) the selected toxicity endpoints.

## Conclusion

RT for HNC induced a significant increase in salivary cytokine levels of IL-1 $\beta$  and IL-6 already after 20 Gy. Unlike some recent published results though, this preliminary analysis did not detect any association between the inflammatory marker concentration changes and the most impairing acute toxicities commonly arising throughout the treatment. Of note, collection of saliva during treatment was difficult in many cases and density

of saliva collected at T1 was usually high, with this probably impacting the absolute concentration of inflammatory markers. This points out the need to develop protocols for corrections of concentrations for saliva density.

## EP-1191 Effect on local control of addition of chemotherapy to radiotherapy for T2 cancer of the hypopharynx

S. Gaito<sup>1</sup>, S. Mehta<sup>1</sup>, A. McWilliam<sup>2</sup>, R. Almond<sup>3</sup>, L.W. Lee<sup>4</sup>, K. Garcez<sup>4</sup>, D. Thomson<sup>4</sup>, J. Price<sup>1</sup>, K. Mais<sup>4</sup>, A. McPartlin<sup>4</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom ; <sup>2</sup>University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom ; <sup>3</sup>The Christie NHS Foundation Trust, Clinical Outcomes Unit, Manchester, United Kingdom ; <sup>4</sup>The Christie NHS Foundation Trust, Head and Neck Clinical Oncology, Manchester, United Kingdom

## Purpose or Objective

A benefit from chemo-radiotherapy (CRT) for bulky stage II hypopharyngeal squamous cell cancer (HPSCC) has proponents but limited supporting evidence. We investigate the effect on local control (LC) of the addition of chemotherapy (CT) to radiotherapy (RT) for T2 HPSCC.

## Material and Methods

A retrospective analysis was performed of patients with T2 (node negative or positive) HPSCC receiving definitive RT or CRT at a single academic cancer centre. Patient and disease characteristics were obtained from electronic records. Primary gross tumour volumes were calculated from CT planning scans or diagnostic imaging. LC analysis was censored at time of first failure or death. The logrank test was used for correlation between tumour volume and LC. Cox proportional hazard modelling of LC by treatment received was performed to account for competing risks.

## Results

62 patients were identified, treated from April 2007 to July 2016. Patient demographics, treatment received and site of first failure are shown in table 1. Median follow-up in patients not experiencing failure was 25 months (range 1-107 months) and 20 months (3-85 months), and median time to first failure 12.2 months (2 - 58 months) and 6.4 months (3-77 months), after RT or CRT respectively. Initial local failure occurred in 10% (3) and 39% (12) of those patients receiving CRT or RT ( $p = 0.047$ , HR = 0.272, 95% C.I. 0.075-0.982). After RT, a significant negative correlation was identified between primary tumour volume and local control (spearman rho -0.59,  $p = 0.008$ ). Patients with primary tumour volumes  $> 8 \text{ cm}^3$  vs  $\leq 8 \text{ cm}^3$  had significantly worse local control rates ( $p = 0.01$ ) after RT.

Site of first failure (n (%))	Local	12 (39)	3 (10)
	Regional	0 (0)	8 (26)
	Distant	4 (13)	5 (16)

### Conclusion

In this cohort the addition of CT to RT is associated with improved LC for T2 HPSCC. Patients with larger tumours were more likely to experience local failure after RT, and for this group treatment intensification with CTRT may be of benefit, even in node negative patients. Competing risk analysis has been used to account for the risk of early distant failure or death and censure in node positive patients receiving CTRT. Moreover, local failure is known to remain the predominant site of first recurrence, and risk of local failure is known to be increased, in node positive patients after CTRT. Tumour biology or first site of failure variation between the two groups is therefore unlikely to explain the significant difference in LC identified.

### EP-1192 Hair loss during intensity modulated radiotherapy for nasopharyngeal carcinoma

N. Fourati<sup>1</sup>, Z. Fessi<sup>1</sup>, W. Mnejja<sup>1</sup>, L. Farhat<sup>1</sup>, T. Sahnoun<sup>1</sup>, W. Siala<sup>1</sup>, J. Daoud<sup>1</sup>

<sup>1</sup>Hopital Habib Bourguiba, Radiation Oncology, Sfax, Tunisia

### Purpose or Objective

Hair loss is a common complication of brain tumor radiotherapy but has not been reported following conventional radiotherapy of nasopharyngeal carcinomas (NPC). The use of posterior fields during intensity modulated radiotherapy (IMRT) of NPCs made hair loss common. The aim of this study was to evaluate all patients treated with IMRT for NPC to determine correlation between scalp doses and hair regrowth.

### Material and Methods

Twenty-one patients treated with IMRT for NPC were prospectively followed during the radiotherapy period and up to 6 months after the end of the irradiation. All patients had 7 fields irradiation including a posterior field. A simultaneous boost technique was used to deliver 69.96 Gy in 33 Fractions to the nasopharynx and involved lymph nodes. The scalp was not considered as an organ at risk during radiotherapy planning. To evaluate the doses received, we have delineated the tissue between the skin and the skull taking as an upper limit 6 mm above the upper edges of the posterior field. We then reported the maximum dose (Dmax), the minimum dose (Dmin), the

mean dose (Dmean), the percentage of volume receiving more than 10 Gy (V10Gy), the percentage of volume receiving more than 20 Gy (V20Gy) and the dose received by 50% of the scalp (D50%).

After the end of treatment, patients were followed in consultation at 1 month, 3 months and 6 months to determine the hair regrowth. Mann-Whitney test was used to compare doses between patients with total and partial regrowth at 3 months.

### Results

The median Dmax, Dmin and Dmean were 42.77 (31.86-63.98), 1.32 (0.9-1.96) and 16.11 (12.42-20.66) respectively. The median D50%, V10Gy and V20Gy were 16.91 Gy (9.74-19.85), 69.07% (49.02-80.19) and 35.36% (21.25-49.5) respectively. All patients had hair loss during the treatment phase. After 1 month of the end of treatment, all patients had partial hair regrowth. At 3 months, 7 patients (33.3%) had total hair regrowth. Median Dmean, V10Gy and V20Gy for patients with total regrowth were 16.11Gy (12.48-17.67), 68.81% (49.02-74.3) and 35.36 (21.25-45.79) respectively versus 16 Gy (14.09-20.31), 72.03% (58.32-79) and 34.86% (25.19-49.5) respectively for patients with partial regrowth (p not significant in all cases). At six months, only one patients did not have complete hair regrowth (Dmean: 19.53, V10Gy : 78% and V20Gy: 48.8%).

### Conclusion

During IMRT for NPC a Mean dose of 16 Gy is responsible for acute hair loss in 100% of cases. However, this loss is only transient with partial regrowth from 1 month of the end of treatment and a total regrowth at 6 months in almost all cases. The consideration of scalp as an organ at risk during treatment planning would be necessary. Since the dose limits to be respected are not reported in the literature for the irradiation of the NPC, we propose, through the results of our study, a Dmean < 16 Gy, V10Gy < 68% and V20Gy < 35%.

### EP-1193 Analysis of competing and tumor deaths and predictors factors in advanced head and neck cancer.

I. Zapata Martínez<sup>1</sup>, I. Navarro Doménech<sup>1</sup>, M. Álvarez Pérez<sup>2</sup>, M.J. García Anaya<sup>1</sup>, B.I. Pajares Hachero<sup>3</sup>, M.D. Toledo Serrano<sup>1</sup>, I. Jerez Sainz<sup>1</sup>, R. Ordoñez Marmolejo<sup>1</sup>, A. Otero Romero<sup>1</sup>, R. Correa Generoso<sup>1</sup>, I. García Ríos<sup>1</sup>, A. Román Jobacho<sup>1</sup>, J.A. Medina Carmona<sup>1</sup>, J. Gómez-Millán Barrachina<sup>1</sup>

<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology, Málaga, Spain ; <sup>2</sup>University of Málaga, Pathological Anatomy, Málaga, Spain ; <sup>3</sup>Hospital Virgen de la Victoria, Medical Oncology, Málaga, Spain

### Purpose or Objective

Non-cancer deaths or competing mortality (CM) in locoregionally advanced head and neck cancer (LAHNC) contribute importantly to the poor outcomes of these patients. The objective was to analyze the incidence of CM and tumor mortality (TM) in LAHNC patients and to determine possible prognostic factors.

### Material and Methods

Cohort study of 292 patients with LAHNC treated in our hospital between 2005- 2015 with radiotherapy (RT) in combination with systemic therapy. Nonparametric test was used to analyze the incidence of each death. A Fine and Gray regression model was used to investigate factors associated with CM and TM.

### Results

Median follow-up was 60 months. Performance status, as measured by the Eastern Cooperative Oncology Group (ECOG), which was 0 in 57% (n= 167) of patients. Comorbidity was classified by head and neck comorbidity index (HN-CCI). Moderate or severe grade comorbidity was seen in 18% (n= 53) of cases. Most of the patients (65.5%, n=191) were treated with concurrent chemo-radiotherapy (CRT) treatment and 3D conformal RT technique was used in 74.5% (n=217).

Regarding to toxicity, 55% (n= 160) of the patients presented acute pharyngo-esophageal toxicity grade 3 to 5 (CTCAE v4.0). Chronic toxicity greater or equal to grade 3 (RTOG escale) was presented in 15.5% of patients.

The 5-year cumulative incidence of TM was 39.7%: 36.4% corresponding to primary tumor-death and 3.3% to second tumor-death. The predictors factors of TM were: poor performance status (ECOG 1-2 vs 0; HR 1.52), advanced stage (IVA-B versus III; HR 1.8) and non-CRT treatment versus concurrent CRT regimens (HR 1.76).

The 5-year cumulative incidence of CM was 11.8%. The incidence to CM secondary to acute and chronic toxicity were 5.5% and 1.5%, respectively. The cumulative incidence of death related to comorbidity was 4.4% (Figure 1).

In the multivariate analysis the predictors factors of CM were increased age (HR 1.05) and comorbidity (HR 3.03). Patients with moderate to severe comorbidity presented a CM risk three times higher than those patients with mild or without comorbidity (Table 1). Acute mucositis grade 3 to 5 was associated with CM in the bivariate analysis but not in the multivariate analysis.

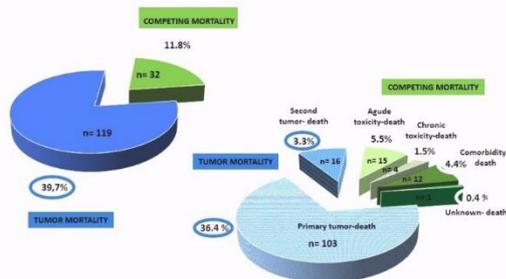

Figure 1: 5-year cumulative incidences of causes of death.

Characteristic	TUMOR DEATH			COMPETING DEATH		
	Hazart Ratio	95% CI	p	Hazart Ratio	95% CI	p
Age	0.99	0.97-1.01	0.23	1.05	1.07-1.09	0.023
HN-CCI (0-1 vs 2-6)	0.8	0.41-1.55	0.5	3.03	1.13-8.08	0.03
ECOG (0 vs 1-2)	1.52	1.03-2.25	0.03	0.97	0.44-2.13	0.94
Stage (III vs IV)	1.8	1.16-2.72	0.008	0.63	0.29-1.39	0.25
Treatment (RCT vs non-RCT)	1.76	1.17-2.6	0.007	0.68	0.29-1.55	0.36

Table 1: Multivariate analyses of predictors factors of competing and tumor mortality.

### Conclusion

This study demonstrates an important incidence of competitive deaths in patients with LAHNC treated with combined treatments. Among the factors that predict these deaths, age and, especially, moderate-severe comorbidity have been identified. Tumor deaths were associated with poor performance status, stage IV, and concurrent RT plus anti-EGFR. All these factors must be considered especially in the choice of the combined treatment of patients with LAHNC.

### EP-1194 Acute toxicity in nasopharyngeal cancer patients treated with IMRT followed by proton therapy boost

<sup>1</sup>European Institute of Oncology, Division of Radiation Oncology, Milan, Italy ; <sup>2</sup>National Center of Oncological Hadrontherapy, Radiotherapy Unit, Pavia, Italy ;

<sup>3</sup>European Institute of Oncology, Division of Epidemiology and Biostatistics Unit, Milan, Italy ; <sup>4</sup>University of Turin, Department of Oncology- Radiation Oncology, Turin, Italy ; <sup>5</sup>University Hospital- Novara, Division of Radiation Oncology, Novara, Italy ; <sup>6</sup>European Institute of Oncology, Division of Oncology, Milan, Italy ; <sup>7</sup>ICS Maugeri- I.R.C.C.S, Unit of Radiation Oncology, Pavia, Italy ; <sup>8</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

### Purpose or Objective

To compare radiation-induced acute toxicity in patients (pts) affected by locally advanced nasopharyngeal cancer (NPC) treated with sequential intensity modulated radiotherapy (IMRT) and proton therapy boost (mixed beam-MB approach) with an historic cohort of pts treated with a full course of only IMRT.

### Material and Methods

From June 2012 to November 2017, 27 consecutive pts with locally advanced NPC (cT3-4, any N, M0) were treated with MB approach. It consisted in a first phase of treatment performed with IMRT up to 54-60 Gy followed by a second phase performed by proton therapy boost (with pencil beam scanning) up to 70-74 Gy RBE (Relative Biological Effectiveness) prescribed to the macroscopic disease according to the pre-treatment radiologic images. This cohort were compared to an historic cohort of 17 consecutive pts treated with only IMRT only. Pts treated with IMRT only received a total dose of 69.96 Gy. A standard fractionation schedule (1.8-2.12 Gy/fraction, 1fraction/day, 5 fractions/week) was used in both cohorts. Concurrent (with or without induction) platinum-based chemotherapy was administered in all pts. The acute-toxicity profile was considered as the worst event occurred during the entire course of treatment according to Common Terminology Criteria Adverse Events V4.03 scale.

### Results

The 2 cohorts of pts were comparable with no significant differences regarding clinical parameters. The prescribed total dose was significantly higher (p=0.02) in pts treated with MB compared to those treated with only IMRT only. Acute grade 3 mucositis and grade 2 xerostomia were found in 11% and 76% (p=0.0002) and 7% and 35% (p=0.02) of pts treated with MB and IMRT, respectively. No other significant differences were found among the analyzed parameters. For MB cohort median follow-up was 25 months. All but one pts achieved complete tumor response and no patients developed local and/or regional recurrences. At last follow up, 22 pts were still alive with no evidence of disease. For IMRT only cohort median follow-up was 51 months. One patient died one week after the end of radiotherapy for treatment-related toxicity. One patient did not achieve a complete response to treatment on the primary tumor. He progressed on both primary tumor and neck lymph node and died 19 months from the end of treatment. Three patients experienced tumor local progression after 19, 51 and 82 months, respectively; 2 pts experienced also lymph node recurrences and 1 patient also lymph node metastasis

### Conclusion

Our results suggest that sequential MB approach for locally advanced NPC pts is safe with an excellent acute toxicity profile. Preliminary results on clinical outcome are encouraging but need to be confirmed in larger cohort of pts with a longer follow-up

### EP-1195 Functional assessment of late toxicity and quality of life after IMRT for sinonasal carcinoma

M.B. Sharma<sup>1</sup>, K. Jensen<sup>2</sup>, S.F. Urbak<sup>3</sup>, M. Funding<sup>3</sup>, A. Amidi<sup>4</sup>, C. Grau<sup>5</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus, Denmark ; <sup>3</sup>Aarhus University Hospital, Department of Ophthalmology,

Aarhus, Denmark ; <sup>4</sup>Aarhus University Hospital, Unit for Psychooncology and Health Psychology- Department of Psychology and Behavioural Sciences, Aarhus, Denmark ; <sup>5</sup>Aarhus University Hospital, Department of Oncology- Danish Center for Particle Therapy, Aarhus, Denmark

#### Purpose or Objective

Proton therapy (PT) may be beneficial in the treatment of sinonasal carcinomas (SNC) as normal tissue may be spared and radiation-induced sequelae, thus, reduced. Evaluation of late toxicity is important for patient selection and evaluation of PT. Therefore, we aimed to objectively assess late toxicity and quality of life (QoL) in patients treated with intensity modulated radiotherapy (IMRT) for SNC.

#### Material and Methods

All patients who were alive, without recurrence, and who had received IMRT for SNC between January 2008 - January 2017 were eligible for this cross sectional study. Out of 26 eligible patients, 18 consented to participate. All participants had been treated with primary or postoperative IMRT with or without concomitant chemotherapy. Late toxicities were evaluated with a battery of standardized neurocognitive tests assessing different cognitive domains, comprehensive objective ophthalmological examination, blood samples and synacthen test evaluating pituitary function, and olfactory assessment with the Brief Smell Identification Test (BSIT). QoL was evaluated with EORTC QLQ-C30, EORTC QLQ-BN20, Sinonasal Outcome Test-22 (SNOT-22) and Hospital Anxiety and Depression Scale (HADS). In addition, diffusion-weighted magnetic resonance imaging of the brain was performed. These results are not included here.

#### Results

Thirteen males and five females were enrolled; median age was 70.5 years (range 47-83). Participants were treated with a prescribed dose of 60-68 Gray to T-sites in the nasal cavity (n=11) or the maxillary sinus (n=7). Compared with normative data, patients evidenced poorer neurocognitive functioning in several cognitive domains including processing speed ( $p<0.05$ ), verbal learning and memory ( $p<0.01$ ), attention and working memory ( $p<0.05$ ), and verbal fluency ( $p<0.01$ ). Assessment of vision revealed a significant correlation between max radiation dose to the chiasm and grade 3 visual acuity impairment ( $p=0.046$ ) (CTCAE ver. 4.0). The function of the pituitary gland did not present any significant dose response correlations; however, there was an indication of a relationship between higher doses and more affected hormone levels in all axes. Olfactory functioning was impaired (BSIT  $\leq 8$  points) in 15/18 patients. In the global QoL analyses, the most affected domains were social-, emotional-, and physical functions, whereas drowsiness and fatigue were the highest scoring symptoms. No abnormal depression scores were found, but 15/18 participants reported increased anxiety. Anxiety was related to a poorer outcome in the global QoL score ( $p=0.029$ ). SNOT-22 evaluated the impact of sinonasal symptoms on the QoL. The areas that affected the QoL most were lack of smell or taste, thick nasal discharge, need to blow the nose, and blocked nose.

#### Conclusion

The results of the present study indicate considerable toxicity subsequent to IMRT with a substantial influence on patient QoL. Due to these initial findings, the study group intent to perform a larger nationwide study.

#### EP-1196 Treatment of elderly head and neck cancer patients: Update on comorbidity impacts and complications

H. HA<sup>1</sup>, S.E. Combs<sup>1</sup>, S.U. Pigorsch<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- TUM Munich, Dept. of RadioOncology and Radiation Therapy, Munich, Germany

#### Purpose or Objective

The management of elderly patients with head and neck cancer (HNC) still remains a challenge with no clear guidelines. Selection criteria for treatment decision are yet elaborative and based on specific factors impacting the patient's performance status. The aim of this retrospective study is to derive recommendations for daily practice and to develop the optimized individual treatment concept for elderly patients  $\geq 70$  years.

#### Material and Methods

146 patients with HNC treated by any kind of radiotherapy (RT) aged  $\geq 70$  years at diagnosis (median age 77.9 years, SD +6.37) at the Dept. of RadioOncology and Radiotherapy at the Technical University Munich between February 2009 and December 2016 were analyzed. The data collection is based on patient's medical records, tumor registry and the department's internal database. Kaplan-Meier Analysis, log rank test and univariate analysis were utilized to compare the outcome survival (OS) stratified by age, treatment, treatment intention, TNM staging and comorbidity impacts via Age-adjusted Charlson Comorbidity Index (ACCI) differentiated in groups: Low (3-5): n = 89 (61.0%); medium (6-8) n = 41 (28.1%); high (9-11) n = 16 (11.0%).

#### Results

Patients with all radiotherapy approaches (definitive, adjuvant or palliative) were included in this analysis. The median OS of all patients was 41.7 mo. (95%CI: 34.2-49.2 mo.). The single dose of RT varied between 1.7-2.7 Gy and the total doses between 4-70.4 Gy depending on the treatment concept. There are significant differences of OS in all categories: Age category (70-79 yrs.: 50.0 months (95%CI: 40.7-59.4mo) vs. 80-89 yrs.: 25.0 months (95%CI: 16.6-33.3mo) vs.  $\geq 90$  yrs.: 13.0 months (95%CI: 1.2-24.8mo) and ACCI Groups (Low ACCI: 50.1 mo. (95%CI: 40.6 - 59.7 mo.) with a mortality of 34 (37.4%) pts. vs. Medium ACCI: 20.9 mo. (95%CI: 10.0 -29.8 mo.) with a mortality of 25 (61.0%) pts. vs. High ACCI: 24.8 mo. (95%CI: 9.8 - 39.7 mo.) with a mortality of 10 (62.5%) pts.), and treatment (RT alone med. OS 31.9 mo. (95%CI: 24.7-39.0 mo.) vs. CRT med. OS 73.9 mo. (95%CI: 60.4-87.4 mo.). Most benefit for younger patients with the best survival prognosis after CRT and a lower ACCI. Therapy-induced complications were detected such as radiomucositis n = 72 (49.3%), radiodermatitis n = 60 (41.1%), dysphagia n = 50 (34.2%), nausea n = 20 (13.7%), PEG complication n=18 (12.3%), additional chemotherapy induced anemia n = 10 (6.8%), mouth dryness n = 8 (5.5%). Required supportive placements included PEG tube n = 52 (35.6%), tracheostomy n = 32 (21.9%), port catheterizations n = 24 (16.4%).

#### Conclusion

Analyzing ACCI groups within the CRT collective was to assess a possible influence on OS. The evaluation is skewed due to a small number of patients with a high ACCI Score who underwent CRT. The impact of therapy-induced complications on the outcome survival and therapeutical process needs to be put into consideration. The assessment of required supportive placements can be a useful predictor to measure the severity of adverse events.

#### EP-1197 Pattern, timing, and detection of recurrence in HPV positive oropharyngeal cancer

M. Echevarria<sup>1</sup>, L. Harrison<sup>1</sup>, A. Trotti<sup>1</sup>, J. Caudell<sup>1</sup>

<sup>1</sup>H. Lee Moffitt Cancer Center and Research Institute, Radiation Oncology, Tampa, USA

#### Purpose or Objective

HPV positive oropharyngeal cancer has a new staging system, reflecting their higher cure rates. Given high cure rates, the most efficient surveillance scheme and optimal post treatment monitoring tools for this patient population have not been established. We therefore sought to evaluate the pattern, timing, and detection of

recurrence in HPV positive oropharyngeal cancer to identify optimal post-treatment diagnostic tools.

#### Material and Methods

After institutional review board approval, records of patients with non-metastatic HPV-associated oropharyngeal cancer were retrospectively reviewed. We identified 406 patients with biopsy-proven, HPV positive oropharyngeal cancer treated with definitive radiotherapy. Patients were followed at intervals of 3 months and all patients underwent imaging 2-3 months post treatment in the form of PET/CT or neck CT. Locoregional control (LRC) and freedom from distant metastasis (FFDM) were estimated according to Kaplan-Meier method and comparisons were made by log rank test.

#### Results

The median follow up for all patients was 40 months. The 3 year LRC for the entire cohort was 91.3%. Patients with AJCC 8<sup>th</sup> edition stage I, stage II, and stage III had a LRC of 94.9%, 85.7%, and 82.3% respectively. There were a total of 30 locoregional recurrences, 28 (93.3%) of which presented with either symptoms or persistent disease on 2-3 month post treatment imaging. Of these 28 patients, 13 patients were found to have recurrent disease on the initial 2-3 month post treatment imaging and 15 patients presented with symptoms that led to the identification of recurrent disease. 3-year FFDM for the entire cohort was 88.4% and when stratified by stage patients with stage I, II, and III had a FFDM of 91.6%, 87.6%, and 74.1%, respectively. There were a total of 31 distant recurrences, 25 (80.6%) of which were identified due to symptoms or on 2-3 month post treatment imaging. Of these 25 patients, 15 patients were found to have recurrent disease on the initial 2-3 month post treatment imaging and 10 patients presented with symptoms that led to the identification of recurrent disease.

#### Conclusion

Our results showed that identification of the majority of locoregional and distant recurrences was either symptom driven or identified in the initial post treatment imaging performed 2-3 months after completion of radiation. Based on these results it is reasonable to follow patients clinically with a history and physical examination with direct visualization and to forgo further imaging after the initial post treatment imaging shows a complete response.

#### EP-1198 Knowing the oropharyngeal cancer associated with the human papillomavirus

L. Gutierrez Bayard<sup>1</sup>, M.D.C. Salas Buzón<sup>1</sup>, S. Garduño Sánchez<sup>1</sup>, M.J. Macías Lozano<sup>1</sup>, R. Rodríguez Sánchez<sup>1</sup>, S. Sayago Gil<sup>1</sup>, V. Díaz Díaz<sup>1</sup>, E. Gonzalez Calvo<sup>1</sup>, I. Villanego Beltrán<sup>1</sup>, A. Ruiz Herrero<sup>1</sup>, M. Lorente Sánchez<sup>1</sup>, J. Jaén Olasolo<sup>1</sup>

<sup>1</sup>Hospital Universitario Puerta del Mar, Radiation Oncology, Cadiz, Spain

#### Purpose or Objective

For resected HPV-positive oropharynx squamous cell carcinoma (HPV+ OPSCC) high node number is a critical determinant of survival, based on the 8th edition American Joint Committee on Cancer staging system. In our study, we analyzed the relationship between the number of affected lymph nodes (LNs), neck level and the pattern of failure (local, regional, and distant recurrences).

#### Material and Methods

We retrospectively studied 28 HPV+ OPSCC patients treated with neck dissection (ND) and either resection or radiotherapy of the primary tumor between 2014 and 2017. External beam radiation (+/- chemotherapy) was given based on the pathologic findings.

#### Results

Metastatic pathologic LNs were the following : 0% (0/5) in level I, 78.5% (22/28) in level II, 25% (7/28) in level III,

9.1% (2/22) in level IV, and 9% (1/11) in level V. The level V LN was clinically evident preoperatively. 24.2% elective neck dissection contained occult LNs, all of which were in level II and without extranodal extension. 18 (64.28%) patients underwent adjuvant radiation; 7 (25%) patients underwent adjuvant chemoradiation. With a mean follow-up of 25 months on multivariate analysis, >5 involved lymph nodes was significantly associated with worse progression free survival (PFS) (P=0.001). Rates of 3-year locoregional recurrence (LRR) in patients with ≤5 vs > 5 were 8% and 23% (P=0.1). Rates of 3-year distant metastases (DM) were 14% and 52% between ≤5 and >5 (P<0.001).

#### Conclusion

For p16+OPSCC, therapeutic NDs should include any levels bearing suspicious LNs and levels II, III, and IV, while elective NDs should be encompass at least levels II and III, followed by indicated adjuvant treatment, are associated with a low nodal recurrence rate. Patients with more than 5 involved lymph nodes appear to have worsened rates of disease recurrence. While these patients appear to be at high risk of both LRR and DM, the predominant mechanism of failure is distant (over 50%). More ambitious studies are necessary that allow to enlarge our knowledge in this entity.

#### EP-1199 Metastatic lymph node features with and without extracapsular extension in head and neck Squamous Cell Carcinoma

J. Zheng<sup>1</sup>, A. Flaman<sup>2</sup>, D. Yegendorf<sup>3</sup>, B. Purgina<sup>2</sup>, S. Chakraborty<sup>4</sup>, M. Gaudet<sup>1</sup>, H. Alain<sup>1</sup>

<sup>1</sup>The Ottawa Hospital Regional Cancer Centre, Radiation Oncology, Ottawa, Canada ; <sup>2</sup>The Ottawa General Hospital, Anatomical Pathology, Ottawa, Canada ; <sup>3</sup>University of Ottawa, Science, Ottawa, Canada ; <sup>4</sup>The Ottawa General Hospital, Radiology, Ottawa, Canada

#### Purpose or Objective

In Head and Neck Squamous Cell Carcinoma (HNSCC) patients with metastatic involved cervical lymph nodes, extra-capsular extension (ECE) carries with it increased risks of local recurrence and distant metastases. ECE is an indication for chemo-radiation after neck dissection which adds significant toxicity. This can potentially be avoided if patients could be risk stratified for ECE prior to surgery. We aim to analyze clinical, pathological and pre-operative radiological features of these patients to better risk stratify for presence of ECE.

#### Material and Methods

HNSCC patients aged 18 years and older diagnosed between October 2010 and May 2017 at a single institution. Patients had pathological positive metastatic lymph nodes and undergone neck dissection without neo-adjuvant treatment. The patients' clinical information, pathological reports and pre-operative CT scans were obtained from the Ottawa Hospital electronic medical record and clinical imaging software. In cases of incomplete pathology data, slides were re-examined by a pathologist. Suspicious lymph nodes from each CT scan were matched to metastatic lymph nodes from dissection specimens based on corresponding level, size and morphological features. Statistical analyses were done through Chi-squared testing.

#### Results

Clinical and pathological data of 142 patients were analyzed in this study. ECE was present in 45 patients (32%) and absent in 90 (63%) while unknown for 7 (5%) patients. An association was found between the number of positive lymph nodes and the presence of ECE. For patients with 1-2 metastatic lymph nodes and 3 or more metastatic lymph nodes, the rate of ECE was 18% and 60% respectively (p<0.001). p16 status was only reported for 63 patients but was also associated with ECE. It was present in 19% of p16 positive and 46% of p16 negative

patients ( $p=0.03$ ). There were no significant associations between ECE and gender, age at diagnosis and pathological tumour grade.

Pre-operative CT scans of 80 patients were examined and 136 metastatic lymph nodes were matched to pathological data. Of this data set, 30 (22%) lymph nodes were positive for ECE. There was a non-statistically significant trend towards more incidence of ECE seen in matted nodes against discrete nodes (27% vs. 15%,  $p=0.14$ ) and those with necrosis (27% vs. 14%,  $p=0.11$ ). No association was found between ECE and size or eccentricity of LN as well as smoothness or distinctness of LN borders. Radiological features such as calcified and cystic lymph nodes were too rare to have statistical significance.

#### Conclusion

We were able to demonstrate a statistically significant association between presence of ECE and number of metastatic lymph nodes as well as p16 status. Analysis of radiological features did not reveal any associations with ECE. Further analysis will be required to see if a combination of clinical and radiological features is best at predicting presence of ECE.

#### EP-1200 Is skin dose distribution a predictive factor for the development of severe radiation dermatitis?

P. Bonomo<sup>1</sup>, C. Talamonti<sup>2</sup>, L. Marrazzo<sup>2</sup>, I. Desideri<sup>1</sup>, D. Pezzulla<sup>1</sup>, L. Dominici<sup>1</sup>, A. Rampini<sup>3</sup>, S. Bertocci<sup>3</sup>, R. De Majo<sup>3</sup>, C. Gasperi<sup>4</sup>, A.S. Curion<sup>4</sup>, L. Lastrucci<sup>3</sup>, S. Pallotta<sup>2</sup>, L. Livi<sup>1</sup>, S. Caini<sup>5</sup>

<sup>1</sup>Azienda Ospedaliero-Universitaria Careggi, Radiation Oncology, Florence, Italy; <sup>2</sup>Azienda Ospedaliero-Universitaria Careggi, Medical Physics, Florence, Italy; <sup>3</sup>Ospedale San Donato, Radiation Oncology, Arezzo, Italy; <sup>4</sup>Ospedale San Donato, Medical Physics, Arezzo, Italy; <sup>5</sup>Cancer Research and Prevention Institute ISPO, Cancer Risk Factors and Lifestyle Epidemiology Unit, Florence, Italy

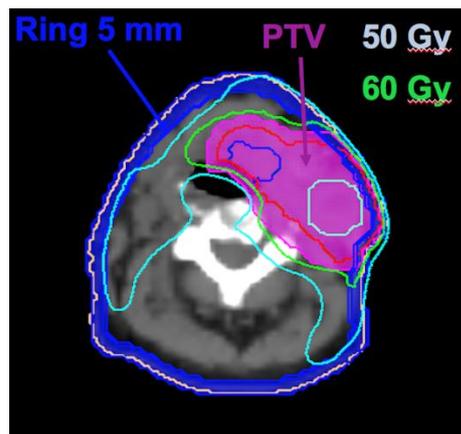

#### Purpose or Objective

In the context of locally advanced HNSCC, no biomarkers are available to predict the development of radiation dermatitis (RD). In the absence of putative skin dose constraints, large variability exists in IMRT planning optimization to avoid the potential risk of undue toxicity. The aim of our work was to assess whether skin dose-volume parameters may be predictive of severe RD.

#### Material and Methods

We retrospectively reviewed consecutive patients treated at two fellow institutions between Oct. 2011 and Nov. 2017 for locally advanced HNSCC. A 2:1 frequency-matched cohort analysis was performed to identify patients with similar demographic and disease-features who received cisplatin or Cetuximab. On the native planning CT scans, 3 skin ring structures were semi-automatically delineated by subtracting 2, 3 and 5 mm below the external patient surface (figure 1: 5 mm example), extending between the upper and lower limits of PTV plus a fixed 1 cm margin. For all 3 skin ring ROI's, the following dosimetric parameters were collected: V50, V60, maximum absolute dose expressed in terms of point value and percentage of total prescription dose. Acute toxicity was prospectively recorded according to CTCAE v. 4.1. A total dose of 66-70.5 Gy was delivered in 30-35 fractions with conventional or accelerated fractionation (dose per fraction, 2/2.12/2.35 Gy, respectively). A 3-5 PTV margin was added to CTV's (3 mm in case of daily image guidance). HPV status was not routinely available until 2015. To assess whether any patient, disease, treatment and skin dose distribution - related characteristics correlated with the development of G3/G4 RD, categorical and continuous variables were tested with Fisher's exact chi-square test and Mann-Whitney test, respectively. A multivariate Poisson regression analysis was performed when multiple risk factors with a p value <0.05 were identified in the univariate analysis. A ROC

curve analysis was applied to estimate the predictive accuracy of dosimetric threshold values for G3/G4 RD.

#### Results

Ninety-patients were evaluated (table 1). G3/G4 RD, oral mucositis and dysphagia developed in 37 (41.1%), 40 (44.4%) and 24 (24.4%) patients, respectively. As expected, the G3/G4 RD was numerically higher in the cetuximab group (50% vs 36.6% in the cisplatin cohort;  $p=0.122$ ). In univariate analysis, PS >1, weight loss at end of RT > 10 Kgs, mean relative dose intensity of Cetuximab, 2 mm skin ring V50 and V60 were significantly correlated with G3/G4 RD. In multivariate analysis, PS >1 and marked weight loss were the only 2 factors that retained significance ( $p=0.028$  and  $0.030$ , respectively). The best predictive accuracy of skin ring ROI's for G3/G4 RD was provided by 19.9 cc of 2 mm skin ring at 50 Gy and 5.8 cc of 2 mm skin ring at 60 Gy (both AUC 0.61).

Characteristic	No. of patients (%), n = 90	Cisplatin cohort (%), n = 60	Cetuximab cohort (%), n = 30

sequential	27 (30%)	18 (30%)	9 (30%)
SIB	63 (70%)	42 (70%)	21 (70%)

#### Conclusion

Along with known risk clinical factors occurring during RT such as a marked weight loss, the extent of a 2 mm skin ring ROI receiving 50 and 60 Gy may help predict beforehand the development of severe RD.

### EP-1201 Outcomes in young patients (<math>\leq 40</math>) treated for oral cavity squamous cell carcinoma in the modern era

A. Billfalk Kelly<sup>1</sup>, L. Lin<sup>2</sup>, W. Xu<sup>2</sup>, S.H. Huang<sup>1</sup>, R. Wu<sup>1</sup>, A. Bayley<sup>1</sup>, S. Bratman<sup>1</sup>, J. Kim<sup>1</sup>, M. Giuliani<sup>1</sup>, J. Ringash<sup>1</sup>, J. Waldron<sup>1</sup>, B. O'Sullivan<sup>1</sup>, J. Cho<sup>1</sup>, D. Goldstein<sup>3</sup>, A.A. Hosni<sup>1</sup>, A. Hope<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada ; <sup>2</sup>Princess Margaret Cancer Centre, Biostatistics, Toronto, Canada ; <sup>3</sup>Princess Margaret Cancer Centre, Surgery, Toronto, Canada

#### Purpose or Objective

Outcomes of oral cavity squamous cell carcinoma (OSCC) tend to be worse than other head and neck squamous cell carcinomas (HNSCC) despite modern surgical and radiation techniques and the use of postoperative concurrent chemotherapy in high risk OSCC. Anecdotal evidence has suggested that OSCC patients under the age of 40 have aggressive disease. We evaluated the outcomes of OSCC patients <math>< 40</math> treated in the modern IMRT era at our institution.

#### Material and Methods

After obtaining REB and institutional approval, OSCC patients under 40 were identified from our prospectively collected database. Details were collected in relation to tumor and treatment factors. Oncologic outcomes including overall survival, disease free survival, and loco-regional control were determined for this sub-set. Overall survival (OS) and disease-free survival (DFS) were analyzed using Kaplan Meier method and loco-regional control was evaluated using competing risk analysis.

#### Results

From 1183 consecutive patients with OSCC treated with curative intent between 2005 and 2017, 57 patients (5%) under the age of 40 were identified. The median age was 33 years (range 18-39). In the study cohort 42% of patients were female and 58% male; 61% of patients were lifelong non-smokers, with only 23% current smokers, and 16% ex-smokers; 44% were non-drinkers. ECOG performance status was 0-1 in 92.9% (one 2, 3 missing data). Surgery was to the primary lesion only in 26%, to the primary with an ipsilateral neck dissection in 53%, and 21% had surgery to the primary with bilateral neck dissections. Only 5% of patients had positive microscopic resection margins. Lymph node involvement with extra-nodal extension was seen in 17% of patients, 5% had LVI and 37% had PNI. Almost 60% received definitive surgery alone, while in 40% surgery was followed by adjuvant radiotherapy; among these, 65% received concurrent chemotherapy. The adjuvant radiotherapy dose received ranged from 56Gy in 40 fractions to 70.72Gy in 35 fractions; 26% of patients received 60Gy in 30 fractions, and 52% receiving 66Gy in 33 fractions. Almost half, 44%, had stage I disease, 10.5% stage II, 16% stage III, 28% stage IV; 1 patient's biopsy showed CIS despite a large tumor. Serious comorbidity was present in 8 patients: 6 with previous malignancies (10.5%), 1 with Fanconi's Anaemia, and 1 with severe SLE causing renal failure. With a median follow-up of 4.27 (5.03 in survivors) years, 1-year OS was 94% (0.88-1), 3-year OS 84% (0.75-0.95) and 5-year OS 82% (0.71-0.93). DFS was 84% (0.74-0.94) at one year, and 66% (0.54-0.81) at 5 years. Event free survival was 87% at 1 year (94-74), 79% at 3 years (88-65) and 74% at 5 years (84-57).

#### Conclusion

The clinical impression of poor outcomes for patients aged under 40yrs may represent recall bias. Such treated curatively for OSCC in our institution appear to have acceptable OS and DFS.

### EP-1202 Associations between smoking cessation after radiotherapy for larynx cancer and patient outcomes

A. Srivastava<sup>1</sup>, J. Contreras<sup>1</sup>, M. Daly<sup>1</sup>, H. Gay<sup>1</sup>, W. Thorstad<sup>1</sup>, A. Apicelli<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Radiation Oncology, Saint Louis, USA

#### Purpose or Objective

Continued tobacco use is known to be a poor prognostic factor among patients undergoing radiation therapy (RT) for cancers of the head and neck. However, this relationship is not well characterized for carcinomas of the larynx/hypopharynx (LNX/HPX), which are almost exclusively associated with tobacco use. Therefore, in this study we sought to evaluate whether there was a disease control and survival benefit to smoking cessation after RT for cancers of the LNX/HPX.

#### Material and Methods

An institutional database of patients with squamous cell carcinoma of the LNX/HPX treated with definitive intent RT between 2012 and 2017 was reviewed. Patients were eligible for inclusion if they had a documented history of tobacco use at the beginning of RT and were planned to undergo definitive therapy. Following completion of therapy, patients were stratified into two cohorts based on continued tobacco use. The student's t-test and Fisher exact test were utilized to compare baseline clinical and demographic covariates. The Kaplan-Meier method and log-rank test were used to estimate and compare locoregional control (LRC), distant control (DC), and overall survival (OS) between the cohorts, and Cox regression tests were used to identify predictors of these outcome metrics.

#### Results

A total of 102 patients were eligible, and 34 (33.3%) continued smoking following definitive therapy. Most patients (52/102, 51%) underwent surgery, and the majority (71/102, 70%) received concurrent chemotherapy with RT. Median follow-up time was 26 months (range 1-64). Baseline demographic and clinical characteristics were similar between the groups, but smoking cessation was less common among African Americans ( $p=0.03$ ). At two years of follow up, actuarial LRC rates were 63% for patients who continued to smoke and 79% for patients who stopped ( $p=0.02$ ) while DC rates were 86% and 90%, respectively ( $p=0.53$ ). There was a survival benefit in patients who stopped smoking (92% v. 78%,  $p=0.01$ ). On multivariate analysis, smoking status post RT (hazard ratio [HR]: 2.6, 95% confidence interval [CI]: 1.8-3.9;  $p=0.01$ ), higher performance status (HR: 2.3, 95% CI: 1.4-4.2,  $p=0.03$ ), and advanced tumor stage (HR: 2.9, 95% CI: 1.7-5.8,  $p=0.02$ ) were predictive of worse OS. Notably there was no association between number of pack-years previously smoked and disease outcome ( $p=0.21$ ).

#### Conclusion

Smoking cessation after definitive treatment of larynx/hypopharynx cancer is associated with a significant increase in OS regardless of extent of smoking history, underscoring the importance of smoking cessation.

### EP-1203 Characterization of DCE-MRI parameters associated with advanced mandibular osteonecrosis

A.S.R. Mohamed<sup>1</sup>, R. He<sup>1</sup>, Y. Ding<sup>1</sup>, J. Wang<sup>1</sup>, B. Elgohari<sup>1</sup>, H. Elhalawani<sup>1</sup>, J. Johnson<sup>1</sup>, J. Stafford<sup>1</sup>, J. Bankson<sup>1</sup>, V. Sandulache<sup>2</sup>, C. Fuller<sup>1</sup>, S. Lai<sup>1</sup>

<sup>1</sup>The University of Texas- MD Anderson Cancer Center, Radiation Oncology, Houston, USA ; <sup>2</sup>Baylor College of Medicine, Otolaryngology, Houston, USA

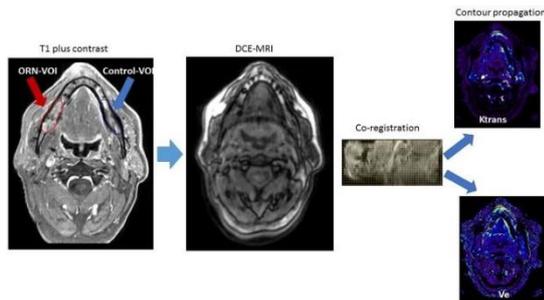

#### Purpose or Objective

We aim to characterize the quantitative DCE-MRI parameters associated with advanced mandibular ORN following definitive radiotherapy for head and neck cancer patients.

#### Material and Methods

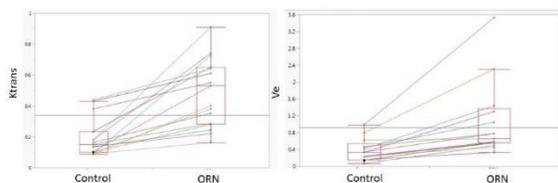

Patients with advanced ORN after curative-intent radiation treatment of head and neck cancer were prospectively enrolled in an observational imaging study after institutional-review board approval and study-

specific informed consent. Eligibility criteria included; age > 18 years, pathological evidence of head and neck malignancy with a history of curative-intent external beam radiotherapy; patients with clinically confirmed high-grade ORN requiring surgical intervention; and no contraindications to MRI. Prior to DCE-MRI, T1 mapping was performed using a total of 6 variable flip angles. The DCE-MRI acquisition consisted of a 3D SPGR sequence to gain a sufficient signal-to-noise ratio (SNR), contrast, and temporal resolution. Images were acquired every 5.5 s for a total of 5 minutes. Extended Toft's pharmacokinetic model was used for analysis. Motion correction was applied to enhance the quality of map computation. Manual segmentation of advanced ORN 3-D volume was done using anatomical sequences (T1, T2, and T1+contrast) to create ORN volumes of interest (ORN-VOIs). Subsequently, normal mandibular VOIs were segmented on contralateral healthy mandible of similar volume and anatomical location (i.e. mirror image) to create self-control VOIs. Finally, anatomical sequences were co-registered to DCE sequences and contours were propagated to respective Ktrans and Ve quantitative parameter maps. The workflow is summarized in Figure 1.

## Results

Seventeen patients with advanced ORN requiring surgical resection of the mandible were analyzed. Median age at diagnosis was 59 years (range 38-72), and 88% were men. Primary tumors were localized to the oropharynx (n=9), oral cavity (n=4), salivary glands (n=2) and nasopharynx (n=2). All patients were treated with intensity modulated radiotherapy (IMRT) to a median dose of 70 Gy in 33 fractions. Using matched pairs analysis, we measured higher Ktrans and Ve values in ORN-VOIs compared with control regions (0.49 vs 0.19 min<sup>-1</sup>, p<0.0001 and 1.2 vs 0.6, p=0.01; respectively). The median relative increase of Ktrans in ORN-VOIs was 2.7 fold greater than that of healthy mandibular control VOIs (range 1.4-7.8); the relative increase of Ve in ORN-VOIs was 2.6 fold greater than that of healthy mandibular control VOIs (range 1.1-8). Figure 2 depicts boxplots of ORN vs Control VOIs parameters.

## Conclusion

Our results confirm there is a quantitatively significant higher degree of leakiness in the mandibular vasculature as measured using DCE-MRI parameters of areas affected with advanced grade of ORN versus healthy mandible. We were able to measure significant increases in both parameters (2.7 fold Ktrans, 2.6 fold Ve) compared to values from non-ORN mandibular bone. Further efforts are ongoing to validate these findings and to establish DCE-

MRI parameter thresholds for early detection of subclinical cases of ORN.

## EP-1204 Quantitative signal intensity kinetics of normal tissues of the head and neck on the MR-Linac.

F. Gregucci<sup>1,2</sup>, H. Bahig<sup>1</sup>, A.S. Mohamed<sup>1</sup>, R. He<sup>3</sup>, B.A. Elgohary<sup>1</sup>, H. Lee<sup>4</sup>, Y. Ding<sup>4</sup>, J. Wang<sup>4</sup>, H. Elhalawani<sup>1</sup>, G.S. Ibbott<sup>4</sup>, M. Chetvertkov<sup>4</sup>, G. Bosco<sup>4</sup>, S. Ikner<sup>4</sup>, S.P. Ng<sup>4</sup>, D.C. Fuller<sup>1</sup>

<sup>1</sup>University of Texas MD Anderson Cancer Center, Radiation Oncology, Houston, USA ; <sup>2</sup>University of Padova, Radiation Oncology, Padova, Italy ; <sup>3</sup>University of Texas Medical School, Diagnostic and Interventional Imaging, Houston, USA ; <sup>4</sup>University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA

## Purpose or Objective

The MR-Linac, a hybrid device combining a magnetic resonance with a linear accelerator, holds the promise of online anatomic and functional imaging which would allow daily radiotherapy adaptation. In this study, we sought to quantitatively assess the repeatability and reproducibility of signal intensity (SI) over time from serial T1- and T2-weighted magnetic resonance imaging (MRI) acquired on the MR-Linac with standardized acquisition parameters and under stable conditions.

## Material and Methods

6 healthy volunteers underwent 7 serial, immediately consecutive T1- and T2-weighted MRI studies of the head and neck (H&N) region using a 3 Tesla MR-Linac. Normal tissue volume of interest (VOI) were defined based on spin-echo sequences T1- and T2-weighted imaging. For a total of 42 MRI studies, we performed manual segmentation using T2-spin-echo sequence, for the following VOI: mandible, parotid glands, submandibular glands, sternocleidomastoid muscles, spinal cord and vertebral body. Deformable image registration was performed between the different MRI time points in T1 and T2 sequences, all VOI were then propagated and reviewed by expert radiation oncologists. From these serial MRI studies, a collection data concerning the VOI has been created bringing out a quantitative analysis of the following SI parameters: mean, max and min values. For the statistical analysis the VOI were grouped in the following 4 tissue categories: gland (G), bone (B), muscle (M) and nerve (N).

## Results

The mixed model estimates on T1-MRI showed that max, min and mean values of SI were for G group -1002.88 (t=0.0014), -161 (t=0.0005) and -394.56 (t<0.0001), respectively; for B group -384.73 (t=0.178), -202.41 (t<0.0001) and -442.24 (t<0.0001), respectively; for M group -1008.08 (t=0.0013), 26.69 (t=0.513) and -91.18 (t=0.283), respectively; for N group 1962.63 (t=0.0004), 230.41 (t=0.0029) and 603.68 (t=0.0003), respectively. The mixed model estimates on T2-MRI showed that max, min and mean values of SI were for G group -9.97 (t=0.03), 11.39 (t<0.0001) and 6.49 (t=0.04), respectively; for B group -0.59 (t=0.89), 3.43 (t=0.12) and 12.44 (t=0.0008), respectively; for N group 66.75 (t<0.0001), 17.00 (t<0.0001) and 27.35 (t<0.0001), respectively. The F-test in T1- and T2-weighted MRI showed differences between the different VOI groups in max, min and mean SI values (f<.0001 for all) but no SI differences inside the same VOI group and between the different time points for each VOI groups.

## Conclusion

The SI kinetics for analyzed tissue categories on T1 and T2-spin-echo sequences are reproducible and repeatable between different subjects and over the time, keeping unchanged the MRI acquisition parameters. These results could be an helpful tool for future studies of correlation between SI kinetics deviation and observed toxicity profile for the purpose of developing predictive models in H&N cancer.

**EP-1205 A new alpha particle treatment for recurrent or aggressive head and neck squamous cell carcinoma**  
A. Popovitzer<sup>1</sup>

<sup>1</sup>Rabin Med. Ctr. Beilinson Campus, Department of Radiation Oncology, Petah-Tikva, Israel

**Purpose or Objective**

The first clinical trial in humans with skin and oral cavity squamous cell carcinoma was performed in order to evaluate the effect of a unique intra-tumoral alpha radiation based tumor ablation treatment termed Diffusing Alpha emitters Radiation Therapy (DaRT). DaRT relies on alpha particles and thus, effective against hypoxic tumors. DaRT seeds can be produced with various intensities, sizes, and shapes and enable custom designed seeds. In our prior animal studies, we demonstrated the effectiveness of the treatment in mice for many tumors. In this first Human study, we evaluated its role for Skin and Oral Cavity Squamous cell Carcinoma.

**Material and Methods**

Materials/Methods: A Radium-224 loaded sources (DaRT seeds) were inserted into solid tumors and released by recoil short-lived alpha-emitting atoms (Rn-220, Po-216, Pb-212, Bi-212, Po-212, Tl-208). These atoms disperse in the tumor and spray it with highly destructive alpha radiation. The decay products diffuse in the tumor mass to a distance of at least 5 mm. Thus, a sizable fraction of the tumor is irradiated by alpha particles, and because of their short half-life, only small amounts of the isotopes disperse in the body.

**Results**

Results: A feasibility and safety clinical study is ongoing and currently, 18 patients were treated. All patients were radiation resistant recurrent histopathological confirmed skin or head and neck SCC, and tumor size  $\leq 5$  centimeters in the longest diameter, were enrolled. Treatment was delivered based on a CT-simulation pre-treatment plan. The Ra-224 Alpha DaRT Seeds were inserted under local anesthesia using a specially designed Alpha DaRT Applicator. The seeds (1 cm long and 0.7 mm in diameter) each carrying a dose of 2  $\mu$ Ci were placed 6 millimeters from each other. CT was used to check the position of the radioactive seeds. Two to four weeks after implantation the seeds were removed, and six weeks after treatment CT was performed to assess the effect of treatment. Blood tests and urinalysis were performed during the treatment. The Age of the patients ranged between 70 to 94 (median 81). Eleven patients had recurrent oral cavity SCC and seven diagnosed with aggressive skin SCC. All were treated within radiation failure fields (Radiation dosage  $>60$  Gy). With a median follow up of 5 months, All tumors responded to the treatment; 13 tumors had a complete response, five tumors showed a partial response. No major toxicity was noted. The areas around the treated tumors were not necrotic and no radionecrosis developed

**Conclusion**

Conclusion: In this feasibility and safety human study we demonstrated that alpha particles based DaRT exhibit enhanced radiobiological potential. The treatment was effective against radio-resistant SCC tumors without major toxicity.

**EP-1206 SRS/SRT for patients with brain Metastasis RPA Class II disease: Results from Single institution**

M. El-Haddad<sup>1</sup>, O. AlSalih<sup>2</sup>, L. Eley<sup>1</sup>, E. Johnson<sup>1</sup>, M. Chandrasekaran<sup>1</sup>, K. Nyathi<sup>1</sup>, H. Trieu<sup>1</sup>, S. Kumar<sup>1</sup>, C. Birch<sup>1</sup>, F. Sheikh<sup>3</sup>, H. Joy<sup>3</sup>, P. Grundy<sup>4</sup>, J. Ching<sup>1</sup>, J. Duffill<sup>1</sup>, S. Geoff<sup>1</sup>

<sup>1</sup>University hospital southampton, Clinical Oncology, Southampton, United Kingdom ; <sup>2</sup>St Thomas' Hospital

Guy's Hospital, Cancer Center, London, United Kingdom ; <sup>3</sup>University hospital southampton, Department of Radiology, Southampton, United Kingdom ; <sup>4</sup>University hospital southampton, Wessex Neurosurgery Center, Southampton, United Kingdom

**Purpose or Objective**

Recursive partitioning analysis is one of the important factor that determine patients' prognosis and choice of our treatment. The aim of this study is to emphasize the role of stereotactic radiosurgery (SRS)/radiotherapy (SRT) in patients with brain metastasis RPA class II.

**Material and Methods**

Hundred and twenty-four patients treated for brain metastasis at University hospital Southampton between November 2016 and June 2018. Eighty-eight (71%) patients were treated with SRS, 36 (29%) patients treated with SRT, choice of SRS/SRT was chosen depending on tumour size and dose to normal brain tissue or proximity to normal risk structures e.g. brain stem. Median dose for SRS patients was 18Gy single fraction (range: 12-21Gy), and for SRT 21Gy in 3-5 fractions (range: 21-25Gy). All patients treated on linear accelerator ELKTA® with Agility™MLC and Exactrac™ system. Dose prescription ranged between 60% and 72% isodose line. <sup>TM</sup>. OAS calculated from the date if treatment till date of last follow-up.

**Results**

Median age at referral was 65 year, with 50% of the patients aged between 56 and 71 year. Fourteen patients were between 76 and 80 year. Sixty-seven female (54%) and 57 (46%) male. Fifty patient (40%) had lung cancer diagnosis, 19 patients (15%) diagnosed with melanoma the rest were between, Breast 14 patients (11%), renal cell 12 patients (10%), colorectal 8 patients (6%) others 21 patients (18%). Main toxicity profile was brain oedema and need for steroid longer than our defined protocol of 8 days, one patient had brain stem necrosis following single fraction 15Gy for 2.5cm lesion, improved on steroids for 8 weeks without evidence of recurrence. Survival analysis was done for 81 patients only, 10 patients didn't have follow up data, the rest of patients were enrolled at a later time and did not have a minimum follow-up of 6 months at the time of the last data cutoff. Median overall survival for the whole group was 15 months (95% CI 10.05 -19.94), progression free survival 12 months (95% CI 8.88 -15.11). Majority of our patients 65% classified as Class II disease OAS for this group was 11 months (95% CI 8.17-13.8) and PFS was 10 months (95% CI 8.07 -11.7).

**Conclusion**

SRS/SRT is effective in patients with brain metastasis Class II RPA longer follow-up is still needed.

**EP-1207 Fractionated stereotactic radiation therapy for resected brain metastases: a preliminary report**

A. Di Marzo<sup>1</sup>, F. Trippa<sup>1</sup>, P. Anselmo<sup>1</sup>, F. Arcidiacono<sup>1</sup>, S. Terenzi<sup>1</sup>, L. Draghini<sup>1</sup>, M. Italiani<sup>1</sup>, M. Casale<sup>1</sup>, M. Muti<sup>1</sup>, S. Fabiani<sup>1</sup>, E. Maranzano<sup>1</sup>

<sup>1</sup>"S. Maria" Hospital Terni, Radiotherapy Oncology Centre, Terni, Italy

**Purpose or Objective**

Cavity stereotactic radiosurgery (SRS) or fractionated stereotactic radiation therapy (FSRT) are emerging treatment options after surgical resection of brain metastases (BM). Recent randomized trials, aimed to clarifying the adverse effects of postoperative whole-brain radiation therapy (WBRT) for BM have confirmed the association of neuro-cognitive and quality of life decline with WBRT. The recent phase 3 NCCTG study comparing SRS and WBRT for resected BM showed comparable overall survival and superior preservation of cognitive function after SRS, supporting the rationale for limiting WBRT to only patients where it is clinically essential. We present a preliminary report of our experience on surgical cavity FSRT.

### Material and Methods

Between May 2011 and August 2018, 19 patients (pts) with surgical resected BM were irradiated with FSRT in 5 fractions. Median age was 66,5 years (range 50-74); primary tumor was non-small cell lung cancer (7 pts), breast cancer (4 pts), gastrointestinal cancer (5 pts), others (3 pts). All patients were evaluated by Karnofsky performance status (KPS) and neurologic functional score (NFS). Localization was obtained using fusion imaging from computed tomography (CT) and magnetic resonance imaging (MRI) of the brain. Gross tumor volume (GTV) was defined as radiologically visible surgery cavity in contrast-enhancing T1-weighted MRI sequences, clinical target volume (CTV) was coincident with GTV and planning target volume was GTV/CTV plus an additional 2-3 mm in all directions (average PTV 28.6 cc). Pts were treated with a 6-MV linear accelerator fitted with a dynamic micro-multileaf collimator. Ten pts received 5x6 Gy and eight 5x7 Gy. All pts were followed by MRI and clinical examination 3 months after FSRT and at 3 months intervals thereafter. Local control (LC) was defined as a lack of relapse of the irradiated surgical cavity, and brain control (BC) as LC in absence of other documented BM. A brain failure at the site of FSRT was defined "in-field relapse", whereas appearance of new BM "out-field relapse".

### Results

After a median follow-up of 16 months (range 4-79), 17 of 19 pts were evaluable because one was lost to follow up and one too early. 9 pts (52,9%) had LC and BC, seven (41,1%) reached LC without BC, one (6%) had in- and out-field relapse. So, in 16 (94,1%) pts, postoperative FSRT reached a LC and in more than one-half LC and BC. All pts in progression were re-irradiated, four with SRS, two with WBRT and two with WBRT plus SRS to a second progression. Altogether, after cavity stereotactic radiotherapy, 19 new lesions were treated with SRS. No acute neither late toxicity was registered, no treatment-related NFS decline was observed.

### Conclusion

Our preliminary report showed that surgical cavity FSRT for resected BM was effective in more than one half of pts with a good neuro-cognitive outcome. WBRT and/or SRS can be reserved to pts with brain progression of disease.

### EP-1208 Twenty years experience in treating Childhood medulloblastoma: Between the past and the present .

J. Khalil<sup>1</sup>

<sup>1</sup>National Institute of Oncology Sidi Mohamed Ben Ab, Radiotherapy, Rabat, Morocco

### Purpose or Objective

Medulloblastoma (MB) is the most common primary malignant central nervous system tumor of childhood. These last decades, treatment modalities have largely evolved resulting in better survival rates. Nevertheless, long term toxicities are a major concern in this setting.

### Material and Methods

Our study is a retrospective one conducted at Xinhua Hospital in Shanghai, China. It included 121 patients treated for medulloblastoma from 1993 to December 2013.

### Results

Mean age at diagnosis was 6.7 years (range 1-14.3 years). Total surgical resection was achieved in 60% of the cases. Classic medulloblastoma was found in 59% of the cases. Adjuvant radiotherapy was delivered in all cases and chemotherapy concerned 70.2% of the studied cohort. The median follow-up time of the study was 84 months (range, 24-120months). 5 and 10 years Progression free survival (PFS) were 83.2% (95% CI), 69.5% (95% CI) and 5 years and 10 years Overall survival (OS) were 82.5% (95% CI), and 72.5% (95% CI). Patient's age significantly influenced survival; patients under 3 years old had the worse outcomes (P=0.01). T and M stages also significantly

impacted survival rates, advanced stages were associated with lower rates (P= 0.08 and 0.05 respectively). Finally, patients receiving Temozolomide had bad outcomes when compared to the new standard protocol used in the department (P=0.03). The most commonly reported late toxicity was growth suppression in 35 patients (52.2%).Hypothyroidism requiring hormone replacement was recorded in 29% of the cases. Hearing loss, and problems including poor concentration, poor memory and learning difficulties were reported in 19% and 25% of the cases respectively. Second cancers were noted in three cases.

### Conclusion

Overall, our results are comparable to those reported in the literature; nevertheless efforts should be made to ensure longer follow ups and correctly assess treatment related toxicities.

### EP-1209 First clinical results using HyperArc™ and Linac-based VMAT radiosurgery in brain metastases.

F. Alongi<sup>1,2</sup>, F. Gregucci<sup>1</sup>, R. Mazzola<sup>1</sup>, N. Gajj-Levra<sup>1</sup>, M. Rigo<sup>1</sup>, V. Figlia<sup>1</sup>, L. Nicosia<sup>1</sup>, S. Corradini<sup>3</sup>, F. Ricchetti<sup>1</sup>, R. Ruggeri<sup>1</sup>

<sup>1</sup>Hospital Sacro Cuore Don Calabria- Cancer Care Center, Radiation Oncology, Negrar, Italy ; <sup>2</sup>University of Brescia, Radiation Oncology, Brescia, Italy ; <sup>3</sup>LMU University Hospital, Radiation Oncology, Munich, Germany

### Purpose or Objective

The use of Stereotactic Fractionated Radiotherapy (SFRT) or Radiosurgery (SRS) is increasing in the treatment of brain metastases (BMs), also for multiple BMs. Aim of the present study is to evaluate safety and effectiveness of SRS/SFRT for BMs, using a new non-coplanar mono-isocenter technique (HyperArc™ Varian Medical System).

### Material and Methods

Patients with a diagnosis of BMs with a diameter inferior to 3 cm, a life expectancy more than 3 months and good performance status, were eligible for Linac-based volumetric modulated arc therapy (VMAT) SFRT/SRS with HyperArc™. Clinical evaluation and MRI were requested after 45-60 days by the SRS/SFRT, and every 2-3 months during follow-up (FU). A retrospective analysis of patients, BMs, treatment characteristics and outcomes included toxicity, local control (LC), overall survival (OS) and intracranial time to progression (iTTP), were performed.

### Results

From August 2017 to May 2018, 381 BMs in 64 patients were treated. Two hundred forty-six BMs (43 patients) were evaluated, 73 BMs (10 patients) were excluded due to Karnofsky performance status (KPS) < 60 and died before first control and 62 BMs (11 patients) did not yet perform FU visit at the time of the analysis. The median BMs number for each patients was 5 (range 1-21). With a median FU time of 6 months (range 1-10), 244 out 246 (99%) BMs were controlled (18% complete response; 41% partial response, 40% stable disease), only 2 BMs (1%) showed a progression disease, at the first control. No acute (within 3 months) and late (above 3 months) toxicities were reported. At the time of analysis, median OS has not yet been achieved, while median iTTP was 5 months. In univariate analysis, statistically negative prognostic factors for OS were histology of primary tumor (P=0.009): lung/breast cancer had better survival rates as compared to melanoma/other; cumulative volume of intracranial disease  $\geq 15$ cc (P=0.04) and systemic progression disease (P=0.005). At multivariate analysis, cumulative volume of intracranial disease  $\geq 15$ cc (P=0.04) and systemic progression disease (P=0.009) were confirmed independent negative prognostic factors for OS. Considering CR/PR as "local treatment response", while SD/PD as "not local treatment response", the analysis of LC profile stratified by histology, PTV and BED, using Chi-square test, showed that melanoma/other histological

type ( $P=0.0001$ ), PTV $>1$  cc ( $P=0.041$ ) and BED $<47.2$  Gy ( $P=0.0001$ ) were negative predictive factors of response.

#### Conclusion

The present data showed that SFRT/SRS with HyperArc™ is safe and effective for multiple BMs, mostly in appropriately selected patients. The utilization of SFRT/SRS for BMs is promising and should be explored in randomized trial.

#### EP-1210 Local control and toxicity of IORT with low energy X-rays after resection of brain metastasis

H. Kahl<sup>1</sup>, S. Sabine<sup>2</sup>, M. Heiko<sup>3</sup>, G. Ute<sup>3</sup>, K. Ina<sup>3</sup>, H. Volkmar<sup>3</sup>, M. Christoph<sup>4</sup>, B. Ansgar<sup>4</sup>, K. Jürgen<sup>2</sup>, S. Georg<sup>1</sup>  
<sup>1</sup>Klinikum Augsburg, Strahlenklinik, Augsburg, Germany ;  
<sup>2</sup>Klinikum Augsburg, Stabsstelle Medizinphysik, Augsburg, Germany ;  
<sup>3</sup>Klinikum Augsburg, Neurochirurgische Klinik, Augsburg, Germany ;  
<sup>4</sup>Klinikum Augsburg, Klinik für Diagnostische Radiologie und Neuroradiologie, Augsburg, Germany

#### Purpose or Objective

The paradigm of adjuvant radiotherapy after resection of brain metastasis is changing from whole brain irradiation (WBI) to localized brain radiotherapy (LBRT). Improving survival of stage IV patients, puts neurologic late toxicity more and more into focus. IORT with low energy is a promising method to apply LBRT for brain metastasis as it maximally shortens the resection radiation interval as well as the time to the start of mostly needed systemic treatment compared to external beam radiation.

#### Material and Methods

We performed a retrospective analysis of patients treated with low energy X-ray IORT after resection of brain metastasis (mamma carcinoma 6, colorectal cancer 5, melanoma 4, NSCLC 4, renal cell carcinoma 2, other 2) between 2013 and 2018 at the Klinikum Augsburg. In total 25 metastases were resected in 22 patients (9 males/13 females) and treated with IORT using the Intrabeam system. Four patients had recurrent disease, of which 3 were pretreated with WBI. All patients fitted to RPA class 1 and 2 (8 and 14 patients). Median age was 60.8 years (44-82 years), median applied dose 20Gy (16-20Gy) on the surface of the applicator and median applicator size 2.5 cm (1.5 -4cm). None of the patients received additional planned WBI. Actuarial overall survival (OS), local control rate (LC), distant brain control (DC) were calculated by the Kaplan-Meier method and put into context with published and own data of adjuvant LBRT with radiosurgery (SRS) or hypofractionated stereotactic radiotherapy (HSRT).

#### Results

With a median follow up (FU) of 12.1 months (1 to 48 months), actuarial overall survival (OS) @ 1 year (2 years) was 73% (60%). The LC (actuarial LC @1year/@2years) of all 25 lesions was calculated 88% (85%/53%). DC of the 22 patients @1year (@2years) was 44% (44%). Only 3 patients received WBI as salvage after IORT (14%), all other distant recurrences were treated and controlled with SRS. We found a symptomatic brain necrosis rate of 4% (1 lesion/pre-treated with WBI+SRS boost), but found asymptomatic radiotherapy induced MR alterations also in the FU of 2 other patients (8%/cumulative 12%). One air embolism occurred during the IORT procedure. One patient developed a lethal infarction of the a. cerebri media 14 days post surgery. One patient with 2 consecutive resections and IORT procedures developed a bacterial meningoencephalitis and one postoperative thrombopenic bleeding requiring surgery occurred. No other healing complications were observed. There was no increased use of steroids post operatively compared to patients with brain metastasis resection only.

#### Conclusion

IORT with low energy is a feasible option to apply LBRT after resection of brain metastasis providing comparable local control with no increased toxicity compared to

postoperative external beam LBRT. It provides the chance of earlier start of systemic treatment after resection of brain metastasis compared to external beam LBRT.

#### EP-1211 Radiation necrosis after SRS for intracranial metastases from lung cancer: A retrospective review

A. Sharma<sup>1</sup>, L. Mountjoy<sup>2</sup>, R. Butterfield<sup>3</sup>, N. Zhang<sup>3</sup>, H. Ross<sup>2</sup>, S. Schild<sup>4</sup>, J. Ashman<sup>4</sup>, T. Daniels<sup>4</sup>, H. Paripati<sup>2</sup>, M. Mrugala<sup>1</sup>, S. Vora<sup>4</sup>, N. Patel<sup>5</sup>, R. Zimmerman<sup>5</sup>, T. Sio<sup>4</sup>, A. Porter<sup>1</sup>

<sup>1</sup>Mayo Clinic Arizona, Neuro-Oncology, Phoenix, USA ;  
<sup>2</sup>Mayo Clinic Arizona, Hematology/Oncology, Phoenix, USA ;  
<sup>3</sup>Mayo Clinic Arizona, Research Biostatistics, Phoenix, USA ;  
<sup>4</sup>Mayo Clinic Arizona, Radiation Oncology, Phoenix, USA ;  
<sup>5</sup>Mayo Clinic Arizona, Neurosurgery, Phoenix, USA

#### Purpose or Objective

Radiation therapy is the primary treatment of intracranial metastasis (ICM) from lung cancer. Radiation necrosis (RN) occurs post-treatment with an incidence of 5-24%. Radiographically, RN remains a diagnostic quandary that can appear indistinct from tumor progression. We reviewed the spectrum of imaging changes in patients with SRS-treated ICM from lung cancer (LC) in an effort to classify potential risk factors for RN and to identify radiographic differentiators of RN versus tumor progression.

#### Material and Methods

Patients with LC and ICM who received stereotactic radiosurgery (SRS) for treatment between 2013 and 2018 at our institution were retrospectively reviewed at our institution. Sixty-three patients were identified. Demographics, tumor type, ICM burden and location, chemotherapy, surgery, and SRS details as well as outcomes were recorded. Magnetic resonance imaging (MRI) was reviewed and evaluated using the Response Assessment in Neuro-Oncology criteria (RANO).

#### Results

Of the 63 patients included in this study, clinical and radiographic criteria for RN were seen in 24 (38%) as early as 2 months and as late as 5 years post-RT. Six were taken to the OR because of refractory symptoms and were found to have pathology-proven RN. Patients with RN were significantly more likely to have had resection of an ICM (45.8%) prior to radiation than patients who did not have RN (20.5%,  $p=0.04$ ). No significant differences were found in location, size, or genetic profile of lesions, but a non-significant trend for RN was seen in younger patients (average age 64 vs 68,  $p=0.08$ ). Twenty patients received treatments directed towards RN - steroids, surgery, laser ablation or bevacizumab. The 4 remaining Patients who did not receive treatment had clinical/functional decline and lower overall survival (OS) of 13 months, vs 21.5 months if they did receive treatment. 85% of patients treated for RN experienced radiographic and clinical benefit. When steroids were used alone, the rate of improvement was 85.7% (6/7). There was 100% improvement with laser ablation (4/4) and bevacizumab (4/4). Surgical resection of RN resulted in improvement in 4/6 patients (66%), however the remaining two were left with increased neurologic morbidity that likely hastened death. All surgical specimens collected showed necrotic changes with only one revealing a mix of RN and tumor.

#### Conclusion

We present one of the larger case series of ICM in LC and their treatment outcomes. Our observation of RN as late as 5 years post-RT for ICM necessitates clinician awareness and early intervention to reduce morbidity. Younger age and prior surgical resection are potential risk factors for RN. Providers should keep a high index of suspicion for RN as development can occur several months after treatment for ICM. Several treatment options showed benefit without increased morbidity and improved survival in this cohort,

and should be considered if tissue diagnosis is not available.

#### EP-1212 Clinical outcome in brain metastases from breast cancer treated with stereotactic radiotherapy

G. Riva<sup>1</sup>, A. Ferrari<sup>1</sup>, S. Durante<sup>1</sup>, D. Ciardo<sup>1</sup>, G. Piperno<sup>1</sup>, M.C. Leonardi<sup>1</sup>, S. Vigorito<sup>2</sup>, E. Rondi<sup>2</sup>, R. Orecchia<sup>3</sup>, B.A. Jereczek-Fossa<sup>1</sup>

<sup>1</sup>Istituto Europeo di Oncologia - IEO, Radiotherapy, Milan, Italy ; <sup>2</sup>Istituto Europeo di Oncologia - IEO, Medical Physics, Milan, Italy ; <sup>3</sup>Istituto Europeo di Oncologia - IEO, Scientific Director, Milan, Italy

#### Purpose or Objective

The objective of this study was to report our institutional experience with CyberKnife in the stereotactic radiation treatment (SRT) of patients with brain metastases.

#### Material and Methods

One-hundred and two consecutive patients with brain metastases from breast cancer (199 lesions) were treated with brain SRT with CyberKnife from 02/2012 to 11/2017 as first brain radiation treatment and reviewed retrospectively for patient, tumor, and imaging characteristics. Parameters included demographics, histology and primary tumor characteristics, presence and control of extracranial disease, number of lesions and tumor volume. The imaging characteristics assessed were complete response (CR), partial response (PR), stable disease (SD), local (LF) and distant brain failure (DBF). Overall survival (OS) and local control (LC) at 2 years were evaluated

#### Results

After a median follow-up of 11.6 months (range 2.6-65.6), at least one radiological evaluation was available for 152 brain metastases (76 patients, all women). Most of the lesions (41%) were treated with a single session of SRT with a total dose of 21 Gy, other fractionations (24 Gy in 2 or 3 sessions) were preferred in case of two or more concomitant metastases or in case of greater volume of the target.

CR, PR and SD as best response were reported in 67 (44%), 56 (37%) and 26 (17%) of 152 lesions respectively, while 3 (2%) lesions had a progression disease at first control.

Fifteen out of 149 (10%) lesions showed LF after a median of 12.5 months (range 1.2-63.4).

Forty-seven (61%) women out of 76 developed DBF after a median of 7.0 months (range 1.0-39.6).

Radionecrosis was radiologically (11c-methionine Positron Emission Tomography and/or Nuclear Magnetic Resonance with gadolinium) diagnosed for 14 lesions (13 patients, 17%) in a median time of 7.3 months (range 2-20.4). Seven (9%) women referred neurological symptoms (such as seizures), a neurosurgical treatment was needed for 3 of them in order to control symptoms.

At the time of assessment, 36 (47%) patients are still alive, 32 (42%) died for tumor progression and 8 (11%) were lost to follow-up. OS after 2-years is 52%, LC after 2-years is 63%.

Table 1: Characteristics of patients and treatment outcomes

Characteristics	Value
Patients treated	102
Lesions treated	199
Patients with radiological evaluation	76
Lesions with radiological evaluation	152
Median age, years	52.8 (range, 32 – 82)
Sex, patients (% of 76)	
F	76 (100%)
M	0 (0%)
Histology of primary tumor, patients (% of 76)	
Luminal A	10 (13%)
Luminal B	41 (54%)
Triple negative	13 (17%)
Erb-B2 overexpression	12 (16%)
Maximum radiological response, lesions (% of 152)	
CR	67 (44%)
PR	56 (37%)
SD	26 (17%)
PD at first radiological control	3 (2%)
Local failure, lesions (% of 149)	
Yes	15 (10%)
No	134 (90%)
Distant brain failure, patients (% of 76)	
Yes	47 (62%)
No	29 (38%)
Radionecrosis, lesions (% of 152)	
Yes	14 (9%)
No	138 (91%)

#### Conclusion

Our results showed the efficacy in the treatment of brain metastases from breast cancer with CyberKnife SRT. Correlation between clinical (volume of brain disease) and histological parameters with favorable outcome is under investigation.

#### EP-1213 Prediction of new brain metastases after radiosurgery: validation of two nomograms in our serie.

C. De la Pinta Alonso<sup>1</sup>, R. Hernández<sup>1</sup>, E. Fernández-Lizarbe<sup>1</sup>, M. Martín<sup>1</sup>, C. Vallejo<sup>1</sup>, M. Martín Martín<sup>1</sup>, A.B. Capúz<sup>2</sup>, S. Barrio<sup>3</sup>, M. Torres<sup>3</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Ramón y Cajal Hospital, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Ramón y Cajal Hospital, Medical Physics, Madrid, Spain ; <sup>3</sup>Ramón y Cajal Hospital, Radiotherapist, Madrid, Spain

#### Purpose or Objective

Prediction of patients at highest risk for brain recurrence after radiosurgery remains a clinical concern. The aim of our study was to evaluate two published nomograms (Ayala et al and Rodrigues et al) to predict the risk of brain recurrence in a Spanish-population treated with radiosurgery in our institution.

#### Material and Methods

We retrospectively identified 85 patients diagnosed of brain metastases who had undergone radiosurgery from 2006 through 2018 at the Ramón y Cajal University Hospital (Madrid). Clinical factors and performance status of the nomograms for prediction of brain recurrence were assessed.

#### Results

Median follow-up time was 9 months. Among the 85 patients, 13 (15.3%) developed brain recurrence. We evaluated our data set with the nomograms models. Because of missing data, 12 of the 85 patients were excluded. We analyzed 3, 6, 9-months probabilities of recurrence in Ayala nomogram and 1-year with the Rodrigues nomogram. Only patients with brain recurrence were included in our validation. Calibration for 3, 6, 9-months to and 1-year probability of free brain recurrence for the nomogram showed good model calibration with intermediate correlation of nomogram-predicted probability of brain recurrence and observed probability of brain recurrence as estimated by the Kaplan-Meier method. The best correlation was in terciles in Ayala nomogram and deciles in Rodrigues nomogram. We have stratified patients in three groups in Ayala nomogram: low risk of recurrence (11-79points), intermediate risk (80-140points) and high risk (140-260points). We have stratified patients in two groups in Rodrigues nomogram:

low risk of recurrence (0-150 points), and high risk (151-350 points).

#### Conclusion

The Ayala nomogram shows validity in our population and allows users to integrate the information from different variables to provide precise risk stratification. The Rodrigues nomogram don't show validity in our population. We have validated these nomograms in our Spanish population and we are considering new lines of study.

#### EP-1214 Patterns of care: Treatment of glioblastoma in elderly patients

C. Straube<sup>1</sup>, S. Antoni<sup>2</sup>, P. Schaffer<sup>3</sup>, J. Gempt<sup>4</sup>, C. Zimmer<sup>5</sup>, B. Meyer<sup>6</sup>, S.E. Combs<sup>1</sup>, F. Schmidt-Graf<sup>2</sup>  
<sup>1</sup>Klinikum rechts der Isar- TU München, Department of Radiation Oncology, München, Germany ; <sup>2</sup>Klinikum rechts der Isar- TU München, Department of Neurology, München, Germany ; <sup>3</sup>MVZ InnMed Oberaudorf, Praxis für Strahlentherapie, Oberaudorf, Germany ; <sup>4</sup>Klinikum rechts der Isar- TU München, Department of Neurosurgery, München, Germany ; <sup>5</sup>Klinikum rechts der Isar- TU München, Department of Neuroradiology, München, Germany ; <sup>6</sup>Klinikum rechts der Isar- TU München, Department of Neurosurgery, München, Germany

#### Purpose or Objective

The optimal treatment for elderly glioblastoma patients is certainly unknown. We surveyed the pattern of care and the outcome of elderly glioblastoma (GBM) patients treated with varying adjuvant treatments, including radiotherapy (RT), temozolomide regimens, best supportive care (BSC).

#### Material and Methods

Patients older than 65 years who underwent surgery for GBM between 2010 and 2016 at the Klinikum rechts der Isar, Munich, and who were treated with adjuvant therapies or underwent BSC were eligible. We analysed the median overall survival (mOS) by the Kaplan-Meier method and extracted prognostic factors with Cox regression modeling.

#### Results

200 patients (106 female, 94 male) with a median age of 74 years (65-91 years) and a median Karnofsky performance status before adjuvant therapy of 80 (20-100) met the criteria. MGMT promotor was evaluated in 109 patients and was methylated in 40 cases, 123 were IDH wild type and 77 unknown. 45 patients underwent biopsy (8 got resection afterward), 92 partial and 63 gross total resections.

mOS of the entire cohort was 5.5 months. 76 patients underwent RT only (mOS 4.96 months), 10 received chemotherapy (CT) (mOS 9.90 months) and 54 RT and concomitant CT (mOS 13.73 months). Active adjuvant treatments with radiation therapy (HR 1.52 if no RT), MGMT promotor methylation (HR 0.49 if present), as well as the presence of paresis (HR 0.28 if no present), were significant prognostic factors in a multivariate model.

52 patients underwent treatment for progressive disease (mOS 13.77 months), including 23 patients undergoing second surgery, 14 patients (mOS 13.77 months) salvage RT or RCT and 15 patients (mOS 11,45 months) salvage CT. Patients undergoing BSC were generally in a worse physical condition (KPS 60 vs. KPS 80,  $p < 0.001$ ) and older (77.5y vs. 73.8y,  $p < 0.001$ ).

#### Conclusion

Our data underline the efficacy of active adjuvant treatment for GBM, optimally with RCT, even in an elderly cohort. As expected, the performance status after surgery is the most important predictor for BSC.

#### EP-1215 Fibroblast Activating Protein specific PET for advanced target volume delineation in Glioblastoma

P. Windisch<sup>1</sup>, M. Röhrich<sup>2</sup>, S. Regnery<sup>1</sup>, E. Tonndorf-Martini<sup>1</sup>, T. Held<sup>1</sup>, K. Lang<sup>1</sup>, D. Bernhardt<sup>1</sup>, S. Rieken<sup>1</sup>, U. Haberkorn<sup>2</sup>, J. Debus<sup>1</sup>, S. Adeberg<sup>1</sup>  
<sup>1</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>Heidelberg University Hospital, Department of Nuclear Medicine, Heidelberg, Germany

#### Purpose or Objective

To assess target volume alterations when contouring is based on PET-CT with 68Ga-radiolabeled ligands of Fibroblast Activating Protein, FAPI-02 and FAPI-04, versus conventional pretreatment imaging with contrast enhanced CT and MRI.

#### Material and Methods

Fourteen Glioblastoma (GBM) patients treated between 10/2017 and 08/2018 received an additional FAPI-PET prior to treatment. As one patient's tumor, the only one with an IDH-mutation, showed very low FAPI-enhancement compared to healthy appearing normal tissue, analysis was carried out with the remaining 13 patients. Three different FAPI-GTVs were created using a 5-, 7- and 10-fold threshold of increased uptake compared to normal tissue (FAPIx5, FAPIx7, FAPIx10). Following GTV delineation, according to the EORTC guidelines, based on thresholds the volumes were corrected for false-positive enhancement.

MRI-GTVs were created based on T1-weighted Gd-enhancement. Based on these GTVs, MRI-CTVs were created by adding a 20 mm margin. Applying another 3-5 mm margin to the MRI-CTV resulted in the MRI-PTV.

#### Results

GTVs based on MRI resulted in a median volume of 33.8 ml (range: 0.5 - 88.2 ml) while GTVs based on FAPIx5, x7 and x10 resulted in volumes of 49.6 ml, 33.7 ml and 23.8 ml respectively (ranges: 3.5 - 115.6 ml, 2.1 - 99.7 ml and 1.4 - 76.7 ml). FAPI-GTVs were significantly different from MRI-GTVs for FAPIx5 ( $p = 0.022$ ) and FAPIx10 ( $p = 0.068$ ) but not FAPIx7 ( $p = 0.95$ ).

As MRI- and FAPI-GTVs were not congruent, adding FAPI-GTVs to MRI-GTVs to create a combined MRI/FAPI-GTV resulted in an increase of the median volume of 17.7 ml, 8.9 ml and 3.9 ml (ranges: 2.9 - 49.3 ml, 1.6 - 32.4 ml and 0.8 - 18.7 ml) for FAPIx5, x7 and x10 respectively which corresponds to increases of the MRI-GTV by 55.6%, 27.3% and 17.2% (ranges: 20.0 - 586.3%, 12.4 - 311.8% and 3.9 - 164.7%). Changes to the MRI-GTVs caused by adding FAPI-GTVs were highly significant for all FAPI-PET thresholds ( $p < 0.001$ ).

Median MRI-PTV was 271.5 ml (112.4 - 490.9 ml). To determine whether FAPI-GTVs were included in the MRI-PTV, we calculated the overlap between both volumes. While in almost all patients PET-GTVs were completely included in the much larger MRI-PTVs as expected, one patient's FAPI-GTV was not entirely covered by the MRI-PTV (30.9 ml, 21.3 ml and 13.5 ml of uncovered FAPI-GTV respectively).

No complications occurred during either MRI or FAPI-PET.

#### Conclusion

FAPI-PET can provide additional insight into GBM spread compared to conventional pretreatment imaging and might therefore prove to be especially useful for treatment planning in radiation oncology but also for surgical interventions. Further research is warranted to assess appropriate thresholds for different patients and possible prognostic significance of tracer uptake.

#### EP-1216 Single- versus 2-session Gamma Knife surgery for symptomatic midsize brain metastases

S. Yomo<sup>1</sup>

<sup>1</sup>Aizawa Hospital, Division of Radiation Oncology- Aizawa Comprehensive Cancer Center, Matsumoto, Japan

### Purpose or Objective

Two-session Gamma Knife surgery (GKS) has been recently demonstrated as an effective and less invasive alternative for large metastases (BM) not amenable to microsurgical resection. Taking these results, a clinical question arises as to whether this treatment strategy further improve treatment outcome of symptomatic midsize BM (2-10mL). The aim of the present study was to compare the local therapeutic effects and toxicities of single-session and 2-session GKS in the treatment of symptomatic midsize BM.

### Material and Methods

Patients with focal neurological deficits attributable to midsize BM who underwent upfront GKS from 2011 to 2018 were retrospectively identified from an institutional database. Patients both with post-GKS imaging studies and neurological evaluation on outpatient visit were eligible. The combined endpoint, imaging and/or functional worsening of the lesion treated, was compared between the 2 treatment arms after 1:1 propensity score matching.

### Results

A total of 214 symptomatic midsize BM in 183 cancer patients were identified, including 145 and 69 tumors treated with single-session and 2-session GKS, respectively. After propensity score matching, 63 pairs of tumors were obtained. Gray test showed that two-session GKS achieved a longer local progression-free interval compared with single-session GKS ( $p = 0.035$ ). Two-session GKS was also associated with greater immediate improvement in KPS scores ( $18 \pm 15$  vs  $11 \pm 13$ ,  $p = 0.008$ ). Overall survival time in single- and 2-session GKS were 13.4 months and 15.0 months, respectively ( $p = 0.47$ ).

### Conclusion

Two-session GKS could achieve more durable local tumor control and functional improvement than single-session SRS for patients with symptomatic midsize BM, although overall survival advantage did not become evident.

**EP-1217 Reirradiation of recurrent gliomas with CyberKnife® SRS/SRT: a monoinstitutional experience**  
V. Borzillo<sup>1</sup>, E. Scipilliti<sup>2</sup>, R. Di Franco<sup>1</sup>, F. Cammarota<sup>1</sup>, P. Muto<sup>1</sup>

<sup>1</sup>Istituto Nazionale Tumori Fondazione Pascale, UOC Radioterapia, Napoli, Italy; <sup>2</sup>Università Federico II, Dipartimento di scienze biomediche avanzate, Napoli, Italy

### Purpose or Objective

The aim of our study was to retrospectively evaluate the efficacy and toxicity of reirradiation with Cyberknife (CK) stereotactic radiosurgery (SRS)/ stereotactic radiotherapy (SRT) in patients with recurrent gliomas pre-irradiated.

### Material and Methods

Between May 2013 and August 2018, 33 patients (56 lesions) with recurrent gliomas (RGs), previously treated with standard Radiotherapy (RT) (50-60 Gy; 1.8-2Gy/fx) with or without concomitant and adjuvant temozolomide (TMZ), were reirradiated with CyberKnife®SRS/SRT. The median time interval between primary RT and reirradiation was 22 months (range 2-116). Twenty patients had a grade IV (GBM), eleven grade III and 2 grade II gliomas. Median Karnofsky performance status was 80 (range 30-100). The total prescription dose of CyberKnife®SRS/SRTretreatment was 20-30 Gy in 5 fractions (fs), 20-26Gy in 4 fs, 15-24 Gy in 3 fs, and 12-24 Gy in single fraction (fx) at isodose line of 80% (range 75-80%). We calculate median overall survival (OS) from the diagnosis date and median OS from reirradiation. Acute and late toxicities were graded according to Radiation Therapy Oncology Group scale.

### Results

Median follow-up was 8 months (range 0-41). 28/33 patients were evaluable for the FU, because 5 patients died before the first FU. Median OS after SRS/SRT was 8 months (range 0.16-43) for all patients, 6 months (range 0.16-41) for GBM and 15 months (range 0.23-43) for grade

II-III. Median OS from the diagnosis was 37 months (range 12-168) for all patients, 28 months (range 14-80) for GBM and 103 months (range 12-168) for grade II-III. No toxicity during treatment was observed, and all patients completed the CK treatment. No patient developed severe (> grade 3) toxicity. Radiation necrosis was observed in 5 patients (15%).

### Conclusion

Our retrospective experience demonstrates that CK® SRS/SRT retreatment is a feasible and well tolerated option for recurrent Gliomas previous irradiated. In these patients the better treatment choice remains individual and based on a multidisciplinary evaluation. However, a longer follow-up and enrolment of more patients are needed to confirm our results and to guide us in choosing the most appropriate treatment.

**EP-1218 Upfront stereotactic radiosurgery in patients with brain metastases from small cell lung cancer**

S. Yomo<sup>1</sup>

<sup>1</sup>Aizawa Hospital, Division of Radiation Oncology- Aizawa Comprehensive Cancer Center, Matsumoto, Japan

### Purpose or Objective

Because of the high likelihood of multiple brain metastases (BM) from small cell lung cancer (SCLC), the role of focal treatment using stereotactic radiosurgery (SRS) has yet to be determined. We aimed to evaluate the efficacy and limitations of upfront SRS for patients with BM from SCLC.

### Material and Methods

Patients with BM from SCLC who received upfront SRS from 2009 to 2018 without prophylactic or therapeutic whole brain radiotherapy (WBRT) were retrospectively identified from an institutional database. Overall survival (OS), neurological death-free survival, remote and local tumor recurrence rates were analyzed.

### Results

None of 86 consecutive patients were lost to follow-up and the median follow-up for censored observations was 10.3 months. The median age was 69 years, and the median Karnofsky performance status was 90. One- and 2-year OS rates were 37% and 11%, respectively. The median OS time was 8.7 months. One- and 2-year neurological death-free survival rates were 11% and 18%, respectively. In total, 240/301 tumors (80%) in 70 patients (81 %) with radiological follow-up data were evaluated. One- and 2-year rates of remote BM relapse were 57% and 62% (per patient), respectively. One- and 2-year rates of local control failure were 16% and 21% (per lesion), respectively. Repeat SRS, salvage WBRT and microsurgery were subsequently required in 36, 14 and 2 patient, respectively. Symptomatic radiation injury, treated conservatively, developed in 3 patients.

### Conclusion

The present study suggested upfront SRS to be a potentially effective and minimally invasive treatment option for BM from SCLC. Although repeat salvage treatment was needed in nearly half of patients to achieve control of distant BM, such continuation of radiotherapeutic management might contribute to reducing the rate of neurological death.

**EP-1219 Prognostic factors of salvage stereotactic radiotherapy for recurrent high-grade glioma.**

K. Takehana<sup>1</sup>, M. Uto<sup>1</sup>, K. Ogura<sup>2</sup>, Y. Arakawa<sup>3</sup>, Y. Mineharu<sup>3</sup>, T. Mizowaki<sup>1</sup>

<sup>1</sup>Kyoto University Hospital, Department of Radiation Oncology, Kyoto, Japan; <sup>2</sup>Kobe City Medical Center General Hospital, Department of Therapeutic Radiology, Kobe, Japan; <sup>3</sup>Kyoto University Hospital, Department of Neurosurgery, Kyoto, Japan

### Purpose or Objective

The treatment of recurrent high-grade glioma (HGG) is challenging. Various treatments including salvage stereotactic radiotherapy (SRT), salvage surgery, bevacizumab (BEV) or chemotherapy are used, but optimal treatment strategy is still unknown. We reviewed patients with recurrent HGG treated with salvage SRT to analyze feasibility, safety and prognostic factors.

### Material and Methods

We retrospectively analyzed patients with histologically proven recurrent HGG who received salvage SRT from October 2007 to February 2018 at our hospital. Patients younger than 18 years old or who received no follow-up MRI were excluded. Overall survival (OS) and progression-free survival (PFS) were calculated by Kaplan-Meier method from the start date of salvage SRT. Cox proportional hazard model was used for multivariate analysis. Toxicity was evaluated by CTCAE version 4.0. A p-value < 0.05 considered to be significant.

### Results

A total of 86 eligible patients were identified. Patient characteristics were as follows; male/female=54/32, median age 52 years old (range, 19-88), latest WHO grade before salvage SRT III/IV=29/57. Initial recurrence pattern was local/diffuse/distant/multiple=46/22/6/12. Clinical target volume was defined as only contrast-enhancing lesion for 27 patients, and contrast-enhancing lesion and high-intensity area on fluid-attenuation inversion recovery image for 59 patients. Median interval between initial radiation and initial recurrence was 12.2 months (range, 1.0-447.3). Median planning target volume was 40.8cc (range, 1.4-491.1). Median prescribed dose of salvage SRT was 25Gy (range, 22.5-35Gy). BEV was administered to 70 patients, of which 51 patients were BEV naïve at salvage SRT and 19 patients were BEV failed at salvage SRT. Median follow-up period was 8.1 months from the start date of salvage SRT. The median OS was 10.4 months (95% confidence interval [CI]: 8.8-12.8) and the median PFS was 6.5 months (95% CI: 4.6-8.3). By multivariate analysis, more than 1 year interval between initial radiation and initial recurrence (HR 0.44, 95% CI: 0.25-0.79, p<0.01) and BEV naïve at salvage SRT (HR 0.37, 95% CI: 0.18-0.75, p<0.01) were identified as favorable factors of OS. Diffuse pattern at initial recurrence (HR 2.35, 95% CI: 1.18-4.68, p=0.04) and WHO grade IV (HR 2.26, 95% CI: 1.20-4.28, p=0.01) were unfavorable factors for OS. Diffuse pattern at initial recurrence (HR 1.80, 95% CI: 1.02-3.17, p=0.04) and WHO grade IV (HR 1.78, 95% CI: 1.05-3.01, p=0.03) were unfavorable factors for PFS.

Grade 2 or higher radiation necrosis developed in 7 patients. Six of them were improved with corticosteroid or BEV but 1 patient required surgery.

### Conclusion

Salvage SRT was feasible and safe treatment for recurrent HGG. Further prospective trials are needed to determine optimal sequencing or combination with BEV.

### EP-1220 Initial Clinical Experience of Carbon Ion Re-Irradiation of Recurrent High-Grade Glioma

Abstract withdrawn

### EP-1221 Palliative cranial irradiation improves survival in PCNSL patients ineligible for systemic therapy

J. Song<sup>1</sup>, R. Samant<sup>1</sup>, X.Y. Fan<sup>2</sup>, M. Jay<sup>3</sup>, H. Chaudry<sup>3</sup>, D. MacDonald<sup>3</sup>, I. Bence-Bruckler<sup>3</sup>, V. Nair<sup>1</sup>

<sup>1</sup>The Ottawa Hospital, Radiation Oncology, Ottawa, Canada ; <sup>2</sup>The Ottawa Hospital, Pathology and Laboratory Medicine, Ottawa, Canada ; <sup>3</sup>The Ottawa Hospital, Hematology, Ottawa, Canada

### Purpose or Objective

Primary central nervous system lymphoma (PCNSL) is a very rare type of cancer representing only 3% of all CNS

malignancies and 1% of non-Hodgkin lymphomas (NHL). Prognosis is generally poor with a median survival of less than 3 months if untreated. Standard of care for PCNSL is upfront high-dose methotrexate-based chemotherapy, with or without whole brain radiotherapy (WBRT). However, in recent years, the role of WBRT in a primary management has been questioned due to its toxicity and lack of convincing data for survival benefit. Even its role in a palliative setting remains to be clearly elucidated. In this retrospective study, data on WBRT for patients who are ineligible for systemic therapy were analyzed and correlated to patient outcomes, compared to the supportive care only.

### Material and Methods

Patients diagnosed with PCNSL between 2002 and 2017 were selected. Patients were excluded if they received systemic therapy or focal radiation only. Data on patient demographics and WBRT (total dose, fractionation, tumor biologically effective dose [a/b=10, BED<sub>10</sub>]) were collected and correlated with clinical outcomes. Survival curves were generated with the Kaplan-Meier method and compared using the log-rank test. Multivariate analysis was performed where prognostic variables and patient outcomes were correlated with the Cox proportional hazard model.

### Results

A total of 48 patients were selected for analysis. Median age at diagnosis was 74 years (range 30-89 years) and median follow up among survivors was 4.4 years. The majority (85.4%) of tumors were identified as diffuse large B-cell lymphoma (DLBCL) on histology. Among all patients, 29 (60.4%) patients completed WBRT, 2 (4.2%) patients did not complete WBRT and 17 (35.4%) patients received no treatment. Median time interval between diagnosis and WBRT was 34 days (range 7-359 days). Median overall survival (OS) was 4.4 months. Patients who received WBRT had significantly better OS (8.8±1.8 months) compared to those with no WBRT (3.3±1.0 months) (p=0.003). In multivariate analyses, the addition of WBRT was associated with improved OS (hazard ratio [HR] 0.37, 95% CI 0.18-0.76, p=0.006). Among patients who received WBRT, whole brain dose higher than 30Gy was not associated with survival outcomes (p=0.43). However, a higher dose (35Gy, p=0.051) and BED<sub>10</sub>(45Gy, p=0.017) to gross tumor were associated with improved OS.

### Conclusion

PCNSL patients who are ineligible for systemic therapy may still benefit from WBRT with a significant improvement in survival outcomes, compared to the best supportive care. Dose escalation through the addition of a gross tumor boost in these patients was associated with an improved overall survival. Future prospective studies are necessary to test the validity and confirm the significance of our study results.

### EP-1222 Simultaneous Integrated Boost in Anaplastic Astrocytoma: a propensity score matching analysis

W.C. You<sup>1</sup>, C. Chen<sup>1</sup>, J. Lin<sup>1</sup>

<sup>1</sup>Taichung Veterans General Hospital, Department of Radiation Oncology, Taichung City, Taiwan

### Purpose or Objective

Local recurrence remains a major cause of disease progression in anaplastic astrocytoma (AA). Escalation of radiation dose may lead to better results. The aim of this study is to evaluate the impacts of temozolomide chemoradiation with simultaneous integrated boost (CCRT-SIB) on clinical outcomes in the AA patients.

### Material and Methods

We retrospectively searched all AA patients who had received surgical resection followed by chemoradiation in our institute from September 2004 to June 2015. Exclusion criteria is histology of oligodendroglioma or the oligodendroglial component was >10%. In CCRT-SIB protocol, a field-in-field escalation of 2.3 Gy per fraction

to tumor bed was applied in addition to 54-60 Gy/30 fractions chemoradiation with temozolomide, with a total of 69 Gy/30 fractions. Univariate and multivariate analyses were utilized for the possible prognostic factors of overall survival (OS).

#### Results

A total of 51 AA patients were identified and 42 patients were enrolled in final analysis by using 1:2 propensity score matching of Karnofsky performance status and extent of resection among the AA patients. The median follow up time is 41 months. CCRT-SIB is associated with better OS (hazard ratio HR: 0.32, 95% CI: 0.11-0.96;  $p=0.042$ ) in univariate analysis. On the contrary, contrast-enhanced AA had worse OS (HR: 6.12, 95% CI: 1.33-28.22;  $p=0.02$ ). The 3-year PFS rate and OS rate in CCRT-SIB was 59.1% and 75%. Acute and long term neurotoxicity was similar.

#### Conclusion

Our study revealed better OS and PFS in the AA patients treated with CCRT-SIB. Further prospective randomized trial is encouraged to define the role of CCRT-SIB.

#### EP-1223 Clinical experience and outcomes of radiosurgery with a single isocentre for 2-10 brain metastases.

S. Rogers<sup>1</sup>, N. Lomax<sup>1</sup>, S. Alonso<sup>1</sup>, B. Eberle<sup>1</sup>, S. Gomez Ordonez<sup>1</sup>, J. Schürkens<sup>1</sup>, E. Rabe<sup>1</sup>, J. Fandino<sup>2</sup>, O. Riesterer<sup>1</sup>, G. Lutters<sup>1</sup>, S. Bodis<sup>1</sup>

<sup>1</sup>Kantonsspital Aarau, Radiation Oncology- KSA-KSB, Aarau, Switzerland ; <sup>2</sup>Kantonsspital Aarau, Neurosurgery- KSA-KSB, Aarau, Switzerland

#### Purpose or Objective

Commercial software has recently become available to facilitate radiosurgery (RS) treatment planning and delivery by using a single isocentre for multiple brain metastases (BMs). Patients with multiple BMs represent 38% of our BM RS case load and have increased by 50% in the last 2 years. We have reviewed our initial experience of the feasibility and efficacy of the single isocentre dynamic conformal arc (SIDCA) technique.

#### Material and Methods

**Methods:** 51 patients, each with 2-10 BMs, have been treated on a Novalis STx Linac in our centre to date. 20 consecutive patients, planned with SIDCA (Elements Multiple Metastases v1.5, Brainlab), were included in the analysis. The standard dose prescription was 1 x 20 Gy, (V20Gy = 99%, with Dmax 115-130%), a 1 mm planning margin with a maximum of 10 cm<sup>3</sup> brain-GTV to receive 10 Gy per metastasis.

#### Results

The 20 patients had a total of 72 BMs. 70% of patients had NSCLC, the female to male ratio was 11:9 and the median age was 70 years (51-81 yrs). In 8/20 patients, BMs were grouped into 2-3 isocentres for either clinical indications (e.g. fractionated RS due to volume or postoperatively) or rotational uncertainties (> 4cm from isocentre) rather than increase the planning margin. Dose prescriptions were 52/72 BMs: 1 x 20 Gy, 7/72: 1 x 15-18 Gy, 13/72: 5 x 5-6 Gy according to patient and tumour factors. Mean single fraction PTV dose (59 BMs) was 22.1 Gy (15.8-23.95 Gy) and mean fractionated PTV dose (13 BMs) was 32.93 Gy (27.41-33.85 Gy). For single fractions, median PTV volume was 0.29 cm<sup>3</sup> (0.09-2.78 cm<sup>3</sup>) with a median total PTV volume of 1.08 cm<sup>3</sup> (0.36-7.74 cm<sup>3</sup>) per patient. For fractionated RS, these median volumes were 3.95 cm<sup>3</sup> (2.36-11.9 cm<sup>3</sup>) and 10.2 cm<sup>3</sup> (6.3-22.9 cm<sup>3</sup>) respectively. 5/20 patients had previous or simultaneous RS to single metastases or a surgical cavity, which increased the irradiated volumes and therefore sum plans were generated (Eclipse, Varian). At 6 week clinical follow-up, 3 patients still required steroids. 5 patients developed distant brain failure 3-6 mths after RS, of whom 3 received further SIDCA RS to the new BMs. 11 patients have died (med OS 6 mths, 2-13 mths); of these 9/11 patients (82%),

showed control of the irradiated BMs (3 CR, 3 PR, 4 SD according to the RANO criteria) at last follow-up.

#### Conclusion

SIDCA has been successfully implemented for patients with multiple BMs (and is also in routine use for patients with single BMs, as it can considerably decrease the duration of RS planning, verification and reporting). The irradiation of multiple BMs up to 4cm from the isocentre with the same fractionation scheme and a 1 mm margin is feasible, efficient and effective in daily practice. Local control rates > 80% are equivalent to those achieved in our centre with RS for single BMs.

#### EP-1224 Re-Irradiation in Recurrent Gliomas:

##### Treatment outcome and Prognostic factors

M. Mukherjee<sup>1</sup>, J. Bhattacharya<sup>1</sup>, T. Shahid<sup>1</sup>, V.

Kontham<sup>1</sup>, R. Rajan<sup>1</sup>, R. Talukdar<sup>1</sup>, A. De<sup>1</sup>

<sup>1</sup>Apollo Gleneagles Hospital, Radiation Oncology, Kolkata, India

#### Purpose or Objective

Gliomas have diverse prognoses that differ primarily depending on histologic subtype, grade and molecular marker expression. Even after aggressive multimodal treatment, most gliomas eventually recur. Treatment options for recurrent gliomas include surgery, chemotherapy, and re-irradiation. We sought to review our institutional experience with re-irradiation in the management of recurrent gliomas.

#### Material and Methods

We retrospectively reviewed 31 patients with recurrent or progressive gliomas who received re-irradiation between January 2012 and December 2016. Majority (20 patients) constituted High Grade Glioma. (Grade III and IV). Though the recurrence was more in Grade IV Glioma but these patients were not included in our analysis because of their poor performance status and Re-RT was not feasible in them. All the patients were assessed for Re-Surgery. Re-irradiation was offered to recurrent glioma patients with good performance status and at least 6 months had passed after initial radiotherapy (RT). All the patients were treated after doing planning CT Scan (Non-Contrast) and MRI of Brain (3 D FSPGR sequence) with I.V contrast and images were fused for target delineation. Target volume was delineation was kept conservative and the mean volume was 80 cc (50 to 140 cc). Technique of Radiotherapy was IMRT/VMAT and fractionation used was conventional. 11 patients were treated with concurrent oral Tab TMZ and 1 patient was treated with Inj Bevacizumab, 2 weekly cycle.

#### Results

Out of 31 patients, 11 patients were found to be fit for Re-Surgery but only 8 patients agreed to do so. All the patients received Re-Radiation. Median doses of re-irradiation and initial RT were 45.0 Gy and 59.4 Gy, respectively. The median time interval between initial RT and re-irradiation was 18 months. The median PFS and OS after re-irradiation were 3 and 7 months respectively. 12-month OS rate was 40%. 3 patients developed radiation necrosis and needed prolonged steroid therapy. In univariate analysis, Karnofsky performance status (KPS)  $\geq 70$  ( $p < 0.001$ ), re-irradiation dose  $\geq 45$  Gy ( $p = 0.040$ ), and longer time interval between initial RT and re-irradiation ( $p = 0.040$ ) were associated with improved OS. In multivariate analysis, KPS ( $p = 0.030$ ) and length of time interval between initial RT and re-irradiation ( $p = 0.048$ ) were important predictors of OS. Use of TMZ did not show any benefit. Molecular markers were not available for most of the patients and hence correlation could not be done.

#### Conclusion

Re-irradiation in conjunction with surgery could be a salvage treatment for very selected recurrent glioma patients with good performance status. Re-irradiation was associated with only modest palliative and survival

benefits in this retrospective review. Difficulties separating toxicity due to retreatment versus tumor progression and limited patient survival following retreatment preclude definite conclusions. Radiation necrosis was infrequent. In spite of multimodality treatment, the treatment outcome remains dismal.

#### EP-1225 Stereotactic Radiotherapy for Spine metastases using Brainlab® Elements Spine: preliminary results

N. Gaj Levra<sup>1</sup>, M. Rigo<sup>1</sup>, V. Figlia<sup>1</sup>, R. Mazzola<sup>1</sup>, L. Nicosia<sup>1</sup>, F. Ricchetti<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Alongi<sup>1,2</sup>  
<sup>1</sup>IRCCS Ospedale Sacro Cuore-Don Calabria, Radiation Oncology, Negrar, Italy ; <sup>2</sup>University of Brescia, Radiation Oncology, Brescia, Italy

#### Purpose or Objective

Stereotactic body radiation therapy is an emerging treatment option in several anatomical sites. Recently a new dedicated software (Brainlab® Elements Spine SRS™) has been developed in order to optimize the stereotactic body radiation treatment (SBRT) workflow in oligometastatic patients with spinal lesions. The prescription of ablative radiation dose to spine allows to potentially increase the probability to eradicate the metastatic disease and consequently improved local control. We report the initial experience of SBRT in spine metastases.

#### Material and Methods

Between March and September 2018, 27 spinal metastases on 16 patients underwent to spinal SBRT. The clinical target volume (CTV) was automatically generated on CT scan with fusion-image magnetic resonance imaging (MRI) and or PET-CT according to international spine radiosurgery consortium consensus<sup>1</sup>. A margin of 1 mm in all directions was added for the planning target volume (PTV). Dose prescription varied between 12 Gy to 30 Gy in 1 to 3 fractions. The dose-volume constraints for spinal was  $D_{1cc} < 13$  Gy in single fraction and  $D_{1cc} < 20$  Gy in 3 fractions. SBRT was delivered with volumetric modulated arc technique (VMAT) using multiple Arcs. Daily CBCT was performed. The patients were evaluated at the end of treatment, 3 months for toxicity and treatment response with MRI or PET-CT.

#### Results

The main patients' and lesions' characteristics are summarized in Table 1. In 4 patients a previous conventional radiation treatment to the vertebra was performed and a SBRT re-treatment was proposed. Before SBRT treatment median Numerical Rating Scale (NRS) was 2 (range 0-7). This value was confirmed at the end of SBRT. At the time of follow-up, we evaluated 10 patients out of 16. Median follow-up was 3 months (range 2-6 months). Local control of the spinal metastatic site was observed in all cases and at the time of follow-up NRS was 0 (range 0-3). No cases of  $\geq 3$  toxicity were reported.

Table 1 Summary of patients' and lesions' characteristics

Patients' and lesions' number	16 and 27
Mean age (range) [years]	66 (45-83)
Gender (M:F)	11:5
Primitive cancer (lesions' number)	
Prostate	9
Breast	9
Lung	4
Pancreas	1
Melanoma	1
Renal	3
Metastatic vertebra	
Cervical	5
Dorsal	18
Lumbar	4

#### Conclusion

SBRT by means of Brainlab® Elements Spine SRS™ seems to be a feasible, safe and effective treatment in oligometastatic patients with spinal metastases. A higher accrual and longer follow-up are necessary to establish its role in spinal oligometastatic patients.

#### EP-1226 Survival in patients with melanoma brain metastases treated by stereotactic radiotherapy

S. Lambert<sup>1</sup>, A. Huchet<sup>1</sup>, R. Trouette<sup>1</sup>, V. Karahissarlian<sup>1</sup>, C. Pouypoudat<sup>1</sup>, V. Atallah<sup>1</sup>, C. Dutriaux<sup>2</sup>, V. Vendrely<sup>1</sup>  
<sup>1</sup>CHU Bordeaux, Radiotherapy, Bordeaux, France ; <sup>2</sup>CHU Bordeaux, Dermatology, Bordeaux, France

#### Purpose or Objective

The development of immunotherapy or targeted therapies improved survival of patients treated for melanoma in last decade. Brain is one of the most frequent site of metastases in melanoma, treated by stereotactic radiotherapy (SR) whenever possible. The main side effect of this treatment is the development of radionecrosis in the irradiation field. The objective of this retrospective study is to evaluate the Overall Survival (OS), the event-free survival (EFS) (progression or radionecrosis) inside the radiation field, and the progression-free survival outside the radiation field, in patients treated for melanoma's brain metastases by SR.

#### Material and Methods

Ninety Four patients treated by SR, in our center, between first January 2011 and 31 december 2017 were included. Patients's prognostics characteristics before irradiation: number of metastases, Karnofsky Performance status (KPS), and the Graded prognostic assessment (GPA) score were collected for all of them. Datas about progression or radionecrosis were registered from radiologist's reports of follow-up's MRI after SR. Survival was calculated from the last irradiation day, with a Log-Rank method.

#### Results

With a median follow up of 11, 2 months. The KPS was at least 80% for 87 patients (93%), the number of brain metastasis was less than 3 for 88 patients (94%), and 69 patients (74%) had a GPA score of 3 or 4. The median OS was 12,2 months, with a 1-year OS and a 2 years OS respectively of 51% and 38%. The median EFS inside the radiation field was 14,9 months with a 1-year EFS and a 2 years-EFS of respectively 56% and 36%. The median progression-free survival outside the radiation field was 50% with a 1-year and 2-years progression-free survival of respectively 37% and 30%.

#### Conclusion

With an OS, at one and two years of respectively 51% and 38%, our results are similar to recent studies and confirm an improve of survival for melanoma patients with brain metastases treated by stereotactic radiotherapy.

#### EP-1227 The impact of first MR in clinical decision making of patients with HGG treated with RTCT

M. Cantarella<sup>1</sup>, F. Pasqualetti<sup>2</sup>, A. Gonnelli<sup>2</sup>, A. Molinari<sup>2</sup>, F. Paiar<sup>2</sup>  
<sup>1</sup>Casa di Cura San Rossore, Radiotherapy, Pisa, Italy ; <sup>2</sup>Azienda Ospedaliera Universitaria Pisana, Radiotherapy, Pisa, Italy

#### Purpose or Objective

Standard up-front therapy of high grade glioma (HGG) is focused on the so called Stupp protocol, that includes surgical resection followed by radiotherapy (RT) combined with concomitant and adjuvant chemotherapy with temozolomide (TMZ). As supported by several international guidelines, disease assessment is performed using magnetic resonance (MR) one month since the end of RT and then every 3 months: in case of tumour progression the administration of temozolomide (the most active agent against glioma) is interrupted and salvage therapy or best supportive care are recommended. The aim of this study is to investigate in a retrospective

manner the real value of first MR following RT and its relevance in clinical decision making about up-front therapy.

#### Material and Methods

Between April 2005 and July 2017, data of 78 patients (pts) with a proven diagnosis of HGG and treated with Stupp protocol at the University Hospital of Pisa were collected. Tumor progression was defined according to Mac-Donald's Criteria. Considering the potential presence of pseudo-progression (PSP) and the evolutionary pattern of the suspected recurrences, lesions suggestive for tumor progression inside the radiotherapy field were investigated with a new MR after 6-8 weeks. Otherwise, the presence of new lesions outside the radiotherapy field was interpreted as disease progression (PD) and patient's therapy was changed. Presence or absence of symptoms, extent of surgery and MGMT methylation status were recorded.

#### Results

The first MR after RT-CT evidenced infield progression (interpreted as PSP) in 16 pts (20.5%) and outfield progression in 8 (10.2%). Three out of 8 patients with outfield progression were symptomatic for the tumor growth. The second MRI confirmed the presence of PSP in 10 pts out of 16 pts whereas in 6 patients a true progression (PD) was present since the first MR.

#### Conclusion

In absence of symptoms, the first MR after radiochemotherapy influenced clinical decision making (sending the patients to further salvage therapy or BSC) only in 5 out of 78 patients (6.4%). In 72 patients, even in presence of radiological signs suggestive for disease progression inside the RT field, clinical decision making did not change. Further studies involving a higher number of patients are required in order to confirm our findings.

#### EP-1228 Omission of WBI does not impair cerebral control in solitary brain mets treated with focal RT

H. Kahl<sup>1</sup>, H. Müller<sup>2</sup>, V. Heidecke<sup>2</sup>, G. Stüben<sup>1</sup>

<sup>1</sup>Klinikum Augsburg, Strahlenklinik, Augsburg, Germany ;

<sup>2</sup>Klinikum Augsburg, Neurochirurgische Klinik, Augsburg, Germany

#### Purpose or Objective

Does omission of whole brain irradiation (WBI) lead to inferior neuro-cerebral control (NC) in unselected patients with singular brain metastasis?

#### Material and Methods

This is a retrospective study of 166 consecutive patients treated for singular brain metastasis from 1.1.2010 to 31.7.2017 at the radiotherapy department of Klinikum Augsburg. As endpoints overall survival (OS), local (LC) and distant (DC) cerebral control rates as well as the definitive NC were analyzed. 45 patients had a neurosurgical resection and a whole brain irradiation (OP+WBI/ median FU 8.1 months), 23 patients received a percutaneous stereotactic irradiation of the tumor cavity after resection (OP+SX/ median FU 11.3 months). 13 patients had an intraoperative radiotherapy of the tumor cavity with 50kV X-rays (OP+IORT/median FU 13.9 months). 85 patients were treated with radiosurgery alone (SX/ median FU 8.1 months). 128 patients (OP+WBI 29/OP+SX 18/ OP+IORT 13/SX 68) with available MR FU were used for the Kaplan-Meier estimation of LC, DC and NC. The term neuro-cerebral control (NC) - was introduced to evaluate the efficiency of all treatment strategies including salvage therapies (SX/OP/WBI) with regard to tumor control in the brain during the total course of disease. In this context NC is not achieved, if the last MRI of the CNS shows progressive disease independent of the patient's definitive cause of death.

#### Results

1-year OS (2-years OS) for OP+ WBI was 46% (33%), for OP+SX 82% (67%), for OP+IORT 92% (82%) and for SX 62%

(41%). 1y LC for OP+WBI was 69.4%, for OP+SX 79.4%, for OP+IORT 82% and 84.4% for SX. As expected 1y-DC of the OP+WBI patients (88.7%) was better than the 1y-DC of the focally irradiated patients (72.7% OP+SX/ 40% OP+IORT/50.9% SX). All patients with cerebral recurrences were treated with salvage therapy according to their pattern of relapse (SX/ WBI/ OP+/- IORT or SX). As a result of all treatments following 1y-NC were achieved: 68.9% OP+WBI, 88.9% OP+SX, 78.8% OP+IORT and 88.2% SX. 2y-NC was: 63.6% OP+WBI, 71.1% OP+SX, 78.8% OP+IORT and 88.2% SX. WBI could be avoided for most of the patients within the first (2<sup>nd</sup>) year: OP+ SX 94.4% (85.0%), OP+IORT 72.9% (72.9%), SX 74.8 % (60.4%).

#### Conclusion

This data provides further evidence for safe omission of WBI even in an unselected patient group with singular brain metastasis. All focal forms of radiotherapy +/- surgery used at the Klinikum Augsburg lead to a good persistent cerebral control (NC), despite of inferior DC compared to patients treated with WBI. For 2 out of 3 patients WBI was never necessary in the whole course of disease. However, regular MR Imaging is essential to detect and treat frequent distant relapses before they get symptomatic for the patients.

#### EP-1229 Repeated intracranial radiotherapy/SRT-Analysis of efficacy and safety including EQD2 sum plans

C. Schröder<sup>1</sup>, I. Stiefel<sup>1</sup>, S. Tanadini-Lang<sup>1</sup>, I. Pytko<sup>1</sup>, M. Guckenberger<sup>1</sup>, N. Andratschke<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland

#### Purpose or Objective

The number of patients receiving cranial re-irradiation for primary or metastatic lesions is rapidly growing since the introduction of stereotactic radiation techniques. Hence, it is possible to deliver multiple treatments in a very localized way, therefore sparing organs at risk and allowing for repetitions. Still the effect of multiple stereotactic treatments has to be carefully evaluated regarding safety and efficacy. We therefore analyzed diametrical and clinical data of patients receiving repetitive cranial irradiation using EQD2 sum plans created with non-rigid-registration to allow for optimal dose summation.

#### Material and Methods

We retrospectively analyzed the data of 76 patients that received repeated cranial radiotherapy from February 2013 to September 2016. 34 of those patients suffered from primary brain lesions (e.g. Glioblastoma), 42 from brain metastases. Patients with primary brain tumors received stereotactic radiotherapy to the GTV defined in a treatment-planning MRI plus a 3mm margin to derive the PTV, those with brain metastases to the GTV plus a 1 mm (definite RT) or 2 mm (adjuvant RT) margin.

EQD2 sum plans using non-rigid registration were calculated for all courses of intracranial radiotherapy using Aria Eclipse (Varian Medical Systems, Version 10) and MIM (MIM Software Inc. Version 6.7.9). Dose parameter were calculated for common organs at risk (e.g. brainstem) and target volumes (PTV). Clinical and radiological data was collected at regular follow-up appointments including toxicity, local control and survival.

#### Results

In total 76 patients received at least 2 courses of intracranial radiotherapy. 23 a third, 8 a fourth and 3 a fifth course of radiotherapy. The median prescription dose was 30 Gy for all RT courses combined. The median Dmean of the brain was 35 Gy (range 0.9 - 57.7 Gy) with a median D(1cc) of 99.1 Gy (range 40.9 - 142.2). The median D(1cc) of the brainstem was 38.4 (range 0.1 - 94.6 Gy), the median D(0.1cc) of the Chiasm was 33.2 (range 0.04 - 72.2 Gy). 74 % of patients suffered from low grade (G1-G2) acute toxicity, usually in the form of headache (18.4

%) and fatigue (19.7 %). There were only 2 >G3 toxicities with one patient developing seizures and one fatal radionecrosis.

At the time of analysis, 40 patients are still alive. Median OS from the time of first re-irradiation was 57 months (range 4 - 186 months). When looking at all treatment courses combined up to 58 % of patients had an intracranial controlled disease after any course of radiotherapy.

#### Conclusion

Repeated radiotherapy appears both safe and efficient in patients with recurrent primary or secondary brain tumors. There were only few high grade treatment related toxicities.

#### EP-1230 Hippocampal sparing radiotherapy in patients with primary brain tumors (PBT)

M. Konopka-Filippow<sup>1,2</sup>, E. Sierko<sup>1,2</sup>, D. Hempel<sup>1,2</sup>, E. Szweczek<sup>3</sup>, M. Wojtukiewicz<sup>2</sup>

<sup>1</sup>Comprehensive Cancer Center in Bialystok, Department of Radiotherapy, Bialystok, Poland ; <sup>2</sup>Medical University of Bialystok, Department of Oncology, Bialystok, Poland ; <sup>3</sup>Comprehensive Cancer Center in Bialystok, Department of Physics, Bialystok, Poland

#### Purpose or Objective

Radiotherapy (RT) is an integral part of brain cancer treatment in patients with primary brain tumors (PBT), but is also associated with deteriorated cognitive and memory functions. The aim of study was to report a dosimetric profile of contralateral hippocampal sparing (HS) RT for the treatment of PBT.

#### Material and Methods

HS RT was delivered in 15 patients with PBT using the volumetric modulated arc therapy (VMAT) technique between May 2016 and February 2018 at Comprehensive Cancer Center in Bialystok, Poland. The medical records and dosimetric parameters of RT plans: volumes of hippocampi, planning target volume (PTV), mean dose (Dmean), maximum dose (Dmax), D98% on hippocampus, D2% and Dmean on other organs at risk (OARs) (optic nerves, optic chiasm, lenses, brainstem) expressed as equivalent to a 2-Gy dose (EQD2/2) were analyzed. RT plans were designed in Monaco Treatment Planning System, version 5.11.02, algorithm Monte Carlo Phantom.

#### Results

The median age was 55.4 (range 33-72) years and 62.5% were female. Eleven patients (73.3%) had WHO grade III or IV tumor, whereas 4 patients (26.6%) had grade II tumor. The median PTV volume was 428.01 (range 135-800) cm<sup>3</sup> and the median prescribed dose was 60 (range 40-60) Gy. Concurrent chemotherapy was administered to nine patients (60%). Dmean and Dmax to the contralateral hippocampus was 12.64 (range 2.7-40) Gy and 15.87 (range 1,7-51) Gy, respectively.

#### Conclusion

Effective HS was made possible with the development of sophisticated RT delivering techniques such as VMAT. The contralateral hippocampus could be effectively spared in patients with PBT via VMAT. Further investigation is needed to qualify patients who will most benefit from HS - RT of the PBT.

#### EP-1231 Immune checkpoint inhibitor and encephalic radiotherapy: Toxicity and Adverse events

P. Matteucci<sup>1</sup>, B. Santo<sup>1</sup>, E. Ippolito<sup>1</sup>, P. Zuccoli<sup>1</sup>, G.M. Petrianni<sup>1</sup>, P. Trecca<sup>1</sup>, S. Gentile<sup>1</sup>, M. Miele<sup>1</sup>, S. Palizzi<sup>1</sup>, L. Trodella<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Università Campus Bio-Medico Roma, Radioterapia Oncologica, Roma, Italy

#### Purpose or Objective

Recently, immune checkpoint inhibitors (ICIs) have shown highly promising responses in solid tumors. Intracranial metastases are a common cause of morbidity and

mortality in patients with tumor, and are frequently managed with radiation therapy (RT). The safety of cranial RT in the setting of treatment ICIs has not been established. We aimed to assess toxicity and adverse events (AEs) in a cohort of patients who received cranial RT and were treated with anti programmed cell death-1 (PD-1).

#### Material and Methods

We identified 12 patients with advanced solid tumors (10 Non Small Cell Lung Cancer (NSCLC) -83.3%-, 1 melanoma-8.3%- and 1 renal cell carcinoma-8.3%-) with brain metastases, who received cranial RT and were treated with anti PD-1. RT-related AEs were retrospectively evaluated and analyzed according to ICI treatment status, cranial RT type, and timing of RT with respect to ICI.

#### Results

We enrolled 12 patients, between July 2017 and May 2018: 7 (58.3%), 2 (16.7%), and 3 (33.3%) patients received stereotactic RT, whole brain RT or both, respectively. 33.3% of patients received more than one stereotactic course. We observed seizures in one patient during whole brain RT who was symptomatic before treatment; Levitaceram dose escalation and mannitol were used to control seizures. We observed only one radionecrosis (8.33%) occurring 2 months after the end of stereotactic RT. We observed no significant difference in acute neurological toxicity between patients who received whole brain RT or stereotactic RT. Additionally, there was no difference in AE rates on the basis of timing of ICI administration with respect to RT. Cognitive evaluation is in full swing. The median follow up was 5 months, but 2 patients (16.7%) died before follow up and 2 (16.7%) haven't reassessed yet. 6 patients (50%) had brain MRI after RT: 2 (33.3%) had brain progression after stereotactic RT, 3 (50%) complete response after stereotactic RT and 1 (16.7%) partial response after whole brain RT. 2 patients (16.7%) died before MRI evaluation for extracranial disease progression and 4 patients (33.3%) will have MRI in the next few months.

#### Conclusion

Treatment with an ICI and cranial RT was not associated with a significant increase in RT-related AEs, suggesting that use of anti PD-1 in patients receiving cranial RT may have an acceptable safety profile. Nonetheless, additional studies are needed to validate this approach.

#### EP-1232 Hypofractionated RT in very elderly patients (≥ 75 years) diagnosed with GBM

C. Cavallin<sup>1</sup>, C. Mantovani<sup>2</sup>, G.C. Iorio<sup>1</sup>, I. Chiovatero<sup>1</sup>, S. Martini<sup>1</sup>, V. De Luca<sup>1</sup>, C. Palladino<sup>1</sup>, M. Levis<sup>2</sup>, F. Franchino<sup>3</sup>, R. Rudà<sup>3</sup>, U. Ricardi<sup>1</sup>

<sup>1</sup>University of Turin, Department of Oncology- Radiation Oncology, Torino, Italy ; <sup>2</sup>AOU Città della Salute e della Scienza, Department of Oncology- Radiation Oncology, Torino, Italy ; <sup>3</sup>AOU Città della Salute e della Scienza, Department of Neuro-Oncology, Torino, Italy

#### Purpose or Objective

Glioblastoma (GBM) is a highly aggressive tumor with a very dismal prognosis. Elderly patients are at poorer prognosis compared to younger ones and in some cases the benefit of hypofractionated radiotherapy (HFRT) +/- temozolomide (TMZ) is questionable. In this study, We aimed to report the efficacy of a HFRT schedule (42 Gy/14 fr) in a very elderly population (≥ 75 years) and to identify any prognostic factor for this critical group of patients.

#### Material and Methods

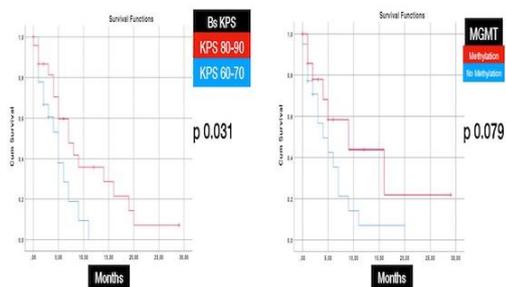

We retrospectively analysed the data of 45 very elderly patients ≥ 75 years affected with GBM, treated at our Institution between 2010 and 2018 with tridimensional conformal radiotherapy (3D-CRT). The median age at diagnosis was 76 years old (range 75-85). All patients underwent a multidisciplinary evaluation before treatment. Thirty-three patients (73,3%) underwent an upfront surgical approach: 17 (38%) underwent a

macroscopically radical resection while 16 (35,5%) received a partial resection. The remaining 12, deemed as non-surgical patients, had just a neuroradiological diagnosis of GBM in 10 cases, while 2 of them (4,4%) were biopsied. MGMT promoter was methylated in 33,3% (15/35 patients) of the surgical cohort. IDH-1 mutation was reported in just 1 patient (1/35, 2,2%). Oral temozolomide (TMZ) was given, either in the concomitant or in the adjuvant setting, to 15 (34,9%) and to 20 patients (50%) respectively. Overall survival (OS) was estimated since the last day of HFRT.

### Results

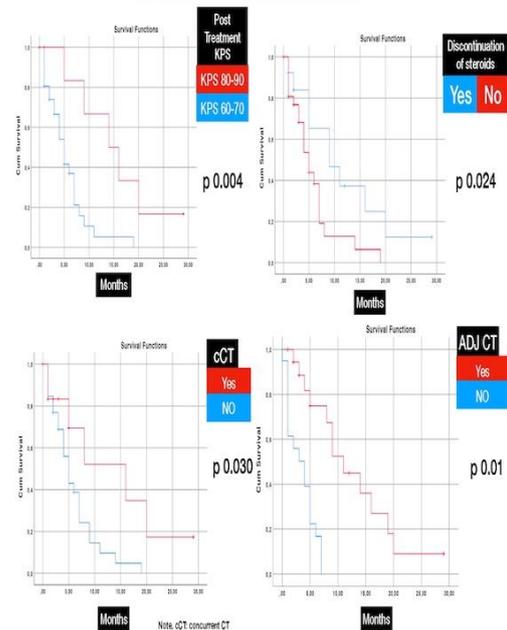

All patients completed the prescribed RT course of 42 Gy in 14 daily fractions (3 Gy/die), except one (2,2%) that was stopped at a total dose of 36 Gy, due to the worsening of neurological conditions. Median OS was only 6 months for the overall population. We observed that baseline (Bs) KPS was related to OS; in fact, patients with KPS >70 had a longer median survival time (7 vs 5 months,  $p$  0.031) compared to patients with KPS  $\leq$ 70. MGMT promoter methylation is related with a marginal OS benefit (median OS 9 vs 4 months,  $p$  0.079) (Fig1).

Fig.1 Pre-Treatment Prognostic Factors

Moreover, we observed that post-HFRT KPS >70 ( $p$  0.004), discontinuation of the steroid therapy ( $p$  0.024) and administration of concurrent ( $p$  0.030) or adjuvant CT ( $p$  0.01) were related to a better OS (Fig2).

Fig.2 Post-Treatment Prognostic Factors

At the multivariate analysis (MVA) administration of adjuvant CT was the only variable related to a better survival ( $p$  0.04; HR 0,268, CI 0,074-0,964), while KPS >70 post HFRT conferred a marginal survival benefit ( $p$  0.06; HR 0,125, CI 0,014-1,103).

### Conclusion

In the management of very elderly GBM patients, HFRT 3D-CRT, eventually combined with concurrent or adjuvant TMZ, appears to be a feasible and beneficial therapeutic option in patients with favorable features, such as good Bs KPS and MGMT promoter methylation. On the other hand, We suggest an accurate clinical and radiological multidisciplinary evaluation for patients at poorer prognosis (baseline KPS 60-70 and un-methylated MGMT promoter), in order to select the best treatment option (HFRT vs best supportive care) on a *case by case* strategy definition.

### EP-1233 Stereotactic radiosurgery to brain metastases using Varian HyperArc in the Beatson Cancer Centre

O. Kjartansdottir<sup>1</sup>, A. Williamson<sup>2</sup>, A. Patibandla<sup>1</sup>, S. Currie<sup>3</sup>, R. Carruthers<sup>4</sup>, A. Chalmers<sup>4</sup>, A. James<sup>1</sup>, S. Nowicki<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom ; <sup>2</sup>Beatson West of Scotland Cancer Centre, Radiotherapy, Glasgow, United Kingdom ; <sup>3</sup>Beatson West of Scotland Cancer Centre, Physics, Glasgow, United Kingdom ; <sup>4</sup>Institute of Cancer Sciences- University of Glasgow, Clinical Oncology, Glasgow, United Kingdom

### Purpose or Objective

Stereotactic radiosurgery (SRS) has been established as an effective way of treating patients with metastases, delivering high doses to target lesions whilst sparing normal tissues in a highly conformal way. The Varian HyperArc VMAT treatment planning system utilizes several specialized functions to optimize a treatment plan, including 5 non-coplanar hemi-arc beam arrangements, automated settings for isocentre location and collimator angles, aiming to further increase conformity of target dose while reducing doses to surrounding normal tissues. HyperArc became available for clinical use in the Beatson Cancer Centre in October 2017. Prior to this we had already moved from a multi- to a single-isocentre

approach utilizing 2 co-planar full arcs 10X FFF (Flattening Filter Free) VMAT. The aim of this study was to review SRS treatment delivered via HyperArc in the Beatson Cancer Centre to determine if further optimization was achieved.

#### Material and Methods

We reviewed data on the first 36 patients treated using HyperArc planned SRS from October 2017 to September 2018, compared to a cohort of 105 patients treated with SRS with the previous technique. For treatment planning GTV was defined as the edge of the targeted contrast enhancing lesion on fused CT/MRI images. The PTV (there was no CTV) was generated by geometrically expanding the GTV by 2mm. Treatment was prescribed to the 80% isodose line. The evaluated parameters for PTV were dose, volume, number of lesions and gradient index (GI). Clinical records were reviewed to obtain information on age, gender, histology and adverse events reported within one week of SRS.

#### Results

36 patients were identified. Median age was 64 and 58% were female. Primary sites were 47% lung, 24% breast, 13% renal, 8% melanoma and 8% others. The most frequent radiosurgical dose delivered to the isocentre was 20Gy (58%) followed by 16Gy (31%). 75% had a single lesion, 17% had 2 lesions and 8% had 3 or more lesions treated. The median GI for single metastases was 2.98 (range 2.48-3.81) compared to a median GI of 3.47 (range 2.58-4.87) for the previous cohort ( $p < 0.01$ ). Median GI for multiple metastases was 3.33 (range 2.35-3.95) compared a median GI of 4.06 (range 2.76-5.17) for the previous cohort ( $p < 0.01$ ). The median PTV was 4.69cm<sup>3</sup> (range 0.45-16.74) compared to 6.0cm<sup>3</sup> (range 0.46-28.63) for the previous cohort. The only reported toxicity was one patient who had a seizure post SRS. Treatment response was assessed using MRI at 6 weeks and was similar for the 2 cohorts.

#### Conclusion

For patients with brain metastases, treatment with SRS delivered via HyperArc planning results in better conformity compared to the previous treatment planning system, with a more rapid fall-off in dose outside the treated lesion reducing the brain volume receiving significant dose. With the increasing use of SRS to treat patients with multiple metastases, this will potentially reduce the morbidity of the treatment.

#### EP-1234 Salvage radiotherapy and radiosurgery for first progression of supratentorial glioblastoma.

K. Nikitin<sup>1</sup>, A. Belyashova<sup>1</sup>, A. Golanov<sup>1</sup>, S. Zolotova<sup>1</sup>  
<sup>1</sup>Burdenko Neurosurgical Institute, Department of Radiation Oncology, Moscow, Russian Federation

#### Purpose or Objective

radiosurgery, hypofractionated and conventional fractionated irradiation was delivered for patients with first progression of supratentorial primary glioblastoma in Burdenko Neurosurgical Institute in 2009-2018. Authors presented a retrospective analysis of clinical data.

#### Material and Methods

130 patients (74 man and 56 women) with histologically confirmed primary glioblastoma (NOS - 115, IDH-wild type - 15 patients) were included in the study. Patient age was 18 - 74 years, mean age was 46 years. All patients underwent tumor removal (total, subtotal or partial) followed by conformal radiotherapy (58-63 Gy in 29-33 fractions) to primary tumor site with temozolomide. After completion of radiotherapy all patients received adjuvant chemotherapy with temozolomide. Mean time from completion of radiotherapy to first progression was 9.3 months.

First progression as single growing lesion in primary tumor region (locally) was observed 102 (78.5%) patients. Single distant new lesion in brain parenchyma with absence of progression in primary site had 17 (13%) patients. Multifocal progression (multiple new lesions) occurred in 11 (8.5%) patients. At the time of progression patients

started second-line chemotherapy or salvage irradiation or its combination.

13 patients with lesions smaller than 11 cm<sup>3</sup> received stereotactic radiosurgery with single dose of 15-24 Gy delivered with CyberKnife or Novalis (6 MeV LINAC). 69 patients with bigger tumors (8 - 48 cm<sup>3</sup>, median volume - 12.7 cm<sup>3</sup>) were irradiated with 3 to 7 fractions every day or every other day up to total dose of 21 - 39.5 Gy with CyberKnife. 48 patients with large lesions (63 - 382 cm<sup>3</sup>, median - 213 cm<sup>3</sup>) received 54-60 Gy in 30 fractions with Novalis or Primus (6 MeV LINAC).

#### Results

Mean follow-up was 13.3 months. Mean time from salvage irradiation to second progression was 6.2 months, mean overall survival after salvage irradiation was 18 months. Preliminary results showed better survival in patients received bevacizumab-based chemotherapy.

In 12 of 152 irradiated lesions (8%) clinically significant radiation necrosis developed, all were successfully treated with bevacizumab.

#### Conclusion

salvage irradiation with bevacizumab is an appropriate option for non-invasive treatment for first progression of supratentorial glioblastoma.

#### EP-1235 Response to re-RT helps deciding dose and predicts survival in Diffuse Intrinsic Pontine Glioma

J. Manjali<sup>1</sup>, T. Gupta<sup>1</sup>, J. Goda Sastri<sup>1</sup>, G. Chinnaswamy<sup>2</sup>, V. M Patil<sup>3</sup>, R. Krishnatry<sup>1</sup>

<sup>1</sup>Tata Memorial Hospital, Radiation Oncology, Mumbai, India ; <sup>2</sup>Tata Memorial Hospital, Paediatric Oncology, Mumbai, India ; <sup>3</sup>Tata Memorial Hospital, Medical Oncology, Mumbai, India

#### Purpose or Objective

Retrospective review for re-irradiation(reRT) in Diffuse Intrinsic Pontine Glioma (DIPG).

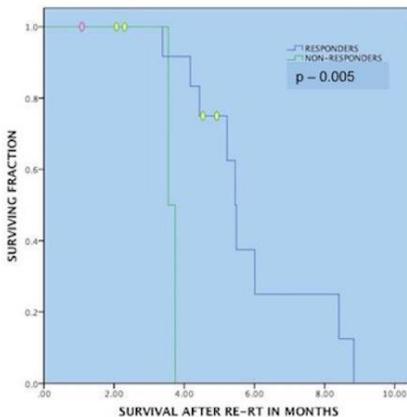

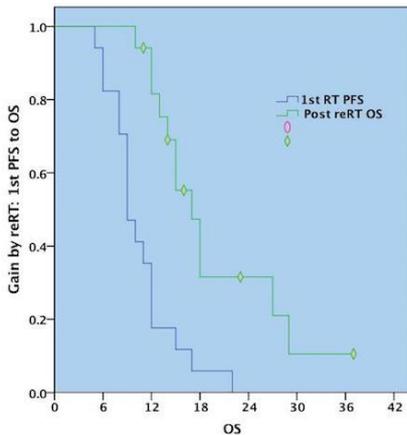

#### Material and Methods

Retrospective review of patients who underwent reRT since April 2016. The demographic, clinical and treatment details (descriptive statistics) are reviewed. The outcomes (progression-free survival; PFS, Overall Survival; OS: using Kaplan Meier and Log-rank test) and steroid use rates (descriptive statistics) is determined. OS difference for non-responders vs responders on reRT (at 10<sup>th</sup> -15<sup>th</sup> fraction clinical improvement determining total reRT dose <30.6 vs 39.6-45Gy respectively) using log-rank test.

#### Results

All consecutive 17 patients who received reRT were included. Their median age-at-initial diagnosis was 8 years, mean Lansky play-performance scale (LPS) of 65, diagnosed with >2/3 clinical criteria + all radiological criteria (100%) and received initial radiotherapy (RT) 54Gy/30# using 3DCRT resulting in >50% clinical improvement in all patients. The median PFS post-RT was 9.8 months (m). The progression defined as clinical and radiological criteria of diagnosis; all patient had >2/3 clinical criteria where five (29.4%) satisfied all three, mean LPS of 60 and mean post-RT time: 9.2 (4-20.5) m (Fig 1). ReRT was done using 3DCRT in all but one patient (IMRT) to a dose ranging 30-45 Gy. Four patients received <30Gy while rest between 39-43.2Gy. Four patients who received <30Gy, three either deteriorated or did not show any clinical improvement at 10<sup>th</sup> -15<sup>th</sup> fraction (18-27 Gy) despite suitable steroid doses, while one had extensive infiltrative disease limiting the reRT dose (30.6Gy). Remaining 13 patients showed clinical improvement mild to modest and were continued to pre-decided clinician dose (39.6-45Gy). The patient with extensive disease received 30.6Gy also showed good clinical improvement at the end of reRT (40%). The steroid dependency was reviewed in all 13 responders; all were on steroids at the time of reRT initiation, 46.2% were completely off, 38.5% were tapering 41.7% at the end of reRT. Later at one-month post reRT, 61.5% were able to get completely off

steroids. Two patients with good improvement post reRT developed intra-tumoral bleed on day 15 & 45 and succumbed. The post reRT 13 progression were noted where local and disseminated were 10 and 3 respectively. The median OS of the whole group was 15.3 m with OS at 12, 18 and 24 m of 81.6+9.6, 39.1+13.1 and 20.9+12% respectively. The median survival addition with reRT was 4.6 m (Fig 1,  $p < 0.001$ ). The median OS for patients receiving  $< 30\text{Gy}$  versus  $39.6\text{-}45\text{Gy}$  was 3.6 and 4.9 m respectively ( $p = 0.14$ ). The median OS for reRT responders vs non-responders was 4.9 vs 3.5 m ( $p = 0.005$ , Fig 2).

### Conclusion

ReRT can be considered in appropriately selected patients with DIPG at progression with good symptomatic benefit, modest toxicity, and acceptable survival. Clinical improvement on reRT by the 10-15<sup>th</sup> fraction can guide reRT dose in patients already on reRT.

### EP-1236 Volumetric assessment of cerebral edema after fractionated SRT for multiple brain metastases

H. Inokuchi<sup>1</sup>, Y. Ishihara<sup>1</sup>, K. Okano<sup>1</sup>, A. Kawamura<sup>1</sup>, K. Tsutsui<sup>1</sup>, M. Hiraoka<sup>1</sup>

<sup>1</sup>Japanese Red Cross Society Wakayama Medical Center, Department of Radiation Oncology, Wakayama, Japan

### Purpose or Objective

Fractionated stereotactic radiotherapy (FSRT) is emerging new technology which enables simultaneous irradiation for multiple, large brain metastases using linear accelerator (LINAC). The aim of this study was to evaluate local control and peritumoral cerebral edema after LINAC based FSRT as a first line therapy for multiple brain metastases.

### Material and Methods

We performed an IRB-approved retrospective analysis of patients underwent LINAC-based, image-guided, frameless FSRT consisting of 35Gy/5 fractions for lesions 1-15 cc and 30Gy/5 fractions for lesions 15cc< at our institution from August 2015 to August 2018. MRI were recorded at the initial time as a baseline and 2 months after the FSRT. Volumetric assessment of tumor regression and its relations to peritumoral edema were performed using contrast enhanced T1MRI, T2 weighted-MRI and perfusion-MRI.

### Results

We have treated 32 patients with 104 multiple brain metastases ranging 2 to 14 metastases (median 5). Primary cancer sites were lung (27), breast (3), cervix (1), and kidney (1). The mean metastases volume decreased from  $4.67 \pm 5.22$  cc to  $2.54 \pm 2.48$  cc ( $p = 0.001$ ), and the mean edema volume decreased from  $20.11 \pm 20.23$  cc to  $11.35 \pm 20.47$  cc ( $p = 0.02$ ). Cumulative tumor volumes were 2.5-39.6cc (median 22.4cc). The pre-existing edema was reduced in 78% ( $n=25$ ), stable in 22% ( $n=7$ ) at the time of first 2-months follow-up. Reduction of  $>75\%$  in existing edema was associated with the cumulative tumor volumes  $< 10$  cc ( $p = 0.03$ ) and primary adeno lung cancer ( $p = 0.02$ ). In 9/104 (8.6%) metastases, local failure was diagnosed with a mean follow-up time of 7.4 months (range 1-34 months). Estimated 1-year local control was 90.6%. Overall, 24/27 (88%) patients suffered from symptomatic edema was improved. No patients who were without symptoms at baseline developed signs of intracranial pressure following LINAC based FSRT.

### Conclusion

LINAC based stereotactic radiotherapy for multiple metastatic brain lesions demonstrated a relatively safe and effective treatment outcome with early shrinkage of lesions and peri-tumoral edema. Further investigation is needed to clarify the optimal dose fractionations.

### EP-1237 Vestibular schwannoma: Results of hypofractionated stereotactic radiotherapy

P. Pierre-Marie<sup>1</sup>, S. Tringali<sup>2</sup>, G. Beldjoudi<sup>1</sup>, P. Pommier<sup>1</sup>, R. Tanguy<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiotherapy, Lyon, France ;

<sup>2</sup>Centre Hospitalier Lyon Sud, Head and Neck, Lyon, France

### Purpose or Objective

Vestibular schwannomas (VS) are rare and symptoms commonly include unilateral hearing deficiencies, tinnitus and loss of balance. The management of VS may involve surgery, radiotherapy or watchful waiting. In our institution, the required attitude is defined in a multi-disciplinary staff with neurosurgeons, radiologists, head and neck surgeons and radiation therapists. For patients addressed to radiation therapy, we chose to use hypofractionated stereotactic radiotherapy (HFSRT) in 3 or 5 fractions to benefit the radiobiological advantages of fractionation. This study assesses the outcome of HFSRT for VS at a single institution.

### Material and Methods

We analyzed a retrospective case series. Patients were identified from patient records and a retrospective review of case notes and imaging reports was undertaken. All treatment was performed on a Cyberknife device. Two dose protocols were provided: 21 Gy in 3 fractions classically for stage II and for some stage III schwannomas and for the largest stage III 25 Gy in 5 fractions. All treatments were completed on a seven-day period. We assessed tumor response and recorded toxicity.

### Results

From November 2010 to December 2016, 64 patients were treated in our institution for their VS with an HFSRT protocol. Ten (15.6%) patients had a previous surgery and were treated on a progressing schwannoma with a mean 50 months between surgery and radiation therapy (range:

7-202 months). They mainly had Koos's stage II (N=37) and stage III (N=22) VS treated with 3 x 7 Gy (N=47) or 5 x 5 Gy (N=17) dose protocols. We reached a median follow-up of 28 months (range: 7-80 months).

The treatment was well tolerated with only four grade III acute toxicities (loss of balance for all this four, associated with a headache and tinnitus for one of these) and no grade IV or V. All of them were resolute with symptomatic treatment (corticosteroids). As late toxicity grade III or more we noticed one Bell's palsy, which was resolute with symptomatic treatment and one trigeminal neuralgia occurring 16 months after radiation therapy.

More than 50% of the population had a stable hearing after treatment.

Thirty three patients presented VS necrosis, appearing with a median delay of 7 months (range: 3-16 months). On the 64 patients we noted only 2 recurrences leading to a control rate of 97.1%. These recurrences occurred after 3 and 40 months.

These two patients benefited from salvage surgery and were free of any recurrence at the last consultation. They both were treated with upfront radiotherapy with a 3-fractions protocol on Koos's stage III VS. With few recurrences, the analyze of recurrence factors was narrow but we found as clinical factors influencing the risk of relapse the maximum size of more than 20 mm ( $p=0.003$ ) and on dosimetrical factors a conformal index  $<1.1$  ( $p < 0.0001$ ).

#### Conclusion

Our results suggest that our HFSRT using 21 Gy in 3 fractions or 25 Gy in 5 fractions is a well-tolerated and effective regimen.

#### EP-1238 Inter-observer variability in target delineation for brain metastases in stereotactic radiotherapy

S. Di Biase<sup>1</sup>, F. Patani<sup>1</sup>, D. Fasciolo<sup>1</sup>, C. Rosa<sup>1</sup>, C. Di Carlo<sup>1</sup>, A. Allajbeji<sup>1</sup>, L. Gasparini<sup>1</sup>, A. Delli Pizzi<sup>2</sup>, M. Trignani<sup>1</sup>, L. Caravatta<sup>1</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>SS. Annunziata" Hospital, Department of Radiotherapy - G. D'Annunzio University, Chieti, Italy ; <sup>2</sup>SS. Annunziata" Hospital, Department of Radiology - G. D'Annunzio University, Chieti, Italy

#### Purpose or Objective

In stereotactic radiotherapy for brain metastases (BM), target delineation is based on MRI co-registered with simulation-CT and involves a well-defined volume represented by enhancing area on T1 weighted sequences, defined as gross tumor volume (GTV). In these conditions, a limited inter-observer variability (IOV) could be expected. However, studies found significant differences in shape, size, and location in radiosurgery targets showing also an impact in plan conformity. The aim of this study was to quantify the IOV of target delineation in BM.

#### Material and Methods

A case of brain metastasis was proposed to 11 Radiation Oncologists (RO) of our Department. RO delineated GTV on T1 MRI co-registered with planning-CT using MIM Maestro software (MIM Software Inc). GTVs were analyzed and compared to a benchmark volume performed by a Neuroradiologist and a RO with expertise in brain radiotherapy jointly. The analysis of the obtained volumes was based on: DICE similarity index, Jaccard index, mean distance to agreement (MDA), Hausdorff distance, GTVs volumes, common volume (AV100), encompassing volume and centroids.

#### Results

The lesion had a well-defined small spheric appearance with a homogeneous contrast enhancement and without edema. The reference GTV volume was 1.04 cc. Mean participants volume was 1.14 cc (range 0.88-1.34 cc). Volumetric analysis of GTVs and similarity and discordance analysis of targets are reported in Table 1. Mean distance

of centroids (MDC) from the reference centroid was 0.27 mm. Mean DICE was 0.90 (range 0.85-0.92).

	cc
Mean volume	1,14
Median volume	1,13
Min volume	0,88
Max volume	1,34
Common volume, AV100	0,84
Encompassing volume	1,48
Reference volume	1,04
Similarity and discordance parameters	
Mean HD	1,96 mm
Mean MDA	0,28 mm
Mean DICE	0,90
Mean Jaccard	0,74
MDC	0,27 mm

Table 1. Volumetric and similarity/discordance analyses of targets.

HD: Hausdorff distance; MDA: Mean distance to agreement; MDC: Mean distance of centroids

#### Conclusion

In contrast to studies reporting IOV in SRT, our work pointed out a little variability. The peculiar appearance of the considered metastasis could have contributed to the agreement obtained. Anyway, our result need to be confirmed taking into account metastases of heterogeneous appearance and in this direction further evaluations are ongoing. Moreover, it should be evaluated the dosimetric implications of small IOV, due to the high dose ad rapid fall-off of stereotactic radiotherapy.

#### EP-1239 Role of perilesional edema in patients with glioblastoma undergoing adjuvant chemo-radiation

V. Nardone<sup>1</sup>, M. Gaetano<sup>1</sup>, M.G. Calvanese<sup>1</sup>, A. Di Biase<sup>1</sup>, I. Nuzzo<sup>2</sup>, L. Di Rienzo<sup>1</sup>, I. D'Onofrio<sup>1</sup>, M.G. Calvanese<sup>1</sup>, P. Pastina<sup>3</sup>, C. Guida<sup>1</sup>, C. Vitale<sup>2</sup>, P. Tini<sup>1</sup>, S. Cappabianca<sup>2</sup>, L. Pirtoli<sup>3</sup>

<sup>1</sup>Ospedale del Mare, Radiation Therapy Unit, Napoli, Italy ; <sup>2</sup>University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy ; <sup>3</sup>Unit of Radiation Therapy, University Hospital of Siena, Siena, Italy

#### Purpose or Objective

The present study was designed to evaluate the role of perilesional edema calculated on pre-surgery MRI as a prognostic factor in patients with glioblastoma undergoing adjuvant chemo-radiation.

#### Material and Methods

We performed a retrospective analysis on 140 patients with glioblastoma undergone surgery and adjuvant chemo-radiation (C-RT) between January 2010 and December 2015.

Both perilesional edema (PE) and gross tumor volume (GTV) were contoured on MRI. We also calculated PE/GTV ratio, and PE + GTV (TV). Cut-offs were calculated with the software X-Tile. We correlated progression free survival (PFS) and overall survival (OS) with these parameters and the known prognosticators (surgery, KPS, age, MGMT status), with Kaplan Meier method (univariate) and Cox Regression Analysis (multivariate).

#### Results

A total of 140 patients were included in the analysis (mean age 61 years, median 64 years, range 35-84 years, 91 males and 49 females). Ninety-nine (70%) developed recurrence, whereas 90 patients (64%) died during the follow up.

We weren't able to calculate a cut-off value for both PE and GTV, but the found a cut-off for the PE/GTV ratio ( $>4$ ) for OS survival analysis.

The significant parameters at univariate analysis were KPS ( $p < 0,001$ ), surgery ( $p < 0,001$ ) and MGMT status ( $p < 0,001$ )

for PFS analysis, KPS ( $p < 0.001$ ), surgery ( $p: 0.005$ ), MGMT ( $p: 0.001$ ) and PE/GTV ratio ( $p: 0.005$ ).

At multivariate analysis of OS, the only significant parameters were MGMT ( $p: 0.011$ ), KPS ( $p: 0.008$ ) and PE/GTV ( $p: 0.034$ ).

#### Conclusion

Our results suggest that the PE/GTV ratio, together with the known clinical parameters, could play a role in the prognosis of glioblastoma patients.

#### EP-1240 Hypofractionated radiotherapy for non resectable glioblastoma multiforme patients

I. Nieto Regueira<sup>1</sup>, O. Virginia<sup>1</sup>, M. Victor<sup>1</sup>

<sup>1</sup>Hospital Meixoeiro VIGO, Radiation Oncology, Vigo, Spain

#### Purpose or Objective

Glioblastoma multiforme is one of the worst prognosis tumor of the central nervous system.

The first step in the treatment is complete surgical resection and it is a good medium and long term prognosis factor when performed.

In fact, when complete surgical resection is not possible, disease free survival and global survival decline significantly.

Radiotherapy is the other treatment that improves survival and local control. 1- year overall survival is observed in operated and irradiated patients and decreases to 3-4 months in non-resectable patients. Temozolomide, as concomitant treatment to radiotherapy, increases an average of 3 months the survival. Standard radiotherapy dose is 60 Gy in 2 Gy /fraction.

In the past higher doses have not shown a benefit in trials. Brachytherapy or radiosurgery have not shown any benefit either.

The aim of this prospective trial is to evaluate altered fractionation in these patients.

#### Material and Methods

Between 2014 January and 2017 December we treated 48 patients with non-resectable Glioblastoma multiforme with hypofractionated radiotherapy. 53% were males. The average age was 54 years-old. The media total dose administered was 70 Gy (66-74 Gy) The media dose per fraction was 2,45 Gy ( 2,2-2,6) 38 patients were treated with IMRT (79%).

Brain stem, optic pathways, pathway and motor cortex were protected, with a prescribed maximum dose of 54 Gy to brain stem and optic pathway and 60 Gy to motor pathway and cortex respectively.

#### Results

6 patients didn't finish radiotherapy treatment due to neurological clinical worsening caused by disease progression, observed on CT scan (12%).

In the remaining patients an increased acute side effects were not observed during the radiotherapy treatment. On the one-month follow-up MRI an increased of edema and contrast enhancement were observed in 31 patients (64%). These radiological findings improved in successive MRI in 25 patients (52%)

Media overall survival observed were 14 months. 9 patients underwent surgery after radiotherapy treatment. Radionecrosis was observed in 6 anatomopathological studies. The media overall survival in these patients were 18 months (14-23 months).

#### Conclusion

Hypofractionated radiotherapy is a well-tolerated treatment for unresectable Glioblastomas patients.

The contrast enhancement on the 1-month follow-up MRI was due to Pseudoprogression, and associated to a good prognosis.

Radionecrosis after surgical resection is associated to a better prognosis too.

Hypofractionated radiotherapy treatment improves overall survival in these patients.

#### EP-1241 Radiosurgery reirradiation of brainstem: clinical evaluation and its radiobiological correlation.

V. Pinzi<sup>1</sup>, D.M. Elena<sup>2</sup>, M. Marchetti<sup>1</sup>, L. Fariselli<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Neurosurgery- Unit of Radiotherapy, Milan, Italy ;

<sup>2</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Health Department, Milan, Italy

#### Purpose or Objective

The main studies focused on radiosurgery-induced toxicity to the brainstem are only few. One of the largest studies by Trifiletti et al. analyzed 547 patients with 596 brainstem metastases treated with SRS. The authors found that brainstem tumor location or volume of tissue receiving 12 Gy were not correlated to a severe toxicity. On the other hand, Foote et al. analyzed 149 patients and concluded that doses  $\geq 15$  Gy to the brainstem conferred a significant increase in risk for cranial nerve complications and that the dosimetric factors predictive of cranial nerve palsy included  $D_{max} \geq 17.5$  Gy and prescribed dose  $\geq 12.5$  Gy. However, there are even less studies about radiosurgery re/irradiation of brainstem, unless for the impact of previous WBRT on the toxicity rate after SRS for brainstem metastases. The objective of the study was to analyse the radiation-related toxicity of the brainstem radiosurgery re-irradiation and its correlation with radiobiological parameters.

#### Material and Methods

We analyzed 12 patients who underwent re-irradiation for progression or relapse of tumors of the brainstem or close to it. The toxicity was recorded based on CTCAE scales. The clinical results were correlated with radiobiological parameters through the linear-quadratic model to express the re-irradiation tolerance in cumulative equivalent total doses when applied in 2Gy fractions (EQD2cumulative). We used  $\alpha/\beta$  values of 2.1 and 3.3Gy.

#### Results

The histology was high-grade glioma in 4 patients, metastases in 5, meningioma in 2 and unknown in 1 patient. Three patients underwent 5 radiation treatments (1 3Dconformal RT, 4 SRS), 1 patient received 4 RT treatments (1 3DCRT and 3 SRS), 1 patient received 3 RT treatments (3 SRS), 6 patients received one 3DCRT and 1 SRS course, 1 patient received two SRS treatments. The cumulative EQD2 (3,3) ranged 26.5-116.2Gy (mean  $\pm$  S.D:  $73 \pm 26.9$ Gy). The cumulative EQD2 (2,1) ranged 30.5-130Gy (mean  $\pm$  S.D:  $79.5 \pm 29.4$ Gy). The mean time interval between radiotherapy courses was  $18.7 \pm 20$  months (range 0-72 months; median 12 months; n = 23). The mean PTV was  $119.9 \pm 369.5$ cc (range 0.1- 1455.6). The mean follow-up was 44 months (range 10-145 months). At the time of analysis 7 patients were alive. No radionecrosis was reported. Only 1 patient developed G1 ataxia and dysphagia and only 1 patient developed a G2 ataxia. Both patients showed a neurological improvement after 1 month of corticosteroid therapy.

#### Conclusion

The overall outcome in the twelve described patients seems to be encouraging. Modern irradiation systems make it reasonable to administer successive irradiation treatments. Involving only 12 patients, this analysis cannot be expected to provide ground for us to draw definitive conclusions. However, the retrospective EQD2 values reported in this study can be used as starting point for a study focused on dose-reference for safe re-treatments.

#### EP-1242 Multisession radiosurgery re-irradiation for glioblastoma recurrence: a retrospective analysis.

V. Pinzi<sup>1</sup>, A. Viola<sup>2</sup>, M. Marchetti<sup>1</sup>, P. Gaviani<sup>3</sup>, E. Anghileri<sup>3</sup>, L. Fariselli<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Neurosurgery- Unit of Radiotherapy, Milan, Italy ;

<sup>2</sup>University of Milan, Radiation Oncology, Milan, Italy ;

<sup>3</sup>Fondazione IRCCS Istituto Neurologico C. Besta, Neuro-oncology, Milan, Italy

#### Purpose or Objective

Despite being various treatment strategies available, recurrent multiforme glioblastomas (rGBM) are difficult to manage. Limited evidence exists to suggest the superiority of any treatment modality for rGBM. The aim of this study is to evaluate the effectiveness of multisection radiosurgery (mRS) reirradiation as salvage treatment in terms of overall survival (OS) and progression free survival (PFS).

#### Material and Methods

Patients previously treated with surgery and chemoradiotherapy and re-irradiated with radiosurgery for rGBM from January 2014 to December 2016 were considered eligible. Global OS (gOS) was defined as the time between first surgery and death, OS as the time between the end of reirradiation and death, PFS as the time between reirradiation and disease progression. The statistical analysis was conducted using the Kaplan-Meier method.

#### Results

Forty-six patients were included in the analysis. Median time from primary treatment to recurrence was 14 months (range 1-79 months). Median follow-up was 4 months (range 2 days-32 months). All patients were treated with robotic radiosurgery (CyberKnife®). At the time of the analysis six of the 46 patients were alive. The median survival from initial diagnosis was 26 months (range 12-107 months). The 1-, 2-, and 3-years actuarial survival rates from diagnosis were 100, 70, and 50% respectively. Median survival following mRS was 7 months (range 1-24 months). The 1-, and 2-years actuarial survival rate following mRS were 29, and 11% respectively. The acute toxicity rate was 17%.

#### Conclusion

Our data suggest that mRS is a safe and effective treatment option for patients with rGBM. Further research and prospective studies are needed to better define the parameters of re-irradiation in this subset of patients.

#### EP-1243 Bevacizumab as treatment option for cerebral radiation necrosis A case series of 22 patients

R. Bodensohn<sup>1</sup>, I. Hadi<sup>1</sup>, D.F. Fleischmann<sup>1</sup>, C. Belka<sup>1</sup>, M. Niyazi<sup>1</sup>

<sup>1</sup>University Hospital- LMU Munich, Department of Radiation Oncology, Munich, Germany

#### Purpose or Objective

Radiation necrosis is one of the most serious adverse effects after cranial radiation therapy. The VEGF inhibitor Bevacizumab might be a feasible therapeutic option for symptomatic radiation necrosis when traditional treatments such as dexamethasone or mannitol fail. However, so far only few randomized studies with small cohorts (such as Levin et al with n=14) exist to show a beneficial effect for patients. Therefore, real life data is needed in order to support the data. This retrospective monocentric case study evaluates patients who received bevacizumab due to radiation necrosis in relation to clinical development.

#### Material and Methods

Using the internal database for cytostatic medication all patients who received bevacizumab in our department were identified. Only patients who received bevacizumab for radiation necrosis were included. Next to general patient characteristics symptoms before, during and after treatment and use of dexamethasone were evaluated using medical reports and internal documentation. The symptoms were coded with the CTCAE code for general neurological symptoms. Each patient received a code directly before each cycle and after the treatment (approximately 6 weeks). Additionally, the daily dose of dexamethasone was collected at these times. The patients that either improved in the symptoms or received less

dexamethasone after treatment or both were considered having benefitted a form the therapy.

#### Results

22 patients who received bevacizumab due to radiation necrosis were identified. For 10 patients (45,5%) the symptoms improved, 11 patients (50,0%) did symptomatically not improve during the treatment, 1 patient (4,5%) worsened. With 14 patients (63,6%) the dexamethasone dose could be reduced during therapy, 5 patients (22,7%) received the same dose of dexamethasone before and after treatment and 3 patients (13,6%) received a higher dose after treatment. According to this analysis 18 patients (81,8%) were able to benefit from the treatment with bevacizumab. No severe adverse effects e.g. bleedings were reported.

#### Conclusion

Bevacizumab is a good therapeutic option for patients with radiation necrosis as a complication after cranial radiation therapy. Patients could benefit from this treatment by improving symptomatically or through reduction of dexamethasone.

#### EP-1244 The impact of multidisciplinary tumor board in brain tumor management: the OMNYBuS Project

S. Chiesa<sup>1</sup>, C. Mazzeola<sup>2</sup>, G. Sabatino<sup>3</sup>, S. Gaudino<sup>1</sup>, M. Iezzi<sup>1</sup>, S. Luzi<sup>1</sup>, F. Beghella Bartoli<sup>1</sup>, G. La Rocca<sup>3</sup>, G.F. D'Onofrio<sup>3</sup>, C. Colosimo<sup>1</sup>, A. Olivi<sup>3</sup>, V. Valentini<sup>1</sup>, M. Balducci<sup>1</sup>

<sup>1</sup>Istituto di Radiologia-Fondazione Policlinico A. Gemelli IRCCS- Università Cattolica Sacro Cuore, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche, Rome, Italy; <sup>2</sup>Istituto di Radiologia-Fondazione Policlinico A. Gemelli IRCCS, Dipartimento Scienze Radiologiche- Radioterapiche ed Ematologiche, Rome, Italy; <sup>3</sup>Istituto di Radiologia-Fondazione Policlinico A. Gemelli IRCCS- Università Cattolica Sacro Cuore, Dipartimento Scienze dell'invecchiamento- neurologiche- ortopediche e della Testa-Collo- UOC Neurochirurgia, Rome, Italy

#### Purpose or Objective

A shared decision making in multidisciplinary context has become the standard practice for cancer care worldwide. The aim of the OMNYBuS project is to investigate the impact of tumor board in brain tumor management in order to obtain the best personalized treatment plan.

#### Material and Methods

Neurosurgeons, radiation oncologist, radiologist, anatomic pathologists and residents were involved in the multidisciplinary discussion. In this first phase of the study, we collected data retrospectively obtained from one year experience of multidisciplinary tumor board in order to arrange a strategy of the prospective phase. The primary endpoint was the evaluation of management change rate in terms of exchange, addition, or subtraction of treatment modality. The secondary endpoints were the delay considering treatment starting time, extra diagnostic work-up and time needed for academic discussion.

#### Results

Between March 2017 and March 2018, 148 consecutive cases were presented and discussed: 33,3% high grade gliomas, 10,8% anaplastic astrocytomas, 6,5% oligodendrogliomas, 2,2% low grade gliomas, 14% meningiomas, 14% single metastases, 8,6% multiple metastases, 5,4% other type of lesion. The multidisciplinary discussion focused on diagnostic imaging results and interpretation, medical, surgical, and/or radiation treatment planning, and pathology results and interpretation. The median time for case discussion was 10 minutes with a median tumor team members presence of 22 clinicians. The therapeutic plan change rate was 9.2%, mostly for high grade gliomas. A reduction of diagnostic work-up accounted for 65,7%. No delay was observed in treatment starting time.

### Conclusion

Almost all respondents indicated that these meetings were "very beneficial" to their own practice and these data emphasize the fact that in a relevant number of cases the initial treatment strategy could be modified after a multidisciplinary discussion. The retrospective phase allows us to elaborate case report form for data collection in order to prospectively analyze the adherence to guidelines, the reduction of diagnostic work-up and the patients related outcomes. We are using the new schedule for data collection in our multidisciplinary clinical practice.

### EP-1245 Evolution of non functioning pituitary adenoma after first surgery : long follow-up of 256 patients.

T. Charleux<sup>1</sup>, V. Vendrely<sup>1</sup>, A. Huchet<sup>1</sup>, R. Trouette<sup>1</sup>, A. Tabarin<sup>2</sup>, V. Jecko<sup>3</sup>, H. Loiseau<sup>3</sup>, C. Dupin<sup>1</sup>  
<sup>1</sup>Bordeaux University Hospital, Radiation Oncology, Bordeaux, France ; <sup>2</sup>Bordeaux University Hospital, Endocrinology and Metabolism, Bordeaux, France ; <sup>3</sup>Bordeaux University Hospital, Neurosurgery, Bordeaux, France

### Purpose or Objective

Pituitary adenomas account for 14 to 18% of all primary brain tumours. Our objective was to evaluate therapeutic outcome after the first surgery in non functioning pituitary adenomas (NFPA).

### Material and Methods

Between January 1978 and 2018 all patients treated by surgery for NPFA with at least 2 MRI in the follow-up and an endocrinologic follow-up in our hospital were included in this retrospective study. Evaluation concerned patients and tumor characteristics, radiation therapy data, time between each surgical procedure. Analysis of survival was done according to Kaplan Meier method.

### Results

Between 1978 and January 2018, 256 patients were treated by surgery for NPFA at our institution. Mean age at surgery was 55 [18 - 86] with 59% male. Mean tumor size was 29 mm [12 - 60] and post-operative MRI found residual tumor in 87 % of patients. Mean follow up was 10,2 years [0,6 - 40,1]. Median time to second treatment (second surgery or radiation therapy) was 10.3 years and only 32% did not need second treatment at 15 years. First event at 5, 10 and 15 years, was second surgery for 11%, 18% and 32% of patients and radiation therapy for 26%, 32% and 36%. After a second surgery, half of the patients were irradiated within 1,8 years and only 27% of patients did not receive radiotherapy within 5 years. All together, 32%, 43% and 61% of patients received radiation therapy within 5, 10 and 15 years after surgery for NPFA. After radiation therapy, 7% of patients had another surgery at 5 years and 9% at 10 and 15 years.

Patients treated by radiation therapy following surgery have a risk to suffer from gonadotropic, corticotropic and/or thyrotropic deficiencies in 65%, 66% and 73% of the cases. At least 14 to 38% of these are induced by the RT. Two patients had cerebral tumors : 1 meningioma present at first surgery, and a glioblastoma appeared after 13 years after radiation therapy. Six percent of patients had stroke both in the group treated with radiation therapy (6/107) or than without radiation therapy (9/149)

### Conclusion

After a first surgery for NPFA, most of patients needed another treatment (surgery or radiotherapy). In case of a second surgical resection, 73% of them received radiation therapy within the next 5 years, whereas in case of radiation therapy as second treatment, 8% needed surgery within the next 5 years.

### EP-1246 Outcomes and health-related quality of life in large skull base meningiomas treated with protons

D. Amelio<sup>1</sup>, D. Scartoni<sup>1</sup>, S. Lorentini<sup>1</sup>, L. Widesott<sup>1</sup>, R. Righetto<sup>1</sup>, I. Giacomelli<sup>1</sup>, M. Schwarz<sup>1</sup>, M. Amichetti<sup>1</sup>  
<sup>1</sup>Centro di Protonterapia, U.O. Protonterapia- Azienda Provinciale per i Servizi Sanitari - Trento, Trento, Italy

### Purpose or Objective

To report preliminary results of active beam scanning proton therapy (PT) for large skull base benign meningiomas (LSBM)

### Material and Methods

Thirty-three patients (pts) with LSBM were treated with PT between January 2015 and June 2018. Median age was 53 years (range, 28-82) while KPS ranged between 60 and 100 (median 90); 26 were female (79%), and 7 were male (21%). Twelve pts (36%) had histologically proven World Health Organization (WHO) Grade I tumors. In remaining pts diagnosis was based on the typical imaging appearance of benign meningioma. All patients received PT for residual, progressive or non-operable lesions. Newly diagnosed tumors received total dose of 50 GyRBE (RBE: relative biologic effectiveness) while progressing meningiomas 54 GyRBE. All the treatments were delivered at 2 GyRBE per fraction. Treatment planning was based on morphological magnetic resonance imaging (MRI) with contrast enhancement medium administration and 68-Ga-DOTATOC-PET. GTV ranged from 21 to 107 cc. Toxicity was assessed according to Common Terminology Criteria for Adverse Events version 4.0. Health-related (HR) quality of life (QoL) was assessed by the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ)--C30 and EORTC Quality of Life Questionnaire Brain Cancer Module (QLQ-BN20). Median follow-up (FU) time was 12 months (range, 3-41)

### Results

All pts completed the treatment without breaks. Registered acute side effects include grade 1 (12%) and grade 2 (9%) skin erythema, grade 1 (9%) and grade 2 (9%) alopecia, grade 1 (48%) fatigue, grade 1 (6%) and grade 2 (15%) conjunctivitis, grade 1 (15%) pain, grade 1 (15%) blurred vision, grade 1 (15%) headache, and grade 2 (9%) skin hyperpigmentation. One pts experienced grade 3 pain. There were no further grade 3 or higher acute toxicities. Registered late side effects include grade 1 (9%) and grade 2 (9%) alopecia, grade 1 (12%) fatigue, grade 1 (9%) and grade 2 (6%) headache, grade 1 (6%) dizziness, grade 1 (6%) blurred vision, grade 1 (6%) and grade 2 (6%) pain, grade 1 (6%) dry eye, and grade 1 (9%) skin hyperpigmentation. One pts experienced grade 3 pain. There were no further grade 3 or higher late toxicities. During follow-up one pts (3%) with cavernous sinus meningioma experienced complete obstruction of intracavernous carotid artery with mild transient symptoms that resolved in few days and brain tissue ischemia detected at MRI (grade 2). Before irradiation this pts already had a meningioma-related near-complete obstruction of the intracavernous carotid artery and received a vascular surgery evaluation. Currently, absolute tumor control is 100%. Moreover, relief of symptoms recorded before irradiation occurred in 27% of pts. The treatment was associated with improvement or stability in most of the preselected HRQoL domains

### Conclusion

PT is feasible and safe treatment for pts with LSBM with a favorable effect on HRQoL. Longer FU is necessary to assess definitive efficacy

### EP-1247 The patterns of care and management of brain metastases in a large Oncology centre

M. O' Cathail<sup>1</sup>, R. Bentley<sup>1</sup>, V. Crosby<sup>2</sup>, L. Aznar-Garcia<sup>1</sup>, A. Wilcock<sup>2</sup>, J. Christian<sup>1</sup>

<sup>1</sup>Nottingham University Hospital, Oncology and radiotherapy, Nottingham, United Kingdom ;

<sup>2</sup>Nottingham University Hospital, Palliative care, Nottingham, United Kingdom

### Purpose or Objective

Brain metastases (BM) affect up to 40% of patients with metastatic disease. Recent advances in systemic therapy means patients are living longer whilst the widespread availability of stereotactic radiosurgery (SRS) for brain metastases provides a realistic expectation of local control in suitable patients. There is a lack of data on the prevalence of treatment modalities used and the patterns of care these patients experience. We aim to quantify the proportion of patients receiving SRS, Whole brain radiotherapy (WBRT), neurosurgery and best supportive care (BSC) in a tertiary oncology centre.

### Material and Methods

Over a two year period (1<sup>st</sup> Jan 2016 - 31<sup>st</sup> Dec 2017), adult patients with a new radiologically confirmed diagnosis of BM were identified by retrieving all MRI and CT head scans that contained the words 'metastases', 'metastasis' or 'met' in the report. Only patients with a confirmed primary cancer were included. Patients who underwent SRS, WBRT or surgery were considered to have received 'treatment' for their BM. Receiving systemic anticancer treatment or steroids were not considered to be 'treatment'. Patients who did not receive 'treatment' for their BM were identified as BSC.

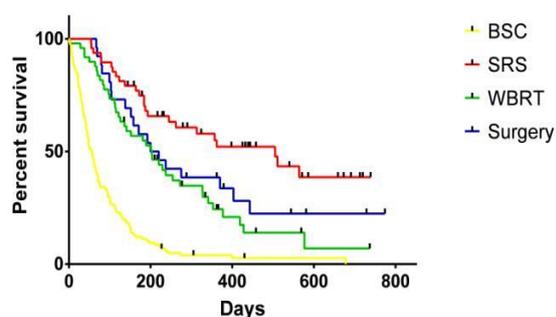

### Results

Of 2,422 scans, reviewed, there were 236 cases of newly diagnosed BM. The median age at diagnosis was 65 years (range 30-87). The median survival across all groups was 115 days (range 1-829). There were more females (58%) than males (42%). Lung cancer was the most common primary site (49%), followed by breast (20%) and melanoma (13%). At the time of diagnosis, 47% had controlled extracranial disease. Lung primaries carried the worst prognosis (median survival 95 days) with breast (202 days) the best.

Half of the cases received some form of treatment for their BM with the other half receiving BSC. There were 127 treatments delivered to 118 patients. WBRT (39.5%) and SRS (39.5%) were the most common with surgery used in 21%. Treatment modality varied according to primary tumour site. In breast WBRT (54%) was the most common treatment followed by SRS (15%). In lung and melanoma, this was reversed with SRS (21% & 53% respectively) more commonly used than WBRT (14% & 6% respectively). Patients who received SRS lived the longest; their median survival was not reached at assessment, compared to surgery (210 days) and WBRT (202 days). We identified 7 cases who received WBRT where an opportunity to give SRS may have been missed.

Of the 50% of patients who did not receive any treatment; median survival was 55 days. Of these, 62% had contact with palliative care services. Amongst treated patients, 54% were seen by palliative care.

Survival by treatment modality

### Conclusion

Half of all patients receive no brain directed therapy. Radiotherapy is the most common treatment though SRS may have been to 7 others who WBRT. We suggest a well resourced and dedicated dedicated BM MDT would provide

more consistent decision making as which was established this year in our centre. We will reassess the patterns of care after a year.

### EP-1248 Stereotactic radiotherapy for brain metastasis and systemic therapies: a safe combination?

M. Manicone<sup>1</sup>, M. Galaverni<sup>1</sup>, I. Renna<sup>1</sup>, P. Ciammella<sup>1</sup>, L. Giaccherini<sup>1</sup>, F. Bellafiore<sup>1</sup>, G. Timon<sup>1</sup>, F. Vigo<sup>1</sup>, A. Rosca<sup>1</sup>, D. Ramundo<sup>1</sup>, M. Galeandro<sup>1</sup>, M.P. Ruggieri<sup>1</sup>, T. Palmieri<sup>1</sup>, A. Botti<sup>2</sup>, R. Sghedoni<sup>2</sup>, E. Cagni<sup>2</sup>, M. Orlandi<sup>2</sup>, M. Russo<sup>3</sup>, C. Bonelli<sup>4</sup>, M. Pagano<sup>4</sup>, C. Iotti<sup>1</sup>  
<sup>1</sup>Azienda USL-IRCCS di Reggio Emilia, Radiation Oncology Unit, Reggio Emilia, Italy; <sup>2</sup>Azienda USL-IRCCS di Reggio Emilia, Medical Physics Unit, Reggio Emilia, Italy; <sup>3</sup>Azienda USL-IRCCS di Reggio Emilia, Clinical Neurology, Reggio Emilia, Italy; <sup>4</sup>Azienda USL-IRCCS di Reggio Emilia, Medical Oncology Unit, Reggio Emilia, Italy

### Purpose or Objective

Stereotactic Radiotherapy (SRT) is an effective treatment for brain metastases (BM) and is generally safe. Aim of this retrospective study was to compare toxicities and efficacy of SRT alone and in combination with systemic therapies in patients with BM.

### Material and Methods

We analyzed all patients treated between 2010 and 2017 at our institution with SRT for BM, with or without concurrent systemic therapy (defined as administered within four weeks of SRT).

We evaluated in this cohort of patients the haematological and neurological toxicities, brain progression free survival (bPFS) and overall survival, stratifying patients for yes/no systemic therapy.

### Results

Data on 45 patients were obtained. Median age at diagnosis of BM was 66 years (range 37-90 yrs). At the time of initial presentation, the majority of patients had ECOG performance status of 0-2.

The most common primary tumors were lung, breast, melanoma and kidney. Sixty percent of SRT treatments were delivered concurrently with systemic therapy, of which 56% were with conventional chemotherapy and 44% with targeted and immunotherapy agents. Patients were divided in two groups: SRT alone and SRT/systemic therapy. No differences between the two groups in terms of clinical and treatments characteristics were found. Median follow up was 10 months (range 1-65). Myelosuppression was minimal after treatment, with 9% grade 2-4 toxicity; grade  $\geq 2$  neurological symptoms were reported in 11% of patients, with one grade 5 neurological toxicity. There was no difference in haematological ( $p=0.79$ ) and neurological ( $p=0.96$ ) toxicities between the two groups. Histologically confirmed radionecrosis was reported in 2 patients (one in SRT alone and one in SRT/systemic therapy group) and radiologically suspected radionecrosis in 2 patients both in the group of concurrent therapy (one with chemotherapy and one with target therapy).

Median bPFS was 12.1 months, without any significant difference between the two groups ( $p=0.49$ ). To date 29 patients have died, of which 3 for brain progression, 13 for systemic progression and two for both systemic and brain progression. Nine patients were died for no tumor related causes and 2 patients for unknown causes. Median OS for entire group was 8.13 months without any difference between the two groups of patients. ( $p=0.37$ ).

### Conclusion

SRT for BM can be safely delivered concurrently with systemic therapy without significant increase in toxicity.

### EP-1249 Impact of retreatment or chemotherapy on survival in patients affected by a recurrent Glioblastoma

C. Mazzarella<sup>1</sup>, S. Chiesa<sup>1</sup>, S. Bracci<sup>2</sup>, T. Zinicola<sup>2</sup>, S. Longo<sup>2</sup>, F. Beghella Bartoli<sup>2</sup>, S. Luzi<sup>2</sup>, G. Sabatino<sup>3</sup>, A.

#### Purpose or Objective

Optimal management for recurrent glioblastoma (GBM) has not been established. Many therapies have been assessed with limited results and without significant increase in progression-free survival (PFS), or overall survival (OS). The object of this retrospective analysis was to evaluate the impact on OS with different salvage therapies, including systemic therapy, or re-irradiation plus systemic therapy or supportive care in patients affected by recurrent GBM to generate new hypotheses for future trials.

#### Material and Methods

Patients (pts) affected by GBM's recurrence and treated with according to EORTC 26981-22981-NCIC trial, were included. Those who died less a month after progression or with a poor performance status were excluded. Patients were subdivided into 3 groups: reirradiation plus chemotherapy (group A), chemotherapy alone (group B), supportive care (group C). Overall Survival was estimated using the Kaplan-Meier method and compared between three groups.

#### Results

The analysis included 217 pts with GBM who developed relapse from January 2009 to May 2016. Among them, 153 patients were evaluable for this analysis; 64 patients were excluded because they died less than one month after progression or for a poor performance status. Sixty-nine out of 153 patients (45%) belonged to Group C, 63 (41%) to group B, and 21 (14%) to group A. Median follow-up was 48 months in all patients. Median survival time from diagnosis was 18 months for the entire cohort: 14 months for patients of Group C, 28 months for group B, and 30 months for those of group A. The kind of treatment at recurrence time proved to significantly impact on OS ( $p=0.0001$ ).

#### Conclusion

Patients who did not receive any treatment had poorer survival than those who received chemotherapy alone or in combination with radiotherapy. Latter had a significantly better survival than chemotherapy group. Further investigations are needed to define the optimal choice of therapy, and in particular the role of re-irradiation and systemic treatment in patients with recurrent GBM.

#### EP-1250 Outcomes of Multiple Brain Metastases Radiosurgery with Gantry-Based Linac

P. Castro Peña<sup>1</sup>, C. Nino de Guzman<sup>1</sup>, D. Venencia<sup>1</sup>, L. Suarez Villasmil<sup>1</sup>, J. Suarez<sup>1</sup>, S. Zunino<sup>1</sup>  
<sup>1</sup>Instituto Zunino - Fundacion Marie Curie, Radiation Oncology, Cordoba, Argentina

#### Purpose or Objective

To evaluate tolerance, toxicity and survival in patients with multiple brain metastases treated Novalis-BrainLab SRS platform.

#### Material and Methods

Between Nov'16&Dec'17, 24patients were treated with SRS of multiple brain metastases(2 to 23). Seven patients had previously received WBRT; . The brain was the only organ with metastases in 13/24 patients. Nineteen patients showed neurologic symptoms prior to diagnosis. For CT simulation a Frameless Brainlab System was utilized. Treatment planning was performed using Elements TPS

v1.5 (BrainLab). The patients were positioned on a 6D couch and snap verification in each angle was done. Radiosurgery was given by Novalis Tx accelerator HDMLC-IGRT with ExacTrac V6 using 6 MV photon beam with dose rate 1000 MU/minute. Early and late toxicities as well as survival were evaluated in all the patients. Patients with up to 5 metastases were compared with te ones with 6 or more, and the ones with a tumor volume <10cc were compared with the rest with >10cc tumor volume. OS from SRS until last follow up or death, and progression-free survival (PFS) from SRS until first brain progression or last follow up, were estimated by the Kaplan-Meyer method.

#### Results

Mean age:54.2years [10.3-73.9] and mean follow-up 8.16 months [3.2-16.6].The mean number of lesions per patient was 7 [2-23] while the average volume of irradiated metastases was 1.34 cc [0.02-20.8].The prescribed dose was 22.2Gy[20.0-35.0] in1-5 fractions. The brain volume receiving 12Gy=53.7cc[4.3-600.0].5 patients were re-irradiated because of tumor regrowth (22 lesions) or new lesions (12 lesions); Of the 24 patients, 19 showed no symptoms of early toxicity whereas the remaining 5 presented G1-2 toxicity .Late toxicity was evaluated in 19 patients who survived for more than 3 months. Of the 19 patients, 12 did not show any toxicity while the remaining group presented G1-2 toxicity .No differences were found in patients with 5 or more metastases regarding the presence or absence of toxicities, or related to fractioning.The overall survival (OS) for the 24 patients at 6 months was 71%, and at one year 59%. No differences were found in the OS of patients with five or more metastases when compared with patients with less than five lesions (Cox-Mantel test,  $p = 0.806$ ); There were no differences when comparing patients with a total volume of metastases <10 cc and  $\geq 10$  cc (Cox-Mantel test,  $p = 0.865$ ). The progression-free survival (PFS) at 6 months was 89% and at one year 62%. No differences were found in PFS related to the number of metastases (Cox-Mantel test,  $p = 0.982$ ) or to the total volume of metastases (Cox-Mantel test,  $p = 0.296$ ).

#### Conclusion

Despite the number of patients limiting the statistical comparison of subgroups, results suggest that irradiation to multiple metastases is safe with Novalis Plataform and Elements SRS, showing acceptable toxicity and survival. If well in literature a detrimental in OS is described with a total tumor volume >10cc, we didn't find these difference.

#### EP-1251 focal hypofractionated stereotactic radiation therapy for brain metastases

H.J. Rosales Gonzalez<sup>1</sup>, H. Perez Montero<sup>2</sup>, A. Alvarez<sup>1</sup>, A. Mañes<sup>1</sup>, S. Comas Anton<sup>1</sup>, E. Luguera<sup>3</sup>, G. Antelo<sup>1</sup>, E. Baena<sup>1</sup>, M. Villalobos<sup>1</sup>, S. Villà<sup>1</sup>  
<sup>1</sup>Catalan Institute of Oncology, Radiation Oncology, Badalona, Spain ; <sup>2</sup>Catalan Institute of Oncology, Radiation Oncology, Hospitalet, Spain ; <sup>3</sup>Catalan Institute of Oncology, Medical Physics, Badalona, Spain

#### Purpose or Objective

Patients diagnosed with brain metastases have been traditionally treated with surgery, stereotactic radiosurgery (SRS) or whole-brain radiotherapy (WBRT). Focal Hypofractionated Stereotactical Radiation Therapy (FHSRT) may offer an alternative approach to conventional treatments for central nervous system metastases. Our objective was to analyze FHSRT outcomes at our institution.

#### Material and Methods

We retrospectively reviewed the records of 93 patients who were treated at our institution between 2014 and 2017. Eighty-two were diagnosed with a single metastasis, 19 patients with 2 metastases and 9 patients with 3 or more metastases. A total of 110 treatments were performed. Twenty-seven patients were treated with

surgical resection followed by FHSRT and 83 with FHSRT only. Most frequent histology of primary site was lung cancer in 62.72% of patients and breast cancer in 13.63%. Planning CT scans were performed with patient in supine position using high precision head mask-fixation system. Gross tumor volume (GTV) was defined using the planning CT scan registered with the diagnostic MRI. A 3 mm expansion was given to the GTV for defining the planning target volume (PTV). Treatments were performed using dynamic conformal arches (VMAT) with 6 MV energy photons. Dose prescribed was 27 Gy in 3 fractions for 67 treatments. Other dose schemes were: 24 Gy in 3 fractions for 20 treatments; 30 Gy in 10 fractions for 8 treatments; 35 Gy in 5 fractions for 7 treatments, 30 Gy in 5 fractions for 7 treatments and 30 Gy in 3 fractions for 1 treatment. Kaplan-Meier actuarial method was used for the analysis of the overall survival, disease free survival and the correlation of the dose scheme and time to progression.

### Results

Local progression was observed in 54 of the 110 treatments, among these, there were 26 patients who had one single lesion and 28 who had 2 or more lesions. In the local progression group, 42 patients receive further treatment. Twenty-two receive re-irradiation using FHSRT, 13 with WBRT, 5 where treated with SRS and 2 with surgical resection. Twelve patients did not receive any further treatment. Median overall survival was 8.36 months (r: 1-45). The median disease free survival was 6.7 months (r: 1-43). Grade 2 toxicity (CTCAE v4) was observed in 3 patients, and 10 patients presented neurological symptoms during FHSRT. Radiation necrosis was confirmed in 3 patients, 2 by RMI and 1 with coline PET-TC. When analyzing by subgroups the different dose schemes used, no statistically significant differences were found with respect to the time of recurrence.

### Conclusion

FHSRT is an effective alternative treatment for non-multiple brain metastases with high local control and acceptable tolerance. There were no differences regarding the prescribed doses and the time to progression. More data is needed in order to establish the optimal fractionation and dose scheme to be used.

### EP-1252 Brain metastases postoperative stereotactic RT: WBRT free survival predicted by an external nomogram

A. Mousli<sup>1</sup>, B. Bihin<sup>2</sup>, T. Gustin<sup>3</sup>, G. Koerts<sup>4</sup>, M. Mouchamps<sup>5</sup>, J. Daisne<sup>1</sup>

<sup>1</sup>Université Catholique de Louvain- CHU-UCL-Namur- site Sainte-Elisabeth, Radiation Oncology, Namur, Belgium ; <sup>2</sup>Université Catholique de Louvain- CHU-UCL-Namur- site Godinne, Biostatistics Unit, Yvoir, Belgium ; <sup>3</sup>Université Catholique de Louvain- CHU-UCL-Namur- site Godinne, Neurosurgery, Yvoir, Belgium ; <sup>4</sup>Centre Hospitalier Régional, Neurosurgery, Namur, Belgium ; <sup>5</sup>Centre Hospitalier Régional, Neurosurgery, Liège, Belgium

### Purpose or Objective

Patients with brain metastases (BM) represent an extremely diverse group with substantial variability in risk of intra-cranial failure and survival. Patient selection for stereotactic radiotherapy (SRT) alone is complex and requires considering multiple predictive factors. Given that the ultimate goal of SRT is to prolong survival without whole brain radiotherapy (WBRT), a nomogram based on multi-institutional data was developed by another team to display 6 and 12 months WBRT-free survival (WBFS) probabilities (Gorovets, al. IJROBP 2018). The aim of this study was to externally validate this nomogram.

### Material and Methods

We retrospectively reviewed the data of 70 patients treated between 2008-2017 by SRT for resected BM. The primary endpoint was the WBFS. Two subgroups of 35 patients were constructed with respect to the patient score in the nomogram (superior and inferior to the

median). In each group, the observed WBFS was plotted against the predicted WBFS. The ROC curve and AUC were calculated for both 6 and 12 months time points.

### Results

After a median follow up of 16.8 months, the 1-year local and distant brain failure rates were 14.3% and 35.0 %, respectively. The median time to salvage WBRT was 9.6 months. Median time to the first intracranial failure was 7.7 months. At the time of first recurrence, 90 % received local salvage therapy. We performed repeated SRT for 34% and salvage WBRT in 56%. After median time of 8.5 months, 10 patients experienced a second intracranial failure. Eight of 10 patients received further salvage therapy (5 WBRT, 3 SRT). The WBFS rates at 6 and 12 months were 87 % [IC<sub>95%</sub> = 79-95 %] and 56 % [IC<sub>95%</sub> = 45-69%], respectively. In terms of calibration, the 6 months rates were overestimated while they were accurate at 12 months (Fig. 1). It is reflected by the evolution of the cumulative proportion of WBRT or death in both subgroups with observed rates inferior to expectations at 6 months while they superimpose at 12 months (Fig. 2). A ROC curve was plotted for the 6 and 12 months nomogram predictions. AUC values were 0.47 and 0.62, respectively.

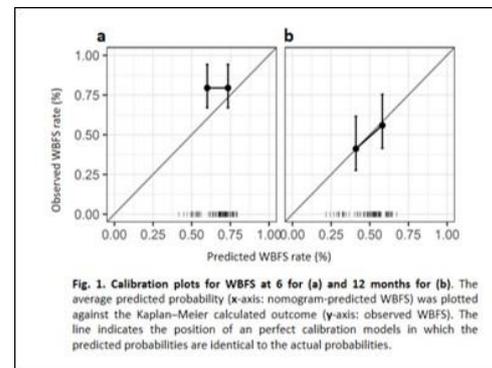

Fig. 1. Calibration plots for WBFS at 6 for (a) and 12 months for (b). The average predicted probability (x-axis: nomogram-predicted WBFS) was plotted against the Kaplan-Meier calculated outcome (y-axis: observed WBFS). The line indicates the position of an perfect calibration models in which the predicted probabilities are identical to the actual probabilities.

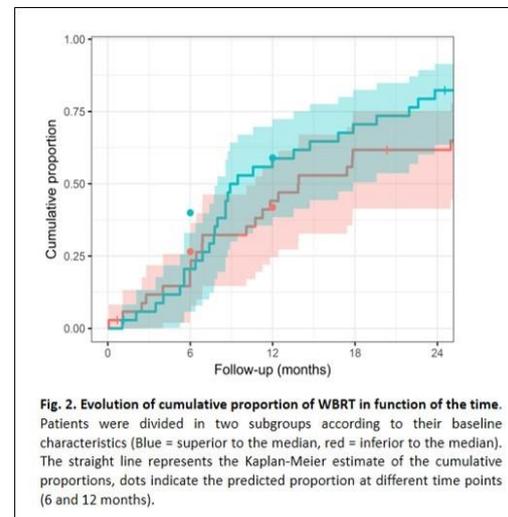

Fig. 2. Evolution of cumulative proportion of WBRT in function of the time. Patients were divided in two subgroups according to their baseline characteristics (Blue = superior to the median, red = inferior to the median). The straight line represents the Kaplan-Meier estimate of the cumulative proportions, dots indicate the predicted proportion at different time points (6 and 12 months).

### Conclusion

In our population of patients with operated BM and then stereotactically irradiated, the nomogram predicted correctly the WBFS at 12 months but not at 6 months. The median time to salvage WBRT was 9.6 months in our series while it was 6.2 months in the series by Gorovets. The fact that one third of our patients were treated with SRT as first salvage treatment may have played a role. Patients were operated and this may also be a confounding factor. All in all, it reflects the inherent limitation of applying prediction models to highly heterogeneous populations. Including more patients and characteristics

(e.g. molecular data) may improve the concordance index.

### EP-1253 Biological target volume using DTI-MRI in postoperative chemoradiotherapy for glioblastoma

A. Trip<sup>1</sup>, M.B. Jensen<sup>2</sup>, J.F. Kallehauge<sup>3</sup>, S. Lukacova<sup>4</sup>  
<sup>1</sup>Aarhus University Hospital and Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>Aarhus University Hospital, Medical Physics, Aarhus, Denmark ; <sup>3</sup>Aarhus University Hospital, Danish Centre for Proton Therapy, Aarhus, Denmark ; <sup>4</sup>Aarhus University Hospital, Oncology, Aarhus, Denmark

#### Purpose or Objective

Glioblastoma (GBM) is a highly aggressive malignant brain tumour with a median overall survival of only 15 months. After postoperative chemoradiotherapy, most recurrences occur within or at the margin of the treatment volume. The standard clinical target volume (CTV) is typically defined as an isotropic 2 cm expansion around the surgical cavity and the area of contrast enhancement. This isotropic margin is not taking into account the preferential tumour growth along the white matter tracts of the brain. Diffusion tensor imaging (DTI) MRI can be used to model white matter tracts. The aim of this phase 1 feasibility study is to evaluate DTI-MRI diffusion growth models in the biological CTV definition of GBM.

#### Material and Methods

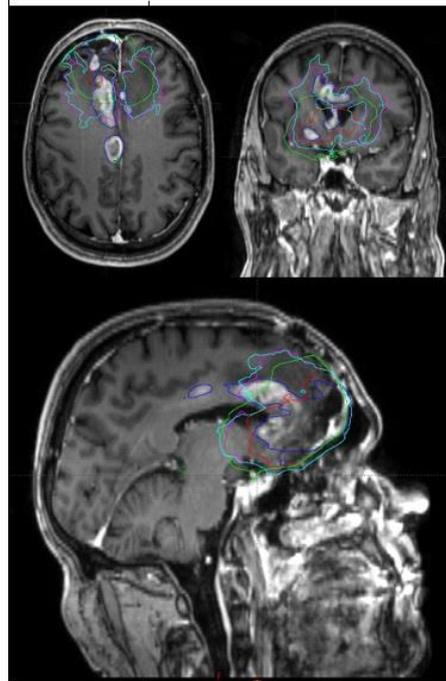

Adult GBM patients referred for postoperative RT were included, and underwent an additional pre-treatment DTI-MRI; actual treatment wasn't altered. The standard CTV was defined as described above, respecting anatomical barriers. DTI-MRI was used to create two biological CTVs, iso-volumetric to the standard CTV, using anisotropic margins based on tensor directionality of  $\gamma_0$  (bCTV $\gamma_0$ ) and  $\gamma_{20}$  (bCTV $\gamma_{20}$ ; higher  $\gamma$  meaning a higher assumed probability of tumour spread along white matter tracts). The similarity of the CTV and the bCTVs was assessed using the Dice similarity score (DSC; 0=no overlap, 1=complete overlap). Treatment effect was assessed by 3-monthly MRI and described by RANO criteria. Progression was defined as central, in-field/marginal and distant with respective  $\geq 95\%$ , 20-95%, or  $< 20\%$  of the recurrence volume (RV) located within the  $D_{95\%}$ . Only patients with an in-field/marginal or distant recurrence were selected for comparison of the bCTVs to the RV. The overlap or minimal distance between the bCTVs and the delineated RV was calculated.

#### Results

Between 10/2016 and 06/2018 38 patients were included. One patient went off-study and one was lost to follow-up, leaving 36 for analyses. Gross total resection was performed in 42% of patients, and 89% completed irradiation to 60 Gy in 30 fractions (Table). At a median follow-up of 9.5 (range 3-21) months, 23 patients had disease progression; 2 clinical, 19 central, 1 in-field/marginal, 2 distant. The median PFS was 7.0 (range 4.5-9.5) months. The mean DSC between CTV and bCTV $\gamma_0$  was 0.75 (range 0.65-0.85), and CTV and bCTV $\gamma_{20}$  was 0.72 (range 0.62-0.81) (bCTV $\gamma_0$  vs bCTV $\gamma_{20}$   $p < 0.001$ ). For patient 1 with a non-central recurrence the CTV/bCTV $\gamma_0$ /bCTV $\gamma_{20}$  overlapped with the RV by 87/90/89% (Figure). For patient 2 the CTV/bCTV $\gamma_0$ /bCTV $\gamma_{20}$  overlapped with the RV by 19/21/25%.

For patient 3 (no overlap) the shortest distance from the CTV/bCTV $\gamma_0$ /bCTV $\gamma_{20}$  to the RV was 4.6/3.6/3.3 cm.

Figure. DTI-MRI based biological target volume in postoperative chemoradiotherapy for GBM.

The standard pre-treatment GTV (red) and CTV (green) are depicted together with the bCTV $\gamma_0$  (magenta) and bCTV $\gamma_{20}$  (cyan) at the co-registered follow-up MRI at time of progression (blue). This example shows the improved overlap of the bCTVs to the recurrence volume at the corpus callosum compared to the standard CTV.

Table. Patient and treatment characteristics for the total study population, patients with a central recurrence and patients with a non-central recurrence.

Characteristic	Total (n=36)	Central recurrence (n=19)	Non-central recurrence (n=3)

\*one patient received 50 Gy in 25 fractions, and one patient received 54 Gy in 27 fractions.

#### Conclusion

Biological DTI-MRI based CTV showed marginal improvement in a limited number of GBM patients with non-central recurrence. Further investigation in a larger cohort including non- iso-volumetric approaches is needed for further improvement in CTV definition.

### EP-1254 When could we spare hippocampus in the WB radiation for the primary central nervous system lymphoma?

F. Beghella Bartoli<sup>1</sup>, T. Zinicola<sup>1</sup>, S. Chiesa<sup>1</sup>, F. Catucci<sup>1</sup>, M. Giraffa<sup>1</sup>, C. Mazzarella<sup>1</sup>, D. Marchesano<sup>1</sup>, N. Dinapoli<sup>1</sup>, F. D'Alò<sup>2</sup>, S. Hohaus<sup>2</sup>, V. Valentini<sup>1</sup>, M. Balducci<sup>1</sup>  
<sup>1</sup>Policlinico A.Gemelli, Radiation oncology department-

*Gemelli ART, Roma, Italy ; <sup>2</sup>Policlinico A.Gemelli, Hematology Department, Roma, Italy*

#### **Purpose or Objective**

One of the main limiting factor of a whole brain radiation therapy (WBRT) is the neurocognitive functions (NCFs) decline, which is mainly caused by the radiation-induced injury to the hippocampus. This study evaluates the correlation between the site of (Primary Central Nervous System Lymphoma) PCNSL lesions and the hippocampal region to generate evidence to routinely spare of the hippocampus during a WBRT.

#### **Material and Methods**

Patients with pathologically proven PCNSL and MRI image pre-treatment were retrospectively reviewed. T1-weighted, axial MR image were imported on Varian Eclipse treatment planning system and registered with the simulation CT. The hippocampus as well as each PCNSL lesions were contoured. Three dimensional envelopes surrounding the hippocampus were generated adding 5, 10, and 15 mm. The minimum margin of 5 mm was considered for systematic setup error and dose fall-off between whole brain clinical target volume and the hippocampus.

#### **Results**

Between 2005 and 2018, 36 pts with 57 lesions were eligible for this study. PCNSL lesions' locations were: deep brain structures (26%), parietal lobe (23%), frontal lobe (19%), temporal lobe (14%), occipital lobe (7%), brainstem (5%), other sites (6%). In 18/57 lesions (31.6%) the distance from the hippocampus region was less than 5 mm and seven of them (12.3%) involved the hippocampus. Lesions over 15 mm from the hippocampus were observed in 30 cases (52.6%), while only the 15,8% was between 5 and 15 mm.

#### **Conclusion**

Our data don't support the routinely sparing of the hippocampal region in PCNSL. It could be considered in selected patients, when the spatial distribution of lesions is far more than 5 mm from the hippocampus.

#### **EP-1255 Health-Related Quality of Life in large recurrence Glioblastoma treated with protontherapy**

*D. Scartoni<sup>1</sup>, D. Amelio<sup>1</sup>, F. Fellin<sup>1</sup>, I. Giacomelli<sup>1</sup>, M. Schwarz<sup>1</sup>, M. Amichetti<sup>1</sup>*

*<sup>1</sup>Centro di Protonterapia, Protontherapy, Trento, Italy*

#### **Purpose or Objective**

Protontherapy (PT) could minimize the risk of side effects compared to conventional photon therapy and therefore reduce the possible detrimental effect on QoL of re-irradiation.

We report the effect of re-irradiation with active scanning PT of large recurrence GBM in terms of quality of life scored by the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ)-C30 and EORTC Quality of Life Questionnaire Brain Cancer Module (QLQ-BN20).

#### **Material and Methods**

Between January 2015 and October 2018 thirty patients with recurrence GBM were re-irradiated with active scanning PT. All patients had been previously treated with photon radiotherapy (60 Gy) with concomitant and adjuvant temozolomide (TMZ). Median age and Karnofsky performance status at re-irradiation were 53 years (range, 30-68 years) and 80%, (range, 60-100%), respectively. Target definition was based on CT, MR, and 18F-DOPA PET imaging. Median CTV (clinical target volume) was 69 cc (range, 11-259 cc). All patients received 36 GyRBE (RBE: relative biologic effectiveness) in 18 fractions, with concomitant TMZ in 7 patients (25%). Subscales within the EORTC QLQ-C30 include five functional scales (physical, role, emotional, cognitive, and social), three symptoms scales (nausea, vomiting, and fatigue), six single-item scales (insomnia, appetite loss, constipation, diarrhea,

dyspnea, and financial effect of tumor/treatment) and global QoL. The BN20 is specifically developed for brain patients and assessed visual disorders, motor function, communication deficit, various disease symptoms, treatment, toxicity and future uncertainty. The patients completed the EORTC questionnaires before starting PT, the day of the end of PT and every follow-up consult (1-month, 3-months) until progression of disease.

#### **Results**

The treatment was associated with stability in most of the preselected HRQOL domains. Global health improved over time with a maximum difference of 6 points between baseline and 3-months follow-up. Social functioning and motor dysfunction improved over time with a maximum difference of 8 and 2 points, respectively. We showed only a small not significance decrease in cognitive and emotional functioning. Interestingly, fatigue remained stable during the analysis such as the other preselected domains. Increase of CTV, use of steroids before protontherapy and concomitant chemotherapy are associated with a statistically significant worse QLQ C30\_Social, QLQ C30\_Physical and BN20\_Motor values.

#### **Conclusion**

Re-irradiation with PT for a large recurrence Glioblastoma is a safe treatment without a negative effect on HRQOL until the time of disease progression.

#### **EP-1256 Influence of PET-imaging during treatment planning on outcome in meningioma patients**

*K. Kessel<sup>1,2,3</sup>, H. Fischer<sup>1</sup>, T. Voglhuber<sup>1</sup>, C. Diehl<sup>1,2</sup>, C. Straube<sup>1,2</sup>, W. Weber<sup>1</sup>, S.E. Combs<sup>1,2,3</sup>*

*<sup>1</sup>Klinikum rechts der Isar- TU München, Department of Radiation Oncology, München, Germany ; <sup>2</sup>Deutsches Konsortium für Translationale Krebsforschung DKTK, Partner Site Munich, München, Germany ; <sup>3</sup>Helmholtz Zentrum München, Institute for Innovative RadiotherapyIRT, München, Germany*

#### **Purpose or Objective**

Radiotherapy (RT) is an alternative treatment to surgery for low-grade meningiomas or applied in an adjuvant setting. In high-grade cases, RT after resection is the treatment of choice.

RT improved over the years, and modern techniques such as IMRT combined with IGRT increase safety and precision. However, during treatment planning, definition of the planning target volume (PTV) remains challenging, and differentiation between healthy tissue, i.e. meninges, post-operative changes, and residual tumor can be difficult using MR and CT imaging alone. In this study, we evaluated the influence of additional PET-imaging on progression-free (PFS) and overall survival (OS).

#### **Material and Methods**

We analyzed 353 patients with primary RT of meningiomas treated between 1994 and 2017. For analyses, we divided the patients in low-grade (n=282) and high-grade (n=71) meningiomas. Table 1 shows the patient characteristic. Previous resection was performed in an adjuvant setting due to subtotal resection or later due to recurrent tumor growth.

Patients were treated with either fractionated stereotactic radiotherapy with a median dose of 54.0 Gy and median single dose of 1.8 Gy, or with radiosurgery with a median dose of 16 Gy. An advanced radiation oncologist delineated PTV based on diagnostic CT and MRI and, if available, additional PET-imaging with either <sup>68</sup>Ga-Dotanoc/Dotatoc, <sup>18</sup>F-FET (fluoroethyltyrosine) or C11 Methionin tracer.

	Low-grade (n=282)	High-grade (n=71)	OS	
			Univariate	Multivariate
Gender				
M	73 (25.9%)	41 (57.7%)		
W	209 (74.1%)	30 (42.3%)		
Age (median, range) [years]	60 (11-86)	62 (24-84)		
Resection				
Yes	179 (63.5%)	70 (98.6%)		
No	103 (36.5%)	1 (1.4%)		
Resection status				
Complete	17 (6%)	24 (33.8%)		
Incomplete	149 (52.8%)	39 (54.9%)		
n/a	13 (4.6%)	7 (9.9%)		
Time resection - RT (median, 95% KI) [months]	8.7 (19.8-31.2)	3.8 (6.3-16.3)		
PET-imaging for RT planning				
Yes	160 (56.7%)	42 (59.2%)		
No	122 (43.3%)	29 (40.8%)		
PET tracer				
68Ga-Dotanoc/Dotatoc	68 (42.5%)	31 (73.8%)		
F-18 FET	23 (14.4%)	5 (11.9%)		
C11 Methionin	69 (43.1%)	6 (14.3%)		

## Results

Median follow-up was 6.2 years (95%-KI: 6.6-7.6). For low-grade meningiomas, mean OS was 15.5 years (95%-KI: 14.7-16.2) and mean PFS was 15.2 years (95%-KI: 14.3-16.0) (median was not reached); for high-grade cases median OS was 12.0 years (95%-KI: 3.8-20.2), and median PFS was 5.0 years (95%-KI: 2.4-7.6).

PET imaging had significant influence on OS (p=0.035) and PFS (p=0.044) for low-grade meningiomas; however, in the multivariate analysis, it remained only significant for PFS. For high-grade cases, PET had no influence.

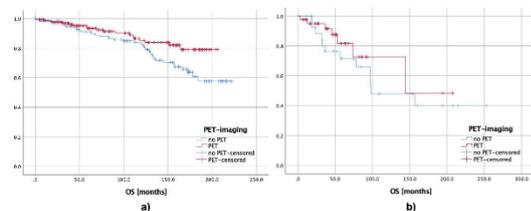

Figure 1: Survival curves of a) low-grade and b) high-grade meningiomas regarding PET based RT planning.

Table 2: Prognostic factors on OS and PFS for both low- and high-grade meningiomas.

	OS		PFS	
	Low-grade (n=282)	High-grade (n=71)	Low-grade (n=282)	High-grade (n=71)
	Univariate	Multivariate	Univariate	Multivariate
PET imaging (yes vs. no)	0.035*	0.382	0.413	-
PET Tracer (68Ga vs. F-18 vs. C11)	0.494	-	0.156	-
Previous resection (yes vs. no)	0.836	-	0.687	-
Resection status (complete vs. incomplete)	0.888	-	0.116	-
Time resection - RT	0.059	-	0.199	-
Age at diagnosis [years]	0.001*	0.001*	0.016*	-
PTV [ml]	0.001*	0.076	0.280	-
Gender (male vs. female)	0.001*	0.002*	0.940	-
	Univariate	Multivariate	Univariate	Multivariate
PET imaging (yes vs. no)	0.044*	0.047*	0.549	-
PET Tracer (68Ga vs. F-18 vs. C11)	0.132	-	0.096	-
Previous resection (yes vs. no)	0.087	-	0.018*	0.036
Resection status (complete vs. incomplete)	0.250	-	0.070	-
Time resection - RT [months]	0.673	-	0.496	-
Age at diagnosis [years]	0.294	-	0.023*	0.104
PTV [ml]	0.041*	0.046*	0.101	-
Gender (male vs. female)	0.214	-	0.403	-

## Conclusion

PET-imaging improves the detection of tumor cells, especially during treatment planning. It showed a significant influence on OS and PFS.

Further sub-analyses will investigate the influence of PET for resected patients, and large tumor volumes and establish cut-off values for which tumor sizes additional PET imaging might be beneficial. For low-grade meningiomas the time between resection and RT was borderline significant. With the factors age, PTV and gender a weighted scoring system will be developed for prognostic assessment.

## EP-1257 Post-operative hypo-fractionated SBRT in a large series of patients with brain metastases

Martinage Makhloufi<sup>7</sup>, R. Mouttet Audouard<sup>1</sup>, L. Basson<sup>1</sup>, X. Mirabel<sup>1</sup>, E. Lartigau<sup>1,8</sup>, D. Pasquier<sup>1,8</sup>

<sup>1</sup>Centre Oscar Lambret, Academic Department of Radiation Oncology, Lille, France ; <sup>2</sup>Centre François Baclesse, Department of Radiation Oncology, Caen, France ; <sup>3</sup>Centre Oscar Lambret, Department of Biostatistics, Lille, France ; <sup>4</sup>Centre Oscar Lambret, Department of Medical Physics, Lille, France ; <sup>5</sup>CHRU Lille, Department of Neurosurgery, Lille, France ; <sup>6</sup>CHU Côte de Nacre, Neurosurgery department, Caen, France ; <sup>7</sup>Centre Oscar Lambret, Department of Clinical Research and Innovation, Lille, France ; <sup>8</sup>Lille University, CRISTAL UMR CNRS 9189, Lille, France

## Purpose or Objective

The aim of this study was to assess, in a large series, the efficacy and tolerance of post-operative adjuvant hypofractionated stereotactic radiation therapy (HFSRT) for brain metastases (BMs).

## Material and Methods

Between July 2012 and January 2017, 160 patients with 167 surgical cavities from 2 centers were operated for BM and treated by HFSRT. Patients had between 1-3 BMs, no brainstem lesion or carcinomatous meningitis. CT scan and gadolinium contrast-enhanced MRI were used for treatment planning. HFSRT was delivered using a CyberKnife®-type robotic accelerator. The primary endpoint was local control. Secondary endpoints were distant brain control, overall survival (OS) and tolerance to HFSRT.

## Results

Seventy-three patients (46%) presented with non-small cell lung cancer (NSCLC), 23 (14%) had melanoma and 21 (13%) breast cancer. Median age was 58 years (range, 22-83 years). BMs were synchronous in 50% of the cases. Median tumor size was 32 mm (range, 7-78 mm) and 75% of the cases (n=124) BMs were supratentorial. Planning MRI was performed in 151 patients (94%).

The most frequent prescription regimens were 24 Gy in 3 fractions (n=52, 33%) and 30 Gy in 5 fractions (n=37, 23%). Local control rates at 6 months, 1 year and 2 years were

91% [95% CI, 85%-95%], 88% [95% CI, 81%-93%] and 81% [95% CI, 70%-88%], respectively. Distant control rate at 1 year was 48% [95% CI, 81%-93%]. In multivariate analysis, primary NSCLC ( $p=0.007$ ), the number of extra-cerebral metastatic sites ( $p=0.003$ ) and planning target volumes ( $p=0.012$ ) were associated with OS. There was no factor predictive of time to local progression. Median OS was 15.2 months [95% CI, 12.0-17.9 months] and the OS rate at 1 year was 58% [95% CI, 50%-65%]. Salvage radiotherapy was administered to 72 patients (45%), of which 49 received new HFSRT. Five patients underwent re-irradiation of the surgical bed by stereotactic radiation therapy. Ten (7%) patients presented late grade 2 and 4 (3%) patients late grade 3 toxicities. Thirteen (8.9%) patients developed radiation necrosis (all grades).

#### Conclusion

This large multicenter retrospective study shows that HFSRT allows for good local control of metastasectomy tumor beds and that this technique is well-tolerated by patients.

#### EP-1258 Predicting Brain V12Gy for Single-Isocenter Multi-Target Stereotactic Radiosurgery (SRS)

H. LIU<sup>1</sup>, T. Li<sup>1</sup>, H. Zhang<sup>2</sup>, W. Shi<sup>1</sup>

<sup>1</sup>Thomas Jefferson University Hospital, Radiation Oncology, Philadelphia, USA ; <sup>2</sup>Monte Vista Christian School, n/a, Watsonville, USA

#### Purpose or Objective

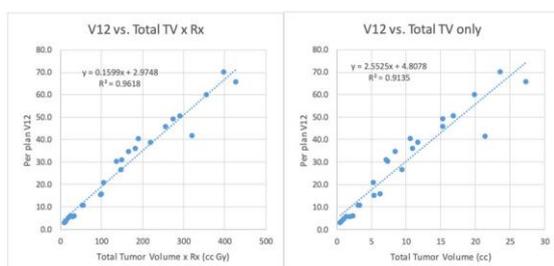

Stereotactic radiosurgery (SRS) for multiple brain metastasis has been shown to provide excellent local control with reduced cognitive impact. For this type of treatment, the volume of brain receiving 12Gy (V12Gy) has been shown to correlate with the occurrence of radionecrosis following SRS. This study aimed to determine a simple and efficient model for predicting V12Gy for patients undergoing stereotactic radiosurgery (SRS) for multiple brain tumors in a single session prior to treatment planning.

#### Material and Methods

30 single-isocenter-multi-target SRS cases planned with Brainlab Elements™ treatment planning system were retrospectively analyzed. A total amount of 221 tumors were prescribed to 15-24 Gy. V12Gy for each individual tumor and for each plan were extracted. Three methods were used to model V12Gy based on anatomy and prescription: a linear regression model on per-plan V12Gy combining all targets, a linear regression model on per-target V12Gy followed by summation per plan, and 3D geometric per-target expansion model that assumes V12Gy occurs at a certain distance outside each target. Actual-vs-predicted graphs and root-mean-square errors for per plan V12Gy were used to assess the prediction accuracy of each model.

#### Results

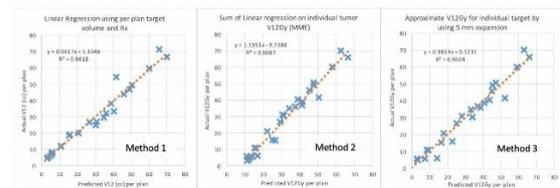

(1) Linear correlation analysis showed improved correlation when using the prescription-weighted sum of tumor volumes per plan (R-square = 0.9618) as input instead of using only total tumor volume (R-square = 0.9135). Using this simple linear model, the predicted V12Gy resulted an RMSE of 3.8 cubic-cm.

(2) The linear fitting model used prescription-weight

individual tumor volume as input to predict individual V12 Gy. Regression using 16-patient training data yielded an R-square of 0.9498. This model was then applied to the whole 30 patients to predict individual V12Gy for each tumor, which was then summed within each patient to give predicted per-plan V12Gy. The predicted V12Gy using this method resulted an RMSE of 5.9 cm<sup>3</sup>, and on average over-predict by 3.4±4.8 cm<sup>3</sup>.

(3) The geometric expansion method showed that a 5 mm expansion from each tumor's equivalent sphere provided most stable prediction of actual V12Gy volumes with a fixed offset of 13.7 cm<sup>3</sup> for nearly all tumor sizes. Using 5 mm expansion minus 13.7 cm<sup>3</sup> as prediction, the predicted V12Gy showed an RMSE of 4.0 cm<sup>3</sup>. This result was not substantially improved over simple linear regression method.

#### Conclusion

In this study we compared three empirical models to predict brain V12Gy using only tumor size and prescription information, which is readily available before planning. The results showed that the simple linear model performed reasonably well and offered very similar goodness of prediction compared to more complicated 2-step or 3D-based models. This linear model used prescription-weighted total tumor volume for a particular patient as input, and could help clinicians decide how many tumors and what prescription should be given without exceeding desired V12Gy limit even before treatment planning, therefore save clinical resources and improve patient throughput.

#### EP-1259 Retrospective Analysis of radiosurgery for ≥ 4 brain metastases from oncogene-addicted NSCLC

Y. Wang<sup>1</sup>, C. Calbat<sup>1</sup>, P. Allen<sup>1</sup>, N. Guha<sup>1</sup>, D. Gomez<sup>1</sup>, J. Li<sup>1</sup>

<sup>1</sup>University of Texas- MD Anderson Cancer Center, Radiation Oncology, Houston, USA

#### Purpose or Objective

The prolonged survival in NSCLC patients with EGFR-mutation or ALK-rearrangement treated with target agents calls for treatment of their brain metastases (BMs) with minimal toxicity and less systemic interruption. Although stereotactic radiosurgery (SRS) without whole brain radiation therapy (WBRT) is the preferred initial strategy for patients with 1-3 BMs, the paradigm remains elude for those with more than 3 cerebral lesions, particularly given the CNS penetration of available target therapies. The current study aims to investigate the overall survival, CNS progression and the rate of salvage WBRT in patients of EGFR-mutated or ALK-rearranged NSCLC with 4 or more BMs treated with SRS.

#### Material and Methods

We retrospectively reviewed NSCLC patients with EGFR-mutation or ALK-rearrangement who received Gamma Knife (GK) radiosurgery for 4 or more BMs in a single radiosurgery session at MD Anderson cancer center between 2009 and 2018. Overall survival, intracranial progression and freedom from WBRT were estimated using Kaplan-Meier analysis.

#### Results

Thirty-two patients, including 25 patients with EGFR mutation and 7 with ALK re-arrangement were identified and included in the current study with a total of 405 lesions treated with SRS. The median follow-up time was

22.8 months (range 1 to 71.4 months). The maximum number of BMs treated in a single GK radiosurgery per patient ranged from 4 to 18 (median 7), and the median number of total BMs treated over 1-5 courses of GK was 9 (range 4 to 37). The median overall survival for all patients was 33.4 months from the time of BM diagnosis. Overall survival was better in patients with fewer total number of lesions developed /treated (70.8 months for patients with 4-10 lesions, 34.5 months for those with 11-19 lesions and 27.7 months for those with >20 lesions), although this difference was not statistically significant ( $p=0.37$ ). The overall survival was not affected by the number of GK courses or the maximum number of BMs treated in a single GK session. Patients who received CNS-active TKIs had longer median survival (53.4 months) than those who received non-CNS active TKIs (33.4 months) ( $p=0.8$ ), and in this population receiving immunotherapy did not influence overall survival. Time to CNS progression after 1<sup>st</sup> course of GK radiosurgery was 10.1 months, and 6.2 and 6.3 months after the 2<sup>nd</sup> and 3<sup>rd</sup> course of GK, respectively ( $p=0.002$ ). Six patients received WBRT after the initial GK (crude rate of 18.8%), and the median time to WBRT was 13.6 months (range 10 to 23.9). Radiosurgery was well tolerated. Symptomatic radiation necrosis (RN) was observed in 4 of 405 treated BMs (0.98%) or 4 of 32 patients (12.5%).

#### Conclusion

In patients with multiple BMs from EGFR-mutated and ALK-rearranged NSCLC, the optimal initial management remains controversial. The results from our current retrospective study support the use of initial radiosurgery without WBRT as an effective and safe strategy for metastatic NSCLC patients with driven mutation and more than 4 BMs.

#### EP-1260 Outcomes of Local Control and CNS Toxicity with Single and Hypofractionated SRS for Brain Metastases

M. Patel<sup>1</sup>, S.R. Marcrom<sup>1</sup>, R.A. Popple<sup>1</sup>, A.M. McDonald<sup>1</sup>, K.O. Riley<sup>2</sup>, B.L. Guthrie<sup>2</sup>, J.M. Markert<sup>2</sup>, C.D. Willey<sup>1</sup>, M. Bredel<sup>1</sup>, J.B. Fiveash<sup>1</sup>

<sup>1</sup>University of Alabama-Birmingham, Department of Radiation Oncology, Birmingham, USA ; <sup>2</sup>University of Alabama-Birmingham, Department of Neurosurgery, Birmingham, USA

#### Purpose or Objective

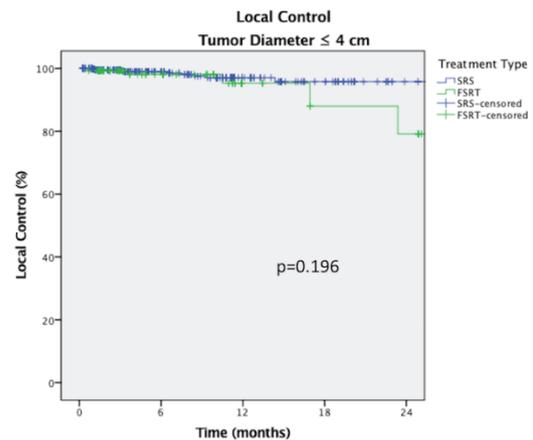

Radiosurgery is a standard management strategy of brain metastases in select patients. The role of single-fraction stereotactic radiosurgery (SRS) and hypofractionated stereotactic radiation therapy (FSRT) is currently evolving, with significant variability in utilization across institutions. We sought to retrospectively evaluate the impact of tumor size and treatment type (SRS vs. FSRT) on local control (LC) and CNS toxicity.

#### Material and Methods

All brain metastases from 2015-2017 treated with single-isocenter volumetric modulated arc therapy (VMAT) LINAC radiosurgery with a 6 DOF couch were captured. Tumors were included for analysis if they received SRS, FSRT, had no prior surgery or radiation, and had available follow-up imaging. The dose was prescribed to the edge of the GTV with no PTV margin. Local failure was defined as a 25% increase in tumor diameter on follow-up MRI or pathologic confirmation of tumor recurrence. Locally controlled tumors were censored at the time of last MRI follow-up, death, or whole brain radiation for distant brain failure. Significant CNS toxicity was per the RTOG definition as irreversible Grade 3 or higher toxicity. LC and CNS toxicity were evaluated by the Kaplan-Meier (KM) method with the log-rank test utilized to compare subgroups. A multivariable analysis (Cox Proportional Hazards model) of potential factors affecting LC was performed.

#### Results

A total of 688 tumors were included, 530 treated with SRS and 158 treated with FSRT. The median radiographic and clinical follow up was 5 months and 7 months, respectively. All subsequent comparisons are given as SRS versus FSRT. The median tumor diameter was 0.82 cm and 1.65 cm ( $p<0.001$ ). The KM estimate of 12-month LC among tumors  $\leq 4$ cm was 97% and 95% ( $p=0.196$ ). KM estimates of 12-month LC for tumors  $\leq 2$ cm was 98% and 100% ( $p=0.352$ ),  $>2$  to  $\leq 3$ cm was 91% and 100% ( $p=0.439$ ), and  $>3$  to  $\leq 4$ cm was 80% and 74% ( $p=0.863$ ). Additionally, KM estimate of 12-month freedom from significant CNS toxicity was 99% and 97% ( $p=0.308$ ) overall and 89% and 100% ( $p=0.128$ ) for tumors  $>3$  to  $\leq 4$  cm. Only tumor volume (HR 1.141;  $p<0.001$ ) was predictive of local failure in a multivariable analysis that included treatment type (HR 0.927;  $p=0.909$ ).

#### Conclusion

SRS and FSRT appear to have a high rate of local tumor control with a low rate of significant CNS toxicity. LC and CNS toxicity outcomes appear to be driven by tumor volume without being significantly affected by treatment type. FSRT appears to offer a safe and effective alternative to SRS in both large and small tumors. In patients with multiple metastases in which a large target requires fractionation, utilizing the same dose and fractionation across all treated targets, regardless of target size, offers an opportunity for improved efficiency in treatment planning and treatment delivery without compromising outcomes.

#### EP-1261 MRI-guided SABR of spinal metastases: comparison of Co-60 and linac treatments

R. Llorente<sup>1</sup>, C. Takita<sup>1</sup>, R. Yechieli<sup>1</sup>, J.C. Ford<sup>1</sup>, K. Brown<sup>1</sup>, M. Samuels<sup>1</sup>, E.A. Mellon<sup>1</sup>

<sup>1</sup>University of Miami/Sylvester Comprehensive Cancer Center / Jackson Memorial Hospital, Radiation Oncology, Miami, USA

*This abstract is part of the media programme and will be released on the day of its presentation*

procedures, which included surgery (12 patients), repeat gamma knife alone (5 patients), or a combination of repeat gamma-knife and surgery (3 patients). Of the patients receiving additional treatments, 14 experienced pain relief at their most recent follow up.

#### Conclusion

Complete pain control following GK treatment for TG neuralgia at one year was found to be 56% in our cohort. It is difficult to discern the actual control rate from the 1999-2006 cohort due to significant loss to follow-up, perhaps due to symptom resolution. 66% of patients in our cohort required additional procedures for pain management, including surgery and repeat GK. Future directions include reviewing more recent cases from 2006-2018, which may have improved follow up and documentation due to implementation of the electronic medical record.

#### EP-1263 Hippocampal avoidance in WBRT for Metastases - Comparative Neurocognitive and Dosimetric Assessment

V. Pareek<sup>1</sup>, R. Bhalavat<sup>1</sup>, M. Chandra<sup>1</sup>

<sup>1</sup>Jupiter Hospital, Radiation Oncology, Mumbai, India

#### Purpose or Objective

Hippocampus is associated with formation and storage of new memory and irradiation of the same during whole brain radiotherapy in brain metastases leads to decline in the neurocognitive function. Recent advancements in radiation delivery in form of IMRT, Hippocampal avoidance has been made possible. We analyze feasibility of hippocampal sparing and associated neurocognitive and dosimetric assessment.

#### Material and Methods

Between June 2016 to December 2017, 125 patients diagnosed radiologically and clinically with brain metastases were included in the study. Mini Mental State Examination (MMSE) and quality of life assessment with EORTC BN20 questionnaire were assessed along with dosimetry. Patients were assessed at baseline and followed by at 1, 3 and 6 months respectively. Factors were compared with the historical group with relation to quality of life especially neurocognitive functioning. Wilcoxon test for multiple comparisons was calculated to detect significant differences in global QoL scores. Dose received in WBRT was 30Gy in 10 fractions in both arms with boost of 9Gy in single metastases.

#### Results

Median age of accrued 125 patients was 48 years. Median D100% and Dmax to contralateral hippocampus was 7.1Gy and 16.7Gy. With IMRT, the doses to other critical structures were reduced. Patients treated with IMRT were found to have achieved desired dose constraints to hippocampus. Assessment of neurocognitive function between two groups, there was no difference at 1 month after treatment, however, difference was seen at 3 and 6 months favouring hippocampal avoidance. No difference noted in other aspects of quality of life between two groups. No severe toxicities (Grade 3 and 4) were noted in either group. Median survival in the HA-WBRT arm was found to be 10.1 months.

#### Conclusion

Conformal avoidance of hippocampus during WBRT is associated with improved neurocognitive function and quality of life. IMRT has found to provide better dosimetric outcomes in HA-WBRT

Electronic Poster: Clinical track: Haematology

---

#### EP-1262 Use of Gamma Knife Radiosurgery for Treatment of Trigeminal Neuralgia

D. Fabian<sup>1</sup>, J. Palmer<sup>2</sup>

<sup>1</sup>The Ohio State University, Radiation Oncology, Columbus, USA ; <sup>2</sup>Palmer, Radiation Oncology, Columbus, USA

#### Purpose or Objective

Gamma Knife radiosurgery (GK) has been shown to relieve symptoms of trigeminal neuralgia (TN). Success rates have been reported to range between 70-90% at a follow up of 19-75 months. Our objective was to evaluate the success rate of GK for TN treatment in our institution and to evaluate the need for additional procedures. Our hypothesis was that the need for additional treatments would be high.

#### Material and Methods

We identified 50 cases of refractory TG treated with GK at our institution from 1999-2006. These patients were retrospectively chart-reviewed and assessed for subjective pain control and need for medical management. Average GK dose was 38 Gy to the 50% isodose; the median dose was 40 Gy to the 50% isodose. Of these 50 cases, only 30 patients had adequate follow up at 1 year.

#### Results

Of the patients with adequate one-year follow up, 17 reported adequate control of their pain following the procedure (56%). 10 (33%) patients reported control at 2 years post first gamma knife treatment and 6 patients (13%) reported control at 5 years post first gamma knife treatment. 20 patients were reported to have additional

EP-1264 Patterns of care for orbital MALToma in Korea throughout 2016: a multicenter cross-sectional study

---

J. Lee<sup>1</sup>, D. Oh<sup>2</sup>, B.O. Choi<sup>3</sup>, K.Y. Eom<sup>4</sup>, J.H. Lee<sup>5</sup>, J.H. Kim<sup>6</sup>, S.W. Lee<sup>7</sup>, Y.K. Suh<sup>8</sup>, C. Suh<sup>9</sup>  
<sup>1</sup>Inha University Hospital, Radiation Oncology, Incheon, Korea Republic of ; <sup>2</sup>Samsung Medical Center-Sungkyunkwan University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Seoul St. Mary's Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>4</sup>Seoul National University Bundang Hospital, Department of Radiation Oncology, Seongnam, Korea Republic of ; <sup>5</sup>St. Vincent's Hospital, Department of Radiation Oncology, Suwon, Korea Republic of ; <sup>6</sup>Kunyang University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>7</sup>Asan Medical Center- Ulsan University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>8</sup>National Cancer Center, Department of Radiation Oncology, Ilsan, Korea Republic of ; <sup>9</sup>Yonsei Cancer Center- Yonsei University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of

### Purpose or Objective

Radiotherapy (RT) is an effective primary treatment for orbital mucosa-associated lymphoid tissue (MALT) lymphoma historically. Recent few studies reported the association between Chlamydia psittaci infection and orbital MALT lymphoma. We aimed to assess the current patterns of care in clinical practice for orbital MALT lymphoma in South Korea.

### Material and Methods

We performed a multicenter, cross-sectional cohort study of patterns of care for orbital MALT lymphoma in South Korea throughout 2016, and overall 8 institutions with 90 patients were participated. All patients diagnosed with orbital MALT lymphoma based on a pathologic confirmation.

### Results

The survey showed that most frequent upfront treatment for orbital MALT lymphoma was RT (80/90, 90%). Other treatments were given to a limited number of orbital MALT lymphoma patients as follows: wait and watch (6/90, 7%), antibiotics (3/90, 3%), and chemotherapy (1/90, 1%). Generally, RT was administered to the entire involved site such as entire conjunctiva/eyelid or entire orbit (96%), with a median total dose of 25.2 Gy. Lens shielding was performed for most patients with conjunctival and eyelid tumors (93%).

### Conclusion

Our findings revealed that RT was the mainstream of orbital MALT lymphoma treatment. Currently, for patients with orbital MALT lymphoma, RT has been performed to the entire involved subsites with a lower dose compared to the past, and lens shielding is applied to minimize the orbital complication.

### EP-1265 Total Skin Irradiation - 15 years of Gliwice experiences

G. Wozniak<sup>1</sup>, T. Latusek<sup>1</sup>, Z. Kaniszewska-Dorsz<sup>1</sup>, W. Mista<sup>1</sup>, B. Jochymek<sup>1</sup>, K. Lukasz<sup>1</sup>, W. Jerzy<sup>1</sup>, S. Blamek<sup>1</sup>  
<sup>1</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy, Gliwice, Poland

### Purpose or Objective

Evaluation of effectiveness and early toxicity of total skin radiation for patients with primary skin lymphoma

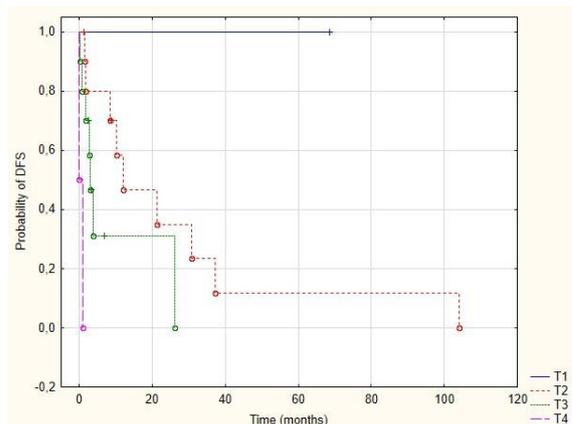

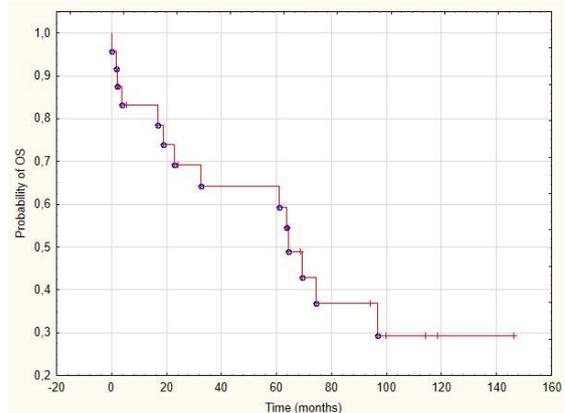

### Material and Methods

Between 2002 and 2017 25 patients with pathological diagnosed primary skin lymphomas were treated with electron radiotherapy using total skin irradiation technique. Male to female ratio was 14 to 11. In almost all patients (22) mycosis fungoides were confirmed. Median age was 66 years. One patient was staged as T1, 11 as T2, 10 as T3 and 3 as T4. Only three patients did not undergo any oncological therapy before radiation. All patients were irradiated 6MeV electron beams using linac. Total

dose ranged between 6 to 36 Gy (median 32) given in 1,5-2 Gy per fraction. In 6 cases additional boost fields for residual disease were used after the end of total skin treatment. Skin reactions and haematological toxicity were assessed with WHO score. OS and PFS were estimated using Kaplan Maier method.

### Results

Median follow up was 20 months. Two patients have not completed treatment. Each patient had skin reaction: 18 were scored as 1st, 4 as 2nd and 1 as 3rd grade. There was not any haematological toxicity observed within the group. Other adverse effects included: alopecia 6pts, conjunctivitis 4pts, general weakness 3pts. In 79% pts disease symptoms regression were observed, including complete response in 20%. Progression was documented in 3 cases. Median time to progression was 7 months, and OS was 64 months. One year PFS was 36% and 5yrs OS was 67%. (Fig1) There was significant differences in PSF depending of T stage (p=0,028) (Fig2). No other factors influencing the OS and PFS were proven. Cox hazard analysis showed that clinical stage and disease regression 6 weeks after radiotherapy are independent risk factors for progression.

### Conclusion

TSI in skin lymphomas using 6MeV electrons is a safe treatment method yielding satisfactory yet short term response rate. Only clinical stage has impact on time to disease progression

### EP-1266 Combination radiotherapy with Nivolumab for refractory classic Hodgkin lymphoma : about two cases

L. De Forceville<sup>1</sup>, B. Deau-Fischer<sup>2</sup>, P. Franchi<sup>2</sup>, A. Arsene-Henry<sup>3</sup>, T. Cassou Mounat<sup>4</sup>, D. Bouscary<sup>2</sup>, Y. Kirova<sup>3</sup>

<sup>1</sup>Hopital Tenon, oncologie médicale, Paris, France ; <sup>2</sup>Hopital Cochin, Hématologie, Paris, France ; <sup>3</sup>Institut Curie, Radiothérapie, Paris, France ; <sup>4</sup>Institut Curie, Médecine Nucléaire, Paris, France

### Purpose or Objective

For patients who experience relapse or refractory Hodgkin Lymphoma (R/R HL), the standard treatment option is high-dose chemotherapy followed by autologous stem cell rescue or transplant (HDT/ASCR). However about 50% of patients will have recurrence after HDT/ASCR and have worse prognosis. The anti-PD1 checkpoints inhibitors have remarkably improved outcomes of patients with R/R HL after HDT/ASCT. On the other hand, radiotherapy is an entire component of salvage therapy and its efficacy is now well established in term of local disease control in sites of R/R HL. Defining the optimal modality and timing of radiotherapy as these new agents arrive is a challenge. The purpose of our paper is to add at the literature two new cases of combination of radiotherapy with immunotherapy in patients who relapse after HDT/ASCT and consolidation with Brentuximab Vedotin (BV).

### Material and Methods

Clinical data were retrospectively collected using the computerized medical records available at the Curie Institute and Cochin Hospital. All imaging have been integrated into the local imaging software and re-read at Institut Curie.

### Results

Case 1: a 27 year-old man was diagnosed in 2015 with stage IV classic Hodgkin Lymphoma, with sus and under diaphragmatic lymph nodes and multiple bone lesions. After 4 cycles of BEACOPP, there was a persistence of a cervical lymph node and mediastinum uptake (Deauville score 4). The patient received a second line with BV-DHAX followed by autologous stem cell transplant (ASCT) in April 2016, resulting in complete metabolic response. A consolidation treatment with BV was initiated. The patient relapsed in June 2017 with cervical and mediastinal lymph nodes (confirmed by biopsy). It was decided an involved sites radiotherapy (30 Gy in IMRT) followed with nivolumab. The patient had now 26 cycles of nivolumab and is in complete response since the third injection.

Case 2: A 21 year-old woman was diagnosed in 2015 with classic Hodgkin Lymphoma stage IIAa, Bulky +. After 2 cycles of BEACOPP, Deauville score was 3. The treatment was de-escalated with ABVD. After 4 cycles, there was a marked increase of the mediastinum uptake. The multidisciplinary team of Cochin opted for a salvage chemotherapy by Brentuximab-DHAX, followed by ASCT and resulting in complete metabolic response. The patient then received a consolidation treatment with BV. The patient relapsed in may 2015 with supra-dipahragmatic nodes and reappearance of the mediastinal mass confirmed by biopsy. The patient received a localized radiotherapy of the mediastinum followed by Nivolumab. After 30 cycles of nivolumab, complete response was maintained, nivolumab was stopped since October 2017 and the patient is still in complete response.

### Conclusion

Involved sites radiotherapy followed by nivolumab is an interesting option for patients with RR/HL who experience a localized relapse after ASCT. This combination may increase the response to checkpoint inhibitors and allow to stop them.

### EP-1267 Deep Inspiration Breath-Hold versus free breathing radiotherapy in mediastinal lymphoma

A. Iversen<sup>1</sup>, H.R. Mortensen<sup>1</sup>, Hanne Krogh Rose<sup>1</sup>, Jolanta Hansen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology and Medical Physics, Aarhus C, Denmark

### Purpose or Objective

Radiotherapy plays an important role in the treatment of mediastinal lymphomas as part of combined modality treatment. However, late effects, e.g. cardiac and lung toxicity as well as secondary cancers due to radiotherapy,

are of great concern especially for mediastinal tumors. It is therefore important to reduce normal tissue dose. Our aim was to evaluate local experience of radiotherapy for mediastinal tumors comparing deep inspiration breath-hold (DIBH) and free breathing (FB) technique with intensity-modulated radiotherapy (IMRT) in regards to normal tissue doses.

### Material and Methods

Since October 2017 12 patients have been planned with both DIBH and FB technique for mediastinal lymphomas according to IROG guidelines. Data on histology, chemotherapy, prior cardiac or lung malfunction and radiotherapy was obtained from the patient files. Target delineation was based on current international guidelines and patients were treated with 24-36 Gy; 2 Gy per fraction. Two IMRT plans were calculated and compared for each patient: one for FB and one for DIBH. All plans were simulated in Eclipse (version 13.7.14, Varian Medical Systems) with the AcurosXB 13.7.14 algorithm using 6-MV photon beams. The IMRT plans consisted of 5 to 7 fixed fields. The dosimetric parameters retrieved for the statistical analysis were PTV coverage, mean heart dose, mean lung dose, and lung V5 and heart V20.

### Results

12 patients were planned with both DIBH and FB IMRT. The patient cohort consisted primarily of men (8 male, 4 female) with a median age of 37 years (range 10-62). All patients received chemotherapy as initial treatment according to national guidelines. Seven patients were treated with radiotherapy in FB and five patients were treated in DIBH. There was no difference in age, total dose, CTV volume or CTV relation to the heart between patients treated with DIBH and patients treated in FB. Patients treated with DIBH had significantly reduced mean dose to total lung,  $V5_{total\ lung}$ , mean heart dose and  $V20_{heart}$  when comparing DIBH IMRT and FB plan IMRT ( $p < 0.5$ ). For three patients, plan robustness and DIBH instability contributed to treatment choice.

### Conclusion

The experience with DIBH IMRT is still limited in our department. Surprisingly, in the first 12 patients, DIBH IMRT was the treatment of choice in only five patients based on reduced doses to lungs and heart. The remaining seven patients were treated with FB IMRT, since no gain in normal tissue doses was obtained with DIBH IMRT. Further data is needed to properly select patients for DIBH IMRT and thereby individualize the radiation plan for the individual patient.

### EP-1268 Primary radiation therapy in stage I/II indolent orbital lymphoma: a single-center analysis

C. Eze<sup>1</sup>, I. Friedrich<sup>1</sup>, D. Reitz<sup>1</sup>, C. Belka<sup>1</sup>, M. Li<sup>1</sup>

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, Munich, Germany

### Purpose or Objective

Non-Hodgkin Lymphoma is a heterogenic group of malignant diseases, which originate from the lymphatic system. They can be subdivided into B- and T-Cell-Lymphoma and classified into indolent/low-grade and high-grade/aggressive lymphoma. Radiotherapy is well-established in the management of stage I/II (Ann Arbor classification) indolent lymphoma. We conducted this retrospective analysis to evaluate the outcomes of patients with localized indolent orbital lymphoma who were treated at our center with definitive radiotherapy.

### Material and Methods

We retrospectively reviewed the medical charts of 47 patients (12 males, 35 females) with 52 lesions treated at our center from 1994- 2012 for histologically confirmed indolent orbital lymphomas. Median age at diagnosis was 63.5 years (range: 20-92) with 25 lesions on the right and 27 on the left. Five patients presented with bilateral involvement. The predominant histological subtype was mucosa-associated lymphoid tissue lymphoma in 84.6% of

cases. Most lymphomas were located in the conjunctiva (34.6%) and the lower or upper eyelids (34.6%). The majority of patients presented with stage I disease (76.9%). Radiation dose ranged from 21.6-45.0 Gy (median 39.8 Gy) in 1.8-2.0 Gy daily fractions. Median follow-up duration was 83 months.

#### Results

All but one patient achieved local complete remission. The 5- year progression-free survival rate was 77.5% (95% CI: 71.2 - 83.8) (Fig. 2). In addition, 5- and 10-year overall survival rates were 84.0% (95% CI: 78.4 - 89.6) and 77.1% (95% CI: 70.2 - 84.0), respectively. Of all patients who died within 5 or 10 years, there was only one documented case of progression. Treatment was in general well tolerated with acute toxicity, e.g. conjunctivitis (42.3%), ophthalmalgia (13.5%) and Keratitis (3.8%) with convalescence in the majority of cases. Late toxicity included all degrees of cataract, 31 patients (59.6%) and of xerophthalmia, 36 patients (69.2%).

#### Conclusion

Our retrospective analysis showed that moderate radiotherapy is an effective treatment modality with excellent local control and moderate late complication rates in the management of stage I/II indolent orbital Non-Hodgkin lymphoma.

#### EP-1269 Local review of lung doses in simultaneous integrated boost (SIB) radiotherapy breast plans

J.F. Calvo Ortega<sup>1</sup>, J. Fernández-Ibiza<sup>1</sup>, S. Moragues

Femenia<sup>1</sup>, C. Laosa-Bello<sup>1</sup>, J. Casals<sup>1</sup>

<sup>1</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

#### Purpose or Objective

To perform a review of the lung radiation doses from breast cancer radiotherapy plans for a specific SIB scheme used in our department.

#### Material and Methods

Lung doses in 185 SIB treatment plans were included in this study. The whole breast ± axillary or supraclavicular lymph nodes and the tumor bed were planned to simultaneously receive 45.57 Gy and 55.86 Gy in 21 fractions, respectively. Supine radiotherapy with no breathing adaptation was performed. Plans were computed using the AAA algorithm of the Eclipse TPS v 13.0 and IMRT technique, modeled for 6 MV photon beams of a Varian Clinac 2100 CD. All plans fulfilled the organ-at-risk dose constraints used in our department for this 21 fraction radiotherapy scheme.

The following metrics were analyzed:  $V5_{ips}$ ,  $V20_{ips}$ , and mean lung dose ( $MLD_{ips}$ ) for the ipsilateral lung, and mean dose to both lungs ( $MLD_{whole}$ ).  $Vx_{ips}$  is the percentage volume of the ipsilateral lung receiving  $\geq x$  Gy. The values of these metrics collected in our plans were compared with the multicentric data recently reported by Aznar et al. in *Radiother Oncol.* 2018 Jan;126(1):148-154, as a way of assessing the quality of our breast plans.

#### Results

For breast plus regional lymph nodes (37 cases), comparison of our values vs. Aznar's values was (average ± standard error): 43.8% ± 2.1% vs. 46.6% ± 6.0% for  $V5_{ips}$ ; 14.3% ± 0.3% vs. 22.8% ± 1.3% for  $V20_{ips}$ ; 9.1 Gy ± 0.4 Gy vs. 11.2 Gy ± 0.5 Gy for  $MLD_{ips}$ ; and 4.8 Gy ± 0.2 Gy vs. 7.3 Gy ± 0.4 Gy for  $MLD_{whole}$ .

For simple breast (148 cases), comparison of our values vs. Aznar's values was (average ± standard error): 29.8% ± 0.8% vs. 40.2% ± 2.2% for  $V5_{ips}$ ; 9.9% ± 0.3% vs. 13.8% ± 0.4% for  $V20_{ips}$ ; 6.2 Gy ± 0.1 Gy vs. 8.6 Gy ± 0.2 Gy for  $MLD_{ips}$ ; and 3.2 Gy ± 0.1 Gy vs. 5.7 Gy ± 0.2 Gy for  $MLD_{whole}$ .

#### Conclusion

Inclusion of the regional lymph nodes considerably increased the metric values relative to irradiation of the whole breast only. Lung average doses attained with the 21 fraction SIB scheme used in our department were always smaller than the reported ones by Aznar et al. This can be considered as a quality test for our designed treatment plans.

#### EP-1270 Outcomes and toxicity of stereotactic radiotherapy for metastatic breast cancer - a retrospective study

M. AL-Hanaqta<sup>1</sup>, M. Niglas<sup>2</sup>, C. Jiang<sup>3</sup>, P. Cheung<sup>2</sup>, W. Chu<sup>2</sup>, H. Chung<sup>2</sup>, S. Myrehaug<sup>2</sup>, I. Poon<sup>2</sup>, A. Sahgal<sup>2</sup>, H. Soliman<sup>2</sup>

<sup>1</sup>Royal medical services, Radiation oncology, Amman, Jordan ; <sup>2</sup>Sunnybrook HSC, Radiation oncology, Toronto, Canada ; <sup>3</sup>University of Toronto, School of medicine, Toronto, Canada

#### Purpose or Objective

Technological advances in radiotherapy have allowed for the delivery of ablative doses to sites of disease in most parts of the body. In this trial, we describe the outcomes of a group of breast cancer patients treated to sites of metastatic disease with stereotactic radiotherapy (SBRT). Predictors of treatment outcomes are also investigated in this cohort.

#### Material and Methods

After institutional research ethics board approval, patients with metastatic breast cancer who received SBRT to metastatic disease from 2011 to 2016 were identified by electronic chart review. Patient demographics, histologic information and clinical data were collected from the electronic patient record and the radiation treatment planning system. Outcomes of interest included local control (LC), overall survival (OS), and progression free survival (PFS). In addition to Kaplan-Meier estimates, univariate analysis using the log-rank test, and multivariate analysis with cox regression was used to assess covariates, which were identified a priori.

#### Results

120 patients between the ages of 25 to 82 (median 54.8 years) with 193 treated lesions were identified. Median follow-up was 9.8 months (range 0.03 to 72.31 months). Patients' estrogen receptor (ER), progesterone receptor (PR) and Her-2 status were 83.9%, 70.7% and 18.4% respectively (maybe better to describe subtype here, e.g. luminal a). 70.3% had lymph node positive disease at diagnosis. The majority of treated lesions were in the spine (45%), followed by liver (20%), lung (18%) and non-spine bone (14%). There were no recorded grade 4 or 5 toxicities, with only 5.3% of patients reporting side effects (most commonly mild pain). 1-year LC, PFS and OS was 88%, 45% and 84% respectively. On univariate analysis, PFS varied depending on treatment indication (oligometastasis, oligoprogression or salvage) with a median PFS of 24.4 months, 5.6 months and 8.1 months respectively ( $p < 0.001$ ). Similarly, a difference in OS by treatment indication was also seen with 1-year survival of 91%, 82% and 57% respectively ( $p < 0.001$ ). Survival was influenced by molecular subtype, with the worst survival seen in patients with triple negative disease ( $p = 0.001$ ).

#### Conclusion

Local control rates remain excellent after SBRT to sites of metastatic disease in this population of breast cancer patients. The most significant risk for these patients remains distant failure, with significantly longer PFS in those being treated for oligometastatic disease in comparison to other indications. Favourable PFS observed in the oligometastases subgroup would support further randomized evaluation of the potential benefit of SBRT in this population, as is currently being performed in other tumour histologies.

### EP-1271 Effects of regular bra-wearing on acute skin toxicity in breast-conserving radiotherapy women

P. Thongkhao<sup>1</sup>, T. Peerawong<sup>1</sup>, R. Jiratrachoo<sup>1</sup>, J. Pruetkitti<sup>1</sup>, A. Geater<sup>2</sup>

<sup>1</sup>Faculty of Medicine- Prince of Songkla University., Radiology, Hat Yai- Songkhla, Thailand ; <sup>2</sup>Faculty of Medicine- Prince of Songkla University., Epidemiology Unit, Hat Yai- Songkhla, Thailand

#### Purpose or Objective

At present, the instruction of wearing bra in daily life during radiotherapy treatment course in breast conserving therapy (BCT) patients is unclear. This study aimed to evaluate the effect of regular bra-wearing during radiotherapy on acute skin toxicity and the quality of life in women with BCT.

#### Material and Methods

This study is a preliminary prospective non-inferiority cohort study. Women with any stage breast cancer who underwent BCT were enrolled from June 2017 to July 2018 at a single tertiary center in the Southern Thailand. The exclusion criteria included patients who underwent an immediate reconstruction, patients with pre-existing skin lesions in the treatment area, and patient with known systemic skin diseases, even not directly affecting irradiated fields. After informed consent was obtained, participants were instructed to wear appropriate bra, record the hours per day of wearing bra in a patient record form, and were told they could freely decide to wear the bra or not. Then all participants were classified by total hours of wearing bra during the radiotherapy treatment course into non-bra-wearing (0 hr.) and bra-wearing groups (>0 hr.). The acute skin toxicity was assessed weekly and one week after treatment end by CTCAE version 4 and the quality of life was assessed before and one week after treatment end by FACT-B Thai version 4. All participants were treated with a dose of 50Gy in 25 fractions over 5 weeks. An addition boost 10-16Gy was given, depending on clinical judgement. Differences in acute skin toxicity grade between the two groups were assessed using Chi-square test or a Fisher's exact test and the quality of life scores were compared using Student's t-test or Wilcoxon rank-sum test.

#### Results

A total of 99 patients were eligible, which 66 patients were in bra-wearing group and 33 patients were in non-bra-wearing group. Baseline patient characteristics were well balanced except for T-stage and median maximum dose. Overall rate of  $\geq$  G2 acute skin toxicity was 29% and began to appear after 4<sup>th</sup> week of treatment in both groups (Figure 1). The rate of  $\geq$  G2 acute skin toxicity was lower in bra-wearing group compared to non-bra-wearing group (16.7% vs. 54.5%,  $p < 0.001$ , respectively). In the multivariate analysis, the statistically significant factors that associated with increased the risk of  $\geq$  G2 acute skin toxicity were non-bra-wearing (0 hr.) ( $p < 0.001$ ), high body mass index ( $p = 0.002$ ), and high percentage of maximum dose ( $p = 0.022$ ) (Table 1). There was no difference in all five parts and total mean scores of after treatment FACT-B Thai between the bra-wearing and non-bra-wearing groups (118.4 vs. 114.7,  $p = 0.256$ , respectively).

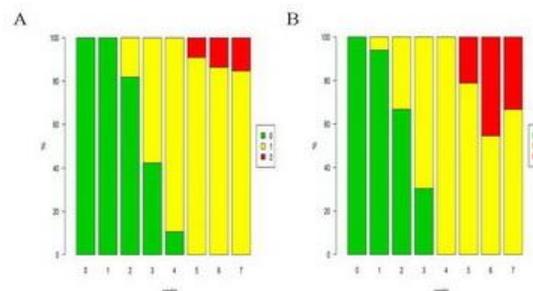

Figure 1. Proportions of acute skin toxicity in each week. (A) bra-wearing group and (B) non-bra-wearing group

Table 1. Multivariate analysis of the predictors for increased  $\geq$  G2 acute skin toxicity

	Adj. OR (95%CI)	P (Wald's test)	P(LR-test)
Total hour wearing bra (hr.)			< 0.001
Ref.= 0			
1-350	0.16 (0.04,0.58)	0.005	
>350	0.08 (0.02,0.43)	0.003	
Body mass index (kg/m <sup>2</sup> )			0.002
Ref.= <18.5			
18.5-24.9	0.46 (0.05,4.19)	0.493	
25-29.9	1.96 (0.2,18.94)	0.56	
$\geq 30$	9.48 (0.82,109.44)	0.072	
Maximum dose (%)			0.022
Ref.= $\leq 107$			
>107-110	1.21 (0.15,9.59)	0.859	
>110	5.62 (0.84,37.53)	0.075	

#### Conclusion

Regular bra-wearing during radiotherapy is not associated with increased the risk of  $\geq$  G2 acute skin toxicity and does not affect the quality of life compared to non-bra-wearing.

### EP-1272 Is hypofractionated nodal radiotherapy safe in the treatment of breast cancer patients?

C. Matthieu<sup>1</sup>

<sup>1</sup>CHU, Radiotherapy, BESANCON, France

#### Purpose or Objective

We retrospectively evaluated safety and efficacy of hypofractionated locoregional radiotherapy (HLRT) in breast cancer (BC) patients. We compared them patients treated, in the same period, with hypofractionated radiotherapy on the breast/wall chest only (HRT).

#### Material and Methods

We reviewed the charts of patients with biopsy-proven BC treated with postoperative HLRT (n= 275, 63%) or HRT (n= 160, 37%) between 2008 and 2011. Incidence of acute and late toxicity was the primary endpoint. Five-year locoregional-free survival (LRR-FS), disease-free survival (DFS) and overall survival (OS) were also analyzed and reported.

#### Results

Median follow-up was 61.7 months. Treatment was globally well-tolerated. Severe acute toxicity was found in 4.4% of the HRT cohort and 3.1% of the HLRT one ( $p = 0.79$ ), usually as dermatitis. HLRT patients presented more frequently G1-2 dysphagia (30.6% vs 0.4%,  $p < 0.001$ ) and/or G1-2 lymphedema (5.6% vs 0.4%,  $p = 0.002$ ). At multivariate analysis, tabagism was the only independent factor statistically influencing the risk of acute toxicity ( $p = 0.047$ ). Concerning late toxicity, HLRT patients presented more frequently G1-2 lymphedema (6.2% vs 0.7%,  $p = 0.003$ ). Five-year LRR-FS was 96.3% in the HRT and 92% in the HLRT population, respectively ( $p = 0.004$ ). Five-year DFS was 92.2% in the HRT and 83.4% in the HLRT population, respectively ( $p = 0.004$ ). Five-year OS was 96.4% in the HRT and 92.6% in the HLRT group, respectively ( $p = 0.027$ ).

### Conclusion

HLRT is safe and the clinical outcomes of our patients are comparable to the results of available randomized trials on hypofractionation for breast cancer. Further, prospective randomized trials are warranted to confirm our data and consider HLRT a standard of care.

### EP-1273 Increasing negative lymph node count prolong survival in breast cancer with neoadjuvant chemotherapy

X. Wang<sup>1</sup>, P. Wang<sup>1</sup>

<sup>1</sup>Tianjin Medical University Cancer Hospital & Institute, Department of Radiation Oncology, Tianjin, China

### Purpose or Objective

Adequate lymph node evaluation is recommended many malignant tumors including breast cancer. However, the role of negative lymph nodes (LNs) remains unclear in breast cancer (BC), especially in the setting of neoadjuvant chemotherapy. A retrospective analysis of BC treated with mastectomy after NAC in our institution was conducted.

### Material and Methods

A total of 435 patients diagnosed with BC who were treated with mastectomy after NAC were included in this analysis. The median age was 49 years old (22-76 years old). The clinical stage distributions were cT1-2 in 245 patients and T3-4 in 190 patients, cN0 in 82 cases, cN1 in 309 cases, and cN2 in 44 cases. The pathological stage distributions were ypT0-2 in 385 patients, ypT3-4 in 187 patients, ypN0 99 cases, ypN1 in 99 cases, ypN2 in 108 cases, and ypN3 in 129 cases.

### Results

With a median follow-up time of 61 months. The 5 year overall survival (5y-OS), 5 year locoregional failure free survival (5y-LRFS), 5 year distant metastasis free survival (5y-DMFS) were 74.8%, 84.1%, and 71.4%, respectively. The median number of dissected LNs is 22, and median positive LNs is 4. In multivariate analysis, negative LN count, estrogen receptor status, pathological T and N stage were independently prognostic factors associated with 5y-LRFS. A critical relationship was observed between negative LNs and 5y-LRFS, with a HR of 0.948 (95% CI: 0.917-0.981),  $p=0.002$ . Patients with negative LN counts more than 10 showed significantly superior 5y-LRFS than those with negative LN count no more than 10 (5y-LRFS were 90.6% in >10 negative LNs vs. 64.8% in  $\leq 10$  negative LNs,  $p=0.000$ ). Interestingly, similar survival trends were showed in patients with N-positive diseases (5y-LRFS were 87.4% in >10 negative LNs vs. 64.0% in  $\leq 10$  negative LNs,  $p=0.000$ ), but not in the N0 disease (5y-LRFS were 96.9% in >10 negative LNs vs. 100% in  $\leq 10$  negative LNs,  $p=0.724$ ). And more importantly, postmastectomy radiotherapy seems to only improved 5y-LRFS in patients with  $\leq 10$  negative LNs (5y-LRFS were 69.0% vs. 27.6% with or without PMRT,  $p=0.002$ ), but not patients with >10 negative LNs (5y-LRFS were 88.4% vs. 85.1% with or without PMRT,  $p=0.257$ ).

### Conclusion

This is the first study to confirm the relationship between negative lymph node count and prognosis of breast cancer in the setting of NAC. More negative lymph nodes imply longer survival, which may help to predict prognosis and make treatment recommendation.

### EP-1274 neoplastic brachial plexopathy in breast cancer survivors: diagnosis traps, RT-VMAT faisibility

S. Delanian<sup>1</sup>, P. Ding<sup>2</sup>, H. Huet de Froberville<sup>2</sup>, C. Boguszewski<sup>3</sup>, P. Pradat<sup>4</sup>

<sup>1</sup>Hopital Saint-Louis- APHP, Oncologie-Radiotherapie-Radiopathologie, Paris, France ; <sup>2</sup>Centre Clinique Porte de Saint-Cloud- Hôpital Americain de Paris, Radiophysique, Boulogne, France ; <sup>3</sup>Centre Clinique Porte de Saint-Cloud- Hôpital Americain de Paris, Radiotherapie, Boulogne, France ; <sup>4</sup>Hopital Pitié-

Salpêtrière- APHP, Oncologie-Radiotherapie-Radiopathologie, Paris, France

### Purpose or Objective

Neoplastic brachial plexopathy (NBP) is a carcinomatous peripheral neuropathy in the axillary-supraclavicular region, often misdiagnosed as a radiation-induced (RI) complication, even when node areas have not been irradiated. The literature is old and limited: series of 5 to 78 cases have been reported in 11 articles over 40 years (1968-2009), while histology, imaging and RT have undergone deep mutations.

### Material and Methods

330 long-survivor patients treated for breast cancer have been referred to Hôpital Saint-Louis (2004 -17), for brachial RI plexopathy round the inclusion period of our therapeutic phase III trial (NCT01291433): 12 % of the patients were finally diagnosed with a neoplastic origin. NBP was established after expertise based on the following arguments: delayed then progressive development of arm lymphedema (75%), intense arm pain, quite fast progressing motor symptoms, ptosis, slight inflammatory signs on MRI and PET-scan imaging (re-interpretation), and axillary volume exclusion of the primary RT volume (dosimetric check).

Fortywomen (65  $\pm$  9y), treated 14  $\pm$  7 years before by surgery (5 N0, 14 N-, 14  $\leq 2N+$ , 7  $\geq 6N+$ ) then radiotherapy (1974-2013), were diagnosed with NBP after 1 to 4 years of neurological evolution.

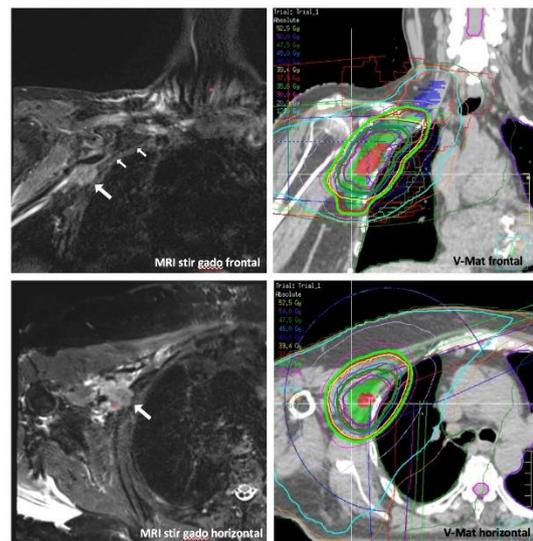

Patients had salvage chemotherapy-hormonotherapy, and for some of them, plexus RT by conformal then V-mat technique.

### Results

According to previous breast RT, 3 NBP prognostic groups were analyzed: 16 [R<sub>0</sub>] (40%) without any node RT, 11 [R<sub>1</sub>] supraclavicular RT only (without axillar), and 13 [R<sub>2</sub>] axillary and supraclavicular RT.

MRI and PET-scan were mis-interpreted either as very slow kinetic tumor (hormono-dependant) or inflammatory NBP. A triangular axillary fixation in the border of previous supraclavicular RT beam, SUV 2-5, was pathognomonic of R<sub>1</sub>NBP group (figure). The time BC-NBP was R<sub>1</sub>14 $\pm$ 7; R<sub>2</sub>12 $\pm$ 6; R<sub>3</sub>16 $\pm$ 7 years.

Plexus RT was done using a classical fractionation in 10 R<sub>0</sub>patients /16; or a salvage fractionation by Vokes protocol (every two weeks), because partial irradiated volume, in 3 R<sub>1</sub>patients/11 (figure); and not in R<sub>2</sub> patients. Radiotherapy allowed controlling pain and reducing motor signs of NBP.

### Conclusion

We describe here one of the largest published series of NBP patients. Diagnosis is often difficult and delayed but necessary, to possibly treat them: chemotherapy in irradiated R<sub>2</sub> patients; usual RT in never irradiated R<sub>0</sub> patients. Salvage plexus RT in R<sub>1</sub> patients was possible. RT was better performed by Vmat technique helping dose/volume homogeneity and sustainable efficiency. Best volume and dose (50Gy) have to be defined for these hyperalgesic and paretic patients.

#### EP-1275 Hypofractionated whole breast irradiation and IOERT in breast cancer: Toxicity and cosmetic outcome

#### Purpose or Objective

To prospectively assess the role of an intraoperative electron tumor-boost (IOERT) in combination with hypofractionated whole breast irradiation (HF-WBI) after breast conserving surgery (BCS) in terms of in breast recurrence (IBR), treatment tolerance and cosmetic outcome.

#### Material and Methods

Patient recruitment within the study protocol (NCT01343459) started in 2011. Treatment consisted of BCS, IOERT of 11.1 Gy and HF-WBI up to total dosages of 40.5 Gy in 15 fractions. Acute toxicity, late reactions and cosmesis were evaluated by CTC-scoring (Vers. 2), LENT-SOMA criteria and by a 5-point-Scoring System (van Limbergen et al), respectively. 5-year IBR will be analyzed in 3 different age groups (35-40y, 41-50y, >50y) and tested against predefined benchmarks by the sequential probability ratio test (SPRT).

#### Results

Of 627 eligible patients 583 were evaluated. For acute effects CTC-score 0-1 was observed in 91-92% at the end of HF-WBI and 4 weeks later. Late toxicity Grading 0-1 (mean values) by LENT-SOMA criterions occurred in 92.7% (89.6-97.3) at 4/5 months up to 96.5% (91-100) at 6 years after HF-WBI. Baseline cosmesis was first assessed after wound healing prior to HF-WBI. Of 583 patients cosmesis was scored as satisfactory (excellent/good) in 84% by subjective (patient) and in 67% by objective (doctor) assessment with no impairment thereafter. After a median follow-up of 45 months (range 0 - 74), no in-breast recurrence was noted.

#### Conclusion

Acute and late treatment tolerance of a combined IOERT/HF-WBI regimen is excellent in mid-term

assessment. With regard to postoperative appearance, early cosmetic results are not impaired

#### Purpose or Objective

A favorable cosmetic outcome has been defined as an important endpoint in breast-conserving therapy. Various evaluation methods have been studied, but the optimal evaluation method has yet to be identified. The present ancillary analysis of JCOG0906 focused on comparing three methods for evaluating breast cosmetic outcomes after hypofractionated whole breast irradiation (HF-WBI).

#### Material and Methods

Between February 2010 and August 2012, 312 Japanese women were registered in a Japanese HF-WBI trial, JCOG0906 (UMIN000003200), and 306 received HF-WBI. Of them, 292 were evaluated for breast cosmetic outcomes before and three years after HF-WBI using three evaluation methods: an institutional evaluation (IE), a panel evaluation (PE), and a computer-program evaluation (CE), on a scale of 4-points (excellent/good/fair/poor). IEs were performed using a check sheet by individual institutional radiation oncologists who directly saw each patient and took a frontal-breast photograph with all personal information masked. PEs and CEs were performed using the 584 photographs of the 292 patients. PEs were assessed by consent of two experts twice, with a three-year interval between the first and second PEs. CE was performed using BCCT. core software individually by two radiation oncologists (A and B). The intra-observer variability of PE, the inter-observer variability of CE, and the degree of agreement between IE and PE or CE were calculated using the kappa (k) and weighted kappa (wk) statistics. The degree of agreement was considered to be poor for kappa values < 0.21, fair for 0.21-0.40, moderate for 0.41-0.60, substantial for 0.61-0.80, and excellent for 0.81-1.00.

#### Results

The agreement between the first and second PEs using 292 photographs before HF-WBI was moderate (k=0.5974, wk=0.6405), and that using 292 photographs three years after HF-WBI was similar (k=0.5303, wk=0.6032). The agreement between A and B on CE using photographs before HF-WBI was substantial (k=0.7210, wk=0.7569), and that using photographs after HF-WBI was similar (k=0.7174, wk=0.7656). The agreement between IE and the second PE using photographs before HF-WBI was fair (k=0.3002, wk=0.3865), and that using photographs after

HF-WBI was similar ( $k=0.3465$ ,  $wk=0.4514$ ). The agreement between IE and CE of A using photographs before HF-WBI was poor ( $k=0.1306$ ,  $wk=0.2158$ ), and that using photographs after HF-WBI was similar ( $k=0.1180$ ,  $wk=0.2240$ ).

#### Conclusion

Although the agreement between IE and CE was poor both before and after HF-WBI, the inter-observer variability of CE was smaller than the intra-observer variability of PE. CE using BCCT. core was considered a reproducible evaluation method when cosmetic changes of breasts that had received HF-WBI were evaluated comparing the photographic appearances before and after treatment.

#### EP-1277 Locoregionally recurrent breast cancer treated with postoperative or salvage radiotherapy

B.H. Kim<sup>1</sup>, K.H. Shin<sup>2</sup>, E.K. Chie<sup>2</sup>, J.H. Kim<sup>2</sup>, K. Kim<sup>3</sup>, S. Kim<sup>1</sup>

<sup>1</sup>SMG-Seoul National University Boramae Medical Center, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Ewha Womans University College of Medicine, Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

The purpose of this study was to investigate the treatment patterns and outcomes of patients receiving radiotherapy (RT) for isolated locoregional recurrence (ILRR) of breast cancer.

#### Material and Methods

We retrospectively analyzed the medical records of 125 patients who were diagnosed with ILRR after initial curative resection (mastectomy or breast-conserving surgery) and underwent RT from 2006 to 2016 at two institutions. The median time from initial operation to ILRR was 38 months. After ILRR, 96 (77%) patients underwent curative resection followed by postoperative RT and 29 (23%) underwent salvage RT. Ninety-eight (78%) patients received systemic chemotherapy. Median RT dose was 51.0 Gy (range: 18.0-70.4).

#### Results

The sites of recurrences were classified as follows: local in 42 (34%) patients, regional lymph nodes in 64 (51%), and combined local and regional sites in 19 (15%). Twenty-eight (22%) patients had received RT for primary breast cancer, but only 10 (8%) underwent re-irradiation. The patterns of treatment were very heterogeneous according to the patient and disease presenting features, and partial breast irradiation or hyperthermia was not performed. Overall, 5-year locoregional progression-free survival, distant metastasis-free survival, progression-free survival (PFS), and post-recurrence overall survival (OS) were 78.4%, 59.0%, 55.0%, and 69.7%, respectively. On multivariate analysis, initial pN0-1 stage, disease-free interval ( $\geq 36$  months), and curative resection for recurrent disease were found to be independently associated with better PFS and OS. When we divided patients into four groups based on the number of prognostic factors, pairwise significant differences in PFS and OS were found. Grade 3 dermatitis and grade 2 lymphedema were observed in 2 (1.6%) and 6 (4.8%) patients, respectively.

#### Conclusion

Most patients with ILRR of breast cancer referred for RT were radiation-naive and re-irradiation was not actively carried out. RT following curative resection could achieve favorable PFS in these potentially salvageable patients without causing severe toxicity. Initial pN stage, disease-free interval, and curative resection for recurrent disease were important prognosticators.

#### EP-1278 Effect of heart's dose reduction by IMRT in postoperative radiotherapy for left-sided breast cancer

K. Ono<sup>1</sup>, T. Taniguchi<sup>1</sup>, K. Shiraki<sup>1</sup>, Y. Itou<sup>1</sup>, O. Tanaka<sup>1</sup>  
<sup>1</sup>Asahi University Hospital, Department of Radiation Oncology, Gifu, Japan

#### Purpose or Objective

To reduce the Heart's dose for patients undergoing postoperative radiotherapy for left-sided breast cancer is critical for the heart disorder. Deep inspiration breath hold and intensity modulated radiation therapy (IMRT) are reported as methods for reducing the cardiac dose, especially for the left anterior descending artery (LAD). We compared the radiation methods of various degrees and examined the details of the difference between static IMRT and volumetric modulated arc therapy (VMAT).

#### Material and Methods

Overall, 20 patients underwent postoperative radiotherapy for left-sided breast cancer from July 2016 to June 2018 at our institute. We conducted the following five treatment plans: 2 field-static IMRT (2 F-S-IMRT), 4 field-static IMRT (4 F-S-IMRT), 40 degrees dual partial arc VMAT (40d VMAT), 80 degrees dual partial arc VMAT (80d VMAT), and 210 degrees partial VMAT (210p VMAT). The prescription dose was 50 Gy/25 fractions for the planning target volume (PTV) in all treatment plans. The dosimetric calculation was optimized to achieve a coverage of 50 Gy prescribed for 95% of PTV by inverse treatment planning using the Monte Carlo algorithm. Each of the five treatment regimens was analyzed by the dose volume histogram (DVH), and the multiple comparison test was performed. The evaluation items were compared on Heart's V10 (coverage of 10% of the volume of the heart), LAD's V10, PTV's D95, and homogeneity index (HI).

#### Results

The coverage of 40d VMAT for the prescribed dose of PTV's D95 was significantly lower than that of the other treatment plans. The D95 of the breast of PTV was approximately 46 Gy. HI was also high, and uniformity within PTV was decreased. For the other treatment plans, D95 showed high PTV coverage, i.e., 48 Gy or higher. 4F-S-IMRT became the best dose distribution (D95 = 49.2 Gy, HI = 1.08 and PTV). As for the dose of Heart and LAD, 2 F-S-IMRT, 40 dV MAT, 80 dV MAT was highly effective in reducing the dose. As for the OAR dose, 2F-S-IMRT was the highest in a reduction effect for the Heart and LAD (the value was V10 = 9.3% of the Heart, V10 = 45.3% of LAD). Table Dose comparison of the PTV, Heart and LAD in the Five plans.

Structure	Dose parameter	2F-S-IMRT	4F-S-IMRT	40dVMAT	80dVMAT	210pVMAT
PTV	D95 (Gy)	48.0 ± 0.9	49.2 ± 0.6	46 ± 1.3	48.3 ± 0.7	48.5 ± 0.6
	HI	1.10 ± 0.02	1.08 ± 0.01	1.15 ± 0.03	1.10 ± 0.02	1.09 ± 0.01
Heart	V10 (%)	9.3 ± 6.1	15.0 ± 6.8	9.6 ± 6.7	10.0 ± 6.7	15.7 ± 10.3
	V10 (%)	45.3 ± 10.7	52.5 ± 14.2	47.3 ± 14.2	46.0 ± 17.7	54.2 ± 16.4

#### Conclusion

2 F-S-IMRT and 40d VMAT had advantage for lowering the dose of OAR, because the number of fields and the irradiation range angle are small. 4F-S-IMRT and 80d VMAT increase an X-ray beam from multiple directions, which ensured not only sufficient coverage of PTV but also reduced the heart's dose. In these methods, dispersion of D95 in PTV may be reduced. The shape of the mammary gland differs in each patient; these methods ensure the possibility of administering optimum dose prescription and thereby have clinical applications.

#### EP-1279 M1 neck lymph node positive without distant metastasis in breast cancer: comparison with stage IIIC

J.S. Klim<sup>1</sup>, K. Kim<sup>2</sup>, K.H. Shin<sup>1</sup>, J.H. Kim<sup>1</sup>, S.S. Kim<sup>3</sup>, T.H. Kim<sup>4</sup>, Y.B. Kim<sup>5</sup>, W. Park<sup>6</sup>, J.H. Kim<sup>7</sup>  
<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Ewha Womans University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Asan Medical Center, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>4</sup>National Cancer Center,

Center for Proton Therapy, Goyang, Korea Republic of ; <sup>5</sup>Yonsei Cancer Center, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>6</sup>Samsung Medical Center, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>7</sup>Dongsan Medical Center, Department of Radiation Oncology, Daegu, Korea Republic of

#### Purpose or Objective

To analyze the treatment outcomes of ipsilateral cervical lymph node (LN)-positive breast cancer in the absence of other distant metastases, and to compare these outcomes with those of supraclavicular LN (SCL)-positive breast cancer.

#### Material and Methods

Seventy-nine breast cancer patients with involvement of ipsilateral cervical LN above the supraclavicular fossa (cervical LN(+) group) were treated with curative intent from 2000 to 2014 at 7 institutions. Most patients (n=75) received systemic chemotherapy (neoadjuvant and/or adjuvant) and breast surgery followed by locoregional radiotherapy. Outcomes of the cervical LN(+) group were evaluated and compared with those of 183 patients with SCL involvement (SCL(+) group) from the KROG 16-14 study.

#### Results

Median follow-up duration was 51.2 months (range, 5.9-138.0). Twenty-two regional failures were found in 15 patients: axillary LN in 8, SCL in 6, internal mammary LN in 3, involved cervical LN in 4, and uninvolved cervical LN in 1. The 5-year overall survival (OS), disease-free survival (DFS), locoregional relapse-free survival (LRRFS), and distant metastasis-free survival (DMFS) rates were 64.9%, 44.8%, 68.9%, and 55.2%, respectively. Neck dissection failed to improve LRRFS and DFS (p=0.901 and 0.366, respectively). After propensity score matching, survival outcomes of the cervical LN(+) and SCL(+) groups were not statistically different (5-year OS, 62.6% vs. 72.2%, p=0.560; DFS, 45.7% vs. 52.2%, p=0.620; LRRFS, 64.7% vs. 78.1%, p=0.110; DMFS, 57.4% vs. 53.2%, p=0.590, respectively).

#### Conclusion

Based on comparable clinical outcomes, breast cancer patients with ipsilateral cervical LN metastases without other distant metastases might benefit from aggressive locoregional and systemic treatments as those with N3c disease.

#### EP-1280 Identification of gene profiles associated to increased risk of acute toxicity in breast cancer

#### Purpose or Objective

To identify gene expression profiles (GEP) associated to increased risk of grade 2+ acute skin erythema after adjuvant breast cancer (BCa) radiotherapy (RT).

#### Material and Methods

BCa pts treated with 3DCRT after breast conserving surgery were considered: 50Gy (2Gy/fr) whole breast photon RT followed in some cases by 10 or 16Gy photon or electron boost to the tumour bed. Acute skin erythema (AE) was assessed using RTOG scoring system before RT and every 5 fractions. Grade 2+ AE before boost was considered as the primary endpoint. Relevant clinical risk factors were prospectively recorded, dosimetric features were extracted from skin dose-volume histogram, with skin defined as the difference between the body contour and a 5mm inner isotropic contour from the body. Peripheral blood was obtained, RNA extracted from mononuclear lymphocytes (after in vitro expansion) and GEP determined using Illumina HumanHT-12 v4 Expression BeadChip (=47000 probes, =37000 genes). Unsupervised clustering was used to reduce the dimensionality of data (partition around medoids). Dosimetric, clinical and genetic variables were included into logistic regression.

#### Results

147 pts were available, 35/147 (24%) pts with grade2+ AE before boost, 82/147 pts had GEP information. Unsupervised clustering selected 208 genes identifying 3 clusters of pts: 38% toxicity in cluster A, 19% and 14% in clusters B and C, respectively (OR=5 for A vs "B OR C", p=0.01). Cluster A was mainly characterized by underexpression of genes involved in immunoregulation, inflammatory processes, antioxidant activity, cell cycle progression and differentiation. Multivariable regression resulted in a 3 variable clinical/dosimetric/genetic model including dose to 20cc of skin (p=0.02, OR=1.4 for 1Gy increase), skin phototype (p=0.05, OR=1.9 1+2 vs >2), GEP cluster (p=0.01, OR=5 A vs B+C). Inclusion of GEP clustering improved likelihood (-86.6 vs -78.9, p=0.05), calibration slope (0.86 and R<sup>2</sup>=0.01 vs 0.93 and AUC (0.62 vs 0.83, p=0.01). The figure shows details on study population, GEP clustering and predictive model curves.

#### Conclusion

Gene expression profiling resulted in the identification of a signature of enhanced radiosensitivity for acute toxicity after BCa RT. This signature was included in a predictive model leading to significant improvement in calibration, likelihood and discrimination.

#### EP-1281 New aspects regarding the treatment of multicentric compared to unifocal breast cancer

C. Matuschek<sup>1</sup>, B. Tamaskovics<sup>1</sup>, W. Budach<sup>1</sup>, J. Haussmann<sup>1</sup>, E. Boelke<sup>1</sup>, F. Djiepmo<sup>1</sup>, T. Fehm<sup>2</sup>, E. Ruckhaeberle<sup>2</sup>, M. Fleisch<sup>2</sup>, S. Roth<sup>1</sup>

<sup>1</sup>University Hospital Düsseldorf, Radiation Oncology, Düsseldorf, Germany ; <sup>2</sup>University Hospital Düsseldorf, Gynecology, Düsseldorf, Germany

#### Purpose or Objective

This study compares retrospectively from 1991-1998 the Overall survival (OS), five year disease related survival (DRS), relapse free and overall survival (RFS) in multicentric breast cancer compared to unifocal breast cancer.

#### Material and Methods

From our cohort including n=482 patients n= 85 (17,6%) presented with multicentric and 397 with unicentric breast cancer. 45% of the 85 multicentric patients and 34% of the 397 unicentric patients were ≤50 years. N=254 patients received breast conserving therapy and n=228 underwent mastectomy. 392 patients received chemotherapy and in n=90 patients no chemotherapy was administered. In the multicentric group n=74 received chemotherapy and n=11 not. N=383 patients were irradiated (n=56 in the multicentric group) and n=99 patients were not irradiated (n=29 in the multicentric group).

#### Results

The five-year OS in the multicentric group was: 78.5%, the RFS was: 75.1%, DRS: 91.8%, compared to the unicentric group: OS: 91.8%, RFS: 91.1%, DRS: 96.1%. In the 85

patient group with multicentric tumors the five year OS was significantly worse than in the 397 for patients with unicentric tumors. P=0,01, HR 3,34. The RFS and DFS were also significantly worse (p=0.000, p=0.012)

#### Conclusion

In our cohort OS, RFS and DFS were statistically significant better in patients with unifocal breast cancer than in multicentric breast cancer. The only significant parameter in the multivariate analysis was the ER-Status. Regarding this, more aggressive treatment (chemotherapy, targeted therapy and radiotherapy) may be necessary.

#### EP-1282 Postmastectomy radiation therapy using VMAT for breast cancer patients with expander reconstructions

F. De Rose<sup>1</sup>, A. Fogliata<sup>1</sup>, D. Franceschini<sup>1</sup>, C. Iftode<sup>1</sup>, S. Cozzi<sup>1</sup>, A. Stravato<sup>1</sup>, G. Masci<sup>2</sup>, R. Torrissi<sup>2</sup>, A. Testori<sup>3</sup>, C. Tinterri<sup>3</sup>, A.V.E. Lisa<sup>4</sup>, A. Veronesi<sup>4</sup>, S. Giannasi<sup>4</sup>, M. Klinger<sup>4</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy ; <sup>2</sup>Humanitas Research Hospital, Medical Oncology, Rozzano Milan, Italy ; <sup>3</sup>Humanitas Research Hospital, Breast Surgery, Rozzano Milan, Italy ; <sup>4</sup>Humanitas Research Hospital, Plastic Surgery, Rozzano Milan, Italy

#### Purpose or Objective

The use of post-mastectomy radiotherapy (PMRT) following immediate breast reconstruction has increased over the past decade, and this integration is becoming crucial in the management of breast cancer patients. We aimed to retrospectively evaluate the complication rates of PMRT to immediate tissue-expander-based reconstructions and the improvement of radiation delivery using VMAT technique.

#### Material and Methods

We retrospectively reviewed clinical data of patients who underwent immediate expander breast reconstruction and received PMRT. All patients underwent VMAT technique to irradiate the reconstructed breast and supraclavicular region. The total dose was 50 Gy delivered in 25 fractions over 5 weeks. Neoadjuvant or adjuvant systemic therapy was administered in all patients. Protective lipofilling was routinely performed at the time of second-stage reconstruction.

#### Results

Between December 2014 and June 2017, PMRT was delivered to 46 consecutive patients with expander reconstruction. Median age was 49 years (range 36-73). Median follow-up was 27.7 months (range 10.8-42.6 months). Only two patients (4.6%) experienced reconstruction failure, in one case due to expander rupture and in the other one due to infection, following the first and the second-stage reconstruction, respectively. In most cases expanders were completely inflated before PMRT (79%). Median expander volume before PMRT was 450 cm<sup>3</sup> (range 140-690 cm<sup>3</sup>). The amount of expander inflation did not significantly affect dosimetry, except for skin dose, with a surface receiving more than 30 Gy of 36.6±0.9 cm<sup>2</sup> and 47.0±2.5 cm<sup>2</sup> for a volume expander below or above the median volume of 450 cm<sup>3</sup>, respectively. However, this variable was not a predictor for complications. Disease progression (local or distant) was recorded in 10.8% of patients.

#### Conclusion

Postmastectomy radiation therapy using VMAT technique for breast cancer patients with expander reconstructions is associated with a very low complication rate after both first and second-stage reconstruction. The expander volume before PMRT does not significantly compromise target coverage or increase dose to organs at risk.

#### EP-1283 Three-dimensional versus four-dimensional dose calculation for breast IMRT

J. Chung<sup>1</sup>, M. Chun<sup>1</sup>, J.M. Park<sup>1</sup>, J. Kim<sup>1</sup>, K. Shin<sup>1</sup>  
<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

This study was performed to analyze the effect of intra-fractional motion caused by free-breathing during breast IMRT by using newly generated "four-dimensional (4D) calculated plan".

#### Material and Methods

From 2017 to 2018, twenty patients diagnosed with left breast cancer from Seoul National University Hospital (SNUH) were enrolled. Every patient was eligible for regional lymph node irradiation including internal mammary node (IMN). After the 3D-CT for the initial plan was taken, 4D-CT comprised of 0% to 90% respiratory phases was taken for every patient. Target contouring was performed on 3D-CT and on all ten respiratory phases of 4D-CT. After IMRT planning on 3D-CT, the plan parameters were copied to all ten respiratory phases of 4D-CT sets. One-tenth of the total dose (43.2 Gy / 16 fx) was applied to each phase, and the dose distribution was re-calculated. Ten re-calculated doses were then summated into one to generate "4D-calculated plan" which was compared with "3D-original plan".

#### Results

Mean PTV volume was 1253.8 ± 575.6 ml. Mean IMN volume was 76.5 ± 16.6 ml. There were no significant differences in conformity and heterogeneity index between the 3D-original plan and the 4D-calculated plan. Mean heart dose was significantly lower in the 4D-calculated plan by 1.7 ± 0.8 Gy (p=0.041), whereas a mean dose of ipsilateral lung did not differ between two plans. When PTV was subdivided into the breast, supraclavicular lymph node (SCL), and IMN, both breast and SCL had no significant differences in mean dose between two plans. However, the mean IMN dose was significantly higher by 2.2 ± 1.8 Gy (p=0.023) in the 4D-calculated plan, compared to the 3D-original plan.

#### Conclusion

The interplay effect between the free-breathing motion and the multi-leaf collimator modulation may have caused a discrepancy in dose distribution, especially in heart and IMN. Therefore heart and IMN doses should be optimized when calculating the delivery dose for the free-breathing left breast IMRT.

#### EP-1284 Older age and comorbidity in breast cancer: is radiotherapy alone the new therapeutic frontier?

E. La Rocca<sup>1,2</sup>, M. Dispinzieri<sup>1,2</sup>, E. Meneghini<sup>3</sup>, A. Fiorentino<sup>4</sup>, F. Bonfantini<sup>5</sup>, S. Di Cosimo<sup>6</sup>, M. Gennaro<sup>7</sup>, V. Cosentino<sup>5</sup>, M. Sant<sup>3</sup>, E. Pignoli<sup>5</sup>, R. Valdagni<sup>1,8</sup>, L. Lozza<sup>2</sup>, M.C. De Santis<sup>2</sup>

<sup>1</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy ; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiotherapy Unit 1, Milan, Italy ; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Analytical Epidemiology and Health Impact Unit, Milan, Italy ; <sup>4</sup>Regional General Hospital "F. Miulli", Department of Radiation Oncology, Acquaviva delle Fonti Ba, Italy ; <sup>5</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy ; <sup>6</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Applied Research and Technological Development DRAST, Milan, Italy ; <sup>7</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Breast Surgery Unit, Milan, Italy ; <sup>8</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Director- Radiation Oncology 1 and Prostate Cancer Program, Milan, Italy

#### Purpose or Objective

To assess the impact of age, comorbidities and hormonotherapy (HT) use in

elderly breast cancer (BC) patients (pts) treated with hypofractionated radiotherapy (Hypo-RT).

#### Material and Methods

From June 2009 to December 2017, 734 ER-positive BC pts (stage pT1-T2, pNx-1, M0 and age over 65 years) receiving Hypo-RT and followed until September 2018, were analyzed. Hypo-RT consisted of 42.4 Gy in 16 daily fractions (2.65 Gy per fraction), while a sequential boost was administered in cases of grade 3 tumor and close or positive margins. Baseline comorbidities included in the hypertension-augmented Charlson Comorbidity Index (hCCI) were retrospectively retrieved. Baseline pts and tumour characteristics were analyzed in relation to HT status (never/discontinued, ongoing) at last contact by chi-2 test. Five-year disease-free survival (DFS) and overall survival (OS) were estimated by Kaplan-Meier method. The log-rank test was used to compare groups. Adjusted hazard ratios (HRs) were estimated by Cox proportional hazards models. In survival analysis, HT use was treated as time-dependent variable. A subgroup analysis was performed on pts aged  $\geq 70$  with a pT1 luminal A BC.

#### Results

The comorbidity was present in about 70% of pts (median age: 74 years). HT has been prescribed in 653 (88.9%) out of 734 analyzed pts. Most of them assumed the prescribed HT and 51 pts (7.8%) discontinued the treatment. Current HT use was less frequent for pts aged  $\geq 80$  ( $p < 0.001$ ) and pts with high comorbidity burden ( $hCCI \geq 2$ ) ( $p = 0.001$ ). At the time of the analysis, 673 (91.7%) pts were still alive and 33 pts (4.5%) experienced a disease progression (local or nodal recurrences and metastases). At a median follow-up 46.8 months (range 4-115 months), the overall 5-year DFS was 86.8% (95% CI 83.2-89.6%) varying between 89.5% for current HT use and 76.6% for no/discontinued HT use (log-rank  $p < 0.001$ ). The prognostic effect of HT was confirmed for pts aged  $\geq 70$  with a pT1 luminal A BC: 5-year DFS were 91.3% and 79% for ongoing HT user and no/discontinued HT user, respectively (log-rank  $p < 0.018$ ). The hazard of disease progression was significantly increased for pts with  $hCCI \geq 2$  and with tumour size  $\geq 1$  cm and strongly decreased for currently ongoing HT users. HT did not impact on OS neither in the whole group nor in pts pT1 luminal A  $\geq 70$  years.

#### Conclusion

This study shows that disease progression was strongly increased for pts with  $hCCI \geq 2$  and tumor size  $> 1$  cm and decreased for HT users. In elderly pts, HT assumption did not show a benefit in terms of survival. Further studies with tailored treatment approaches (RT alone versus RT+HT versus HT alone) are needed on elderly women with BC.

#### EP-1285 Hypofractionated irradiation in elderly breast cancer patients: an observational study

E. La Rocca<sup>1,2</sup>, M. Dispinzieri<sup>1,2</sup>, E. Meneghini<sup>3</sup>, A. Fiorentino<sup>4</sup>, F. Bonfantini<sup>5</sup>, S. Di Cosimo<sup>6</sup>, M. Gennaro<sup>7</sup>, V. Miulli", Radiation Oncology Department, Acquaviva delle Fonti Ba, Italy; <sup>5</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics Unit, Milan, Italy; <sup>6</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Applied Research and Technological Development DRAST, Milan, Italy; <sup>7</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Breast Surgery Unit, Milan, Italy; <sup>8</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Director- Radiation Oncology 1 and Prostate Cancer Program, Milan, Italy

#### Purpose or Objective

To assess efficacy, acute and late toxicity of hypofractionated radiotherapy (Hypo-RT) and impact of age and comorbidities in elderly breast cancer (BC) patients (pts).

#### Material and Methods

From June 2009 to December 2017 we analyzed 808 pts receiving 42.4 Gy in 16 daily fractions (2.65 Gy per fraction). A boost was only administered in cases of grade 3 primary tumor and close or positive margins. Acute and late toxicity was prospectively assessed during and after hypo-RT, based on the RTOG scale. Baseline comorbidities included in the hypertension-augmented Charlson Comorbidity Index (hCCI) were retrospectively retrieved. Five-year disease-free survival (DFS) and overall survival (OS) were assessed by Kaplan-Meier method and log-rank test was used to compare groups of age and comorbidity. Hazard ratios (HRs) were estimated by Cox proportional hazards models adjusting for tumor size, lymph node status, molecular subtype, grading, chemotherapy. Odds ratios (ORs) and 95% confidence intervals (CIs) of acute and late toxicity by of age, comorbidity and boost administration were estimated by ordinal or multinomial logistic models.

#### Results

The median age was 74 years (range 65-91 years), and 76.1% of the pts were over 70 years old. The median follow-up was 46.8 months (range 4-115 months). At baseline, 70.4% of pts were affected by at least one comorbidity. Invasive ductal carcinoma was the most common histological type (81.2%), and the most common subtype was luminal A (46.5%). 21.5% of pts underwent chemotherapy with anthracycline and taxane. Hormonotherapy has been prescribed in 657 (81.4%) pts. At the latest follow-up date, 730 (90.4%) pts were still alive, 47 (5.8%) experienced disease progression (local or nodal recurrences, contralateral BC, metastases), 18 died of BC and 60 died of other causes.

Older age and baseline comorbidity burden were associated with worst prognosis. Five-year DFS was 92.6, 87.2, 83.5 and 71.3% for 65-69, 70-74, 75-79 and  $\geq 80$  years, respectively (log-rank  $p < 0.001$ ). Five-year OS for increasing age-class was 94.7, 93.0, 86.7 and 80.9% (log-rank  $p = 0.002$ ). Five-year DFS and OS were 91.9% and 94.3% for pts without comorbidity and 74.3% and 84.5% for pts with high comorbidity burden ( $hCCI \geq 2$ ) (DFS log-rank  $p < 0.001$ , OS log-rank  $p = 0.017$ ).

Elderly pts had significantly higher odds of increasing score in acute asthenia. Pts with  $hCCI \geq 2$  had significantly increased odds of late edema and late fibrosis. Boost administration was significantly related to increasing score of acute skin toxicity and late fibrosis and edema.

#### Conclusion

Hypo-RT in elderly BC pts aged  $\geq 65$  years is effective and well-tolerated. This study also shows that age and comorbidities negatively impact DFS and OS. Further studies focusing on a better selection of elderly BC pts based on genomic and biological features and with tailored treatment approaches are warranted.

#### EP-1286 StrataXRT is non inferior to Mepitel Film in preventing radiation induced moist desquamation

M.W.T. Chao<sup>1</sup>, S. Spencer<sup>1</sup>, C. Kai<sup>1</sup>, C. Baker<sup>2</sup>, S. Jassal<sup>3</sup>, M. Law<sup>4</sup>, M. Cheng<sup>4</sup>, N. Zantuck<sup>4</sup>, V. Yu<sup>4</sup>, D. Stoney<sup>4</sup>, S.W. Loh<sup>3</sup>, E. Bevington<sup>3</sup>, G. Chew<sup>3</sup>, A. Hyett<sup>3</sup>, M. Guerrieri<sup>1</sup>, H. Ho<sup>1</sup>, M. Ng<sup>1</sup>, J. Wasiak<sup>5</sup>, F. Foroudi<sup>5</sup>

<sup>1</sup>Ringwood Radiation Oncology Centre, Department of Radiotherapy, Ringwood, Australia; <sup>2</sup>St Vincents Hospital, Surgical Oncology, Melbourne, Australia; <sup>3</sup>Austin Hospital, Surgical Oncology, Melbourne, Australia; <sup>4</sup>Maroondah Hospital, Surgical Oncology, Melbourne, Australia; <sup>5</sup>Austin Hospital, Department of Radiation Oncology, Melbourne, Australia

### Purpose or Objective

A within patient non inferiority randomised study was conducted to test whether StrataXRT (SX) was as effective as Mepitel film (MF) in reducing the severity and duration of acute radiation dermatitis (ARD) in breast cancer patients receiving post mastectomy radiation therapy (PMRT).

### Material and Methods

Breast cancer patients undergoing chest wall with or without nodal irradiation radiation therapy were eligible. Lateral and medial halves of the skin areas to be irradiated were randomized to MF or SX. Bolus was applied to the half of the course of radiation therapy (50-50.4Gy). ARD was assessed using the Common Terminology Criteria for Adverse Events scale (version 4.03) weekly for 10 weeks. The outcome measures were occurrence of moist desquamation in each half of the irradiated area, time weighted average (TWA) grade of radiation dermatitis and worst grade of radiation dermatitis over 10 weeks.

### Results

A total of 44 breast cancer patients receiving post mastectomy radiation therapy were recruited between January 2017 and December 2017. Of those, 43% had pathologic stage II and 57% had pathologic stage III disease. Seventy three percent received tangent based inverse planned intensity modulated therapy and 27% received volumetric arc therapy. For the 40 assessable patients (minimum of 6 weekly observations), the maximum grade of ARD in the SX halves were CTCAE grade 1 (30%) and grade 2 (70%) compared with grade 0 (5%), grade 1 (42.5%), grade 2 (50%) and grade 3 (2.5%) in the MF halves. The rate of moist desquamation was 12.5% for SX versus 20% for MF ( $p=0.099$ ).

The TWA of radiation dermatitis in the chest wall halves up to 10 weeks is 0.16 higher for SX vs MF (95% CI: 0.09-0.23). The upper limit of the CI is  $<0.25$  (criterion for non-inferiority set in protocol), it is concluded that SX is not inferior to MF at the 95% level. Although the difference between SX vs MF is statistically significant ( $p=0.0001$ ), it was not clinically significant.

The worst grade of radiation dermatitis in the halves within 10 weeks is 0.15 higher for SX vs MF (95% CI: -0.02-0.32). The upper limit of the CI is  $<0.50$  (criterion for non-inferiority set in protocol), it is concluded that SX is not inferior to MF at the 95% level. The difference between SX vs MF is not statistically significant ( $p=0.075$ ).

### Conclusion

The occurrence of moist desquamation, TWA grade of ARD and the worst grade of ARD for StrataXRT was not inferior to MF.

### EP-1287 Preliminary results of anthocyanin supplementation in breast cancer RT: impact on skin side effects

M. Boccardi<sup>1</sup>, F. Bracone<sup>2</sup>, F. Deodato<sup>1</sup>, A. De Curtis<sup>2</sup>, G. Macchia<sup>1</sup>, S. Cilla<sup>3</sup>, A. Di Castelnuovo<sup>2</sup>, A. Ianiro<sup>3</sup>, C. Cerletti<sup>2</sup>, A.G. Morganti<sup>4</sup>, M.B. Donati<sup>2</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"-Università Cattolica del Sacro Cuore, Radiotherapy Unit, Campobasso, Italy ; <sup>2</sup>IRCCS Neuromed, Dipartimento di Epidemiologia e Prevenzione, Pozzilli, Italy ; <sup>3</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II"-Università Cattolica del Sacro Cuore, Medical Physics Unit, Campobasso, Italy ; <sup>4</sup>Radiation Oncology Center, Department of Experimental- Diagnostic and Specialty Medicine DIMES- University of Bologna, Bologna, Italy

### Purpose or Objective

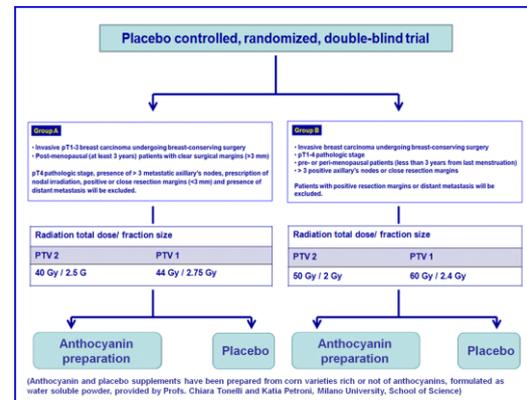

The role of anthocyanins has been studied in the prevention of radiotherapy (RT) side effects. In a prospective randomized study (Athena Project-FP7 European Union), we verified the impact of anthocyanin supplementation on acute and medium-term skin side effects of RT in breast cancer (BC) patients.

### Material and Methods

A double-blind randomized clinical trial with 2 parallel arms (A and B) was designed. BC patients were randomized to assume a preparation containing 125 mg anthocyanins (3 times a day) versus placebo. Supplementation started 1 week before and lasted till the end of RT. One group of patients (MARA3) received 44 Gy simultaneous integrated boost (SIB) over 16 fractions in 3 weeks by an hybrid IMRT class solution; the other group (MARA4) received 60 Gy SIB over 25 fractions in 5 weeks. Patients used a moisturizing cream (® Atonderma) during RT. Clinical evaluation was performed at the end of treatment and skin toxicity was graded according to RTOG score. Moreover, skin parameters, as elasticity (R0, R2 and R5 values), erythema (Mexa\_Er) and pigmentation (Mexa\_M), were measured in predefined areas of the irradiated breast and in the contra-lateral one through a specific device (Cutometer® dual MPA 580), before (T0), at the end (T1) and 1, 6 and 12 months after RT.

### Results

242 patients were eligible and 195 were randomized to groups A and B (Figure 1). Both clinical and cutometer evaluations failed to show differences in terms of skin toxicity (elasticity, erythema and pigmentation) between groups A and B. The elasticity parameters R0 ( $p=0.54$ ) and R2 ( $p=0.27$ ) similarly decreased from T0 in both arms, while Mexa\_M ( $P=0.74$ ) and Mexa\_Er ( $P=0.25$ ) similarly increased in both groups, suggesting no protective effect of anthocyanin supplementation. Neither RT protocol seemed to differently affect elasticity parameters. However, the increase in Mexa\_M and Mexa\_Er was greater in MARA4 (5 week RT) than in MARA3 (3 week RT) ( $p=0.0027$  and  $p=0.0087$ , respectively). Comparing irradiated and contra-lateral breast no differences were observed for R0 ( $p=0.48$ ) and Mexa\_M ( $p=0.14$ ) variations from T0 to T1 in groups A and B. On the contrary, decrease of R2 and increase of Mexa\_Er were observed only in irradiated but not in contra-lateral breast ( $p<0.0001$ ). Clinical toxicity RTOG data did not correlate with variations in parameters recorded by cutometer.

### Conclusion

Preliminary data failed to demonstrate that an anthocyanin supplementation can effectively protect BC patients from skin side effects of two different RT regimens.

### EP-1288 Dosimetric Comparison of Protons and Photons in Musculoskeletal Sparing During Breast Irradiation

A. Prescott<sup>1</sup>, J. Strauss<sup>1</sup>, E. Donnelly<sup>1</sup>, M. Gentile<sup>1</sup>, R. Patel<sup>1</sup>, D. Lipps<sup>2</sup>, S. Oza<sup>3</sup>

<sup>1</sup>Northwestern University, Radiation Oncology, Chicago, USA ; <sup>2</sup>University of Michigan, Kinesiology, Ann Arbor, USA ; <sup>3</sup>Memorial Sloan Kettering, Physical Medicine & Rehab, New York, USA

### Purpose or Objective

Radiotherapy (RT) to the breast has a functional impact on the upper extremity, especially when regional lymphatics are irradiated. This may be mediated in part through RT dose to the adjacent musculature. This study set out to compare the muscle doses deposited with protons vs. photons using 3D conformal RT.

### Material and Methods

Five consecutive patients diagnosed with node positive left-sided breast cancer were included. For a prior dosimetric study, plans were created with pencil beam scanning proton RT at free breathing and 3D conformal RT at DIBH. The plans were optimized for cardiac and pulmonary dose. For this study, the muscle volumes for eleven shoulder muscles anatomically located within or near the treatment field were contoured separately. The volume of each muscle receiving at least 30 Gy (V30 Gy) were calculated for each muscle and compared between treatment modalities using the two-tailed paired Student T test.

### Results

**Table 1: Muscle Dose**

	Photon (mean)	Proton (mean)	p value
Anterior Deltoid	0.6	0.0	0.1165
Infraspinatus	34.6	0.0	0.0251
Latissimus Dorsi	42.7	17.3	0.0406
Pectoralis Major	78.4	79.7	0.5688
Pectoralis Minor	99.9	93.2	0.0042
Posterior Deltoid	12.5	0.0	0.0182
Subscapularis	71.5	30.8	0.0191
Supraspinatus	82.2	0.0	0.0003
Teres Major	67.3	20.8	0.0118
Teres Minor	51.5	0.1	0.0204
Trapezius	28.6	0.0	0.0036

### Conclusion

Pencil beam scanning proton RT delivers less dose to most of the adjacent musculature as compared to 3D conformal RT during irradiation of the breast and draining lymphatics. The largest absolute differences are in the posterior shoulder muscles in the exit of the nodal field. The smallest differences in dose are noted in the pectoralis muscles which receive high dose in both plans. The reduction in muscle dose associated with protons may have implications for upper extremity function, although additional research is required.

### EP-1289 Phase I dose escalation trial using single fraction Stereotactic PBI for early stage breast cancer

A. Rahimi<sup>1</sup>, N. Kim<sup>2</sup>, A. Spangler<sup>2</sup>, M. Leitch<sup>3</sup>, P. Alluri<sup>2</sup>, X. Gu<sup>2</sup>, C. Ahn<sup>4</sup>, S. Goudreau<sup>5</sup>, S. Seiler<sup>5</sup>, D. Farr<sup>3</sup>, R. Woodridge<sup>3</sup>, B. Haley<sup>6</sup>, S. Bahrami<sup>2</sup>, D. Chen<sup>2</sup>, R. Rao<sup>7</sup>, R. Timmerman<sup>2</sup>

<sup>1</sup>University Texas Southwestern Medical Center, Radiation Oncology, Dallas, USA ; <sup>2</sup>University of Texas Southwestern Medical Center, Radiation Oncology, Dallas, USA ; <sup>3</sup>University of Texas Southwestern Medical Center, Surgery, Dallas, USA ; <sup>4</sup>University of Texas Southwestern Medical Center, Biostatistics, Dallas, USA ; <sup>5</sup>University of Texas Southwestern Medical Center, Radiology, Dallas, USA ; <sup>6</sup>University of Texas Southwestern Medical Center, Medical Oncology, Dallas, USA ; <sup>7</sup>Columbia University Medical Center, Breast Surgery, New York City, USA

### Purpose or Objective

To evaluate tolerability of escalating doses of single fraction stereotactic partial breast irradiation (S-PBI) in treating early stage breast cancer after partial mastectomy. We conducted a phase 1 dose escalation trial testing 3 dose levels, 22.5Gy, 26.5Gy and 30 Gy. The primary objective was to escalate the S-PBI single fraction dose utilizing a robotic stereotactic radiation system treating the lumpectomy cavity without exceeding the maximum tolerated dose (MTD) in patients with early stage breast cancer. We report on the first dose cohort.

### Material and Methods

Eligible patients included DCIS or invasive epithelial histologies, AJCC clinical stage 0, I, or II with tumor size <3cm, and negative margins. Prior to simulation 3-4 four gold fiducials were placed around the lumpectomy cavity for real-time respiratory tracking. Dose limiting toxicity (DLT) equaled grade  $\geq 3$  toxicity by CTCAE (version 4) deemed definitely related to treatment for: skin, rib bone(fracture), pulmonary (radiation pneumonitis), or neurological (intercostal or brachial plexus nerves) or any grade 4 or 5 toxicity definitely attributed to therapy. Both patients and physicians completed baseline and subsequent cosmesis outcome questionnaires using a four point scale of - excellent, good, fair, poor. Adjuvant endocrine or chemotherapy was permitted. Starting dose was 22.5 Gy in 1 fraction, dose cohort two is 26.5 Gy and third cohort is 30 Gy. Dose was escalated provided two or fewer of nine patients experienced a DLT within 90 days of treatment within each dose group. If more patients had DLT in a given dose cohort, the MTD would be exceeded.

### Results

11 patients enrolled on cohort one and had a median age of 66 years. All patients had ER/PR+ and Her2/neu- tumor profile. Median follow-up was 18 months. 80% of patients received endocrine therapy and 0% chemotherapy. MTD was not reached in cohort one and dose was escalated to cohort two. There were 19 grade 1 toxicity events, 2 grade 2 toxicities, and 1 grade  $\geq 3$  toxicity (which was breast pain that lasted for two days and resolved after antibiotics). There have been no recurrences or distant metastases. One patient developed fat necrosis and it was diagnosed 12 months after radiation treatment. Physicians scored cosmesis excellent or good in 100%, 100%, 100% and 100% (p=1.00) respectively, at baseline, 3, 6 and 12 months post SBRT, while patients scored the same periods 90.9%, 100%, 100% and 90.0% (p=1.00).

### Conclusion

Dose was escalated to 22.5 Gy in 1 fraction without a DLT and the majority of patient had good or excellent cosmesis. We are currently completing dose escalation for subsequent cohorts of 26.5Gy and 30 Gy in 1 fraction of S-PBI hoping to increase the likelihood of long term tumor control while evaluating toxicity and cosmesis.

### EP-1290 Impact of patient and treatment factors on heart and lung dose in left-sided breast radiotherapy

V.T. Nguyen<sup>1</sup>, T. Finazzi<sup>1</sup>, A. Papachristofilou<sup>1</sup>, F. Zimmermann<sup>1</sup>

<sup>1</sup>University Hospital Basel, Clinic of Radiotherapy and Radiation Oncology, Basel, Switzerland

### Purpose or Objective

The heart and lung are routinely exposed to incidental irradiation during adjuvant radiotherapy (RT) of breast cancer. We analyzed the impact of patient characteristics and treatment factors on heart and lung radiation dose in patients receiving adjuvant radiotherapy for left-sided breast cancer.

### Material and Methods

We identified patients who were treated with adjuvant RT for left-sided breast cancer in our institution between 2013 and 2018. The mean radiation doses to the heart (mean heart dose; MHD) and left lung (mean lung dose;

MLD) as well as V20Gy for both organs were collected from treatment plans. Patients were classified according to RT technique used (3DCRT, IMRT or VMAT) and target volumes treated. Group comparisons were performed to analyze heart and lung doses for different techniques and for RT with and without irradiation of regional lymph nodes (LN). The relationship between patient characteristics (body mass index (BMI), heart and total lung volume) and radiation exposure of the heart and lung was assessed using correlation analyses.

#### Results

A total of 344 female patients treated with adjuvant radiotherapy for left-sided breast cancer were eligible for analysis. Patients received a median dose of 50 Gy to the breast or chest wall +/- regional LN. Two-third (n=227) were treated with 3DCRT, whereas one third (n=117) received IMRT/VMAT. Regional LN irradiation was performed in 32% of patients and more often involved usage of IMRT/VMAT (55.8% of treatments vs. 23.6% for cases without LN irradiation). Overall, IMRT/VMAT showed a higher MHD (4.8Gy vs 3.5Gy;  $p<0.01$ ), left MLD (12.5Gy vs 8.6Gy;  $p<0.01$ ) and V20Gy of the left lung (25% vs 16.9%,  $p<0.01$ ) compared to 3DCRT. In a subgroup analysis of patients without LN irradiation (n=233), a difference remained for left MLD (IMRT/VMAT vs. 3DCRT 9.0Gy vs 7.2Gy;  $p<0.01$ ) and V20Gy of the left lung (18.0% vs 13.6%;  $p<0.01$ ). Inclusion of regional LN increased MHD (5.2Gy vs 3.4Gy;  $p<0.01$ ) and left MLD (14.8Gy vs 7.6Gy;  $p<0.01$ ) as well as V20Gy of the heart (5.3% vs 3.4%;  $p<0.01$ ) and left lung (30.2% vs 14.6%;  $p<0.01$ ) compared to treatment without regional LN. In particular, RT involving the internal mammary LN further increased heart and lung doses compared to RT involving only supraclavicular +/- axillary LN ( $p<0.01$  for all values; MHD 8.3Gy vs. 4.6Gy). Assessment of patient characteristics revealed a weak negative association between total lung volume and both MHD ( $r=-0.38$ ;  $p<0.01$ ) and heart V20Gy ( $r=-0.36$ ;  $p<0.01$ ). In addition, a weak positive correlation of BMI and MHD ( $r=0.25$ ;  $p<0.01$ ) was observed.

#### Conclusion

While IMRT/VMAT has been shown to improve dose homogeneity and conformity in RT for breast cancer, this has to be weighed against an increase in radiation exposure of the lung and potentially the heart. Similarly, the impact of regional LN irradiation on heart and lung dose needs to be considered in clinical decision making. These observations may help tailor personalized RT for patients with left-sided breast cancer.

#### EP-1291 Radiation Treatment Standards and Techniques in Breast Cancer in German speaking countries

M. Mayinger<sup>1</sup>, C. Straube<sup>2</sup>, D. Habermehl<sup>2</sup>, S.E. Combs<sup>2</sup>  
<sup>1</sup>Universitätsspital Zürich, Radiation Oncology, Zürich, Switzerland ; <sup>2</sup>Technical University of Munich, Radiation Oncology, Munich, Germany

#### Purpose or Objective

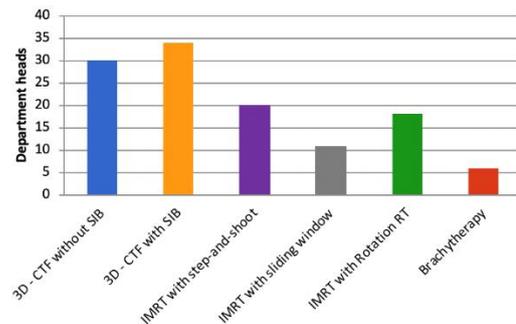

The large amount of prospective trials in early breast cancer has caused a wide variety in possible treatment techniques in early-stage breast cancer. Therefore the aim of this study is to assess radiation treatment standards and techniques in early-stage breast cancer in German speaking countries.

#### Material and Methods

Between July 2017 and August 2017, an email-based survey was sent to all 1408 physicians that are members of the German society of radiation oncology (DEGRO). The survey was completed by 180 physicians including 10 private practice owners and 52 heads of departments of community-hospital or university-hospital based radiation oncology services. The majority (82.1%) of the participants had >15 years of experience in radiation therapy (RT).

#### Results

In the adjuvant treatment of early-stage breast cancer the majority of departments (54.8%) used 3D - conformal tangential fields with a simultaneous integrated boost. 32.3% of the departments used intensity modulated radiation therapy (IMRT) with step-and-shoot, 29.0% with Rotation RT and 17.7% with sliding window (Figure). For internal mammary radiation the majority of participants (74.4%) used image guided radiation therapy (IGRT) with IMRT or volumetric modulated arc therapy (VMAT). When asked in which case participants would perform an irradiation of neck, supraclavicular and infraclavicular lymph nodes 67.2% indicated a case with 1-3 affected lymph nodes, with 100% treating a patient with >3 affected lymph nodes. Several questions focused on the participants' standard treatment plans for various clinical situations.

#### Conclusion

Our patterns of care survey showed that the majority of departments and radiation oncologists in German speaking countries align with the new S3 and AGO guidelines. For the adjuvant treatment of early-stage breast cancer 3D - conformal tangential fields with a simultaneous integrated boost is the preferred treatment technique. The use of IMRT is still limited to a specific patient cohort, although the majority of participants selected IGRT - IMRT / VMAT for irradiating the internal mammary lymphatic chain.

#### EP-1292 Zinc-L-Carnosine prevents dysphagia in breast cancer patients treated with adjuvant radiotherapy

S. Saldi<sup>1</sup>, E. Perrucci<sup>1</sup>, V. Lancellotta<sup>2</sup>, I. Palumbo<sup>2</sup>, L. Falcinelli<sup>1</sup>, C. Mariucci<sup>2</sup>, S. Chierchini<sup>2</sup>, V. Bini<sup>3</sup>, C. Aristei<sup>2</sup>

<sup>1</sup>Santa Maria della Misericordia Hospital, Radiation Oncology, Perugia, Italy ; <sup>2</sup>University of Perugia, Radiation Oncology, Perugia, Italy ; <sup>3</sup>University of Perugia, Internal Medicine Section of Internal Medicine and Metabolic and Endocrine Disease, Perugia, Italy

#### Purpose or Objective

Irradiation of level III and IV draining nodes in breast cancer patients is often associated with dysphagia, requiring treatment with FANS and/or steroids. The present randomized phase III trial determined whether Zinc-L-Carnosine (ZLC, Hepilor®), prevents or delays the onset of dysphagia in these patients.

#### Material and Methods

December 2015-October 2017: 40 breast cancer patients undergoing radiation therapy (RT) to the breast or chest wall and level III and IV lymph-nodes were randomized to receive ZLC or placebo. All underwent RT with Tomotherapy at a total dose of 50 Gy in 25 fractions. 11/40 (27,5%) women who had received conservative surgery were given a 10 Gy boost to the tumor bed, using a simultaneous instantaneous boost technique. The primary end-point was no dysphagia, as evaluated by the CTCAE v 4.0 and EAT-10 questionnaire. The trial was approved by the Regional Ethics Committee and all

patients gave signed informed consent. The Chi-square and Mann-Whitney tests analyzed differences between ZLC and placebo arms. The Kaplan-Meier test estimated the cumulative incidence of dysphagia and the log-rank test compared results. Univariate Cox regression analysis tested relations between toxicity and prognostic factors.

#### Results

All patients completed RT. Treatment arms were matched for age, chemotherapy (CT) and administration of Trastuzumab and hormonal therapy (HT). Overall, the median age was 56 years (range 28-82); 93% received CT before RT, 35% and 70% received, respectively, Trastuzumab and HT during RT. The esophagus median maximum dose (Dmax) was significantly higher in the placebo arm ( $p=0.005$ ). The median dose to the esophagus was similar in both groups ( $p=0.76$ ). Nine (45%) patients in the ZLC arm and 20 (100%) receiving placebo developed G1-G2 dysphagia during RT ( $p<0.0001$ ). No patient developed >G2 dysphagia. Five ZLC patients (25%) and 17 (85%) placebo patients with dysphagia required steroid treatment. ZLC was associated with a later onset and lower risk of G1-G2 dysphagia during RT (cumulative incidence 55.2%, 95%CI: 29.4-81.1 vs 100%, 95%CI: 85.4-100,  $p<0.0001$ ). Univariate analysis showed esophagus Dmax was not a significant risk factor for dysphagia.

#### Conclusion

In our phase III trial ZLC significantly prevented or delayed the incidence of dysphagia in breast cancer patients undergoing RT to the draining nodes. Consequently, the need for steroid therapy was significantly reduced.

#### EP-1293 Hybrid intensity modulated radiation therapy for treatment of cancer of left breast after mastectomy

Abstract withdrawn

#### EP-1294 Prognosis of patients with breast ductal carcinoma-in-situ who underwent breast-conserving surgery

#### Purpose or Objective

We recently demonstrated that California/Van Nuys Prognostic Index (USC/VNPI) score 4-6, Eastern Cooperative Oncology Group (ECOG) E5194 cohort 1 criteria (tumor size  $\leq 2.5$  cm, low-to-intermediate grade disease/without necrosis, and surgical margins  $\geq 3$  mm), estrogen receptor-positive status, and tamoxifen administration were closely associated with lower ipsilateral breast tumor recurrence (IBTR) in our patients

(National Taiwan University Hospital cohort) who were treated with breast-conserving surgery (BCS) for ductal carcinoma in situ (DCIS). This study aimed to whether aforementioned prognostic factors predicted lower IBTR in breast DCIS patients from the other 12 hospitals of Taiwan (Taiwan cohort) who underwent BCS alone.

#### Material and Methods

Data for 910 women with breast DCIS who underwent BCS at Taiwan cohort between January 2004 and December 2011 were analyzed. The patients were divided into different categories according to the recurrence risk predicted using the USC/VNPI score (4-6, 7-9, and 10-12), ECOG E5194 criteria (cohort 1, and non-cohort 1). The IBTR (included DCIS and invasive cancer of the ipsilateral breast area) was calculated by the Kaplan-Meier method. The prognostic effects of age, estrogen receptor status, USC/VNPI score, ECOG E5194 cohort 1 criteria, and tamoxifen use were evaluated by log-rank tests.

#### Results

Of the patients, 549 were treated with breast irradiation after BCS and 361 were not. The patients who were treated with radiotherapy (RT) tended to have higher USC/VNPI scores (7-11) ( $p < 0.001$ ), and to have a trend to meet the ECOG E5194 non-cohort 1 criteria ( $p = 0.091$ ). With a median follow-up of 6.3 years (95% confidence interval 6.1 to 6.5), the 7-year risk of IBTR rate was 3.4% ( $n = 16$ ) in the patients who received RT and 8.3% ( $n = 27$ ) in those who did not ( $p = 0.002$ ). Among the 361 patients who underwent BCS alone, patients with USC/VNPI scores of 4-6 had a lower 7-year IBTR rate than those with USC/VNPI scores of 7-11 (6.6% vs. 14.5%,  $p = 0.015$ ). Similarly, patients in ECOG E5194 cohort 1 criteria had a lower 7-year IBTR rate than those in ECOG E5194 non-cohort 1 (6.5% vs. 14.2%,  $p = 0.001$ ). Furthermore, estrogen receptor-positive status ( $p=0.007$ ) and tamoxifen use ( $p = 0.024$ ) predicted lower IBTR rate in patients who underwent BCS alone.

#### Conclusion

Our results indicate that patients with low USC/VNPI scores (4-6) or meeting the ECOG E5194 cohort 1 criteria of breast DCIS who undergo BCS alone may have a lower IBTR rate. The administration of tamoxifen may reduce IBTR in patients with ER-positive breast DCIS who undergo BCS alone.

#### EP-1295 Impact of Alternative Positioning on Heart/Lung Dose: A Dosimetric Follow-up to the IMPORT LOW Trial

K. Petras<sup>1</sup>, E.D. Donnelly<sup>1</sup>, J.P. Hayes<sup>1</sup>, P. Rino<sup>1</sup>, W. Matthew<sup>1</sup>, J.B. Strauss<sup>1</sup>

<sup>1</sup>Northwestern University, Radiation Oncology, Chicago, USA

#### Purpose or Objective

As outcomes for early-stage breast cancer patients continue to improve, there has been a focus on reducing treatment-associated toxicity. Recently, the IMPORT LOW trial showed that in select low-risk patients, limiting the treated volume to the surgical bed and surrounding tissue was non-inferior to whole breast radiotherapy (RT) with regard to local control and was associated with small improvements in cosmetic results. All patients were treated in the supine position at free breathing. This analysis aimed to evaluate the impact on heart and lung dose when the field design of the IMPORT LOW trial was paired with an alternative positioning technique of either the prone position or deep inspiratory breath hold (DIBH).

#### Material and Methods

The planning CT scans of 30 consecutive early-stage breast cancer patients with available paired image sets at a single institution were identified. The paired image sets were: 1) 10 patients with right-sided breast cancer treated prone and supine; 2) 10 patients with left-sided breast cancer treated prone and supine; 3) 10 patients with left-sided breast cancer treated supine free breathing or

supine DIBH. The parameters of the partial breast RT arm of the IMPORT LOW trial were applied to each available scan and several dosimetric parameters were collected for comparison including mean heart dose, heart V25 Gy, mean ipsilateral lung dose, ipsilateral lung V20 Gy, and PTV coverage.

## Results

Results Table						
	Heart (mm)	p-value	Lung (mm)	p-value	Lung V20	p-value
R Breast Prone	0.35		1.43		2.01	
R Breast Supine	0.19	p=0.006	1.77	p=0.01	2.77	ns
L Breast Prone	0.89		0.71		0.60	
L Breast Supine	0.64	ns	2.19	p=0.001	3.24	p=0.01
L Breast DIBH	0.36		1.47		1.73	
L Breast FB	0.61	p=0.015	1.90	ns	2.58	ns

All doses expressed in Gy  
 mn=mean  
 ns=non-significant

Among patients with right-sided breast cancer, the supine position was associated with lower mean heart dose while the prone position was associated with lower mean ipsilateral lung dose. In left-sided breast cancer patients, the prone position yielded lower ipsilateral mean lung dose and lung V20 Gy values; while DIBH was associated with a lower mean heart dose and a trend towards lower lung V20 Gy (p=0.058).

## Conclusion

For well-selected women with early breast cancer, the IMPORT LOW trial showed that reducing the treated breast volume is equivalent in efficacy to treating the whole breast. Our results show that incremental reductions in heart and lung dose can be achieved by pairing this approach with alternative patient positioning techniques. Overall, the prone position yields the lowest lung dose, while in left-sided disease, DIBH provides optimal cardiac avoidance.

## EP-1296 Breast reconstruction and hypofractionated adjuvant radiotherapy: dosimetric and aesthetic analysis.

E. Bonzano<sup>1</sup>, M. Guenzi<sup>1</sup>, R. Corvò<sup>1</sup>

<sup>1</sup>IRCCS Policlinico San Martino and University, Department of Radiation Oncology, Genoa, Italy

## Purpose or Objective

The aim of our study was to analyze dose distribution, target coverage and doses to organs at risk(OAR) in patients(pts) who underwent Postmastectomy Radiotherapy (PMRT) following tissue expander-implant(TE) breast reconstruction and compare different RT techniques: Three Dimensional Conformal Radiation Therapy(3DCRT) and Helical Tomotherapy(HT). The second endpoint was to evaluate patient's outcome: capsular contracture and aesthetic result.

## Material and Methods

This study was conducted on 53 pts treated from April 2012 to June 2016. PMRT was delivered in a hypofractionated regime of 46 Gy in 20 fractions, 4 times per week. Pts median age was 49y.o.(range 31-78).TE was positioned after mastectomy, progressively inflated, then replaced by a permanent implant, almost 6 months after PMRT. The majority of patients (79.24%) received chemotherapy. Pts started PMRT 3weeks after adjuvant chemotherapy. According to the tumor overexpressed Human Epidermal Growth Factor-2(HER-2) receptor, 24.52% of patients received trastuzumab, as a PMRT concurrent treatment.PMRT was delivered in supine position; 33pts were treated by HT (according to the major complexity to spare OAR), 20pts by 3DCRT. Chest-wall, supraclavicular lymph-nodes, heart, left coronary artery, ipsilateral and contralateral lung, spinal cord, thyroid, contralateral breast and esophagus was delineated. The capsular contracture was evaluated by using the four-

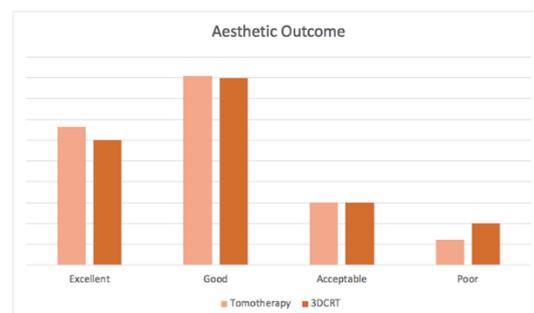

grade Baker scale, the aesthetic result was established according to the Harvard scale.

## Results

The treatment plans were compared using dose-volume histograms(DVHs) for planning target volume(PTV) and different OARs. The PTV minimum, mean and maximum doses, V95 (relative volume of breast PTV receiving 95% of the dose), and the dose at OAR were compared between 3DCRT and HT as reported in table 1. PTV coverage with the 95% isodose as expected was better for HT, as this curve fits best to the concave shape of the PTV compared to the 3DCRT(p<0.0001). A deeper analysis, only on the HT group, demonstrated that the more recent tomotherapy planning had a better dosimetry report than a few years ago. It meant a dose reduction in Dmax for ipsilateral lung and heart (p<0.0374 and p<0.0039). Capsular contracture Baker grade1-2: 1patient (HT) and 2pts (3DCRT). As regard, Baker grade3-4, 4pts (HT) and 2pts (3DCRT). An increased contracture rate was observed in patients who underwent 3DCRT (20%) instead of HT (15.15%). The aesthetic result has been classified as follow: "excellent", "good", "acceptable" and "poor".(Figure1)

Dmean	2.98±2.39	1.29-4.67	5.50±2.34	3.94-15.95	0.1235

Table.1 Abbreviations: D<sub>max</sub> = maximum dose; D<sub>min</sub> = minimum dose; D<sub>mean</sub> = mean dose; V<sub>x</sub> = volume (%) receiving x dose (5y) or higher; SD = standard deviation. The unpaired t-test is used to compare the data.

### Conclusion

This hypofractionated regimen confirmed to be a feasible and safe treatment in reconstructed patients with both techniques. HT was associated with best target dose coverage, but at the cost of a greater OAR exposure to low doses and to higher mean doses. A longer follow-up is needed to assess the impact of low doses to healthy tissues. Both techniques allowed to achieve a good outcome, with a low failure rate.

### EP-1297 Heart of the Matter: A study of 112 left breast cancer patients treated with DIBH

J. Windsor<sup>1</sup>, T. Ramanarasiah<sup>1</sup>, M. Burke<sup>2</sup>, J. Mitchell<sup>2</sup>  
<sup>1</sup>Genesis CancerCare Queensland, Gold Coast, Tugun, Australia ; <sup>2</sup>Genesis CancerCare Queensland, Brisbane, Brisbane, Australia

### Purpose or Objective

To quantitatively compare the dose cardiac structures, including the Left Anterior Descending (LAD) artery, receive when Deep Inspiration (DIBH) technique is employed compared with Free Breathing (FB) technique in a cohort of 112 patients with left sided breast cancer.

### Material and Methods

In 2015, DIBH was first implemented across the 5 centres in our hospital network located in South-East Queensland, Australia. To assess the efficacy of the DIBH method, the first 112 patients with left sided breast cancer were analysed to quantitatively compare cardiac dose between FB and DIBH techniques. Each patient underwent two CT scans, one using standard FB technique and the second scan using Varian Real-time Position Management (RPM) respiratory gating system for DIBH technique. Treatment planning was performed per departmental protocol with tangential fields on each CT scan, using either IMRT or 3D conformal technique and dose fractionation at the discretion of the treating Radiation Oncologist (RO). Subsequent dose-volume histograms were calculated and compared using a paired t-test to evaluate mean dose to heart and Left Anterior Descending (LAD) coronary artery. All doses were compared at 2Gy per fraction equivalent.

### Results

112 patients were assessed for suitability to employ the DIBH technique. 10 patients were excluded from the study due to inability to breath hold or other technical reasons. A total of 102 patients, 101 female and 1 male, between the ages of 36 and 80 (mean 59) with left sided breast cancer were included for comparison. DIBH showed significant reduction in maximum cardiac dose (25.82Gy vs 38.29Gy,  $p < 0.001$ ), mean cardiac dose (1.21Gy vs 1.92Gy,  $p < 0.001$ ), cardiac V25Gy (1.78cc vs 8.46cc,  $p < 0.001$ ) and maximum LAD dose (15.8Gy vs 27.05Gy,  $p < 0.001$ ) compared to FB. A statistically significant increase in volume of lung receiving  $> 50\%$  of the prescribed dose in patients treated with DIBH (168.54cc vs 106.3cc,  $p < 0.001$ ) was noted compared to FB however all DIBH lung doses were within acceptable dose limitations for Organs at Risk (OAR).

Patient Demographics			
Mean Age	59		
Gender	Female	101	
	Male	1	
Radiation Dose To Organs at Risk			
	Free Breathing	DIBH	p-value
Cardiac Maximum Dose (Gy)	38.29	25.82	<0.001
Cardiac Mean Dose (Gy)	1.93	1.21	<0.001
Cardiac V25Gy (cc)	8.67	2.06	<0.001
LAD Maximum Dose (Gy)	27.05	15.8	<0.001
Left Lung V>50% Prescribed Dose (cc)	107	168.53	<0.001

Table 1.1 Comparison of dose to organs at risk between FB and DIBH techniques

### Conclusion

DIBH provides a significant reduction in the mean cardiac dose and LAD dose in patients undergoing left sided breast irradiation. It was possible to implement this technique in majority of the patients and this technique has now been successfully integrated into routine clinical practice.

While it is still early to assess differences in toxicity we are continuing follow up of patients in this cohort and hypothesise reduction in cardiotoxicity in the DIBH group.

### EP-1298 MR-guided delineation of target volumes in internal mammary lymph node radiotherapy

M. Groot Koerkamp<sup>1</sup>, A.C. Houweling<sup>1</sup>, M.E.P. Philippens<sup>1</sup>, M. Albrechts<sup>1</sup>, I.E. Van Dam<sup>1</sup>, J.M. Tjink-Felderhof<sup>1</sup>, E.M. Aalbers<sup>1</sup>, G.G. Sikkes<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, H.J.G.D. Van den Bongard<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

In breast cancer patients with tumorpositive internal mammary lymph nodes (IMN) internal mammary chain irradiation is indicated. Target delineation requires visualization of the internal mammary (IM) vessels. On standard planning-CT (pCT) scans without intravenous (IV) contrast these vessels can be difficult to distinguish. The purpose of this evaluation was to assess if additional non-contrast MR imaging facilitates delineation of IM vessels.

### Material and Methods

Since July 2017, all breast cancer patients with an indication for IMN irradiation at our department underwent 1.5T MR imaging. Patients were scanned in supine RT position, on a 5° wedge and an MR compatible arm support. The anterior receive coil was placed upon height adjustable coil bridges to avoid body contour deformation (Figure 1). Three fat-suppressed MR scans were acquired: a 3D T<sub>1</sub>-weighted spoiled gradient echo (T1w), a T<sub>2</sub>-weighted spin echo (T2w) and a respiratory gated and cardiac-triggered 3D balanced gradient echo (3Dcor) scan. The scans were registered to the pCT based on the region around the manubriosternal joint.

Figure 1: MRI scanning set-up at the 1.5T MRI scanner: flat table top, MR-compatible thorax-arm support, coil bridges and receive coils.

Breast radiation oncologists (ROs) and an RO in-training supervised by a breast RO delineated the IM vessels on the pCT. The use of the MR scans was up to the RO. In September 2018, the ROs filled in a short questionnaire to evaluate the delineation process using the MR images in addition to the pCT. Furthermore, we evaluated the workflow with RTTs that performed the MR scanning and MR-to-pCT registration.

### Results

Eighteen breast cancer patients underwent MR imaging for IM vessel visualization. MR scanning took  $\pm 30$  minutes per patient, including patient set-up. Scan quality was high in all patients, except in one patient due to patient motion caused by pain. According to the RTTs, the 3Dcor scan was most difficult to acquire due to gating and triggering settings to be entered manually. Registration of the T1w and T2w scans to the pCT went well, whereas the 3Dcor scan could not always be matched because the sternum is not clearly visible in this scan.

Six breast ROs and one RO in-training who delineated the scans of these patients evaluated their delineation process. All of them used the T1w scan and four ROs also used the T2w and/or 3Dcor scans. Five ROs (in training) reported that the MR scans (Figure 2) facilitated delineation of the IM vessels, provided that the scans were correctly matched to the pCT. However, three ROs reported no additional value of the MR scans when the IM vessels were already clearly visible on the pCT. One RO

reported no additional benefit of the MR scans at all due to patient motion during scanning.

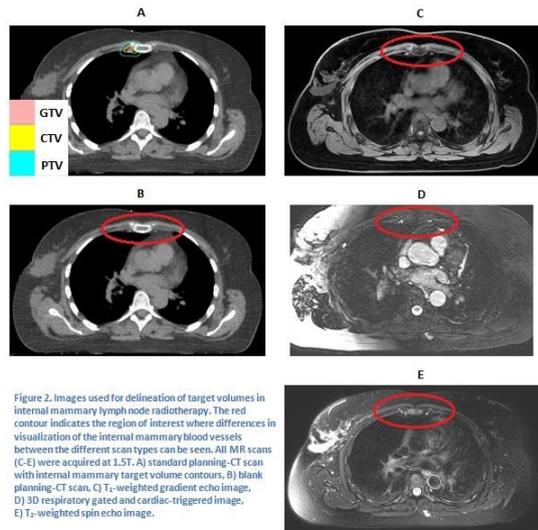

Figure 2. Images used for delineation of target volumes in internal mammary lymph node radiotherapy. The red contour indicates the region of interest where differences in visualization of the internal mammary blood vessels between the different scan types can be seen. All MR scans (C-E) were acquired at 1.5T. A) standard planning-CT scan with internal mammary target volume contours, B) blank planning-CT scan, C) T<sub>2</sub>-weighted gradient echo image, D) 3D respiratory gated and cardiac-triggered image, E) T<sub>2</sub>-weighted spin echo image.

**Conclusion**

MR-guidance facilitated delineation of IM vessels due to the improved visualization of the IM vessels when visualization on pCT was poor. Using a T1w scan only already provided adequate visualization. Our recommendation is to use non-contrast MR imaging for IMN target volume delineation when MR scanning facilities are readily available.

**EP-1299 Lymphatics in breast cancer: healthy nodes versus metastatic nodes**

L. Ernst<sup>1</sup>, K.J. Borm<sup>1</sup>, S.E. Combs<sup>1</sup>, M. Oechsner<sup>1</sup>, M. Düsberg<sup>1</sup>, M.N. Duma<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- TU München, Department of Radiation Oncology, München, Germany

**Purpose or Objective**

Recently, a comprehensive study on PET positive lymph node (Ln) metastases in breast cancer patients has been published (Borm KJ et al. , IJROBP 2018). Nonetheless it is unclear if healthy Ln follow the same distribution pattern. The aim of this study was to detect all visible non pathological Ln in CT data sets in the same patient collective and compare them to the Ln metastases .

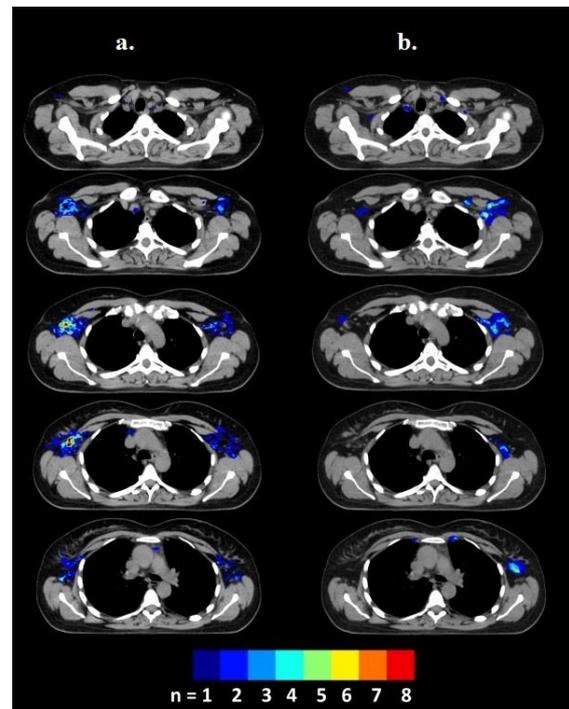

**Material and Methods**

The recently published dataset included 235 patients. Herein we report the (non pathological) contralateral lymph node distribution on the first patients from the same collective. For 34 patients we contoured all visible axillary/paraclavicular and internal mammary Ln contralateral to the primary tumor site. Patients with contralateral (or bilateral) lymph node metastases were excluded from this study. A total of 400 Ln were contoured. The size and localization of the Ln was recorded. The Ln were transferred to a standard patient using rigid and non-rigid registrations to create a “healthy Ln atlas”. Out of 400 Ln, 380 could be successfully transferred to the standard patient. This atlas was compared to the pattern of Ln metastases and to the ESTRO clinical target volume (CTV) contouring guidelines.

**Results**

The average diameter of the healthy Ln was 0.85 ± 0.37 cm and the mean volume was 0.20 cm<sup>3</sup> ± 0.30 cm<sup>3</sup>. Most healthy Ln were found in level I (n = 277; 69.25%), level IV (n = 63; 15.75%) and level II (n = 39; 9.75%), followed by the internal mammary region (n = 17; 4.25%) and level III (n = 4; 1.00%). Similar to this, pathological Ln were also predominantly found in level I (54.5%) and level IV (13.8%). Nonetheless, metastases were more often localized in

level III (10.0%) than in level II (9.8%) or in the internal mammary region (9.5%) compared to the healthy Ln. Figure 1 depicts a comparison of healthy Ln (a) vs pathological Ln (b) in the analyzed 34 patients.

Of 380 healthy Ln 124 (32.6%) were completely within , 128 in partly within (33.7%) and 128 outside (33.7%) the ESTRO CTV , respectively. The largest differences with regard to the CTV coverage (compared to the previous analysis of pathological lymph nodes) were found in the supraclavicular and internal mammary region (see table 1).

	Ln Metastases	partly inside		Healthy Ln	
		outside	inside	outside	inside
Level I	16.5%	48.7%	34.8%	25.3%	38.3%
Level II	14.0%	59.6%	26.3%	10.8%	43.2%
Level III	15.5%	62.1%	22.4%	0.0%	0.0%
supraclavicular region	31.3%	62.5%	6.3%	80.0%	7.3%
internal mammary region	29.1%	67.3%	3.6%	70.6%	29.4%
total	21.2%	53.8%	25.0%	33.7%	33.7%

**Conclusion**

Similar to Ln metastases, healthy lymph node accumulate in certain “hot spots” within the lymphatic drainage system. Even though these hot spots seem to be located in similar regions, there are relevant differences (ESTRO CTV coverage) between the lymph node pattern in healthy and pathological tissue that need to be further investigated.

### EP-1300 Beware of IMRT axillary dose reduction in non-axillary-dissected breast cancer patients

J. Gadea<sup>1</sup>, I. Ortiz<sup>1</sup>, D. Morera<sup>2</sup>, F. Sansaloni<sup>2</sup>, R. Roncero<sup>1</sup>, M. Hernández<sup>2</sup>, L. Valencia<sup>1</sup>, M.J. Sánchez<sup>2</sup>, J.E. Maturana<sup>1</sup>, J. Font<sup>2</sup>, P. José<sup>1</sup>

<sup>1</sup>Hospital Universitari Son Espases, Radiation Oncology, Palma de Mallorca, Spain ; <sup>2</sup>Hospital Universitari Son Espases, Medical Physics, Palma de Mallorca, Spain

#### Purpose or Objective

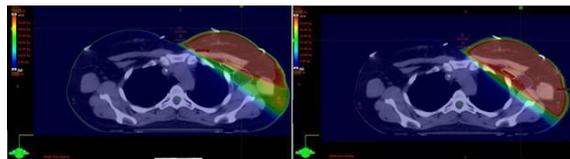

Classically the standard radiotherapy (RT) treatment in breast cancer has been tridimensional conformal radiotherapy (3D-CRT) with two tangential fields. In the IMRT era, homogeneity and conformity of the dose and target coverage has been improved in RT treatments. However, this fact could minimize the incidental irradiation of the axilla with potential clinical consequences. The aim of this study is to compare incidental axillary dose in breast cancer patients treated with IMRT vs 3D-CRT.

#### Material and Methods

Twenty female patients with breast cancer treated with breast-conserving surgery and adjuvant hypofractionated RT were evaluated in this study. Two dose groups were made for the analysis, one no-boost and one boost group for each patient. The total prescribed dose in the boost group was 40.05 Gy in 15 fractions (fx) to the whole breast and a 13.35 Gy/5fx photon boost to tumor bed sequentially in the 3D-CRT treatment and 40.05 Gy in 15fx to the whole breast and a 48 Gy/15fx photon integrated boost in the IMRT treatment. The total prescribed dose in the no-boost group was 40.05 Gy in 15fx for both techniques. Treatment plans were evaluated using cumulative dose-volume histogram data. Breast tissue, axillar node levels I, II and III and Rotter nodes and a sum of all were delineated. For the statistical analysis a T-student test was performed.

#### Results

In the no-boost group, IMRT technique showed significantly lower axillary irradiation compared with 3D-CRT ( $D_{\text{mean}}$  for total axilla: 23.84±6.57 Gy vs 30.53±8.44 Gy,  $p<0.05$ ) (Image 1). In the boost group, IMRT also showed significantly lower axillary irradiation compared with 3D-CRT ( $D_{\text{mean}}$  for total axilla: 25.34±7.07 Gy vs 31.23±8.80 Gy,  $p<0.05$ ). However, the boost location (upper quadrants vs lower quadrants) did not cause statistically significant differences in axillary dose with any of the two techniques. Details of each axillary level are shown in Table 1. When differences between the boost group and no-boost group treated with IMRT were evaluated, a significantly lower axillary irradiation was observed in the no-boost group ( $D_{\text{mean}}$  for total axilla: 25.34±7.07 Gy vs 23.84±6.56 Gy,  $p<0.05$ ). In contrast, although this difference was also seen with 3D-CRT between both groups, it was not statistically significant.

**Image 1** (Left): IMRT plan for a left-sided breast cancer patient with 40.05Gy prescription dose showed in color wash. Axillary levels I (purple), II (green), III (pink) and Rotter (gold) are delineated. (Right): The same patient with a 3D-CRT plan.

**Table 1.** Differences between both techniques in each axillary level separately

BOOST GROUP			
Node level		$D_{\text{mean}}$ (Gy) ± standard deviation	p
I	IMRT	29.63 ± 6.61	<0.05*
	3D	36.24 ± 8.19	
II	IMRT	14.86 ± 8.78	<0.05*
	3D	23.00 ± 12.71	
III	IMRT	8.88 ± 8.26	<0.05*
	3D	14.77 ± 14.05	
NO-BOOST GROUP			
Node level		$D_{\text{mean}}$ (Gy) ± standard deviation	p
I	IMRT	29.00 ± 5.28	<0.05*
	3D	34.77 ± 7.60	
II	IMRT	14.09 ± 8.71	<0.05*
	3D	22.53 ± 12.30	
III	IMRT	8.18 ± 7.59	<0.05*
	3D	14.37 ± 13.54	

\* Statistically significant p-value.

#### Conclusion

Incidental irradiation of the axilla was significantly lower with IMRT compared to 3D-CRT. Therefore, IMRT should be cautiously used in patients with limited positive sentinel lymph node disease who undergo breast conserving treatment without complete axillary lymph node dissection. There is a risk of leaving untreated microscopic node disease in these patients if we do not include axillary levels in the target volume.

### EP-1301 Postoperative EBRT in breast cancer: an analysis on 768 patients about predictors of late toxicity

Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy ; <sup>4</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy ; <sup>5</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Gynecologic Oncology Unit, Campobasso, Italy ; <sup>6</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiology Unit, Campobasso, Italy ; <sup>7</sup>Bellaria Hospital, Radiation Oncology Unit, Bologna, Italy

#### Purpose or Objective

To retrospectively evaluate risk factors for skin and subcutaneous late toxicity in 768 patients (pts) conservatively treated for breast cancer.

#### Material and Methods

We analysed 5-year  $G \geq 2$  skin and subcutaneous late toxicity-free survival (LTFS) stratifying pts based on potential risk factors: hypertension, diabetes, smoking habit, alcohol consumption, chemotherapy, hormonotherapy, stage, PTV volume, and EQD2.

#### Results

Univariate analysis results are shown in table 1. No correlation was found between  $G \geq 2$  LTFS and diabetes, smoking habit and alcohol consumption. Small but statistically significant correlations were found between

hypertension and G3 cutaneous 5-y-LTFS (98.5 vs 100%) and between chemotherapy and G3 subcutaneous 5-y-LTFS (98.4 vs 100%). A trend suggesting an impact of taxan-based chemotherapy schedules on G2 subcutaneous late toxicity was observed. Hormonotherapy with Aromatase Inhibitors (AI) was significantly ( $p < 0.0001$ ) associated with worse G2 subcutaneous 5-y-LTFS (75.6% vs 84.6% and 89.1% for Tamoxifen plus LH-RH analogue and Tamoxifen alone respectively). EQD2 was also related to G2 subcutaneous toxicity: in particular, better outcomes were observed in the group of pts treated with 50.4 Gy in 28 fractions (fr) with sequential electron boost of 10 Gy in 4 fr (EQD2 PTV 48.4 Gy, EQD2 BOOST 59.4 Gy). This was probably related to the used technique for boost delivery (electrons vs concomitant boost with tangential fields in the other two groups). In the two groups treated with IMRT and concomitant boost, G2 subcutaneous toxicity was higher in the one with higher EQD2, as expected. An interesting correlation ( $p = 0.001$ ) was also found between nodal status and G2 subcutaneous toxicity: pts with N2-3 disease, who underwent regional lymphadenectomy (with consequent alteration of lymphatic drainage) had a worse outcome compared to pts with N1 disease, where lymphadenectomy rate was lower. This could also be explained by the different technique (hemi-fields) used for pts who needed lymph nodes irradiation (typically pN2-3). Finally, PTV volume was correlated with G2 skin LTFS ( $p < 0.0001$ ), with a significant difference between values below and above the median (5y-LTFS: 98.4% vs 80.1%).

Table 1: Univariate analysis of risk factors for late toxicity

Factor	No.	n (%)	SIB		SUBCUTANEOUS	
			Rate (%)	HR (95% CI)	Rate (%)	HR (95% CI)
Age (years)	216	100	0.94	0.99	0.98	0.99
Chemotherapy	216	100	1.28	1.08	1.08	1.08
Radiotherapy	216	100	1.58	1.53	1.54	1.53
Hormonotherapy	216	100	1.20	1.05	1.05	1.05
EQD2	216	100	1.05	1.05	1.05	1.05
Nodal status	216	100	1.20	1.05	1.05	1.05
PTV volume	216	100	1.20	1.05	1.05	1.05

**Conclusion**

Our preliminary data confirm that some factors could be related to higher rates of late toxicity in pts treated for breast cancer. This analysis may represent the basis to develop predictive models of late toxicity.

**EP-1302 long-term clinical outcomes of IMRT with simultaneous integrated boost for breast cancer**

H. Lee<sup>1,2</sup>, M. Huang<sup>2,3</sup>  
<sup>1</sup>Ph.D. Program in Environmental and Occupational Medicine- Kaohsiung Medical University and National Health Research Institutes, Radiation Oncology, Kaohsiung, Taiwan ; <sup>2</sup>Kaohsiung Medical University Hospital, Radiation Oncology, Kaohsiung, Taiwan ; <sup>3</sup>Kaohsiung Medical University, Faculty of Medicine-College of Medicine, Kaohsiung, Taiwan

**Purpose or Objective**

To report the long-term survival outcomes and late toxicities resulted from intensity modulated radiotherapy (IMRT) with simultaneous integrated boost (SIB) for breast cancer patients after breast conserving surgery (BCS).

**Material and Methods**

The study included 216 patients with pathologically proven breast cancer who underwent BCS between 2010 and 2013. The median age was 52 years (Range: 21 to 81). All patients received IMRT-SIB to 2 dose levels simultaneously. They received 50.4 Gy at 1.8 Gy per fraction to the whole breast and 60.2 Gy at 2.15 Gy per fraction to the tumor bed by integral boost. The fractionation scheme was biologically equivalent to the sequential boost-technique comprising 25 fractions of 2 Gy

to the whole breast PTV followed by a boost irradiation in 6 fractions, using an alpha/beta ratio of 4 Gy for tumor response, based on the linear-quadratic cell survival model. Dermatological toxicities were assessed and documented in agreement with the Common Toxicity Criteria Adverse Events version 3 (CTCAE v.3.0). Cox regression model and Kaplan-Meier curves were calculated, and the log-rank test was used to evaluate the differences of overall (OS) and disease free (DFS) survival rates between two different modalities of radiotherapy.

**Results**

Among 216 patients, 174 received post-operative radiotherapy with Rapid-Arc and 42 patients had Tomotherapy after BCS. All patients tolerated IMRT-SIB without any interruption. The median follow-up was 6.4 years. Four patients (1.85%) in the entire cohort developed late skin complication after IMRT-SIB. For the entire cohort, the 5-year and 7-year OS rates were 94.4% and 93.1% respectively. The 5-year and 7-year DFS rates were 94.9% and 94.0 % respectively.

**Conclusion**

There exists no statistically significant difference in the rates of locoregional recurrence and overall survival when comparing RapidArc with Tomotherapy. IMRT-SIB was well tolerated with small late skin complication and good survival rates.

**EP-1303 Hypofractionated adjuvant radiotherapy in elderly low risk breast cancer patients: loss or gain?**

A. Fodor<sup>1</sup>, M. Pasetti<sup>1</sup>, P. Mangili<sup>2</sup>, B. Longobardi<sup>2</sup>, F. Zerbetto<sup>1</sup>, L. Perna<sup>2</sup>, I. Dell'Oca<sup>1</sup>, P. Signorotto<sup>2</sup>, R. Tummineri<sup>1</sup>, F. Borroni<sup>1</sup>, C.L. Deantoni<sup>1</sup>, A.M. Deli<sup>1</sup>, N. Slim<sup>1</sup>, A. Chiara<sup>1</sup>, P. Passoni<sup>1</sup>, S. Foti<sup>1</sup>, M. Azizi<sup>1</sup>, C. Fiorino<sup>2</sup>, A. Bolognesi<sup>1</sup>, N.G. Di Muzio<sup>1</sup>  
<sup>1</sup>San Raffaele Scientific Institute, Department of Radiotherapy, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

**Purpose or Objective**

The PRIME II trial (Lancet Oncol 2015) and a recent meta-analysis (Radiother Oncol 2017) suggested that adjuvant radiotherapy does not impact overall survival in elderly patients (pts) with low risk breast cancer (LRBC), and therefore could be omitted. We report here the 5-year outcomes in elderly pts with LRBC treated with whole breast hypofractionated adjuvant radiotherapy (RT).

**Material and Methods**

One hundred forty five pts 70 years or older, with hormonal receptors positive, Her2-negative status (Luminal A/Luminal B Her2-negative) early stage (pTis-pT1c pN0-1a ≤ 3 positive lymph nodes) breast cancer, treated from 02/2009-05/2013, were included in this analysis. The patients were treated with whole breast radiotherapy to 40 Gy/15 fractions with a multiple-segments 3D-CRT technique, without tumor bed boost. Median age was 73 (70-90) years, 8 pts had ductal carcinoma in situ, 25 lobular invasive carcinoma or combination, 98 ductal invasive carcinoma and 14 other histology (mucinous, tubular, papillary); 70 were right sided and 75 left sided tumors. Hormonal therapy was prescribed in 133/ 145 pts. For possible side effects follow up visits were scheduled for 5 years. Acute toxicity during RT was evaluated with RTOG scale, late toxicity with SOMA-LENT score.

**Results**

A median number of 4 (2-6) segments were used to obtain a homogeneous dose distribution. Acute toxicity was: 24.1% G0, 69.0% G1 and 24.1% G2. Half of G2 toxicities were delayed, 7-15 days after RT, and concerned only the inframammary fold; 70% of them had breast volume > 600 cc. Two G2 toxicities were observed in low breast volume pts but with bolus for half therapy. Late toxicity was available for 131 pts: 16 % were G1 edema/dyschromia, rarely persistent over three years, while 7.6% G1 fibrosis/teleangiectasia, starting generally from the third

year after RT. Only one G2 fibrosis/teleangiectasia was observed, but maintaining a good cosmetic result. Four pts were dead at the last follow up: one of head and neck tumor, one of stroke and two of heart attack. The treatment plans of the two pts died of heart attack (one left sided tumor) were revised, but heart dosimetry was very good in both: V95%= 0 cc for both, V 20 Gy 0 for right sided, 0.76 cc for left sided pts and D 5 1.5 Gy for the right sided and 2.03 Gy for left sided patients, respectively. Two pts (1.52%) presented local relapse (4.4 and 7.9 years after HRT), 1 patient lymph-nodal relapse and 4 pts (3.02%) distant relapse.

### Conclusion

Elderly pts with LRBC treated with adjuvant RT showed a good treatment tolerance and low local relapse (LR) rate, lower than the up to 9% reported without RT. Thus, a short, convenient HRT could be prescribed even in the absence of a survival benefit, due to the improvement of the quality of life by the reduction of the LR rate to a very low level.

### EP-1304 What is the benefit of using more beams and/or non-coplanar beams in breast PBS proton therapy?

K. Verhoeven<sup>1</sup>, R. Houben<sup>1</sup>, K. Limpens<sup>1</sup>, M. Velders<sup>1</sup>, F. Visser<sup>1</sup>, G. Vilches-Freixas<sup>1</sup>, C. Ares<sup>1</sup>, G. Bosmans<sup>1</sup>, L. Boersma<sup>1</sup>

<sup>1</sup>GROW School for Oncology and Developmental Biology- Maastricht University Medical Centre, Radiation-Oncology Maastricht Clinic and ZON-PTC, Maastricht, The Netherlands

### Purpose or Objective

Pencil Beam Scanning (PBS) proton therapy (PT) has dosimetric advantages over photon therapy (PhT) in decreasing the dose to the organs at risk (OAR), which potentially leads to a reduction in late toxicity. To reimburse PT in breast cancer (BC) patients in our country a delta normal tissue complication probability (NTCP) of  $\geq 2\%$  for cardiac toxicity should be demonstrated based on the delta mean heart dose (MHD)[Darby et al, 2013] coming from the planning comparison between the PhT plan and the PBS PT plan.

The use of more beams (B) and/or of non-coplanar beams (NCB) will increase the treatment delivery time. Therefore, the aim of this study is to investigate the dosimetric added value of increasing the number of beams as well as the use of NCB in PBS PT for BC patients.

### Material and Methods

Fifteen BC patients (6 right and 9 left-sided) were selected for this dosimetric study. In 9/15 patients the internal mammary lymph node region was included in the target volume and 9/15 patients had an indication for a simultaneous integrated boost (SIB) on the tumor bed or on a macroscopic lymph node. The fractionation schemes used were 15 x 2.67Gy (1/15), 16 x 2.66Gy (5/15) and for SIB: 20 x 2.67Gy (1/15), 21 x 2.66Gy (3/15) or 23 x 2.66Gy (5/15). Six PBS PT plans were calculated for each patient: 2B, 2NCB, 3B, 3NCB, 4B and 4NCB using the RayStation treatment planning system with the Mevion beam characteristics and with the Monte Carlo calculation algorithm. PBS PT plans were made around the planning target volume (PTV). Target coverage and doses to the OARs (MHD, mean lung dose (MLD), contralateral breast (CLB) volume receiving  $\geq 2$ Gy (V2)) were registered. Statistical analysis was performed using the one-sample Wilcoxon rank-signed test with a significance level of  $<0.05$ .

### Results

Four out of 15 (27%) patients would have been accepted for PT according to the delta NTCP criteria. PTV coverage was fulfilled in all the plans (PTV V95%  $\geq 99\%$ ). The increase from 2B to 3B resulted in a small but significant reduction in the MHD (p=0.041) as well as a decrease in the MLD (p=0.001). The addition of an extra beam, thus 4B

instead of 3B, further decreased the MLD (p=0.001) and had a positive impact on the V2 CLB (p=0.009)(table 1). No added value in reducing the dose to the OARs has been observed by using NCB (2B vs 2NCB, 3B vs 3NCB and 4B vs 4NCB), except for the MLD when comparing 3B with 3NCB. The difference in OAR doses with increasing the number of beams or by using NCB did not translate in a delta NTCP of  $\geq 2\%$ .

Table 1. Median MHD, MLD and V2 CLB averaged over 15 patients with the range between brackets for photon plans and PBS PT plans with 2B, 2NCB, 3B, 3NCB, 4B, 4NCB. V2 CLB for photon plans was not available.

	Photon	PBS-PT 2B	PBS-PT 2NCB	PBS-PT 3B	PBS-PT 3NCB	PBS-PT 4B	PBS-PT 4NCB
MHD (Gy)	2.30 (0.50-12.00)	0.82 (0.10-4.83)	1.82 (0.08-4.45)	0.58* (0.09-3.87)	0.62 (0.08-3.74)	0.38 (0.12-3.24)	0.39* (0.11-3.67)
MLD (Gy)	7.96 (2.90-13.00)	6.11 (2.36-10.42)	5.59 (2.03-10.04)	5.87** (2.04-10.05)	5.44** (1.56-9.66)	5.01* (1.51-10.23)	4.82 (1.42-8.71)
V2 CLB (%)		2.49 (0.00-132.40)	0.10 (0.00-126.00)	2.08 (0.00-136.00)	1.56 (0.00-96.31)	0.56* (0.00-90.40)	0.67 (0.00-88.97)

\*p-value  $< 0.05$  between 2B and 3B

\*\*p-value  $< 0.05$  between 3B and 3NCB

\*p-value  $< 0.05$  between 3B and 4B

### Conclusion

Increasing the number of beams in BC PBS PT from 2 to 4 reduces significantly the doses to the OARs (MHD, MLD and V2 CLB), however with questionable clinical relevance. The use of non-coplanar beams does not improve the quality of the PBS proton plans. The perfect balance between reducing the dose to the OARs by using more beams and the time efficiency during PBS PT delivery is not clear and should be balanced out in a one by one basis.

### EP-1305 Long-term results up to 15 years after IORT boost in breast cancer patients

E. Sperk<sup>1</sup>, M. Pez<sup>1</sup>, G. Welzel<sup>1</sup>, A. Keller<sup>1</sup>, Y. Abo-Madyan<sup>1</sup>, M. Ehmann<sup>1</sup>, B. Tuschy<sup>2</sup>, S. Berlit<sup>2</sup>, M. Sütterlin<sup>2</sup>, F.A. Giordano<sup>1</sup>, F. Wenz<sup>1</sup>

<sup>1</sup>University Medical Center Mannheim, Department of Radiation Oncology, Mannheim, Germany; <sup>2</sup>University Medical Center Mannheim, Department of Gynecology and Obstetrics, Mannheim, Germany

### Purpose or Objective

Intraoperative radiotherapy (IORT) given as a boost during breast conserving surgery (BCS) is one of the standard boost methods for breast cancer. This is the first report of a mature and detailed toxicity and outcome follow-up after IORT boost with 50 kV x-rays up to 15 years.

### Material and Methods

Patients undergoing BCS plus IORT boost (med. 20Gy) and subsequent whole breast radiotherapy (WBRT, med. 46Gy) were included in this analyses. Follow-up was done twice yearly for 2 years and then yearly. Toxicity was evaluated according to a modified LENT SOMA scale (mod.: telangiectasia 0=no, 1=present). Cumulative (permanent  $>1=3$  events during follow-up) toxicity rates were calculated using the Kaplan-Meier method. Cumulative outcome (local/axillary recurrence, second breast cancer, metastasis, overall survival) were assessed with the Kaplan-Meier method.

### Results

Between 2002-2014, 400 breast cancers in 398 patients were treated with IORT boost (median age 63 years (30-85y), median follow-up 78 months (2-180)). Median interval between IORT - WBRT was 48 days (13-377), main type was ductal/NST in 70.5%, lobular 24%, T0/1/2: 0.5%/73%/26%, N0/1/2/3: 76%/19%/4%/1%, M0/1: 99%/1%. Chemotherapy/endocrine therapy was given in 35%/83%. Permanent moderate/severe fibrosis was seen in 18.3/19.1/21.2% at 3/5/10y, permanent breast edema  $>1$  in 2.4% at 5/10y, permanent ulceration  $>1$  in 0.3% at 5/10y, permanent lymph edema of the arm  $>1$  in 0.6/1.3% at 5/10y, permanent hyperpigmentation  $>1$  in 0.5% at 5/10y, permanent pain  $>1$  in 8.6% at 5/10y. Severe pain as first event was seen in 4% at 5/10y. Any telangiectasia as first event was seen in 18.3/23.2% at 5/10y. Our results

are in line with historical data (Bartelink JCO 2007, Lancet Oncol 2015: moderate/severe fibrosis 28.1/30.4% at 10/20y). Local recurrence rate was 1.7/2.0/6.6/10.1% at 3/5/10/15y, second breast cancer rate was 3.8/6/10.4% at 5/10/15y, axillary recurrence rate was 0.5/1.5% at 5/8-15y, metastasis rate was 4.1/6.7/14% at 3/5/10-15y and overall survival was 95.7/92.1/81.8/80.7% at 3/5/10/15y, which compares favorably to historical data (Bartelink JCO 2007, Lancet Oncol 2015: Local recurrence as first event 6.4/12/15% at 10/12/15y, metastasis 26% at 20y, overall survival 82/-73/59.7% at 10/15/20y).

#### Conclusion

IORT boost with low kV x-rays is a safe boost method for (high risk) breast cancer patients with a good local and distant control and acceptable toxicity rates during long-term follow-up.

#### EP-1306 Gated treatment of left-sided breast cancer: evaluation of lung movement, irradiated volume and mass

M. Oechsner<sup>1</sup>, M. Duesberg<sup>1</sup>, K. Borm<sup>1</sup>, J.J. Wilkens<sup>1</sup>, S.E. Combs<sup>1,2,3</sup>, M.N. Duma<sup>1,2,3</sup>

<sup>1</sup>Klinikum rechts der Isar- TU München, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Deutsches Konsortium für Translationale Krebsforschung DKTK, Partner Site Munich, Munich, Germany; <sup>3</sup>Institute of Innovative Radiotherapy, Department of Radiation Sciences- Helmholtz Zentrum München, Munich, Germany

#### Purpose or Objective

Treatment of left-sided breast cancer in deep inspiration breath-hold (DIBH), compared to free breathing (FB), was proved to reduce the dose to the heart and mostly also to the lung. For the evaluation of lung dose the dose mass histogram (DMH) seems to be more adequate than the dose volume histogram (DVH). The aim of this study was to compare DVH and DMH parameters for the left lung between treatment in FB and DIBH. Additionally, lung motion between FB and DIBH was analyzed.

#### Material and Methods

31 left-sided breast cancer patients were retrospectively selected. Treatment plans were optimized on CT datasets in FB and DIBH with the Eclipse treatment planning system (Varian Medical Systems, Palo Alto, CA). The CT datasets, structures and dose were transferred to the Matlab software (The MathWorks, Natick, MA) and DVH and DMH were calculated using self-written programs. Mean doses (Dmean) and volumes and masses receiving a certain dose (V5-45 and M5-45) were evaluated.

Using deformable image registration of the open source software Plastimatch we calculated deformation vector fields to analyze the movement of the left lung between FB and DIBH. Mean values for the movement in left-right, antero-posterior and cranio-caudal direction and a 3D vector were calculated and correlated to dose parameters. Data were statistically analysed using the wilcoxon test.

#### Results

The mean lung volume was 1432 ± 290 ml (mean ± standard deviation) in FB and 2581 ± 321 ml in DIBH. The mean lung density changed between FB and DIBH from 0.31 ± 0.05 g/cm<sup>3</sup> to 0.17 ± 0.03 g/cm<sup>3</sup>. Irradiation in DIBH resulted in a significantly reduced Dmean of the left lung: 10.0 ± 1.7 Gy in FB and 8.3 ± 1.5 Gy in DIBH (p<0.01). Relative volumes V5-45 were always smaller in DIBH than in FB (-12% to -51%, Table 1). In contrast to that, absolute volumes V5-45 were larger in DIBH (29% to 63%), except for V45 (-11%). For the irradiated lung mass the mean M5-45 were always larger in DIBH than in FB for both relative and absolute mass. However, some patients had an increased irradiated lung mass in DIBH (e.g. 4 patients for M20) or a decreased absolute irradiated lung volume in DIBH (e.g. 3 for V20).

The mean movement of the left lung between FB and DIBH was 1.5 ± 2.4 mm to the left, 16.0 ± 4.0 mm in anterior, 12.2 ± 4.6 mm in caudal direction with a mean 3D movement of 20.8 ± 4.1 mm (Fig 1). Depending on the individual patients, the ratio between movements in anterior and caudal varied from 89% to -54%, but that had no effect on the resulting dose. Increased lung movement correlated only with an increase in irradiated lung volume.

	FB		DIBH	
	absolut [cm <sup>3</sup> ]	relativ [%]	absolut [cm <sup>3</sup> ]	relativ [%]
V5	449.2 ± 99.2	31.7 ± 5.4	719.1 ± 152.1	28.0 ± 5.5
V10	331.2 ± 81.8	23.3 ± 4.3	480.9 ± 110.7	18.8 ± 4.1
V20	267.5 ± 67.0	18.9 ± 3.6	367.2 ± 86.6	14.4 ± 3.3
V30	232.0 ± 57.2	16.4 ± 3.2	315.2 ± 73.8	12.3 ± 2.9
V40	179.1 ± 49.9	12.6 ± 2.8	225.8 ± 62.2	8.8 ± 2.4
V45	108.1 ± 44.3	7.6 ± 2.5	98.9 ± 55.0	3.8 ± 2.0
	absolut [g]	relativ [%]	absolut [g]	relativ [%]
M5	107.6 ± 23.6	24.8 ± 4.7	102.1 ± 27.6	23.2 ± 5.0
M10	79.6 ± 19.9	18.3 ± 3.7	69.8 ± 20.5	15.8 ± 3.6
M20	65.3 ± 16.0	15.0 ± 3.0	55.7 ± 16.4	12.6 ± 2.9
M30	57.2 ± 13.4	13.1 ± 2.6	48.9 ± 14.2	11.0 ± 2.5
M40	46.0 ± 12.0	10.5 ± 2.3	38.1 ± 11.8	8.6 ± 2.1
M45	31.1 ± 11.0	7.1 ± 2.1	22.3 ± 9.6	5.0 ± 1.8

Table 1

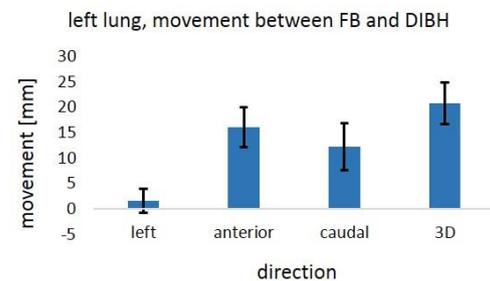

Figure 1

#### Conclusion

Treatment of left-sided breast cancer in DIBH resulted mostly in lower doses to the lung. Despite an increase in absolute irradiated lung volume in DIBH the irradiated lung mass is reduced. But for some patients there can also be a reverse effect. The amount of lung movement depends on the individual patient and correlated only to the absolute irradiated lung volume.

#### EP-1307 Deep inspiration breath-hold technique versus free breathing in RT treatment of left-sided breast

N. Jankarashvili<sup>1</sup>, I. Sikharulidze<sup>2</sup>, R. Sreseli<sup>3</sup>, N. Kartvelishvili<sup>4</sup>, M. Topeshashvili<sup>1</sup>

<sup>1</sup>Academician F. Todua Medical Center-Research Institute of Clinical Medicine, Radiation Oncology, Tbilisi, Georgia; <sup>2</sup>Tbilisi Cancer Center, Oncological Surgery, Tbilisi, Georgia; <sup>3</sup>S. Khechinashvili University Hospital, Chemotherapy Department, Tbilisi, Georgia; <sup>4</sup>S. Khechinashvili University Hospital, Oncological Surgery, Tbilisi, Georgia

#### Purpose or Objective

This study evaluates heart dose for deep inspiration breath hold (DIBH) versus free breathing (FB) technique in patients with left-sided breast cancer. For left-sided breast cancer patients, the heart, major coronary arteries, and left lung tend to be co-irradiated due to their proximity to the anterior chest wall. Therefore, radiotherapy can result in severe complications, and many

epidemiological studies have shown cardiac morbidity and mortality as major complications of left-sided breast/chest wall irradiation

#### Material and Methods

In Academician F. Todua medical center, Research Institute of Clinical Medicine from October 2017 88 patients under 55 underwent radiation therapy to evaluate LAD and heart doses using DIBH (Deep Inspiration Breath-Hold) technique and FB (Free Breathing). Patients were divided in 3 groups: only breast, with regional LNs and with IM chain.

#### Results

##### Target Volume Coverage

The target coverage was  $97.0 \pm 1.5\%$  and  $96.6 \pm 1.2\%$  (for V95) for the FB and DIBH plans, respectively. Other parameters HI and CI were also comparable.

##### Ipsilateral Lung Doses

The ipsilateral lung volumes were analyzed using 4 different dose volume parameters, i.e., V5, V20, V30, and Dmean. While DIBH increases volume of ipsilateral lung about 2 times, we did not find parameters V5, V20, V30 and Dmean appropriate for evaluation, although according to statistical parameters there was slight improvement in DIBH plans comparing with FB plans, but this was not considered comparable.

##### Heart Doses

It was observed, that V25 for the heart, one of the most useful parameter for heart dose evaluation, was almost near to zero in DIBH plans. Our statistical analysis showed that there was a significant reduction in dose to the heart in the DIBH plans for all other parameters too. Table 1 shows the heart dose observed from the FB and DIBH plans.

**LAD Doses** It is known, that the doses received by the LAD are directly proportional to the risk of development of radiation-induced ischemic heart disease. We evaluated LAD doses in the FB and DIBH plans with 4 different dose volume parameters (V5, V10, V25, and Dmean). Table 2 shows the LAD dose observed from the FB and DIBH plans. Very few studies in the literature dealt with doses to the LAD and no standard protocols for the estimation of LAD doses and tolerances have been defined, so we present our statistical data just for comparison in dose difference, which is quite large in the value. For the first group (only breast or chest) the dose is almost negligible in DIBH plans, while for FB plans we have very high doses for all statistical parameters. Furthermore, in the FB plans, there was lot of fluctuation in doses to the LAD due to respiratory motion, which could be avoided in the DIBH plans.

Table 2: LAD Dose parameters for DIBH and FB plans

#### Conclusion

DIBH considerably reduced radiation doses to the heart, lung, and LAD artery without compromising target coverage. For our study patients, the probability of a major coronary event within 10 years will be significantly reduced.

**EP-1308** positional analysis of a personalized breast immobilization technique for whole breast irradiation T. Chen<sup>2</sup>, M. Chung<sup>3</sup>, D. Tien<sup>3</sup>, R. Wang<sup>1</sup>, J. Chiou<sup>1,4</sup>, T. Kuo-Hsiung<sup>3</sup>, L. Long-Sheng<sup>1,5</sup>

Taipei, Taiwan ; <sup>2</sup>Taipei Medical University, School of Biomedical Engineering- College of Biomedical Engineering, Taipei, Taiwan ; <sup>3</sup>National Taipei University of Technology, Department of Electrical Engineering, Taipei, Taiwan ; <sup>4</sup>Taipei Medical University, Department of Radiology- School of Medicine- College of Medicine, Taipei, Taiwan ; <sup>5</sup>Taipei Medical University, Graduate Institute of Biomedical Materials and Tissue Engineering- College of Biomedical Engineering, Taipei, Taiwan

#### Purpose or Objective

Breast-conserving surgery followed by whole breast irradiation (WBI) is the standard treatment for patients with early-stage breast cancers. However, radiation dose to the heart and to the left anterior descending artery (LAD) during WBI is a risk factor of radiation-induced heart disease (RIHD). We developed PERSBRA (PERsonalized BReAst holder) technique to improve cardiac dosimetric profile during left sided WBI. PERSBRA involves a 3D-printed thermoplastic holder that adjusts breast position close to that could be achieved at the prone position. Previously we have reported a significant heart and lung dosimetric profile improvement with this technique. Here we further analyzed interfractional positional stability of the left breast.

#### Material and Methods

Fifteen participants with left-side early stage breast cancer were enrolled in our study. Lead markers were placed on participant's left side, right side and anterior side. Three sets of CT simulation images were acquired in treatment positions (set 1: no PERSBRA; set 2: with PERSBRA; set 3: with PERSBRA and was acquired at 6th day after set 2). The difference of markers' positions between the set 2 CT scans and the set 3 CT scans was recorded to evaluate the changes of breast position. The shape and volume changes were also evaluated from the contours on the set 2 CT scans and the set 3 CT scans. Target volumes and normal organs on all 3 sets were contoured by one radiation oncologist, and treatment plans were calculated with Pinnacle.

#### Results

With this device, the mean dose of heart and LAD in tangential fields was decreased by 28% ( $p < 0.01$ ) and 19% ( $p < 0.05$ ) respectively. The average errors of breast position with PERSBRA were  $0.23 \pm 0.14$ ,  $0.54 \pm 0.15$  and  $0.67 \pm 0.16$  cm in left-right (LR), craniocaudal (CC), and anteroposterior (AP) directions, respectively. The breast shape and volume difference between the set 2 CT and the set 3 CT was less than 1%. When applying set 2 CT-calculated treatment plans on set 3 CT, the PTV coverage ( $V_{95\%}$ ) was  $95.1 \pm 2.7\%$ , and  $D_{max}$  was  $109.4 \pm 0.5\%$ .

#### Conclusion

The radiation dose to the heart during left-sided WBI is a significant issue for early-stage breast cancer patients. Our analysis show that PERSBRA has good interfractional positional stability for breast immobilization and therefore supports its potential as a new option for cardiac sparing.

**EP-1309** Are OAR dose constraints for radical 3DCRT breast plans achievable? A one-year retrospective review.

S. McCauley<sup>1</sup>, B. O'Connell<sup>2</sup>, C. Lyons<sup>3</sup>, R. Evans<sup>3</sup>  
<sup>1</sup>Northern Ireland Cancer Centre, Clinical Oncology, Belfast, United Kingdom ; <sup>2</sup>North West Cancer Centre, Physics, Derry, United Kingdom ; <sup>3</sup>North West Cancer Centre, Clinical Oncology, Derry, United Kingdom

#### Purpose or Objective

Within our centre, a number of 3DCRT (3D Conformal Radiotherapy) breast cancer plans were exceeding mandatory dose constraints to achieve optimal 95% PTV (planning target volume) breast coverage. We performed a one-year retrospective review to ascertain our rate of non-conformity as well as identifying which treatment

plans and which OAR (organ at risk) dose constraints were most at risk of compromise.

#### Material and Methods

With the ARIA System we identified all patients who had radical 3DCRT for breast cancer from March 2017 to March 2018. All plans were peer reviewed, each with their respective PTV and OAR doses and volumes documented. The standards set were by Trust guidelines derived from the RTOG, ESTRO and RCR consensus target volume delineation for breast cancer.

#### Results

A total of 228 3DCRT breast treatments were planned. 88 (38.6%) plans were non-conformal, with 165 OAR dose constraint occurrences.

All 26 (100%) breast plans that included the SCF (supraclavicular fossa) (Breast +SCF +/-Boost) breached OAR dose constraints: 100% exceeded optimal V18Gy dose constraints whilst 80.8% exceeded mandatory V18Gy dose constraints. The mean ipsilateral lung dose of these 26 Breast +SCF plans was 8.76Gy, exceeding mean dose constraint set at <7.5Gy; and the mean ipsilateral V18Gy volume was 19% (mandatory dose constraint <15%). However five of the Breast +SCF +/-Boost plans that did not exceed mandatory OAR dose constraints also did not achieve optimal PTV coverage either (mean PTV95 breast: 92.1% coverage).

Treatment plans that included a boost (Breast + Boost) also had higher rates of OAR non-conformity. Right Breast +Boost: 47.3% compared to 20% of right Breast only plans; Left Breast +Boost: 40% compared with 21.6% of left Breast only plans.

Ipsilateral lung was the most non-conformal OAR dose constraint, with V18Gy exceeding tolerances in 33.3% of 3DCRT plans. The mean lung dose exceeded tolerances in 24.9% of 3DCRT plans.

Site	Left Breast			Right Breast			Total Exceeded (%)
	L Only	L +Boost	L-SCF +/- Boost	R Only	R +Boost	R-SCF +/- Boost	
Total	83	25	8	75	19	18	228
Lung Mean Dose Gy	6	6	6	3	4	16	41 (24.9)
Lung V18 Optimal %	17	9	2	15	9	3	55 (33.3)
Lung V18 Mandatory %	1	-	6	-	-	15	22 (13)
% Exceeding lung constraints	21.6%	40%	100%	20%	47.3%	100%	
Optimal PTV Breast 95% not met	-	-	3 (1-M)	-	-	5 (2-M)	
Optimal PTV SCF 90% not met	-	-	4 (2-M)	-	-	4 (4-M)	
Heart Mean Dose	3	4	1	-	-	-	8 (4.8)
Heart V13Gy %	12	8	7	1	-	-	28 (17)
Contralateral Lung	-	-	3	-	-	1	4 (2.4)
Contralateral Breast	1	-	1	-	2	3	7 (4.2)
Total all OAR exceeded (%)	40 (24)	27 (16)	26 (15)	19 (11.5)	15 (9)	38 (22.4)	165/165 (100)

#### Conclusion

Indubitably, the more radiotherapy that is delivered, the greater the risk of OAR dose constraint non-conformity. Concerning radical 3DCRT breast treatment plans, those necessitating an SCF field or boost will exceed constraints, despite greater allowances provided to achieve optimal PTV coverage. Thus are we asking too much of radiotherapy planning in achieving optimal PTV coverage, and should we consider planning margins to be tighter or relax dose constraints to OAR. On reflection, no patient who exceeded mandatory OAR dose constraints, namely ipsilateral lung V18Gy and mean lung dose, have encountered any pulmonary toxicity to date (range 9 months to 3 weeks), however we do plan to introduce pulmonary toxicity on post radiotherapy follow up assessment systemic questioning. Furthermore, we plan to

implement DIBH (deep inspiration breath hold) techniques and formally assessed set up margins with the use of daily imaging to allow us to reduce the current 1cm PTV margin to SCF, and improve dose constraint conformity.

#### EP-1310 Toxicity evaluation of a hypofractionated WBRT with SIB for breast cancer using TomoDirect

<sup>1</sup>European Institute of Oncology, Division of Radiation Oncology, Milan, Italy; <sup>2</sup>European Institute of Oncology, Department of Epidemiology and Statistics, Milan, Italy; <sup>3</sup>European Institute of Oncology, Unit of Medical Physics, Milan, Italy; <sup>4</sup>European Institute of Oncology, Division of Breast Surgery, Milan, Italy; <sup>5</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy; <sup>6</sup>European Institute of Oncology, Scientific Directorate, Milan, Italy

#### Purpose or Objective

To report tolerance of whole-breast radiotherapy (WBRT) with a simultaneous integrated boost (SIB) to the tumor bed (TB) using hypofractionated schedule delivered with intensity-modulated radiotherapy (IMRT) by means of Tomotherapy (Accuray Inc., Sunnyvale, CA) in Direct modality.

#### Material and Methods

A prospective cohort of patients with early breast cancer, operated on with breast conserving surgery, received 15-fraction schedule consisting of 40.05 Gy (2.67 Gy/fraction) to the whole breast and 48 Gy SIB (3.2 Gy/fraction) to the TB over the period 2013-2017.

The purpose of this analysis was to evaluate acute and intermediate toxicity assessed at the end of radiotherapy (RT) and within 6 months after RT, according to RTOG scale, and at 12 months using the LENT-SOMA scale, alongside cosmesis based on the Harvard criteria.

McNemar's test was used to compare any grade of toxicity, while univariate and multivariate analysis were used to examine predictive factors for severe toxicity at any time.

#### Results

Two hundred and eighty-three patients were analyzed. Acute toxicity was recorded at the end of RT for all patients and in 183 women within the next 6 months: Grade 2 toxicity occurred in 34% and 25% of the patients, respectively (Table 1). No Grade>2 was reported. A significant reduction of any grade toxicity was observed between the end of RT and the first assessment within the 6-month period (median time 3 months). At univariate analysis, age <40 years, breast volume >1000 cm<sup>3</sup> and D<sub>max</sub>≤115% of prescription dose were predictive factors of severe (Grade≥2) acute toxicity. At multivariate analysis, only age and breast volume were confirmed as predictive factors, with Relative Risks (95% Confidence Intervals): 2.02 (1.13-3.63) and 1.84 (1.26-2.67), respectively.

Twelve-month toxicity was available in 113 patients, who showed Grade 0-1 toxicity in 54% of cases (Table 2). Cosmetic evaluation, performed in 102 pts, revealed good-excellent outcome in 86% of the population.

**Table 1:** Acute skin toxicity according to the RTOG scale at two time points.

	3	2 (2)

### Conclusion

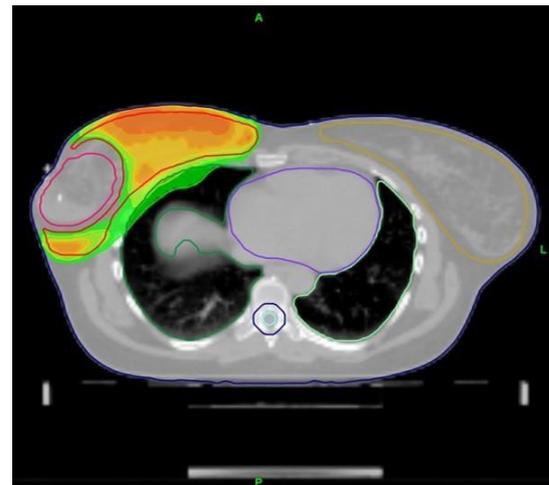

Hypofractionated WBRT with SIB delivered with TomoDirect, is a safe and well-tolerated treatment both in terms of early and intermediate-term toxicity. Predictive factors of severe toxicity might be considered during treatment planning in order to further reduce side effects.

**EP-1311 POLO concept: salvage whole breast radiotherapy with Tomotherapy after intraoperative radiotherapy**

M.A. Gerardi<sup>1</sup>, M.C. Leonardi<sup>1</sup>, E. MIGLIETTA<sup>1</sup>, G. Riva<sup>1,2</sup>, A. Morra<sup>1</sup>, S. Dicuonzo<sup>1</sup>, A. Camarda<sup>1,2</sup>, A. Casbarra<sup>1,2</sup>, C. Fodor<sup>1</sup>, R. Orecchia<sup>3</sup>, B.A. Jereczek-Fossa<sup>1,2</sup>  
<sup>1</sup>European Institute of Oncology, Division of Radiation Oncology, Milan, Italy ; <sup>2</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy ; <sup>3</sup>European Institute of Oncology, Scientific Directorate, Milan, Italy

### Purpose or Objective

To evaluate the dosimetric feasibility of salvage hypofractionated whole breast radiotherapy (WBRT) in patients who received intraoperative radiotherapy with electrons (IOERT) for breast cancer (BC). This approach, called POLO (Partially Omitted LObe), excludes the previous IOERT area from receiving the full prescription dose (Figure).

**Figure:** Transversal computed tomography view with the contouring of PTV, OARs and IOERT area and plan dose distribution.

### Material and Methods

Inclusion criteria were BC patients treated with IOERT full-dose (21 Gy at 90% isodose) who received WBRT as salvage treatment following either a local recurrence treated with repeat BCS (provided that IOERT area was left in place) or unfavorable features of the primary tumor on the final histologic report. All patients received hypofractionated schedules. The previous IOERT area was underdosed using the intensity-modulated radiotherapy (IMRT) by means of Helical Tomotherapy (Tomotherapy Inc., Madison, WI). The 5%, 25%, 50%, and 95% of IOERT volumes were planned to receive less than 20 Gy, 15 Gy, 10 Gy, and 5 Gy, respectively. All patients gave written informed consent.

### Results

From 2012 to 2014, 12 patients were treated with the POLO approach. Nine patients with local recurrence received 45 Gy in 20 fractions (2.25 Gy/fraction) in 4 weeks to the whole breast. Simultaneous integrated boost of 2.5 Gy in 20 fractions (50 Gy total dose) was delivered in 6/9 patients, whose local recurrence occurred distant from the IOERT area. Three patients, turned out to be not ideal candidates for IOERT as the sole treatment for the primary tumor, received WBRT up to 32 Gy in 8 fractions (n=2) and WBRT + irradiation of the infra/supraclavicular nodal region up to 40.05 Gy in 15 fractions (n=1). Median age was 65 years (range 47-76), 5 patients had left- and 7 right-sided BC, all but one had invasive carcinoma. Median tumor diameter was 0.85 cm. Regarding the IOERT volume, the median dosimetric parameters were D<sub>5%</sub>=20.8 Gy, D<sub>25%</sub>=14.3 Gy, D<sub>50%</sub>=9.7 Gy, D<sub>95%</sub>=4.3 Gy. The median values of V<sub>95%</sub>, V<sub>90%</sub>, D<sub>mean</sub> and D<sub>max</sub> of planning target volume (PTV) were 89%, 95%, 100% and 110% of prescribed dose, respectively; regarding boost, V<sub>95%</sub>, V<sub>90%</sub>, D<sub>mean</sub>, and

D<sub>max</sub> were 96%, 98%, 100% and 104% of the prescribed dose, respectively. All organs at risk (OARs) constraints were fulfilled (Table). No toxicity >G2 was reported either at the end of radiotherapy or at the 12-months examination. With a median follow-up time of 45 months (interquartile range 17-67), overall survival, disease-free survival and local control are 100%.

**Table:** Dose/volume constraints and planning values.

OARs	Constraints	Planning values [Gy]
Heart	D <sub>15%</sub> < 20 Gy	7.55 (4.7-17)
	D <sub>20%</sub> < 15 Gy	6.4 (4.4-14.3)
Ipsilateral Lung	D <sub>15%</sub> < 35 Gy	26.9 (19.5-32.2)
	D <sub>20%</sub> < 30 Gy	24.1 (17.6-29.3)
	D <sub>35%</sub> < 20 Gy	17.3 (11.9-20.3)
Contralateral Lung	D <sub>50%</sub> < 15 Gy	13.2 (7.7-14.5)
	D <sub>20%</sub> < 15 Gy	7.3 (4.0-13.1)
	D <sub>35%</sub> < 12 Gy	5.7 (3.0-11.1)
Contralateral Breast	D <sub>50%</sub> < 10 Gy	4.6 (3.0-10)
	D <sub>15%</sub> < 20 Gy	5.3 (3.4-7.0)
	D <sub>20%</sub> < 10 Gy	4.6 (3.2-6.6)
	D <sub>35%</sub> < 7 Gy	4.1 (2.8-5.7)
	D <sub>50%</sub> < 5 Gy	3.3 (2.6-4.8)

### Conclusion

The POLO approach is safe and technically feasible and resulted in high dose conformity of the target with a significant reduction of radiation dose delivered to the previous IORT area. A larger population and a longer follow-up are needed to better evaluate the clinical outcome.

<sup>11</sup>UMC Utrecht, Imaging, Utrecht, The Netherlands

### Purpose or Objective

The goal of this study was to evaluate recently developed expert consensus contouring guidelines in delineating primary breast cancers using MRI in a preoperative setting.

### Material and Methods

MRI-based contouring guidelines for target definition of primary breast tumors on dynamic contrast enhanced (DCE) MRI in supine position were developed by experienced breast radiation oncologists from the International MR-Linac Consortium and a dedicated breast radiologist. Using these guidelines, the gross tumor volume (GTV) was delineated by 6 breast radiation oncologists on 10 pre-treatment DCE-MRI scans from 10 cT1N0 breast cancer patients treated with single-dose preoperative partial breast irradiation (ABLATIVE trial, ClinicalTrials.gov: NCT02316561) in a first contouring

session. Clinical target volumes (CTV) were created by expanding the GTV by 2cm, while excluding skin and chest wall. After the first contouring session, the MRI-based guidelines were adapted, since the observers noted that the distinction between the contrast-enhanced tumor and surrounding vessels and glandular breast tissue was difficult in several cases. Therefore, the final guidelines recommended delineation on the DCE-MRI obtained after approximately 60-120 seconds vs. 300 seconds in the first guidelines. Guidelines did not change on using a diagnostic DCE-MRI (in prone position) to verify tumor spiculae and on including the fiducial marker in the GTV. After a 6-month interval, 5 breast radiation oncologists re-delineated 6 of the 10 cases using the updated guidelines. Three radiation oncologists were common to both meetings. We assessed the mean delineated volumes and the interobserver variation (IOV) during the two sessions. IOV was based on the generalized conformity index (CI). The CI was calculated using the following equation:  $CI = (\sum \text{pairs } ij |Ai \cap Aj|) / (\sum \text{pairs } ij |Ai \cup Aj|)$ .

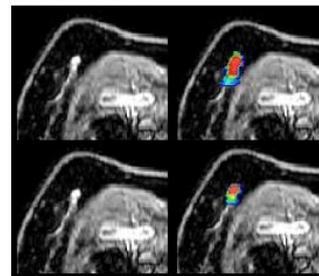

### Results

Following the first contouring session, the conformity indices of GTV varied between 0.28 and 0.77, and of CTV between 0.77 and 0.94 (Table 1). Following the second session, the conformity indices of GTV varied between 0.34 and 0.77, and of CTV between 0.78 and 0.94 (Table 1). The largest variation was observed in patients with increased glandular breast tissue enhancement, with a tumor close to large vessels or with large tumor spiculae (Figure 1).

**Table 1.** GTV and CTV conformity index per patient and moment of delineation. A CI of 1 indicates no interobserver variation, a lower CI indicates higher interobserver variation. \* = Was not delineated during this session. † = based on five observers, one observer delineated another structure than the tumor, this was considered an outlier and removed from the analysis.

Mean GTV volume (in ml)		Conformity index GTV		Mean CTV volume (in ml)		Conformity index CTV

**Figure 1.** Coronal view of delineations of patient 3 during the first (upper row) and second (lower row) session, a blood vessel can be observed caudal of the tumor. Red= delineation by all observers, blue= delineation by 1 observer.

### Conclusion

Using expert-developed MRI-based contouring guidelines resulted in a relatively high interobserver variation in GTV and a low interobserver variation in CTV. The high interobserver variation in GTV can largely be attributed to small breast tumor volumes ( $\leq 1.5$  ml), and artifacts caused by markers and contrast-enhancement of surrounding vessels and breast tissue. In the context of 20mm expansion margins, small discrepancies in GTV contouring do not translate into significant variations in CTV.

### EP-1313 Adjuvant radiotherapy for primary squamous cell carcinoma of the breast

M. Ogita<sup>1</sup>, K. Shiraishi<sup>2</sup>, T. Chang<sup>3</sup>, J. Kawamori<sup>4</sup>, W. Takahashi<sup>1</sup>, T. Kiritoshi<sup>1</sup>, H. Yamashita<sup>1</sup>, K. Nakagawa<sup>1</sup>

<sup>1</sup>The University of Tokyo Hospital, Radiology, Tokyo,

Japan ; <sup>2</sup>Teikyo University Hospital, Radiology, Tokyo, Japan ; <sup>3</sup>National Institute of Radiological Sciences, Research Center Hospital for Charged Particle Therapy, Chiba, Japan ; <sup>4</sup>St. Luke's International Hospital, Radiation Oncology, Tokyo, Japan

### Purpose or Objective

Primary squamous cell carcinoma (SqCC) of the breast is a rare disease comprising only 0.1% of all breast cancer. Because of its rarity, the standard therapy for the breast SqCC has not been established, and the role of adjuvant radiotherapy is unclear.

### Material and Methods

We conducted a multicenter retrospective cohort study in four hospitals. Patients diagnosed with primary breast SqCC who received adjuvant radiotherapy as part of primary definitive treatment were included. Patients received radiotherapy for recurrence or palliative setting were excluded. Clinical outcome and the types of recurrence were examined. Overall survival (OS) and progression-free survival (PFS) were calculated using the Kaplan-Meier method.

### Results

From January 2002 to December 2017, seventeen breast SqCC patients who received adjuvant radiotherapy were included in the analysis. Median follow-up time was 33 months (range; 9-157). Median age was 54 years (range; 29-83). Two (12%), twelve (71%) and three (18%) patients had clinical stage I, II and III disease, respectively. Eleven (65%) patients underwent lumpectomy and subsequently had adjuvant radiotherapy to the conserved breast. Six (35%) underwent mastectomy and had post-mastectomy radiotherapy; five patients to the chest wall and regional lymph nodes and one patient to the chest wall only. Twelve (71%) had neo/adjuvant chemotherapy. Three (18%), ten (59%) and four (24%) patients had pathological stage I, II and III disease, respectively. Five (29%) had ER(+), two (12%) had PR(+) whereas none had HER2 overexpression. Twelve patients had triple negative breast cancer. Four patients (24%), 3 clinical stage II and 1 clinical stage III, had disease recurrence with a median progression-free interval of 292 days. The first site of recurrence was locoregional in 3 and concurrent local and distant metastasis in one. Two local recurrences occurred within the irradiated field. Five patients (37%) died, and four were due to breast cancer. Three-year OS rate was 69%, and three-year PFS rate was 73%.

### Conclusion

Breast SqCC carries a high risk of recurrence and worse prognosis. Multidisciplinary treatment may be required to prevent a recurrence, and further research is needed to clarify the best treatment approach.

### EP-1314 Cardiac structures doses and correlation with mean heart dose in breast radiotherapy treatment

M. Vázquez<sup>1</sup>, A. Giraldo<sup>1</sup>, S. Micó<sup>1</sup>, M. Altabas<sup>1</sup>, D. Sánchez<sup>2</sup>, J. Giralt<sup>1</sup>, V.M. Reyes Lopez<sup>1</sup>

<sup>1</sup>Hospital Universitario Vall d'Hebron, Radiation Oncology, Barcelona, Spain ; <sup>2</sup>Hospital Universitario Vall d'Hebron, Physics Department, Barcelona, Spain

### Purpose or Objective

Several authors have related the late cardiac toxicity in breast cancer (BC) patients to dosimetric parameters such as mean heart dose (MHD), and dose to left anterior descending artery (LAD) and the left ventricle (LV). Due to the difficulty in contouring these structures, we evaluated whether there was a significant correlation between the MHD and different parameters over LAD and LV.

### Material and Methods

We analysed female patients with BC treated with adjuvant Radiotherapy (RT) from January 2010 to December 2010 in our institution. Patients with previous thoracic RT were excluded. For analysis, the sample was

divided into two groups according to tumour laterality. All patients were treated on linear accelerator with 3-dimensional conformal RT technique, following our protocols: whole breast to a total dose of 50 Gy in 2 Gy fractions or 40.05-42.72 Gy in 15-16 fractions and a tumour bed boost of 16 Gy in 8 fractions, if indicated.

The heart, LAD, and LV were contoured retrospectively, according to RTOG guidelines. For each patient, the MHD and dose-distribution parameters of the LAD and LV were extracted from our treatment planning system. Differences were analyzed with two-tailed two-sample unpaired Mann-Whitney U-test ( $\alpha=0.05$ ).

### Results

The study cohort consisted of 117 patients (68 left(L)-sided and 49 right(R)-sided breast cancers) who had been treated in our institution. For analysis, the sample was divided into two groups according to tumour laterality. 89% were breast conserving patients. 33 patients received radiation on their axillary and/or supraclavicular nodes. Table 1 details clinical and dosimetric characteristics of the population according to the fractionation schedule.

For the entire cohort of L-sided patients, the MHD was higher compared to R-sided patients: 5.75 Gy (3.52; 7.4) and 1.25 Gy (1.07;1.5),  $p < 0.005$ , respectively. The mean dose to LAD was 26.4 Gy (9.6; 34.06) for L breast sided patients and 0.95 Gy (0.79;1.13) for R breast sided patients,  $p < 0.005$ . The mean dose to the LV was 9.84 Gy (5.88;12.53) for L-sided patients compared to 0.72 Gy (0.64;0.89) for R-sided patients,  $p < 0.005$ .

For L-sided patients a significant correlation was found between the MHD and the mean dose to the LAD, as shown in Fig.1. For every 1 Gy increase in MHD, mean LAD dose increased by 4.26 Gy. The MHD with the mean LV dose was also correlated (fig.1). A correlation between the dose to the LV and LAD was also demonstrated so that for every 1 Gy increase in mean dose to LV, mean LAD dose increased by 2.4 Gy (95% CI 2.08; 2.76)  $p < 0.001$ . In addition, a correlation between these dosimetric parameters was demonstrated in R-sided patients (Fig2).

	Left breast cancer n=68	Right Breast cancer n=49	p value

Values of qualitative variables expressed in percentages and relative counts; values of quantitative variables expressed in median (25th percentile, 75th percentile). CFRT= conventional fractionated radiation therapy, HFRT= hypofractionated radiation therapy. Y=yes. N=no. LV= left ventricle. LAD= left anterior descending artery.

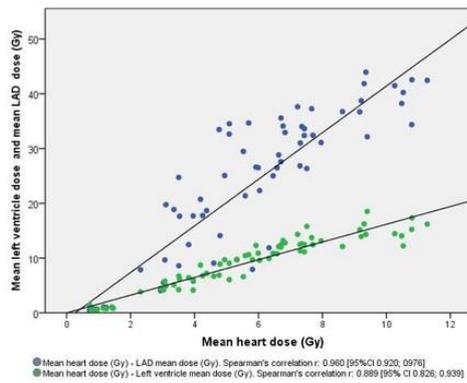

Figure 1. Correlation between MHD (Gy) and mean left ventricle and LAD doses (Gy) in left breast tumour patients.

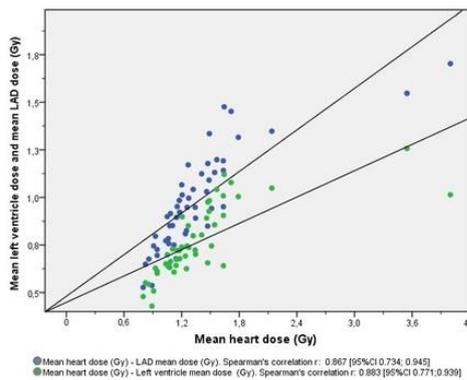

Figure 2. Correlation between MHD (Gy) and mean left ventricle and LAD doses (Gy) in right breast tumour patients.

## Conclusion

A strong correlation between the dose to the heart, LV and LAD was found. This correlation could allow us estimating the dose in LAD and LV through the MHD, being possible to avoid the contouring of the LAD and LV. We are currently working on the validation of a prediction model for acute/ischemic cardiac events in these patients.

## EP-1315 The FAST approach as adjuvant whole breast irradiation for frail breast cancer patients

## Purpose or Objective

To evaluate the outcome in terms of toxicity, local control and survival of elderly breast cancer (BC) patients treated with adjuvant once-weekly hypofractionated radiotherapy (RT).

## Material and Methods

From 7/2011 to 4/2018, 271 BC patients were given received 5.7 Gy once a week for 5 weeks to the whole breast, without the boost to the tumor bed, after breast-conserving surgery. Data were extracted from a dedicated databank for research projects called "Adjuvant radiation treatments with intensity-modulated radiotherapy and/or hypofractionated schedules for breast cancer" which was notified to the IEO Ethical Committee. Patients were

eligible if affected by T1-T3 invasive BC, with no or limited axillary involvement. The scheme was offered to elderly women (age threshold of 65 years) and to those with commuting difficulties or disabling diseases.

## Results

Median age was 76 (45.5-86.4) years. Median follow-up was 24.6 (6.2-65.7) months. Most of BC were T1 (77%), while the remaining were T2 (22.2%), T3 (0.4%). Axillary status was negative in 68.3%, minimally involved in 14.4% (pN1) and not assessed in 17.3% of the cases (Nx). Most of the women received hormonal therapy (84%), while 10.7% received chemotherapy. The schedule was delivered either with three-dimensional conformal RT (n=133) or with intensity-modulated RT (n=138). No statistically significant difference was observed between the two techniques in terms of toxicity and efficacy. For 271 patients, maximum acute toxicity at the end of RT was as follows: grade (G) 1, 2 and 3 erythema in 63%, 7% and 0.4% of patients, respectively. G2 edema was detected in 10% of patients. Desquamation occurred in 4.4% as G1 and 1.5% as G2 of cases. At median 2-year follow up, LENT-SOMA assessment was available for 137 patients. Fibrosis (G1 and G2 in 46.7% and 9.5%, respectively) and skin changes (G1 and G2 hyper- or hypopigmentation in 29.2% and 2.2% respectively, G1 and G2 telangiectasia in 3 patients) were observed. A minority complained pain of G1 (n=26) and G2 (n=2) intensity. Two-year oncologic outcome was assessed for 257 patients. At the last follow-up examination, 244/257 patients were alive and free from any event. There was a total of 5 (1,9%) isolated locoregional recurrences: 4 involved the breast and 1 the axillary lymph nodes. Three women experienced a second cancer in other sites. Two died for other reasons (at 3 years, disease-free survival and overall survival were 100% and 99%) Predictive factors for toxicity were breast volume >500 cm<sup>3</sup> for acute toxicity, while none was correlated with severe late toxicity.

## Conclusion

Toxicity was mild and acceptable with high patients' satisfaction. Local control was acceptable, none died of BC and overall survival was 99% at 3 years.

## EP-1316 Radiotherapy in elderly breast cancer patients with hormone therapy: A population-based study

D. Medenwald<sup>1</sup>, A. Glowka<sup>1</sup>, D. Vordermark<sup>1</sup>, K. Medenwald<sup>1</sup>

<sup>1</sup>Martin Luther University Halle-Wittenberg, <sup>1</sup>Department of Radiation Oncology, Halle/Saale, Germany

## Purpose or Objective

For breast cancer patients above an age of 70 with a stage of pT1 and N0 receiving hormone therapy the value of additional radiotherapy has been challenged. The objective of this study is to analyze treatment patterns and outcomes of elderly female breast cancer patients above an age of 70 years in the general population.

## Material and Methods

This data set incorporates data on incident cancer cases and contains information on stage, histological features, and received treatment and survival outcomes. For this study, we excluded patients where the diagnosis of breast cancer was only available from autopsy/death certificates. Additionally, we only considered data from states with a high coverage of newly diagnosed cases (>70%, East Germany including Berlin, Bavaria, Rhineland-Palatine, Schleswig-Holstein). For subsequent analyses, we considered female breast cancer cases with recorded operative and hormone treatment, and histological confirmation of the cancer diagnosis.

For survival analyses, we used Cox proportional hazard models where we computed hazard ratios (HR) with respective 95 confidence intervals (CI). In order to respect

competing risks we used Fine-Gray models to assess tumor-specific survival. Models were adjusted for age and grading.

### Results

The application of radiotherapy in patients with hormone therapy increased from 71.4% in years before 2005 to 83.3% thereafter. In women aged 70 to 74 years 87.70 received radiotherapy. The figure decreased to 84.4% for patients between 75 and 79 years, and 57.6% in patients with 80 years or older. Considering all patients, only 2.6% were recorded to have died from breast cancer, while of all deaths breast cancer was the leading cause in 17.1%. Median survival was 51 months (95% CI: 45-55 months) for the radiotherapy group and 42 month for the hormone therapy (95% CI: 34-50 months)

Patients treated with additional radiotherapy had a better survival prospect when compared to women who received only hormone therapy (HR= 0.62, 95% CI: 0.52-0.73). Survival analyses revealed a benefit for patients with additional radiotherapy when compared patients with only hormone therapy (HR=0.41, 95% CI: 0.2-0.81) in terms of breast cancer-specific survival. Likewise, non-breast cancer-specific survival was more favorable in the radiotherapy group (HR=0.61, 95% CI: 0.44-0.86).

### Conclusion

Radiotherapy is widely applied in elderly breast cancer patients above an age of 70. However, due to the few deaths from breast cancer the benefit in terms cancer-specific survival remains unclear when population-based data are considered.

### EP-1317 Hyperthermic chest wall re-irradiation in recurrent breast cancer: a prospective observational study

C. De Colle<sup>1</sup>, N. Weidner<sup>1</sup>, V. Heinrich<sup>1</sup>, S. Brucker<sup>2</sup>, M. Hahn<sup>2</sup>, K. MacMillan<sup>1</sup>, U. Lamprecht<sup>1</sup>, S. Gaupp<sup>1</sup>, O. Voigt<sup>1</sup>, D. Zips<sup>1,3</sup>

<sup>1</sup>Eberhard Karls University Tübingen, Radiooncology, Tübingen, Germany ; <sup>2</sup>Eberhard Karls University Tübingen, Department of women's health, Tübingen, Germany ; <sup>3</sup>German Cancer Research Center DKFZ and German Cancer Consortium DKTK partner site Tuebingen, Radiooncology, Tuebingen, Germany

### Purpose or Objective

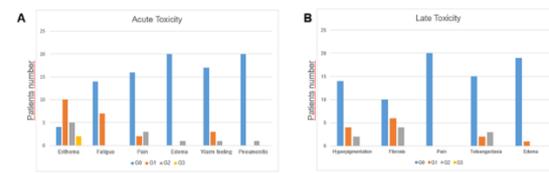

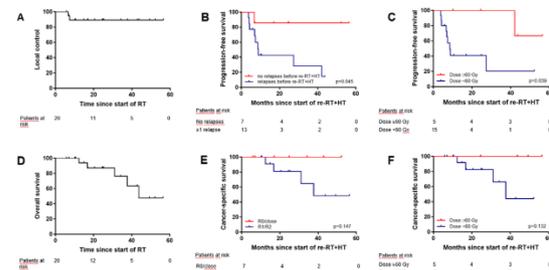

Surgical resection is the standard therapy for recurrent breast cancer (RBC). To increase local control (LC), especially after microscopically (R1) or macroscopically (R2) positive or close resection margins, re-irradiation is indicated. In these cases, radiotherapy (RT) must be carefully evaluated because re-RT might cause relevant toxicities. RT combined with hyperthermia (HT) as adjuvant treatment for RBC has been shown to improve LC compared to RT alone through a radiosensitizing effect. Despite the fact of level I evidence for re-RT+ HT, which was generated in the 1990s, it remains important to prospectively investigate this treatment because diagnosis and treatment of primary and RBC have continuously improved over the last 20 years.

### Material and Methods

Within the prospective registry HT03, patients with resected RBC (R1, R2 or close margins) and previously irradiated were included. Patients were treated with involved field RT to the chest wall limited to the region of recurrence with 50-50.4 Gy in 25-28 fractions followed by a boost up to a total dose of 60-60.4 Gy to the R1/R2 region. Concurrent superficial HT was performed twice per week with a therapeutic temperature of 40° - 42°C applied for 75 minutes. Primary endpoint was LC. In addition, acute and late toxicity according to CTCAE and RTOG criteria, overall survival (OS), cancer-specific survival (CSS) and progression-free survival (PFS) were evaluated.

### Results

Data from 20 patients and a total of 21 RBC were analyzed. Patients were treated with a median re-RT dose of 50.4 Gy (range, 39.6-60.4 Gy) and a median of 11 HT fractions (range, 2-23). Median time between RT and re-RT+HT was 66.2 months (range, 9.2-436.4). Re-RT+HT was well tolerated. Three patients experienced grade (G) 3 acute skin toxicity. No ≥ G3 late toxicity was observed. With a median follow up of 24.7 months (range, 5.8-56.5) two local relapses occurred. Ten patients experienced regional and/or distant disease progression. Five patients died, four of them from breast cancer. PFS was found to be favorable in patients treated with re-RT+HT for the first recurrence and with total doses of 60 Gy. A trend towards better CSS was found in patients with negative or close resection margins and after doses of 60 Gy.

### Conclusion

Re-RT+HT for RBC is well tolerated and provides good LC. Re-RT+HT seems to be more effective when applied at the time of the first relapse and after doses of at least 60 Gy. The registry will be continued for validation in a larger cohort and with longer follow up.

### EP-1318 Hypofractionated radiotherapy for breast cancer in elderly patients: 10 or 5 fractions?

E. Bonzano<sup>1</sup>, G. Polizzi<sup>1</sup>, M. Guenzi<sup>1</sup>, R. Corvò<sup>1</sup>  
<sup>1</sup>IRCCS Policlinico San Martino and University, Department of Radiation Oncology, Genoa, Italy

### Purpose or Objective

The aim of this study, was to compare 5 fractions (fx) one weekly hypofractionated Adjuvant Radiotherapy (RT) versus 10 fx four weekly hypofractionation in elderly patients (pts) affected by early breast cancer and to report clinical outcomes: skin toxicity profile, aesthetic result and treatment feasibility.

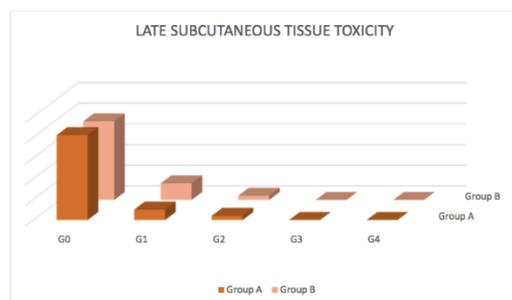

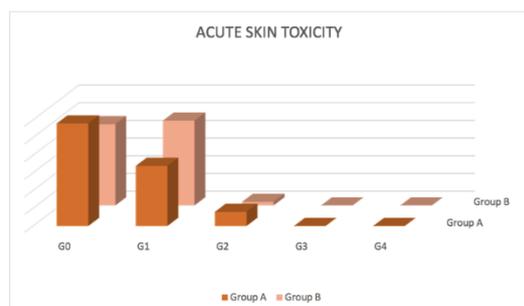

### Material and Methods

This retrospective study was conducted on 96 pts, aged over 70 years old (median age 79 y.o., range 72-95) with no severe comorbidities. From October 2016 to June 2017, pts underwent adjuvant radiotherapy, with two different hypofractionated schedules. The first group (groupA) underwent 28,5 Gray(Gy)/5fractions/1 fraction weekly plus/minus a 2.5 Gy Simultaneous Boost (SIB) on tumor bed in "high risk" cases, the second one (groupB) 35Gy/10 fractions/4 times a week with a concomitant boost of 3 or 4 Gy once a week, according to risk factors. Pts in both groups were pT1-2N0-1a, with different biologic patterns, laterality and size. Treatment was delivered in supine position, with tangential fields. Conventional 3DCRT constraints for lungs and heart were used; V20=0 for Left Anterior Descending Artery (LADCA) was translated to V12 for the one weekly hypofractionation and to V14 for the four weekly one, according to the radiobiological calculation. Acute skin toxicity and late subcutaneous

tissue toxicity were assessed respectively, at the end of RT and one year after treatment. The Radiation treatment tolerance was assessed using the acute and late radiation morbidity scoring criteria from the Radiation Therapy Oncology Group (RTOG) scale. Aesthetic result was evaluated according to the Harvard scale.

### Results

In groupA SIB was added in 22 pts(45%). In groupB a concomitant boost of 3 Gy was added in 31pts and a boost of 4Gy in the remaining 17pts. G3-G4 acute skin toxicity was not observed in both groups; G2 acute side-effects were significantly low: at the end of the treatment only 4 women in groupA and just one in groupB needed topic steroid therapy for G2 dermatitis, which ameliorated within 3 weeks after irradiation. 17 pts (groupA) and 24pts (groupB) showed G1 erythema. Concerning late subcutaneous tissue toxicity (12 months), fibrosis occurred in groupA as follow: G2 2 pts, G1 5pts, G0 41pts; furthermore 1 patient developed hyperpigmentation. As regard group B fibrosis G2 2 pts, G1 8 pts and G0 38pts, 2 patient showed a slight skin retraction. Aesthetic outcomes were from good to excellent in 94% and from fair to poor in 6% in groupA, and respectively 96% and 4% in groupB.

### Conclusion

Once weekly hypofractionated radiation therapy resulted comparable to ten fractions regimen without evidence of inferior treatment feasibility or higher adverse effects. Once weekly radiation therapy can be recommended as a safe and effective alternative for whole-breast adjuvant radiotherapy in elderly pts.

### EP-1319 Second primary lung cancer unlikely associated with irradiated breast cancer population in Taiwan

T.T. Ngo<sup>1</sup>, L. Chien<sup>2</sup>, L. Chen<sup>3</sup>, L. Lu<sup>4</sup>  
<sup>1</sup>Taipei Medical University, International PhD/Master Program in Medicine- College of Medicine, Taipei, Taiwan ; <sup>2</sup>Taipei Medical University, School of Health Care Administration- College of Management, Taipei, Taiwan ; <sup>3</sup>Taipei Medical University, Health and Clinical Data Research Center- College of Public Health, Taipei, Taiwan ; <sup>4</sup>Taipei Medical University, Graduate Institute of Biomedical Materials and Tissue Engineering- College of Biomedical Engineering, Taipei, Taiwan

### Purpose or Objective

Previous studies showed that second primary lung cancer (SPLC) is likely increased with the occurrence of ionizing radiation (RT) on BC patients (pts.). However, RT is not often used alone and SPLC is a rare event, therefore the risk of RT might be overestimated. To test the hypothesis that SPLC is associated with RT, we conduct this national population based, propensity score-matched (PSM) follow up study.

### Material and Methods

We reviewed all Taiwanese female, 20-80 years-old BC pts. in the databases of Taiwanese National Health Insurance and Taiwan Cancer Registry between 01 January 2002 to 31 December 2010. Exclusion criteria are: (1) missing or invalid demographic information; (2) had another cancer diagnosis before and six months post BC diagnosis date (index date, ID). To analysis the risk of RT alone, we excluded pts. (3) had received Cobalt 60 and other RT except linear accelerated RT; (4) had been treated with CT or died within a year after ID. To exclude patients who had uncompleted RT, we did not recruit pts. (5) had more than 1 fraction and less than 49 fractions of RT within one year after ID. We used PMS (1:2) to match pts. with RT (RT group) with those had no RT (non-RT group) to compare the incidence of SPLC later in both groups. The propensity scores for RT were formulated using 6 covariates: age, diagnostic year, social economic status (SES), residence, Charlson Comorbidity Index (CCI), and comorbidities. Standardize mean difference (SMD) and p-value (CI 95%) were used to compare the baseline characteristics of groups. End of follow up time is 31 December 2015 and subdistribution hazard ratio (sHR) was used in competing-risk regression models.

### Results

From 64758 BC recorded in the databases, 48996 pts. were excluded based on mentioned exclusion criteria. Among these 15762 eligible Taiwanese female primary BC pts., 4614 pts. had RT and 11148 pts. without RT. After matching, the differences between two group (age, diagnostic year, CCI and certain concurrent diseases) were reduced and the similarities were increased significantly. We revealed 29 SPLC in RT group (3539 pts., 29657 person-year follow up) and 57 SPLC in non-RT group (7078 pts., 56914 person-year follow up). Adjusted sHR was performed based on competing risk model adjusted for PMS covariates and we observed no difference between the two groups (p=0.949).

BC pts. who have lumpectomy are likely to have less radiation exposure to the lung than those have mastectomy. We divided RT group into two subgroups based on type of their surgery. Significant covariate differences were also observed at baseline. After matching, there were no statistical differences in the SPLC incidences between two groups (p=0.247).

### Conclusion

Our current results showed RT in the absence of CT does not increase the development of SPLC on Taiwanese female BC patients. We need further studies to identify specific agents using concurrent with RT is able to increase the risk of SPLC.

### EP-1320 Estimated survival benefit and cardiovascular risk due to radiotherapy for breast cancer in Chile

T. JP<sup>1</sup>, G. Martinez<sup>2</sup>, C. Sánchez<sup>3</sup>, R. Fernández<sup>2</sup>, L. Bravo<sup>4</sup>, M. Pinto<sup>4</sup>, E. Vinés<sup>1</sup>, T. Merino<sup>1</sup>  
<sup>1</sup>Pontificia Universidad Católica de Chile, Radiation Oncology, Santiago, Chile ; <sup>2</sup>Pontificia Universidad Católica de Chile, Cardiology, Santiago, Chile ; <sup>3</sup>Pontificia Universidad Católica de Chile, Medical Oncology, Santiago, Chile ; <sup>4</sup>Pontificia Universidad Católica de Chile, Oncology, Santiago, Chile

### Purpose or Objective

Improvements in oncologic treatments, including radiation therapy (RT), have decreased death due to breast cancer over the last decades. Up to 33% of deaths are attributed to cardiac causes in this treatment population, and mean heart dose (MHD) is associated with a relative increase in cardiovascular events (CVE) of 16% per Gray. The purpose of this study is to estimate potential survival benefit and cardiac risk of RT in a cohort of Chilean women with breast cancer.

### Material and Methods

Women with breast cancer who received adjuvant 3-D RT with curative intent between May 2017 and August 2018 were eligible for analysis. Predict® version 2.1 online tool and the American Heart Association (AHA) Predictive Score for cardiovascular disease were used to calculate the estimated overall survival and the CVE risk at 10 years. RT volumes and MHD were registered from their RT plans. The increase of CVE risk was estimated based on the model by Darby et al. Mortality from heart attack/stroke was estimated based on HeartScore® from the European Association of Preventive Cardiology, and the reduction on breast cancer mortality from RT based on the EBCTCG meta-analysis.

### Results

Seventy-two eligible women with breast cancer were analyzed, none had bilateral cancer. Mean age was 66 years (range: 43 to 87 yrs). Thirty-two patients (44%) had right breast cancer and 40 (56%) had left breast cancer. Mean baseline AHA 10-year CVE risk was 9.1% (0.2 to 44.6%), 38% were considered as high risk by AHA definition. The estimated mean 10-year mortality from heart attack and stroke was 2.38%. RT volume included the internal mammary chain in 7 (10%) patients, the mean dose to breast or chest wall was 41.6 Gy, the mean heart dose (MHD) was 2.37 Gy (0.6 to 12.9 Gy), 1.54 Gy (0.6 to 8.6 Gy) and 2.96 Gy (0.9 to 12.9 Gy) in whole cohort, right and left treatments, respectively. With RT, the mean 10-year estimated breast cancer survival increased from 64.6% to 68.4% (absolute mortality reduction 3.75%) and the mean the 10-year CVE risk increased from 9.14% to 12.3% (absolute 3.16%, range: 0.02 to 25.37%). If all patients had optimal management of their cholesterol, blood pressure and smoking habit, the 10-year CVE risk would be 7% without RT and 9.5% with RT (absolute increase 2.50%).

### Conclusion

RT for breast cancer increase the 10-year estimated overall survival in 3.75% and the CVE risk in 3.15%. An optimal management of cardiovascular risk and lowering the MHD will maximize the benefit of the treatment.

### EP-1321 Waiting times for breast cancer treatment in Chile according to public or private health insurance

T. IP<sup>1</sup>, C. Gabler<sup>2</sup>, C. Carvajal<sup>2</sup>, C. Osorio<sup>2</sup>, M. Camus<sup>3</sup>, C. Sánchez<sup>4</sup>, M. Silva<sup>2</sup>, T. Merino<sup>1</sup>

<sup>1</sup>Pontificia Universidad Católica de Chile, Radiation Oncology, Santiago, Chile ; <sup>2</sup>Instituto Nacional del Cáncer, Radiation Oncology, Santiago, Chile ; <sup>3</sup>Pontificia Universidad Católica de Chile, Surgical Oncology, Santiago, Chile ; <sup>4</sup>Pontificia Universidad Católica de Chile, Medical Oncology, Santiago, Chile

### Purpose or Objective

Chilean people can either have public or private health insurance. As breast cancer is the leading cause of cancer death in Chilean women, it has been prioritized in Chilean health system by law. It establishes that treatment should start within 30 days of being diagnosed and adjuvant treatment should start within 20 days from indication. The purpose of this study is to report stage of cancer and time from diagnosis to treatment in breast cancer patients according to health insurance system.

### Material and Methods

A retrospective review of the breast cancer database at the Centro del Cáncer of the Universidad Católica de Chile (CECA-UC) and at Instituto Nacional del Cáncer (INC) for patients treated from 2017 to 2018. All breast cancer patients treated at CECA-UC were included and a random sample of equal number of the patients treated at INC where included. Age, tumor size, neoadjuvant treatment, time to surgery and time to radiation were registered. Patients were analyzed according to health insurance (public or private). Student T test for continuous variables and Chi<sup>2</sup> for categorical variables were used.

### Results

Two hundred and seventy-nine women were included (168 public insurance, 111 private insurance), median age was 57 years (range 25-88). The median clinical tumor size (T) was 24.3 mm (2-100), pathologic T was 20.8 mm (0-116). Tumor status was T1 n=157, T2 n=94, T3 n=12. Nodal status was N0=170, N1=64, N2=21, N3=10. Neoadjuvant chemotherapy was received in n=55 and neoadjuvant radiotherapy n=2. By Insurance, public and private, clinical T was 29 and 21.5 mm (p=0.005), pathologic T 22.5 and 19.9 mm (p=0.5), nodal status was N0=92 and 78, N1=36 and 28, N2=18 and 3, N3 8 and 2 (p=0.02), received neoadjuvant chemotherapy 23.8% and 13.5% (p=0.034), respectively. Mean time from diagnosis to surgery in patients without neoadjuvant treatment was 66,4 and 30 days (p=0.001), time from diagnosis to radiotherapy was 263 and 128 days (p< 0.001), and time from surgery to radiotherapy was 153 and 80 days (p<0.001).

### Conclusion

Patients with public insurance have significantly more advanced cancer stage at diagnosis and have a longer time to surgery and to adjuvant radiotherapy than patients with private insurance.

### EP-1322 "Every breath you take": first results of INHALE (Inspiration Breath hold health related QoL) study

E. Ippolito<sup>1</sup>, S. Silipigni<sup>1</sup>, A. Sicilia<sup>1</sup>, S. Palizzi<sup>1</sup>, G.M. Petrianni<sup>1</sup>, B. Santo<sup>1</sup>, S. Gentile<sup>1</sup>, P. Zuccoli<sup>1</sup>, E. Molfese<sup>1</sup>, A. Iurato<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, S. Ramella<sup>1</sup>  
<sup>1</sup>Campus Biomedico University, Radiotherapy, Roma, Italy

### Purpose or Objective

Breath holding (BH) techniques enable clinicians to reduce radiation dose to the heart and the left descending artery (LAD) in left breast cancer patients. Despite such advantages, BH radiotherapy (RT) compared to free breathing RT (FB RT) has been shown to require more efforts during simulation and treatment delivery for both clinicians and patients. The aim of this study is to evaluate whether BH RT affects QoL and physical (fatigue) as well as psychological distress in breast cancer patients. Herewith we report the preliminary results.

### Material and Methods

All breast cancer patients aged less than 60 years old who were referred to our department of radiation oncology were asked to participate in this study. Patient-reported outcomes (PROMs) including EORTC QLQ CD30-BRC23 questionnaire (22 items), FACIT - Fatigue Scale vers. 4 (13 items), Hospital Anxiety and Depression Scale - HADS (14 items) were prospectively collected before the start of adjuvant radiotherapy (baseline) and at the end of treatment. All scores were square-root transformed (scale 0-10). Analysis of covariance (ANCOVA) was used with pre and post radiotherapy change in questionnaires scores as dependent variable, the treatment group (BH vs FB) as independent variable and the baseline measure as covariate.

### Results

Thirty-five consecutive breast cancer patients deemed to start radiotherapy treatment were asked to participate. All accepted to fulfill the questionnaires. Median age was

50 years (range 33-64 years)  
 Fourteen patients (40%) completed chemotherapy before radiotherapy, five patients (14.3%) had trastuzumab and twenty-five patients (80.6%) had hormone therapy during radiotherapy course. At the time of analysis pre and post radiotherapy questionnaires were available for 30 patients (13 left sided; 17 right sided). Depression scores, health related quality of life and fatigue did not change significantly during radiotherapy treatment for both groups (see table1). Patients reporting severe fatigue (FACIT - Fatigue Scale score >7) were 2/30 (6.6%) before and 3/30 (10%) after radiotherapy. Interestingly only one of these patients received BH radiotherapy. Anxiety and depression level was higher than mean score in all patients.

**Table 1**

Outcome	Treatment type	Mean (SD) T0	Mean (SD) T1	p
Overall QOL	FB	4,224 (0,961)	4,331 (0,953)	0,595
	BH	4,239 (0,804)	4,609 (1,851)	
Fatigue	FB	4,100 (1,631)	4,322 (1,637)	0,527
	BH	4,199 (1,590)	4,731 (1,620)	
Anxiety/depression	FB	6,015 (0,620)	5,268 (1,842)	0,392
	BH	6,235 (0,736)	4,568 (2,867)	

T0= pre radiotherapy; T1= post radiotherapy; FB= free breathing; BH= breath hold

**Conclusion**

The study is still ongoing. Preliminary results suggest that BH RT seems to not affect quality of life, psychological distress and fatigue in breast cancer patients undergoing radiotherapy.

**EP-1323 HeartSpare Plus: A comparison of the feasibility and acute toxicity of internal mammary chain RT**

A. Ranger<sup>1</sup>, A. Dunlop<sup>1</sup>, E. Donovan<sup>2</sup>, E. Harris<sup>1</sup>, N.M. DeSouza<sup>1</sup>, H. McNair<sup>1</sup>, A. Kirby<sup>1</sup>  
<sup>1</sup>ICR and Royal Marsden NHS Foundation Trust, Clinical Oncology, Sutton, United Kingdom ; <sup>2</sup>University of Surrey, Centre for Vision Speech and Signal Processing, Guildford, United Kingdom

**Purpose or Objective**

Inclusion of the internal mammary chain in the radiotherapy target volume (IMC\_RT) improves disease free and overall survival in higher risk breast cancer patients but increases radiation doses to the heart. The HeartSpare Plus dosimetry study demonstrated that the use of either modified wide-tangential fields (WT(vDIBH)) or volumetric modulated arc therapy (VMAT(vDIBH)) in combination with voluntary breath hold was capable of reducing mean heart dose to below 4Gy in the majority of patients. The subsequent HeartSpare Plus clinical trial aimed to compare set-up reproducibility, the time taken to deliver IMC-RT using WT(vDIBH) versus VMAT including planning time, dose to target volumes and organs at risk (OAR), and acute toxicities associated with each technique.

**Material and Methods**

Twenty left sided breast cancer patients requiring IMC-RT were randomised to receive WT(vDIBH) or VMAT radiotherapy. Treatment times were compared using unpaired two tailed t tests with a significance level of 0.05 to detect a difference of 5 minutes per fraction between techniques. The population mean displacement (MD), systematic error (Σ) and random error (σ) for CBCT chest wall matches in three planes of movement were

calculated for the two groups using the van Herk method. Dose statistics between groups were compared using a two tailed unpaired t test. Acute skin (RTOG), lung and oesophageal toxicity (CTCAE v 4.03) rates in the two groups were compared using the Mann-Whitney test.

**Results**

Eleven patients were treated with VMAT (three in free breathing (FB) and eight in vDIBH) nine patients were treated with WT(vDIBH). WT(vDIBH) required significantly longer total treatment times than VMAT (Table 1).

	WT(vDIBH) Mean (SD) (minutes)	VMAT Mean (SD) (minutes)	Mean difference (WT-VMAT) (minutes)	P value (95% CI, minutes)
Set up	10.0 (1.0)	6.4 (0.8)	3.6	<0.0001 (2.7 - 4.4)
Verification	1.5 (0.2)	1.6 (0.2)	-0.1	0.8468 (-0.5 - 0.5)
Shift	6.0 (0.8)	3.2 (1.2)	2.8	<0.0001 (2.2 - 3.9)
Treatment	11.2 (2.2)	2.6 (0.6)	8.6	<0.0001 (7.1 - 0.2)
Total	28.1 (3.3)	13.2 (1.7)	14.9	<0.0001 (12.4 - 17.4)

Table 1: Timings in minutes for the component parts of radiotherapy treatments in the two groups, WT(vDIBH) and VMAT

All techniques were equally reproducible. There was no statistically significant difference in MHD or Heart V<sub>17Gy</sub> between VMAT(vDIBH) and WT(vDIBH) (p=0.1269 and p=0.1490 respectively). There was no statistically significant difference in ipsilateral lung V<sub>17Gy</sub>, mean contralateral lung dose or mean contralateral breast dose between the VMAT and WT techniques. The humeral head, oesophagus and thyroid all received a statistically significantly higher dose in the VMAT group when compared to the WT(vDIBH) group (see table 2). There were no statistically significant differences in skin or lung toxicity within 3 months of treatment. Increased rates of oesophageal toxicity were seen during the third week of treatment and two weeks post treatment in the VMAT group but this was not statistically significant (see table 3). One year lung, shoulder and oesophageal toxicity will be presented.

OAR	WT(vDIBH) Mean (SD)		VMAT Mean (SD)		P value
	Mean (SD)		Mean (SD)		
MHD (Gy)	2.6 (1.2)		3.6 (0.7)		0.0422*
Heart V <sub>17Gy</sub> (%)	2.0 (2.3)		4.2 (2.0)		0.0369*
Maximum LAD dose (Gy)	31.2 (7.9)		35.2 (5.5)		0.2210
Ipsilateral lung V <sub>17Gy</sub> (%)	32.8 (3.3)		34.4 (1.4)		0.1604
Mean contralateral lung dose (Gy)	0.6 (0.2)		0.6 (0.1)		0.5889
Mean contralateral breast dose (Gy)	1.6 (1.2)		1.4 (0.5)		0.6830
Mean humeral head dose (Gy)	2.8 (1.0)		16.8 (6.2)		<0.0001
Maximum oesophageal dose (Gy)	20.1 (9.9)		37.3 (8.0)		<0.0001
Mean thyroid dose (Gy)	11.2 (3.1)		22.0 (6.1)		0.0032
Maximum brachial plexus dose (Gy)	40.4 (0.7)		40.1 (0.7)		0.3362

Table 2: Organ at risk dose statistics for WT(vDIBH) and VMAT treatments

\*MHD: acute radiation toxicity in the heart patients treated with VMAT (p=0.0422) and WT(vDIBH) (p=0.0369) respectively. There was no statistically significant difference in MHD (mean dose 1.45) or heart V<sub>17Gy</sub> (mean 3.7%) between VMAT(vDIBH) and WT(vDIBH) (p=0.1269 and p=0.1490 respectively).

OAR	Toxicity Grade	Percentage of patients								
		On treatment			2 weeks post treatment			3 months post treatment		
		WT (vDIBH)	VMAT	P value	WT (vDIBH)	VMAT	P value	WT (vDIBH)	VMAT	P value
Lung (CTCAE pneumonitis toxicity score)	Grade 0	100	80	0.47	89	80	>0.99	89	90	>0.99
	Grade 1	0	0		0	0		0	0	
	Grade 2	0	20		11	10		11	10	
Oesophageal (CTCAE oesophagitis toxicity score)	Grade 0	67	30	0.18	100	80	0.47			
	Grade 1	0	0		0	0				
	Grade 2	33	70		0	20				
Skin (RTOG skin toxicity score)	Grade 0	11	30	0.37	11	30	0.43			
	Grade 1	78	70		67	60				
	Grade 2	11	0		22	10				

Table 3: Acute toxicity for WT(vDIBH) and VMAT treatments. There was no Grade 3 or 4 toxicity in either group.

**Conclusion**

In patients undergoing IMC\_RT, VMAT(vDIBH) is quicker to deliver than WT(vDIBH) but is associated with more persistent acute oesophageal toxicity than WT(vDIBH).

**EP-1324 A Dosimetric Study of Heart and Lung Dose in Breast Radiotherapy-Our Institutional Experience**

C. Mccann<sup>1</sup>, E. Chow<sup>2</sup>, D. Vesprini<sup>2</sup>, L. Eric<sup>2</sup>, C. Paruag<sup>3</sup>, E. Lai<sup>3</sup>, M. Wronski<sup>1</sup>  
<sup>1</sup>Sunnybrook Health Sciences Centre, Odette Cancer Centre- Radiation Therapy Program- Medical Physics, Toronto, Canada ; <sup>2</sup>Sunnybrook Health Sciences Centre, Odette Cancer Centre- Radiation Therapy Program- Radiation Oncology, Toronto, Canada ; <sup>3</sup>Ryerson University, Medical Physics, Toronto, Canada

### Purpose or Objective

Adjuvant radiotherapy for breast cancer treatment has been long shown to reduce the risk of recurrence, but also results in incidental exposure of organs at risk (OAR) such as the heart and lungs. Several studies have reported on cardiac toxicity, showing an increase in the rate of ischemic heart disease after radiotherapy for left-sided breast cancer; and meta-analyses of women treated with breast radiotherapy have shown an increased risk of primary lung cancer, which is even more appreciable in the smoking population. Other potential lung complications from breast radiotherapy include pneumonitis and subsequent fibrosis, the risk of which further increases with the addition of chemotherapy. In this retrospective dosimetric study, we report on the cardiac and lung doses from over 400 breast cancer patients treated with radiotherapy at our centre, with the long-term goal of correlating dose to toxicity.

### Material and Methods

412 breast cancer patients treated with 50Gy in 25 fractions or 42.56Gy in 16 fractions were identified retrospectively. Cohorts were stratified based on the radiation technique including (i) 2-field tangential beam arrangement (n=256) (ii) 3- and 4-field techniques with standard tangents (n=92) and (iii) 4-field technique with wide tangents (n=64) to include the internal mammary chain (IMC), which was further stratified between treatment of right (n=34) and left-sided disease (n=30). Of the latter, patients simulated in free-breathing (n=8) and those simulated with a modified deep inspiration breath-hold technique (mDIBH) (n=22) were analysed separately. Standardized contouring based on the RTOG breast cancer atlas, in combination with standard field based planning was used. Dosimetric heart parameters evaluated included mean heart dose (MHD) and V(50%). Metrics for the combined lung volumes included V5Gy, V20Gy and Mean Lung Dose (MLD). ANOVA was also used to compare the dose between the techniques for statistical significance.

### Results

Dosimetric parameters for heart and lung are reported in table 1 for the different techniques, with the differences shown to be statistically significant. Breast cancer patients treated with radiotherapy which included regional nodal irradiation increased dose to both heart and lungs. mDIBH significantly reduced the dose to the heart as compared to the free-breathing technique.

HEART		Radiotherapy Technique	Standard Tangents (Left and Right)	3,4-Field Standard Tangents (left and Right)	4-Field Wide Tangents (Right side)	4-Field Wide Tangents (Left side, mDIBH)	4-Field Wide Tangents (Left side, free breathing)	One-Way ANOVA
Dosimetric Parameter	V(50%) %	Mean	0.12	0.48	0.28	0.91	2.8	p<<0.001
	Range	0-3.11	0-5.08	0-2.77	0-8.44	0.06-9.55		
MHD (Gy)	Mean	106.6	161.9	160.8	243.2	335.3		p<<0.001
	Range	2-350.2	2.9-398.9	8.2-364.2	149.6-373.7	185.8-648		

LUNGS (combined)		Radiotherapy Technique	Standard Tangents (Left and Right)	3,4-Field Standard Tangents (left and Right)	4-Field Wide Tangents (Right and Left)	One-Way ANOVA
Dosimetric Parameter	V20Gy (%)	Mean	5.47	13.54	17.04	p<<0.001
	Range	0.03-12.63	6.4-24.64	7.59-28.12		
V5Gy (%)	Mean	10.66	21.94	26.05	p<<0.001	
	Range	1.67-22.06	14.91-34.17	14.96-36.6		
MLD (Gy)	Mean	298.87	697.76	853.34	p<<0.001	
	Range	69.3-638.7	401.8-1393.8	421.0-1367.8		

### Conclusion

Standardized contouring and planning facilitates a meaningful dosimetric evaluation of OAR dose associated with breast radiotherapy, which in future studies can be correlated with toxicity. In an era where the benefits of breast radiotherapy well outweigh the risks in the majority of patients, it is important to consider the potential long-term effects of breast cancer radiotherapy from a survivorship lens.

### EP-1325 Personalized Medicine in breast cancer: a nomogram from prognostic score to deescalate radiotherapy

F. Marazzi<sup>1</sup>, A. Mulè<sup>2</sup>, V. Masiello<sup>1</sup>, R. Masetti<sup>3</sup>, R. Barone<sup>4</sup>, G. Franceschini<sup>3</sup>, F. Cacciatori<sup>2</sup>, F. Moschella<sup>3</sup>, C. Cannata<sup>1</sup>, L. Boldrini<sup>1</sup>, G. Mantini<sup>1</sup>, D. Smaniotto<sup>1</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Fondazione Policlinico Gemelli IRCCS, Radioterapia Oncologica, Roma, Italy; <sup>2</sup>Fondazione Policlinico Gemelli IRCCS, Department of Woman and Child Health-Pathology Unit, Roma, Italy; <sup>3</sup>Fondazione Policlinico Gemelli IRCCS, Multidisciplinary Breast Center, Roma, Italy; <sup>4</sup>Fondazione Policlinico Gemelli IRCCS, Università Cattolica Sacro Cuore- Dipartimento Scienze Radiologiche- Radioterapie ed Ematologiche- Istituto di Radiologia, Roma, Italy

### Purpose or Objective

OncotypeDX can enhance prediction of breast cancer recurrence (BRC), guiding adjuvant treatment options. Many studies showed a low local relapse for Recurrence Score (RS) < 18 and probably in these patients would be possible to deescalate adjuvant radiotherapy (RT). However, the opportunity to access this test is not always possible. The aim of this study is to investigate the correlation between classical immunohistochemistry (IHC) and RS in order to offer to clinicians a Decision Supporting System to be validated for deescalating RT

### Material and Methods

All patients who for ER+ HER2- breast cancer underwent Oncotype between 2014 and 2018 were retrospectively included in the study. The data selected for analysis were: age, menopausal status, pT, pN, PVI, IHC, RS and ER, PgR and HER2 expressed on Oncotype analysis. IHC was performed with standardized semi-quantitative method. Multivariable logistic regression analyses were applied to ascertain the associations between all these parameters and RS

### Results

The study comprised 407 patients who underwent Oncotype. Mean age was 53.7 (31-80) and 222 pts (54.55%) were > 50 years old. Oncotype results showed: 67 pts (16.5%) between 0-10, 173 pts between 11 and 18 (42.5%), 133 pts between 19 and 30 (32.7%), and 34 pts > 30 (8.3%). At the logistic regression analysis, RS score was significantly associated with ER (p=0.004), PgR (p<0.0001), and Ki67% (p<0.0001). Above pts with Oncotype ≤18 (0-18), a linear regression showed a model with AUC 0.814 (sensitivity 75%; specificity 75%) (Figure 1). Ten-cross fold validation of the model presented a mean AUC of 0,80 (0.7-0.9). A nomogram was generated for further prospective evaluation, predicting RS score < 18 for internal IHC prognostic factor (Figure 2).

### Conclusion

Prognostic factors present a good correlation with RS score in pts with RS ≤ 18 in our series. A nomogram for physician that enhance a good cost/effectiveness clinical practice need to be tested prospectively for deescalating adjuvant RT

### EP-1326 Assessment of rigorous dosimetry guidelines for a multi-institutional, phase II APBI clinical trial

S. Quirk<sup>1,2</sup>, P. Grendarova<sup>1</sup>, A. Guebert<sup>2</sup>, A. Frederick<sup>2</sup>, I.A. Olivetto<sup>1</sup>, M. Roumeliotis<sup>1,2</sup>

<sup>1</sup>University of Calgary, Oncology, Calgary, Canada;

<sup>2</sup>University of Calgary, Physics and Astronomy, Calgary, Canada

### Purpose or Objective

To compare the clinically achieved dosimetry of ACCEL trial with the trial's rigorous dosimetry guidelines in context with phase III multi-institutional accelerated partial breast irradiation (APBI) trials. These dosimetry guidelines were significantly stricter than dosimetry constraints formally imposed by trial protocol.

### Material and Methods

The ACCEL trial (<https://clinicaltrials.gov/NCT02681107>) is a Canadian, multi-institutional, phase II prospective

clinical trial investigating a new external beam APBI regimen, delivering 27 Gy in five consecutive daily fractions with *dosimetry constraints* consistent with major APBI trials such as ACCEL and NSABP B-39/RTOG-0413 (<https://clinicaltrials.gov/NCT00103181>). For the ACCEL trial, more rigorous *dosimetry guidelines* were established to ensure consistent and highly conformal dose distributions to address the hypothesis that poor dose conformity is important in causing cosmetic deterioration. These *dosimetry guidelines* were based on a retrospective planning study that required substantial APBI planning expertise to implement. In the current work, the clinical implementation of these *dosimetry guidelines* (recommendations and allowed variations) across multiple institutions is evaluated in the context of major APBI trial dosimetry constraints (Table 1). For 215 patients accrued to the ACCEL trial, dose-volume parameters were evaluated to determine the achievability of rigorous dosimetry guidelines in a heterogeneous clinical setting.

Table 1: Comparison of standard trial dosimetry constraints and ACCEL dosimetry guidelines recommendations and allowed variation. These *dosimetry guidelines* were significantly stricter than dosimetry constraints formally imposed by trial protocol.

	Trial Dosimetry Constraints		ACCEL Dosimetry Guidelines	
	NSABP B-39/ RTOG-0413	ACCEL	Recommendation	Allowed Variation
Lung				
V <sub>10%</sub> Rx	< 15%	< 10%	< 5%	5 - 10%
Heart				
V <sub>5%</sub> Rx	< 40%	< 5 - 15%	< 5%	5 - 10%
Ipsilateral Breast				
V <sub>50%</sub> Rx	< 60%	< 50%	< 35%	35 - 45%
V <sub>100%,95%</sub> Rx	< 35%	< 25%	< 10%	10 - 20%

## Results

215 patients planned by 12 dosimetrists and reviewed by 10 physicians and 10 physicists across three institutions were included. All APBI plans met NSABP B-39/RTOG-0413 and ACCEL trial *dosimetry constraints*. Normal tissue dosimetry guidelines for ipsilateral breast, lung, contralateral breast, heart, as well as high dose conformity, were satisfied by 95% of patients within the recommended or allowed variations. The mean ( $\pm$  standard deviation) of the ipsilateral breast V<sub>50%</sub> was 30.8 ( $\pm$ 7.8) % which is a significant improvement on the V<sub>50%</sub> less than 50% dose constraint of the NSABP B-39/RTOG-0413 and ACCEL trials (Figure 1). Similarly, the mean ( $\pm$  standard deviation) of the high dose (volume of 95% prescription dose) ipsilateral breast constraint was 10.5 ( $\pm$ 3.6) % as compared to the NSABP B-39/RTOG-0413 and ACCEL trial constraint of less than 25%.

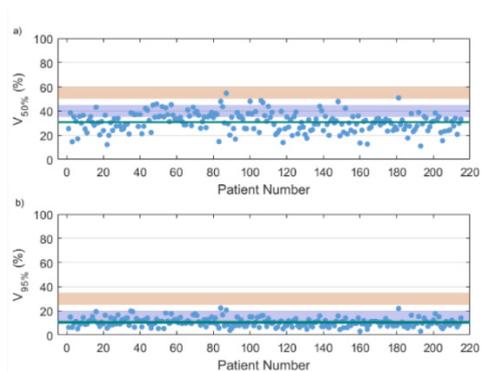

Figure 1: a) Ipsilateral Breast V<sub>50%</sub> and b) ipsilateral breast V<sub>95%</sub> are shown for all 215 patients. The shaded blue region is the acceptable variation of the rigorous ACCEL *dosimetry guidelines* and the shaded orange is the *dosimetry constraints* of the NSABP B-39/RTOG and ACCEL *dosimetry constraints*. The mean value is shown by the green line. For both metrics, the majority of patients, 98.4% and 96.2%, are well within the *dosimetry guidelines* and well below trial constraints.

## Conclusion

The *dosimetry guidelines* are stringent compared to major APBI trial constraints but this work demonstrated they are clinically achievable. These *dosimetry guidelines* provide a tangible means of ensuring consistency in plan quality

and high conformity across multiple institutions and clinicians, which demonstrate a substantial improvement over major APBI trial *dosimetry constraints*.

## EP-1327 Impact of neoadjuvant radiotherapy in locally advanced breast carcinoma

C. Sousa<sup>1</sup>, L. Pinto<sup>2</sup>, M. Cruz<sup>1</sup>, A. Neto<sup>1</sup>, J. Bastos<sup>3</sup>, C. Miranda<sup>1</sup>, G. Melo<sup>1</sup>, L. Khouri<sup>1</sup>, P. Figueiredo<sup>4</sup>, P. Alves<sup>5</sup>  
<sup>1</sup>Instituto Português de Oncologia de Coimbra, Radiotherapy, Coimbra, Portugal ; <sup>2</sup>Instituto Português de Oncologia de Coimbra, Medical Oncology, Coimbra, Portugal ; <sup>3</sup>Instituto Português de Oncologia de Coimbra, Regional Oncology Registry of the Centre, Coimbra, Portugal ; <sup>4</sup>Instituto Português de Oncologia de Coimbra, Anatomical Pathology, Coimbra, Portugal ; <sup>5</sup>Instituto Português de Oncologia de Coimbra- Faculty of Medicine - University of Coimbra, Radiotherapy, Coimbra, Portugal

## Purpose or Objective

The therapeutic approach in locally advanced breast carcinoma remains a clinical challenge. Standard treatment involves systemic therapy with chemotherapy (NACT) and / or hormone therapy (NAHT), surgery and radiation therapy when indicated. More than a third of patients are refractory to systemic cancer treatment, with maintenance of inoperability criteria. There are few data in the literature about alternative treatment when systemic therapy fails. With this study, we intend to evaluate the impact of neoadjuvant radiotherapy (NART) in the treatment of the locally advanced carcinoma.

## Material and Methods

We conducted a retrospective study including female patients, diagnosed with locally advanced invasive breast carcinoma, stages IIB to IIIC, submitted to NART between January 2014 and December 2015 at our institution. The radiotherapy regimens varied between 26Gy / 4Fr / 2,5weeks  $\pm$  30Gy / 10Fr / 2weeks, 50Gy / 25Fr / 5weeks and 60 Gy / 30Fr / 6weeks on the breast volume, supraclavicular and axillary lymph node region. The evaluation of pathological response (pR) was made based on Pinder criteria, divided into three groups: 1 - complete response, 2 - partial response > 90% and 3 - partial response  $\leq$  90%; Primary endpoint: pathological response (pR); Secondary endpoints: overall survival (OS), progression-free survival (PFS). Performed descriptive analysis and survival analysis with Kaplan-Meier method.

## Results

From a total of 51 patients submitted to NART, 42 were included, with a median age of 59 (32-86) years. The most frequent clinical stages were IIIA and IIIB, corresponding to 40.5% and 38.1%, respectively; 35 (83.3%) had lymph node involvement. 22 (52.4%) were basal like (n = 11) and luminal like (n = 11). 26 (61.9%) underwent NACT with anthracyclines and taxanes, 13 (30.9%) NAHT, 5 (11.9%) NART in monotherapy. All included patients underwent mastectomy. Our results: 6 (14.3%) had complete response, 2 of which had only NART. 87% of patients with pR > 90% were under 69 years old. 36 months OS was 64% and PFS was 60%. Subgroup analysis showed 36 months OS of 87% in group 2 versus 48% in group 3, 91% luminal A versus 27% basal like (p < 0.05). After surgery, 19 (45.2%) progressed, of which 17 had distant metastasis, correlated with a worse prognosis (p < 0.05).

## Conclusion

This retrospective study confirms that NART is an effective downsizing treatment in locally advanced breast carcinoma, allowing surgical resection regardless of systemic treatment performed. The pR > 90% is correlated with a better OS. These findings corroborate the literature, with the basal like intrinsic subtype and distant metastasis correlated with worse prognosis.

### EP-1328 A comparison of voluntary vs ABC breath hold in combination with VMAT for pan lymph node breast RT

A. Ranger<sup>1</sup>, A. Dunlop<sup>1</sup>, E. Donovan<sup>2</sup>, E. Harris<sup>1</sup>, N. DeSouza<sup>1</sup>, H. McNair<sup>1</sup>, A. Kirby<sup>1</sup>

<sup>1</sup>ICR and Royal Marsden NHS Foundation Trust, Clinical Oncology, Sutton, United Kingdom ; <sup>2</sup>University of Surrey, Centre for Vision Speech and Signal Processing, Guildford, United Kingdom

#### Purpose or Objective

Breath holding techniques reduce radiation dose to the heart for patients undergoing locoregional breast radiotherapy. This can be achieved either by using machine assisted techniques or voluntary breath hold with no apparent difference in reproducibility between techniques in the context of tangential treatments for the breast/ chest wall. This study aimed to compare the reproducibility of volumetric modulated arc therapy (VMAT) in combination with vDIBH in combination with the active breathing co-ordinator (ABC™, Elekta, Crawley, UK) device. We also aimed to test the feasibility of delivering radiotherapy using vDIBH in combination with VMAT and to patients who require wax bolus for treatment.

#### Material and Methods

Patients requiring locoregional breast radiotherapy including the internal mammary chain (IMC) either with wax bolus or with the combination of VMAT in breath hold were scanned in vDIBH and using the ABC device. Patients were randomised to receive one technique for fractions 1-7 and the other for fractions 8-15. Daily cone beam computer tomography (CBCT) was performed and matched to planning-CT data. Within patient comparisons of mean daily chest wall position were made using a paired t-test. Estimates of population, systematic and random errors were also made. Diaphragm positions in consecutive breath holds were measured and compared between techniques using the Wilcoxon signed-rank test. A novel couch mounted laser was developed to enable the use of vDIBH in combination with VMAT and for patients requiring wax bolus during treatment. Acute skin, lung and oesophageal toxicity was also recorded during and two weeks post treatment.

#### Results

16 patients completed treatment using both techniques. There was no statistically significant difference in mean chest wall displacement between techniques in any direction ( $\leq -1.3\text{mm}$  for ABC,  $\leq -1.5\text{mm}$  for vDIBH, all p non-significant). There was no difference in diaphragm position in consecutive breath holds between techniques (p=0.30, Figure 1) and treatment times were equivalent.

Figure 1: Comparison of diaphragm position using CBCT pre (image a) and post (image b) break in breath hold. Differences in diaphragm position were compared within patients for the vDIBH and ABC techniques.

Patients were successfully treated using VMAT in vDIBH including eleven who required wax bolus. Figure 2 demonstrates the use of the couch mounted laser.

Figure 2: The couch mounted laser (image c) developed for the trial to facilitate the combination of VMAT with vDIBH and the use of vDIBH in patients requiring a wax bolus for treatment. The laser attaches to the couch using suction pads. The laser is positioned using a ball mounted grip to shine the cross hairs onto the patients' skin (images a, b and d). The cross hairs with corresponding mark in free breathing (image a) and breath hold (image b).

Results for acute skin toxicity according to RTOG criteria, acute lung and oesophageal toxicity according to CTCAE criteria during the third week of radiotherapy and two weeks post treatment are presented in table 1. There was no grade 3 or 4 toxicity reported.

Toxicity	On treatment(% of patients)	2 weeks post treatment(% of patients)
Skin	Grade 0	31
	Grade 1	46
	Grade 2	23
	Grade 3	0
Pneumonitis	Grade 0	77
	Grade 1	0
	Grade 2	23
	Grade 3	0
Oesophagitis	Grade 0	92
	Grade 1	0
	Grade 2	8
	Grade 3	0

#### Conclusion

This study demonstrates that it is feasible to use vDIBH in combination with wax bolus or VMAT therapy for the treatment of breast cancer patients. Results support previous data that ABC and vDIBH are comparable in terms of positional reproducibility.

### EP-1329 A Single Pre-Operative Radiation Therapy (SPORT) Phase 1 Trial For Low Risk Breast Cancer

C. Pembroke<sup>1</sup>, M. Yassa<sup>2</sup>, C. Lambert<sup>3</sup>, V. Panet-Raymond<sup>3</sup>, S. Meterissian<sup>4</sup>, F. Tremblay<sup>4</sup>, D. Anderson<sup>5</sup>, P. Vavassis<sup>5</sup>, T. Hijal<sup>3</sup>

<sup>1</sup>Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom ; <sup>2</sup>University of Montreal, Radiation Oncology, Montreal, Canada ; <sup>3</sup>McGill University Health Centre, Radiation Oncology, Montreal, Canada ; <sup>4</sup>McGill University Health Centre, Surgery, Montreal, Canada ; <sup>5</sup>McGill University, Surgery, Montreal, Canada ; <sup>6</sup>University of Montreal, Surgery, Montreal, Canada

#### Purpose or Objective

A single-arm phase 1 feasibility trial offering a preoperative 20Gy fraction for low-risk breast cancer in the post-menopausal setting. We report on our primary objective; feasibility, surgical and cosmetic toxicity at 3 months.

#### Material and Methods

Eligibility criteria for low-risk disease included, age  $\geq 60$  years, unifocal invasive ductal carcinomas  $< 2\text{cm}$ , clinically

node negative, ER positive and HER2 negative. The gross tumour volume (GTV) was defined using mammography, ultrasonography and MRI and grown by 5mm to form the clinical target volume (CTV) and a further 10mm for the planning target volume (PTV). Patients were treated with a single 20Gy fraction to the PTV using volumetric arc therapy up to 72 hours prior to partial mastectomy and sentinel node biopsy. Toxicity was assessed, both subjectively and objectively, using the RTOG-EORTC radiation toxicity scale, NCIC CTCAE and EORTC cosmetic scale at baseline, 48 hours, 14 days and 3,6,9 and 12 months.

#### Results

A total of ten patients with clinical T1N0 invasive ductal carcinomas, with a median age of 69, were treated between October 2016 and March 2018. All patients were planned and treated successfully using pre-defined constraints to a mean PTV of 48.9 cc. Pathological review demonstrated an increase in tumour size by a mean of 2.06mm and all patients were node negative. Four patients had close (<1mm) margins to ductal carcinoma in-situ. Three patients required surgical revision of margins, one of whom chose a subsequent mastectomy and reconstruction following a further close margin. The fourth patient declined surgery and chose to have whole breast radiotherapy (42.56 Gy in 16 fractions). There were no surgical complications, all had grade 1 surgical scar pain and oedema 7 days following theatre but no delays in wound healing were demonstrated. At 3 months, 8 patients reported good (n=7) to excellent (n=1) cosmesis and 2 reported fair results. Six patients reported grade 1 hyperpigmentation and 1 patient had grade 2 and 3 pain and breast oedema respectively.

#### Conclusion

The preliminary results demonstrate feasibility and tolerability following a single pre-operative 20Gy fraction for early stage breast cancer. Continued follow-up is required to meet the secondary objectives including cosmesis at 12 months and ipsilateral breast recurrence.

#### EP-1330 Intraoperative electron radiotherapy (IOERT) boost in early breast cancer: toxicity analysis

C. Vidali<sup>1</sup>, Z. Pellin<sup>2</sup>, M. Severgnini<sup>3</sup>, S. Scomersi<sup>4</sup>, M. Bortul<sup>5</sup>

<sup>1</sup>ASUITS, Radiotherapy, Trieste, Italy ; <sup>2</sup>University of Trieste, Surgery, Trieste, Italy ; <sup>3</sup>ASUITS, Medical Physics, Trieste, Italy ; <sup>4</sup>ASUITS, Surgery, Trieste, Italy ; <sup>5</sup>University of Trieste, Surgery - Breast Unit, Trieste, Italy

#### Purpose or Objective

The clinical activity with IOERT as an anticipated boost in the treatment of early breast cancer started in October 2012 at the Breast Unit of the ASUITS of Trieste.

The aim of this study is to present the results of our experience with particular attention to acute and late toxicity.

#### Material and Methods

Patients with an invasive and unifocal breast tumor - cT1or T2 ≤ 2.5 cm - , cN0-N1 who underwent conservative surgery (quadrantectomy and sentinel node biopsy; axillary dissection only in case of macrometastasis) were eligible to IOERT boost, performed with the mobile LINAC Mobetron.

Two protocols were applied in our Center: 1) IOERT (dose: 10 Gy max. dose) followed by conventional whole breast radiotherapy (WBRT) (50 Gy in 25 fr.); 2) IOERT (11.1 Gy max. dose) followed by hypofractionated WBRT (40.5 Gy in 15 fr.), as in the HIOB Protocol schedule.

Acute toxicity was evaluated after IOERT and at the end of WBRT using the CTCAE 5.0 Toxicity Scoring system and late complications at 6 months and at every further follow-up, using the LENT-SOMA score.

#### Results

From November 2012 to July 2018, 103 IOERT procedures were carried out on 102 patients (one patient had a bilateral synchronous cancer and received the boost bilaterally): in 53 of them (51.46%) IOERT boost was followed by conventional WBRT (group 1) and in 50 of them (48.54%) by hypofractionated WBRT (group 2).

Median age was 67 years (range: 43-85 years); median follow-up was 40 months (range 6-73 months).

Acute toxicity after IOERT boost was present in 19 women (G1 in 14; G2 in 5 cases). Acute toxicity at the end of WBRT was evaluated in 97 patients (two patients refused WBRT; one patient underwent mastectomy and two were lost to follow-up): 74 of them (76.29%) experienced G1 and 7 of them (7.22%) G2 skin toxicity. No differences were observed between the two groups.

Late toxicity was evaluable in 89/97 patients (91.75%) with a minimal follow-up of 6 months (47 in group 1 and 42 in group 2): 19 of them (21.35%) reported G1 and 6 of them (6.74%) G2 toxicity. A statistically significant difference in late toxicity was observed in the two groups in favour of the group treated with hypofractionated WBRT (p=0.004) (Fig. 1).

No local recurrences were observed in the 97 women who concluded the whole treatment, while one patient who had refused WBRT developed a local relapse one year after IOERT. In addition two women developed distant metastases.

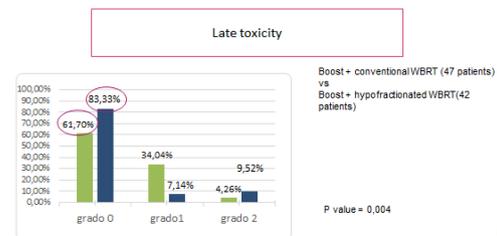

Fig. 1

#### Conclusion

In our experience recurrence rate was very low and acceptable acute and late toxicity were observed, especially in the group of patients who received hypofractionated WBRT after the intraoperative boost. Therefore the use of IOERT as an anticipated boost is encouraged in selected low-risk breast cancer women, even off- clinical trials.

#### EP-1331 Accelerated hypofractionated Whole Breast Irradiation with Concurrent TB Boost: Toxicity and cosmesis

S. Lasheen<sup>1</sup>, S. Shams El Din<sup>1</sup>, R. Moussa<sup>2</sup>, M. Hassan<sup>1</sup>, F. Hagag<sup>1</sup>

<sup>1</sup>NEMROCK Center- Kaser Al-AINI- Faculty of Medicine- Cairo University, Department of clinical oncology, Cairo, Egypt ; <sup>2</sup>NEMROCK Center- Kaser Al-AINI- Faculty of Medicine- Cairo University, Department of medical physics, Cairo, Egypt

#### Purpose or Objective

The safety and efficacy of accelerated hypofractionated WBI has been validated in several clinical trials, however tumor bed boost -when administered in these trials- was prescribed sequential to WBI. The safety of concomitant TB boost in this setting and its impact on cosmetic outcome is of great interest especially in high volume departments to reduce the work load as well as improve patient compliance. The aim of this study is to investigate the use of accelerated hypofractionated WBI with a concomitant TB boost in terms of toxicity and cosmetic outcome.

#### Material and Methods

In this prospective phase II study conducted at the department of clinical oncology, Cairo university, breast cancer patients indicated for post-operative WBI following BCS were recruited to receive an accelerated hypofractionated WBI schedule of 40 Gy/15 fractions over 3 weeks with a concurrent daily boost dose of 8.0 Gy/15 fractions. Dosimetric parameters were set using V38Gy & V36Gy for breast PTV coverage, V45.6Gy and V43Gy for tumor bed PTV coverage, while Dmax and Dmin were used to evaluate homogeneity. Sixty three patients were recruited accordingly, and were followed up for acute toxicity (using CTCAE v3.0 criteria), Late toxicity (reported at least 6 months after end of radiation course and thereafter) and cosmetic outcome (using Harvard score).

#### Results

The study was conducted during the period from June 2014 to June 2017. A total of 63 patients were recruited and followed for a median duration of 24 months (follow-up period ranged from 18 to 32 months). The recruited patients had a median age of 51 years (22-65 years), 24 patients had T1 tumors, 37 had T2 and only 2 recruited patients had T3 disease, and all were node negative. The dosimetric parameters for the coverage of target volumes and dose constrain for OAR were in compatible compliance with our protocol. The mean duration of the whole course of radiation (in days) was 22+/-2.1 days. About 20.63% of the patients had GII acute skin toxicity, while none developed GIII or more acute skin toxicity. As regard late skin toxicity (71.43%) of the patients had G0 late skin toxicity, and (28.57%) of the patients had G1 late skin toxicity no patients had G3 nor G4 late skin toxicity. Till last follow-up date, none of the recruited patients was documented to have >G0 heart nor lung toxicity. Also, none had documented loco-regional nor distant relapse. Regarding cosmetic outcome, 80.95% of the patients were reported as having excellent cosmetic score, while 19% were reported as good (as per Harvard criteria).

#### Conclusion

The proposed accelerated hypofractionated course of WBI with a concurrent TB boost shows acceptable acute toxicity and early cosmetic outcome, however longer follow up is required to better evaluate late toxicity, cosmetic & clinical outcomes.

#### EP-1332 An Urban Institution's Experience with the Oncotype DCIS Score: Predictors and Outcomes

T.Y. Andraos<sup>1</sup>, A. Orisamololu<sup>1</sup>, J. Fox<sup>1</sup>

<sup>1</sup>Montefiore Medical Center, Radiation Oncology, Bronx, USA

#### Purpose or Objective

The Oncotype DCIS Score<sup>®</sup> is a validated predictor of ipsilateral breast recurrence (IBR) in patients (pts) treated with lumpectomy for ductal carcinoma in-situ (DCIS). Criteria for its use are subjective and physician-dependent, and used to guide decision making for adjuvant radiation (RT). We evaluated possible predictors of the DCIS Score<sup>®</sup> and report on outcomes to date in our pt population.

#### Material and Methods

DCIS Scores<sup>®</sup> were available on 90 women who underwent lumpectomy between December 2011 and June 2018. DCIS Scores<sup>®</sup> were reported as low (score 0-38), intermediate (39-54), and high risk (>54). 10 pts' scores were the modified results accounting for age < or >50 and size < or > 1cm. Follow-up (F/U) was calculated from date of initial surgery to date of last mammogram or clinical exam. ANOVA, Chi-Square, and Pearson correlation tests were used to assess statistical comparisons between groups, with p <0.05 considered as statistically significant.

#### Results

Median age was 67 years (30-85). Median size on surgical pathology was 0.6 cm (0 - 4 cm), as measured on a single slide. Grade 1, 2, and 3 DCIS were present in 25 (27.8%),

47 (52.2%), and 18 (20%) of pts, respectively. Necrosis was observed in 46 cases (51.1%). All pts were estrogen receptor (ER) positive; 83 pts (92.2%) were progesterone receptor (PR) positive. Eleven pts (12.2%) underwent re-excision, and surgical margins were ultimately negative ( $\geq$  0.2 cm) in all. Median calculated Van Nuys Prognostic Index (VNPI) score was 6 (3-9). Median calculated Memorial Sloan Kettering (MSK) nomogram value for 10yr IBR risk was 8 (2 - 20). Median DCIS Score<sup>®</sup> was 11(0-79); 72 pts had low risk scores (80%). 26 pts (28.9%) received RT: 5/7 pts who had high risk scores, 6/11 with intermediate and 15/72 with low risk scores. 57 pts (63.3%) received hormonal therapy. High risk DCIS Score<sup>®</sup> correlated with higher nuclear grade (p<0.0001), necrosis (p=0.009), higher VNPI (P=0.002), and PR negativity (p=0.001). Pts with higher DCIS Scores<sup>®</sup> were more likely to have received RT (p=0.001). The MSK nomogram results did not correlate with the DCIS Score<sup>®</sup> results (Pearson correlation coefficient 0.464). Median MSK recurrence risks per Oncotype groupings were 8% in the low Oncotype DCIS risk group, 8% in the intermediate and 7% in pts within the high Oncotype risk group (p=0.256). At a median F/U of 2.13 years (0.04-6.45 years), there is no evidence of recurrence in any patient.

#### Conclusion

Pathologic factors including nuclear grade, necrosis, and PR status are strong predictors of DCIS Scores.<sup>®</sup> The VNPI correlated with DCIS Score<sup>®</sup>, whereas the more comprehensive and widely accepted MSK nomogram did not. Our results suggest a possible underestimation of risk by the MSK nomogram in those with intermediate-high risk DCIS Scores.<sup>®</sup> Long-term F/U is needed to confirm the validity of the DCIS Score<sup>®</sup> in our pt population, and to determine whether this assay versus the MSK nomogram can more accurately IBR risk.

#### EP-1333 Myocardial changes detected using Cardiac MRI in left breast patients treated with Radiation

S. Tang<sup>1</sup>, E.S. Koh<sup>1</sup>, R. Rai<sup>2</sup>, J. Otton<sup>3</sup>, D. Tran<sup>3</sup>, G. Delaney<sup>1</sup>, L. Holloway<sup>2</sup>, B. Schmitt<sup>4</sup>, G. Liney<sup>5</sup>

<sup>1</sup>Ingham Institute for Applied Medical Research, CCore, Liverpool, Australia ; <sup>2</sup>Ingham Institute for Applied Medical Research, Medial Physics, Liverpool, Australia ; <sup>3</sup>Liverpool Hospital, Department of Cardiology, Liverpool, Australia ; <sup>4</sup>Siemens Healthcare Pty Ltd, Siemens Healthcare, Sydney, Australia ; <sup>5</sup>Ingham Institute for Applied Medical Research, MRI Physics, Liverpool, Australia

#### Purpose or Objective

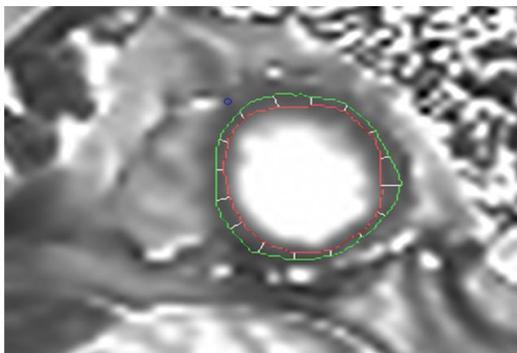

Acute cardiac changes following tangential breast radiation(RT) have been demonstrated using cardiac scintigraphic studies and advanced echocardiographic techniques. This study evaluates the prospective use of cardiac MRI (CMR) in detecting myocardial changes using serial cardiac mapping techniques over a 12 month period.

#### Material and Methods

For 21 left-sided female breast cancer patients (median aged 59 years(38-76)) receiving tangential RT(prospectively recruited between October 2015 and October 2016), three cardiac MRI scans were obtained; a baseline scan 2-3 days before adjuvant RT, 6 - 8 weeks and 12 months respectively following RT. No patients received chemotherapy. A clinical modified look-locker inversion(MOLLI) sequence was used to acquire myocardial short axis T1 maps, pre and 15 minutes post administration of gadolinium-based contrast agent(Gadovist), as well as T2 maps at 3Tesla. Myocardial partition coefficient( $\lambda$ ) was calculated according to ( $\Delta R1$ myocardium/ $\Delta R1$ blood), and extra cellular volume(ECV) was derived from  $\lambda$  by adjusting (1-haematocrit). Two independent T1/T2/ECV map segmentations of the left ventricle were obtained using cvi42, and averaged for analysis(see Figure 1). Single breath-hold SSFP cine acquisitions of the cardiac short axis

were used to determine end diastolic volume (EDV) and end systolic volumes (ESV), LVEF and myocardial mass (systolic and diastolic) indices. Paired t-tests were used to compare the baseline scan with the follow up (6-8 week) and 12 month post treatment scan. A p value of  $\leq 0.05$  was considered significant.

Figure 1 – Segmentation of the left ventricle in short axis (level of mid ventricle) on T1 map

## Results

Mean heart dose was 2.6Gy (1.5-3.9). LVEF, EDV, ESV were not significantly different 6 - 8 weeks, or 12 months following radiotherapy. LV myocardial mass index (LVMMI) (systolic), was significantly increased at 6-8 weeks follow up (53.6 vs 48.4g/m<sup>2</sup> p<0.001) and 12 months (55.5 vs 48.4g/m<sup>2</sup> p<0.001) following radiotherapy. LVMMI (diastolic) was significantly increased at 12 months (mean 58.5 vs 52.2g/m<sup>2</sup> p<0.001). T1 and T2 values were not significantly elevated at the 6-8 week follow up scan, but were significantly elevated at 12 months (T1(ms) - 1213 vs 1246ms p=0.02, T2(ms) - 43.2 vs 45.7ms p<0.01). There was no change in ECV values. Detailed results can be found in Table 1.

Table 1 – Baseline, follow (6-8 weeks) up and 12 month post left breast radiation values

Scan Metric	Baseline Scan	Follow up 6-8 week Scan	12 month Scan
Left ventricular ejection fraction (%)	63.6 (50.2-77.2)	64.7 (56.5-75.3)	64.6 (51.9-80.7)
End diastolic volume (mL)	104.7 (74.0-148.1)	106.0 (80.2-139.8)	107.1 (78.1-160.3)
End systolic volume (mL)	38.0 (23.2-29.3)	37.5 (22.0-51.5)	38.2 (15.8 - 59.3)
Myocardial Mass Index (diastolic) (g/m <sup>2</sup> )	52.2 (39.1-64.5)	57.5 (46.4-59.5) †	58.5 (50.6-75.7) †
T1 Relaxation time (ms)	1213 (1111-1291)	1230 (1165-1311)	1246 (1180-1311) †
T2 Relaxation time (ms)	43.2 (39.6 - 50.1)	42.4 (26.7 - 46.2)	45.7 (41.2-51.7) †
Extracellular Volume (%)	28.4 (23.6 - 32.9)	29.2 (25.3 - 33.0)	27.9 (24.7-37.0)

All reported values are median values (range). †denotes value statistically significant from baseline value with p<0.05.

## Conclusion

Preliminary results suggest that than the myocardial mass index (both systolic and diastolic) increases at 12 months following RT. T1 and T2 values were not significantly different at 6-8 weeks compared with baseline, however were increased at 12 months following radiotherapy. These results may suggest myocardial inflammation post RT occurs and may be detected utilising CMR.

## Electronic Poster: Clinical track: Lung

### EP-1334 Risk factors for esophagitis after hypofractionated palliative (chemo)radiotherapy for NSCLC

C. Nieder<sup>1</sup>, K. Imingen<sup>1</sup>, B. Mannsåker<sup>1</sup>, R. Yobuta<sup>1</sup>, E. Haukland<sup>1</sup>

<sup>1</sup>Nordlandssykehuset HF, Dept. of Oncology and Palliative Medicine, Bodø, Norway

#### Purpose or Objective

Esophagitis influences quality of life and might cause weight loss, treatment interruption and, in severe cases, hospitalization. Previous studies of risk factors mainly relate to curative treatment for non-small cell lung cancer (NSCLC), which often involves concomitant chemoradiation (CRT). Given the uncertainty around extrapolation of dose constraints, we analyzed risk factors in patients treated with hypofractionated palliative regimens, mainly for stage III and IV disease.

#### Material and Methods

A retrospective review of 106 patients treated with palliative 3-D conformal radiotherapy or CRT between 2009 and 2017 was performed. Inclusion criteria: prescribed total dose 30-54 Gy, dose per fraction 2.5-4 Gy (once daily, five fractions per week), esophageal dose >1 Gy. Uni- and multivariate analyses were performed to identify predictive factors for esophagitis grade  $\geq 1$  (CTCAE 5.0). Clinical information was abstracted from our electronic patient record system. All patients were followed during treatment by oncology nurses and physicians. Treatment plans were calculated with Varian Eclipse TPS.

#### Results

Forty percent of patients were treated with 15 fractions of 2.8 Gy (42 Gy) and 30% also received chemotherapy according to the CONRAD study regimen (induction and concomitant Carboplatin/Vinorelbine) published by the Norwegian Lung Cancer Group. Thirty-four percent were treated with 10 fractions of 3 Gy. Stage IV NSCLC was present in 47%. Esophagus Dmax was 39 Gy (population median) and Dmean 15 Gy. Overall 31% of patients developed esophagitis (26% grade 2-3, no grade 4-5). Several dosimetric parameters correlated with the risk of esophagitis (Dmax, Dmean, D5cc, V20, V30, V35, V40). Dmax outperformed other dosimetric variables in multivariate analysis. Furthermore, concomitant chemotherapy significantly increased the risk of esophagitis (for Dmax >39 Gy from 23 to 46%), while oral steroid medication reduced it (all p<0.05 in multivariate analysis). Age, gender and smoking were not significantly associated with esophagitis. When using general NSCLC dose constraints for mean esophagus dose the following rates of grade 2-3 esophagitis were observed: 29% for mean <34 Gy and 22% for mean  $\leq 28$  Gy. In contrast, mean <20 Gy resulted in 11% and mean <15 Gy in 5%. Median actuarial overall survival was 12 months in the CRT cohort and 7 months after RT alone (log-rank p=0.05).

#### Conclusion

In order to reduce the rates of grade  $\geq 2$  esophagitis after hypofractionated palliative treatment lower mean doses than those recommended in other NSCLC settings are preferable. Besides esophageal dose, CRT is the main risk factor for esophagitis. However, CRT also prolongs survival. Additional work is needed to confirm that steroids are able to modify the risk (or to rule out confounding effects of baseline variables not included in our database).

### EP-1335 Interaction of V20 and SUVmax as a predictor of lung toxicity

D. Scepanovic<sup>1</sup>, A. Masarykova<sup>1</sup>, P. Povinec<sup>2</sup>

<sup>1</sup>National Cancer Institute, Radiation Oncology, Bratislava, Slovakia ; <sup>2</sup>PET Centrum BIONT- a. s., Nuclear Medicine, Bratislava, Slovakia

#### Purpose or Objective

The present study aimed to determine if bilateral lung V20 (volume of the whole lung receiving  $\geq 20$  Gy) in connection with the standardized uptake value (SUV) determined with 18F-FDG PET/CT can be used to predict radiation pneumonitis (RP) in lung cancer patients who received radical radiotherapy.

#### Material and Methods

A total of 60 patients with non-small cell lung cancer received 18F-FDG PET/CT examination prior to

radiotherapy. All patients were treated with three-dimensional radiation therapy (3DRT). Radiotherapy was administered five times per week at 1.8-2.0 Gy per time, for a total dose of 60-66Gy. Consecutive eligible patients were assigned to cohorts of nine. SUVmax of each cohort was increased from 3.5 to 6.5, 9.5, 12.5, 15.5, and so on. The cut off value of V20 was 30%.

#### Results

There were 54 patients with V20 < 30% and 6 patients with V20 > 30%. There were no statistically significant differences in the different SUVmax cohorts between the non RP group and the RP group. Eighteen percent of all patients had lung toxicity grade 2. However, no one had severe toxicity. Among our patients there was no difference in the occurrence of lung toxicity either depending of the SUVmax or V20, or their interaction (p=1).

#### Conclusion

In conclusion, the FDG uptake in lung tissue prior irradiation was not associated with the V20 to predict radiation pneumonitis among our patients.

#### EP-1336 Immunogenic prognostic factors in patients with brain metastases from non-small cell lung cancer

H. Doi<sup>1</sup>, K. Nakamatsu<sup>1</sup>, S. Anami<sup>1</sup>, T. Uehara<sup>1</sup>, Y. Wada<sup>1</sup>, K. Fukuda<sup>1</sup>, M. Inada<sup>1</sup>, K. Ishikawa<sup>1</sup>, S. Kanamori<sup>1</sup>, H. Monzen<sup>1</sup>, Y. Nishimura<sup>1</sup>

<sup>1</sup>Kindai University Faculty of Medicine, Department of Radiation Oncology, Osaka-Sayama, Japan

#### Purpose or Objective

Immune checkpoint inhibitors have significantly improved survival outcomes among patients with recurrent and refractory non-small cell lung cancer (NSCLC). Whole brain radiotherapy (WBRT) might be useful for both intracranial tumor control and improving the immune response to systematic disease. This study aimed to identify prognostic factors for brain metastases (BMs) from NSCLC after WBRT. However, there are no clear prognostic factors for WBRT, especially among patients with BMs in terms of their potential immune response. Therefore, the present study aimed to identify prognostic factors for response to radiotherapy among patients with BMs from NSCLC.

#### Material and Methods

This study retrospectively evaluated 100 consecutive patients who underwent WBRT for BMs from NSCLC between December 2012 and October 2017. All patients had pathologically confirmed NSCLC (82 adenocarcinoma, 12 squamous cell carcinoma, and 6 others) and a diagnosis of BMs using images. Blood test data from between 4 weeks before WBRT and the first day of the WBRT course were available. All patients were typically treated using conventional external beam radiotherapy with opposed lateral treatment fields that encompassed the entire brain. The prescribed dose was calculated at the isocenter of the radiation fields based on daily treatments. Patients received a median dose of 30 Gy (range; 14- 45 Gy) in 10 fractions (5- 18 fractions). Clinical factors were tested for associations with overall survival after WBRT.

#### Results

The median follow-up time was 134 days (range: 14-1,395 days), and the median survival time was 143 days, and the 1-year survival rate was 30.4%. Univariate analyses revealed that better survival was associated with an Eastern Cooperative Oncology Group performance status (ECOG-PS) of 0-1, adenocarcinoma pathology, programmed death-ligand 1 (PD-L1) expression, no history of local therapy for BMs, no extracranial disease, LDH levels of <1.5 times the upper limit of normal, a neutrophil-to-lymphocyte ratio (NLR) of <5.0 (11-13), an RPA class of ≤2, and a GPA score of ≥1.5. In the multivariate analyses, better survival was independently associated with PD-L1 expression, no history of local

therapy for BMs, no extracranial disease, and an NLR of <5.0.

#### Conclusion

A low NLR and positive PD-L1 expression independently predict prognosis in patients with BMs from NSCLC after WBRT. These findings suggest that the potential immune response may influence survival among patients with BMs.

#### EP-1337 IMRT/VMAT vs. 3DCRT: the pathological and the clinical outcomes in LANSCLC treated with trimodality

S. Appel<sup>1</sup>, Y.R. Lawrence<sup>1</sup>, Z. Symon<sup>1</sup>, O. Haisraely<sup>1</sup>, M. Perlman<sup>2</sup>, E. Ofek<sup>2</sup>, D. Alezra<sup>1</sup>, T. Katzman<sup>1</sup>, N. Honig<sup>1</sup>, M. Ben-ayun<sup>1</sup>, T. Rabin Alezra<sup>3</sup>, S. Dubinsky<sup>1</sup>, J. Kraitman<sup>1</sup>, L. Tsvang<sup>1</sup>

<sup>1</sup>Chaim Sheba Medical Center, Radiation Oncology, Ramat Gan, Israel ; <sup>2</sup>Chaim Sheba Medical Center, pathology, Ramat Gan, Israel ; <sup>3</sup>Tel-Aviv Sourasky Medical Center, Radiation Oncology, Tel Aviv, Israel

#### Purpose or Objective

More advanced radiation techniques, such as Intensity-modulated radiotherapy (IMRT) and Volumetric Arc Therapy (VMAT) are associated with better normal-tissue sparing compared with traditional 3-dimensional conformal radiation (3DCRT). Conversely, these techniques require a high degree of technical expertise and may potentially inadvertently under-dose tumor due to interplay between beam intensity-modulation and tumor movement. We sought to assess the impact of different radiation techniques on pathological and clinical outcomes in non-small cell lung cancer (NSCLC).

#### Material and Methods

We conducted a retrospective analysis of LANSCLC patients treated with neoadjuvant chemoradiation followed by surgery between August 2012 and August 2018 at the Sheba Medical Center. We recorded the patient, stage, histology, and treatment details. Radiation dose was prescribed to cover 95% of PTV to high dose (60 Gy); contouring was according to the co-registered PET-CT, without elective nodal irradiation and delivered with daily on-board image guidance (IGRT including KV/KV or CBCT). Primary endpoints were pathologic regression scored according to College of American Pathologists recommendations, as well as the average percent of residual tumor cells.

Additional endpoints: surgical margins, the local control rates (LC), disease free (DFS) and overall survival (OS). For the purposes of analysis IMRT and VMAT were combined into a single category. Statistics included non parametric tests, Kaplan Meier estimates; and log rank test

#### Results

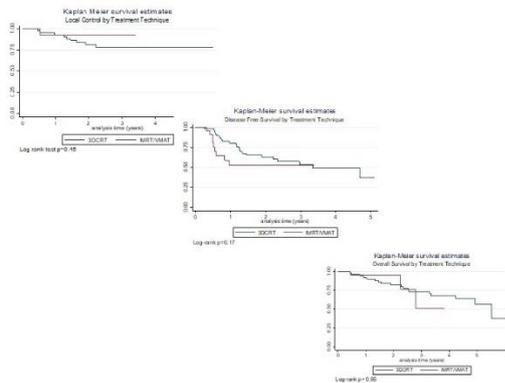

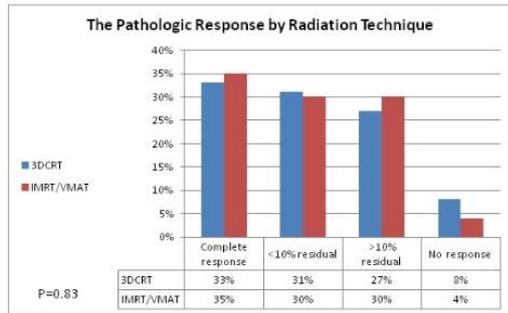

Our cohort included 74 pts, mean age 65.9 (45-79.7), males in 51/74 (69%) adenocarcinoma in 46/74 (62.1%) squamous in 21/74 (28.3%), stage 3 in 59/74 (79.7%), chemotherapy with platinum-based doublets in 72/74 (97.3%).

Radiation dose was 54 Gy and above in 90.5%, mode 59.2Gy. Radiation technique was 3DCRT in 51/74 (68.9%), IMRT in 5/74 (6.7%) and VMAT in 18/74 (24.3%). The use of IGRT-CBCT was in 14/23(61%) in IMRT/VMAT technique, compared to the 12/51(23.5%) in 3DCRT p<0.001.

Major pathologic response (including pCR and <10% residual cells) was similar between radiation techniques: for 3D: 32/51 (62.7%) and for IMRT/VMAT: 15/23 (65.2%) p=0.83. The rate of pCR was similar: for 3DCRT 17/51 (33.3%) and for IMRT/VMAT 8/23 (34.8%) p=0.9. Percent of pathological residual disease (mean±SD) was for 3DCRT: 16 % (SD±25.5) and for IMRT/VMAT: 22% (SD±27.2) p=0.36. Margins were negative in 90.1% (46/51) of patients treated with 3D vs. 89.4% (17/19) in IMRT/VMAT p=1.

At median follow-up of 3.2 years, 2 year local control of 83% (95%CI 70-91%), 2 yrs DFS was 59% (95%CI 46-70) and 3 yrs OS was 72.3% (95%CI 58-82). There was no difference

in LC (p=0.45) DFS (p= 0.17) and OS (p=0.9) between the techniques.  
 We found statistically significant improved in DFS in the major pathological response: HR 2.3 (95%CI 1.13-4.75) (p=0.02).

**Conclusion**

When used to treat NSCLC in the neoadjuvant setting, both IMRT/VMAT and 3DCRT produce comparable clinical and pathologic tumor-control outcomes.

**EP-1338 Hypofractionated Chemoradiotherapy for stage-3 Non-small cell Lung cancer- Single centre experience**

A. Patibandla<sup>1</sup>, N. Mohammed<sup>1</sup>, I. Brisbane<sup>1</sup>, P. McLoone<sup>2</sup>, J. Hicks<sup>1</sup>

<sup>1</sup>Beatson West of Scotland Cancer centre, Clinical Oncology, Glasgow, United Kingdom ; <sup>2</sup>University of Glasgow, Statistics, Glasgow, United Kingdom

**Purpose or Objective**

Concurrent chemoradiotherapy is standard of care for locally advanced stage-3 non-small cell lung cancer (NSCLC). Hypofractionated radical radiotherapy ( 5500cGy in 20 fractions over four weeks ) with chemotherapy (cisplatin & vinorelbine) has been proven safe and effective in a randomised phase -2 trial(SOCCAR trial). In this retrospective study we looked at our institutional experience of delivering this regimen.

**Material and Methods**

Electronic records were retrospectively reviewed for all stage-3 NSCLC patients who had SOCCAR regimen from January 2012 to December 2016. Data was censored on 31<sup>st</sup> March 2018. Kaplan-Meier analysis was used to estimate median survival.

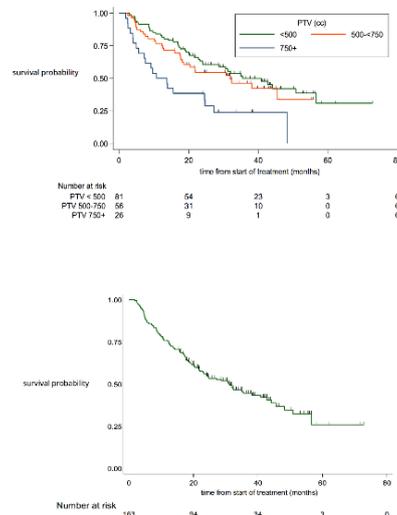

**Results**

Total of 163 patients, all the stage-3 NSCLC patients treated with SOCCAR regimen between January 2012 to December 2016. Median age- 63 years.

All patients except one were staged by PET-CT prior to starting treatment. All were either ECOG performance status of 0 or 1. Squamous cell carcinoma- 55%,

Adenocarcinoma- 31%, other- 14%.

Median follow up was 3.2 years. Median overall survival 31.2 months (95% CI 21.9- 42.8). On treatment toxicity was tolerable with no treatment related deaths. 20% had local recurrence, 23% had distant metastases and 7% had local recurrence & distant metastases. 77% of patients were treated by Volumetric modulated arc radiotherapy (VMAT) plan and 23% by conventional plan. The larger the planning target volume (PTV) lesser the median overall survival.

**Conclusion**

Hypofractionated radiotherapy with chemotherapy was well tolerated in stage -3 NSCLC patients. Toxicity was minimal and no non-cancer death within 90 days of treatment. Overall median survival was superior to all arms in recently published international phase 3 trials.

**EP-1339 Clinical outcomes of stereotactic radiotherapy using flattening-filter-free in lung cancers**

T. Taweesakulvashra<sup>1</sup>, S. Kitpanit<sup>1</sup>, A. Songthong<sup>1</sup>, C. Chakkabat<sup>1</sup>, N. Amornwicheit<sup>1</sup>, P. Alisanant<sup>1</sup>, C. Nantavithya<sup>1</sup>, C. Lertbutsayanukul<sup>1</sup>, K. Shotelersuk<sup>1</sup>, C. Khorprasert<sup>1</sup>, D. Kannarunimit<sup>1</sup>

<sup>1</sup>King Chulalongkorn Memorial Hospital- Chulalongkorn University, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand

**Purpose or Objective**

SBRT using FFF has been increasingly applied due to its benefits in escalating dose rate, short treatment time and less out-of-field dose, however, studies investigating outcomes and toxicities of this technique in lung cancers are lacking. Thus, we conducted a review to assess efficacy in terms of 2-year local control (LC), progression free survival (PFS), overall survival (OS) and treatment-related toxicities in patients with early-stage NSCLC and oligometastatic lung cancers.

**Material and Methods**

From February 2014 to July 2018, 101 patients underwent lung SBRT with FFF were retrospectively reviewed. All patients underwent SBRT with VMAT and unflatten beam using 6 and 10 MV photon. Patients with follow up period less than six months or lack of follow-up imaging were excluded. Dose and fractionation were selected from our institutional protocol. LC, PFS and OS were analyzed using Kaplan-Meier method. Early and late toxicities (6 months after SBRT) were evaluated. All target lesions were accounted for LC assessment.

## Results

101 patients and 143 lesions with median follow up time of 24 months were included for the analysis. 22 patients with 22 lesions were early NSCLC and 79 patients with 121 lesions were lung metastases in which 40% were from colorectal cancers and 21.4% were from primary lung cancers. SBRT fractionation ranged from 48-60 Gy in 3-5 fractions (10-18 Gy/fraction, BED 100-151 Gy10) and 25-60 Gy in 1-7 fractions (5-25 Gy/fraction, BED 36-180 Gy10) for early NSCLC and oligometastatic lung cancers, respectively. All patients completed treatment without any interruption. Mean tumor volume was 22.7 cc and mean PTV volume was 52.1 cc. 2-year LC, PFS and OS were 90.9%, 50.3% and 83.5% for early NSCLC, and 92.6%, 50% and 74.8% for metastatic lung cancers. Early toxicity was low with only five percent reporting CTCAE grade 2. The most common acute toxicity was pneumonitis (23.7%). No toxicity greater than grade 2 was found for early and late toxicity. BED>70 Gy10 was associated with better OS compared with less than 70 Gy for lung metastasis (HR 0.29, 95%CI = 0.09-0.84).

## Conclusion

Lung SBRT using FFF-technique provides promising clinical outcomes for both early-stage NSCLC and oligometastatic lung cancer patients. BED>70Gy10 in metastatic lung cancers may be adequate to yield good LC and OS. A prospective study is encouraged to confirm this result.

### EP-1340 Lactate dehydrogenase predicts survival in small cell lung cancer patients with brain metastases

S. Anam<sup>1</sup>, H. Doi<sup>1</sup>, K. Nakamatsu<sup>1</sup>, T. Uehara<sup>1</sup>, Y. Wada<sup>1</sup>, K. Fukuda<sup>1</sup>, M. Inada<sup>1</sup>, K. Ishikawa<sup>1</sup>, S. Kanamori<sup>1</sup>, Y. Nishimura<sup>1</sup>

<sup>1</sup>Kindai University Faculty of Medicine, Department of Radiation Oncology, Osaka-Sayama, Japan

## Purpose or Objective

Small-cell lung cancer (SCLC) represents < 20% of total lung cancer cases with poor survival outcome especially in patients with extensive disease. SCLC patients often develop brain metastases (BMs) over the course of the disease. However, specific predictors for outcomes associated with SCLC and BMs remain unclear.

## Material and Methods

Between February 2008 and December 2017, we identified 48 consecutive patients with BMs from SCLC who underwent WBRT at our institution. All patients had pathologically confirmed SCLC with a diagnosis of BMs, which was based on images. Blood test data between 4 weeks before the WBRT and the first day of WBRT treatment were available. When WBRT started, all patients had extracranial diseases except for one. The median age was 70 years; 42 (88%) and 6 (13%) patients were male and female, respectively. At the initial staging, 32 (67%) and 16 (33%) patients had extensive disease (ED) and limited disease (LD) SCLC, respectively. In addition, 22 (46%) patients had BMs at the time of the initial diagnosis of SCLC. All patients were typically treated with WBRT using conventional external beam radiotherapy and lateral-opposed treatment fields that encompassed the entire brain. Thirty-three (69%), 6 (13%), and 9 (19%) patients received the prescribed total dose of 30 Gy in 10 fractions, 37.5 Gy in 15 fractions, and 40 Gy in 16 fractions, respectively.

## Results

Forty patients died in the follow-up period. Symptoms due to BMs were observed in 25 (52%) patients. Among the 25 patients with symptomatic BMs, 16 (64%) showed symptom improvement after WBRT. The median survival was 232 days and the 1- and 2-year overall survival rates were 34.4% and 5.8%, respectively. The intracranial failures were found in 36% of patients. Univariate analyses revealed that longer survival was associated with 5 factors: Eastern Cooperative Oncology Group performance status (ECOG-PS) of 0-1 (p=0.0006), asymptomatic BMs

(p<0.0001), LDH levels in the normal range (p=0.0036), RTOG-RPA class 2 (p=0.0013), and a GPA score of ≥1.5 (p=0.0486). In patients with normal and elevated LDH values, the 1-year survival rate was 54.7% and 17.6%, respectively. No significant impact on survival after WBRT was observed for the clinical stage at the initial diagnosis, presence of BMs at the initial diagnosis, maximum diameter of BMs, number of BMs, prescription dose of WBRT (Gy), or the pre-WBRT serum levels of NLR and PLR. In multivariate analyses, elevated LDH levels (p=0.0133) and presence of symptoms due to BMs (p=0.0130) were found as significant independent predictors of poor survival.

## Conclusion

The present study revealed that high LDH level and the existence of BM-related symptoms predict a significantly poor survival after WBRT for BMs from SCLC. Elevated LDH may yield valuable information to identify patients with BMs who have poor survival outcomes.

### EP-1341 Evaluation of tumor motion variability with and without abdominal compression plate in lung SBRT

K. Talapatra<sup>1</sup>, V. Raturi<sup>1</sup>, R. Vadgaonkar<sup>1</sup>, S. Jadhav<sup>1</sup>, P. Chadha<sup>1</sup>, V. Mhatre<sup>1</sup>, S. Pilakkal<sup>1</sup>

<sup>1</sup>Kokilaben Dhirubhai Ambani Hospital and Medical Research Institute, Radiation Oncology -, Mumbai, India

## Purpose or Objective

To evaluate the significance of abdominal compression plate (ACP) with respect to variability in lung tumor motion and setup.

## Material and Methods

Fifteen consecutive lung cancer patients who received SBRT in our institute between January 2016 and December 2016 were enrolled prospectively. All patients were immobilized using Vacloc on SBRT base plate. Out of fifteen, six patients were treated with ACP and remaining nine were treated without plate. Cone beam CT scan was acquired before delivery of each fraction and appropriate shifts were applied after matching target volumes and OARs. Mean and standard deviation were calculated. Unpaired t test used for statistical analysis and all values p<0.05 was considered as statistically significant.

## Results

Tumor was located in upper lobe for 10 patients, in middle lobe for 2 and in lower lobe for 3 patients. Mean tumor motion was observed without ACP in comparison to with ACP is cranio-caudal (CC) direction 0.36±0.2cm versus 0.37±0.15 cm (p=0.28, CI: 0.32 to 0.1), in antero-posterior (AP) direction 0.34±0.2 cm versus 0.37±0.15 cm (p=0.879, CI: 0.19 to 0.22), in medio-lateral (ML) 0.38±0.14 cm versus 0.26 ±0.09 cm (p=0.1, CI: 0.25 to 0.02) and rotation motion observed was pitch 0.77°±0.46° versus 0.37° ± 0.1° (p=0.06, CI: 0.82 to 0.02), roll 1.24 °±0.8° versus 0.36°±0.21° (p=0.02, CI: 1.6 to 0.14), yaw 0.04°±0.43° versus 0.28°±0.18° (p=0.001, CI: 1.17 to 0.36).

	SBRT lung	Vertical (cm)	Lateral (cm)	Longitudinal (cm)	Pitch (°)	Roll (°)	Rotational (°)
N	Without ACP	9	9	9	9	9	9
	With ACP	6	6	6	6	6	6
Mean	Without ACP	0.338	0.377	0.358	0.767	1.24	1.05
	With ACP	0.237	0.267	0.375	0.370	0.368	0.282
Standard error mean	Without ACP	0.0673	0.0467	0.0679	0.155	0.267	0.144
	With ACP	0.0572	0.0395	0.0617	0.0437	0.0894	0.0759
Median	Without ACP	0.280	0.340	0.300	0.750	1	0.880
	With ACP	0.185	0.220	0.340	0.405	0.345	0.265
Standard deviation	Without ACP	0.202	0.140	0.204	0.465	0.801	0.433
	With ACP	0.140	0.0967	0.151	0.107	0.219	0.186
Variance	Without ACP	0.0408	0.0196	0.0414	0.217	0.642	0.187
	With ACP	0.0196	0.00935	0.0229	0.0114	0.0480	0.0346

## Conclusion

This study demonstrates the benefit of the abdominal compression plate in respiratory tumor motion to produce a high efficient decrease in breathing induced tumor motion especially the rotational movements (roll and yaw).

**EP-1342 SBRT for central lung malignancies using a Simultaneous Integrated Protection (SIP) approach**  
 R. Mazzola<sup>1</sup>, R. Ruggieri<sup>1</sup>, F. Vanessa<sup>1</sup>, R. Michele<sup>1</sup>, G.L. Niccolò<sup>1</sup>, R. Francesco<sup>1</sup>, N. Luca<sup>1</sup>, C. Stefanie<sup>2</sup>, A. Filippo<sup>1</sup>  
<sup>1</sup>Sacro Cuore Don Calabria Cancer Care Center, Radiation Oncology, Negrar, Italy; <sup>2</sup>University Hospital- LMU, Radiation Oncology, Munich, Germany

#### Purpose or Objective

It is recognized that Stereotactic Body Radiotherapy (SBRT) for centrally located lung malignancies is affected by high rates of severe toxicity. In the present study, we report the clinical outcomes following a novel intensity-modulated radiotherapy prescription dose, termed simultaneous integrated protection (SIP) for nearby organs at risk (OARs).

#### Material and Methods

The present study is a mono-institutional prospective observational study. The inclusion criteria were: single central lung lesion receiving SBRT; absence of extra-thoracic disease; Karnofsky performance status > 70; maximum tumor diameter < 5 centimeters (cm); at least 6 months of follow up after SBRT. Lung malignancies were defined as central according to the International Association for the Study of Lung Cancer (IASLC) recommendations (i.e., tumor within 2 cm to any mediastinal critical structure). The prescribed total doses of SBRT were: 70 Gy in 10 fractions and 60 Gy in 8 fractions. For ultra-central located lesions, a dose of 60 Gy in 10 fractions was delivered. The main planning instructions were: (1) to remain within the limits of the given dose constraints for an OAR; (2) to make use of the maximum possible dose to the OARs to minimize dose inhomogeneity for PTV. SBRT-related toxicity was prospectively assessed according to Common Terminology Criteria for Adverse Events (CTCAE) v4.0. The primary clinical end-point was the toxicity SBRT-related. Secondary endpoint was local control.

#### Results

According to the inclusion criteria of the present analysis, 40 patients affected by a single central malignancy were selected. The median follow up was 20 months (range 6-58 months). The median age was 72 years (range 30-81 years).

The median distance between tumor and mediastinal healthy structures was 0.6 cm (range 0- 1.8 cm). The one-year local control rate was 91%. The median time to local progression was 13 months (range 6-46 months). One-year distant progression free survival rate was 71.7%. At the time of the analysis, the 1- and 2- years overall survival rates were 86.9% and 72.6%, respectively. Acute and late clinical pulmonary toxicity  $\geq$  grade 2 were recorded in 2 out of 40 patients (5%) and 3 out of 40 patients (7%). No patient experienced cardiac toxicity. No narrowing or stenosis of any airway or vessel was registered.

#### Conclusion

SBRT using a PTV-SIP approach for single central lung malignancies allowed to achieve low toxicity SBRT-related with acceptable local control.

#### EP-1343 Multimodality Repeated-Ablative Therapies In Oligorecurrent Pulmonary Metastatic Disease

A. Macagno<sup>1</sup>

<sup>1</sup>Paoli-Calmettes Institute, Radiotherapy, Marseille, France

#### Purpose or Objective

Stereotactic radiotherapy (SBRT) and percutaneous thermal-ablation (TA) are surgery alternatives for the management of pulmonary oligometastases. In this collaborative work we analysed patients who undergone iterative focal ablative treatments on pulmonary oligometastases. We hypothesized that some of these

patients, although with progression with additional pulmonary oligometastases, would still have a potentially curable oligometastatic disease and repeated ablative therapies could delay systemic treatment.

#### Material and Methods

From October 2011 to November 2016, a retrospective analysis was performed at 2 academic centre including patients treated with SBRT and TA for pulmonary oligometastases.

#### Results

**Patient characteristics:** A total of 198 lesions were treated for 102 patients; 45 patients (44.1%) underwent repeated focal treatment at the pulmonary site for an oligorecurrent disease. The median follow-up of the cohort was 22.5 months. Respectively, 29 patients, 12 patients and 4 patients had 2, 3 and 4 treatment sequences. The median interval between the first and the 2<sup>nd</sup>, the 2<sup>nd</sup> and the 3<sup>rd</sup>, and the 3<sup>rd</sup> and the 4<sup>th</sup> sequence was respectively 13 months, 12.5 months and 10.5 months. A colorectal or renal primary cancer was found significantly more often in multi-treated oligorecurrent patients in contrast to a bronchopulmonary primary cancer.

**Treatment characteristics:** The number of lesions treated by TA, SBRT and surgery are respectively 95, 103 and 14 lesions. 31 patients had a treatment combining several types of ablative techniques either to treat several pulmonary lesions during the same sequence, or during different treatment sequences. Patients treated with SBRT had more significantly central topography lesions compared to those treated with TA (p <0.005). Lesions treated with SBRT were significantly larger in diameter than those treated with TA (p = 0.003).

**Patient outcome:** The 3-year overall survival rates of patients who had a single treatment sequence versus those with repeated treatments were respectively 73.9% and 78.8%, not significantly different (p = 0.86). The 3-year systemic therapy free survival of multi-treated oligorecurrent patients was 51.2%. In univariate analysis, only WHO status is significantly associated with OS (p=0.04).

Tolerance of repeated treatments was excellent, one grade 4 toxicity was observed.

#### Conclusion

We established the first series of repeated multimodal local treatment for oligometastatic or oligorecurrent disease. These repeated treatments are effective with acceptable pulmonary toxicity. OS of patients treated with curative intent on several oligometastatic events is similar of those treated for a single oligometastatic event. Ablative treatments of their oligometastases may delay the use of systemic treatments, with the clinician's main concern being the maintenance of quality of life.

#### EP-1344 Helical Tomotherapy based SBRT in early stage lung cancer: a mono-institutional study (2014-2018)

F. Pastore<sup>1</sup>, A. Rese<sup>1</sup>, F. Francomacaro<sup>1</sup>, F. Cammarota<sup>1</sup>, G. Ametrano<sup>1</sup>, D. Toledo<sup>1</sup>, V. Iorio<sup>1</sup>

<sup>1</sup>Emicenter, Radiation Oncology, Mondragone, Italy

#### Purpose or Objective

To evaluate the use of Helical Tomotherapy (HT) based SBRT in the treatment of early stage lung cancer patients. The HT system employs a compact 6 MV Linac-based on CT ring gantry to rotationally deliver intensity modulated fan beams. Patients are translated through-out the gantry on a treatment couch, resulting in helical irradiation geometry. The HT unit also contains a mega-voltage CT detector array located opposite the radiation source for pre-treatment verification, allowing accurate re-positioning. This technique permits to precisely target tumors while minimizing impact on surrounding healthy tissue.

### Material and Methods

45 patients with early stage lung cancer (cT1-T2, cN0) were treated in our institution from 2014 to 2017 with HT-SBRT. No patients had positive lymphnodes in previous CT or PET/CT scan. No patients were fit for surgical indication due to concomitant medical conditions. The patients was placed with arms above the head, while the hands held a support such as a handlebar. All the CT images were acquired from the skull base to 3 cm below the diaphragm. CT axial scanning was performed at 3-mm intervals: for this purpose a CT Multislice GE Healthcare Discovery 590HT was used. The radiation oncologists contoured the volumes of interest (CTV) according to the RTOG guidelines. The planning target volume (PTV) was generated from the CTV volume by adding a 3 mm margin in all directions. Accurate delineation of organ at risk was performed. Treatment plans were evaluated on a dedicated TPS. In these patients, we used several radiotherapy schedules, according to volume, site of the lesions and guidelines.

### Results

At 2-year follow-up, we observed complete response in 18 patients (40%), partial response in 14 (31%), stable disease in 9 (18%), progressive disease in 5 (11%). The median OS was 40 months. We analyzed acute and late toxicity: G1 Radiation Pneumonitis was seen in 10/45 patients (22%) and G2 was observed in 4/45 patients (8%). No patients need hospitalization. Moreover, G1 dyspnea was observed in 4 patients (11%) and G2 in 2 patients (5%). G1 radiation esophagitis was seen in 4/45 patients (8%). Other major complications (pain or hematologic) were not observed. Radiation-induced rib fracture was not seen in our group of patients.

### Conclusion

HT is a safe and feasible technique to treat patients with early stage lung cancer. Acute toxicity was acceptable. This study had several limitations: a small number of patients, an heterogeneous clinical and radiological presentation of treated lung cancer and an incomplete follow up. Also the use of different fractionation must be enrolled into the limits of these analysis.

### EP-1345 Serum Lactate Dehydrogenase: A Predictor of Therapeutic Response to Radiation Therapy in SCLC?

L. Ana Rita Carvalho da Costa<sup>1</sup>, G. Sofia<sup>1</sup>, A. Gonçalo<sup>1</sup>, R. Darlene<sup>1</sup>, F. Paula<sup>1</sup>, M. Margarida<sup>1</sup>, P. Gabriela<sup>1</sup>  
<sup>1</sup>Centro Hospitalar de São João, Radioterapia, Porto, Portugal

### Purpose or Objective

Increased values for serum lactate dehydrogenase (LDH) were significantly associated with a reduced duration of survival in patients with small cell lung cancer (SCLC) in several studies published in recent years. Although serum LDH has been reported as a prognostic biomarker in SCLC, it is not known whether this is due in part to a worse tumor response to radiation therapy. Little is known about how this factor influences prognosis, including the probability of long-term disease-free survival. The present retrospective study aims to analyze whether there is a correlation between the serum LDH and the radiation therapy response and prognostic significance of serum LDH in SCLC treated with thoracic irradiation.

### Material and Methods

This retrospective study included all patients diagnosed with SCLC and serum LDH levels at diagnosis and before radiation therapy, treated with thoracic irradiation at CHSJ, between January 2005 and April 2018. A database was created with information obtained from patients' clinical records. The serum LDH was registered at diagnosis and before radiation therapy and its possible association with treatment response, time to tumor relapse/progression, progression-free survival (PFS) and overall survival (OS) was assessed. Statistical analysis was performed with SPSSv24. The impact of the raised values

for serum LDH on cancer outcomes was evaluated using the Fisher Exact Test, Kaplan-Meier plots and the log rank test.

### Results

The study included 45 patients, 31 males and 14 females, with a median age of 66 years. Median follow-up time was 16 months. Sixteen patients diagnosed with localized disease, who underwent concurrent or sequential chemoradiation therapy, and 29 patients presented with disseminated disease at the diagnosis, having performed thoracic consolidation irradiation after a good response to chemotherapy. Of the 45 patients, 18 were in the high serum LDH group and 27 were in the normal serum LDH group. In comparison to a normal serum LDH, a high serum LDH was significantly associated with worse OS (11.8 months vs 20.6 months,  $p=0,049$ , CI 95%) and worse PFS, but not statistically significant (9.9 months vs 16.1 months,  $p=0.138$ , CI 95%). There was no relation between a high serum LDH and treatment response.

### Conclusion

Current knowledge about prognostic factors in SCLC includes serum LDH, with high serum LDH being a poor prognostic factor with shorter survival time. The mechanisms underlying this association are not fully understood, and the impact of serum LDH on the response to radiation therapy is not known. The present study showed that there is no association between an increased LDH value and a worse response to radiotherapy, although patients with increased LDH value had shorter PFS and OS. However, due to the small sample size, no definite conclusions can be drawn, and future studies are needed to safely assess a possible relationship between serum LDH and response to radiation therapy.

### EP-1346 A framework for systematic clinical evaluation of the MR-linac for treatment of lung cancer patients

### Purpose or Objective

Our objective is to evaluate the introduction of the MR-linac (MRL) for the treatment of lung cancer patients via a systematic approach: R-IDEAL.

### Material and Methods

A recent innovation in radiotherapy is the MR-linac (MRL) developed by Elekta and Philips. The MRL combines a 1.5 T MRI with a 7 MV linac. It allows the acquisition of high resolution MR images for on treatment verification, adaption and response monitoring. Seven cancer institutions from Europe and North America, are working within the Elekta MR-Linac Consortium to evaluate the MRL within a framework called 'R-IDEAL' (Radiotherapy Idea Development Exploration Assessment Longterm Evaluation) (Verkooijen et al. Frontiers in Oncology 2017).

## Results

**STAGE 0:** We defined in 80 patients the optimal MRI sequences suitable for GTV and organ at risk (OAR) contouring: T2 Turbo Spin Echo (TSE), T2 TSE with fat sat, T1 radial gradient echo, and DIXON TSE. Two radiology-led workshops were organized and inter-observer agreement was assessed for OARs. These led to a consensus-based OAR atlas. A study is being prepared to compare the image quality of the current standard CBCT and MR images at baseline and mid-treatment for treatment verification and set-up correction.

**STAGE 1:** we will investigate the clinical feasibility of the MRL for standard of care radiotherapy and the scope for adaptive radiotherapy (margin reductions) and detecting changes in oxygenation during treatment on the MRL in patients with locally advanced (LA) Non-small Cell Lung Cancer (NSCLC).

**STAGE 2a/b :** Based on the results from stage 1 we will design a study aiming to reduce margins around the tumour and dose escalate in patients with LA NSCLC. Table 1. summarizes the ongoing and planned work within the Elekta MR-Linac Consortium.

	Pre-clinical studies	Idea	Development	Exploration	Assessment
	Stage 0	Stage 1	Stage 2a	Stage 2b	Stage 3
<b>Purpose</b>	Technical preparatory studies	Real time use of the MRL for treatment delivery in vivo	In vivo demonstration of the feasibility for treatment delivery	Pre-clinical proof of early clinical effectiveness and safety of the innovation	Final comparison of innovation against standard treatment
<b>Outcomes and planned work</b>	Development of MR-Linac sequences Development of a consensus atlas for MR-guided lung radiotherapy Comparison of quality of the pre-taken cone beam CT (CBCT) vs MR-Linac on image guidance	Investigation of the feasibility of standard RT on the MRL and real-time RT adaptation	Final answer to a cohort study of patients with reduced PTV margins	Investigation of dose escalation with hypofractionated RT in locally advanced NSCLC	Randomized controlled trial: standard of care vs dose escalated hypofractionated RT

## Conclusion

The aim of this programme of work is to generate robust evidence to support the introduction of the MRL and to improve outcomes of patients with LA NSCLC.

### EP-1347 “Risk adaptive” dose prescription in central NSCLC lesions in early stage NSCLC and lung metastases

M. Rigo<sup>1</sup>, N. Giaj-Levra<sup>2</sup>, V. Figliar<sup>2</sup>, R. Mazzola<sup>2</sup>, L. Nicosia<sup>2</sup>, F. Ricchetti<sup>2</sup>, R. Ruggieri<sup>2</sup>, F. Alongi<sup>3</sup>

<sup>1</sup>Istituto Oncologico Veneto - IRCCS Sacro Cuore Don Calabria Hospital, Radiation Oncology, Padova, Italy ;

<sup>2</sup>IRCCS Sacro Cuore Don Calabria Hospital, Radiation Oncology, Negrar-Verona, Italy ; <sup>3</sup>IRCCS Sacro Cuore Don Calabria Hospital - University of Brescia, Radiation Oncology, Negrar-Verona, Italy

### Purpose or Objective

Stereotactic ablative radiotherapy (SABR) is considered an innovative approach in early stage non-small cell lung cancer (NSCLC) and lung oligometastases. Initial experiences evaluated SABR in inoperable central (<2 cm from large bronchial tree) lung tumors located. Unacceptable levels of severe lung toxicity have been reported and “risk adaptive” dose prescription was considered an additional tool to overlap organs at risk (OAR). Aim of this study was to evaluate efficacy (local control) and tolerability in patients with a diagnosis of primary or metastatic central lung lesion, treated with a “risk adaptive” SABR approach.

### Material and Methods

Patients aged  $\geq 18$ -years with a histological or radiological proof of single central early stage NSCLC or lung oligometastases were enrolled. OAR were: homolateral lung, heart, spinal cord, esophagus, bronchial tree and chest wall. Total radiation dose was decided according to “risk adaptive” approach. In the case of overlap, sparing of the OAR was favoured to target volume coverage. A number of daily fractions between 4 and 10 was prescribed.

Radiological response was assessed according to RECIST, acute (<6 months) and late ( $\geq 6$  months) clinical and radiological toxicities were scored using Ickeoe et al. criteria and Common Terminology Criteria for Adverse Events version 4.0, respectively.

### Results

From January 2012 to September 2018, 29 patients with early stage or oligometastatic lung metastases received a SABR treatment. Median Biological equivalent dose prescription and fractions were: 105 Gy (range 96-119) and 10 (range 4-10), respectively. Median follow-up was 19 months. Local control was reported in 25 patients (86%), a local progression in 4 patients (14%). Early radiological abnormalities were identified as follows: no changes in 15 patients (52%), patch ground glass opacity in 9 (31%) and patchy consolidation and ground glass opacity in 5 (17%). Late radiological abnormalities were as follows: no changes in 5 cases (17%), scar-like pattern in 8 (28%), mass-like pattern in 10 (34%), not available in 6 cases (21%). Acute and late clinical pulmonary toxicity  $\geq$  grade 2 were recorded in 2 out of 29 patients (7%) and 3 out of 23 patients (13%).

### Conclusion

SABR “risk adaptive” prescription in inoperable central lung tumors is considered a safe and efficacy treatment. Higher accrual and follow-up are necessary to confirm these data.

### EP-1348 Clinical outcome of one-fraction early-stage lung SBRT: is it an option in selected patients?

I. Rodrigues<sup>1</sup>, T. Figueiredo<sup>1</sup>, J. Gagean<sup>1</sup>, C. Ferreira<sup>1</sup>, S. Conde<sup>1</sup>, L. Carvalho<sup>1</sup>, J. Cardia<sup>1</sup>

<sup>1</sup>Instituto Português de Oncologia do Porto Francisco Gentil, External Radiotherapy Department, Porto, Portugal

### Purpose or Objective

In our Institution, we follow an in-house protocol that encompasses fractionation schedules and constraints included in the RTOG 0813, 0236 and 0915 protocols (1x30Gy, 3x18-20Gy, 4x12-12.5Gy and 5x10Gy). Recently, ACROP-ESTRO guidelines suggested different fractionation schedules (3x15Gy and 4x12Gy), obtained by consensus among representatives from several European SBRT centers. The main purpose of this retrospective study was to evaluate the influence of fractionation on clinical outcome (global, specific and local progression-free survival) and toxicity in early-stage lung cancer patients in our Institution.

### Material and Methods

We retrospectively analysed all patients treated with SBRT for primary early-stage lung cancers in our department between 1st January 2012 and 31st December 2016. Treatments were carried according to RTOG protocols, and one-fraction schedules were selected for small peripheral tumors located away from the chest wall.

### Results

Between 2012 and 2016, 143 early-stage lung cancer patients (with 149 tumors) underwent SBRT. Most were males (79%) with a median age of 73 years (ranging from 51 to 91). Median follow-up was 22 months. Median maximum diameter was 2.3cm (from 0.7 to 5.5). Most tumors were adenocarcinomas (69%), followed by squamous carcinomas (28%). Thirty seven tumors were irradiated with 1 fraction of 30Gy, 18 with 3 fractions of 18-20Gy, 52 with 4 fractions of 12-12.5Gy and 39 with 5 fractions of 10Gy. As a result, 49.7% tumors remained stable, 24.8% exhibited a complete response and 19.5% a partial response. Disease progression was eventually observed in the treated area in 14 patients (9.8%), elsewhere in the lung in 16 patients (11.2%), in the lymph nodes in 15 (10.5%), and a distal progression was noted in 11 patients (7.5%). At 18 months, overall survival (OS) was 77.3%, disease-specific survival (DSS) was 91.9% and local progression-free survival (L-PFS) was 93.7%. The most

common acute toxicity was G1 fatigue (in 13 patients). The most frequently documented late side effect was G1 pneumonitis in 46 patients (followed by G1 dyspnea in 12, G1 thoracic pain in 11, and G1 cough in 10). Two ribs fractures occurred, and no toxicities greater than G3 were observed. Different fractionation schedules (including one-fraction) did not have an impact in OS, DSS or L-PFS, both in tumors  $\leq 2$ cm, and in tumors  $> 2$ cm, and no schedule exhibited a trend towards worse outcomes.

#### Conclusion

In our series, OS, DSS and L-PFS are in accordance with literature-reported outcomes. Although the low number of progressions may limit the analysis, one-fraction SBRT does not seem to be inferior to other fractionation schedules in appropriately selected patients. The low number of observed side effects (namely  $G \geq 3$ ) also did not allow us to infer any correlation with the fractionation schedule.

#### EP-1349 Three-d Surface Imaging as preferred tool for patients' set up in frameless SBRT for lung cancer

C.M.E. Perotti<sup>1</sup>, C. Pisani<sup>1</sup>, G. Loi<sup>2</sup>, A. Belli<sup>1</sup>, C. Bolchini<sup>1</sup>, Y. Huang<sup>3</sup>, J. Lyu<sup>3</sup>, M. Krengli<sup>4</sup>

<sup>1</sup>University Hospital "Maggiore della Carità", Department of Radiotherapy, Novara, Italy ; <sup>2</sup>University Hospital "Maggiore della Carità", Department of Medical Physics, Novara, Italy ; <sup>3</sup>Sichuan Cancer Center, Department of Radiation Oncology, Chengdu, China ; <sup>4</sup>University of "Piemonte Orientale"- University Hospital "Maggiore della Carità", Department of Translational Medicine- Department of Radiotherapy, Novara, Italy

#### Purpose or Objective

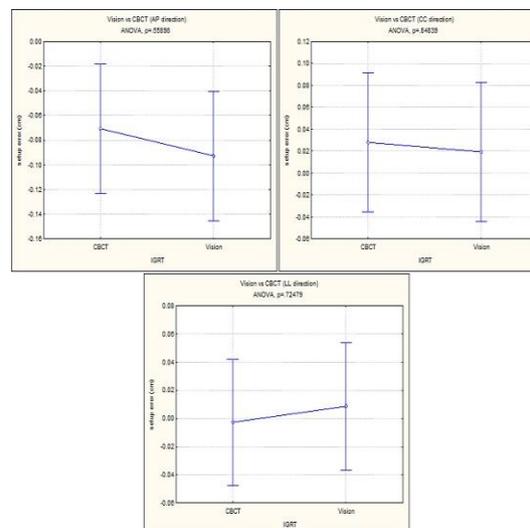

Surface-based image guided radiotherapy (IGRT) allows positioning and/or monitoring patients receiving radiation treatment in 3 dimensions (3D), without the use of ionizing radiation. The purpose of this study is to investigate the usage of 3D Surface Imaging, specifically the Vision RT's AlignRT system, as the primary tool for the set up of patients who are treated with frameless stereotactic body radiotherapy (SBRT) for lung cancer by comparison with cone-beam computed tomography (CBCT).

#### Material and Methods

Twenty patients (12 men and 8 women) were included in the study. For each fraction of treatment the patients were positioned using the AlignRT system and the vertical, longitudinal and lateral shifts were measured with the CBCT according the Cartesian axis system. Surfaces were captured just before CBCT acquisitions. The data were retrospectively retrieved, manually researching the medical records reporting the values of the shifts detected with CBCT. The mean, the range and the standard deviation relative to the shifts were calculated with respect to the X, Y and Z axes. The agreement between the two different procedures was then analyzed with the Bland-Altman test, which allows to evaluate the correlation between two systems that measure the same parameter.

#### Results

The mean of the shifts was found to be equal to -0.08 cm (range -0.3; 0.5) for the Z axis, equal to 0.01 cm (range -0.7; 0.5) for the X axis and 0.04 cm (range -0.8; 0.6) for the Y axis. The standard deviation was 0.21 cm for the Z axis, 0.22 cm for the Y axis and 0.23 cm for the X axis, respectively; these standard deviation values probably reflect the presence of some outliers values that are highly likely to represent data entry errors.

#### Conclusion

Three - dimensional surface imaging is confirmed to be a reliable method for patients' setup, able to guarantee high precision in the delivery of SBRT treatment.

#### EP-1350 DART-bid by VMAT for locally advanced NSCLC: Low toxicity, encouraging survival and tumor control

K. Wurstbauer<sup>1</sup>, R. Pinter<sup>1</sup>, M. Meinschad<sup>2</sup>, M. Kazil<sup>1</sup>, T. Hernler<sup>3</sup>, P. Cerkl<sup>3</sup>, T. Künzler<sup>2</sup>, A. De Vries<sup>1</sup>

<sup>1</sup>Academic Teaching Hospital, Radiation Oncology, Feldkirch, Austria ; <sup>2</sup>Academic Teaching Hospital, Medical Physics, Feldkirch, Austria ; <sup>3</sup>Academic Teaching Hospital, Pneumology, Hohenems, Austria

#### Purpose or Objective

Results of 60 Gy with concurrent chemotherapy for locally advanced NSCLC are disappointing. DART- bid (dose-Differentiated Accelerated RadioTherapy - 1,8 Gy twice daily) is a radiation dose-intensified approach, sequentially combined with chemotherapy. Our experience up to now is reported.

#### Material and Methods

55 widely unselected patients (85% in stages IIIA-C, 8<sup>th</sup> edition) were treated from 1/2015 until 5/2018. >5% weight loss/ 3 months in 31%, KI <80% in 24% of patients. Overall doses applied were as follows: Primary tumors 73.8 - 90.0 Gy, in positive correlation to tumor volumes; nodes 61.2 Gy; nodes electively 45 Gy (to sites about 6 cm cranial of macroscopically involved nodes); fractional doses 1.8 Gy bid; interval 8h.

GTV (ITV) to PTV: 7 mm; planning with the intention to spare as much as possible of the ipsilateral (tumorbearing) lung; application by VMAT; cone beam CT before every fraction.

Duration of radiotherapy 31 days median (28-37 days); in 89% of the patients 2 cycles platin-based chemotherapy were given before, with a target interval between chemotherapy and radiotherapy of < 8 days.

#### Results

With a median follow-up time of 12.6 months (3.9-37.5 m.) the 1-year overall survival rate is 72%, the median overall survival time 24.1 months; for the 21 patients (38%), matching with the RTOG 0617 inclusion criteria, the 1 year survival rate amounts to 78% and the median overall survival time is not reached.

7 local recurrences and 5 isolated regional recurrences occurred, resulting in local and regional tumor control rates at 1 year of 86% and 90%, respectively.

Acute adverse effects of pneumonitis grade 2 and 3 occurred in 4 and 1 patients, respectively; acute

esophagitis grade 1, 2, 3 in 18%, 53%, 2% of the patients, respectively. No acute toxicity grade 4 or 5 occurred. In 2 patients with central tumors and close vicinity to great vessels, a treatment relationship to lethal haemorrhages, 7 and 9 months after the end of radiotherapy, cannot be excluded. Besides that, no late toxicity >grade 1 was observed.

#### Conclusion

This accelerated, differentiated dose-intensified approach yields encouraging results for survival and tumor control; along with in general low toxicity up to now.

#### EP-1351 Long-term survival with FDG-PET directed therapy in NSCLC with synchronous solitary brain metastasis

S.J. Newman<sup>1</sup>, N. Bucknell<sup>1</sup>, M. Bressel<sup>1</sup>, P. Tran<sup>1</sup>, B. Campbell<sup>1</sup>, N. Haghighi<sup>1</sup>, D. Kok<sup>1</sup>, M. MacManus<sup>1</sup>, C. Phillips<sup>1</sup>, M. Shaw<sup>1</sup>, A. Wirth<sup>1</sup>, G. Wheeler<sup>1</sup>, D. Ball<sup>1</sup>, S. Siva<sup>1</sup>

<sup>1</sup>Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia

#### Purpose or Objective

At diagnosis, approximately 10% of all patients with NSCLC have intracranial metastases, and 1% have synchronous solitary brain metastasis (SSBM). In similar cohorts treated radically to both sites published 5-year overall survival (OS) is 11-21%. Use of FDG-PET can significantly alter staging, treatment choices and intent. We investigate the outcomes of patients diagnosed with NSCLC and SSBM and treated with radical local therapies in the FDG-PET era.

#### Material and Methods

In this retrospective study, eligible patients had histologically-confirmed NSCLC and SSBM staged with FDG-PET and received radical treatment from 1/2/1999 to 31/12/2017. A lung-molecular graded prognostic assessment (lung-molGPA) score was assigned for each patient using age, ECOG score, and, if performed, molecular status. Overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier methods. Cox proportional hazard models determined prognostic factors for PFS.

#### Results

Forty-nine patients were eligible. Median age was 63 years (range: 34-76). Thirty (61%) were male. Nineteen patients (39%) were ECOG 0, 26 (53%) ECOG 1 and 4 (8%) ECOG 2. Sixty-seven percent were  $\geq$ T2 and 47% were  $\geq$ N2 (Table 1). Forty-six of 48 patients (1 unknown) (96%) had MRI brain. For intrathoracic disease, 10 patients (20%) had surgery, surgery and RT in 1 (2%), surgery and adjuvant chemoRT in 2 (4%), surgery and adjuvant chemotherapy in 2 (4%), chemoRT in 29 (59%), SABR in 4 (8%) and fractionated RT in 1 (2%). For intracranial disease, 20 patients (41%) had surgery, 7 (14%) definitive SRS and 22 (45%) had adjuvant RT. For adjuvant RT, 20 had whole brain RT and 2 had SRS cavity boost. Median follow up of all patients was 3.9 years. Median time to first relapse was 6 months (95%CI: 5-11). At 2 years, 45% of first failures were intracranial only (95%CI: 30-59). At 2 years PFS was 13% (95%CI: 6-28). At 2 and 5 years, OS was 56% (95%CI: 43-73) and 30% (95%CI: 18-51), respectively (Figure 1). In  $\geq$ N1 disease, 5 year OS was 34% (95%CI: 18-63). On univariable analysis, lower ECOG (HR 2.28, 95%CI: 1.17-4.43, p=0.014) and higher lung-molGPA scores (HR 0.26, 95%CI: 0.11-0.61, p=0.002) were associated with significantly longer OS. Higher lung-molGPA was associated with significantly longer PFS (HR 0.47, 95%CI: 0.24-0.94, p=0.031). On multivariable analysis, lung-molGPA (HR 0.33, 95%CI: 0.15-0.71, p=0.005) and N-stage (HR 1.56, 95%CI: 1.13-2.15, p=0.007) were significant positive and negative prognostic factors, respectively, for PFS.

Table 1: Tumour pathology and staging

Tumour type

KRAS	5 (56%)
Unknown	40
Tumour stage	
T0	1 (2%)
T1	15 (31%)
T2	20 (41%)
T3	8 (16%)
T4	5 (10%)
Nodal stage	
N0	22 (45%)
N1	4 (8%)
N2	20 (41%)
N3	3 (6%)

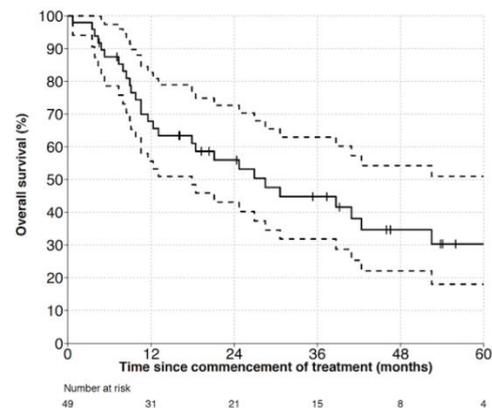

Figure 1: Five year overall survival

#### Conclusion

Patients with NSCLC and SSBM staged with FDG-PET had a 5 year OS of 30% when treated radically to both sites. This is greater than previously reported outcomes. For  $\geq$ N1 patients, the 5 year OS was 34%, which to our knowledge is the longest reported survival in similar populations. These results suggest that such patients should be treated with aggressive local therapy, as this can be associated with long-term OS and possible cure.

#### Purpose or Objective

The standard treatment of locally advanced non-small cell lung cancer (LA-NSCLC) has changed with the PACIFIC trial, stating that the addition of 1-year adjuvant immune checkpoint inhibitor therapy after completed concomitant chemoradiotherapy increases the 2-year survival rate compared to placebo. Inclusion criteria were a WHO performance status (PS) of 0-1 and no sign of progression. Adjuvant therapy should start within 42 days of completed chemoradiotherapy.

The aim of this analysis was to determine the fraction of patients with LA-NSCLC that have PS 0-1 within six weeks after completion of concomitant chemoradiotherapy and would hence be candidates for adjuvant immune checkpoint inhibitor therapy.

#### Material and Methods

We are currently recruiting patients with LA-NSCLC in a national multicenter randomized phase III isotoxic dose escalation trial. In the study the control arm receives 66 Gy in 33 fractions concomitantly with cis- or carboplatin every third week and fixed dose vinorelbine 50 mg three times weekly. The concomitant chemoradiotherapy is preceded by a single series of induction platinum-based combination chemotherapy. Radiotherapy is delivered with intensity modulated or volumetric arc modulated therapy. Daily image guidance with conebeam CT and treatment adaptation guidelines are used.

The trial inclusion criteria are cytology or histology proven LA-NSCLC and PS 0-1. Diagnostic procedures include FDG-PET/CT and endobronchial ultrasound (EBUS) with aspiration cytology from central mediastinal nodes. We are investigating the possibility of an amendment to allow for adjuvant immune checkpoint inhibitor therapy to enable continuous inclusion in the study. Thus, an unplanned interim analysis was performed within the trial, analyzing only baseline characteristics and PS at the first clinical follow-up six weeks post radiotherapy.

#### Results

Patients were included from January 2015 and forward. Data lock for the interim analysis was September 1<sup>st</sup>, 2018. 124 patients had completed their treatment and attended their first clinical follow-up. Clinical report form was filled out for 109 patients; PS data were missing for ten patients, leaving 99 for analysis. Patient characteristics are shown in Table 1. PS at start and six weeks after end of radiotherapy are shown in Figure 1. No patients were in PS 3 or 4 after radiotherapy.

#### Conclusion

The majority of patients (85%) with LA-NSCLC, who were staged with EBUS and PET/CT and received state-of-the-art concomitant chemoradiotherapy in a randomized dose escalation trial, remained in PS 0-1 after finished radiotherapy and were thus candidates for adjuvant immune checkpoint inhibitor therapy.

<sup>1</sup>Centre François Baclesse, Radiotherapy, Caen, France ;

<sup>2</sup>Centre Léon Bérard, Radiotherapy, Lyon, France ;

<sup>3</sup>Centre François Baclesse, Clinical research, Caen, France ;

<sup>4</sup>Institut de Cancérologie de Lorraine, Radiotherapy, Nancy, France ;

<sup>5</sup>Institut Gustave Roussy, Radiotherapy, Villejuif, France ;

<sup>6</sup>Centre Hospitalier Intercommunal de Créteil, Pneumology, Créteil, France ;

<sup>7</sup>Centre François Baclesse, Pneumology, Caen, France

#### Purpose or Objective

While stereotactic irradiation (SBRT) of cerebral metastases is standard in oligometastatic lung cancer, the clinical benefit of SBRT in extracranial metastases depending on metastatic burden and aggressiveness awaits evidence. The aim was to assess feasibility and efficacy of a radical approach on all extracerebral metastatic sites among lung cancer patients with an "oligo" disease.

#### Material and Methods

This retrospective multicentric study in four French cancer centers included patients treated with SBRT on all their extracerebral metastatic sites corresponding to the following settings : extracerebral oligometastatic (one to five lesions at diagnosis), oligorecurrent (metastatic relapse with one to five metastases), oligoprogressive (1-5 progressive lesions with all other lesions controlled by systemic treatment) or oligopersistent (consolidative

radiotherapy with 1-5 residual lesions following systemic treatment) lung cancer.

#### Results

91 patients and 99 metastases were included. Local control was 91%, median progression free survival (PFS) was 6.3 months [4 ; 8.1] and median overall survival was 28.2 months [20.1 ; 35.5]. There were significant differences between metastatic settings : median overall survival was not reached in the oligometastatic group, 33 months in the oligorecurrence group, 28.2 months in the oligopersistent group and only 6.5 months in the oligoprogressive group. Metastatic site, nodal status and free interval for oligorecurrent patients were significant prognostic factors. Toxicities were moderate since only 5.5% of patients experienced grade 3 acute toxicities and none had late grade 3-4 toxicity. SBRT allowed delaying the administration of systemic treatments since more than half of the patients could remain free from systemic treatment for several months.

#### Conclusion

Optimal dose, fractionation and timing regarding association with systemic treatments remain to be defined. Aggressive metastatic management seemed feasible and appeared to delay reintroduction of systemic treatments. Larger scale randomized studies are necessary to demonstrate survival benefit.

#### EP-1354 Impact of Pulmonary SABR on Pulmonary Function Tests: Report of a single institution experience

M. Keys<sup>1</sup>, S. O'Sullivan<sup>1</sup>, R. Mc Dermott<sup>1</sup>, N. Wallace<sup>2</sup>, M. Dunne<sup>1</sup>, J. Armstrong<sup>1</sup>, P. Thirion<sup>1</sup>

<sup>1</sup>St. Luke's Radiation Oncology Network, Radiation Oncology, Dublin 6, Ireland ; <sup>2</sup>Cork University Hospital, Radiation Oncology, Cork, Ireland

#### Purpose or Objective

Pulmonary Stereotactic Body Radiotherapy (SABR) is a well established standard alternative therapy for patients (pts) diagnosed with inoperable early-stage Non Small Cell Lung Cancer (NSCLC). The impact of SABR on pulmonary function remains unclear. Results from retrospective studies suggest a minimal if any decline in post-SABR pulmonary function. The results were also mixed with regard to the Pulmonary Function Test (PFTs) parameter effected. We report here a single institution experience comparing prospectively acquired pre and post-SABR PFTs.

#### Material and Methods

From March 2014 to May 2018, 84 pts. with documented PFTs pre- and post-SABR (within 1 year post therapy) were identified. The main characteristics of the population included: median age of 75 years (from 59-91years), female predominant (57%), underlying COPD stage 3-4 (23.8%), and ex- or active smoker (87.6%). All pts. except for one were treated for NSCLC, pathologically proven in 86 pts. The tumour locations were mostly in the upper lobes (58.3%) and peripheral (88.1%). The median GTV and PTV volumes were 11.68cm<sup>3</sup> (from 1.04 to 52.58cm<sup>3</sup>) and 33.11cm<sup>3</sup> (from 6.39 to 116.72cm<sup>3</sup>) respectively. The protocol driven radiation schedules used were 54Gy/3 (11.9%), 60Gy/5 (73.8%) and 60Gy/8 (14.3%). Paired-samples t-tests were conducted to evaluate the Pre- and post-SABR PFT values and independent samples t-tests and ANOVA were conducted to compare the results between demographic characteristics.

#### Results

Pre- and post-SABR FEV<sub>1</sub> data was available for all 84 pts. The median pre- and post-SABR FEV<sub>1</sub> was 1.41L (from 0.4 to 2.9L) and 1.3L (from 0.45 to 2.8L) respectively. Overall There was a statistically significant post-SABR FEV<sub>1</sub> decrease, with a mean decrease of .05L [95% CI: 0.002 to 0.11, p=0.04]. Pre- and post-SABR DLCO was available in 68 pts. The median pre- and post-SABR DLCO was 9.1 ml/mmHg/min (from 0.6 to 20.7) and

9.5ml/mmHg/min (from 1.35 to 26.1) respectively. Overall there was a statistically significant post-SABR DLCO decrease, with a mean decrease of 2.5% [95% CI: 0.1-4.89, p=0.04]. However Individual variation was observed with a decrease observed in 40 pts, an increase in 22, and no change in 6. The only identified negative risk factor for post-SABR DLCO reduction was female gender.

#### Conclusion

The present study found a statistically significant post-SABR DLCO and FEV<sub>1</sub> decrease, however with significant inter-individual variation. Whether this is a temporary or permanent change, we were unable to assess this. Whether this decrease translates into a functional change is unlikely but not proven. The clinical significance and reversibility need to be further studied through large scale clinical trials and compared to other therapeutic alternatives.

#### EP-1355 Oligo-progressive status exhibits unfavorable survival in pulmonary oligo-recurrence treated by SABR

H. Lee<sup>1,2</sup>, J. Tsai<sup>3</sup>, S. Chen<sup>4</sup>, I. Lai<sup>5</sup>, C. Chen<sup>2,6</sup>, C. Ho<sup>7</sup>, J. Chiou<sup>1,2</sup>, Y. Kuo<sup>4</sup>

<sup>1</sup>Taipei Medical University Hospital- Taipei Medical University, Department of Radiation Oncology, Taipei, Taiwan ; <sup>2</sup>Taipei Medical University, Taipei Cancer Center, Taipei, Taiwan ; <sup>3</sup>Taipei Medical University-Shuang Ho Hospital, Department of Radiation Oncology, New Taipei City, Taiwan ; <sup>4</sup>China Medical University Hospital, Department of Radiation Oncology, Taichung, Taiwan ; <sup>5</sup>Taipei Veterans General Hospital, Division of Radiation Oncology- Department of Oncology, Taipei, Taiwan ; <sup>6</sup>Wan Fang Hospital- Taipei Medical University, Department of Radiation Oncology, Taipei, Taiwan ; <sup>7</sup>Camillians Saint Mary's Hospital Luodong, Department of Radiation Oncology, Yilan, Taiwan

#### Purpose or Objective

Oligo-progression exhibits distinct biological signatures during the evolution of cancer metastasis, but its clinical significance has not been clarified. We investigated the treatment outcome of stereotactic ablative radiotherapy (SABR) for pulmonary oligo-recurrence in metastatic cancer patients with controlled extrapulmonary diseases and evaluated the prognostic value of oligo-progressive status of targeted lung tumors.

#### Material and Methods

The patient inclusion criteria were pulmonary oligometastases with controlled primary and extrapulmonary disease, SABR as the primary local treatment for oligo-recurrent lung tumors, and consecutive imaging follow-up. Pulmonary oligo-recurrence was defined as ≤5 metastatic lung tumors with absent or controlled disease elsewhere. The status of targeted lung tumors were further classified into oligo-progressive and controlled status to indicate the drug resistance developing in lung or not, respectively. Overall survival (OS) and prognostic variables were evaluated using Kaplan-Meier analysis and Cox regression model.

#### Results

Thirty-two patients with sixty-seven lung tumors treated with SABR were enrolled. With a median follow-up period of 19.5 months, the median OS was 33.0 months. Oligo-progressive status (P = .0413) and an increased number of lung tumors (P = .0217) were independently associated with inferior OS. A higher biological effective dose (BED<sub>10</sub>) (P = .0423) was independently correlated with longer in-field radiographic progression-free survival. Synchronous metastases (P = .0133) and an Eastern Cooperative Oncology Group score of ≥1 (P = .0010) were significantly associated with inferior out-field radiographic progression-free survival. Grade 2 radiation pneumonitis occurred in six (18.8%) patients. No toxicity above grade 2 was recorded.

### Conclusion

Oligo-progressive status of lung tumors exhibits a less favorable survival outcome in metastatic patients with pulmonary oligo-recurrence treated by SABR.

### EP-1356 Targeted therapy with or without Radiotherapy in EGFR/ALK mutant NSCLC with Brain Metastases

I. Císcar García<sup>1</sup>, M. Martín Martín<sup>1</sup>

<sup>1</sup>Ramon y Cajal University Hospital, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

The treatment of brain metastases of non-small cell lung cancer (NSCLC) especially those with EGFR and ALK mutation is controversial. TKIs may have more than 70% intracranial response rate in these patients, and delay radiotherapy until progression of disease has been proposed. The purpose of this study is to analyze the treatment and the results in our patients with brain metastasis of EGFR mutant or ALK positive NSCLC.

#### Material and Methods

Eligible patients were those diagnosed between January 2013 and December 2017 with brain metastases (found at diagnosis or at progression) from NSCLC. We registered the local and systemic progression and the type of treatment and moment received. We analyzed the brain progression free survival without radiation therapy (RT) and we compared the overall survival (OS) between patients treated with RT at diagnosis of the metastases and those who were treated at progression.

#### Results

43 patients with NSCLC and EGFR/ALK mutation, presented brain metastases throughout the disease evolution. 29 (67.5%) had EGFR, 13 (30%) ALK and 1 (2.3%) had ROS mutation. At diagnosis, those who had more than 3 brain metastases were 18 (62%) with EGFR mutation and 8 (57%) with ALK mutation. 21 patients (48.8%) were treated with initial radiotherapy and TKI, while in 16 patients (37.7%) the radiotherapy was delayed until the cerebral progression. 6 (14%) did not receive radiotherapy treatment: 3 of them because they died from the disease one month after diagnosis of brain metastases and were excluded for survival analysis. The type of radiotherapy used was holocraneal in 25 patients (58.1%), fractionated stereotactic in 4 patients (9.3%) and radiosurgery in 8 patients (18.6%). 5 received surgery and subsequent radiotherapy (2 fractionated and 3 radiosurgery). For patients with second-generation TKIs, the median lifetime of the communication of the cerebral results of diagnosis of brain metastasis was for 9 months and for the states with Erlotinib and Gefitinib or CT for 7 months. For patients with EGFR mutant tumors who were treated with delayed radiation therapy, the median time to brain progression was 7 months and 5 months for ALK and ROS. When they received radiotherapy at the diagnosis of brain metastases, the median to progression was the same for the two types of mutation, 13 months. The median overall survival for patients with EGFR mutation treated with RT at diagnosis of brain metastases was 16 months, while for patients as well as at 12 months, for ALK positive patients it was 21 and 23 months respectively, these differences were not significant.

#### Conclusion

Up front radiotherapy does not improve overall survival in patients with brain metastases of EGFR mutant or ALK positive non small cell lung cancer, but the potential benefit of delaying radiotherapy must be balanced with the short time of brain progression. We haven't found significant differences in the brain response between front and second-line TKIs.

### EP-1357 Spinal metastases from non-small cell lung cancer; is it a surrogate of bad outcome?

L. Krozkin<sup>1</sup>, I. Ospovat<sup>2</sup>, D. Machievsky<sup>2</sup>, E. Gez<sup>2</sup>, S. Soifer<sup>2</sup>, B. Corn<sup>2</sup>, Y. Natan Hoz<sup>2</sup>, O. Gutfeld<sup>2</sup>, D. Limon<sup>2</sup>  
<sup>1</sup>Soroka Medical Center, Radiotherapy, Beer Sheva, Israel ; <sup>2</sup>Tel Aviv medical center, Radiotherapy, Tel Aviv, Israel

#### Purpose or Objective

Bone metastases are a common event in patients with non-small cell lung cancer (NSCLC). One of the most common sites is the spinal column. The epidemiology of symptomatic spinal metastases in patients with NSCLC is not well described. The goal of this study was to describe this population of patients.

#### Material and Methods

Our database was retrospectively reviewed for patients treated with radiotherapy (RT) to spinal metastases from NSCLC, over a period of 2 years (2016-2017). From the database we documented patients, disease and treatment characteristics.

#### Results

78 patients were treated with RT for NSCLC spinal metastases over a period of 2 years. Of the patients, 68% were male, the median age was 64.4 years. 81% were diagnosed with adenocarcinoma, 17% with squamous cell carcinoma. 11.5% of the patients have EGFR mutation, none had ALK mutation. The location of the metastases was thoracic spine in 62% of patients, 47% in lumbar spine, 31% in sacrum and 13% in cervical spine. 40% presented with lesions in more than one spinal sub-site. Median time from diagnosis of metastatic disease to first treatment of spinal metastases was 1.9 months. The majority of patients (96%) were treated with a fractionation of 20-30Gy in 5-10 fractions, only 3 patients were treated with a single fraction of 8Gy, no patient was treated with stereotactic RT. About 10% were treated with a second course of RT, none to the same location. However, the two patients that required a third course of RT, were re-irradiated to previously treated lesions. Median survival was 5.5 months for the entire cohort. Patients with EGFR mutation had better survival (12.7mo vs. 4.4mo, p=0.046). Other tumor, treatment and patient parameters, didn't influence survival.

#### Conclusion

The most pronounced findings in our cohort of patients with metastatic NSCLC and spinal metastases, treated with RT, was the short time from disease diagnosis to spinal treatment and the relative short survival, when compared to known survival of stage IV NSCLC. This suggest that spinal metastases in NSCLC may predict a more aggressive course of disease.

### EP-1358 SBRT for de novo pulmonary tumors in patients with completely resected early stage NSCLC

Q. Zhao<sup>1</sup>, J. He<sup>1</sup>, Z. Zeng<sup>1</sup>

<sup>1</sup>Zhongshan Hospital- Fudan University, Department of radiation oncology, Shanghai, China

#### Purpose or Objective

Following surgery for early-stage non-small cell lung cancer (NSCLC), de novo pulmonary tumors are common. This study aimed to assess the efficacy, patterns of failure, and toxicity of stereotactic body radiotherapy (SBRT) in the treatment of de novo pulmonary tumors following curative resection of early stage NSCLC.

#### Material and Methods

We reviewed the medical data of patients who had received definitive intent SBRT for small lung cancer at Zhongshan Hospital, Fudan University, between June 2011 and December 2017. Patients who had experienced complete resection for prior early-stage NSCLC before SBRT were identified for further analysis. Incidences of loco-regional recurrence (LR) and distant metastasis (DM) were evaluated using the alternative cumulative incidence competing risk method. The probability of survival was estimated using the Kaplan-Meier method.

## Results

Thirty-three patients with 36 lesions were eligible and included in this study. The median follow-up time was 32 months. Estimated incidences of LR and DM were 37.62% and 15.92%, respectively, at 1 year and 48.02% and 21.23%, respectively, at 2 years. The progression-free survival and overall survival of all patients were 62.40% and 90.30%, respectively, at 1 year and 52.00% and 69.90%, respectively, at 2 years (Figure 1). Twenty-six patients experienced grade 1 SBRT-related toxicity, 11 patients experienced grade 2 SBRT-related toxicity, and 3 patients experienced grade 3 toxicity. There were no grade 4/5 toxicities or SBRT-related deaths during the follow-up period (Table 1).

## Conclusion

SBRT appears to be a safe and potentially effective alternative therapeutic option for de novo pulmonary tumors following early-stage NSCLC radical resection, despite impaired pulmonary reserve.

### EP-1359 Dosimetric Appraisal of VMAT for Stereotactic Radiosurgery in Lung Lesions in Comparison to Robotic Radiosurgery

E. Erdogan<sup>1</sup>, P. Boydak<sup>1</sup>, B. Eren<sup>1</sup>, F. Aksaray<sup>1</sup>  
<sup>1</sup>Okmeydani Training and Research Hospital, Radiation Oncology, Istanbul, Turkey

## Purpose or Objective

Role of stereotactic radiosurgery in the treatment of lung tumors has been well defined. Stereotactic radiosurgery techniques improvements are developing everyday. Comparisons of dosimetric quality has always been an ongoing subject of new conducting clinical trials. The aim of this study is to compare the dosimetric characteristics of robotic and conventional linac-based SBRT techniques for lung cancer.

## Material and Methods

Ten patients with lung patients were replanned with MONACO treatment planning system (ELEKTA Infinity Linac) which use MONTECARLO algorithm. Plans were created using 2 half arcs VMAT with CyberKnife (which use MONTECARLO algorithm) and dosimetric indices compared for both treatment platform. Identical image and contour sets were used for both modalities. Dose for organ at risk for SpinalCord, Oesofagus, R-L Lung for 1000cc, heart. PTVmax, treatment time, conformity index (CI), homogeneity index (HI), number of monitor units (MU). CI calculated for both platform manually as a ratio of total volume covered by reference isodose and the target volume ( $CI = VRI/TV$ ). D2-D98/D50 formula used for calculation HI (ICRU 62 reports) Statistical calculations were made by SPSS Statistics 22. The Shapiro-Wilk test used for normality in frequentist statistics. Paired sample t-test and Wilcoxon signed-rank test were used for normally and not normally distributed dependent samples. Differences were considered statistically significant if p values were < 0.05.

## Results

Robotic radiosurgery technique can achieve high degree of conformity (median CI=1.41) surrounding the inhomogeneous dose distribution (median HI= 0.27) at the cost of treatment time (mean 53 minutes). Volumetric modulated arc therapy technique improved this inhomogeneity (median HI= 0.05) and treatment time (estimated between 5 and 9 minutes) at the cost of conformity (median CI= 0,95). The number of MU necessary to deliver the prescribed dose was significantly greater in the case of CyberKnife system (p< 0.01). The dose to 1000 cc lung was well below institutional constraints for both modalities. Steep dose gradient near target volume were significantly better at CyberKnife system for all isodose volumes (80%, 60% and 40% isodose volumes) (p< 0.01)

## Conclusion

The dose distribution and dosimetric parameters of both the CyberKnife and VMAT plans are clinically acceptable lung treatment requirements. While the CyberKnife may deliver less lung dose than linac-based systems for tumors close to the anterior chest wall. Although there are some differences in dosimetric analysis, it is likely that robotic radiosurgery and volumetric modulated arc therapy plans would be clinically indistinguishable.

### EP-1360 Salvage SBRT for postoperative recurrence of NSCLC

S. Aoki<sup>1</sup>, H. Yamashita<sup>1</sup>, W. Takahashi<sup>1</sup>, K. Nawa<sup>1</sup>, T. Ota<sup>1</sup>, Y. Nozawa<sup>1</sup>, S. Ozaki<sup>1</sup>, T. Nakamoto<sup>1</sup>, K. Nakagawa<sup>1</sup>  
<sup>1</sup>University of Tokyo Hospital, Radiology, Tokyo, Japan

## Purpose or Objective

Standard treatment for patients with early-stage non-small cell lung cancer (NSCLC) who undergo surgery and subsequently develop local failure or intrathoracic oligo-recurrence remains controversial. We aimed to assess the feasibility of stereotactic body radiotherapy (SBRT) for these patients. We also evaluated factors associated with indices of survival.

## Material and Methods

Patients treated with SBRT for NSCLC recurrence who previously underwent curative surgical resection from October 2011 to October 2016 were evaluated. Post-recurrence survival and toxicity were analyzed, and prognostic factors for overall survival (OS), progression free survival (PFS) after salvage SBRT were identified by univariate and multivariate analysis.

## Results

A total of 51 patients and 58 tumors were analyzed. Median follow-up time was 25 months (35 months for surviving patients), and median OS after salvage SBRT was 32 months. The 1- and 3-year OS, PFS rate was 82.4% and 59%, 82.4% and 59%, respectively. Only 4 patients (7.8%) developed local failure. Median local control rate (LCR) was 71 months and the 1- and 3-year LCR was 97.8% and 94.9%. Four patients experienced grades ≤3 radiation pneumonitis and one experienced grade 5. Gender, location, type of surgery (lobectomy or limited suurgery), and operability of recurrent tumors were independent prognostic factors for OS.

## Conclusion

This study suggested that salvage SBRT is effective and well-tolerated in recurrent NSCLC patients with postoperative locoregional recurrence.

### EP-1361 Survival after two schedules of SBRT to centrally located lung tumors

M. Jelin<sup>1</sup>, C. Kristiansen<sup>1</sup>, S.S. Jeppesen<sup>1,2</sup>, M. Nielsen<sup>3</sup>, O. Hansen<sup>1,2,4</sup>

<sup>1</sup>Odense University Hospital, Dept. Oncology, Odense, Denmark ; <sup>2</sup>Odense University Hospital, AgeCare. Academy of Geriatric Cancer Research, Odense, Denmark ; <sup>3</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark ; <sup>4</sup>University of Southern Denmark, Institute of Clinical Research, Odense, Denmark

## Purpose or Objective

It is a challenge to apply stereotactic radiotherapy (SBRT) to centrally located non-small cell lung cancer (NSCLC). Initially we used 80 Gy/8F (BED10= 160 Gy), but changed the schedule to 50 Gy/5F (BED10=100 Gy). We here report the survival data for patients who were treated with either of the two schedules.

## Material and Methods

All patients have been prospectively registered. Additional data have been obtained retrospectively from patients files. Included patients were patients treated initially with one of the two schedules. Patients treated for recurrent disease, and patients treated in combination with

peripheral SBRT or conventional radiotherapy were excluded. The SBRT was given as 4-D VMAT. The 80 Gy/8 F or 50 Gy/5F was dosed centrally.

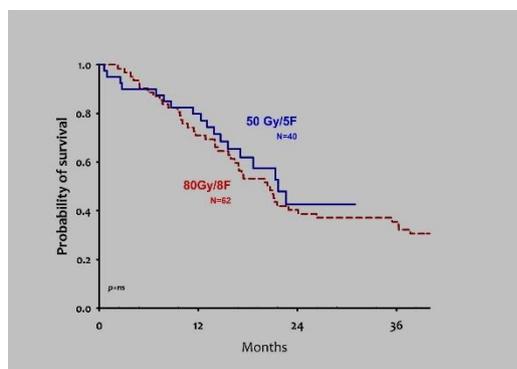

### Results

From 2012 to 2015 62 patients received 80 Gy and from 2016 to 2017 40 patients received 50 Gy.

**Table: Patient characteristics**

	50 Gy/5G N=40	80 Gy/8F N=62	Gy/8F
Age (yr.)	73.2 (86.4)	(46.8; 75.9; 90.5)	(50.0;
Sex			
Female	18 (45%)	35 (56%)	
Male	22 (55%)	27 (44%)	
Performance status			
0-1	20(50%)	32 (52%)	
2	12 (30%)	22 (36%)	
3	8 (20%)	8 (13%)	
FEV1% of predicted	59% (21-117%)	66% (22-123%)	
Stage (TNM7)			
I	15 (27.5%)	17 (27%)	
II	22 (55%)	35 (56.5%)	
III-IV	2(7.5%)	10 (16%)	
Histology			
Squamous carcinoma	19 (47.5%)	22 (35%)	
Adenocarcinoma	18 (45%)	24 (39%)	
Other histology	2(5%)	12 (19%)	
Unknown	1 (2.5%)	4 (6.5%)	

**Figure: Overall survival**

The median overall survival was 20.5 mo. in the 80 Gy group and 21.7 mo. in 50 Gy/5 (p=ns). The median cancer related survival was 59.7 mo. and not reached, respectively (p=ns).

### Conclusion

No difference was observed between the schedule groups in neither overall survival nor cancer specific survival.

### EP-1362 Re-Irradiation Of Whole Brain For Symptomatic Progression In Lung Cancer Patients

J.P. Agarwal<sup>1</sup>, S. Karmakar<sup>1</sup>, N. Mummudi<sup>1</sup>, A. Tibdewal<sup>1</sup>  
<sup>1</sup>Tata Memorial Hospital HBNI, Department of Radiotherapy, Mumbai, India

#### Purpose or Objective

Whole brain radiation therapy (WBRT) is an effective palliative measure and provides durable symptom relief in lung cancer patients with multiple brain metastases (BM). Clinico-radiological progression of BM after WBRT is a common and challenging scenario; treatment is tailored,

with various factors like driver mutation status, age, performance status, progression free interval and time since last irradiation influencing the treatment decision. Surgery or focal RT with stereotactic techniques may be an option for patients with oligo-metastases. However, they might not be a feasible option for patients with multiple BM. We aim to study the impact and outcome of patients with BM from lung cancer receiving WBRT for clinico-radiological progression.

#### Material and Methods

We retrospectively analyzed patients with BM from lung cancer who were registered at Tata Memorial Hospital, Mumbai, India between November 2012 to August 2017 and had undergone two courses of WBRT. Data of patients were retrieved from electronic medical records. Patients were treated using conventional or conformal technique with either tele-cobalt or Linear accelerator

#### Results

Out of 315 patients OF lung cancer, diagnosed and treated with WBRT for BM, 23 received re-WBRT. There were 12 men and 11 women with median age of 51 years (range 30 to 70yr with adenocarcinoma in 21 patients. Driver mutation status was positive in 65% patients (9 with EGFR and 6 with ALK mutation positive) and a majority of patients (83%) had BM at presentation. Clinico-radiological progression was the commonest indication of re-WBRT; only one patient had radiological progression alone. A majority of these patients had developed new symptoms while about 30% had recurrence of previous symptoms. Mean Karnofsky performance score (KPS) prior to re-WBRT was more than 70 in 13 patients (57%). Mean time interval between the two courses of WBRT were 17.1 months (range 5-33 months). Most patients received WBRT using a conventional technique (91%) and were treated in a tele-cobalt unit (83%). Re-WBRT fractionation schedule was 25 Gy/10 fractions (n=12, 52%) or 20 Gy/5 fractions (n=10, 44%). Mean biological effective dose (BED<sub>2Gy</sub>) for the first and second courses of WBRT were 63.75 Gy and 57.5 respectively. The average cumulative BED<sub>2Gy</sub> was 121 Gy (range 108-135 Gy). Almost all patients received short acting steroids during the course of re-WBRT. All patients completed the course of treatment. At the time of analysis, 7 patients were alive; median survival of patients after re-WBRT was 9 weeks (range 1-78 weeks).

#### Conclusion

In lung cancer patients with symptomatic progression of multiple BM and good prognostic features (driver mutation positive, good performance status and long time interval since last WBRT), re-WBRT is a safe and feasible option.

### EP-1363 Stereotactic Ablative Radiotherapy For Lung Cancer In Elderly Patients.

A. Revelant<sup>1</sup>, M. Emilio<sup>1</sup>, T. Marco<sup>2</sup>, D.P. Antonino<sup>1</sup>, G. Carlo<sup>1</sup>, F. Giuseppe<sup>1</sup>, P. Elisa<sup>1</sup>, M. Fabio<sup>1</sup>, N. Federico<sup>1</sup>, Z. Umberto<sup>3</sup>, P. Jerry<sup>4</sup>, F. Giovanni<sup>1</sup>  
<sup>1</sup>Centro di Riferimento Oncologico, Radiation Oncology, Aviano, Italy ; <sup>2</sup>Azienda Sanitaria Universitaria Integrata, Radiation Oncology, Udine, Italy ; <sup>3</sup>Azienda Ospedaliera Santa Maria degli Angeli, Pneumology, Pordenone, Italy ; <sup>4</sup>Centro di Riferimento Oncologico, Epidemiology, Aviano, Italy

#### Purpose or Objective

According to available evidences, stereotactic ablative radiotherapy (SABR) has been widely analyzed in elderly and appear to have similar benefits to their younger counterpart. However, for the definition of elderly often is used 70 years as threshold (as illustrated in International Society of Geriatric Oncology's Guidelines). The aim of this study is to demonstrate effectiveness and safety of using SABR in older patients (> 80 years old), with primary lung cancer, comparing the outcome in term of local control (LC), progression-free survival (PFS) and overall survival (OS) with younger patients at 1, 2 and 3 years. We didn't use the data at 5 years, because the event death is

influenced more by other factors (e.g. cardiac failure) than from lung cancer.

#### Material and Methods

We retrospectively reviewed clinical charts and treatment planning of early stage (Stage IA, IB) lung cancer patients treated with SABR between 2008 and 2016. We consider only patients  $\geq 65$  years old. All patients underwent at least one FDG-PET/CT exam before SABR. Total dose was 40-52 Gy in 5-8 fractions. The planning target volume was defined as the GTV, identified on CT simulation, plus 5 mm on axial plane and 10 mm on craniocaudal plane. We divided patients into two groups (group A:  $\leq 80$  years versus group B:  $> 80$  years) and clinical data were compared. LC, PFS and OS were analyzed with log-rank test. Acute and late toxicities were scored with CTCAE v. 4.03.

#### Results

A total of 88 patients were treated and analyzed (group A: 55 patients, M/F=38/17, median age= 73 years; group B: 33 patients, M/F=22/11, median age= 83 years). Median follow-up was 26 months (29 for Group A and 23 for Group B). LC at 1, 2 and 3 years was respectively 96%, 91% and 84% in group A vs. 96%, 81% and 81% in group B (p-value= 0.50). PFS at 1, 2 and 3 years was respectively 78%, 65% and 45% in group A vs. 76%, 51% and 39% in group B (p-value=0.59). OS at 1, 2 and 3 years was respectively 85%, 72% and 57% in group A vs. 88%, 58% and 45% in group B (p-value= 0.40).

No statistical significance was reached between Group A and B in terms of LC, PFS and OS. No differences in acute toxicity was shown among the two groups. We registered only two cases of late G3 pneumonitis (1 in group A and 1 in group B).

#### Conclusion

No significant difference in toxicity and compatible results in LC, PFS and OS were observed between patients younger or older than 80 years and this suggests that SABR is a feasible and effective treatment modality also in elderly population without risks of severe toxicity.

#### EP-1364 Haemoglobin and albumin levels, as clinical predictors in SBRT for early stage NSCLC

D.C. Moreno Santiago<sup>1</sup>, A. Giraldo Marin<sup>1</sup>, M. Ramos

Albiac<sup>1</sup>, J. Giralto Sagrera<sup>1</sup>

<sup>1</sup>Vall D'Hebron Hospital, Radiation Oncology, Barcelona, Spain

#### Purpose or Objective

The purpose of this study was to investigate serum albumin and haemoglobin levels as prognostic factors of stereotactic body radiotherapy (SBRT) for early stage NSCLC.

Numerous authors have reported that sex, age, Eastern Cooperative Oncology Group performance status (PS), tumour size, and T-stage are prognostic factors of early-stage NSCLC treated with SBRT. Following the steps of surgical series, many authors have tried to identify blood examination data commonly available in clinical settings and use that data to predict outcomes of SBRT.

#### Material and Methods

Retrospectively, we analyzed pre-treatment levels (considered up to one month prior to treatment) of haemoglobin and albumin to determine the impact on patient outcomes, such as: overall survival (OS); and event-free survival (EFS: local, regional or distance failures; and death), in patients with early stage NSCLC treated with SBRT in our centre, between February 2015 and January 2018.

Survival rates were estimated with Kaplan-Meier analysis, and multivariable analysis was completed using Cox proportional hazards model.

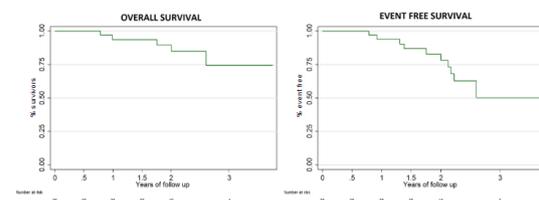

#### Results

Of all patients with diagnosis of early stage NSCLC treated with SBRT in our centre, 36 were included in this analysis (table 1). None of the patients had received previous

treatment with radiotherapy or chemotherapy in the past 5 years. Four patients were treated with SBRT after they refused surgery. The mean and median age was 72 years (range 54-89), with a mean follow up of 24 months (see Table1). The 2-year OS and EFS rates were 89.6% and 82.8%, respectively (fig. 1). In the multivariate analysis, significant factors for OS were albumin level HR= 0.05, 95% CI 0.00 - 0.50; p=0.01; and haemoglobin level HR= 0.43, 95% CI 0.22 - 0.83; p=0.01. The 2-year local, regional and distant control rates, were 93.1%, 93.1% and 95.8%, respectively. As expected, T stage was a significant predictive factor for local control (p=0.02). 5 patients died at the end of the follow up, none, however, related to treatment toxicity or tumour progression. In the multivariate analysis, the significant factors for EFS were as well: albumin level HR= 0.10, 95% CI 0.02 - 0.63; p=0.01; and haemoglobin level HR= 0.53, 95% CI 0.32 - 0.85; p=0.01.

Multivariate Cox proportional hazards regression was used to determine the optimal cut points: haemoglobin level  $>12.4\text{g/dL}$  was related with better OS and EFS, HR= 0.06, 95% CI 0.01 - 0.52; p=0.01 and HR= 0.17, 95% CI 0.05 - 0.64; p=0.01 respectively. Moreover, Albumin level  $>3.7\text{g/dL}$  was related too, with better OS and EFS HR= 0.13, 95% CI 0.02 - 0.78; p=0.03 and HR= 0.04, 95% CI 0.0 - 0.36; p=0.01 respectively.

#### Conclusion

In the setting of SBRT for early-stage NSCLC, our results shows that, pre-treatment haemoglobin  $<12.4\text{g/dL}$  and/or serum albumin  $<3.7\text{g/dL}$ , are objective laboratory tests, feasible for estimation of prognosis of patients with early stage NSCLC.

**EP-1365 SBRT as salvage therapy for oligometastatic pleural mesothelioma after initial curative therapy**  
C. Schröder<sup>1</sup>, I. Opitz<sup>2</sup>, M. Guckenberger<sup>1</sup>, R. Stahel<sup>3</sup>, W. Weder<sup>2</sup>, R. Förster<sup>1</sup>, N. Andratschke<sup>1</sup>, O. Lauk<sup>2</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland; <sup>2</sup>University Hospital Zürich, Department of Thoracic Surgery, Zürich, Switzerland; <sup>3</sup>University Hospital Zürich, Department of Medical Oncology, Zürich, Switzerland

**Purpose or Objective**

Patients with recurrent pleural mesothelioma after initial multimodal treatment presenting with very limited recurrences represent a challenge, as the optimal treatment strategy balancing toxicity and efficacy has not been defined yet. SBRT might be a promising option for these patients since it delivers a local ablative biologic dose of radiation. The intent of this retrospective analysis was to evaluate the feasibility of a novel strategy to integrate SBRT as first salvage therapy for limited pleural recurrences in pleural mesothelioma.

**Material and Methods**

Between 2005 and 2018, 21 patients with the histopathological diagnosis of malignant pleural mesothelioma (MPM) were treated with hypofractionated radiotherapy for oligometastatic progression. Most patients initially presented with stage III disease (57 %). Only one patient had distant metastases upon first diagnosis. The median age at first diagnosis was 65 years (range 33 - 75 years). Out of these 21 patients, 12 received induction chemotherapy prior to surgery, whereas in total 18 patients underwent macroscopic complete resection (MCR). 3 patients had additional intracavitary chemotherapy and 3 patients were treated with chemotherapy alone without any other treatment. Clinical and radiological data was collected at regular follow-up appointments including toxicity, local control and survival.

**Results**

A total of 50 lesions in recurrent MPM were treated with SBRT. A total of 21 patients received 1 course of radiation treatment, 10 of those received a second and 4 a third course of radiotherapy (RT). The median number of fractions at all courses was 5 (range 3 - 20) with a median dose per fraction of 5 Gy (range 2.5 - 12.5 Gy). The median total treatment dose was 30 Gy (20 - 50 Gy) with a median prescription isodose line (IDL) of 65 % (65 - 100 %). Median follow-up of all patients from diagnosis on was 124 weeks (range 32 - 662 weeks). At the time of analysis, 11 patients were still alive. Intrathoracic out-of-field or in-field recurrence after SBRT was observed in up to 62% of patients. After the first course of SBRT, a total of 13 patients had a thoracic recurrence (11 out-of-field, 2 in-field). After the second and third course the number of patients with thoracic recurrence was 6 and 2, respectively (each with 50 % in-field-recurrence). 12-months-local control was 85.2 % with a median time to local recurrence of 11 months. The median PFS after SBRT was 6 months (range 0 - 21 months) and the median OS from first diagnosis was 44 months (range 9 - 152 months). The OS at three years was 33 %. Overall, the radiation treatment was very well tolerated. Only 2 patients experienced above Grade 3 toxicities.

**Conclusion**

This analysis demonstrates the feasibility of an SBRT approach for recurrent MPM. SBRT with its few and low graded side effects was well tolerated even after multiple repetitions. Local control was excellent with a good median OS of 44 months.

**EP-1366 Repeated thoracic high-dose radiotherapy-Analysis of efficacy and safety including EQD2 sum plans**

C. Schröder<sup>1</sup>, I. Stiefel<sup>1</sup>, S. Tanadini-Lang<sup>1</sup>, I. Pytko<sup>1</sup>, M. Guckenberger<sup>1</sup>, N. Andratschke<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland

**Purpose or Objective**

Thoracic re-irradiation for primary or metastatic intrathoracic lesions remains a challenge regarding the balance between local efficacy and acceptable treatment related toxicity, as no firm data for safe guidance for re-treatment exists. In this retrospective analysis, we analyzed dosimetric data of patients that received re-irradiation of the thorax by generating EQD2 sum plans of all thoracic treatments. Furthermore, we looked at the clinical outcome of patients, including overall survival (OS) and toxicity.

**Material and Methods**

We retrospectively analyzed the data of 42 patients who received repeated high dose radiotherapy (RT) or stereotactic body radiotherapy (SBRT) for thoracic lesions from 12/2011 to 01/2017. Most patients had NSCLC (n=20), followed by esophageal cancer (n=6) and SCLC (n=4). Sum plans of 2Gy equivalent dose distributions (EQ2Gy) using non-rigid image registration to the latest planning CT scan were calculated for all courses of thoracic radiotherapy using Aria Eclipse (Varian Medical Systems, Version 10) and MIM (MIM Software Inc. Version 6.7.9). Dose parameter were calculated for common organs at risk (e.g. lung) and target volumes (PTV). Clinical and radiological data were collected at regular follow-up appointments.

**Results**

In total 42 patients received at least 2 courses of thoracic RT. 8 patients a third and 2 a fourth course of RT. For first treatment, 14 patients (33.3%) received an SBRT. For the second and third course 23 (54.8%) and 6 (75%) patients received treatment as SBRT. For the fourth course no patients received SBRT.

The median prescription dose (EQD2) was 42.2Gy<sub>10</sub> for all RT courses combined. The median volume of the combined PTV was 276cc (range 40-1115cc). The D1cc for the PTV ranges from 60.7-324.9 Gy<sub>10</sub> (median 108.4Gy<sub>10</sub>). Regarding organs at risk the median Dmean of both lungs was 10.1Gy<sub>3</sub> (range 1.9-17.9Gy<sub>3</sub>) with a median V(20Gy<sub>3</sub>) of 13.6% (range 0.5- 6.7%) and a maximum D1cc of 253.9Gy<sub>3</sub> (median 93.2Gy). The median Dmean of the esophagus was 20.7Gy<sub>3</sub> (range 2.78- 60.6Gy<sub>3</sub>) with a median D1cc of 58.7Gy<sub>3</sub> (range 7.9-100.6Gy<sub>3</sub>). The highest D1cc for the bronchial tree was 129.8Gy<sub>3</sub> (median 70.5Gy<sub>3</sub>) and 63.9Gy<sub>2</sub> for the spinal cord (median 35.6Gy<sub>2</sub>). The median follow-up was 33 months (range 3-191 months). Median OS of all patients after first re-irradiation was 19 months (range 1-45 months). At the time of analysis 18 patients were still alive 80% of patients suffered from mild G1-G2 toxicity, mostly in terms of coughing (20%). Only one patient suffered from a >G3 toxicity. This patient had a fatal esophageal rupture 16 months after re-irradiation of an NSCLC (esophagus D1cc=48.4 Gy).

**Conclusion**

Even though several organs at risk received a maximum D1cc of >100 Gy, thoracic irradiation proved to be safe with acceptable toxicities and effective with an excellent overall survival. Still, larger data sets with cumulative EQD2Gy dosimetric evaluation are necessary to define robust criteria for safe re-irradiation.

### Purpose or Objective

Target volume delineation is subject to inter-observer variability (IOV) and thus a major source of uncertainty in radiation treatment planning. IOV in the context of treatment adaptation is largely unknown. We analysed IOV of the primary gross tumour volume (GTV) and clinical target volume (CTV) in locally advanced NSCLC delineated by experts in the pre- and mid-treatment (PT and MT) setting.

### Material and Methods

Five patients from routine clinical practice, who underwent repeat imaging, were selected such that a variety of features likely to prompt adaptation, e.g. atelectasis, central primary tumour, was included. Brief case reports and CT imaging data were sent to six observers, supplemented with FDG-PET studies in two cases at PT and three at MT. Observers received PT and MT imaging data at least one week apart and were asked to delineate the GTV and CTV in their own treatment planning system and to comment on their delineation process, i.e. on how GTV to CTV expansion and adaptation were performed. Delineations were rasterised on a 1mm<sup>3</sup> grid and their compatibility assessed with the Generalised Conformity Index (Cl<sub>gen</sub>). Differences in IOV between PT and MT were probed with Wilcoxon signed-rank tests and the correlation between GTV and CTV IOV evolution with Spearman rank correlation. While it is respectively impossible and very difficult for these tests to show two-sided  $\alpha=0.05$  significance at  $n=5$ , more powerful parametric alternatives cannot credibly be employed.

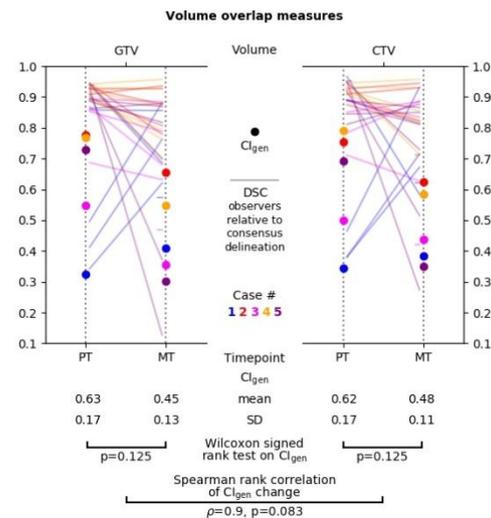

### Results

A total of 109/120 delineations were received and analysed. Figure 1 shows an overview of IOV in terms of volume overlap. All but one case saw a reduction of Cl<sub>gen</sub> when transitioning from PT to MT ( $p=0.125$  for both GTVs and CTVs). Agreement in corresponding GTV and CTV delineations was generally comparable at individual time points, and there was a trend of a correlation between GTV and CTV Cl<sub>gen</sub> changes ( $p=0.9$ ,  $p=0.083$ ). This behaviour is consistent with almost all observers adopting an isotropic GTV to CTV expansion of 5 mm with rare editing for anatomical boundaries at either time point. MT GTV delineations were only occasionally adopted from PT after image registration (9/28 analysed observers and cases), the remainder contoured anew. Post-transfer adaptation to changed anatomy was performed by one observer, and inclusion of PT GTV in MT CTV by two. Figure 2 shows the two cases demonstrating the most extreme changes in IOV (improvement and deterioration). In both cases large volumes of consolidated lung lead to increased IOV, but at different time points. Shortcomings of this in

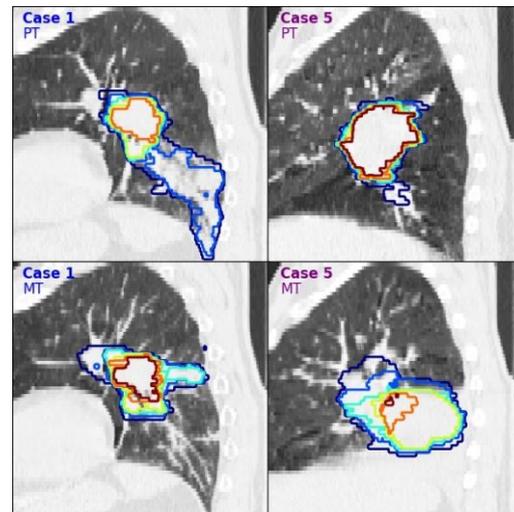

silico contouring challenge were incomplete FDG-PET availability and a lack of contrast-enhanced CT, both current clinical standard. Modern MRI would also have been welcomed by many.

### Conclusion

Differing approaches of reacting to intra-therapeutic changes further increase IOV in target volume delineation in the adaptive setting. Consensus guidelines and in-depth analysis of per-treatment tumour shrinkage patterns are urgently needed.

**Fig. 1:** Statistical overview of delineation overlap metrics. The Generalised Conformity Index (Cl<sub>gen</sub>) is shown for each case and time point for Gross Tumour Volume (GTV) and Clinical Target Volume (CTV) delineations. Its summary statistics are printed below, alongside the results of 1) hypothesis tests for a non-zero change in Cl<sub>gen</sub> when transitioning from pre- to mid-treatment time points (PT to MT), and 2) the correlation of those Cl<sub>gen</sub> changes between GTV and CTV delineations. The changes in Dice Similarity Coefficients (DSC) for each observer relative to a median consensus delineation (i.e. the collection of voxels delineated by at least half the observers) are depicted for comparison. Only a stub at either PT or MT is shown for observers who did not provide delineations for both.

**Fig. 2:** Illustration of pre- and mid-treatment inter-observer variability in GTV delineation for two cases of NSCLC. Central sagittal slices are superimposed with contours representing the fraction of observers who included the contained voxels in their delineation (from the exterior inwards: dark blue: 1/6 observers, maroon: 6/6 observers). **Abbreviations:** (P/M)T, (pre/mid)-treatment. **Left:** Case 1 (cT4N2M0 NSCLC of the left pulmonary hilum with bronchial involvement) demonstrating dystelectasis and infiltrative changes at PT, which resolved during therapy. **Right:** Case 5 (cT3N0M0 NSCLC of the right lower lobe) developed pronounced atelectasis. **Note:** only 5 PT delineations received for Case 1.

**EP-1368 Circulating cell free DNA during chemo-radiotherapy in non-small cell lung cancer patients**

**Purpose or Objective**

To determine the change over time in circulating cell free DNA (cfDNA) in patients with locally advanced non-small cell lung cancer (NSCLC) during chemo-radiotherapy. Furthermore, the possibility for detection of circulating cell free tumor DNA (ctDNA) was assessed using shallow whole genome sequencing (sWGS) and size selection.

**Material and Methods**

Ten patients were included in a two-phase trial. The first four patients had blood samples taken prior to treatment and at 30 minutes, 1 hour and 2 hours after treatment to estimate the short-term dynamics of cfDNA after a therapy session. The remaining six patients had one blood sample taken on six treatment days 30 minutes post radiotherapy to measure the changes in cfDNA. Presence of ctDNA as indicated by chromosomal aberrations was investigated using sWGS. The sensitivity of the method was further enhanced using *in silico* size selection.

**Results**

The cfDNA concentration from baseline to 120 min after therapy was stable within 95% tolerance limits of +/- 2 ng/ml cfDNA. Changes in cfDNA were observed during therapy with an apparent qualitative difference between adenocarcinoma (average increase of 0.69 ng/ml) and squamous cell carcinoma (average increase of 4.0 ng/ml), see Figure 1. Silent chromosomal profiles were observed in 18 out of 23 samples across the two cancer types using sWGS. Size selection enhanced the detection rate from 22% to 74%. Tumor shrinkage on daily cone beam computer tomography scans during radiotherapy did not correlate with changes in concentration of cfDNA.

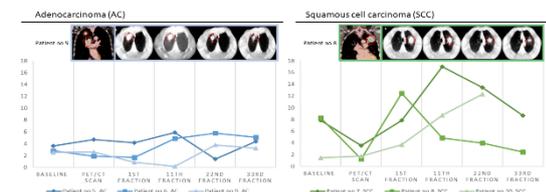

Figure 1. Representative PET/CT and CBCT scans and fluctuation in cfDNA concentration during radiation therapy in adenocarcinoma patients (AC) and patients with squamous cell carcinoma (SCC). Representative scans on corresponding time points are shown for AC (Patient 9) and for SCC (Patient 8).

**Conclusion**

cfDNA remain stable during the first 2 hours after a treatment fraction. However, based on the sWGS profiles, ctDNA represented only a minor fraction of cfDNA in this group of patients. The detection sensitivity of genomic alterations in ctDNA strongly increases by applying size selection.

**EP-1369 Heart delineations based on 3DCT, AVG and MIP scans: are they representative of the total motion?**  
 E. Vasquez Osorio<sup>1</sup>, H. McCallum<sup>2</sup>, S. Iqbal<sup>3</sup>, A. Bedair<sup>4</sup>, A. McWilliam<sup>1</sup>, G. Price<sup>1</sup>, J. Byrne<sup>2</sup>, D. Cobben<sup>5</sup>  
<sup>1</sup>University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom ; <sup>2</sup>Northern Centre for Cancer Care- Freeman Hospital, Radiotherapy Physics, Newcastle upon Tyne, United Kingdom ; <sup>3</sup>Northern Centre for Cancer Care- Freeman Hospital, Radiotherapy, Newcastle upon Tyne, United Kingdom ; <sup>4</sup>North West Cancer Centre, Clinical Oncology, Derry-Londonderry, United Kingdom ; <sup>5</sup>Christie NHS-University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom

**Purpose or Objective**

Evidence is emerging that the heart is more radiosensitive than previously assumed [1-2]. However, only delineations on the average projection or 3D CT scans are used for treatment planning. Therefore the motion of this organ due to respiration and contraction is not accounted for. In this pilot study, we assessed how representative the delineations based on the 3D CT scan, average (AVG) and maximum intensity projections (MIP) are.

**Material and Methods**

Both 3D and 4D CT scans for 10 lung cancer patients treated by SABR were used in this study. Median delineations, derived from 3 independent observers following a previously agreed protocol, were calculated on the 3D CT, AVG, MIP and 25% exhale scans. Delineations on each 4D phase scan (n=8) were created by propagating the median 25% exhale contours using RayStation v5.99. The volume representing the maximum extent of motion was estimated as the union of all 4D phase delineations (U4D), see figure 1 for an example. Surface distances from the U4D to 3D, AVG, MIP volumes were calculated. Distances in the most extreme surface points (1cm most superior/inferior, 10% most right/left/anterior/posterior) are reported.

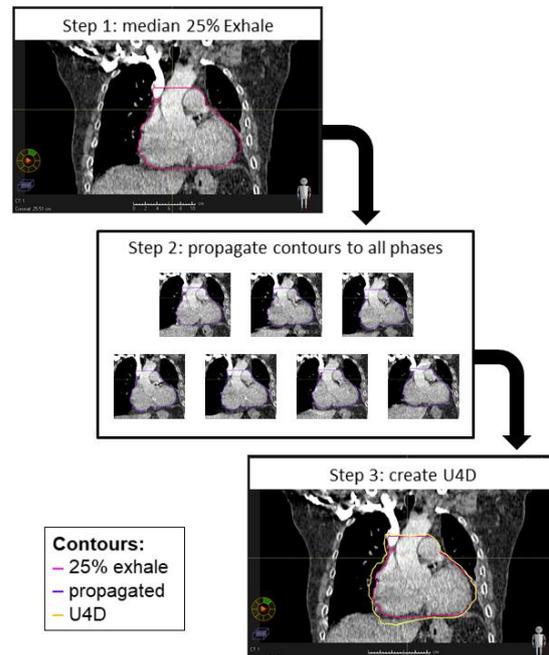

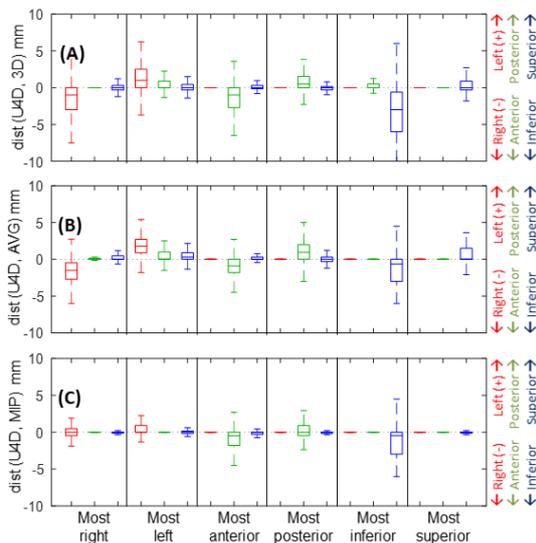

Fig 1: Creating the maximum extent of motion as the union of all 4D phase delineations (U4D).

**Results**

Figure 2 shows the distances for the most extreme surface points, for each delineation and direction (left-right, anterior-posterior and superior-inferior) summarized for

all patients. From the three delineations, MIP is the 'closest' to the maximum extent of motion, followed by AVG and 3D (smaller boxes and closer to zero).

**Fig 2:** Box plot reporting distances of the most extreme points from the maximum extent of motion volume (U4D) to the (A) 3D, (B) AVG and (C) MIP volumes, discriminated by direction. The lines inside the boxes represent the medians, the boxes extend between the 25 and 75 percentiles and the whiskers represent Tukey fences (1.5 x inter-quartile range).

### Conclusion

None of the delineations represented the heart's maximum extent of motion; the MIP was the 'most representative' volume. Current work includes determining the margin required for any of the delineations to better represent the maximum extent of motion. Research including dosimetric measurements and inter-observer variability is needed to determine the relevance of creating a planning organ at risk volume (PRV) of the heart.

[1] Johnson-Hart et al. *IJROBP*. 2018 Oct 1;102(2):434-442.

### EP-1370 The impact of fractionation on lymphocyte counts in stage III NSCLC received chemoradiotherapy

Q. Zhao<sup>1</sup>, J. He<sup>1</sup>, Z. Zeng<sup>1</sup>  
<sup>1</sup>Zhongshan Hospital- Fudan University, Department of radiation oncology, Shanghai, China

### Purpose or Objective

Radiation-related lymphopenia (RIL) is associated with inferior clinical outcomes in lung cancer patients treated with radiation (RT) and immune checkpoint inhibitors (ICIs) following RT. This study was performed to investigate whether fractionation regime affects the peripheral total lymphocyte counts (TLCs) in definitive concurrent chemoradiotherapy (CCRT) for unresectable stage III non-small lung cancer (NSCLC).

### Material and Methods

We retrospectively reviewed 118 patients undergoing definitive CCRT for stage III NSCLC. Dose given to tumor and fractionation received determined by doctor and the intention from patients. The baseline of TLCs was defined as the value measured within one week before RT and a lymphocyte nadir was calculated as the minimum value measured during period of definitive RT. Patients were categorized into three groups. Group A received 2.0-2.2 Gy per fraction (ConRT), while group B received 2.3-2.8

Gy per fraction (moderately HypoRT, mHypoRT), and group C received 3 Gy per fraction Gy (HypoRT).

### Results

There were 52 (44.1%) patients in the ConRT group, 34 in mHypoRT (28.8%) and 32 (27.1%) in HypoRT. Median planning target volume was larger in ConRT (283.89 cm<sup>3</sup>) than in mHypoRT (154.35 cm<sup>3</sup>, P = 0.005) and in HypoRT (118.76 cm<sup>3</sup>, P = 0.001) while there were no difference in gross tumor volume between groups (P = 0.395). Three groups had similar median baseline of TLCs (P = 0.959). During radiation, 70.59% of mHypoRT patients had severe lymphopenia (ie, TLC <500 cells/μl) vs 48.08% of ConRT patients, and 37.50% of HypoRT patients (P < 0.021). Multivariate linear analyses demonstrated that lower baseline TLCs (P < 0.001), higher mean lung dose (P = 0.004) and mHypoRT (P = 0.014) were significantly risk factors of RIL. Higher post-RT TLCs was associated with improved progression-free survival (hazard ratio [HR]: 0.585; 95% confidence interval: 0.369-0.926; P = 0.022) regardless of fractionation regime.

### Conclusion

HypoRT may be more appropriate fractionation regime in definitive concurrent chemoradiotherapy for unresectable stage III non-small lung cancer (NSCLC) as it brings less severe RIL compared with mHypoRT and higher radiation dose compared with ConRT. Further large-scale studies are needed to confirm our findings.

### EP-1371 Impact of target volume delineation on weekly simulation CT during conformal radiotherapy in NSCLC

S. Silipigni<sup>1</sup>, A. Carnevale<sup>1</sup>, C.G. Rinaldi<sup>1</sup>, E. Ippolito<sup>1</sup>, A. Di Donato<sup>1</sup>, P. Matteucci<sup>1</sup>, G.M. Petrianni<sup>1</sup>, S. Palizzi<sup>1</sup>, P. Trecca<sup>1</sup>, B. Santo<sup>1</sup>, L. Trodella<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, S. Ramella<sup>1</sup>  
<sup>1</sup>Campus Biomedico University, Radiotherapy, Roma, Italy

### Purpose or Objective

Anatomical changes during radiotherapy in lung cancer might contribute to target missing and discrepancies between planned and delivered doses. Modern radiotherapy techniques manage the geometrical uncertainties of treatment planning and treatment delivery and thereby improve target coverage with a much steeper dose gradient and less irradiated normal tissue. The aim is to evaluate the shrinkage of target volume in patients with locally advanced NSCLC treated with concurrent radiochemotherapy (RCT) with an adaptive approach

### Material and Methods

Patients with locally advanced NSCLC treated with RCT were investigated. All patients had stage IIIA/IIIB or intrathoracic relapse after surgery. Treatment was performed with a linear accelerator (Varian Medical System) in a photon regimen, with a 6/15-MV nominal energy and three-dimensional conformal technique with multiple planar and nonplanar beams. Concurrent chemotherapy regimens were platinum-based doublets or monotherapy. All patients received a weekly CT simulation. On each weekly CT the CTV was delineated and in case of tumor's shrinkage, a new CTV was created and a new treatment plan outlined ("replanning")

### Results

From 2012 to 2014 replanning was outlined in 50 patients of 217 patients with locally advanced NSCLC treated with RCT and subjected to weekly simulation CT. Patients' characteristics were: mean age 69.6 years (range 38-92), squamous histology 56%, 32% adenocarcinoma, other 12%, stage IIIA 58% and IIIB 42%. The median total dose delivered was 66.6Gy (range 45-75.6) with standard fractionation. Median CTV at CT simulation was 125.2 cc. Contouring CTV on the weekly CT, we observed a progressive shrinkage of the target volume, in particular at the median dose of 19.8, 27, 36 Gy and 45 Gy we registered a reduction of 13%, 20%, 16%, and 43 %

respectively. The replanning has been performed at a median dose of 45Gy. Median CTV at replanning volume was 74.7 cc

#### Conclusion

Tumor shrinkage is common during RCT in NSCLC. There are points in time during the treatment course when it may be appropriate to adapt the plan to improve sparing of normal tissues. In our patients population in which an adaptive replanning was performed we early observed a tumor reduction (13% after 2 weeks of treatment). We are trying to understand if there are volume reduction patterns that can influence prognosis and therefore help to classify lung neoplasms in different groups

#### EP-1372 External Validation of a Survival Score for Limited Disease Small Cell Lung Cancer (LD-SCLC)

L. Käsmann<sup>1</sup>, R. Abdo<sup>1</sup>, C. Eze<sup>1</sup>, M. Dantes<sup>1</sup>, J. Taugner<sup>1</sup>, K. Gennen<sup>1</sup>, O. Roengvoraphoj<sup>1</sup>, D. Rades<sup>2</sup>, M. Niyazi<sup>1</sup>, C. Belka<sup>1</sup>, F. Manapov<sup>1</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>University of Luebeck, Department of Radiation Oncology, Luebeck, Germany

#### Purpose or Objective

Definitive chemoradiotherapy is the standard treatment for limited disease small cell lung cancer (LD-SCLC). However, median survival in LD-SCLC ranges between 16 and 24 months due to early locoregional failure and metastases and not all patients can tolerate such intensive regimen. Defined subgroups such as patients in reduced health condition, with severe comorbidities or elderly need to be critical considered before treatment allocation. Patients with a poor survival prognosis should be offered a short course of treatment to avoid spending a substantial proportion of their limited remaining time with receiving chemoradiotherapy. In order to personalize treatment regimens a survival score for these patients was developed. The aim of this study is to validate the survival score for LD-SCLC in an independent patient collective.

#### Material and Methods

We collected data of all patients treated with chemoradiotherapy (CRT) for LD-SCLC between 2004 and 2015. The validation cohort of this study included 78 patients. 38% of all patients were treated with concurrent CRT. The survival score was calculated by independent prognostic factors namely gender, Karnofsky performance status (50-70 versus 80-100%), Tumor substage (very limited disease versus limited disease) and hemoglobin level before radiotherapy (< 12 mg/dl versus ≥ 12 mg/dl). Scoring points were derived from 2-year survival rates divided by 10 and added to scores for individual patients. Three groups were formed (9-13, 14-18 and 19-26 points). The 2-year survival rate of each group from the original study was compared to its corresponding group from this validation study.

#### Results

Median survival time in our patient collective is 17 months (range: 1-123months). 1- and 2-year-survival rates are 60% and 36%. In the current validation study, the 2-year survival rates were 0% in the 9-13 points group, 35% in the 14-18 points group and 43% in the 19-26 points group, respectively (p=0.018). The difference in 2-year survival between the 9-13 points and the 14-18 points group was significant in the complete cohort (p=0.007) as well after stratification of concurrent CRT in the validation cohort (p<0.001), whereas the difference between the 14-18 points and the 19-26 points group was not (p=0.602, p=0.770).

#### Conclusion

The score was reproducible and valid to estimate the 2-year survival rate of patients with LD-SCLC. In order to improve the differentiation between patients with an intermediate and a favorable survival prognosis, the scoring system needs further development.

#### EP-1373 Introducing PET CT in SBRT lung cancer follow-up: Preliminary results of our center protocol.

J. Luna<sup>1</sup>, D. Gonsalves<sup>1</sup>, L. Guzman<sup>1</sup>, M. Rincón<sup>2</sup>, M. Montero<sup>1</sup>, A. Ilundain<sup>1</sup>, W. Vasquez<sup>1</sup>, M.E. Lopez<sup>1</sup>  
<sup>1</sup>Fundación Jiménez Díaz, Radiation Oncology, Madrid, Spain; <sup>2</sup>Fundación Jiménez Díaz, Physics Radiation Oncology, Madrid, Spain

#### Purpose or Objective

To describe the preliminary results conducted for a follow-up protocol in primary lung cancer with stereotactic body radiation therapy in our center. The primary end point for this prospective study is to describe the morphologic and metabolic changes documented in the follow up with Positron emission tomography scan (PET CT) and the clinical decisions surrounding it.

#### Material and Methods

A multidisciplinary team consisted in radiation oncologist, radiologist and nuclear medicine specialist developed in 2014 a protocol for follow up in patients treated with SBRT for the lung cancer.

A Tomography (CT) and PETCT have to be present at the diagnoses.

SBRT treatment consisted in a 4D CT simulation scans with an Elekta frame based immobilization system and free breathing. The plan was delivered using Beam Modulator Linac with HEXA POD system and ELEKTA XVI CBCT system for quality assurance. Fractioning was determining by physician criteria.

Our follow-up included a CT scan at 2 months post treatment, then 2-3 months a PETCT and a second PETCT 2 month later for confirmation of results.

After these first three studies, if the patient presented a complete response (1° arm), as determine in the PERCIST 1.1 (PET Response Criteria in Solid Tumors), a CT every 6 months for the first 3 years were done.

If the patient presented a partial response or stable (2°arm), a follow up with PETCT was done every 6 months for the first 3 years. It was recommended in 1° arm that a progression had to be confirmed with a PET and in the 2° arm two possible options were available: a PETCT in 3 months or a biopsy.

We reviewed the clinical records from the patients involved in the study between April 2015 and November 2017 and analyzed local control rate (LC), loco regional progression (PLR) and systemic progression rate (PSR).

#### Results

We enrolled 31 patients. 77.4 % were men. The median age was 73 years (range 61-81 years). The localization for the tumor was 61 % peripheral, 22.5% central and 16.4% ultra central. The mean size of the tumor treated was 19.5 mm and with mean SUV max of 11.36 (sux max 1.4 - 31.7). The most frequent fraction prescription was 5 session of 10 Gy per session. The patients included in 1° arm follow up were 9.6%.

Median follow up of 19.22 months. LC was 96.8 %, PSR 16.4% and PLR 9.6%.

In 1° arm follow up, 2 patients presented a local progression with a complete response in PET CT.

In 2° arm, 3 patients went for lung biopsy because a disease progression with a negative results afterwards.

In both arms, 3 patients presented a radiological regional progression (lymph node ipsilateral) diagnosed in PET went for biopsy: 2 were negative and 1 positive

#### Conclusion

In our preliminary results, PET is useful to determine a morphologic and metabolic response in SBRT.

Developing a follow up protocol including PETCT for SBRT allows a homogeneity approach to clinical decisions.

#### EP-1374 ECOG-PS and its changes in inoperable stage III NSCLC patients treated with chemoradiotherapy

L. Käsmann<sup>1</sup>, J. Taugner<sup>1</sup>, C. Eze<sup>1</sup>, M. Dantes<sup>1</sup>, O. Roengvoraphoj<sup>1</sup>, K. Gennen<sup>1</sup>, M. Karin<sup>1</sup>, A. Tufman<sup>2</sup>, M.

Niyazi<sup>1</sup>, C. Belka<sup>1</sup>, F. Manapov<sup>1</sup>  
<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Thoracic Oncology Centre Munich Ludwig-Maximilians University, Division of Respiratory Medicine and Thoracic Oncology Department of Internal Medicine V, Munich, Germany

#### Purpose or Objective

The Eastern Cooperative Oncology Group performance score (ECOG-PS) is widely used in clinical routine to quantify patients' general condition. We evaluated ECOG-PS before, after and its alteration in the course of chemoradiotherapy (CRT) in patients with stage III non-small cell lung cancer (NSCLC).

#### Material and Methods

The data of ninety-eight patients with NSCLC of UICC 7<sup>th</sup> edition stage IIIA/B and performance status ECOG 0-1 before treatment was evaluated. ECOG-PS before treatment, on first medical aftercare and the difference between, was examined for their impact on overall survival (OS) from initial diagnosis and time to local progression (TTLP), time to distant metastasis (TTDM) and event free survival (EFS) from the first day of irradiation.

#### Results

The majority of patients were treated with concurrent (79%) or sequential (11%) chemoradiotherapy, while 51% received induction chemotherapy. Median survival for the entire cohort was 20.8 (range: 15.3-26.2) months. Our cohort consisted of 62% males and 38% females. Before treatment ECOG-PS was 0 in 48% and 1 in 52% of patients, their median OS, one-year and two-year survival was 26.4 months, 85%, 53% and 18.9 months, 69%, 37% (p=0.108). After completion of CRT ECOG-PS was 0 in 34%, 1 in 46%, 2 in 18% and 3 in 2% of patients, median OS, one-year and two-year survival was 40.3 months, 88%, 64% for ECOG-PS 0, 19.3 months, 82%, 40% for ECOG-PS 1, 11.9 months, 50%, 28% for ECOG-PS 2 and 7.6 months, 0%, 0% for ECOG-PS 2 (p<0.001). During treatment ECOG-PS remained the same in 62%, was reduced by one in 3% and was increased by one in 30% and by two in 5% of patients. Taken together, 65% of patients had the same or better (=stable) and 35% of patients had worse ECOG-PS after CRT, with median OS, one-year and two-year survival of 29.3 months, 84%, 53% and 13.7 months, 62%, 29%, respectively (p<0.001). Increase of ECOG-PS during treatment impaired OS in both patient subgroups with initial ECOG-PS 0 (p=0.005, median OS 19.1 vs 31.4 months) and 1 (p=0.001, median OS 22.9 vs 11.1 months). Distant metastasis (DM) were diagnosed in 40 patients after completion of CRT. ECOG-PS before and after CRT did not predict occurrence of DM. Patients with an ECOG-PS increase during treatment however showed significantly more distant metastasis (53% vs 35%) with a median TTDM of 9.1 months (p<0.001). EFS was not affected by ECOG-PS before treatment but was impaired by ECOG-PS increase during CRT with median EFS of 9.4 vs 7.7 months (p=0.049) and by ECOG-PS after CRT with median EFS of 9.6 months, 9.0 months, 7.9 months and 3.5 months for ECOG-PS 0, 1, 2, 3, respectively (p=0.018). TTLP was not affected by ECOG-PS before and after treatment or ECOG-PS increase during treatment.

#### Conclusion

ECOG-PS and its changes have a strong impact on patients' outcome. Reduction of performance status was a significant negative factor for patients' probability to develop DM, for EFS and OS.

#### EP-1375 Heterogeneity score in inoperable stage III NSCLC patients treated with definitive chemoradiotherapy

J. Taugner<sup>1</sup>, L. Käsmann<sup>1</sup>, C. Eze<sup>1</sup>, M. Dantes<sup>1</sup>, O. Roengvoraphoj<sup>1</sup>, K. Gennen<sup>1</sup>, M. Karin<sup>1</sup>, A. Tufman<sup>2</sup>, M. Niyazi<sup>1</sup>, C. Belka<sup>1</sup>, F. Manapov<sup>1</sup>  
<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology- Munich- Germany., München,

Germany; <sup>2</sup>Thoracic Oncology Centre Munich Ludwig-Maximilians University, Division of Respiratory Medicine and Thoracic Oncology Department of Internal Medicine V, Munich, Germany

#### Purpose or Objective

Stage III non-small cell lung cancer (NSCLC) represents a very heterogeneous disease regarding principal patient- and tumor characteristics. In clinical routine, a simple heterogeneity score may further aid in personalizing multimodal therapy.

#### Material and Methods

The data of ninety-nine consecutive patients with performance status ECOG 0-1 treated until the end of 2016 with multimodal approach for inoperable NSCLC (UICC 7<sup>th</sup> edition stage IIIA/B) were evaluated. Patient- and tumor-related factors were examined for their impact on overall survival. Factors showing a significant negative association with patient prognosis were scored with one point each. Three subgroups with low, intermediate and high risk (0-1, 2-3 and 4-5 points) score were defined. The results were then validated in our own prospective cohort, which started January 2017 and includes 35 patients with at least one year of follow-up.

#### Results

The majority of patients were treated with concurrent (78%) or sequential (11%) chemoradiotherapy, while 53% received induction chemotherapy. Median survival for the entire cohort was 20.8 (range: 15.3-26.3) months. Age (p=0.020), gender (p=0.007), cumulative pack years (PY) (p=0.015), tumor-associated atelectasis (p=0.004) and histology (p=0.004) were shown to have a significant impact on survival. 12, 59 and 28 patients were defined to have a low, intermediate and high-risk heterogeneity score. Median survival, 1-, 2- and 3-year survival rates were distributed as follows: not reached, 100%, 83% and 67% in the low, 22.9 (16.3-29.5) months, 80%, 47% and 24% in the intermediate and 13.7 (11.1-16.3) months, 57%, 25% and 18% in the high-risk subgroup, respectively (p<0.001). Even though median survival was not yet reached in our validation cohort (low risk: 4; intermediate risk: 15; high risk: 16 patients), it has revealed a one-year survival trend with 100% for the low risk, 93% for the intermediate risk and 69% for the high risk subgroup (p=0.100).

#### Conclusion

A simple heterogeneity score was developed for inoperable stage III NSCLC patients with good performance status receiving multimodal therapy. The score may aid physicians to infer clinical outcomes and optimize everyday decision-making as well as planning of prospective studies.

#### EP-1376 Robotic SBRT with fiducial tracking for medically inoperable peripheral stage I NSCLC: final report

S. Kataria<sup>1</sup>, N. Aghdam<sup>1</sup>, M. Repka<sup>2</sup>, M. Marin<sup>3</sup>, L. Campbell<sup>1</sup>, S. Suy<sup>1</sup>, S. Collins<sup>1</sup>, E. Anderson<sup>4</sup>, J. Lischalk<sup>1</sup>, B. Collins<sup>1</sup>

<sup>1</sup>Georgetown University Hospital, Radiation Medicine, Washington DC, USA; <sup>2</sup>NYU Winthrop Hospital, Radiation Oncology, Mineola- New York, USA; <sup>3</sup>New York Medical College-Metropolitan Hospital, Internal Medicine, New York- NY, USA; <sup>4</sup>Georgetown University Hospital, Pulmonary & Critical Care Medicine, Washington DC, USA

#### Purpose or Objective

Published data have demonstrated robotic SBRT with fiducial tracking to be an effective alternative treatment for medically inoperable patients with peripheral Stage I NSCLC. Limited data, however, is available regarding the long term outcomes associated with using this technique. Here we report our institutional experience treating this patient population.

#### Material and Methods

Medically inoperable patients due to age or other comorbidities with biopsy proven peripheral Stage I NSCLC and a minimum follow up of 7 years were evaluated. PET/CT imaging was completed for staging. Three to five gold fiducial markers were implanted in or near tumors under CT guidance or via electromagnetic navigational bronchoscopy to serve as targeting references. Gross tumor volumes were contoured using lung windows. The margins were expanded by 5 mm to construct the planning treatment volume (PTV). Doses delivered to the PTV ranged from 45-60 Gy in 3 or 5 fractions. Treatments were delivered daily utilizing the CyberKnife system with fiducial tracking. Pulmonary function testing was completed a median 49 days prior to the start of SBRT and 1 year after completion. Clinical examination and PET/CT imaging were completed at 6 month follow up intervals.

#### Results

From August 2005 to August 2011, forty patients (median age 76 years) with a median maximum tumor diameter of 2.7 cm (range, 1.4-5.0 cm) were treated and followed for a minimum of 7 years or until death. A median dose of 50 Gy was delivered over a median 7 days (range, 3-13 days). The median follow up for all and alive patients was 4.6 and 8.9 years, respectively. There were 2 primary tumor failures, 1 involved lobe failure, and 1 nodal failure. The 5 year Kaplan-Meier primary tumor control, LC, LRC, distant control, and DFS estimates were 95%, 91%, 88%, 82%, and 70%, respectively. Overall survival (median 4.5 years) and cancer specific survival estimates at 5 and 8 years were 43% and 23%, and 79% and 62%, respectively. Nine patients, all whom had fiducials placed under CT guidance, developed a pneumothorax requiring chest tube placement: no pneumothoraces were observed following bronchoscopic fiducial placement. The 5 year cumulative incidence of radiation induced rib fracture (RIRF) was 53%, with a median time to fracture of 39 months. There was no difference in percent predicted FEV1 one year following SBRT; there was, however, a modest decline of 7.4% (p=0.02) in the percent predicted DLCO at one year.

#### Conclusion

Our institution's medically inoperable Stage I NSCLC outcomes compare favorably with conventional SBRT outcomes from RTOG 0618. Bronchoscopic fiducial placement minimizes the risk of pneumothoraces requiring chest tube placement. Although the RIRF rate was high, the majority of patients were asymptomatic, diagnosed via surveillance PET/CT imaging, and required only conservative management.

#### EP-1377 Role of psoas volume in locally advanced or metastatic NSCLC patients undergoing radiation therapy

V. Nardone<sup>1</sup>, S. Falivene<sup>1</sup>, Giugliano, Francesca Maria<sup>1</sup>, F. Scala<sup>2</sup>, Tini, Paolo<sup>3</sup>, Pirtoli, Luigi<sup>3</sup>, C. Guida<sup>1</sup>, S. Cappabianca<sup>2</sup>

<sup>1</sup>*Ospedale del Mare, Radiation Therapy Unit, Napoli, Italy*; <sup>2</sup>*University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy*; <sup>3</sup>*Unit of Radiation Therapy, University Hospital of Siena, Siena, Italy*

#### Purpose or Objective

To evaluate the volume and median intensity of psoas muscle on CT imaging at the time of diagnosis as a prognosticator in patients with locally advanced or metastatic NSCLC undergoing chemotherapy or radio/chemotherapy.

#### Material and Methods

We included patients with NSCLC undergoing palliative radiation therapy at our Department between January 2010 and December 2017. We contoured on CT made at the diagnosis the volume of right and left psoas volume from the cranial border of L4 till the caudal border of L5. We calculated the median volume between the sides and we divided the median volume for the height of the muscle

(Median Area, MA), and we also divided the MA for the median intensity in Hounsfield Units (MA/I). We analyzed overall survival (OS) with these parameters (using the median value as cut-off) and the known prognosticators (age, ECOG, stage, previous surgery, number of metastases), with Kaplan Meier method (univariate) and Cox Regression Analysis (multivariate).

#### Results

We included 138 patients (97 males and 41 females), with a median age of 67 years (mean 64 years, range 30-84 years). At univariate analysis of OS, the significant parameters were the ECOG (p<0,001), the MA (p:0,001), MA/I (p:0,005), previous surgery (p:0,001), number of metastases (p<0,001). At multivariate analysis, only ECOG (p:0,004), MA (p:0,005), number of metastases (p:0,001) resulted significant.

#### Conclusion

MA and MA/I in NSCLC patients could represent an independent prognosticator of survival, and could help to stratify the patient's prognosis.

#### EP-1378 Brain imaging pre/post treatment in cN2 non-small cell lung cancer treated with chemo-radiation

C.W.E. Chan<sup>1</sup>, H.W.G. Gan<sup>1</sup>, P. Lyons<sup>1</sup>, P. Mcloone<sup>1</sup>, N. Mohammed<sup>1</sup>

<sup>1</sup>*Beatson West of Scotland Cancer Centre- Glasgow- UK, Clinical Oncology, Glasgow, United Kingdom*

#### Purpose or Objective

The incidence of brain metastases (BM) ranges from 10-47% and increases with more advanced non-small-cell lung cancer (NSCLC). Stage 3 NSCLC has 20% of patients diagnosed with BMs, and hence British Thoracic Society (BTS) guidelines state that brain imaging should be performed as part of pre-treatment staging. Asymptomatic BM identified on imaging may alter treatment. Therefore, the aims of this study are to assess pre-treatment imaging in radically treated cN2 NSCLC patients, the incidence of BM after definitive treatment and outcomes.

#### Material and Methods

Patients with stage cN2 NSCLC diagnosed between January 2013 to December 2016 and treated with chemo-radiation therapy (CRT) in the West of Scotland were analysed retrospectively using electronic patient records. Information of pretreatment investigations, treatment given, subsequent follow-up and outcomes were collated and analysed.

#### Results

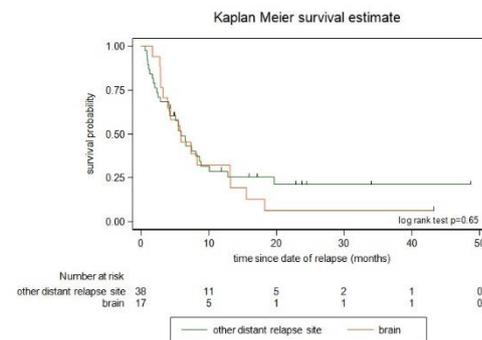

107 patients with stage cN2 NSCLC treated with CRT were identified and analysed. The median age was 65 years (26-84 years), 56(52%) female and 51(48%) male. ECOG performance status was recorded as 0, 1 and 2 in 55, 47 and 3 patients. TNM staging was T1(11%), T2(25%), T3(27%), T4(34%), Tx(2%) and all patients were cN2, M0(96%) and M1(4%). Pathology was squamous cell in 50%, adenocarcinoma 42% and other in 8%. 7 patients also demonstrated ALK or EGFR variants. Radiotherapy dose was 55Gy in 20 fractions over 4 weeks using volumetric modulated arc radiotherapy (VMAT) or 3DConformal radiotherapy. Nine patients received neoadjuvant chemotherapy and all patients had concurrent platinum doublet.

All patients underwent a positron emission tomography (PET) scan, but only 45 patients (41%) had a pre-treatment brain scan, of which 27 were CT scans and 18 were MRI scans. The proportion of brain scans performed increased over time:

Year	Imaged	No Image	Proportion
2013	5	17	0.23
2014	9	15	0.37
2015	16	27	0.37
2016	15	5	0.75

Chi-square for trend  $p=0.0015$

104 patients underwent follow-up imaging at a median of 49(IQR 22.5-87.5) days from end of treatment. During the follow-up period 56(51%) patients experienced distant relapse, of which 18(32%) had BM. Distant relapse occurred within 3 months of the end of treatment for 11 patients, of which 2 patients were diagnosed with BM. The median overall survival of patients relapsing with BM was 5.9 months(95% CI: 2.9-13.1) and with other site of relapse was 5.9 months(95% CI: 4.1-8.6). (See figure)

### Conclusion

Our study shows that clinicians have increasing awareness of the need for pre-treatment brain imaging in cN2 patients for radical treatment. This can still be improved further. After CRT, one third of patients relapsed with symptomatic BM for whom survival was poor. Progress in BM treatment warrants investigating the impact of routine follow up brain imaging after treatment.

### EP-1379 RE-STARTing after lung cancer: impact of a wellbeing event on global health status of survivors.

E. Ippolito<sup>1</sup>, M. Fiore<sup>1</sup>, C. Greco<sup>1</sup>, S. Silipigni<sup>1</sup>, B. Floreno<sup>1</sup>, M. Miele<sup>1</sup>, B. Santo<sup>1</sup>, L. Trodella<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Campus Biomedico University, Radiotherapy, Roma, Italy

### Purpose or Objective

Modern therapies led to an increased survival for patients with lung cancer. Therefore there is a need for dedicated survivorship care for these patients. The aim of this study was to investigate the impact of one day wellbeing event (RE-START initiative) on their health and QoL.

### Material and Methods

Patients with primary lung cancer treated in our institution, after the completion of cancer treatment and in clinical remission were asked to participate in the event. During the event, there were talks providing information on diet, keeping active and managing stress. During the event participants completed a survey package that included the Psychological General Well Being Index (22 items) for distress assessment, NCCN Survivorship Assessment for physical wellness evaluation (14 items), World Cancer Research Fund Cancer Risk derived questionnaire for Dietary and Lifestyle Habits (11 items). The same survey package was completed 3 months after the event by phone interviews.

### Results

From 2015 to 2017, 100 survivors were asked to participate in the event. 51 patients (51%) agreed to participate but only 19 (19%) patients were present. Baseline mean anxiety and depression level were 15.8 (scale 0-25, where the highest score corresponds to the lowest level of anxiety) and 11.83 (scale 0-15, where the highest score corresponds to the lowest level of depression) respectively. Only 25% of patients reported high level of anxiety. Only one patient (8%) showed severe depression. No change was detected three months after the event. Almost half of patients presented pain at baseline (56%) while 38% of patients experienced fatigue. Pain and fatigue improvement after the event occurred in 4 patients (27%). Most of patients reported healthy habits (67-100%). Improvement in dietary habits after the event was also reported (5-10%).

### Conclusion

Only few patients participated in the event. However information provided during the event led patients to modify their habits. Through the questionnaires we were able to identify subgroups of survivors with severe anxiety and depression to whom dedicate intervention strategies

### EP-1380 Intra-fractional Motion in Lung SBRT Treatments with Different IGRT Techniques

I.F. Durmus<sup>1</sup>, B. Tas<sup>1</sup>, A. Okumus<sup>1</sup>

<sup>1</sup>Yeni Yuzyil University Gaziosmanpasa Hospital, Department of Radiation Oncology, Istanbul, Turkey

### Purpose or Objective

Investigation of intra-fraction in 4D-CT and DIBH-CT techniques in lung SBRT treatments.

### Material and Methods

Intra-fraction motion was monitored in 76 fractions of 15 patients with lung SBRT. In 9 patients, 4D-CT scans were acquired into consideration in consideration of all phases of respiration, and ITV was created by adding a margin depending on the amount of motion of the GTV. PTV was created by including safety margins in ITV. Prior to the treatment, 4D-CBCT scanning was performed to ensure the accuracy of the target and patient position. Then, while the VMAT field was irradiated, CBCT scanning was performed simultaneously. After the treatment field was completed, the amount of motion in the target was determined. In this way, intra-fraction motion was monitored in 51 fractions of 9 patients. For the 6 patients with the catalyst surface scanning system, breath was restricted in the determined phase range (deep breath) of the respiration and a CT scan was performed. PTV was created by adding only one safety margin to the GTV, despite limited respiratory in patients scanned by DIBH-CT. Prior to the treatment, CBCT scanning was performed to ensure the accuracy of the target and patient position. Then, while the VMAT field was irradiated, CBCT scanning was performed simultaneously. After the treatment field was completed, the amount of motion in the target was determined. In this way, intra-fraction motion was monitored in 25 fractions of 6 patients.

### Results

The mean deviation ( $\pm$  direction) during treatment was 4 cm with 4D-CT and 0.13 cm with DIBH-CT. In 76 fractions of 15 patients, the maximum deviation was obtained smaller than 0.3 cm. A deviation of greater than 0.3 cm was obtained with the DIBH-CT on the vertical axis and 4D-CT on the longitudinal axis (Table1).

Intra-Fraction CBCT		Lateral (cm)	Longitudinal (cm)	Vertical (cm)
4D-CT (51)	Mean	0.07±0.07	0.10±0.08	0.10±0.09
	Maximum	0.3	0.35	0.29
DIBH-CT (25)	Mean	0.11±0.08	0.14±0.09	0.10±0.09
	Maximum	-0.23	-0.29	0.4

### Conclusion

When the intra-fraction deviation amounts in 76 fractions were examined by 4D-CT and DIBH-CT techniques, it was determined that treatment could be performed reliably with ITV 3 mm safety margin in both IGRT techniques.

In case of maximum deviation of  $\pm 2$  mm during treatment;

- With 4D-CT, safe treatment can be performed in 96.1% of all fractions in the lateral direction, in 90.2% of all fractions in the longitudinal direction, and in 90.16% of all fractions in the vertical direction.
- With DIBH-CT, safe treatment can be performed in 84% of all fractions in the lateral direction, in 76% of all fractions in the longitudinal direction, and in 92% of all fractions in the vertical direction.

Movement management was provided by DIBH-CT and 4D-CT techniques. However, there may be intra-fractional movement in the tumor. PTV should be created by adding 3-5mm safety margin to ITV.

### EP-1381 Stereotactic Body Radiotherapy for Unresectable Locally-Advanced Non Small Cell Lung Cancer

F. Arcidiacono<sup>1</sup>, M. Casale<sup>1</sup>, P. Anselmo<sup>1</sup>, F. Trippa<sup>1</sup>, L. Draghini<sup>1</sup>, S. Terenzi<sup>1</sup>, A. Di Marzo<sup>1</sup>, M. Italiani<sup>1</sup>, S. Fabiani<sup>1</sup>, E. Maranzano<sup>1</sup>  
<sup>1</sup>Radiotherapy Oncology Centre, Santa Maria Hospital, Terni, Italy

#### Purpose or Objective

Conventional fractionated radiotherapy (cRT) concurrent with chemotherapy (ChT) is the standard of care in unresectable locally-advanced non small cell lung cancer (LA-NSCLC). The majority of patients (pts) cannot tolerate this treatment due to its toxicity, so sequential ChT followed by cRT is the more frequent choice in clinical practice. Recently, stereotactic body radiotherapy (SBRT) has been used instead of cRT in early-stage NSCLC offering superior control with less toxicity. Few studies exist on SBRT in LA-NSCLC. We present our experience on this last topic.

#### Material and Methods

Between June 2015 and July 2018, 17 LA-NSCLC pts who underwent SBRT were analyzed. 13/17 (76%) pts received neoadjuvant ChT before SBRT. All pts had CT-PET before SBRT. In pts submitted to neoadjuvant ChT the target volume was the residual disease defined on the basis of CT-PET images. A specific treatment planning for primary tumor (T) and lymph-node/s (N) was done in 9 (53%) pts, while in remaining 8 (47%) the planning target volume (PTV) included both T and N. All pts repeated CT-PET 3 months after treatment and thereafter every 4-6 months. Response, cancer specific survival and toxicity were evaluated.

#### Results

Median age was 72 years (55-81). At diagnosis, 8 (47%), 7 (42%) and 2 (11%) pts had clinical N1, N2 and N3, respectively. Primary tumor was central in 12 (71%) and peripheral in 5 (29%) pts. Median PTV for T and N separately treated were 17.2 cc (8.7-67.96) and 15.02cc (9.9-72.3), while for T and N treated in the same target

median PTV was 91.86 cc (53.2-165.9). Median prescribed dose was 40 Gy (35-55) and 35 Gy (35-45) in 5 fractions to T and N, respectively. At the first follow up, all (100%) pts had a metabolic response at PET-CT. After a median follow-up of 7 months (range, 4-41) there were 3 (18%) local recurrences (LR), 2 (12%) regional node (RN) recurrences and 1 (6%) distant progression (DP). Median LR-free survival (FS), RN-FS and DP-FS were 6 (2-41), 7 (2-41) and 7 months (2-41), respectively. Median overall and cancer specific survival were 7 months (2-41). Of note, 2 pts who had hemoptysis before SBRT resolved the symptom after treatment. No patients developed > grade 2 CTCAE toxicity.

#### Conclusion

SBRT was a feasible, safe and effective treatment in selected unresectable LA-NSCLC pts. Although preliminary outcomes were promising in terms of results and toxicity, larger and more mature studies are needed before the routinely use in clinical practice.

### EP-1382 Texture analysis of FDG-PET in NSCLC treated with SBRT: a validation study of two prognostic features

M. Bertolini<sup>1</sup>, M. Galaverni<sup>2</sup>, M. Manicone<sup>2</sup>, I. Renna<sup>2</sup>, P. Ciammella<sup>2</sup>, L. Giaccherini<sup>2</sup>, F. Bellafiore<sup>2</sup>, G. <sup>1</sup>Azienda USL-IRCCS di Reggio Emilia, Medical Physics Unit, Reggio Emilia, Italy; <sup>2</sup>Azienda USL-IRCCS di Reggio Emilia, Radiation Oncology Unit, Reggio Emilia, Italy; <sup>3</sup>Azienda USL-IRCCS di Reggio Emilia, Nuclear Medicine Unit, Reggio Emilia, Italy

#### Purpose or Objective

To validate the prognostic value of two textural features of 18F-FDG PET/CT in SBRT-treated early-stage NSCLC

#### Material and Methods

HISTO\_Kurtosis and Long-Run Low Gray-level Emphasis (GLRLM\_LRLGE) are textural features that predicted recurrence free survival (RFS) in a previous analysis on 18F-FDG PET/CT of patients with early stage NSCLC treated with SBRT at our center. We validated this findings in a wider patient population. Twenty-six patients with early stage NSCLC between 2010 and 2017 underwent a 18F-FDG PET/CT before SBRT treatment. In PET image sets of every patient a volume of interest was defined around the tumor by two experienced radiation oncologists. An automatic segmentation was performed inside this volume by using a fixed threshold of 40% of maximum SUV (standardized uptake value). For each volume 45 textural features were calculated using LIFEX software. For each patient clinical data about age, gender, Karnofsky Performance Status (KPS), initial stage, histology, location, prescribed biological effective dose, local recurrence, lobar recurrence, regional recurrence, distant recurrence and death were acquired. Study endpoint was recurrence free survival (RFS). Cut-off values were obtained using a support vector machine (SVM) based analysis and RFS were compared using log-rank test analysis.

#### Results

Median age of the population was 75 years (range 53-90) with 19 men and 7 women. The majority of patients (22) had KPS  $\geq$  80. Stage was T1N0M0 in 10 patients, T2N0M0 in 11, T3N0M0 in 5. Pathological diagnosis was achieved in 15 patients (7 adenocarcinomas and 8 squamous cell carcinomas). Tumor was located in upper lung field in 11 patients, in middle in 1 and in lower in 14. Most of the patients (20) were treated with BED  $\geq$  100 Gy, calculated using linear quadratic model with an  $\alpha/\beta$  ratio of 10 Gy. The median follow-up period was 17.5 months for the entire population and 20 months for the surviving patients. 1-year OS was 69% (CI 64-74). At final follow-up, 13

patients had recurrences: local (n=2), lobar (n=1), regional (n=2), distant (n=6), local and regional (n=1), local, regional and distant (n=1). SVM model found that HISTO\_Kurtosis and GLRLM\_LRLGE can describe patients with any disease recurrence (AUC=0.65). A cutoff of HISTO\_Kurtosis=2.5 obtained with log-rank test was able to classify the population in high and low recurrence risk (p=0.03).

#### Conclusion

Among baseline 18F-FDG PET/CT textural feature, HISTO\_Kurtosis and GLRLM\_LRLGE confirmed as predictors of RFS in our analysis. Although this needs further validation on a larger series of patients, it may reveal helpful in identifying patients who will benefit from closer surveillance or adjuvant therapy.

#### EP-1383 Cytokine profile of NSCLC patients treated with chemoradiotherapy regarding to radiation pneumonitis

Abstract withdrawn

#### EP-1384 Analysing stage III cN2 NSCLC treated with surgery or concurrent chemo-radiation

P. Lyons<sup>1</sup>, H.W.G. Gan<sup>1</sup>, C.W.E. Chan<sup>1</sup>, E. McCully<sup>1</sup>, S. Ansel<sup>1</sup>, M. Philip<sup>1</sup>, N. Mohammed<sup>1</sup>

<sup>1</sup>Beatson West Of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom

#### Purpose or Objective

Non-small cell lung cancer (NSCLC) patients with stage 3 N2 disease are a heterogeneous group of patients who are offered surgery or chemo-radiotherapy. ESMO lung cancer guideline recommends consideration of surgery for early stage NSCLC - cT1-3 N0-cN2 M0. And inoperable, locally advanced patients are treated with radical chemo-radiation (CRT) if permissible. This study investigated the outcomes of stage 3 N2 patients either diagnosed after surgery or before CRT in order to compare their survival outcomes.

#### Material and Methods

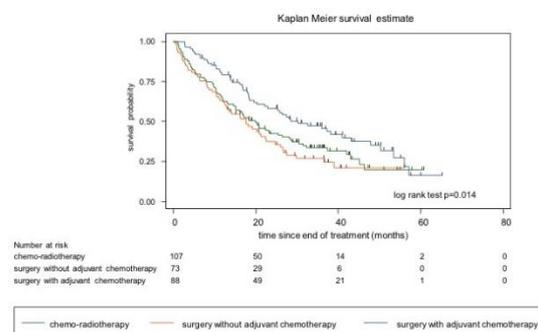

Patients with stage cN2 NSCLC diagnosed from January 2013 to January 2016, and treated with chemo-radiation or patients who underwent lung resection and had a diagnosis of pN2 in the West of Scotland were identified. A retrospective audit of patients was performed.

#### Results

We identified 161 patients with pN2 diagnosis after lung resection and 107 patients with cN2 diagnosis treated with concurrent chemo-radiation. The demographic data was similar between the surgical and CRT group except that the surgical pN2 group had prior clinical staging of cN0 (43%), cN1 (25%) and cN2 (31%) as opposed to CRT patients, which were all cN2.

In addition, only 88 patients (54%) of the surgical pN2 group were given adjuvant chemotherapy as opposed to all CRT cN2 patients.

The median overall survival (OS) of the surgical pN2 group was not significantly different compared with the more advanced cN2 CRT patients who had median survival 19.9 months (95% CI 14.6-26.4m), However, median OS in patients with surgical pN2 who received adjuvant chemotherapy had significantly higher overall survival than surgery alone - 30.2 months versus 17.6 months (95% CI 12.3-22.6m) (p=0.003) (Figure 1).

#### Conclusion

It is clear that NSCLC patients with pN2 disease (includes cN0-2) are not comparable with cN2 patients in terms of burden of disease. Yet our study demonstrated that median OS was not statistically different. This was because 43% patients were cN0 and were considered fit for surgery but not chemotherapy, resulting in 46% of pN2 patients not given adjuvant chemotherapy.

Hence, further investigation of the mediastinal nodal staging is warranted and possibly to reconsider mediastinal staging of PET negative nodes. In addition, patients considered for surgery should be assessed in terms of fitness for both surgery and chemotherapy or else be considered for chemo-radiation.

#### EP-1385 Does pneumonitis increase in irradiated lungs during immunotherapy? A generating hypotheses study

C. Mazzarella<sup>1</sup>, A. Martino<sup>2</sup>, A.R. Alitto<sup>1</sup>, F. Preziosi<sup>1</sup>, F. Catucci<sup>1</sup>, A. Petrone<sup>1</sup>, M. Campitelli<sup>1</sup>, F. Marazzi<sup>1</sup>, G.C. Mattiucci<sup>2</sup>, G. Palazzoni<sup>2</sup>, V. Valentini<sup>2</sup>, G. Mantini<sup>2</sup>  
<sup>1</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS, Scienze Radiologiche- Radioterapiche ed Ematologiche, Rome, Italy ; <sup>2</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS-Università Cattolica del Sacro Cuore, Scienze Radiologiche- Radioterapiche ed Ematologiche, Rome, Italy

#### Purpose or Objective

Immunotherapy with immune checkpoint inhibitors (ICIs) revolutionized therapy of advanced non-small-cell lung cancer (NSCLC). Nivolumab have been shown to improve overall survival in advanced, metastatic patients (pts) with NSCLC. Nevertheless, immune-related pneumonitis is a potentially fatal toxicity of anti-PD-1/PD-L1. This study investigates the role of chest radiotherapy (RT) and the development of immune-related pneumonitis in NSCLC treated with nivolumab.

#### Material and Methods

Consecutive patients with locally-advanced or metastatic NSCLC treated with nivolumab as second or third-line therapy for recurrent or progressive disease, between May 2017 and March 2018 were included. Patient demographics, treatment, adverse event and RT data including type of RT, volume of RT and number of courses were collected. Toxicity was evaluated according to the common terminology criteria for adverse events (CTCAE) version 4.0.

#### Results

Seventeen patients were treated, mostly male (65%), current or former smokers (76.5%) with Eastern Cooperative Oncology Group (ECOG) PS score <2 (88%). Median age was 67 years (range: 49-79). Previously 15/17 (88.2%) patients had undergone radiotherapy on the thoracic disease or for metastatic sites. Mean number of nivolumab cycles was 12 (range: 1-26). 11/17 (64.7%) patients had only locally-advanced disease. Of 15 patients who received any RT, we observed 3/15 (20%) G2/G3 pneumonitis and 1/15 (6.6%) G4. Only 1/4 (25%) pneumonitis occurred in RT field.

### Conclusion

Even if pneumonitis incidence is maybe higher in irradiated lung patients treated with nivolumab, the finding of clear factors that could cause this event needs to be identified. Moreover, research of preliminary predictive factors (functional tests, RT technique, patients intrinsic factors) could be useful to improve treatment option choices and also toxicity occurrence prevention.

### EP-1386 Stereotactic body radiation therapy for central early non small cell lung cancers- Yes! Its possible

R. Harjani Hinduja<sup>1</sup>, J. Zheng<sup>1</sup>, G. Cook<sup>1</sup>, R. MacRae<sup>1</sup>, J. Pantarotto<sup>1</sup>

<sup>1</sup>University of Ottawa, Radiation Oncology, Ottawa, Canada

### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) is a standard treatment for early non small cell lung cancers. Concerns exist about its use in centrally located tumours. RTOG 0813 demonstrated the efficacy and tolerability of SBRT in centrally located tumours. However, there is a reluctance in many institutions regarding its widespread adoption into clinical practice. We report our institutional experience with treatment of central tumors.

### Material and Methods

We retrospectively reviewed consecutive medically inoperable early central NSCLC patients treated with SBRT in an ethics approved study. All tumours were biopsy proven and adequately staged by Positron Emission Tomography (PET) scan. The end points of interest were Local Recurrence Free Survival (LRFS) and Overall Survival (OS). The outcomes were compared based on ECOG status, left versus right sided tumours, histology, age adjusted Charlson Comorbidity index, SUVmax and pre-treatment Hemoglobin and Poly-Morpho-Nuclear (PMN) leucocytes.

### Results

92 patients who underwent SBRT for centrally located lung tumours were eligible. The median age was 75 years, (56 to 90 years). 40(43.5%) were males. The median age adjusted comorbidity index was 5. 86% were current/former smokers. 28, 34, 27 and 3 patients had ECOG 0, 1, 2 and 3 respectively. 52.2% had left and 47.8% had right sided tumours. 28.3% were squamous cell carcinomas, 50% were adenocarcinomas and remaining 21.7% included large cell and NSCLC-NOS. All patients were PET staged and the median SUVmax was 6.85. The most common dose schedule was 60Gy in 8 fractions. The dose fractionation was increased in 14 patients to deliver treatment in 15-20 fractions. The median BED was 105Gy. The median OS was 47 months as compared to 53 months for peripheral tumours in the database (p=0.08). The median local recurrence free survival (LRFS), Regional recurrence free survival (RRFS) and Distant relapse free survival (DRFS) was 40 months, 47 months and 45 months, respectively. Lower ECOG score patients had better OS as compared to higher ECOG score (median OS- 42, 61, 35 and 18 months, respectively p=0.05) and a trend towards better LRFS (P=0.07). Patients with pre-treatment hemoglobin >130g/L and PMN leucocyte count > 5\*10<sup>9</sup>/L were associated with improved OS (p= 0.03 and p= 0.003 respectively). Adenocarcinomas had a higher LRFS and OS as compared to squamous cell carcinomas, however this was not statistically significant (median OS- 65 and 47 months respectively, p= 0.2), (median LRFS of 47 and 35 months respectively, p= 0.10). There was no difference in LRFS or OS when stratified by age adjusted Charlson comorbidity score, SUVmax or location of left/right side.

### Conclusion

SBRT for centrally located tumours is feasible with outcomes comparable to published literature. Lower ECOG performance score, pre treatment hemoglobin >

130, PMNs > 5 and adenocarcinoma histology have a better outcome.

### EP-1387 Managing isolated local/regional recurrences after SBRT for inoperable early lung tumors - a dilemma

R. Harjani Hinduja<sup>1</sup>, J. Zheng<sup>1</sup>, J. Pantarotto<sup>1</sup>, R. MacRae<sup>1</sup>

<sup>1</sup>University of Ottawa, Radiation Oncology, Ottawa, Canada

### Purpose or Objective

Stereotactic Body Radiation Therapy (SBRT) is an accepted standard treatment for treatment of stage I medically inoperable non-small cell lung cancers (NSCLC). The most common mode of failure for these patients is distant failure. Among the few percentage of patients who fail locally or regionally, salvage treatment options are limited in this frail population. We aim to evaluate our experience in salvage treatments at local or regional isolated failures after SBRT.

### Material and Methods

We retrospectively reviewed failure patterns and subsequent treatments for our early NSCLC patients treated with SBRT/ hypo-fractionated radiation therapy between 2009 and 2015 in a research ethics board approved study. Local and regional recurrences were noted and then were categorized into isolated local/regional /loco-regional versus widespread progression (along with distant metastases). Salvage treatments offered to loco-regional recurrences were reviewed.

### Results

511 patients who received SBRT/hypo-fractionated radiation therapy were eligible for the study. 475 (92.95%) of the tumours were treated with SBRT. 395 (77.6%) were peripheral tumours and 114 (22.4%) were central. The median BED was 132Gy. With a mean follow up of 4.5 years, 47(9.2%), 47 (9.2%) and 85 (16.7%) experienced local, regional and distant failures respectively. Of these, 38 patients experienced isolated local and/or regional failure (21- local, 11- regional and 6 local and regional failure; with no distant failure). 21.05% (8) tumours received salvage treatment with modalities like RFA (3), re-irradiation with or without chemotherapy (5). Of the non-salvaged tumours (30), 16 (53.33%) received palliative treatments (7- palliative radiation, 9- palliative chemotherapy). The most common reason for non-salvaged tumors was poor performance score (Eastern Cooperative Oncology Group score 3 or 4), followed by dearth of local options. 13 additional patients developed loco regional failure with time-separated distant metastases (with distant failure at minimum 3 months after loco-regional failure), of which 6 were salvaged locally.

### Conclusion

Although, the outcomes for stage I medically inoperable patients are impressive with the advent of stereotactic body radiation therapy, management of local and regional recurrences remains a dilemma owing to poor performance status and overall frailty of this population.

### EP-1388 SABR Following Pneumonectomy: A Systematic Review of Clinical and Toxicity Outcomes

A. Louie<sup>1</sup>, A. Ariffin<sup>1</sup>, F. Al-Shafa<sup>1</sup>, R.G. Boldt<sup>1</sup>, A. Warner<sup>1</sup>, G. Rodrigues<sup>1</sup>, D. Palma<sup>1</sup>

<sup>1</sup>London Health Sciences Centre South West Regional Cancer Program, Department of Radiation Oncology, London, Canada

### Purpose or Objective

Survivors of lung cancer are at risk of second primary lung cancers (SPLCs), which are often curable. However, in patients who have previously undergone pneumonectomy, treatments options are limited. The aim of this study is to perform a systematic review of publications examining

treatment planning considerations, clinical outcomes, and toxicity rates of SABR following pneumonectomy.

#### Material and Methods

A systematic review of the literature was conducted in accordance with PRISMA guidelines using PubMed and EMBASE from inception to July 2018. A total of 220 entries were identified. Articles were limited to those published in the English language. 114 unique articles were assessed for eligibility. Inclusion criteria consisted of non-review articles involving at least 2 patients who received lung SABR post-pneumonectomy. Two reviewers independently performed abstract and full-text review, with discrepancies settled by a third reviewer.

#### Results

Of the 114 articles identified by the initial search, 10 articles comprising 108 patients who received lung SABR post-pneumonectomy met inclusion criteria. Median age was 70.8 (range 58.0-75.5), and most patients were male (median 77.0%, 73.9-100%, n=5). The weighted average incidence of grade 3 or higher toxicity was 11.7% (0-33.3%, n=9). There were 2 treatment-related deaths from one case series. Another death was reported that was infectious in nature, but the attributable effects of radiation could not be ruled out. The median 1-year rate of logoregional control was 90.2% (range 84.0-100%, n=6), which is consistent with previously published SABR data. Median BED<sub>10</sub> was 107.9 Gy (87.5-151.2 Gy, n=8), and the most common dose fractionation schemes were 54 Gy in 3 fractions (n=7), 48 Gy in 4 fractions (n=6), and 50 Gy in 5 fractions (n=5). The majority of studies used 4DCT image acquisition (9/10), a technique that captures a 3DCT volume over a period of time thereby describing the motion of a desired target. Respiratory gating was only employed in a single study.

#### Conclusion

SABR appears to be a safe and effective option for solitary pulmonary nodules in survivors of lung cancer with prior pneumonectomy. Multi-institutional and/or prospective studies would be helpful to determine the true risk and appropriateness of SABR in this high-risk patient population.

#### EP-1389 Lowered Whole Brain Irradiation Dose for Non-Small Cell Lung Cancer Patients with Brain Metastases

Y. Wang<sup>1</sup>

<sup>1</sup>Taipei Tzu Chi Hospital, Radiation Oncology, New Taipei City, Taiwan

#### Purpose or Objective

Non-small cell lung cancer (NSCLC) patients with brain metastases are traditionally treated with 30 Gy of whole brain irradiation (WBI). However, it has been reported to be correlated with neurocognitive function decline. In this study, we analyzed the survival of patients treated with different WBI dose to evaluate if lowered WBI dose provides comparable treatment outcome.

#### Material and Methods

We reviewed stage IV NSCLC patients with brain metastases who underwent brain irradiation at our hospital with the following exclusion criteria: 1) previous brain irradiation history; 2) brain metastases resected before irradiation; 3) poor medical condition with early termination of radiotherapy. The radiotherapy regimen for brain metastases varied from WBI only, WBI followed by metastatic tumor boost, to boost alone without WBI. The Graded Prognostic Assessment (GPA) score was calculated for each patient by their age, Karnofsky performance scores, number of cranial metastases, and if extracranial metastases were present. The survival time was calculated from the day radiotherapy completed. Kaplan-Meier survival analyses were performed separately for patients received WBI dose > 21 Gy (HWBI group) or ≤21 Gy (LWBI group) in each GPA class, and the difference between the groups was tested with the log-rank test.

#### Results

From Apr, 2010 to May, 2015, 77 patients were included in this study. Forty-two patients received WBI dose more than 21 Gy, and the other 35 received ≤21 Gy. In the GPA class 0-1, the median survival of HWBI group (n=21) was longer than the LWBI group (n=13) (2.26 vs. 1.03 months, p=0.075). In the GPA class 1.5-2.5, the median survival of HWBI group (n=20) was shorter than the LWBI group (n=20) (23.13 vs. 29.37 months, p=0.09).

#### Conclusion

With the potential of better neurocognitive function preservation, WBI dose ≤21 Gy showed a survival outcome non-inferior to 30 Gy. Although no significant difference detected, there is a trend encouraging to apply lower WBI dose to patients with higher GPA scores (1.5-2.5) for better survival benefit. Further prospective trials are required to confirm the optimal brain radiotherapy regimen for NSCLC patients with brain metastases.

#### EP-1390 Association between heart dose and survival for NSCLC patients underwent VMAT

C. XIE<sup>1</sup>, X. Jin<sup>1</sup>

<sup>1</sup>the 1st Affiliated Hospital of Wenzhou Medical University, Radiation and Medical Oncology, Wenzhou, China

#### Purpose or Objective

One critical finding of RTOG 0617 was that heart dose could impact the early overall survival (OS) of non-small cell lung cancer (NSCLC) patients underwent radiotherapy (RT), although mixed results were reported in studies trying to confirm this finding, studies all suggested that heart dose should be minimized during radiotherapy planning based on the known adverse effects of RT on vasculature and cardiac function. Intensity-modulated radiotherapy (IMRT) had been demonstrated to decrease the dose to lung and heart compared with 3D conformal radiotherapy. As an extended form of IMRT, volumetric modulated arc therapy (VMAT) is able to achieve similar dosimetric distribution while decreasing MU and treatment delivery time compared with IMRT. The purpose of this study is to investigate the efficacy and safety of VMAT, as well as the association of lung and heart dosimetry with OS in the NSCLC patients treated by VMAT.

#### Material and Methods

200 consecutive inoperable NSCLC patients treated by VMAT from March 2011 to September 2016 were retrospectively reviewed. OS rates were estimated with the Kaplan-Meier method. The Cox regression model estimated the hazard ratio (HR) and the corresponding 95% confidence interval (CI) for univariate (UVA) and multivariate (MVA) analyses. Multivariate model building was performed using stepwise regression (modification of the forward selection method) techniques utilizing significant univariate factors to avoid over-fitting the model.

#### Results

There were 174 NSCLC patients enrolled in this study with a median age of 63 years (range from 34-86 y). The average OS for these patients were 25.02 months with a median followup of 14.77 months. For an average prescribed dose of 55.90±0.50 Gy, the mean dose, V25, V30 and V 50 to heart were 16.03±0.63, 28.73%±1.51%, 25.80%±1.42%, and 8.38%±0.86%, and the mean dose, V5, V10, V13, V20 and V30 to lung were 13.78±0.31

Gy, 55.07%±1.54%, 40.68%±1.30%, 33.2%±1.09%, 23.03%±0.67%, and 15.22%±0.42%, respectively. Univariate analysis indicated that V30 of heart was associated with overall OS with a p value of 0.044, no other heart and lung dosimetric parameters was associated with OS. The V13 of lung was associated with acute radiation pneumonia with an RP rate of 9.78%. The dosimetric values of heart and lung were strongly correlated with each other.

#### Conclusion

Heart dose was associated with OS for advanced NSCLC treated by VMAT.

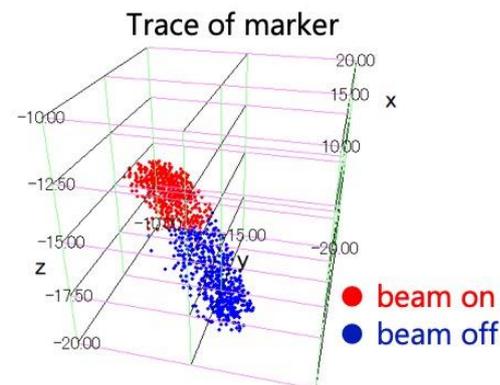

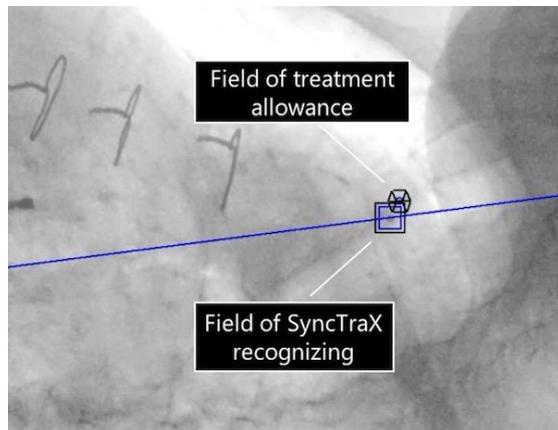

#### EP-1391 Stereotactic body radiotherapy using a new real-time tumor tracking system and fiducial markers

Y. Hiroshima<sup>1,2,3</sup>, K. Nitta<sup>1</sup>, T. Saitoh<sup>1</sup>, T. Ohno<sup>4</sup>, K. Shinoda<sup>1</sup>, Y. Tamaki<sup>1,5</sup>

<sup>1</sup>Ibaraki Prefectural Central Hospital, Radiation Oncology, Kasama, Japan ; <sup>2</sup>University of Tsukuba, Radiation Oncology- Faculty of Medicine, Tsukuba, Japan ; <sup>3</sup>University of Tsukuba Hospital, Radiation Oncology, Tsukuba, Japan ; <sup>4</sup>Dokkyo Medical University- Koshigaya Hospital, Radiology, Koshigaya, Japan ; <sup>5</sup>University of Tsukuba Hospital, Ibaraki Clinical Education and Training Center, Tsukuba, Japan

#### Purpose or Objective

A new fluoroscopic real-time tumor tracking radiotherapy (RTRT) system; the SyncTraX FX4 (Shimadzu Co., Kyoto, Japan) enables that transmits an irradiation permission signal to a treatment device while a fiducial marker is within a planned position and stops transmission when it comes off (Fig 1). In addition, while a system works, it can record a fiducial marker position quantitatively (Fig 2). Using this system, we can reduce the irradiation volume of normal tissue while guaranteeing the positional accuracy of the tumor even under free breathing and improve the patients' burden and adverse events. We report the safety and the feasibility of the stereotactic body radiotherapy (SBRT) using this system.

#### Material and Methods

Between October 2017 and June 2018, a total of 8 patients and 9 sites treated by SBRT with this system were retrospectively reviewed. This study included 7 men and 1 woman, whose age ranged from 66 to 86 (median 75). Treated sites of organ were lung (n=6) and liver (n=3). All of lung tumors were primary tumors and liver tumors were metastatic tumors. All patients were inserted several

fiducial markers, namely Visicoil to the liver and Disposable Gold Marker (Olympus Co. Tokyo, Japan) to the lung, on 1-2 weeks before CT. Patients planned as treated under free-breathing were taken CT with exhalation breath, and breath-hold were taken with inhalation breath. TrueBeam STX was used as the treatment device, and irradiation method was fixed multiple irradiation. Prescribed dose was 55.0 Gy/ 4 fr (n=8) or 66.0 Gy/ 10 fr (n=1), and all of them were D95 prescription, planned with RayStation. Average PTV volume treated was 33.9cc (range, 9.82-115cc). Conformity index in each irradiation field was 0.82-0.9, and the mean value was 0.86.

#### Results

Follow-up period was 2.3-8.8 months (median 5.1). As acute adverse event, radiation pneumonitis of grade 2 was observed in 1 patient in lung tumor patients. No serious adverse events related to radiotherapy and inserting fiducial markers were observed during the period. Local recurrence was observed in 1 patient, and distant metastasis was observed in 1 patient. Although treatment on free breathing was the basis, it was possible to shorten patient radiation exposure and treatment time by using in combination with respiratory arrest system. In the liver, to follow fiducial markers was difficult on the perspective direction, there were cases where a change was necessary in treatment plan.

#### Conclusion

SBRT using the SyncTraX FX4 system and fiducial markers was suggested as a safe and less burdensome treatment.

#### Electronic Poster: Clinical track: Upper GI (oesophagus, stomach, pancreas, liver)

#### EP-1392 Preoperative image-guided identification of response to nCRT in esophageal cancer (PRIDE study)

A. Borggreve<sup>1</sup>, I. Defize<sup>1</sup>, G. Meijer<sup>1</sup>, H. Van Laarhoven<sup>2</sup>, H. Langendijk<sup>3</sup>, V. Mul<sup>3</sup>, F. Voncken<sup>4</sup>, M. Verheij<sup>4</sup>, P.S.G. University Medical Center Utrecht<sup>1</sup>, P.S.G. The Netherlands Cancer Institute<sup>4</sup>, P.S.G. University Medical Center Groningen<sup>3</sup>, P.S.G. Amsterdam University Medical Centers<sup>5</sup>

<sup>1</sup>University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>Amsterdam University Medical Centers, Department of Medical Oncology, Amsterdam, The Netherlands ; <sup>3</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands ; <sup>4</sup>The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, The Netherlands ; <sup>5</sup>Amsterdam University Medical Centers, Cancer Center Amsterdam, Amsterdam, The Netherlands

#### Purpose or Objective

Nearly one third of patients undergoing neoadjuvant chemoradiotherapy (nCRT) for locally advanced esophageal cancer have a pathologic complete response (pCR) of the primary tumor upon histopathological evaluation of the resection specimen. The primary aim of this study is to develop a model that predicts the probability of pCR to nCRT in esophageal cancer, based on diffusion-weighted magnetic resonance imaging (DW-MRI), dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), <sup>18</sup>F-fluorodeoxyglucose positron emission tomography and computed tomography (<sup>18</sup>F-FDG PET-CT). Accurate response prediction could lead to a patient-tailored approach with omission of surgery in the future in case of predicted pCR or additional neoadjuvant treatment in case of non-pCR.

#### Material and Methods

The PRIDE study is a prospective, single arm, observational multicenter study that will develop a multimodal prediction model for histopathological response to nCRT for esophageal cancer. A total of 200 patients with locally

advanced esophageal cancer - of which at least 130 patients with adenocarcinoma and at least 61 patients with squamous cell carcinoma - scheduled to receive nCRT followed by esophagectomy will be included. The primary modalities to be incorporated in the prediction model are quantitative parameters derived from MRI and <sup>18</sup>F-FDG PET-CT scans, which will be acquired at fixed intervals before, during and after nCRT. Secondary modalities include blood samples for analysis of the presence of circulating tumor DNA (ctDNA) at 3 time-points (before, during and after nCRT), and an endoscopy with (random) bite-on-bite biopsies of the primary tumor site and other suspected lesions in the esophagus as well as an endoscopic ultrasonography (EUS) with fine needle aspiration of suspected lymph nodes after finishing nCRT. The main study endpoint is the performance of the model for pCR prediction. Secondary endpoints include progression-free and overall survival.

#### Results

If the multimodal PRIDE concept provides high predictive performance for pCR, the results of this study will play an important role in the accurate identification of esophageal cancer patients with a pCR to nCRT. These patients might benefit from a patient-tailored approach with omission of surgery in the future. Vice versa, patients with non-pCR might benefit from additional neoadjuvant treatment.

#### Conclusion

**Trial registration:** The article reports on a health care intervention on human participants and was prospectively registered on March 22, 2018 under ClinicalTrials.gov Identifier: NCT03474341

#### EP-1393 Prospective fiducial placement in liver tumours: Effectiveness, placement 'quality' and toxicities

K. Katak<sup>1</sup>, S. G<sup>2</sup>, R. Madhavan<sup>1</sup>, T. Tatineni<sup>1</sup>, S. P. G<sup>3</sup>, J. J<sup>3</sup>, D. Dutta<sup>1</sup>

<sup>1</sup>Amrita Institute of Medical Sciences- Kochi, Radiation Oncology, Kochi, India ; <sup>2</sup>Amrita Institute of Medical Sciences- Kochi, Radiology, Kochi, India ; <sup>3</sup>Amrita Institute of Medical Sciences- Kochi, Radiation therapy, Kochi, India

#### Purpose or Objective

Fiducial placement in liver tumours (HCC) for Robotic Radiosurgery (Cyberknife, CK) treatment is considered crucial step of treatment and also associated with morbidity. Present prospective study evaluating the associated effectiveness, quality of fiducial placement and toxicities.

#### Material and Methods

Between Mar 2017-Mar 2018, 36 HCCs accrued in the ethical & scientific committee approved prospective study for CK treatment. Three fiducials were placed in liver (CT/USG guided) for tracking. Fiducials placed by radiologist (RD) with ideal fiducials will be equidistant from each other (max distance 5 cm, min distance 2 cm). Quality of fiducial placement as RD and radiation oncologist (RT) were assessed by "institution" defined scale. Placement time, pain score, complications, recovery time and factors influencing fiducial placement were analysed

#### Results

Thirty six patients (Male 92%, mean age 60.2 yrs, ECOG 0-1 92%, Child-Pugh A 89%, B&C 11%, majority in seg II & VI, PVT disease 64%) with HCCs underwent fiducial placement under guidance (CT scan 69%). 5, 4 & 3 fractions were in 29 (80%), 16 & 4%. Time for placement <20 min, within 45 min and >45 min were in 55%, 36% and 8% respectively. Three patients (8%) had gross displacement (2 in lung, 1 in abdomen) immediately after placement. One patient (4%) expired after fiducial placement (<72 hours) with decompensation. Five patients (15%) had minor complications (pain abdomen 2, pneumothorax 2). RD & RT Score values of poor, fair, good are 6%, 14%, 80% and

8%, 19%, 72% respectively. Correlation between RT & RD score was satisfactory (Pearson correlation test: 0.001). Placement time of 10-20 min, 20-45 min and more than 45 min were in 55%, 36% and 8% patients respectively. Poor pain score (3/4) was in 6% only. Good RT Score, good RD Score and poor pain score, in seg VII-VIII (n=12) and other segments (n=24) were 83% & 67% (p-value: 0.484); 83% & 79% (p-value: 0.186); nil & 8% (p-value: 0.69) respectively. In Child Pugh A (n=32) and B&C (n=4) were 78% & 25% (p-value: 0.08); 87% & 25% (p-value: 0.029) and 6% & 75% (p-value: 0.024) respectively. PS also influenced RT score (p-value: 0.014), RD score (p-value: 0.003), pain score (p-value: 0.016). Fiducial placement score improved from 30% in 1st 10 patients to 93% in last patient cohort (p-value: 0.023). Fiducial placement time reduced from 42.2 min to 14.3 min (p-value: 0.069) in the same cohort. Interfiducial distance, angle and distance from centre max and min are 4.7 & 2.4 cm; 82.7 & 28.5 degree and 5.1 & 2.1 cm respectively

#### Conclusion

Fiducial placement is safe and in experienced hands, quality of placement is 'good' in majority. Major complications and admission after fiducial placement is rare. Patients with poor Child Pugh Score, extensive liver involvement, poor PS have higher probability of complications. Segment of liver involved, BCLC stage do not influence fiducial placement quality.

#### EP-1394 Prognostication of HCC with PVT treated with SBRT: Early results from a prospective study in India

T. Tatineni<sup>1</sup>, K. Katak<sup>1</sup>, R. Madhavan<sup>1</sup>, S. G<sup>2</sup>, R. Das<sup>1</sup>, D. Dutta<sup>1</sup>

<sup>1</sup>Amrita institute of medical sciences, Radiation oncology, Kochi, India ; <sup>2</sup>Amrita institute of medical sciences, Radiologist, Kochi, India

#### Purpose or Objective

Present prospective study evaluating role of Radiosurgery (CK) in Indian patients and analyzed prognostic factors

#### Material and Methods

Inoperable HCC with PVT with good performance status, liver function were accrued after radiological diagnosis for CK (M6). Fiducial placement (3 number) done as per protocol. Triple phase contrast CT scan done, planning done with Multiplan. PVT categorized as Chen classification. GTV is gross contrast enhancing mass within the main portal vein, its tributaries and adjacent paranchymal disease. PTV margin was 2-3 mm. Dose as per established risk stratification protocol. Mean liver dose <15Gy & 800 cc liver <8Gy. Dosage was 22-50Gy/5fr. Prognostication done with Chen, Child Pugh (CP), AFP, CLIP score, GRETCH, BCLC classification and response to treatment, dosage

#### Results

: 27 HCC with PVT accrued in the study [mean age 59.1 yrs, 94% male; Child Pugh A 63%, B 30%; BCLC C 93% & D 7%; PS0-1: 89%, KPS>80: 81%; co-morbidities 40%; infective 15%, Alcohol intake 26%]. Patients presented with abdominal pain (44%), fatigue (30%), ascitis (15%) and melena (11%). CP Score 5,6,7 & 8 was in 37%,26%,19% & 19% respectively. 40% patients presented with abdominal pain, 30% with fatigue. 15% patients had focal disease with PVT, liver involvement >50% & <50% in 44% and 40%. 16% underwent TACE before SBRT. 56% received sorafenib after SBRT. PVT Chen classification VP2, VP3 & VP4 were in 22%, 33%, 41% respectively. CLIP score 1, 2, 3, 4, 5 was in 4%, 26%, 30%, 33% and 7% respectively. Mean follow up was 7 months (range 1.7-17.6 months). Mean actuarial OS was 10.8 months (SEM: 1.48; 95%CI: 7.8-13.7). At last follow up, 16/27(59%) were alive and 11/27(41%) were dead. 6(22%) had complete PVT response, 3(11%) had stable disease with partial PVT response, 7 (30%) have local progression, 3 (27%) had metastatic disease (1 lung, 2 spine) and 8 (73%) expired with local progression. No death due RILD. 6/27 (22%) patients had radiologically confirmed

re-canalization [5 in PVT & 1 in IVC]. Post-CK, 8% patient underwent TACE and 4% had TARE. Mild GI toxicities (Gr I-II) in 10 (40%), fatigue (Gr II-III) 7 (28%). One (4%) patient had Gr III GI toxicity and one (4%) patient had decompensation (<4wk) after treatment. Gender (p=0.542), infective etiology (p=0.356), alcohol intake (p=0.983), pre-CK AFP (p=0.581), BCLC stage (p=0.660), adjuvant Sorafinib (p=0.324) did not influence survival functions. Patients with PVT response (p=.003) had better survival. 1-yr actuarial OS in dose delivered (<39Gy Vs >39Gy: 65% vs 40%); CLIP Score (1-2 Vs 3-6: 75% Vs 40%); CP Score (5-7 Vs 8-9: 78% Vs 42%) & PVT Score (VP1-2 Vs 3-4: 67% Vs 56%) showed trend towards improved survival.

#### Conclusion

CyberKnife is safe & effective option in Indian HCC with PVT patients. Good PVT response, higher dose delivered, CP score, CLIP Score and PVT score have prognostic significance. RT dose and PVT response may be included in response assessment scoring system.

#### EP-1395 Radiation Dose to the Thoracic Vertebral Bodies is Associated with Acute Hematologic Toxicities

F. Lingli<sup>1</sup>, D. Xiaobo<sup>1</sup>

<sup>1</sup>Mianyang Central Hospital, Oncology, Mianyang, China

#### Purpose or Objective

Mean thoracic vertebral body(TVB) dose and low-dose parameters (V5-V20) are associated with severe acute hematologic toxicities(HT)during concurrent chemoradiotherapy (CRT) for lung cancer, in which optimal dosimetric cut-off points have been identified. Esophageal cancers are closer to TVBs than lung cancer and require longer radiation fields and different chemotherapy regimens. The optimal dosimetric cut-off points for TVBs in lung cancer maybe unsuitable for esophageal cancers. We aimed to explore factors associated with HT during CRT and optimal dosimetric cut-off points for TVBs in esophageal cancer.

#### Material and Methods

From January 2010 to June 2018, we selected patients with esophageal squamous cell carcinoma confirmed by pathology. We retrospectively examined radiotherapy plans for all patients who met the criteria and outlined the TVB dose for each patient. Average TVB dose and parameter data of V5-V60 were recorded on the dose-volume histogram diagram. Weekly blood routine results were recorded from the start of CRT to 2 weeks after the end of radiotherapy. At the same time, baseline data of age, ECOG score, body mass index, clinical stage, tumor length, induction chemotherapy, concurrent radiotherapy regimen, radiation dose, and radiotherapy modality were recorded. Simple logistic regressions were used to determine the correlation of all clinical and dosimetric parameters with HT. Multiple logistic regression models included dosimetric parameters and other variables with P<0.3 on univariate analysis. The receiver operating characteristic (ROC) curve was used to analyze optimal dose limiting points.

#### Results

A total 126 patients were included (90 males and 36 females), with average age 60 years. Only 7 (5.6%) patients received induction chemotherapy; the rest received CRT. A total 103 patients (81.7%) received intensity-modulated treatment. Of all patients, 53 (42.1%) received platinum plus taxane, 66 (52.4%) platinum plus fluorouracil, and 7 (5.5%) other regimens. The median radiotherapy dose was 60Gy (50-70Gy). Hematological toxicity grade 3 and above (HT3+) occurred in 34 of 126 patients, with incidence 27.0%. The average TVB dose was 32.65 Gy, V5 70.06%, V10 67.03%, V15 65.13%, V20 63.32%, V30 59.06%, V40 50.05%, V50 28.18%, and V60 8.48%. Age, concurrent chemotherapy regimens, TVB V30 and V40 were associated with HT(P<0.05). The threshold of TVB V40 was 35.75% for HT3+ occurrence; the incidence of HT3+ could be reduced from 29.7% to 15.9% by maintaining

the TVB dose below this threshold. The threshold of TVB V30 was 78.9%; the incidence of HT3+ could be reduced from 36.4% to 20.4% by maintaining the TVB dose below this threshold. Over age 61 years, concurrent chemotherapy with platinum plus taxane increased the incidence of HT3+.

#### Conclusion

The occurrence of HT in esophageal squamous cell carcinoma was associated with age, chemotherapy regimen, and TVB V30 and V40. Limiting the TVB dose and adjusting the chemotherapy regimen could reduce occurrence of HT3+.

#### EP-1396 the role of multidisciplinary team in radiotherapy for esophageal cancer

S. Zhao<sup>1</sup>, S. Wang<sup>1</sup>, F. Xu<sup>1</sup>, Y. Han<sup>1</sup>, W. Qi<sup>1</sup>, K. Youlia<sup>2</sup>, J. Chen<sup>1</sup>

<sup>1</sup>Ruijin Hospital- Shanghai Jiaotong University School of Medicine, radiation oncology, Shanghai, China ; <sup>2</sup>Institut Curie, radiation oncology, Paris, France

#### Purpose or Objective

To assess the effects of multidisciplinary team(MDT) on outcome of patients with esophageal cancer(EC) who had underwent radiotherapy, using propensity score matching. This is a retrospective cohort study

#### Material and Methods

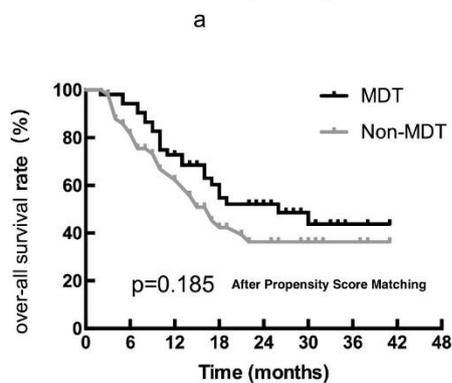

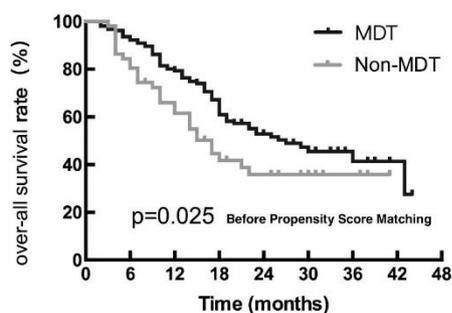

We collected all patients diagnosed with EC in radiation oncology department at our institution from January 2015 to May 2017. The patients were divided into groups by those who were presented and not presented at MDT meeting(MDT and non-MDT). Propensity-score matching was applied at a ratio of 1:1 comparing the two groups.

Variables	Before matching				After matching			
	All n=212	MDT n=87	Non-MDT n=125	X2 P	All n=166	MDT n=83	Non-MDT n=83	X2 P

patient, tumor, treatment characteristics before and after propensity score matching

#### Results

There were totally 212 patients analyzed, 157 with MDT and 55 non-MDT. In the unmatched population, there was no difference in patients and tumor characteristic between two group. In treatment options, the patients with MDT had significantly more in receipt of chemotherapy than non-MDT group(84.7% vs. 69.1%;  $\chi^2=6.373$ ;  $P=0.012$ ). In MDT group, there were longer median overall survival (OS) ( $P=0.025$ ) than in non-MDT group, as well as in subgroup analysis for the patients with PS status 0-1( $P<0.05$ ), with SCC( $P<0.05$ ), stage I-II( $P<0.01$ ), high-middle differentiation( $P<0.01$ ), with surgery( $P<0.01$ ). After propensity score matching for the similar characteristics including the treatment option, patients with phase I-II stage or high-middle differentiation had better survival in MDT group( $P<0.01$ ,  $P<0.05$ ). MDT was an independent predictor of receiving chemotherapy obtained in the regression analysis(OR, 2.827; 95% CI, 1.218-6.558).

Kaplan-Meier analysis of overall survival of MDT and Non-MDT groups

### Conclusion

MDT was associated more chemotherapy receipt in patients underwent radiotherapy for esophageal cancer, which may improve OS.

### EP-1397 S-1 versus S-1 plus cisplatin concurrent radiationtherapy for esophageal cancer: a mid-term report

Y. Wen<sup>1</sup>, Z. Zhao<sup>1</sup>, Y. Chen<sup>2</sup>, Y. Gui<sup>3</sup>, X. He<sup>4</sup>, Q. Yang<sup>5</sup>, M. Sun<sup>6</sup>, J. Miao<sup>7</sup>, Q. Jia<sup>8</sup>, H. Tian<sup>9</sup>, X. Du<sup>1</sup>

<sup>1</sup>Miayang Central Hospital, Oncology Department, Miayang, China; <sup>2</sup>Jiayang People's Hospital, Oncology Department, Jiayang, China; <sup>3</sup>Affiliated Hospital of North Sichuan Medical College, Oncology Department, Nanchong, China; <sup>4</sup>Langzhong people's Hospital, Oncology Department, Langzhong, China; <sup>5</sup>Ziyang People's Hospital, Oncology Department, Ziyang, China; <sup>6</sup>The first people's Hospital of Guangyuan, Oncology Department, Guangyuan, China; <sup>7</sup>Zigong Fourth People's Hospital, Oncology Department, Zigong, China; <sup>8</sup>The second people's Hospital of Jiangyou, Oncology Department, Jiangyou, China; <sup>9</sup>The first people's Hospital of Jiangyou, Oncology Department, Jiangyou, China

### Purpose or Objective

The chemotherapy regimens for concurrent chemotherapy and radiotherapy for esophageal cancer (EC) often comprise two drugs. However, retrospective studies have reported severe toxicity for patients with EC receiving radiotherapy combined with two-drug chemotherapy. While the incidence of side effects of single-drug chemotherapy is relatively low. Therefore, we designed a prospective, randomized, multicenter phase II trial to compare the efficacy and toxicity of combining S-1 or S-1 plus cisplatin with intensity-modulated radiation therapy for esophageal squamous cell carcinoma.

### Material and Methods

This randomized, controlled, multicenter trial compared S-1 versus S-1 plus cisplatin concurrent radiotherapy in patients with esophageal squamous cell carcinoma. Eighty-eight patients with unresectable or who were

medically unfit for surgery for esophageal squamous cell carcinoma (clinical stage I to III) were randomly assigned to receive four cycles (two concomitant and two postradiotherapy) of S-1 or S-1 plus cisplatin along with radiotherapy 60-66Gy/30 to 33 fractions. The primary outcome was the complete response rate of the primary tumor as measured by endoscopy and computer screening at three months after treatment completion. The secondary outcomes included survival and toxicity.

### Results

In August 2018, 88 patients were enrolled, 43 of which were evaluated by gastroscopy (45 cases have not yet been followed up by gastroscopy), including 25 cases in the experimental group receiving S-1 concurrent intensity-modulated radiotherapy treatment and 18 cases in the control group receiving concurrent S-1 plus cisplatin intensity-modulated radiation therapy. In the experimental group, 13 patients (52%) achieved complete remission, six (24%) achieved partial remission, four (16%) had stable disease, and two (8%) had progressed. In the control group, eight patients (44.4%) achieved complete remission, seven (38.9%) achieved partial remission, two (11.1%) had stable disease, and one (5.6%) had progressed. There was no significant difference in the rates of complete remission between the two groups ( $P > 0.05$ ). The radiotherapy completion rates were 95.6% and 88.9% in the experimental and control groups, respectively. The radiotherapy interruption rates in the two groups were 52% and 55.5%, respectively. The chemotherapy completion rates were 100% and 88.9% in the experimental and control groups, respectively. The chemotherapy interruption rate was 4% in the experimental group and 11.1% in the control group. The incidence of grade 2, 3, and 4 hematological toxicity was 56%, 4%, and 0%, respectively, in the experimental group and 66.6%, 16.6%, and 5.5%, respectively, in the control group.

### Conclusion

Conclusions: The mid-term data of this trial indicate that S-1 synchronous intensity-modulated radiation therapy is no significant differences in complete response rate to S-1 combined with cisplatin synchronous intensity-modulated radiation therapy, with fewer side effects. Therefore, patients are more likely to complete treatment with S-1 synchronous intensity-modulated radiation therapy alone.

### EP-1398 Lymphopenia and accidental splenic doses for locally advanced gastric cancer

F. Sert<sup>1</sup>, D. Yalman<sup>1</sup>, S. Ozkok<sup>1</sup>

<sup>1</sup>Ege University Medical School&Hospital, Radiation Oncology, Izmir, Turkey

### Purpose or Objective

Considering the high recurrence and mortality rates, additional predictive and/or prognostic factors have to be identified for the patients with locally advanced gastric cancer (LAGC). There is limited data evaluating the certain reason of lymphopenia and the relation between splenic doses and immunological response including NLR (neutrophil-to-lymphocyte ratio) and white blood cell counts over oncological outcomes for the patients with LAGC. The purposes of the present study are to determine the effect of CRT (chemoradiotherapy)-induced lymphopenia, and irradiated splenic volume and splenic doses on oncological outcomes in patients with LAGC.

### Material and Methods

A consecutive cohort of 52 patients with LAGC (pT3-4 and/or pN0-3b) treated with adjuvant CRT at our department between 2005 and December 2016 was identified for this trial. The absolute neutrophil, lymphocyte and platelet counts were recorded prior to any treatment (baseline), just after the completion of CRT, and 2-6 weeks after the completion of CRT (control evaluation).

## Results

The median clinical follow-up time from the beginning of first CT application was 30 months (range, 8-130 months). The incidence of severe lymphopenia was only 1% at control evaluation but it was 93% after CRT ( $p < .001$ ). The median OS time was 24 months (range, 8-126 months). The 2, 3, and 4-year OS rates were 65%, 59%, and 52%, respectively. There was no statistically significant difference in OS in patients with severe lymphopenia and SIR positivity after CRT ( $p = .75$ , and  $p = .31$ , respectively). Additionally, the severity of baseline lymphopenia or lymphopenia at the control evaluation had no effect on OS rates ( $p = .75$ , and  $p = .92$ , respectively). Median RFS time was 20 months (range, 6-120 months). The 2, 3, and 4-year RFS rates were 58%, 55%, and 50%, respectively. In univariate analysis, stage 3 disease ( $p < .001$ ) and MDLN ratio  $> 20\%$  ( $p < .001$ ) had negative effect on OS. In multivariate analysis for OS, stage III disease ( $p = .041$ ) and MDLN ratio  $> 20\%$  ( $p = .032$ ). In univariate analysis for RFS, stage 3 disease ( $p = .001$ ), and MDLN ratio  $> 20\%$  ( $p = .011$ ) had negative effect. MDLN ratio  $> 20\%$  was the only significant prognostic factor for RFS in multivariate analysis ( $p = .033$ ). In the ROC analysis, the AUC for mean splenic doses was 0.741 for OS ( $p = .042$ ) and 0.680 for RFS ( $p = .050$ ). Mean splenic dose  $\geq 35$  Gy was a significant poor prognostic factor for OS and RFS ( $p = .042$ , and  $p = 0.50$  respectively). Maximum splenic dose  $\geq 58$  Gy effected OS unfavorably ( $p = .050$ ). Volumetric modulated arc therapy (VMAT), intravenous CT, and age  $\geq 65$  years were significant predictors for severe lymphopenia.

## Conclusion

Severe lymphopenia could not be accepted as a predictive or prognostic factor for LAGC. Mean and maximum splenic doses should be kept on mind while evaluating the treatment DVHs. Age of patient, iv usage of concomitant CT agent and VMAT are the factors which can influence the ALCs of patients. Disease-related factors such as stage and metastatic lymph node ratio are seen the most important factors.

## EP-1399 A Pilot Study of Apatinib Combined with SBRT To Advanced Pancreatic Cancer

G. MA<sup>1</sup>, M. Shuo<sup>2</sup>, Z. Shuman<sup>1</sup>, X. Li-ang<sup>1</sup>

<sup>1</sup>4th Hospital Hebei Medical University, Radiotherapy, shijiazhang, China ; <sup>2</sup>Syracuse University, new York, USA

## Purpose or Objective

The primary endpoint: progression-free survival (PFS)

The secondary endpoint: overall survival (OS) and safety.

## Material and Methods

The study enrolled 10 patients with advanced pancreatic adenocarcinoma from Dec. 2015 to Apr. 2018. In the first week, all the patients were treated with Apatinib 500mg daily. At the same time, treatment plans of SBRT were finished. From the second week, Apatinib was taken 500mg daily and SBRT were going concomitantly. SBRT regimen was 50Gy/20F/4W. Same dosage of Apatinib was continued alone after SBRT to disease progression, death, or intolerable toxicity.

## Baseline Characteristics

Characteristic	n=10
Age(years)	
Median(range)	66(43-84)
Sex	
male	4(40%)
female	6(60%)
ECOG PS	
1	1(10%)
2	2(20%)
3	7(70%)
Stage	
III	9(90%)
IV	1(10%)

## Results

All patients were followed up for the tumor response evaluation. The median progression-free survival (PFS) was 4.5 months (95% CI, 3.47 to 5.53). The median overall survival (OS) was 7.5 months (95% CI, 5.95 to 9.05).

## Safety and Tolerability

Hypertension is one of the most frequent adverse events, which appeared in 3 of 10 pts. There also were some other AEs, Hand-food syndrome 2, proteinuria 1, diarrhea 1, fatigue 1, oral mucositis 1 and thrombocytopenia 1. AEs could be better controlled and no treatment-related hemorrhage occurred.

AE(%)	All Grade3/4
Hypertension	3 0
Hand-food syndrome	2 0
proteinuria	1 0
diarrhea	1 0
fatigue	1 0
oral mucositis	1 0
thrombocytopenia	1 0

## Conclusion

Our Results indicates that Apatinib combined with SBRT exhibits safety and efficacy to advanced pancreatic adenocarcinoma. More patients should be enrolled and observed

## EP-1400 Comparing Treatment Plans for Proximal and Middle/Distal Stomach Cancer: IMRT, VMAT, and Tomotherapy

Y. Chen<sup>1</sup>, J. Lin<sup>1,2</sup>, S. Huang<sup>1</sup>, Y. Chou<sup>3</sup>, M. Li<sup>1</sup>, J. Tsai<sup>1,2</sup>

<sup>1</sup>Shuang Ho Hospital- Taipei Medical University, Department of Radiation Oncology, New Taipei City, Taiwan ; <sup>2</sup>School of Medicine- College of Medicine- Taipei Medical University, Department of Radiology, Taipei, Taiwan ; <sup>3</sup>National Defense Medical Center, School of Public Health, Taipei, Taiwan

## Purpose or Objective

Adjuvant chemoradiotherapy is viewed as a definitive treatment after resection of stomach cancer (SC). To protect normal tissue, several highly conformal radiotherapy modalities evolved. Therefore, we aimed to compare dosimetric parameters of helical tomotherapy (TOMO), volumetric-modulated arc therapy (VMAT), and intensity-modulated radiotherapy (IMRT) in the adjuvant treatment of SC in different locations.

## Material and Methods

This retrospective study was conducted from January 2013 to May 2017 and included 11 patients with gastric cancer receiving adjuvant chemoradiotherapy after total

gastrectomy. Both IMRT and VMAT plans were generated on the Pinnacle treatment planning system and TOMO plans were generated using a helical tomotherapy system. Adjuvant radiotherapy was prescribed with a total radiation dose of 50.4 Gy in 28 fractions.

#### Results

In proximal SC, TOMO achieved a significantly lower dose for the heart, total kidney, left kidney, and liver than that of IMRT or VMAT ( $p < 0.05$ ). In middle/distal SC, lower total kidney mean dose and V20 were observed with TOMO compared with IMRT ( $p = 0.010$  and  $0.011$ , respectively) and VMAT ( $p = 0.049$ ;  $p = 0.014$ ).

#### Conclusion

For the adjuvant treatment of gastric cancer, TOMO not only provided superior dose sparing for total kidney, left kidney, and liver V30 in patients with proximal gastric cancer but also significantly lowered the heart dose in proximal SC when compared to IMRT or VMAT plan.

#### EP-1401 Practice-based clinical outcome of definitive radiation therapy for superficial esophageal cancer

T. Uno<sup>1</sup>, H. Kobayashi<sup>1</sup>, M. Watanabe-Nemoto<sup>1</sup>, R. Harada<sup>1</sup>, M. Saito<sup>1</sup>, A. Kanazawa<sup>1</sup>, Y. Iwai<sup>1</sup>, K. Murakami<sup>2</sup>, H. Matsubara<sup>2</sup>

<sup>1</sup>Chiba University Hospital, Department of Radiology, Chiba-City, Japan ; <sup>2</sup>Chiba University Hospital, Department of Esophageal-Gastro-Intestinal Surgery, Chiba-City, Japan

#### Purpose or Objective

To evaluate treatment patterns and clinical outcome of definitive radiation therapy for patients with T1b superficial esophageal cancer unfit for or refused definitive surgery in the Authorized Institute for Board Certified Esophageal Surgeon in Japan.

#### Material and Methods

Treatment chart of 51 patients (men/women: 44/7) with T1b superficial esophageal cancer treated with definitive radiation therapy between 2000 and 2017 were retrospectively reviewed. The median age was 77 years with a range of 52 to 88. The tumor length ranged from 2 to 15 cm (median, 5 cm). Thirty-eight patients did not have surgical candidate due to several reasons such as medical condition, high age, and preceding other cancer treatment. Thirteen patients including 5 with primary tumor located at the cervical esophagus refused surgery. All patients received external beam radiation therapy using linear accelerator with high-energy X-ray. The median total dose was 60 Gy. Field of radiation therapy was individualized considering patient and clinical factors such as age, performance status, primary tumor location and tumor length; local field with no lymph node prophylaxis was used in 11, long-I field in 17, long-T field in 18, and short-T field in 5. Every patient received computer-based adaptive 3D treatment. Seven patients underwent intracavitary brachytherapy using Ir-192 high-dose-rate remote after-loading system. Prescribed dose of brachytherapy was 10-12 Gy in 2 fractions of 5 mm submucosa. Concurrent chemotherapy (CDDP+5FU) was used for 32 patients.

#### Results

Eight patients had local recurrence and only 3 patients developed isolated regional recurrence outside the field of radiation therapy. At the time of data analysis, a total of 20 patients have died. Of those, however, esophageal cancer specific death was only 6 patients. Six patients had died of other cancer; HCC in 2, gastric cancer in 2, tongue cancer in 1 and pancreatic cancer in 1. The 3- and 5-year cause-specific survival rates were 83% and 69%. Among clinical factors such as age, gender, primary site, tumor length, tumor depth, use of concurrent chemoradiation (CCRT), field of RT and initial response, only the use of CCRT significantly influenced overall survival (OAS at 3 year, 56% and 70%,  $p=0.01$ ). Tumor location had marginal impact on OAS. None of 8 patients with Ce-Ut lesion had

died of esophageal cancer. Grade 3 or worse non-hematological toxicities were within acceptable range.

#### Conclusion

Treatment results of radiation therapy for patients with superficial esophageal cancer mainly unfit for surgery were retrospectively analyzed. Adaptive RT-field setting prevented isolated regional recurrence in superficial esophageal cancer.

#### EP-1402 Hypofractionated radiotherapy for patients with bulky unresectable biliary tract cancer

W. Kong<sup>1</sup>, J. Yang<sup>1</sup>, J. Yan<sup>1</sup>, J. Liu<sup>1</sup>, Z. Xia<sup>1</sup>, S. Li<sup>1</sup>, Y. Qiu<sup>2</sup>, B. Liu<sup>1</sup>

<sup>1</sup>Drum Tower Hospital- Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, The Comprehensive Cancer Centre, Nanjing, China ; <sup>2</sup>Drum Tower Hospital- Medical School of Nanjing University & Clinical Cancer Institute of Nanjing University, Department of General Surgery, Nanjing, China

#### Purpose or Objective

The treatment options are limited for the patients with unresectable biliary tract cancer (BTC), especially after the failure of the first-line chemotherapy. Although target therapy and checkpoint inhibitor therapy have improved the prognosis of a variety of advanced cancers in recent years, it has not been successful in treating advanced BTC. Unresectable advanced biliary tract cancers are often accompanied by extensive invasion or regional lymph node metastasis, and conventional radiotherapy can only achieve palliative effects. This study was the first to use helical tomotherapy-based hypofractionated radiotherapy to treat patients with bulky locally advanced and unresectable BTC (excluded diffuse metastatic disease).

#### Material and Methods

In total, we retrospectively analyzed 23 patients with bulky unresectable BTC (tumor size >10cm) treated by tomotherapy-based hypofractionated radiotherapy at Drum Tower Hospital between Feb 2015 and Oct 2017. The irradiated sites covered primary tumors and areas of local invasion, including metastatic lymph nodes that were confined to the abdominal or retroperitoneal space. Cox regression modal and Kaplan-Meier analysis were used to analyze the associations between patients' characteristics and overall survival (OS).

#### Results

The median total radiation dose was 54Gy (range 28-72Gy) and median biologically effective dose (BED) was 74.4Gy (range 37.8-115.2Gy). The median planning target volume (PTV) was 445.79cm<sup>3</sup>. Based on the various PTVs, patients received 2.4-6Gy/fraction with 8-28 fractions. After the radiotherapy, the local control rate was 65.2% and the median OS was 11.3 months (range 2.1-31.9 months). The most common cause of death was out-field failure and only three patients died of in-field failures. The longest survival was 31.9 months. BED  $\geq 70$ Gy significantly improved OS, compared to BED <70Gy (16.8 months vs. 5.05 months) (hazard ratio [HR] 0.146, 95% confidence interval [CI] 0.028-0.762,  $P=0.022$ ). No patients developed grade  $\geq 4$  toxicities.

#### Conclusion

Helical tomotherapy-based hypofractionated radiotherapy was effective and well tolerated for patients with bulky unresectable BTC. The dose escalation with higher BED could improve the survival for such patients. This might be a treatment option for patients with locally advanced biliary tract cancer, which cannot obtain benefit from the first-line chemotherapy.

#### EP-1403 Retrospective evaluation of usefulness of MR-guided adaptive radiotherapy of gastric MALT lymphoma

K. Okuma<sup>1</sup>, H. Okamoto<sup>1</sup>, K. Iijima<sup>1</sup>, F. Nishioka<sup>1</sup>, T. Kashiwara<sup>1</sup>, S. Shima<sup>1</sup>, M. Uematsu<sup>1</sup>, H. Igaki<sup>1</sup>, Y.

Nakayama<sup>1</sup>, J. Itami<sup>1</sup>, N. Murakami<sup>1</sup>, S. Nakamura<sup>1</sup>  
<sup>1</sup>National Cancer Center Hospital, Radiation oncology,  
 Tokyo, Japan

#### Purpose or Objective

It is well known that significant variations in stomach size, shape, and respiratory motion lead to uncertainties in target localization during treatment for stomach. For this reason, planning target volume (PTV) margin is large for the external beam radiation therapy (RT) of gastric mucosa-associated lymphoid tissue (MALT) lymphoma.

Magnetic-resonance (MR) -guided-online-adaptive-radiotherapy is a promising tool for gastric radiotherapy. Our online-adaptive-radiotherapy (On-line ART) process relies on daily image overview by the managing radiation-oncologist, who determines the need for creating a predicted plan if significant inter-fractional anatomical changes are noted.

In this study, the usefulness of MR guided adoptive radiation therapy of gastric MALT lymphoma was evaluated.

#### Material and Methods

Fifty-nine years old female patient with gastric MALT lymphoma underwent breath-hold radiotherapy on the MRI-cobalt system (ViewRay MRIdian system, Oakwood Village, OH, US). The prescribed dose to PTV (defined as a 5 mm expansion of the entire stomach) was 24 Gy in 12 fractions. The patient was instructed to not eat or drink starting four hours prior to treatment. Sagittal slice cine-MR images were acquired through the center of the stomach at 4 frames per second throughout the treatments. Clinical target volume (defined as the entire stomach) and organ at risks (OARs) were contoured on the first frame of the MR cine and tracked for the first 20 min of each treatment using offline optical-flow based deformable registration.

#### Results

The patient underwent RT as scheduled, without any significant adverse effects. MR-guided gating was performed with beam off when  $\geq 10\%$  of the stomach volume exceeded the 3.0-mm boundary expansion. Significant inter-fractional stomach variations on the order of 5.0 cm were observed. N = 12/12 fractions were adapted based on On-line ART. The mean dose of the CTV was 23.79 Gy (V100 = 99.13%).

#### Conclusion

Superior soft-tissue visualization combined with the MR-guided RT ability to dynamically adjust the treatment plan and/or gate the treatment delivery to account for intra-fractional anatomical changes offers great promise to further enhance treatment precision for gastric sites. This approach brings valuable opportunities to decrease overall toxicity profiles.

#### EP-1404 SBRT as definitive treatment of adrenal gland metastases: a single center experience

O. Hernando Requejo<sup>1</sup>, M. Peñacoba<sup>2</sup>, E. Sanchez Saugar<sup>1</sup>, M. Lopez Gonzalez<sup>1</sup>, X. Chen<sup>1</sup>, R. Alonso Gutierrez<sup>1</sup>, A. Montero Luis<sup>1</sup>, R. Ciervide Jurio<sup>1</sup>, J. Valero Albarran<sup>1</sup>, M. Garcia-Aranda Pez<sup>1</sup>, P. Fernandez Leton<sup>3</sup>, J.M. Perez Moreno<sup>3</sup>, J. Garcia Ruiz-Zorrilla<sup>3</sup>, D. Zucca Aparicio<sup>3</sup>, L. Alonso Iracheta<sup>3</sup>, M.A. De la Casa de Julian<sup>3</sup>, J. Marti Asenjo<sup>3</sup>, B. Alvarez Rodriguez<sup>1</sup>, A. Acosta Rojas<sup>1</sup>, J. Plama Delgado<sup>1</sup>, M.C. Rubio Rodriguez<sup>1</sup>

<sup>1</sup>Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Radiation Oncology, Madrid, Spain ;

<sup>2</sup>Hospital Universitario Marques de Valdecilla, Radiation Oncology, Madrid, Spain ; <sup>3</sup>Hospital Universitario Madrid Sanchinarro - Grupo Hospital de Madrid, Radiation Physics, Madrid, Spain

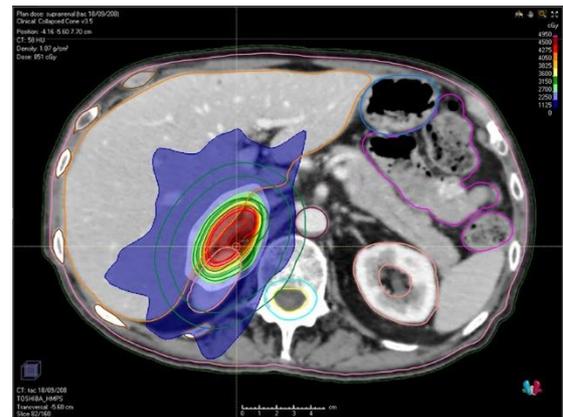

#### Purpose or Objective

Adrenal gland metastases are a common problem in oncology, causing abdominal pain, nausea and vomiting,

leading to patient discomfort. Classical treatment includes surgical resection or chemotherapy, being palliative conformal 3D Radiotherapy the only non-invasive local treatment available. Recently new definitive treatment modalities such as Radiofrequency ablation and SBRT have been developed with promising results. The aim of this study is to analyze the safety and efficacy of SBRT treatment for adrenal gland metastases.

#### Material and Methods

From April 2008 to September 2018 a total of 32 selected patients have been treated of adrenal gland metastases with SBRT at our Institution. Treatment techniques included fiducial-based Adaptive Respiratory Gating (7 patients), Dampening (19) and Active Breathing Coordinator (6). Treatment planning included 7 patients with VMAT, 11 with 3D Conformal Radiotherapy and 6 with IMRT (Fig1). Toxicity was evaluated with CTCAE v5.0. Statistical analysis included descriptive tests and Kaplan Meier curves for survival.

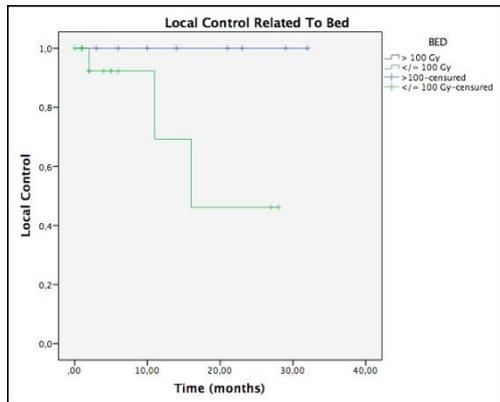

#### Results

All patients (18 males and 14 females) completed treatment as scheduled. The most common location of the primary tumor was lung (75%). Other locations were: gynecological (6%), colorectal, melanoma and sarcoma (3% each). Sixteen patients received SBRT for right adrenal gland, 15 for left gland and 1 for both glands. Median dose of 47 Gy (range 24-60 Gy) and median dose/fraction of 12 Gy (range 5-20 Gy) was administered. The median PTV size and volume was 31 mm and 57 cc respectively.

With a median follow up of 13.2 months local control crude rate was 88.89%. Five patients achieved a complete response, 11 partial response, 7 stable disease and 3 local progression. Estimated local control at 16 months was 77.3%. Median local failure free survival was not reached. Other distant metastases appeared in 85.2% of patients. Median overall survival was 12 months. Fifty seven percent of patients were alive at 12 months.

As prognostic factors we found that left adrenal metastases had statistically significant worse local control than right adrenal ones, which is straightly related with the total dose administered. Doses with BED above 100 Gy (BED- $\alpha/\beta_{10}$ ) had statistically significant better local control than those treated with BED of 100 Gy or below (Fig2). Local control after SBRT was not related with overall survival.

Tolerance to the procedure was generally good. Ten patients presented acute toxicity, being asthenia Grade 1 or 2 the most frequent in seven patients. Chronic toxicity was reported in two patients (6.25%), one Grade 3 enteritis and one Grade 3 abdominal abscess. No Grade 4-5 acute or chronic toxicity was reported.

#### Conclusion

In our experience SBRT for adrenal gland metastases is safe and effective, achieving good local control rates, which are directly related with the total dose administered. Further studies are needed to consolidate these results and evaluate the influence of SBRT in patient survival and quality of life.

#### EP-1405 Feasibility study of fiducial markers in oesophageal cancer radiotherapy

A. Morton<sup>1</sup>, D. McIntosh<sup>1</sup>, S. Currie<sup>2</sup>, A.J. Stanley<sup>3</sup>, S. Paterson<sup>4</sup>, D. Grose<sup>1</sup>, H. Marashi<sup>1</sup>, V. MacLaren<sup>1</sup>  
<sup>1</sup>Beatson West of Scotland Cancer Centre, Clinical Oncology, Glasgow, United Kingdom ; <sup>2</sup>Beatson West of Scotland Cancer Centre, Physics, Glasgow, United Kingdom ; <sup>3</sup>Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom ; <sup>4</sup>NHS Forth Valley, Gastroenterology, Larbert, United Kingdom

#### Purpose or Objective

To determine whether insertion of 5mm radio-opaque gold fiducials (Cook Medical USA) during EUS impacts on inter- and intra-observer variability when defining oesophageal cancer GTV.

#### Material and Methods

14 patients with oesophageal cancer planned to undergo radical radiotherapy, with or without chemotherapy, underwent EUS to place 1-2 fiducials at the proximal and distal end of tumour unless stricturing prevented this. GTV of primary tumour was defined on a planning CT retrospectively 3 times by 3 separate clinicians using fiducials with CT-PET and EUS report.

#### Results

13 patients were imaged with 4 having superior/ inferior markers visible. 8 had only superior and 1 had no visible markers (4 due to stricturing tumours preventing placement, 5 due to marker migration). Unfortunately 1 patient died of mediastinitis secondary to oesophageal perforation following EUS at which stage the trial stopped early.

Intra-observer variability is shown in the attached table for clinicians 1, 2 and 3. Each clinician completed 3 separate contours and these were compared for all 13 cases. Inter-observer variability was assessed by comparing the first contours from each clinician, then the second contours separately followed by the third as shown in table as contour 1, 2 and 3.

For example in 'Contour 2' column, there were 3 contours for all 13 patients representing the second volume done by each of the 3 clinicians. For each patient the maximum difference between the 3 contours in the position of the

superior slice was established. The median and range of the final 13 differences in position in cm is documented. The same was done for the inferior slices. As the 13 tumours varied in size looking at cm<sup>3</sup> was less useful for difference in volume, instead percentage difference between the largest and smallest volume was used. E.g. if largest volume is 16cm<sup>3</sup> and smallest is 8cm<sup>3</sup> then there is a 50% difference in the volumes.

	Intra-observer Variability			Inter-observer Variability		
	Clinician 1	Clinician 2	Clinician 3	Contour 1	Contour 2	Contour 3
<b>Superior Slice</b>						
Median Variability (cm)	0	0.2	0.2	0.4	0.4	0.4
Range of Variability (cm)	0 - 1.2	0 - 0.8	0 - 2.4	0 - 2.4	0 - 2	0 - 2.4
<b>Inferior Slice</b>						
Median Variability (cm)	0.2	0.6	0.4	0.6	0.6	0.6
Range of Variability (cm)	0.2 - 1.4	0.2 - 1.0	0.2 - 3.4	0.2 - 1.4	0.2 - 3.4	0.2 - 1.4
<b>Volume</b>						
Median Variability (%)	8.8%	11.7%	17.2%	20.2%	25.9%	28.6%
Range of Variability (%)	4.1 - 32.4%	2.3 - 27.5%	3.1 - 59.1%	8.5 - 44.1%	6.7 - 56.4%	6.1 - 63.1%

#### Conclusion

Inter and intra-observer variability was significant despite markers; small variations at the inferior and superior border still contributed to considerable variation in the final volume.

Fiducial placement and retention at the inferior border was lower than would be anticipated, however inter-observer variability was similar to the superior slice. In the context of multi-modality imaging techniques to identify GTV, it is likely marker contribution has been restricted. Cases where they are most likely to contribute are tumours difficult to appreciate on imaging. Given the rare but recognised complication of death following perforation at EUS, identifying patients most likely to benefit is key.

#### EP-1406 Mapping Pattern of LNMs for Postoperative Radiotherapy in TESCC: Defining the Clinical Target Volume

J. Yu<sup>1</sup>, C. Li<sup>1</sup>, W. Ouyang<sup>1</sup>, Y. Xu<sup>1</sup>, J. Zhang<sup>1</sup>, C. Xie<sup>1</sup>  
<sup>1</sup>Zhongnan Hospital of Wuhan University, Radiation and Medical Oncology, Wuhan, China

#### Purpose or Objective

The clinical target volume (CTV) for postoperative radiotherapy for thoracic esophageal squamous cell carcinoma (TESCC) needs to be defined. The study aim was to map the first metastatic lymph nodes (LNMs) in a computed tomography (CT)-based atlas and to guide CTV delineation in postoperative radiotherapy for TESCC.

#### Material and Methods

Sixty-nine patients with primary regional LNMs after esophagectomy were included. The LNM epicenters were registered onto corresponding anatomic axial CT images of a standard patient in the treatment position, with reference to the surrounding vascular and bony structures. The LNM sites were based on lymph node map of esophageal cancer, AJCC 8<sup>th</sup>. Accordingly, regional lymph node stations 1 to 8M were defined as the upper-middle mediastinum region (UMMR); stations 8Lo, 9, and 15 were defined as the inferior mediastinum region (IMR); and stations 16 to 20 were defined as the upper abdominal lymph node region (UAR). The lymph metastasis risk for different segments was assessed.

#### Results

One hundred and seventy-nine LNMs were mapped onto standard axial CT images. The upper-middle mediastinum region (station 1 to 8M) was the most common site for LNMs. It contained 97% of metastases in the upper segment, 90% in the middle segment, and 66% in the lower one. Advanced pathological stage ( $\geq$ IIIB) might be a predictive factor for upper abdominal region (UAR) relapse in lower TESCC. Lower cervical para-tracheal LNMs were within a 4.3-cm bilaterally expanded area from the midline and a 2.2-cm expanded area from the anterior, from the superior border of the C7, to the inferior border of the first thoracic vertebra.

Table 1. Patient characteristics

Variable	Value	
Age (y), median (range)	56 (44-80)	
Sex		
Male	60 (87.0%)	9 (13.0%)
Female		
Surgical	type	
Ivor-Lewis	15 (21.7%)	
Sweet	41 (59.4%)	13 (18.9%)
Location	Upper	
Middle	11 (15.9%)	
Low	31 (44.9%)	27 (39.2%)
Grade		
Well	8 (11.6%)	
Median	32 (46.4%)	
Poor	24 (34.8%)	
Undifferentiated	5 (7.2%)	
Stage		
I	12 (17.4%)	
II	19 (27.5%)	
III	30 (43.5%)	8 (11.6%)
IVa		
Adjuvant chemotherapy		
Yes	17 (24.6%)	52 (75.4%)
No		

### Conclusion

A modified target from the upper border of C7 to the lower border of the carina of the trachea could cover the high-risk area of TESCC. UAR seems to be an elective irradiation target for lower TESCC at pathological IIIB stage or above.

### EP-1407 Sarcopenia is a weak prognostic factor before chemoradiotherapy of esophageal carcinomas

B. Bethsabée<sup>1</sup>, Q. Laurent<sup>1</sup>, C. Pierre<sup>2</sup>, H. Valerie<sup>1</sup>, G. Sophie<sup>1</sup>, A. Thomas<sup>3</sup>, L. Nelson<sup>3</sup>, G. Jean-Marc<sup>3</sup>, C. Hennequin<sup>1</sup>

<sup>1</sup>Hôpital Saint-Louis, Radiation Oncology, Paris, France ; <sup>2</sup>Hôpital Saint-Louis, Surgery, Paris, France ; <sup>3</sup>Hôpital Saint-Louis, Gastro-enterology, Paris, France

### Purpose or Objective

Sarcopenia seems to be an important prognostic factor of esophageal carcinoma (EC) before surgery. Data are less convincing before chemoradiotherapy (CRT) and this prompts us to review our experience in a recent cohort study.

### Material and Methods

Between 2010 and 2015, all patients with a locally advanced EC treated with upfront CRT and a CT-scanner at the time of CRT available were included. All patients had an 18-FDG-PET-CT to eliminate distant metastases. Decision of surgery was performed after CRT (40-50 Gy) according to tumor extension, performance status (PS), comorbidities and response to CRT. To evaluate sarcopenia, a single slice at the L3 level was identified and total skeletal muscle (TMA) and subcutaneous and visceral fat were measured. The skeletal muscle index (SMI) is calculated as follows: TMA/height<sup>2</sup> (m<sup>2</sup>). Sarcopenia was internationally defined as a SMI of  $\leq 39$  cm<sup>2</sup>/m<sup>2</sup> for women and  $\leq 55$  cm<sup>2</sup>/m<sup>2</sup> for men. We used also the definition given by Martin et al. (JCO, 2013): for patients with a body mass index (BMI) < 25, SMI < 41 cm<sup>2</sup>/m<sup>2</sup> for women and < 43 cm<sup>2</sup>/m<sup>2</sup> for men; if BMI  $\geq 25$ , SMI < 41 cm<sup>2</sup>/m<sup>2</sup> for women and < 53 cm<sup>2</sup>/m<sup>2</sup> for men.

### Results

104 patients were included: Mean age: 63 yrs. Men: n=72. PS 0: 32; PS 1: 59; PS 2: 13. T-stage: T2: 4; T3: 95; T4: 5. N stage: N1-2: 76. Weight loss >5%: n=74. Surgery after CRT: 39. Histology: Squamous cell cancer (SCC): 69. Mean SMI was 35 cm<sup>2</sup>/m<sup>2</sup> for women and 46 cm<sup>2</sup>/m<sup>2</sup> for men. According to the international definition, sarcopenia was found in 84 pts (81%). It was correlated to initial BMI, but not to age, weight loss, PS or T stage. According to the

Martin's definition, 64 pts (61.5%) had sarcopenia. 3-year overall survival (OS) was 34.6%. Prognostic factors for OS in univariate analysis were initial PS and surgery. Sarcopenia, using international or Martin's definition, was not significantly associated with OS. However, when using the median SMI for each sex as a cut-off (a lower level than the other definitions), sarcopenia is associated with OS (at 3 years: 43.3% vs 26.2%; p=0.02). However, in multivariate analysis, only PS remains statistically associated with OS. There was no correlation between fat measurements and OS.

### Conclusion

High level of sarcopenia is associated with OS in patients with EC treated with up-front CRT; but its prognostic value is low and disappears in multivariate analysis.

### EP-1408 Cardiac dose and treatment-elicited inflammation are related to poor survival in esophageal cancer

Y. Ho<sup>1</sup>, J. Lin<sup>1</sup>, T. Chou<sup>1</sup>, L. Hung<sup>1</sup>, C. Huang<sup>1</sup>, C. Pi<sup>1</sup>, T. Chang<sup>1</sup>, M. Liu<sup>1</sup>

<sup>1</sup>Changhua Christian Hospital, Radiation Oncology, Changhua City, Taiwan

### Purpose or Objective

Definitive concurrent chemoradiation (CCRT) is the standard treatment for esophageal cancer with cervical location or non-surgical candidate and able to tolerate chemoradiation. Studies have correlated cancer-related inflammatory response and treatment-related toxicities with worsening survival. The purpose of this study was to evaluate the prognostic factors and normal tissue dosimetric parameters affecting overall survival (OS), as well as the predictive values on OS of the levels of neutrophil to lymphocyte ratio (NLR) at baseline, during-CCRT and post-CCRT periods.

### Material and Methods

Between 2010 and 2015, 110 newly diagnosed stage II and III patients, with the majority of squamous cell carcinoma, were identified from our institution. Patients' clinical, dosimetric, and laboratory data at baseline, during and post-CCRT were collected by review of medical records. The Cox proportional hazard model was used to identify the potential risk factors for OS. Thresholds were chosen to increase specificity and to dichotomize continuous variables, as the median for heart mean dose and baseline NLR, and the upper quartile for increased NLR during-CCRT.

### Results

Median follow up was 21.0 months (range 3-95 months) and overall survival was 20.6 months. A total of 75% of patients had stage III disease and all patients completed definitive CCRT. Two-year OS and five-year OS were 27% and 16%. Univariate analysis showed that male gender (p = 0.035), stage (II vs. III, p = 0.058), ECOG performance status (0 vs.  $\geq 1$ , p = 0.031), mean heart dose (>2070.5 vs.  $\leq 2070.5$  cGy, p = 0.017), baseline NLR (>3.56 vs.  $\leq 3.56$ , p = 0.005) and increased NLR during-CCRT (>27.46 vs.  $\leq 27.46$ , p = 0.022) were significantly associated with poor OS. On multivariate analysis, stage (Hazard Ratio [HR] 1.71; 95% CI 1-2.9, p = 0.048), performance status (HR 5.89; 95% CI 2.21-15.67, p < 0.001), mean heart dose (HR 1.71; 95% CI 1.09-2.68, p = 0.02), baseline NLR (HR 1.9; 95% CI 1.19-3.04, p = 0.007) and increased NLR during-CCRT (HR 2.58; 95% CI 1.52-4.39, p < 0.001) remained significantly associations with reduced OS.

### Conclusion

Mean heart dose > 2070.5 cGy, baseline NLR > 3.56 and increased NLR during-CCRT > 27.46 were poor prognostic markers for OS in esophageal cancer patients receiving definitive CCRT. Minimal cardiac dose during radiotherapy and novel therapy targeting tumor or treatment-elicited inflammatory response might improve survival for patients with esophageal cancer underwent definitive CCRT.

**EP-1409 QoL for Gem and ABX plus SBRT versus Gem and S-1 plus SBRT in metastatic pancreatic cancer**

X. Zhu<sup>1</sup>, C. Yangsen<sup>1</sup>, Z. Xianzhi<sup>1</sup>, S. Yuxin<sup>1</sup>, J. Xiaoping<sup>1</sup>, Q. Shuiwang<sup>1</sup>, C. Fei<sup>1</sup>, J. Zhen<sup>1</sup>, F. Fang<sup>1</sup>, J. Zhen<sup>1</sup>, Z. Huojun<sup>1</sup>

<sup>1</sup>Changhai Hospital, Radiation Oncology, Shanghai, China

**Purpose or Objective**

Nearly 50% of patients had metastatic pancreatic cancer at initial diagnose. Therefore, priority may be given to quality of life, which required improvement of survival without simultaneously compromise of health-related quality of life (HRQOL) during treatment. Moreover, radiotherapy could be an option for amelioration of local symptoms in addition to potential abscopal effects, contributing to improvement of HRQOL. Hence, we sought to evaluate the HRQOL after SBRT and different chemotherapy regimens in the management of metastatic pancreatic cancer.

**Material and Methods**

Patients with biopsy-proven and radiographically metastatic pancreatic cancer were included and prospectively followed up from 2013 to 2017. Chemotherapy was delivered after SBRT with an interval of 3 weeks, which were required for 4 cycles. The regimens were gemcitabine plus nab-paclitaxel (GT group) or gemcitabine plus S-1 (GS group). The Chinese version of Brief Pain Inventory (BPI) and 5-level European quality of life 5-dimensions (EQ-5D-5L) were used in this study. Due to limited survival of patients with metastatic pancreatic cancer, questionnaires were completed before SBRT and right after the whole treatment. Patient-reported global changes and scores of questionnaires were assessed. To be simplified, all changes were stratified into "better", "no change" and "worse" in the analysis. Data were analyzed with Spearman's rank correlation, ordinal regression. Propensity score matched analysis were further performed to evaluate these two regimens.

**Results**

Seventy-five and eighty-nine patients received gemcitabine plus nab-paclitaxel and gemcitabine plus S-1, respectively. No differences of baseline characteristics were found between these two groups. No differences of BPI scores were found between pre- and post-treatment in each group, while only the post-treatment EQ-5D-5L score was higher than that at baseline in GS group ( $P < 0.001$ ). The response "better" of BPI was found in 15 and 38 patients in GT and GS group, respectively ( $P < 0.001$ ). On multinomial logistic regression, compared with GS group, the probability of GT group achieving "better" global change of BPI was 0.289 ( $P = 0.015$ ). The "better" change of EQ-5D-5L was found in 20 and 42 patients in GT and GS group, respectively ( $P < 0.001$ ). After multinomial analysis, compared with GS group, the probability of GT group gaining improvement of EQ-5D-5L was 0.334 ( $P = 0.031$ ). After propensity score matching analysis, more patients had improvement of BPI and EQ-5D-5L in GS group compared with GT group ( $n = 24$  vs.  $n = 12$ ,  $P = 0.002$ ;  $n = 28$  vs.  $n = 16$ ,  $P = 0.002$ ). No grade 3 or more radiation-induced toxicity occurred. More patients in GT group experienced grade 3 or more hematological and gastrointestinal toxicity than those in GS group ( $n = 25$  vs.  $n = 16$ ,  $P = 0.024$ ;  $n = 17$  vs.  $n = 10$ ,  $P = 0.049$ ).

**Conclusion**

GS may achieve better HRQOL than GT. Therefore, GS may be an alternative of GT for metastatic pancreatic cancer, especially for Asians.

**EP-1410 PET compared to CT in target delineation for SBRT of pancreas adenocarcinoma.**

C. De la Pinta Alonso<sup>1</sup>, J.D. García<sup>2</sup>, D. Sevillano<sup>2</sup>, A. Martínez-Lorca<sup>3</sup>, R. García<sup>4</sup>, M. Martín<sup>1</sup>, M. Martín<sup>1</sup>, R. Hernanz<sup>1</sup>, E. Fernández-Lizarbe<sup>1</sup>, T. Muñoz<sup>1</sup>, J.A. Domínguez<sup>1</sup>, J.F. Crespo<sup>5</sup>, C. Vallejo<sup>1</sup>, A. Hervás<sup>1</sup>, F. López<sup>1</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Ramon y Cajal Hospital, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Ramon y Cajal Hospital, Medical Physics, Madrid, Spain ; <sup>3</sup>Ramon y Cajal Hospital, Nuclear Medicine Department, Madrid, Spain ; <sup>4</sup>Ramon y Cajal Hospital, Radiology Department, Madrid, Spain ; <sup>5</sup>Ramon y Cajal Hospital, Nursery Department, Madrid, Spain

**Purpose or Objective**

In SBRT quality control of target delineation pancreatic tumors is essential to deliver adequate doses of radiation to the primary tumor while preserving adjacent healthy organs. The purposes of this study was to evaluate the variability in contouring of these tumors in our center and our hypothesis is that PET allows better visualization of pancreatic tumours and will optimize the accuracy of tumor delineation for SBRT compared with CT only.

**Material and Methods**

A planning CT and PET/CT were performed in all patients. Gross tumor volume (GTV) in both CT and PET/CT were delineated. 8 physicians of Radiation Oncology Department performed the contours. Pancreatic locations included bed surgery recurrence, pancreatic body (2p) and pancreatic-head. The cases show different difficulty: low acquisition contrast, previously treated with chemotherapy or low SUV in PET/CT. In both CT and PET, the GTV volumes, conformity index (CI) and distance between the centers of mass (dCOM) were compared.

**Results**

Four patients were included. The GTV volume as defined on CT was in all cases larger or at least as large as the GTV volume on PET. The median GTV volume on PET was 7,1 mL (range, 1,7-14,9 mL), compared to 12,5 mL on CT (range 5-18,6 mL). Contouring of pancreatic adenocarcinoma on CT resulted in non-statistically significant larger lesions (mean increase 5,46mL) compared with PET ( $p = 0.254$ ). Variability between observers in CT was minor than PET (17,14 vs 23,45mL). Overlap ratio has not showed differences between CT and PET.

**Conclusion**

PET and TC seems to represent extend of the GTV in pancreatic tumors accurately. Contouring based on CT-only could result in an overestimation of the actual tumor volume, which may cause overdosage of the GTV in SBRT treatment plans by this combining CT and PET could be help in contouring. The interobserver variability in target delineation of pancreatic tumors GTV in this study is noteworthy. We consider need multi-institution studies involving abdominal SBRT require appropriate quality assurance programs for target delineation.

**EP-1411 What is the best imaging study to contouring liver metastases in SBRT?**

C. De la Pinta Alonso<sup>1</sup>, J.D. García<sup>2</sup>, D. Sevillano<sup>2</sup>, R. García<sup>3</sup>, A. Martínez-Lorca<sup>4</sup>, M. Martín<sup>1</sup>, E. Fernández-Lizarbe<sup>1</sup>, M. Martín<sup>1</sup>, J.A. Domínguez<sup>1</sup>, R. Hernanz<sup>1</sup>, T. Muñoz<sup>1</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Ramon y Cajal, Medical Physics, Madrid, Spain ; <sup>3</sup>Hospital Ramon y Cajal, Radiology Department, Madrid, Spain ; <sup>4</sup>Hospital Ramon y Cajal, Nuclear Medicine, Madrid, Spain

**Purpose or Objective**

In SBRT tumor delineation is essential to deliver adequate doses of radiation while preserving adjacent healthy organs. Defining liver metastases gross tumor volume (GTV) requires multimodal imaging, acquired in different perfusion phases. Most liver metastases can be imaged in the portal venous phase. The purposes of this study was to evaluate the variability in contouring of these tumors in our center and compare three studies: CT, MRI and PET

**Material and Methods**

Anonymous, multiphase-CT, MRI and PET/CT obtained from five patients (6 lesions) with liver metastases were

included and distributed to a panel of 8 radiation oncologists. Liver locations were segments II, IV (2) and VI (3). The cases show different difficulty: low acquisition contrast, previously treated with chemotherapy, inhomogeneous liver parenchyma or low SUV in PET/CT. The agreement was assessed using the kappa-statistic. Agreement interpretation was evaluated using Landis and Koch's interpretation. The institutional review boards approved the study.

#### Results

The median GTV volume on MRI was 2,8 mL (0,7-16,1 mL), compared to 3mL on CT (0,6-8,6 mL) ( $p=0,07$ ). The median GTV volume on PET was 6 mL (2,5-18mL), compared to 3mL on CT (0,6-8,6 mL) ( $p=0,15$ ). Variance between observers in CT was minor that MRI and PET (5,75 vs 9 vs 19,9). The index of agreement was low (0,083) between CT and MRI in all patients. The index of agreement was low ( $kappa=0,005$ ) between CT and PET in all patients.

#### Conclusion

In cases with well-defined tumor CT is more easy and reproducible. In cases with no defined tumor in CT we need other tools: MRI and/or PET/CT. The interobserver variability in target delineation in this study is noteworthy. Multi-institution consensus was necessary.

#### EP-1412 Excellent pCR rate in patients with HCC after SBRT +/- TACE as bridging to liver transplantation

S. Gerum<sup>1</sup>, C. Heinz<sup>2</sup>, C. Belka<sup>3</sup>, P.M. Paprottka<sup>4</sup>, J. Neumann<sup>5</sup>, E. De Toni<sup>6</sup>, M. Guba<sup>7</sup>, F. Roeder<sup>8</sup>

#### Purpose or Objective

**Background:** To report histopathological response rate and overall outcome after stereotactic body radiotherapy (SBRT) +/-TACE (transarterial chemoembolisation) as bridging to orthotopic liver transplantation (OLT) in patients with hepatocellular carcinoma (HCC).

#### Material and Methods

**Patients and methods:** We retrospectively analyzed 6 patients with 7 HCC lesions, who had been listed for orthotopic liver transplantation and had received SBRT as bridging treatment. All patients fulfilled EASL criteria for diagnosis and Milan criteria for OLT eligibility. All patients were judged ineligible for other locally ablative treatments (except TACE) or surgical resection by multidisciplinary evaluation. 4 patients received SBRT within 6 weeks from TACE of the same lesion(s). Liver function was Child-Pugh class A in 3, B in 2 and C in 1 patient(s). Cause of underlying cirrhosis was toxic in 2, hepatitis viral infection in 2 and autoimmune in 2 patients. Dose and fractionation varied dependent on localisation, size, motion and liver function. 6/7 lesions were treated with 37.5 Gy prescribed to the surrounding 65% isodose in

3 fractions. Immobilization included a vacuum pillow in all and abdominal compression in 5 patients. Treatment planning was based on contrast-enhanced 4D-CT using an ITV concept with a PTV margin of 6 mm. Daily image guidance was performed with CBCT using fiducial markers or lipiodol enhancement after TACE.

#### Results

**Results:** Median interval between SBRT and OLT was 6 months (range 1-8 months). Median follow-up from SBRT was 24 months (range 7-79). All patients remained locally and distantly controlled until OLT. In 5/6 patients and 6/7 lesions no residual HCC (pathologic complete response) was found in the explanted liver. The only patient with residual disease had been treated with SBRT only (no TACE) and received OLT early (1 month) after SBRT. No acute toxicity from SBRT was observed, except deterioration of liver function in the CP C patient salvaged by OLT. One patient died shortly after OLT due to postoperative complications and one due to distant failure 9 months after OLT, resulting in a 2yr-OS rate of 66%.

#### Conclusion

**Conclusion:** SBRT with or without TACE is a locally effective and well-tolerated bridging treatment for HCC patients listed for orthotopic liver transplantation.

#### EP-1413 Correlation between N-L Ratio, P-L Ratio and Survival in patients with LAPC: A new prognostic factor?

P. Trecca<sup>1</sup>, M. Fiore<sup>1</sup>, C. Greco<sup>1</sup>, E. Ippolito<sup>1</sup>, R.M.

D'Angelillo<sup>1</sup>, L. Trodella<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Campus-Bio Medico University, Radiotherapy Unit, Rome, Italy

#### Purpose or Objective

The aim of the study was to investigate the role of inflammatory markers such as neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) in predicting the prognosis of patients with locally advanced pancreatic cancer (LAPC) treated by radiochemotherapy (RCT)

#### Material and Methods

Fifty-two patients (F:30; M:22; median age 64 years, range 40-75 yrs) with histologically proven pancreatic ductal adenocarcinoma enrolled in a prospective one-armed phase II study were evaluated. All patients were treated with gemcitabine-based RCT after an accurate pre-treatment staging. NLR and PLR were calculated from data collected within 14 days before the start of the concurrent RCT. We stratified population into groups according to the cut-off values: NLR<3 (n=30 pts), NLR ≥3 (n=22 pts), PLR<200 (n=38 pts), PLR ≥200 (n=14 pts). Survival data among subgroups classified by each factor were analyzed via the Kaplan-Meier curve and compared by the log-rank test.

#### Results

For NLR<3 and NLR≥3 groups, respectively, median OS were 17.7 months and 13 months ( $p=0.15$ ), and median PFS were 12.4 months and 18.1 months ( $p=0.4$ ). For PLR<200 and PLR≥200 groups, respectively, median OS were 21.5 months and 12.4 months ( $p<0.001$ ), and median PFS were 20 months and 12.5 months ( $p=0.2$ ).

#### Conclusion

These data suggest that high NLR and high PLR could predict worst OS and PFS. More studies with a large population may be useful in order to validate NLR and PLR as predicting markers for prognosis of patients with LAPC.

#### EP-1414 SBRT for the treatment of hepatocellular carcinoma: a retrospective multicenter study

N. Scher<sup>1</sup>, F.G. Riet<sup>2</sup>, G. Janoray<sup>1</sup>, K. Debbi<sup>1</sup>, S. Levy<sup>1</sup>, P. Louisot<sup>1</sup>, E. Chajon<sup>2</sup>, E. Salame<sup>1</sup>, I. Barillot<sup>1</sup>, R. De Crevoisier<sup>2</sup>, G. Calais<sup>1</sup>, S. Chapet<sup>1</sup>

<sup>1</sup>Hopital Bretonneau, Centre, Tours, France ; <sup>2</sup>Centre Eugene Marquis, Bretagne, Rennes, France

#### Purpose or Objective

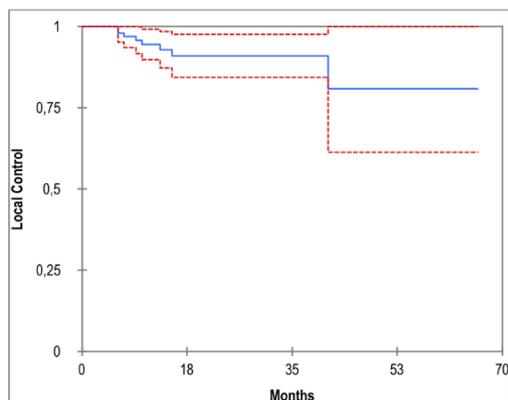

To describe local control, overall survival, progression-free survival and toxicities of Cyberknife® based stereotactic body radiation therapy (SBRT) in the treatment of hepatocellular carcinoma (HCC).

#### Material and Methods

The records of all the patients treated for HCC at the Eugene Marquis center, Rennes and the Bretonneau Hospital, Tours; between November 2010 and December 2016, were reviewed. The treatment was performed as a salvage treatment; as a bridge to liver transplantation or if no other treatment was possible.

#### Results

136 patients were consecutively included in the study. The median follow-up was 13 months. The median total dose prescribed, median fractionation and median overall treatment time were respectively 45 Gy, 3 fractions and 5 days. The overall survival, progression-free survival and local control rates at 1 year and 2 years were 79.8% and 63.5%; 61.3% and 39.4%; 94.5% and 91%. Two grade 3 acute toxicity events and two grade 4 late toxicity events corresponding to a duodenal ulcer have been reported. Seven patients underwent classic RILD (radio-induced hepatitis) and thirteen patients showed non-classical RILD. BCLC stage, WHO grade and PTV volume were correlated with overall survival in univariate Cox analysis.

#### Conclusion

SBRT is an effective and well tolerated in the treatment of inoperable HCC or as a bridge to liver transplantation. The toxicity is mainly related to cirrhotic background and requires a selection of patients and strict dose constraints.

#### EP-1415 Preliminary results of a phase II study of induction Folfirinox followed by chemoradiation in LAPC

P. Trecca<sup>1</sup>, M. Fiore<sup>1</sup>, R. Coppola<sup>2</sup>, L.E. Trodella<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, L. Trodella<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>Campus-Bio Medico University, Radiotherapy Unit, Rome, Italy ; <sup>2</sup>Campus-Bio Medico University, General Surgery, Rome, Italy

#### Purpose or Objective

The aim of this study was to evaluate the safety and efficacy of induction FOLFIRINOX followed by a high weekly dose of gemcitabine-based radiochemotherapy in patients with borderline resectable or unresectable locally advanced pancreatic cancer.

#### Material and Methods

This trial was performed as a single-center one-armed phase II study. From January 2015 we evaluated twenty-two patients with borderline resectable or unresectable pancreatic cancer (characteristics of patients are summarized in table 1). A pre-treatment staging was performed with CT scan, 18FDG PET-CT scan and laparoscopy. Patients with metastatic disease were excluded. Suitable patients received chemotherapy with

Folfirinox (four cycles every 14 days). Patients without disease progression after restaging received conformal radiation therapy with concurrent gemcitabine at the dose of 600 mg/mq weekly.

Characteristic	No of patients (N = 22)	%
<b>Age (years)</b>		
Median	63.5	
Range	48-79	
<b>Sex</b>		
Male	10	45,5
Female	12	54,5
<b>ECOG performance status</b>		
0	22	100
1	0	0
<b>CA 19-9 at diagnosis, U/mL</b>		
Median	4219	
Range	<2-8945	
<b>Tumorlocalization</b>		
Head	18	81,8
Body/Tail	4	18,2
<b>Resectability status</b>		
Borderline resectable	6	27,3
Locally advanced unresectable	16	72,7

#### Results

Further to the results of the pre-treatment workup, nine patients (40,9%) were excluded from the protocol because of the evidence of metastatic disease, and thus a total of thirteen patients were consequently enrolled. Five patients (38,5%) had a progression of disease after induction chemotherapy. Eight patients (61,5%) completed radiochemotherapy. Of these, four patients underwent surgical radical resection (30,8%). At the present, the median Overall Survival was 13,8 months and the median Progression Free Survival was 18,9 months. For the entire cohort of patients the treatment was well tolerated. Only haematological grade 3-4 toxicities were observed.

#### Conclusion

Although the follow-up time is limited, these preliminary data of the protocol treatment show promising results for patients with borderline resectable and unresectable pancreatic cancer. The enrollment is actually ongoing. Continued optimization in multimodality therapy and an accurate patient selection are crucial for the appropriate treatment of patients.

***This abstract is part of the media programme and will be released on the day of its presentation***

54.8%, and abdominal discomfort: 64.2%). Median time to symptom progression was 89 days (range: 12-392 days), in which patients with CR+PR at 1 month had more durable control of symptoms than those with SD+PD (median 114 days vs. 55 days, p=0.24). Treatment is well tolerated with only 2 patients (3.8%) developing grade 3 toxicities. (fatigue, n=1; vomiting, n=1). AFP response, radiological response rate, and disease control rate at 3 months were 38.6%, 15.2%, and 54.6% respectively.

**Table 1.** Bar Chart showing proportion of patients with clinical improvement of pain and abdominal discomfort at 1 month (CR+PR, SD, and PD)

**Table 2.** Symptom response (CR, PR, SD & PD), response duration, and overall survival of patients

**EP-1417 Palliative Liver Radiotherapy (RT) of Advanced Hepatocellular Carcinoma (HCC) in Endemic Population**

C.L. Chiang<sup>1,2</sup>, C.S. Yeung<sup>3</sup>, N.S. Wong<sup>3</sup>, K.C. Tsang<sup>1</sup>, B.Y. Chan<sup>1</sup>, S.K. Ha<sup>1</sup>, C.H. Ho<sup>3</sup>, F.A. Lee<sup>3</sup>

<sup>1</sup>The University of Hong Kong, Department of Clinical Oncology, Hong Kong, Hong Kong SAR China ; <sup>2</sup>HKU-Shenzhen Hospital, Department of Clinical Oncology, Shenzhen, China ; <sup>3</sup>Tuen Mun Hospital, Department of Clinical Oncology, Hong Kong, Hong Kong SAR China

**Purpose or Objective**

This study aims at evaluating the symptom response, response duration, and toxicity of palliative liver radiotherapy (RT) in advanced HCC patients in endemic area.

**Material and Methods**

We reviewed the clinical records of unresectable HCC patients treated with palliative RT (8Gy single fraction) in our institution. Eligible patients were unsuitable or refractory to TACE and SBRT, with an index symptom of pain or abdominal discomfort. Physician reported symptoms [complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD)] were documented monthly at the first 3 months and every 3 months thereafter till death. The primary outcome was the percentage of patients with clinical improvement of index symptom (CR+PR) at 1 month. Secondary outcomes were symptom response duration, toxicities, alpha-feto protein (AFP) response (>20% drop from baseline), and radiological response.

**Results**

Fifty-two patients were included in the study. Thirty-eight (73%) were hepatitis B carriers; median size of the largest tumor was 13cm (range 3-24cm); 33 (63.5%) had tumor involvement >50% of total liver volume. Fifty-one (98.1%) were Barcelona Clinic Liver Cancer (BCLC) stage C and twenty-three of them (45.1%) received Sorafenib after radiotherapy. The index symptom was pain in 34 patients, and abdominal discomfort in 18 patients. At 1 month, 57.8% of patients had improvement of symptoms (pain:

**Conclusion**

Substantial patients had improvement of index symptoms after receiving palliative liver RT with median response duration of around 3 months. The treatment is well tolerated with minimal toxicities.

**EP-1418 Initial results of carbon ion radiotherapy combined with S-1 for locally advanced pancreatic cancer**

Y. Mori<sup>1</sup>, M. Okamoto<sup>1</sup>, H. Kiyohara<sup>2</sup>, H. Katoh<sup>3</sup>, K. Shibuya<sup>1</sup>, T. Kaminuma<sup>1</sup>, S. Shiba<sup>1</sup>, N. Okano<sup>1</sup>, T. Ohno<sup>1</sup>, T. Nakano<sup>1</sup>

<sup>1</sup>Gunma Heavy Ion Medical center, Radiation oncology, Maebashi-city, Japan ; <sup>2</sup>Maebashi red cross hospital, Radiation oncology, Maebashi-city, Japan ; <sup>3</sup>Kanagawa cancer center, Radiation oncology, Yokohama city, Japan

**Purpose or Objective**

Generally, patient with locally advanced pancreatic cancer (LAPC) is treated with chemotherapy alone or X-ray radiotherapy (RT) concurrent with gemcitabine (GEM). Median survival time (MST) of standard treatment is about 14 months. Recently, there was a report of carbon ion radiotherapy (C-ion RT) with concurrent usage of GEM for LAPC which showed 2-year overall survival (OS) rate and MST 48% and 22.5 months, that is better outcome compared with other treatment for LAPC. However, there is no report for C-ion RT combined with other chemotherapy. On the other hand, postoperative adjuvant chemotherapy with S-1 significantly extended both overall and relapse-free survival of Japanese patients with resected pancreatic cancer compared with GEM. [OM1] [Office2] Thus, we hypothesize that C-ion RT concurrent S-1 (tegafur/gimeracil/oteracil potassium) is more effective for LAPC and started prospective phase II study in our institute.

**Material and Methods**

Eligibility criteria: (1) Pathologic confirmation of pancreatic invasive ductal carcinomas or clinical diagnosis by imaging. (2) Absence of distant metastasis (patients with para-aortic lymph node metastasis were eligible) (3) Unresectable primary tumors due to T4 disease based on the 7th edition of TNM classification, involving either the celiac axis or the superior mesenteric artery. (4) Without gastrointestinal ulcer (stomach, duodenum) (excluding repaired ulcer) (5) Age at registration is from 20 to 80 years old (6) ECOG performance status (PS) of 0 to 2. (7) Without the surgical resection history to a pancreatic cancer. Without the radiotherapy to a pancreatic cancer. Treatment: Prescribed doses were 55.2 Gy [relative biological effectiveness (RBE)] in 12 fractions. Concurrent S-1 was administered orally during 28 days, the dose levels were 80 mg/-1.00 m<sup>2</sup>, 100 mg/1.00-1.50 m<sup>2</sup>, 120 mg/1.50- m<sup>2</sup> per day. Clinical outcome measures: The primary endpoint was overall survival (OS). The secondary endpoints were local control (LC) rate, progression free survival (PFS) rate and adverse effects. Toxicity was graded using Common Terminology Criteria for Adverse Events, version 4.0 (CTCAE 4.0).

**Results**

There were 13 patients enrolled this study from January 2016 to December 2017 in our institute. MST was 23.4 months. 1 and 2-year OS was 100% and 38%. 1 and 2-year LC are 80% and 28%. 1 and 2-year PFS rate are 60% and 49%. There were occurrences of acute toxicity, leukopenia grade 2 in 2 patients and grade 3 in 1 patient, anemia grade 2 in 2 patients and grade 3 in 1 patient, thrombocytopenia Grade 2 in 1 patient. There is no patient with Grade 4 or higher. There were no occurrences of late toxicity of grade 3 or higher.

**Conclusion**

Initial results show that C-ion RT combined with S-1 appears to be tolerated and not inferior compared with GEM for LAPC. Although there are still few cases, C-ion RT combined with S-1 is also considered to be one of the options of treatment for LAPC.

**EP-1419 Salvage concurrent chemoradiotherapy for postoperative locoregional recurrence of esophageal cancer**

T. Kiritoshi<sup>1</sup>, H. Yamashita<sup>1</sup>, W. Takahashi<sup>1</sup>, M. Ogita<sup>1</sup>, K. Nakagawa<sup>1</sup>, O. Abe<sup>1</sup>

<sup>1</sup>The University of Tokyo Hospital, Radiology, Bunkyo-ku, Japan

**Purpose or Objective**

The aim of this study was to evaluate clinical results of salvage CRT for locoregional recurrence after esophagectomy for squamous cell carcinoma of esophagus.

**Material and Methods**

We performed a retrospective review of 73 consecutive patients who received salvage chemoradiotherapy between 2001 and 2017 for locoregional recurrence of esophageal carcinoma after curative surgery. The intended radiotherapy regimen was 50-60 Gy in 25-30 fractions combined with concurrent platinum-based chemotherapy. The endpoints of this study were overall survival, progression free survival and prognostic factors. Survival rates were estimated using the Kaplan-Meier method, and statistical analysis was performed using the log-rank test. Univariate and multivariate analysis were performed using the log-rank test and the Cox proportional hazards model respectively.

**Results**

The median follow-up period for survivors was 42.7 months. The 1-, 2-, 3-year overall survival were 82.4%, 46.2% and 33.8% respectively with a median survival time of 21.6 months. Out of all 73 patients, 29 patients were alive beyond 2 years from salvage therapy. The median PFS time was 9.7 months. Ten patients survived for more than 5 years from the start of salvage chemoradiotherapy. Overall survival was significantly longer in the nedaplatin plus S-1 group (median 29.1 months, 95% CI 15.2-66.4) than other chemotherapy group (median 16.7 months, 14.0-24.6; hazard ratio 2.34; p=0.012). Re-recurrence within irradiated field was seen in 26 patients and was significantly correlated with shorter overall survival (hazard ratio 3.12; p<0.01).

**Conclusion**

Salvage chemoradiotherapy using nedaplatin plus S-1 could be a new treatment option for locoregional recurrence after esophagectomy for esophageal squamous cell carcinoma.

**EP-1420 Utility of FIB-4 index for hepatocellular carcinoma patients treated with proton beam therapy**

Y. Sekino<sup>1</sup>, T. Okumura<sup>1</sup>, N. Fukumitsu<sup>2</sup>, T. Iizumi<sup>1</sup>, D. Miyauchi<sup>1</sup>, N. Mizoguchi<sup>1</sup>, K. Murofushi<sup>1</sup>, K. Ohnishi<sup>1</sup>, M. Mizumoto<sup>1</sup>, T. Nonaka<sup>1</sup>, K. Nakai<sup>1</sup>, H. Ishikawa<sup>1</sup>, K. Tsuboi<sup>1</sup>, H. Sakurai<sup>1</sup>

<sup>1</sup>Faculty of Medicine- University of Tsukuba, Radiation Oncology & Proton Medical Research Center, Tsukuba, Japan ; <sup>2</sup>Kobe Proton Center, Radiation Oncology, Kobe, Japan

**Purpose or Objective**

The FIB-4 index is a simple noninvasive index for evaluating hepatic fibrosis which consists of age, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and platelet count (PLT). This index is reported to be a significantly useful noninvasive surrogate marker for prognosis of hepatocellular carcinoma (HCC) patients received hepatectomy. However, the FIB-4 index has not been validated specifically in HCC patients receiving proton beam therapy (PBT). The purpose of this study is to evaluate the prognostic performance of the FIB-4 index for HCC patients treated with PBT.

**Material and Methods**

A total of 55 consecutive HCC patients treated with PBT at the University of Tsukuba between 2001 and 2013 were analyzed. Eligibility criteria included patients with a single lesion, tumor size of ≤5 cm and Child-Pugh (CP) A5. Patients with vascular invasion were excluded. The cutoff

value for the FIB-4 index was determined with the result from a receiver operating characteristic curve analysis. The effect of the FIB-4 index on overall and recurrence-free survival was retrospectively evaluated.

#### Results

Median age was 70 years old (range: 39-87). Median follow-up period was 64 months. Median tumor size was 30 (range: 12-50) mm. The cutoff value for the FIB-4 index was set to 3.5. The median FIB-4 index was 3.45 (range: 1.2-10.4) with 51% at  $\leq 3.5$  (low FIB-4 group) ( $n = 28$ ) and 49% at grade  $> 3.5$  (high FIB-4 group) ( $n = 26$ ). The PFS and OS rates for the entire cohort at 3 and 5 years were 57%, 45% and 85%, 66%, respectively. The PFS rate for the low FIB-4 group at 3 and 5 years were 59% and 50% and for high FIB-4 group 53% and 36%, respectively ( $p=0.259$ ). The OS rate for the low FIB-4 group at 3 and 5 years were 89% and 76% and for high FIB-4 group 80% and 53%, respectively. A statistically significant difference was recognized between the groups ( $p=0.011$ ).

#### Conclusion

The FIB-4 index appears to be a promising predictor of long-term outcomes for HCC patients treated with PBT.

#### EP-1421 Combined chemoembolization and radiotherapy for hepatocellular carcinoma with portal vein thrombosis

K. Treewatthanawong<sup>1</sup>, N. Amornwichee<sup>1</sup>, A. Prayongra<sup>1</sup>, P. Alisanant<sup>1</sup>, C. Khorprasert<sup>1</sup>, K. Shotetersuk<sup>1</sup>

<sup>1</sup>King Chulalongkorn Memorial Hospital, Division of Therapeutic Radiation and Oncology- Department of Radiology, Bangkok, Thailand

#### Purpose or Objective

Patients with hepatocellular carcinoma with portal vein thrombosis have limited choice of therapy due to extensive disease and poor underlying liver function. We conducted a retrospective analysis of patients with hepatocellular carcinoma (HCC) with portal vein thrombosis (PVT) who underwent transarterial chemoembolization (TACE) and radiotherapy (RT) to evaluate the efficacy and toxicity.

#### Material and Methods

In this study, non-metastatic HCC with PVT patients treated with TACE and RT from March 2010 to December 2017 were retrospectively reviewed. Primary outcome was response of PVT. Secondary outcomes included response of tumor, overall survival (OS), acute toxicities and prognostic factors for OS.

#### Results

80 patients were included for analysis. Median patient age was 61.71 years old (50.5-72.92). Mean of the tumor diameter was 7.12 cm (range, 1-20 cm). Fifty-nine (74.7%) patients had main or first branch PVT. Mean radiation dose was 41.35 Gy (range, 8-60 Gy) at 1.8-10 Gy per fraction. For PVT, the response rate was 32.4% and the complete response rate was 5.6%. For primary tumor, the response rate was 50% and the complete response rate was 2%. The median survival was 12 months (10.89-13.11). The 1, 2- and 3-year survival rates were 44.6%, 22.6% and 10%, respectively. On univariate analysis, age, Child-Pugh classification, MELD score, ECOG, serum level of AFP, HBV infection, tumor size, site of PVT and response of PVT were not significant prognostic factors for OS. The BED was insignificant associated with the response of PVT. Grade 3 and 4 hepatotoxicity occurred in 9.2% of patients. There was no treatment-related death.

#### Conclusion

TACE plus RT is a safe and practical treatment option for HCC with PVT. However, further prospective large-scale study is required to evaluate the optimal patient selection, dose/fractionation and prognostic factors related to response and toxicities.

#### EP-1422 Unresectable biliary cancer: results of a pooled analysis of combined CHEMORADIOTHERAPY

Orsola-Malpighi Hospital, Department of Medical and Surgical Sciences - DIMES- University of Bologna, Bologna, Italy ; <sup>3</sup>Sacred Heart Catholic University, Radiation Oncology Department, Rome, Italy ; <sup>4</sup>"Giovanni Paolo II" Foundation- Catholic University of the Sacred Heart, Radiation Oncology Unit, Campobasso, Italy ; <sup>5</sup>"Giovanni Paolo II" Foundation- Catholic University of the Sacred Heart, Medical Oncology Unit, Campobasso, Italy ; <sup>6</sup>"Giovanni Paolo II" Foundation- Catholic University of the Sacred Heart, Medical Physics Unit, Campobasso, Italy ; <sup>7</sup>Gemelli University Hospital- Università Cattolica del Sacro Cuore, Digestive Endoscopic Unit, Rome, Italy

#### Purpose or Objective

To retrospectively evaluate the outcome of a combined modality treatment based on chemoradiation (CRT) +/- brachytherapy (BRT) in a pooled analysis of 3 series from different institutions of patients with unresectable biliary cholangiocarcinoma (CC).

#### Material and Methods

Data of patients with intrahepatic CC (ICC), Klatskin's Tumor (KT), distal extrahepatic CC (ECC), and gallbladder cancer (GBC) diagnosed from 1991 to 2017 were retrospectively analyzed. The treatment was mainly based on concurrent chemotherapy (CT) plus external beam radiotherapy (EBRT), +/- BRT boost. The Kaplan-Meier method was used to calculate survival curves in terms of overall survival (OS). Log-rank test was used to compare survival curves.

#### Results

Seventy-eight patients were included in this analysis (59%: males; 41%: female; median age: 67 years). A minority of patients (7.7%) were treated for disease recurrence after surgery. According to TNM, 77.6% of patients had a T stage  $> 3$  and 79% of patients were treated with CRT while 21% received EBRT followed by sequential CT. Median EBRT dose was 50 Gy (range: 16-75 Gy) delivered with conventional fractionation. CT was based on Gemcitabine or 5-Fluorouracil. BRT was prescribed to 50% of patient with a median dose of 7 Gy. Reported Grade  $\geq 3$  acute GI and hematological toxicity were 13.0% and 7.9%, respectively. No other severe acute toxicities were reported. One- and 2-year OS were 60.1 % and 29.2%, respectively (median: 15 months), while 1- and 2-year PFS were 42.4% and 7.8%, respectively. Analyzing the impact of BRT on OS, 24-month OS was 22.9% for the BRT group, and 36.2% for EBRT alone, while at 48-months, OS was 9.8% for the BRT group, and 0.0% for the group without BRT ( $p = 0.68$ ).

#### Conclusion

Combined modality treatment (CRT + BRT) in unresectable biliary cancer was associated with acceptable toxicity and OS almost comparable to the actual standard (CT). Further prospective studies are needed to improve outcome by using advanced treatment techniques and innovative combined modality therapies.

### Purpose or Objective

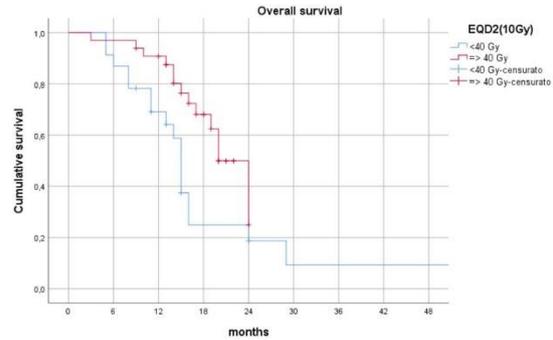

Locally advanced pancreatic cancer (LAPC) presents an intermediate prognosis between resectable and metastatic patients, with a median overall survival (OS) ranging from 9 to 13 months. A standard treatment approach is lacking with large variation between different institutions. We performed a real-life study retrospectively reviewing the experience of 6 different centers treating LAPC with stereotactic body radiotherapy (SBRT).

### Material and Methods

We included 56 pts with LAPC, undergoing SBRT +/- chemotherapy (CT) with multiagent CT regimens. Exclusion criteria were metastatic disease and radical surgical treatment. Only palliative surgery was allowed. Median total dose, median dose/fraction, and median equivalent dose (EQD<sub>2</sub>[ $\alpha/\beta$ ]<sub>10Gy</sub>) for SBRT were 30 Gy (range: 18-45), 6 Gy (range: 4-10), and 40 Gy (range: 23-65) respectively. Toxicity was evaluated by CTCAE version 5.0 scale. Overall survival, local control (LC), and disease metastasis-free survival (DMFS) were estimated and compared by Kaplan-Meier and log-rank methods, respectively.

### Results

We included 56 pts in this analysis (M/F: 31/25; median age: 68, range: 36-89). Median, 6 months, 1-year, and 2-year OS were: 19.0 months, 92.9%, 81.9%, and 27.1%, respectively. Six months, 1-year, and 2-year LC were: 92.5%, 76.3%, and 55.4% (median LC was not reached), respectively. Median, 6 months, 1-year, and 2-year DMFS were: 15.0 months (range 12.0-17.9), 87.3%, 59.5%, and 26.0%, respectively. A better prognosis was recorded in pts treated with both neoadjuvant (median OS: 15.0 vs 24.0 months, p=0.002) and adjuvant CT (median OS: 15.0 vs 29.0 months, p=0.017). Patients treated with a total SBRT dose  $\geq$ 30 Gy (p=0.030), with a fractionation dose  $\geq$  6 Gy (p= 0.014), and with a computed EQD<sub>2</sub>[ $\alpha/\beta$ ]<sub>10Gy</sub>  $\geq$ 40 Gy (p= 0.007) had a better OS. Total dose (p= 0.024) and EQD<sub>2</sub>[ $\alpha/\beta$ ]<sub>10Gy</sub> (p= 0.024) were significantly associated to higher local control. Gastrointestinal (GI) acute toxicity rates were as follows: G1: 24.4%, G2: 2.3%, G3: 0.0%. Only one case of G3 GI late toxicity (2.5%) was recorded.

### Conclusion

SBRT +/- CT resulted tolerable and effective in this "real-life" retrospective analysis. Further prospective studies are needed to define optimal radiation schedules and integration modalities with systemic therapies.

### EP-1424 SBRT vs chemoradiation: a case-control study (PAULA-2)

Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Rome, Italy; <sup>9</sup>Università Campus Biomedico, Department of Radiotherapy, Rome, Italy; <sup>10</sup>Azienda Ospedaliero Universitaria Careggi AOUC- Università di Firenze, Department of Radiotherapy, Firenze, Italy; <sup>11</sup>IRCCS AOU San Martino- IST, Department of Radiotherapy, Genova, Italy; <sup>12</sup>Azienda Ospedaliera San Gerardo, Radiotherapy Unit-, Monza MI, Italy; <sup>13</sup>Fondazione del Piemonte per l'Oncologia FPO- IRCCS Candiolo, Department of Radiotherapy, Torino, Italy; <sup>14</sup>University Hospital, Radiotherapy Unit, Verona, Italy

### Purpose or Objective

Treatment of locally advanced pancreatic cancer (LAPC) is controversial. SBRT is an emerging radiotherapy technique able to achieve high local control rates. We performed a case control study comparing outcome in terms of local control (LC), disease metastases-free survival (DMFS), and overall survival (OS) between two cohorts of patients treated with chemoradiation (CRT) +/- chemotherapy (CT) or SBRT +/- CT.

### Material and Methods

Patients (pts) treated with CRT +/- neoadjuvant CT, +/- adjuvant CT (control group: CG) were matched to pts treated with SBRT +/- neoadjuvant CT, +/- adjuvant CT (case group: SG) based on age ( $\leq$ / $>$  65years), tumor diameter (<3.0 cm; 3.0-3,9 cm; and  $\geq$  4.0 cm), clinical T stage, clinical N stage, neoadjuvant CT, adjuvant CT. Matching was performed without knowledge of outcomes. Median dose in pts treated with SBRT was 30.0 Gy (range: 18.0-35.0) and median dose in pts treated with EBRT was 50.4 Gy (range: 18.0-63.0). Survival curves were assessed

by Kaplan-Meier method and compared using longrank test.

### Results

Ninety-two LAPC patients were enrolled (CG/SG: 46/46 pts; M/F: 52/40; median age: 65.5 years, range: 36.0-89.0, median follow-up: 17.0 months, range: 3.0-70.0). At univariate analysis no significant differences between the two groups were recorded. Results in terms of OS, LC, DMFS are shown in the table.

	Groups	6 months (%)	12 months (%)	24 months (%)	Median (months)	p value
OS	CG	95.5	79.0	47.2	21	.702
	SG	91.5	82.8	33.1	19	
LC	CG	86.3	66.9	59.6	31	.271
	SG	93.2	75.8	53.5	NR*	
DMFS	CG	83.8	64.5	51.2	31	.084
	SG	87.0	53.9	16.9	14	

\*NR: not reached

### Conclusion

This case-control study shows that the two treatment approaches achieved comparable outcomes in patients with LAPC.

### EP-1425 MRI heterogeneity analysis for predicting response to neoadjuvant therapy in oesophageal cancer

K. Owczarczyk<sup>1</sup>, C. Kelly-Morland<sup>1</sup>, C. Yip<sup>2</sup>, M. Siddique<sup>1</sup>, N. Maisey<sup>3</sup>, A. Qureshi<sup>3</sup>, J. Gossage<sup>4</sup>, G. Cook<sup>1</sup>, V. Goh<sup>1</sup>  
<sup>1</sup>King's College London, Department of Cancer Imaging-Division of Imaging Sciences and Biomedical Engineering, London, United Kingdom ; <sup>2</sup>National Cancer Centre Singapore, Department of Oncology, Singapore, Singapore ; <sup>3</sup>Guy's and St.Thomas' Hospital NHS Foundation Trust, Department of Oncology, London, United Kingdom ; <sup>4</sup>Guy's and St.Thomas' Hospital NHS Foundation Trust, Department of Upper GI Surgery, London, United Kingdom

### Purpose or Objective

Response to neoadjuvant treatment has been shown to be a major predeterminant of survival in oesophageal cancer. The ability to predict response prior to oesophagectomy would allow for adaptive treatment approaches with potentially improved outcomes. We hypothesized that heterogeneity analysis of MRI may be predictive of response to neoadjuvant treatment.

### Material and Methods

Prospective IRB approved study of patients with oesophageal cancer undergoing neoadjuvant chemotherapy or chemoradiotherapy (CRT) followed by oesophagectomy. Three MRI scans including a 3D T2w ECG and respiratory-triggered sequence as well as Diffusion Weighted Imaging (DWI) sequence (b=0,100, 900) were carried out at baseline (T0), following first cycle of chemotherapy (or 10# of CRT, T1) and prior to surgery (T2).

VOIs were outlined in 3D on T2w sequences & ADC parametric maps, generating 6 VOIs per case (T2w and DWI at each timepoint). Heterogeneity analysis was carried out using in-house software. Highly correlated features ( $p > 0.8$ ) were excluded. Seven imaging features were analysed per case - Mean Intensity, Intensity SD, Intensity CoV, Entropy (Ent), Kurtosis (Kurt), Mean Fractal Lacunarity (MFL) and VOI volume (cm<sup>3</sup>). Primary outcome was Mandard tumour regression grade in the resected specimen (good response TRG1-2 (<10% residual tumour cells) vs no response TRG4-5 (>50%)).

Predictive value of imaging features was assessed in univariate analysis using false discovery rate (FDR) corrected cut-off of  $p < 0.05$  (Benjamini Hochberg correction for multiple testing). Huber method was used to minimise risk of model overfitting. Wilcoxon non-parametric test was used to compare values between subgroups. Selected features were assessed in a clinico-

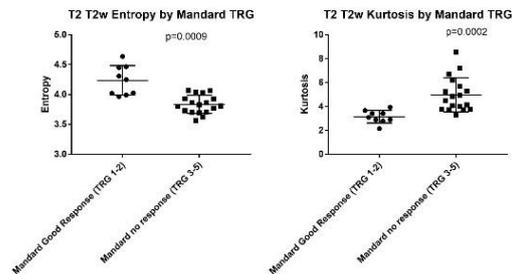

pathological multivariate model using Cox proportional hazard ratio.

### Results

Out of 41 patients recruited, 33 underwent surgery (27/33 male, median age 65±11, 30 adeno/ 3 SCC, 30 NACT/ 3CRT). 12/33 were good responders, 14/33 showed no response.

In univariate analysis, T2 T2w Kurt and T2 T2w Ent were predictive of good response (FDR  $p = 0.0001$  and  $0.0002$ , respectively), whilst T2 T2w MFL, T2 T2w Ent and T2 volume were predictive of no response (FDR  $p = 0.03$ ,  $0.04$ ,  $0.04$ , respectively). None of the DWI derived features met the predefined FDR cut-off.

T2 T2w Kurt was significantly lower whilst T2 T2w Ent was significantly higher in good responders ( $p = 0.0002$ ,  $0.0009$ , respectively). Spearman  $\rho$  between linear Mandard TRG and T2 T2w Kurt and Ent was  $0.55$  ( $p = 0.002$ ) and  $-0.62$  ( $p = 0.0005$ ), respectively. Dichotomised T2 T2w Kurt (>median vs  $\leq$  median) remained significantly predictive of good response in multivariate model including age, gender, cT (cT2 vs cT3-4), cN (cN0 vs cN+) and histopathology (SCC vs adeno) with an OR  $0.04$  ( $0.001-0.48$ ,  $p = 0.008$ )

### Conclusion

This prospective data shows that heterogeneity analysis has a role in predicting pathological response to treatment in oesophageal cancer and warrants investigation in a larger patient cohort.

### EP-1426 Postoperative Radiotherapy In Pancreatic Cancer Patients. A Single Institution Experience

M. Caroprese<sup>1</sup>, M. Tirozzi<sup>1</sup>, G. Porri<sup>1</sup>, I.R. Scognamiglio<sup>1</sup>, E. Toska<sup>1</sup>, L. Faraci<sup>1</sup>, A. Perillo<sup>1</sup>, F. Pati<sup>1</sup>, A. Farella<sup>1</sup>, R. Solla<sup>2</sup>, S. Clemente<sup>1</sup>, M. Consoni<sup>1</sup>, R. Pacelli<sup>1</sup>

<sup>1</sup>University "Federico II" School of Medicine, Department of Advanced Biomedical Sciences, Napoli, Italy ;

<sup>2</sup>National Research Council, Institute of Biostructures and Bioimages, Napoli, Italy

### Purpose or Objective

Pancreatic cancer is the fourth leading cause of cancer-related deaths worldwide. At present, the only chance for cure and prolonged survival is surgical resection with macroscopic tumor clearance. Even following potential curative resection more than 80% of the patients ultimately die of the disease due to local recurrence and/or distant metastasis. The high rate of local recurrence is predetermined by the microscopic frequently incomplete resections as a result of the anatomical location of the tumor and the growth pattern of pancreatic cancer cells. According to the Royal College of Pathologists (RCP), positive surgical margin status is defined as the microscopic presence of tumor cells within 1 mm of the resection margin. The aim of this study was to determine the impact of margin status on disease free survival (DFS) and overall survival (OS) in patients undergoing adjuvant radiotherapy.

### Material and Methods

Thirty-two consecutive patients treated by radiotherapy for M0 pancreatic adenocarcinoma at the Radiotherapy Department of the University "Federico II" (Naples, Italia)

between November 2011 and April 2018 were enrolled. Radiation treatment was delivered after surgery with or without neoadjuvant chemotherapy with doses ranging between 45 and 56Gy, concurrently with radiosensitizing chemotherapy. Clinical and pathological characteristics of all patients are reported in Table 1. Prognostic impact of surgical margin status were estimated by the Kaplan-Meier method. Log-rank test was used to compare survival between groups.

	PSM (n=11)	NSM (n=21)	p value	Overall (n=32)
Age	66 (48-78)	62 (51-74)	0.184	63 (48-78)

Table 1 Clinical and pathological characteristics of all patients. PSM= positive surgical margins, NSM=negative surgical margins

## Results

Of 32 total patients, 11 (34.4%) had positive surgical margin (PSM) status and 21 (65.6%) negative surgical margin (NSM) status. The median follow-up period was 28.5 (IQR: 17.25-35.75) months; of the 20 (62.5%) observed deaths, all of these were directly tumor-related. Only six patients (18.8%) resulted free of recurrent disease. First recurrence was loco-regional for 9 patients (29.0%) and distant for 10 (32.3%) patients; 7 patients (22.6%) presented both. Median DFS among the PSM and NSM groups was 11 versus 13 months, respectively ( $P=.965$ ); no differences in OS were also seen between the two groups ( $P=.550$ ). The results are reported in Figure 1.

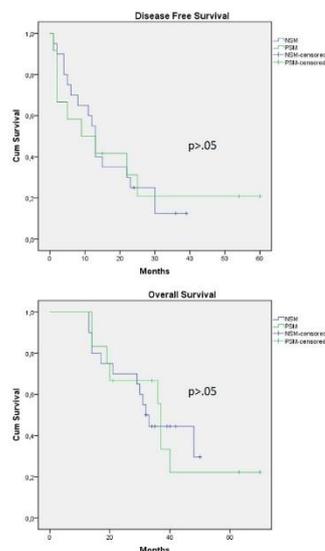

Figure1 Disease free survival (DFS) and Overall survival (OS). PSM= positive surgical margins, NSM=negative surgical margins.

## Conclusion

Although a positive surgical margin status may be suggestive of high local recurrence rate, in our small series of patients affected by locally advanced pancreatic cancer treated with adjuvant chemo-radiotherapy there were no DFS or OS difference between PSM and NSM groups.

## EP-1427 Prognostic role of neutrophil-to-lymphocytes ratio in pancreatic cancer

M. Caroprese<sup>1</sup>, I.R. Scognamiglio<sup>1</sup>, M. Tirozzi<sup>1</sup>, F. Piccolo<sup>1</sup>, E. Scipilliti<sup>1</sup>, A. Roscigno<sup>1</sup>, J. De Robbio<sup>1</sup>, M.V. Agbaje Olufemi<sup>1</sup>, M. Sorrentino<sup>1</sup>, A. Farella<sup>1</sup>, C. Oliviero<sup>1</sup>, M. Conson<sup>1</sup>, R. Pacelli<sup>1</sup>  
<sup>1</sup>University "Federico II" School of Medicine, Department of Advanced Biomedical Sciences, Napoli, Italy

## Purpose or Objective

Pancreatic cancer is one of the most aggressive malignancy with dismal 1- and 5-year survival rates of 21% and 3% respectively. Although a high neutrophil-to-lymphocyte ratio (NLR) has been reported to be a predictor of poor survival in patients with pancreatic cancers, its prognostic role in patients with locally advanced pancreatic cancer undergoing radiotherapy remains unclear. The aim of the present study was to determine the prognostic role of NLR in patients with locally advanced pancreatic cancer undergoing radiotherapy.

## Material and Methods

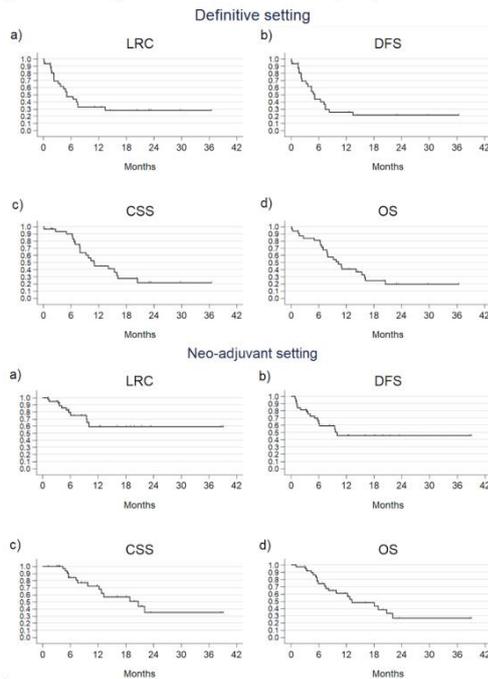

Fifty-three consecutive patients treated by radiotherapy for M0 pancreatic adenocarcinoma at the Radiotherapy Department of the University "Federico II" (Naples, Italia) between January 2011 and April 2018 were enrolled. Radiation treatment was delivered with a dose range between 45 and 56Gy, after a neoadjuvant chemotherapy or after neoadjuvant chemotherapy and surgery, concurrently with radiosensitizing chemotherapy. Two different contexts were defined with regard to target extension, namely tumor site only (T) irradiation, tumor site + prophylactic regional nodes irradiation (T+N). Univariate and multivariate analyses were performed to identify clinicopathological predictors of disease free survival and overall survival, including pre-radiotherapy NLR. NLR was defined as the absolute neutrophil count divided by absolute lymphocyte count. A low-NLR was defined as  $NLR < 1.2$  and a high-NLR was defined as  $NLR \geq 1.20$ .

## Results

Clinical and pathological characteristics of all patients are reported in Table 1. Median follow-up was 18 months. 47

Figure 1. Oncological results for definitive and pre-operative treatments

In DE cohort, 1-year LC (local control) and LRC (local-regional control) were 45.5% (SD:9.7;95%CI:26.3-62.9) and 32.58% (SD:8.9;95%CI:16.5-50.1). One-year DFS (disease-free survival), CSS (cancer-specific survival) and OS (overall survival) were 25.5% (SD:8.3;95%CI:11.3-42.4), 45.1% (SD:9.6;95%CI:26.1-62.4) and 40.6% (SD:8.9;95%CI:23.3-57.3), respectively. For patients who underwent a trimodality strategy, 1-year LC and LRC were 77.6% (SD:8.6;95%CI:55.2-89.8) and 59.4% (SD:10.1;95%CI:37.2-76.0), respectively. Finally, 1-year DFS, CSS and OS were 45.5% (SD:9.5;95%CI:26.5-62.7), 72.3% (SD:8.5;95%CI:51.7-85.3) and 60.7% (SD:8.6;95%CI:41.8-75.2).

#### Conclusion

Our retrospective clinical and dosimetric data show the feasibility of VMAT in the DE and PO treatment of oesophageal cancer patients for both SCC and adenocarcinoma histology, with a mild toxicity profile and robust dosimetric results for both target coverage and sparing of organs at risk.

#### EP-1429 IG-IMRT improves short-term survival for lymph node metastases from hepatocellular carcinoma

Z. Haige<sup>1,2</sup>, S. Jing<sup>1</sup>, C. Yixing<sup>1</sup>, Z. Zhaochong<sup>1</sup>  
<sup>1</sup>Zhongshan Hospital- Fudan University, Department of Radiation Oncology, Shanghai, China ; <sup>2</sup>Luoyang Central Hospital, Department of Radiation Oncology, Luoyang, China

#### Purpose or Objective

To evaluate the responses and toxicities in hepatocellular carcinoma (HCC) patients with abdominal lymph node metastasis (LNM) treated with either Image-guided Intensity-modulated radiotherapy (IG-IMRT) or non-IG-IMRT.

#### Material and Methods

We retrospectively reviewed 85 HCC patients with regional LNM treated with IG-IMRT or non-IG-IMRT (including IMRT and 3D-CRT) according to patients' intention at our institution between 2011 and 2016. They were identified as HCC by clinical diagnosis with LNM appeared synchronously or metachronously at the confirmation of HCC. The radiation dose to GTV arranged 44.3 to 75.9 Gy, which was limited by Organ At Risk (mainly limited by gastrointestinal tract). The tumor

responses, local control rate, overall survival and toxicities were evaluated.

#### Results

Mean dose of biological effective dose (BED) with  $\alpha/\beta = 10$  Gy delivered by IG-IMRT group was  $67.23 \pm 8.48$  Gy vs.  $63.43 \pm 5.01$  Gy ( $p = 0.008$ ) by non-IGRT group. The objective response rates (ORR) of IG-IMRT vs. non-IGRT was 95.3% vs. 80.9% ( $P = 0.085$ ). The actuarial local control rate of IG-IMRT vs. non-IGRT was 74% vs. 52.3% at one-year, and 69% vs. 47% at two-year. ( $p = 0.019$ ), which showed the advantage of IG-IMRT. Longer median overall survival was found in IG-IMRT group (15.3 months) than that in non-IGRT group (9.7 months), ( $p = 0.098$ ). One-year overall survival of IG-IMRT vs. non-IGRT was 69% vs. 38.1%, ( $P = 0.006$ ). However, two-year overall survival of them was 19.3% vs. 14.5% ( $p = 0.066$ ) with p-value was 0.098 which indicated no superiority of long-term survival of IG-IMRT. Number of lymph node  $\geq 2$ , previous treatment without surgery were negative independent prognostic factors, while  $BED_{10} \geq 65$  Gy was a protective factor. Toxicities were mild for both groups while IG-IMRT showed less late hepatic toxicity.

#### Conclusion

Dose delivered by IG-IMRT is slightly higher which appears to be more effective and shows a superiority of short-term survival and local control rate in HCC patients with LNM.

#### EP-1430 Can SBRT improve the prognosis of unresectable pancreatic cancer? Clinical results on 106 patients

T. Comito<sup>1</sup>, C. Franzese<sup>1</sup>, E. Clerici<sup>1</sup>, P. Navarria<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, S. Carrara<sup>2</sup>, L. Rimassa<sup>3</sup>, S. Tomatis<sup>1</sup>, A. Zerbi<sup>4</sup>, M. Scorsetti<sup>1</sup>

<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy ; <sup>2</sup>Humanitas Research Hospital, Gastroenterology, Rozzano Milan, Italy ; <sup>3</sup>Humanitas Research Hospital, Oncology, Rozzano Milan, Italy ; <sup>4</sup>Humanitas Research Hospital, Pancreatic Surgery, Rozzano Milan, Italy

#### Purpose or Objective

Pancreatic cancer is characterized by a poor prognosis. Surgery is the gold standard of care, however more than 50% of patients are unresectable at the time of diagnosis. In patients with locally advanced pancreatic cancer (LAPC), the integration of chemotherapy (CT) and chemo-radiation treatment (CRT) is the current therapeutic option, associated with a significant toxicity rate and with a disappointing overall survival (OS). In the last years, the role of stereotactic body radiotherapy (SBRT) in the treatment of LAPC was investigated. Higher local control related to the high doses employed, short overall treatment time and sequential integration with systemic therapy, represent the crucial advantages of SBRT over conventional CRT. Objective of this study is to assess the efficacy of SBRT in patients with inoperable LAPC.

#### Material and Methods

Patients with unresectable LAPC with maximum tumor diameter  $\leq 5$ cm, without lymph node disease and without distant metastasis were treated with SBRT, after multidisciplinary board evaluation. Prescription dose was 45Gy in 6 fractions. Primary end-point was freedom from local progression (FFLP). Secondary end-points were overall survival (OS), progression-free survival (PFS) and toxicity. Local control (LC) was defined according to RECIST v1.1 criteria. Acute and late toxicity was scored according to the NCI Common Terminology Criteria for Adverse Events (CTCAE) v3.0.

#### Results

Between January 2011 and December 2017, 106 patients (49 male-57 female) with LAPC were treated with SBRT at Humanitas cancer Center. Median age was 68.5 years (range 41-88 years). 58 patients (55%) received CT before SBRT, for a median time of 5 months (range 3 - 10

months). Median follow-up was 86 months (range 2-88 months). FFLP was 83% and 67% at 1 and 2 years, respectively. At univariate ( $p < 0.03$ ) and multivariate analysis ( $p < 0.001$ ), lesion size was significant for LC. Median PFS was 11 months. Median OS from diagnosis was 17 month. CT administered before SBRT ( $p < 0.005$ ) and FFLP ( $p < 0.002$ ) were significantly correlated with OS. Grade 3 gastrointestinal toxicity was detected in 2% of patients.

#### Conclusion

SBRT is an effective and safe local therapy for selected patients with LAPC. Our results suggest that the stereotactic treatment may be a promising therapeutic option in the multi-modality treatment of these patients

#### EP-1431 Impaired health in long term survivors of esophageal cancer after neo-adjuvant chemoradiotherapy?

C. De Groot<sup>1</sup>, K. Muijs<sup>1</sup>, J. Plukker<sup>2</sup>, P. Van Luijk<sup>1</sup>, H. Langendijk<sup>1</sup>, J. Beukema<sup>1</sup>

<sup>1</sup>UMCG, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>UMCG, Surgical Oncology, Groningen, The Netherlands

#### Purpose or Objective

Due to the clinical introduction of neo-adjuvant chemoradiotherapy (nCRT) prior to surgery, the number of long-term survivors of esophageal cancer (EC) is rising. Therefore, treatment-related toxicity, in particular cardiopulmonary toxicity, becomes increasingly important. The primary objective of this cross-sectional pilot study was to identify (subclinical) cardiopulmonary dysfunction in EC patients after nCRT followed by surgical resection as compared to surgery alone.

#### Material and Methods

EC survivors who were 5-15 years after curative resection with (n = 20) or without (n = 20) nCRT were enrolled. All patients underwent the following examinations; anamnesis (incl ACE-27), physical examination, quality of life (QoL) questionnaires, blood tests and a 6-minute walking test.

#### Results

Patient characteristics at baseline and at the time of the cross-sectional measurements are listed in *table 1*. Using the EORTC -C30, a trend towards impaired role functioning in the nCRT group was observed (89 v 95,  $p = 0.13$ ). Additionally, fatigue was more common after nCRT (14.9 v 9.2;  $p = 0.13$ ). Other domains, symptom scales and global QoL were similar in both groups. The 6-minute walking test showed reduced exercise tolerance in the nCRT group. In this group, 11 (55%) patients had poor scores (<80% of predicted; corrected for age, gender and BMI) compared to 5 (25%) in the surgery alone group ( $p = 0.07$ ). ACE-27 scores increased over time in both groups. Although statistically significance was not reached in this small cohort ( $p = 0.11$ ), the increase in ACE score was more pronounced in the nCRT group ( $\Delta$ ACE = 0.75) compared to those treated with surgery only ( $\Delta$ ACE = 0.30). Moreover, patients in the nCRT group were younger and had shorter (follow up) time to develop toxicity/comorbidity (average FU time: 88 v 126 months). Similar results were found for the cardiovascular subscale of the ACE-27, which showed again a marked increase after nCRT ( $\Delta$ ACE=0.80 v 0.35;  $p = 0.10$ ). This was in particular due to a higher incidence of de novo atrial fibrillation after nCRT (CTCAE v4.0  $\geq$  grade 2: 5 v 1 new cases,  $p = 0.08$ ).

Relatively high serum NT-proBNP levels were found in both groups (*table 1*). After excluding patients with known cardiovascular disease from the analysis, average NT-proBNP levels in the surgery alone group decreased to normal (115 ng/L) whereas levels in the nCRT group remained elevated (271 ng/L;  $p = 0.06$ ). Troponin-T levels are similar in both groups and all in the normal range.

Table 1: Patient characteristics

	Surgery (n = 20)	nCRT (n = 20)	
<b>General characteristics</b>			
<b>Sex</b>			P = 0.26
- Male	17 (85%)	14 (70%)

<b>NT-ProBNP</b>	214.8 (SD 406.1)	267.0 (SD 305.4)	P = 0.66
<b>NT-proBNP excl CVD<sup>3</sup></b>	115.2 (SD 75.9)	270.8 (SD 313.8)	P = 0.06
<b>Troponin T</b>	13.9 (SD 8.6)	10.6 (SD 4.6)	P = 0.13

Abbreviations: AC = Adenocarcinoma; SCC = squamous cell carcinoma.

<sup>1</sup>Adult Comorbidity Evaluation Questionnaire. Scoring: 1=mild, 2=moderate, 3=severe.

<sup>2</sup>Sub score on cardiovascular disease section ACE-27.

<sup>3</sup>After exclusion of patients with known cardiac disease. Surgery n=15, nCRT n=18.

#### Conclusion

Despite younger age and shorter follow up, patients treated with neo-CRT showed more increase in (cardiac) comorbidity scores compared to patients who underwent surgery alone. In addition, their exercise tolerance seems to be worse as well. The results of this pilot study emphasizes the need for further research in larger cohorts of patients.

#### EP-1432 Re-irradiation of abdominal malignancies: toxicity, cumulative dose and outcome

L. Caravatta<sup>1</sup>, F. Fiorica<sup>2</sup>, F. Dionisi<sup>3</sup>, C. Rosa<sup>1</sup>, L. Boldrini<sup>4</sup>, M. Lupattelli<sup>5</sup>, D. Genovesi<sup>1</sup>, M. Massaccesi<sup>6</sup>  
<sup>1</sup>"SS Annunziata" Hospital- "G. D'Annunzio" University, Radiation Oncology Unit, Chieti, Italy ; <sup>2</sup>University Hospital Ferrara, Department of Radiation Oncology, Ferrara, Italy ; <sup>3</sup>Azienda Provinciale per i Servizi Sanitari- APSS, Proton Therapy Unit- Department of Oncology-, Trento, Italy ; <sup>4</sup>Fondazione Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Radiology Department, Rome, Italy ; <sup>5</sup>University of Perugia and Perugia General Hospital, Radiation Oncology Section, Perugia, Italy ; <sup>6</sup>Fondazione Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Radiological- Radiotherapy and Hematology Sciences, Rome, Italy

#### Purpose or Objective

A systematic review about abdominal re-irradiation (Re-I) was performed, on behalf of the Association of Radiation Oncology (AIRO) study group for the re-irradiation, aiming to explore the toxicity, cumulative dose and outcome.

#### Material and Methods

A computerized search of the literature was performed by MEDLINE, EMBASE, OVID, and Cochrane database. The computer search was supplemented with hand searches of reference lists. Only studies analyzing reporting toxicity and/or safety as outcomes of patients re-treated where Re-I involved overlap with previous radiotherapy (RT) were taken into consideration. Retrospective and prospective studies with at least 10 patients were

included. To improve the comparability of the different Re-I regimens and to assess the relationship between RT dose and toxicity, when not reported in the study, equivalent dose in 2 Gy fractions was calculated according to the linear-quadratic model.

### Results

Nine studies met the inclusion criteria, published between 2002 and 2017. Only 2 were prospective trials. Overall, 203 patients were definitely re-irradiated within the abdomen. Patients presented recurrence of pancreatic (100 patients), liver (38 patients) and gastro-esophageal (14 patients) cancer. Median follow-up from Re-I ranged from 5.9 to 28 months. Previous RT was delivered with a median dose of 50.4 Gy (45 to 74.5 Gy) using conventional fractionation; in 1 study a stereotactic RT (SBRT) boost was delivered after conventional external beam RT. The mean time relapsed since previous RT ranged from 2 to 32 months (median time=18 months). Technique used for Re-I were SBRT (5 studies), intensity modulated RT (1 study), <sup>125</sup>I seed interstitial brachytherapy (1 study) and proton therapy (2 studies). Re-I prescription doses were variable (22.5 Gy in 3 fractions to 126,5 Gy with brachytherapy with <sup>125</sup>I). Regarding to toxicities, 29 episodes of G3 toxicity were reported: 15 episodes were acute (transient RILD, abdominal pain and bleeding, anorexia and fatigue), whereas 14 were late (RILD, bowel obstruction, gastric perforation). Relationship between cumulative dose and toxicities rate ( $\geq$ G3) is reported in Table 1. The 1-year overall survival rate was reported in 8 studies and resulted as 48.2% (95%CI:38.1-61%). The 1-year local recurrence free survival rate obtained from 7 studies was 70.7% (95% CI: 62.8-79.7%). Improvements in pain was evaluated in 5 studies, with 72.8% of patients experiencing pain relief.

Table 1: Relationship between cumulative dose for acute responding and for late responding tissue according to the linear-quadratic model and toxicities rate

Author et al.	Previous RT	EQD2 acute tissue and tumor (Gy)	EQD2 late tissue (Gy)	Cumulative acute dose (Gy)	Cumulative late dose (Gy)	Acute toxicities $\geq$ G3	Late toxicities $\geq$ G3
Daghighi et al. 2016	Previous RT	49.56 and 56 (SBRT)	48.38 and 52.8 (SBRT)	67.25(*) and 80.81	88.38 and 92.8 (*)	11% (3/27)	7% (2/27*)
	Re-I	31.25	40				
Haque et al. 2009	Previous RT	34.5 median dose	40.85 median dose	67.54	71.9	8% (1/13)	8% (the same pt)
	Re-I	33.04 median dose	31.05 median dose				
Huang et al. 2016	Previous RT	49.5 (no tox) and 52.5 (tox)	20.8 (no tox) and 20.1 (tox)	82.4 (no tox) and 95.1 (tox)	33.1 (no tox) and 50.3 (tox)	9.2% (4/36)	25% (9/36)
	Re-I	33.9 (no tox) and 40.6 (tox)	12.3 (no tox) and 10.2 (tox)				
Kooget al. 2017	Previous RT	49.56	48.38	80.81 and 129.48 (RS)	88.38 and 188.38 (RS)	8.7% (2/23)	-
	Re-I	31.25 and 79.92 (RS)	40 and 140 (RS)				
Yao et al. 2015	Previous RT	50.1	50.5	123.1	84.5	0	0
	Re-I	73	34				
Lomnicka et al. 2012	Previous RT	49.56	48.38	81.44	93.38	0	7.1% (2/28)
	Re-I	33.88	45				
Abuazam et al. 2012	Previous RT	48	48	156	138	0	0
	Re-I	88	90				
Boisard et al. 2017	Previous RT	49.56	48.38	108.96	107.78	20% (3/15)	0
	Re-I	59.4	59.4				
Fernandez et al. 2016	Previous RT	54	54	109.8	109.8	13% (2/14)	0
	Re-I	54	54				

RT: radiotherapy; Re-I: re-irradiation; EQD2: equivalent dose in 2 Gy fractions; SBRT: stereotactic radiation therapy; RS: radiosurgery; pt: patient \*previous SBRT

### Conclusion

Few studies, most of them retrospective, are actually available in the literature able to reach our requisites. Based on the results of our analysis, abdominal re-irradiation seems to be safe feasible in terms of severe toxicities with good local control and symptoms palliation. Prospective studies or large data collections seem to be necessary to define patients selection criteria to ensure maximal benefit of Re-I treatment approach.

### EP-1433 GTV contouring in hepatocellular carcinoma: a comparison between two imaging techniques

C. De la Pinta Alonso<sup>1</sup>, J.D. García<sup>2</sup>, D. Sevillano<sup>2</sup>, R. García<sup>3</sup>, M. Martín Martín<sup>1</sup>, M. Martín Sánchez<sup>1</sup>, T. Muñoz<sup>1</sup>, E. Fernández-Lizarbe<sup>1</sup>, R. Hernández<sup>1</sup>, J.A. Domínguez<sup>1</sup>, C. Vallejo<sup>1</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Ramon y Cajal, Medical Physics, Madrid, Spain ; <sup>3</sup>Hospital Ramon y Cajal, Radiology Department, Madrid, Spain

### Purpose or Objective

Definition of gross tumor volume (GTV) in hepatocellular carcinoma (HCC) requires dedicated imaging in multiple contrast medium phases. MRI has an important role in

evaluation of HCC. The aim of this study was to evaluate the interobserver agreement in GTV of HCC in a multicenter panel and compare MRI and CT in GTV delineation.

### Material and Methods

After the institutional review boards approved the study we analyzed anonymous, multiphase-planning CT, and MRI obtained from five patients with HCC. Eight radiation oncologist in our center using CT and MRI to delineate GTVs of hepatocellular carcinomas. Liver locations were segments II, IV, V, VI and VIII. The cases show different difficulty: low acquisition contrast, previously treated with transarterial-chemoembolization, arterial thrombosis, or inhomogeneous liver parenchyma due to cirrhosis. In both CT and MRI, the GTV volumes and distance between the centers of mass (dCOM) were compared. The index of agreement was evaluated according to Landis and Koch.

### Results

The GTV volume as defined on CT was in all cases larger or at least as large as the GTV volume on PET. The median GTV volume on MRI was 2 mL (0,4-85,6 mL), compared to 3,55mL on CT (0,2-64 mL) (p=0.09). Variance between observers in CT was minor than MRI (259,3 vs 332,4). The index of agreement was low (0,029) between CT and MRI in all patients.

### Conclusion

In cases with well-defined tumor CT is more easy and reproducible. In cases with no defined tumor in CT we need other tools as MRI. The interobserver variability in target delineation of HCC in this study was noteworthy.

### EP-1434 Neoadjuvant chemoradiotherapy in patients with esophageal or esophageal gastric junction cancer

<sup>1</sup>San Raffaele Scientific Institute- Milano- Italy, Radiation Oncology, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute- Milano- Italy, Surgery, Milan, Italy ; <sup>3</sup>San Raffaele Scientific Institute- Milano- Italy, Clinical Oncology, Milan, Italy ; <sup>4</sup>San Raffaele Scientific Institute- Milano- Italy, Pathological Anatomy, Milan, Italy ; <sup>5</sup>San Raffaele Scientific Institute- Milano- Italy, Nuclear Medicine, Milan, Italy ; <sup>6</sup>San Raffaele Scientific Institute- Milano- Italy, Radiation Oncology, Milano, Italy

### Purpose or Objective

to report our experience in patients (pts) with esophageal (EC) or esophageal gastric junction (EGJ) cancer treated with neoadjuvant chemoradiotherapy IG-IMRT PET based.

### Material and Methods

from April 2014 to April 2018, 56 pts (m: 43, f: 13), with histologically proven EC or EGJ were treated according to CROSS study. Median age at diagnosis: 56 years (28-80), median KPS: 90 (80-100). Twenty-eight pts had adenocarcinoma (50%), 27 pts had squamous cell carcinoma (48.2%), 1 pt had adeno-squamous carcinoma (1.7%). All pts underwent c-e CT and PET simulation, repeated for restaging. Radiotherapy (RT) consisted in 41.4 Gy in 23 fractions combined to chemotherapy (ChT) with carboplatin and paclitaxel.

### Results

clinical stage was: T1: 1pt (2%), T2: 14 pts (25%), T3: 38 pts (68%), T4: 3 pts (5%), N0: 11 pts (20%), N+: 45 pts (80%). The site of tumor was proximal/middle third in 4 pts (8%), middle/middle-distal third in 34 pts (60%), distal third/distal-EGJ/ EGJ in 18 pts (32%). Median tumor length was 4 cm (0.8-15 cm). RT was delivered by Tomotherapy in 37 pts (66%) and by VMAT in 19 pts (34%). All pts completed RT. Median cycles of ChT was 5 (2-6 cycles), 70% pts received a full dose of ChT. G3 acute haemathological toxicity was: neutropenia in 3.5 % (2pts), lymphopenia in 67.8% (38 pts), anemia in 1.7% (1pt). G3

gastrointestinal toxicity occurred in 14.2% (8 pts). Three pts (5.3%) had bacterial pneumonia (1 pt G5). Responses: 55/56 pts were available (1 pt early lost). Median time to restaging was 42 days (14-87 d). CT/PET showed local RP in 27 pts, SD 9 pts, RC 18 pts, PD in 1pt. Median time from CT/RT to surgery was 61 days (15-148). Forty-three pts (75%) underwent surgery, 13 excluded (7 for PD, 3 for worsening clinical condition, 1 died, 1 lost, 1 pt had cCR). One pt underwent urgent surgery 15 days after CT/RT because of aorto-esophageal fistula. Post-surgery stage was T0: 7pts (16%), T1: 9 pts (22%), T2: 12 pts (28%), T3: 14 pts (32%), T4: 1 pt (2%); N0: 25 pts (58%), N+: 18 pts (42%). Forty-one/ 43 pts (95.3%) had R0. Mandard TRG was: TRG1: 7 pts (16.5%), TRG2: 8 pts (18.5%), TRG3: 22 pts (51%), TRG4: 6 pts (14%). At a median follow up of 17.4 months (4.1-49.4 m): 25/43 pts (58%) are free from disease, and 18/43 pts (42%) had a progression disease (2 of them had a local relapse concomitant to distant progression). Median time to progression was 20 months (1.5-96.9 m). Median OS of all pts was 17.4 months (3-49.4 m).

#### Conclusion

Our data seems to be comparable to CROSS data in term of R0 and toxicity profile. In patients treated with IG-IMRT and chemotherapy, lymphopenia was the major cause of not optimal tolerability of treatment and could explain the onset of pneumonia and the difference between TRG responses.

#### EP-1435 Impact of diabetes on outcome and toxicity of chemoradiation for esophageal squamous cell carcinoma

D. Bierbaumer<sup>1</sup>, S. Muench<sup>1</sup>, B. Haller<sup>2</sup>, D. Habermehl<sup>1</sup>, P.T. Pfluger<sup>3</sup>, K. Stemmer<sup>3</sup>, S.E. Combs<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- Technical University Munich- Ismaninger Str. 22, Department of Radiation Oncology, 81675 Munich, Germany ; <sup>2</sup>Klinikum rechts der Isar- Technical University Munich- Grillparzerstr. 18, Institute of Medical Informatics- Statistics and Epidemiology- Medical School, 81675 Munich, Germany ; <sup>3</sup>Helmholtz Zentrum München- Ingolstädter Landstraße 1, Insitue for Diabetes and Obesity, 85764 Neuherberg, Germany

#### Purpose or Objective

For patients with locally advanced squamous cell carcinoma of the esophagus (SCC), international guidelines recommend neoadjuvant chemoradiation (nCRT) with subsequent surgery or definite chemoradiation (dCRT) for patients unsuitable for surgery. Until now, there are conflicting data regarding the impact of diabetes on the effectiveness and toxicity of chemoradiation in these patients. Aim of this study was to compare oncologic outcome and toxicity between patients with and without diabetes mellitus type 2 (DTM2) undergoing nCRT or dCRT for locally advanced SCC.

#### Material and Methods

In total, 108 patients with locally advanced SCC were included in this analysis. Within this cohort, we identified 25 patients with DMT2 with a median haemoglobin A1c (HbA1c) of 6.7%. Baseline and tumor characteristics, oncologic outcome and toxicity of these patients were compared to 83 patients without diabetes. For the analysis of toxicity, patients were stratified by therapy.

#### Results

Patients with DTM2 were had a significantly higher body mass index (BMI) than patients without DTM2 (median BMI 27.2 vs. 22.7 Kg/m<sup>2</sup>, p=0.001). However, no further differences regarding baseline and tumor characteristics were seen between both patient groups. In addition, there was no significant difference in terms of progression-free survival (median PFS 14.0 months (DTM2) vs 13.9 months (no DTM2), p=0.147). Concerning OS, there was a trend towards an increased OS in patients without DTM2 (median OS 23.3 months (DTM2) vs. 25.6 months (no DTM2), p=0.095). However, within a multivariable Cox regression

model, diabetes did not independently affect OS. After nCRT and surgery 25% (no DTM2) and 38% (DTM2) of patients had a pathologic complete tumor response (p=0.721). When stratifying patients by therapy, higher rates of anemia were seen in patients with DTM2 after nCRT (≥II° 60% vs. 34%, p=0.0001). However, this difference was not confirmed in patients undergoing nCRT. In addition, no significant differences were seen for the rates of leukopenia and thrombocytopenia between both groups.

#### Conclusion

While there was a small trend towards an increased OS in patients without DTM2, DTM2 did not affect PFS or histopathologic tumor response in patients undergoing neoadjuvant or definite chemoradiation for esophageal squamous cell carcinoma. However, higher rates of anemia were seen in diabetic patients undergoing nCRT.

#### EP-1436 SBRT for large hepatocellular cancer unsuitable for other therapies: Results from a clinical audit

<sup>1</sup>Tata Memorial Hospital, Radiation Oncology, Mumbai, India ; <sup>2</sup>Tata Memorial Hospital, Radiation Physics, Mumbai, India ; <sup>3</sup>Tata Memorial Hospital, Surgical Oncology, Mumbai, India ; <sup>4</sup>Tata Memorial Hospital, Gastroenterology- Department of digestive diseases and clinical nutrition, Mumbai, India ; <sup>5</sup>Tata Memorial Hospital, Medical Oncology, Mumbai, India

#### Purpose or Objective

To evaluate the outcomes of liver stereotactic radiotherapy (SBRT) in the treatment of large hepatocellular carcinomas (HCC) that are unsuitable for, or refractory to prior liver-directed therapies.

#### Material and Methods

Between March 2015 and June 2018, patients with primary HCCs refractory or progressive to or unsuitable for treatment with loco-regional therapies were treated with SBRT. Only patients of Child status A5-B7 and with adequate normal liver reserve of 700 cc or higher were eligible. SBRT was delivered using IMRT or VMAT using video bio-feedback based deep inspiration breath-hold technique to a total dose of 25-54 Gy in 5-6 fractions. Overall survival (OS) and progression free survival (PFS) were determined by Kaplan-Meier analysis. In-field, out-of field recurrences and toxicities were also assessed. Univariate and multivariate analysis was performed to assess impact of various prognostic factors on outcome.

#### Results

Twenty one patients with large HCCs were treated. The median tumour diameter was 9.6 cm (5-21) and median GTV volume was 350 cc (32.9-2541.5 cc). Overall, 57.1 % patients were BCLC B and 42.9 % patients were BCLC C. Majority of the patients (80.9%) had some form of previous therapy (TACE, Sorafenib, RFA, PVE). The median SBRT dose prescription was 42Gy/6 fractions (24-54 Gy). The median normal liver volume was 1080 cc (423-1979 cc) and median normal liver dose was 15.3 Gy. At a median follow up of 9 months (1-26 mths), only 9.5% patients (n=2) had in-field tumour progression, 14.3% (n=3) had out of field new lesions and 33.3% (n=7) had extra-hepatic distant failure. The 1 year and 2 year local control rate was 88% and 43% respectively. The median overall survival for the entire cohort was 13 months (3-36) respectively. The 1- and 2 - year overall survival rates were 51% and 15% respectively. Overall rate of grade ≥ III toxicity attributable to SBRT was 14%. Patients with Child A 5 liver function status had a better overall survival (21 months) than Child A 6 and Child B7 patients (11 months and 8 months respectively) [p value = 0.01]. BCLC class B patients had a better overall survival (17 months) than BCLC C (8 months), however this was not significant [p

value = 0.184]. Also, tumours with GTV < 350 cc volumes had a better overall survival (24 months) compared to GTV of greater than 350 cc (8 months) [p value = 0.004]. On multivariate analysis tumour volume >350 cc remained the only predictor for adverse OS (p=0.005).

#### Conclusion

This study showed that SBRT can be used safely and effectively to treat large HCCs with or without prior loco-regional therapies, resulting in good local control and survival with acceptable toxicity.

#### EP-1437 The prognostic significance of neutrophil / lymphocyte ratio for SBRT of cholangiocellular carcinoma

N. Bartl<sup>1</sup>, S. Adebahr<sup>1</sup>, S. Kirste<sup>1</sup>, I. Popp<sup>1</sup>, H. Schäfer<sup>1</sup>, A. Grosu<sup>1</sup>, T.B.B. Brunner<sup>1</sup>, E. Gkika<sup>1</sup>

<sup>1</sup>Medical Center- Faculty of Medicine- University of Freiburg- German Cancer Consortium DKTK Partner Site Freiburg- German Cancer Research Center DKFZ- Heidelberg- Germany, Department of Radiation Oncology, Freiburg, Germany

#### Purpose or Objective

In this analysis, we evaluated the prognostic significance of the neutrophil / lymphocyte ratio (NLR) in patients treated with stereotactic body radiation therapy (SBRT) for cholangiocellular carcinomas.

#### Material and Methods

Consecutive patients (n = 26) with histologically confirmed cholangiocellular carcinoma who were treated with SBRT between 2007 and 2017 are included in this analysis. The majority of patients were treated for local recurrence after primary therapy or as primary therapy because there was no operative treatment option. Patients received a median total dose of 50 (range 21-66) Gy in 3-12 fractions.

#### Results

Median survival was 14 months with overall survival (OS) 1 year after SBRT of 61% with median progression-free survival (PFS) at 13 months and 51% at 1 year. The local control was 72% after 1 year. The median NLR was 3 (range 2-10) with a median CRP of 15 (3-96) mg / L with a median bilirubin of 1 (1-22) mg / dL and a median LDH of 233 (156-462) U / l. The OS did not correlate significantly with the NLR (HR 1.231, 95% CI 0.992-1.572, p = 0.059) neither was it correlated with NLR above the median (18 vs 14 months, p = 0.34). Furthermore, no correlation could be shown between CRP, LDH or bilirubin with overall Survival.

#### Conclusion

In this analysis, no correlation could be demonstrated between NLR and survival in patients with cholangiocellular carcinoma treated with SBRT.

#### EP-1438 Safety and tolerability of liver re-irradiation using high dose SBRT

D. Gabrys<sup>1</sup>, R. Kulik<sup>2</sup>, L. Dolla<sup>2</sup>, K. Trela-Janus<sup>1</sup>, A. Roch-Zniszczol<sup>1</sup>, S. Blamek<sup>1</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland ; <sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Radiotherapy and Brachytherapy Planning, Gliwice, Poland

#### Purpose or Objective

The liver can tolerate a high dose of radiation if a sufficient volume of healthy liver tissue is spared. In the current paper we examined the safety and tolerability of liver reirradiation and dose volume histograms (DVH) of combined treatment plans.

#### Material and Methods

From patients who were treated with at least twice SBRT irradiation to the liver we choose 23 patients treated with high dose liver irradiation. The patients underwent retreatment for a primary (one patient with HCC) or metastatic recurrent or new liver tumour. With the use of

Velocity, a treatment planning evaluation system, we integrated imaging scans and treatments information from particular patient. Therefore, combined dose was associated with images for review of treatment plans using isodose curves and DVH. Furthermore we analysed blood parameters and patient performance status.

#### Results

Several fractionation schemes were used, for primary therapy of 12-15 Gy to the total dose 36-48 Gy, for second course of irradiation of 10-15 to the total dose 30-48, third (8 pts) of 3-15 Gy to the total dose 15-50. Median total dose was 90 Gy (range 72-209). Median highest total radiation dose to one GTV volume was 48 Gy (range 36-95).

Stereotactic radiotherapy is a good local therapy for liver tumours since in majority of cases (28 GTV) first liver re-irradiation was administered to previously non-irradiated area and only in 6 GTV to previously treated volume. Median interval from initial RT to first retreatment was 8.5 months (range 3.4-50.8). Patients who underwent third radiotherapy were irradiated for recurrent tumour after first treatment (4 GTV) and after second course (4 GTV), but also 3 patients underwent radiotherapy to previously not irradiated volume. Median time from first radiotherapy to last visit was 19.5 months (range 3.5-60). We did not notice significant decrease in mean liver volume which was 1516 cm<sup>3</sup> (range 947-2875) at the time of first radiotherapy and 1458 cm<sup>3</sup> (range 1047-2673) at last treatment, although it was irradiated with high doses. Median dose to the 700 cm<sup>3</sup> of functional liver was 16.8 Gy (range 3.7-33.7). The cumulative mean dose to the liver was 20.2 Gy (range 10.2-32.7). mean volume receiving 10 Gy was 61.5 % (range 26-80.2), and 21 Gy was 36.3 % (range 13.5-54.9). High doses used in our patients did not translate into significant liver dysfunction. Grade 1 increase in the level of AST was found in 5 patients, and only in one patients grade 2. Grade 1 ALT increase was found in 1 patients, and single patients experienced G1, and G2 increase of bilirubin level. The elevation of liver enzymes was related to the progression of the disease within and outside the liver.

#### Conclusion

High dose re-irradiation with SBRT to the liver tumors is a safe and tolerable option that allows prolongation of survival with advanced liver disease. Prospective studies are needed to establish accurate dose constraints and treatment guidelines.

#### EP-1439 The role of FDG PET / CT in SBRT of primary tumors in the upper abdomen

N. Bartl<sup>1</sup>, S. Adebahr<sup>1</sup>, S. Kirste<sup>1</sup>, I. Popp<sup>1</sup>, H. Schäfer<sup>1</sup>, A. Grosu<sup>1</sup>, T.B. Brunner<sup>1</sup>, E. Gkika<sup>1</sup>

<sup>1</sup>Medical Center- Faculty of Medicine- University of Freiburg- German Cancer Consortium DKTK Partner Site Freiburg- German Cancer Research Center DKFZ- Heidelberg- Germany, Department of Radiation Oncology, Freiburg, Germany

#### Purpose or Objective

In this analysis, we evaluated the role of FDG PET / CT in the planning of stereotactic body radiation therapy (SBRT) of primary tumors in the upper abdomen (pancreatic carcinoma, cholangiocellular carcinoma, hepatocellular carcinoma).

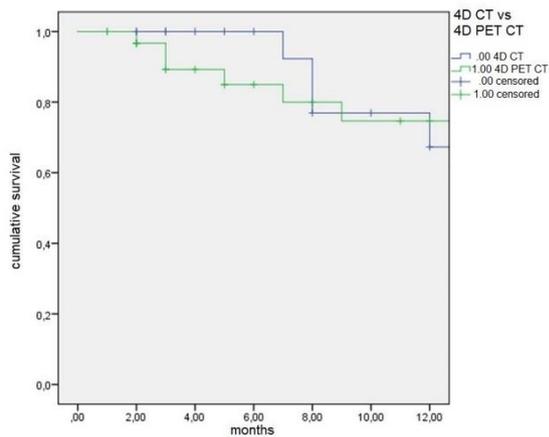

#### Material and Methods

Consecutive patients (n = 101) who were treated with SBRT for upper abdominal carcinoma [pancreas n = 17, cholangiocellular carcinoma (CCC), n = 37, hepatocellular carcinoma (HCC), n = 48] were included in this analysis. In total, 42 patients (41%) had FDG PET / CT or 4D FDG PET / CT available for defining the target volume and 59 patients (59%) had no FDG PET / CT.

#### Results

The local control (LC) was 75% for all treatments after 1 year. In the patients who had FDG PET / CT, the LC was

75% at 1 year and at 73% ( $P = 0.74$ ) in patients without FDG PET / CT. Overall survival was median at 13 months (95% CI 8,663-17,337) for the entire cohort and at 10 months for those without FDG-PET / CT versus 14 months for FDG-PET / CT, with no statistical relevance ( $p = 0.18$ ). For the CCC, the LC was 90% for the FDG-PET / CT ( $n = 20$ ) patients at 1 year and 76% for the FDG-PET / CT ( $n = 17$ ) patients ( $p = 0.4$ ). For pancreatic carcinoma, LC was 60% at 1 year in both groups (with FDG-PET / CT,  $n = 12$ , and without FDG-PET / CT,  $n = 5$ ), and LC was at 1 year for HCCs 75% in the group with FDG-PET / CT ( $n = 10$ ) and 82% in the group without FDG-PET / CT ( $n = 32$ ). FDG PET / CT did not affect survival in any of the subgroups. In Klatskin tumors and in pancreatic carcinomas, however, local congestion and inflammation revealed false positive findings.

### Conclusion

The FDG-PET / CT seems to play a role in the definition of the target volume for the CCCs in contrast to the HCCs (LC after 1 year 90% vs 76%). For pancreatic carcinoma, it is rather unclear because of the small number of patients who did not have FDG PET / CT at the time of the target volume definition. Furthermore, it has to be taken into account that Klatskin's tumors and pancreatic carcinomas may be falsely positive due to local congestion and Inflammation.

### EP-1440 Early and late toxicity of hypofractionated stereotactic radiotherapy in hepatic tumors

M. Le Bon<sup>1</sup>, B. Celine<sup>2</sup>, K. Fabrice<sup>3</sup>

<sup>1</sup>Centre Léon Bérard, Radiothérapie, Lyon, France ;

<sup>2</sup>Centre Jean Perrin, Radiothérapie, Clermont-Ferrand, France ;

<sup>3</sup>Centre Jean Perrin, Physique médicale, Clermont-Ferrand, France

### Purpose or Objective

To evaluate the outcomes of stereotactic radiation therapy for primary and secondary liver tumors in terms of efficacy and safety.

### Material and Methods

Between December 2013 and June 2016, 25 patients were included. Treatment was performed on a linear accelerator Novalis TX<sup>®</sup>. The prescription dose was 42 to 60 Gy in 3 to 5 fractions. Local control at 1 year was evaluated with mRECIST and RECIST criteria. Acute and late toxicity were evaluated with CTCAE v4.0 criteria.

### Results

Median follow-up was 10.5 months. Treatment tolerance was good with few side effect  $\geq 3$ , no acute toxicity and only one late toxicity.

We have highlighted that hepatic artery hemorrhage was associated with the presence of a biliary prosthesis in contact with the artery ( $p = 0.006$ ) and in the irradiation

field. There was no correlation with the dose delivered to the artery and hepatic artery hemorrhage.

Univariate analysis of predictive factor of late toxicity after stereotactic body radiotherapy in hepatic tumors in 25 patients

late toxicity	Gr 0-1	Gr 2-3-4	p-value
Sex (H/F)	73,7%	75%	$p=0,68$
Age (average, year)	70,6	61,6	$p=0,05$
OMS			$p=0,37$
0	10	5	
1	7	1	
2	2	2	
Larger diameter (average, cm)	27,6	38,2	$p=0,05$
GTV Volume (average, cm <sup>3</sup> )	32,3	49,6	$p>0,05$
PTV Volume (average, cm <sup>3</sup> )	143,5	169,9	$p>0,05$
EQD2 <sub>100</sub> (average, Gy)	68,3	78,4	$p>0,05$
Number of fractions (average)	4,5	4,6	$p>0,05$
Vrs 18 Gy/3F (average, mL)	1083,0	1096,5	$p=0,96$
Vrs 15 Gy/5F (average, mL)	1163,5	1177,0	$p=0,91$
V21 Gy / foie (average, mL)	281,1	398,9	$p=0,24$
Average dose to Liver-GTV (average, Gy)	10,1	10,9	$p>0,05$
Maximum dose to great vessels (average, Gy)	33,3	38,9	$p>0,05$
Ethical marker without / with	RR 1 [0,3-2,9]		$p=0,62$
Azotherapy/IMRT	RR 1,1 [0,4-3,4]		$p=0,61$
Prosthesis yes/no	all toxicities		$p=0,54$
	RR 1,9 [0,5-7,2]		
	hemorrhage		$p=0,006$
	RR		

M : man, F : female, EQD2<sub>100</sub>: biological equivalent dose at 2 Gy per fraction with an  $\alpha/\beta$  at 1 for the tumor.

GTV : Gross Tumor Volume, PTV : Planning Target Volume, Vrs 18 Gy/3F : volume of healthy liver receiving

18 Gy for treatments in 3 fractions, Vrs 15 Gy/5F : volume of healthy liver receiving 15 Gy for treatments in 5

fractions, V21 Gy : volume of liver receiving 21 Gy, Average dose to Liver-GTV : average dose received by the

healthy liver, RR : relative risk.

### Conclusion

Stereotactic radiation therapy for liver tumors allow a good local control with poor secondary effects. Be careful with patients with biliary prostheses in the vicinity of the target volume because there is a risk of hemorrhage of the hepatic artery in contact with the prosthesis.

### EP-1441 Chemoradiotherapy with weekly Carboplatin and Paclitaxel in elderly patients with oesophageal cancer

S. Pan<sup>1</sup>, M. Abraham<sup>2</sup>, L. Bhatt<sup>1</sup>, H. Sheikh<sup>1</sup>, G. Radhakrishna<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Clinical Oncology,

Manchester, United Kingdom ;

<sup>2</sup>The Christie NHS Foundation Trust, Dietetics, Manchester, United Kingdom

### Purpose or Objective

Definitive chemoradiation for oesophageal cancer preferentially utilises cisplatin and a fluoropyrimidine chemotherapy concurrent with 50Gy in 25 fractions of radiotherapy. However, this regimen can be challenging to deliver in the elderly or frail population. A phase II trial of concurrent chemoradiotherapy with weekly carboplatin and paclitaxel for advanced oesophageal cancer has shown comparable outcomes.

We report a single institution retrospective series utilising concurrent radiotherapy 50Gy in 25 fractions with weekly carboplatin and paclitaxel in the elderly population.

### Material and Methods

All patients of 70 years and above treated with concurrent chemoradiation with weekly carboplatin and paclitaxel from January 2016 to April 2018 were included in this retrospective analysis. Demographics and clinical information were obtained from the electronic system. Radiation was delivered using IMRT (intensity modulated radiation therapy) technique with a total dose of 50Gy in 25 fractions. Patients received weekly

concurrent paclitaxel (50mg/m<sup>2</sup>) and carboplatin (area under the curve, AUC 2). All patients had image-guidance using cone beam CT as per NRG guidelines.

#### Results

There were a total of 19 patients with a median age of 77 (range 70 -85). Sixty-eight percent (68%) of patients were male, 89% had performance status of 0-1 and 79% had an adenocarcinoma primary.

The median overall survival has not been reached. One year survival rate is 83%. Median time to clinical progression is 13 months (range 3 - 21). All patients had stable or improvement in their swallowing function following treatment.

A total of 17 patients (89%) completed 4 or more cycles of weekly chemotherapy. Reasons for early discontinuation of chemotherapy include Grade 2 neutropenia, Grade 2 thrombocytopenia and intercurrent infection. All 19 patients completed the course of 25 fractions of radiotherapy.

There was no Grade 3 or 4 toxicities. Grade 2 oesophagitis occurred in 7 patients (37%). Seven patients had prophylactic feeding tube inserted, which were removed within 3 months of treatment, apart from two patients. Of the other 12 patients, none required feeding tube insertion. Only 6 (32%) patients lost 5-10% of their baseline weight.

Sixteen patients had their initial three month follow-up with restaging CT scan of thorax, abdomen and pelvis, and endoscopic assessment to evaluate the disease response. The remaining three opted to have only clinical follow-up. Of the sixteen, 12 patients (75%) had biopsy confirmation of no residual disease present. The remaining four patients had persistent disease but no visceral metastatic disease at three months, apart from one patient who had new supraclavicular and paratracheal lymph node.

#### Conclusion

This retrospective study indicates that weekly concurrent regime is well tolerated, and may be considered for elderly patients. Further study into the efficacy of the regimen including the utility of induction Carboplatin and Paclitaxel is warranted.

#### EP-1442 Clinical and pathological response after neoadjuvant/radical CH-SBRT for pancreatic adenocarcinoma

X. Chen<sup>1</sup>, E. Sanchez<sup>1</sup>, M. Lopez<sup>1</sup>, O. Hernando<sup>1</sup>, A. Montero<sup>1</sup>, J. Garcia<sup>2</sup>, M.A. De la Casa<sup>2</sup>, M. Garcia Aranda<sup>1</sup>, R. Ciervide<sup>1</sup>, J. Valero<sup>1</sup>, J. Palma<sup>1</sup>, R. Alonso<sup>1</sup>, J.M. Perez<sup>2</sup>, D. Zucca<sup>2</sup>, L. Alonso<sup>2</sup>, P. Garcia de Acilu<sup>2</sup>, J. Marti<sup>2</sup>, P. Fernandez Leton<sup>2</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>University Hospitals HM Sanchinarro - Puerta del Sur, Radiation Oncology, Madrid, Spain ; <sup>2</sup>University Hospitals HM Sanchinarro - Puerta del Sur, Medical Physics, Madrid, Spain

#### Purpose or Objective

Pancreatic adenocarcinoma (PA) remains one of the most lethal malignancies. Surgery is the only curative treatment. Chemotherapy (CH), radiotherapy or both are now being studied as neoadjuvant approaches. We are going to review feasibility and single centre experience with stereotactic body radiation therapy (SBRT) and a gating technique as a neoadjuvant or radical treatment in PA.

#### Material and Methods

Since February 2014, 36 patients (p) with a median age of 67 years (range 43-86) with histologically proven adenocarcinoma of the pancreas were enrolled on this protocol. Six p (16.7 %) were treated with a radical intent and 30 p (83.3 %) as a part of a neoadjuvant treatment. For all patients treated with neoadjuvant intent, CH had given before SBRT. Neoadjuvant CH schedule: 26 p received gemcitabine nab-paclitaxel, 4 p FOLFIRINOX, 1 p XELOX and 1 p unknown CH schedule. Prior to radiation,

at least 2 gold fiducials markers were located into the tumour guided by gastro-endoscopic ultrasound. All SBRT treatments included intravenous and oral contrast CT or PET-CT for GTV delineation. Intensity-modulated radiation therapy (IMRT) and daily image-guided radiation therapy (IGRT) with intrafraction control of tumour motion with a Novalis ExacTrac Adaptive Gating System were performed in all patients. Total dose: 50 Gy in 5 fractions were prescribed in all patients.

#### Results

With a median follow-up (FU) of 9.4 months (range 1 - 47.9 months), 12 p (33 %) are alive without tumour, 2 p (5.5 %) are alive with distance metastases and 17 p (47.2%) have died; median overall survival (OS) was 14.9 months (range 6.6 - 53.4 months) and the actuarial 12 and 24 months OS was 73% and 53% respectively. Thirty three p (91.7%) remain locally controlled and median time to local progression after SBRT was 9 months (range 0,33 - 47.9 months). For any kind of progression disease, the actuarial progression-free survival at 12 and 24 months were 82.2% and 61.8% respectively. Twenty one patients (58.3%) underwent surgery. Tumour-free margins were achieved in 18 p (85.7%). Twenty pathological evaluation were done: 14 p (70%) achieved tumour free lymph node status. Tumour regression grade (TRG) was analysed in 17 p: 7 p complete response or marked response (TRG 0 - 1: 41.2%), 9 p moderate response (TRG 2: 52.9%) and 1 p poor response (TRG 3: 5.9%). Pancreatic SBRT was well tolerated in our cohort of patients. No grade 3 or higher toxicity was observed.

#### Conclusion

In our experience, pancreatic SBRT is a feasible and well-tolerated treatment. As neoadjuvant treatment, increase tumour-free margins and induce tumour regression. Most patients are free from local progression. The benefit of survival will be evaluated with longer FU.

#### EP-1443 Real-time tumor tracking in pancreatic SBRT by percutaneous US-guide implantation of transponders

J.F. Castilla Martinez<sup>1</sup>, R. Chicas-Sett<sup>1</sup>, J. Godoy<sup>1</sup>, C. Hernandez<sup>2</sup>, I. Morales-Orue<sup>1</sup>, M. Zajac<sup>1</sup>, J. Zafra<sup>1</sup>, M. Lloret<sup>1</sup>, P.C. Lara<sup>3</sup>

<sup>1</sup>Dr. Negrin University Hospital of Gran Canaria, Radiation Oncology, Las Palmas, Spain ; <sup>2</sup>Dr. Negrin University Hospital of Gran Canaria, Radiology, Las Palmas, Spain ; <sup>3</sup>San Roque Hospital/Universidad Fernando Pessoa Canarias, Oncology, Las Palmas, Spain

#### Purpose or Objective

SBRT is gaining acceptance in locally advanced pancreatic cancer treatment. Anyhow critical surrounding organs and treatment toxicity makes crucial to tailor irradiation to the tumor volume sparing as much normal tissue as possible. The aim of this study is to assess for the first time the feasibility of percutaneous ultra sonogram (US)-guided implantation of electromagnetic transponders of the Calypso 4D Tracking System in locally advanced pancreatic cancer. As a secondary objective, to assess intra and inter-fractional pancreatic movement during SBRT treatment.

#### Material and Methods

Seven patients with locally advanced pancreatic cancer were included in this study between September 2017 and September 2018. Under percutaneous ultrasound guidance, 3 transponders were implanted in triangulated coordinates into the pancreas. The Calypso System's tracking mode was used to monitor inter and intra-fractional motion.

#### Results

Successful percutaneous US-guide implantations were achieved for all 21 transponders. No adverse events related to the implantation were reported. Transponder positioning was stable during the whole SBRT treatment (5 fractions/every other day) with a mean change in the geometrical inter-transponder position of 0.3 mm (SD 0.05

- 0.4; range, 0.1 - 0.5 mm;  $p=0.37$ ) in all 35 SBRT session among all patients.

Inter-fractional motion measurements were based on more than 25,000 registries for each patient. Pancreatic movement was scored in the left-right (X), superior-inferior (Y), and anterior-posterior (Z) axes in real time using Calypso's transponders tracking mode. There was a major pancreatic movement in the Y-axis:  $10\pm 1.2$ mm, compared to the X-axis:  $4\pm 0.4$ mm and Z-axis:  $5\pm 0.3$ mm. Mean intra-fractional motion was also found to be larger for the Y-axis:  $5\pm 3.6$ mm than X-axis:  $3\pm 2.3$  mm and Z-axis:  $4\pm 3.1$ mm.

#### Conclusion

Our results suggest that percutaneous US-guided implantation is feasible with limited side effects or risk of migration. Significant motion of the tumor was reported during and between treatments. Cranial-caudal movement (Y-axis) ranged 10mm representing a challenge for adequate tumor coverage. Standardized PTV margins for pancreatic SBRT should take this movement into consideration. Real-time tumor tracking may allow for a more accurate delivery of radiation therapy in pancreatic cancer.

#### EP-1444 Clinical results of proton beam therapy for unresectable intrahepatic cholangiocarcinoma

S. Shimizu<sup>1</sup>, T. Okumura<sup>1</sup>, N. Mizoguchi<sup>1</sup>, H. Numajiri<sup>1</sup>, K. Murofushi<sup>1</sup>, K. Onishi<sup>1</sup>, Y. Oshiro<sup>1</sup>, M. Mizumoto<sup>1</sup>, T. Nonaka<sup>1</sup>, H. Ishikawa<sup>1</sup>, H. Sakurai<sup>1</sup>

<sup>1</sup>Proton Beam Therapy Center-University of Tsukuba Hospital, radiation oncology, Tsukuba city, Japan

#### Purpose or Objective

Surgery is considered the only curative treatment for intrahepatic cholangiocarcinoma (ICC). However, most patients with ICC present with unresectable disease at the time of diagnosis, only approximately 30% of the patients with ICC have operable disease. The standard of therapy for unresectable ICC is chemotherapy, but the median survival time (MST) is less than 1 year. Recent progress of radiotherapy has made it possible to deliver high doses to the tumor, and some studies have suggested efficacy of radiotherapy for unresectable ICC. Proton beam therapy (PBT) can deliver much higher doses to the tumor while keeping dose constraint to surrounding normal tissues. In this study we evaluated the clinical outcome and prognostic factors of PBT for patients with unresectable ICC.

#### Material and Methods

From October 2001 to March 2017, 37 patients with unresectable ICC (Stage I, II, IVa, IVb: 4, 4, 19, 10) were treated with PBT. The reason of unresectable disease were medically inoperable (old age, poor performance status (PS)), tumor progression, and both for 5, 22, and 10 patients, respectively. The patients group included 22 male and 15 female, and the median age was 68 years old (range: 32-87 years old). Twelve, 19, and 6 patients had PS of 0, 1, and 2, respectively. Child-Pugh score was A for 27 patients, and B for 10 patients. Ten patients had multiple tumors, and 10 patients had distant metastases. Jaundice was observed in 11 patients. Patients were classified into curative group (25 patients) and palliative group (12 patients), depending on whether the planning target volume covered all the macroscopic tumors or not. The treatment dose was 66Gy in 10 fractions, 72.6 GyE in 22 fractions, and 74.0 Gy in 37 fractions for 1, 21, and 5 patients, respectively. Sixteen patients received concurrent chemotherapy.

#### Results

Median follow-up time for patients alive at time of analysis was 37.5 months. The MST for 37 patients was 15 months, and overall survival time was 60%, 41%, 31% at 1, 2, and 3 years, respectively. One- and 2- year local control rates were 94% and 69%, respectively. According to multivariate analysis, curative treatment ( $p=0.008$ ), lack of jaundice

( $p=0.039$ ), and chemotherapy after PBT ( $p=0.003$ ) were significant factor for favorable survival. The MST for curative and palliative group was 25 and 7 months, respectively. No severe (grade 3) acute toxicities were observed. As for late toxicity, 3 patients experienced grade 3 biliary tract infection, but the causal relationship with irradiation was unclear.

#### Conclusion

The PBT could deliver high doses to the tumor safely, and may contribute to improvement of local tumor control and survival for patients with unresectable ICC.

#### EP-1445 Gastroduodenal toxicity in patients having bile duct brachytherapy for perihilar cholangiocarcinoma

N. McDonnell<sup>1</sup>, C. Deufel<sup>1</sup>, K. Merrell<sup>1</sup>, M. Neben Wittich<sup>1</sup>, T. Whitaker<sup>1</sup>, W. Harmsen<sup>2</sup>, K. Fruth<sup>2</sup>, M. Haddock<sup>1</sup>, C. Hallemeier<sup>1</sup>

<sup>1</sup>Mayo Clinic, Radiation Oncology, Rochester, USA ; <sup>2</sup>Mayo Clinic, Biomedical Statistics and Informatics, Rochester, USA

#### Purpose or Objective

For patients with localized, unresectable perihilar cholangiocarcinoma (pCCA), an approach of neoadjuvant chemoradiotherapy (CRT), bile duct brachytherapy (BT), and orthotopic liver transplantation has shown favourable survival. This study aims to determine if there is a correlation between BT gastroduodenal (GD) dose and GD adverse events (AEs).

#### Material and Methods

This was a single institution retrospective review of all patients with localized, unresectable pCCA who received CRT and biliary high dose rate (HDR) BT as planned neoadjuvant therapy before liver transplant. Patients received external beam RT (EBRT, planned dose of 45 Gy in 30 fx, twice per day over 3 weeks) with concurrent 5-fluorouracil. Between 0 and 4 weeks after completion of EBRT, HDR BT (Iridium-192 remote afterloading system) was administered through 1-2 nasobiliary or percutaneous transhepatic catheter(s). CT-based BT treatment planning was utilized, with the target volume typically including a 1 cm radial expansion from the centre of the involved perihilar bile ducts. The duodenum/stomach was contoured and dose was converted to biologically equivalent dose (BED) using  $\alpha/\beta=3$ . Treatment was 1-4 fx administered over 1-2 days. Following completion of BT, patients received maintenance capecitabine until liver transplant. GD AEs were graded using NCI-CTCAE, v5.0. Cumulative incidence of grade 2+ and 3+ GD AEs was determined from date of BT, with death a competing risk. Univariable regression models were generated to examine for potential correlation between patient, disease, and treatment variables and GD AEs.

#### Results

The study included 120 patients treated from 2009-2018. Median age was 54 years (range 24-73) and 73% were male. 61% had primary sclerosing cholangitis and 45% had a history inflammatory bowel disease (IBD). Delivered EBRT dose was 45 Gy in 95% (range, 42-50 Gy). HDR BT schedule was 9.3 Gy/1 fx (74%), 16 Gy/4 fx (15%), 12.4 Gy/2 fx (6%), or other (5%). The median GD D0.1cc was 4.27 Gy and the median BED<sub>3</sub> was 12.67 Gy. Median follow up after BT was 14 months (range 1-99 months). Grade 2+ and 3+ GD AEs occurred in 38% (n=46) and 28% (n=34). Grade 3+ GD AEs were haemorrhage (n=17), stricture (n=11), ulcer (n=5), gastritis/duodenitis (n=4), and perforation (n=1). Median time from BT to first grade 3+ AE was 5.8 months (range 0.1-64). At 12 months, the cumulative incidence of G2+ and G3+ GD AEs were 33% (95% CI: 24-42%) and 23% (95% CI: 14-31%), respectively. On univariable analysis, there was no association between age, gender, PSC, history of IBD, or EBRT dose and risk of grade 2+ or 3+ GD AEs (all  $P>0.05$ ). BT GD D0.1cc (minimum dose to the 0.1 cc

receiving the greatest dose) was associated with risk of G2+ ( $p<0.01$ ) and G3+ ( $p=0.048$ ) GD AEs, as was BED<sub>3</sub> ( $<0.01$  and  $<0.01$ ).

#### Conclusion

For patients with pCCA receiving CRT and HDR BT, higher BT GD D0.1 cc and higher BED<sub>3</sub> were both associated with an increased risk of GD AEs.

#### EP-1446 Clinical efficacy and safety of consolidative radiotherapy in the maintenance treatment of mCRC

Z. LIN<sup>1</sup>, Z. Danyang<sup>1</sup>, Y. Dandan<sup>1</sup>, W. Jing<sup>1</sup>, Z. Tao<sup>1</sup>

<sup>1</sup>Union Hospital- Tongji Medical College- Huazhong University of Science and Technology, Cancer Center, Wuhan, China

#### Purpose or Objective

For metastatic colorectal cancer (mCRC) patients responding to induction therapy, maintenance treatment prolongs the progression-free survival (PFS) while maintains quality of life. The purpose of this study was to evaluate the clinical efficacy and safety of local consolidative radiotherapy in maintenance treatment for patients with limited mCRC.

#### Material and Methods

Between October 2011 and June 2017, 19 mCRC patients (6 males and 13 females) who achieved a partial response (PR) or stable disease (SD) to induction chemotherapy and received subsequent consolidative radiotherapy of metastatic lesions and maintenance treatment were retrospectively enrolled.

#### Results

The median age was 57 years (range 33 to 70). Nine patients received local consolidative radiotherapy to liver (median BED=66.3 Gy), 6 patients to pelvis (median BED=60.0 Gy), 5 to lung (median BED=78.0 Gy), and others. The incidence of LR failure was 5.3% and 21.1% at 1 and 2 years, respectively. The incidence of distant failure was 47.4% and 68.4% at 1 and 2 years, respectively. The median OS was 35.5 months (95% CI, 13.41-57.59), and median PFS was 12.4 months (95% CI, 1.77-23.03). Main grade 3 or 4 toxicities were leukopenia ( $n=2$ , 10.5%). The most common adverse events were leukopenia ( $n=14$ , 73.7%), thrombocytopenia ( $n=7$ , 36.8%), anemia ( $n=5$ , 26.3%), transaminase elevation ( $n=5$ , 26.3%), and diarrhea ( $n=2$ , 10.5%).

#### Conclusion

Consolidative radiotherapy prior to maintenance treatment improved local control and prognosis of mCRC patients with acceptable toxicities. Despite the limited data of present study, it could be contemplated as an effective therapeutic alternative in selected patients.

#### EP-1447 Effect of waiting time to radiation on local control and overall survival in rectal cancer

A. Tangkananan<sup>1</sup>, R. Jiratrachu<sup>1</sup>

<sup>1</sup>Prince of Songkla University, Division of Radiation Oncology- Department of Radiology- Faculty of Medicine, Songkla, Thailand

#### Purpose or Objective

To evaluate the effect of waiting time to radiation after diagnosis on local control and overall survival in locally staged rectal cancer patients, and to show the cause of prolonged waiting time: referring pathway or internal radiation oncology division.

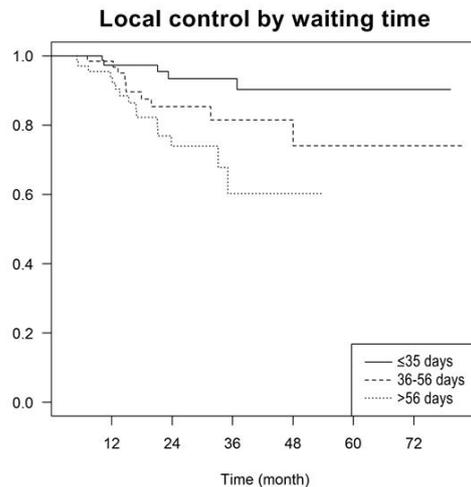

#### Material and Methods

A data of 275 patients with locally staged adenocarcinoma of rectum who were treated with radiation as neoadjuvant concurrent chemoradiation or definite concurrent chemoradiation between January 2011 and December

2016 were reviewed. Waiting time was defined as interval between the pathological diagnosed date until the first fraction of radiation delivered date. Referring pathway interval was defined as time from the pathological diagnosed date to the first date of radiation oncologist and patient meeting. Internal radiation oncology division interval was defined as time from the first date of radiation oncologist and patient meeting to the first fraction of radiation delivered date.

#### Results

The median waiting time was 41 days (IQR 25, 56.2); referring pathway interval 27 days (IQR 13, 44), internal radiation oncology division interval 11 days (IQR 8, 16). The estimated 5-year local control and overall survival were 76.8% (95%CI 68.4-86.2) and 61.7% (95%CI 54-70.5), respectively. In patients who had local recurrence, the median waiting time was 57 days (IQR 40, 78.8) compared with 42 days (IQR 27, 64) in patients who did not have (P-value 0.014). According to waiting time  $\leq 35$  days, 36-56 days and  $>56$  days, the estimated 5-year local control were 90%, 74%, 60% respectively as shows in figure 1. Using waiting time  $\leq 35$  days as the reference group, the HR of local recurrence were 4.49 (95%CI 1.2-16.83, P-value 0.026) with waiting time 36-56 days and 9.05 (95%CI 2.23-36.79, P-value 0.002) with waiting time  $>56$  days. Multivariate analysis showed that ECOG score, radiation dose and surgery were associated with local recurrence. We did not found the relationship between waiting time and overall survival.

**Figure 1** Estimated local control by waiting time

#### Conclusion

Prolonged waiting time to radiation was strongly associated with poorly local control but not overall survival. The main duration of waiting time was referring pathway interval.

#### EP-1448 Preoperative VMAT with simultaneous integrated boost for locally advanced distal rectal cancer

Y. Yang<sup>1</sup>, Q. Liu<sup>2</sup>, P. Zhao<sup>1</sup>, J. Qian<sup>1</sup>, Q. Peng<sup>1</sup>, Y. Zhu<sup>1</sup>, L. Feng<sup>3</sup>

<sup>1</sup>the Second Affiliated Hospital of Soochow University, Radiotherapy & Oncology, Suzhou, China ; <sup>2</sup>Beijing Luhe Hospital Affiliated to Capital Medical University, Radiation Oncology, Beijing, China ; <sup>3</sup>Chinese PLA General Hospital, Radiation Oncology, Beijing, China

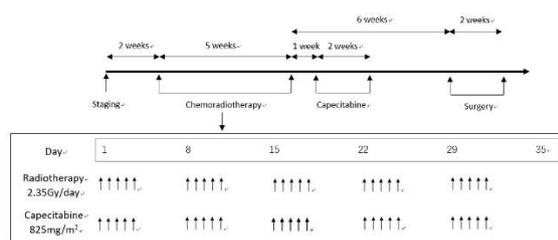

#### Purpose or Objective

The aim of this study was to evaluate the safety and clinical efficacy of a combined preoperative regimen consisting of volumetric modulated arc therapy-

simultaneous integrated boost and capecitabine chemotherapy for distal rectal cancer.

#### Material and Methods

A total of 26 patients with locally advanced distal rectal cancer were enrolled from March 2015 to May 2016. The tumor had to have evidence of cT3-T4 with any N, or any T with N1 or N2 disease on pelvic magnetic resonance imaging (MRI), staged according to the 2009 classification of the American Joint Committee on Cancer (7th edition). The radiation dose fractionation was 58.75 Gy/25 fractions (2.35 Gy/fraction) for rectal tumor and pelvic lymph node metastasis and 50 Gy/25 fractions for pelvic lymph node stations, accompanied with simultaneous capecitabine chemotherapy. Completion of the simultaneous chemotherapy was ensued by 1 week of rest and then another cycle of induction chemotherapy with capecitabine. A radical rectal cancer surgery was performed 6-8 weeks after the simultaneous chemoradiotherapy. The primary endpoints were the complete pathological response rate and the postoperative sphincter preservation rate. This study was a non-randomized, open-labeled, single-arm, single-institution, prospective, phase II trial. All patients provided written informed consent before they were recruited for the study.

#### Results

All 26 patients completed the neoadjuvant chemoradiotherapy, among which 25 received surgical treatment, and 1 patient declined the surgery due to severe perianal edema. The postoperative complete pathological response rate was as high as 32% (8/25), while the sphincter preservation rate was 60% (15/25); the overall T/N downstaging rate was 92% (23/25), and the R0 resection rate was 100%. During the chemoradiation, the occurrence rate of grade 1 adverse reactions was 85% (22/26), including 10 hematologic toxicities, 11 cases of diarrhea, 12 cases of excretory response, 9 cases of radiodermatitis, and 5 cases of hand-foot syndrome; the occurrence rate of grade 2 acute adverse reactions was 53.8% (14/26), including 7 cases of hematologic responses, 8 cases of diarrhea, and 2 cases of radiodermatitis. There were 2 cases of grade 3 acute adverse reactions, both of which were radiodermatitis. None of the acute adverse reactions were more severe than grade 4. After the surgery, there was one case of ureteral injury and one case of intestinal obstruction, but no perioperative deaths occurred.

#### Conclusion

In conclusion, the chemoradiation regimen of preoperative VMAT-SIB<sub>58.75Gy</sub> and a single cycle of induction chemotherapy with capecitabine for patients with distal rectal cancer is safe and feasible with a satisfactory complete pathological response rate, sphincter preservation rate, and R0 resection rate.

#### EP-1449 Prognostic Value of Volumetric PET Parameters in Patients with Locally Advanced Rectal Cancer

F. Sert<sup>1</sup>, A. Oral<sup>2</sup>, R. Savas<sup>3</sup>, D. Yalman<sup>1</sup>, S. Ozkok<sup>1</sup>

#### Purpose or Objective

For locally advanced rectal cancer (LARC) patients, preoperative neoadjuvant radiochemotherapy followed by total mesorectal excision (TME) is the standard treatment. The aim of our study is to determine the prognostic and/or predictive role of 18F-FDG PET/CT parameters such as SUVmax, SUVmean, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG=MTVxSUVmean) for the patients with LARC treated with neoadjuvant radiotherapy±chemotherapy(nCRT).

#### Material and Methods

Between January 2005 and December 2016, a total of 106 patients with clinical T3-4 and/or N+ rectal cancer without distant metastasis were included this retrospective evaluation. Totally 106 patients met our criteria. Median age was 61 (range, 29-86) and 54% of them were female. Patient characteristics are shown in table 1. Correlation between metabolic and volumetric parameters and tumor characteristics was evaluated. Prognostic factors for overall survival (OS), local recurrence-free survival (LRF5), and distant metastasis-free survival (DMFS) were analyzed. All patients were treated with concurrent chemotherapy except 18 (17%) of them. Among the patients receiving concurrent chemotherapy 68 (64%) received oral capecitabine, and 20 (19%) received 5-Fluorouracil with leucovorin during RT.

#### Results

The median follow-up duration for all patients and surviving patients was 39.0 months (range, 6-103 months) and 40 months (range, 22-103 months), respectively. Sixteen patients (15%) developed distant metastases, and

5 (5%) had local/locoregional failure. Pathologic complete response (pCR) was defined as the absence of viable cancer cells in the resected specimen (ypT0N0). pCR was achieved in 17% of all cases (18/106). According to TRG system, grade 0-1 and grade 2-3 responders were 45 patients (42.5%) and 61 patients (57.5%), respectively. The mean  $\pm$  SD SUVmax, SUVmean, MTV and TLG were  $16.9 \pm 9.6$  (range, 3.6 - 60.2),  $9.6 \pm 6.3$  (range, 2.4 - 49.2),  $24.7 \pm 26.4$  cm<sup>3</sup> (range, 2.8 -160.5 cm<sup>3</sup>) and  $268.7 \pm 474.5$  (range, 21.8 -3,092.0) for the entire group, respectively. There was a weak correlation between SUVmax of primary rectal tumors and MTV (Pearson correlation coefficient [r] = 0.238; p < 0.001). On the other hand, SUVmax of primary rectal tumors and TLG were significantly correlated (r=0.538; p < 0.001). Neither SUVmax nor SUVmean were affected by patient and tumor characteristics. On the other hand, volumetric FDG-PET parameters, such as MTV and TLG, were significantly higher in patients with larger tumors ( $\geq 3$  cm) and middle rectum located tumors compared to the patients with smaller tumors (<3 cm), and proximal or distal rectum located tumors. Posttreatment extensive stage of disease (p=.013), absence of concomitant CT (p=.012), MTV  $\geq 14.65$  cm<sup>3</sup> (p=.008), and TLG  $\geq 117.00$  (p=.023) were unfavorable prognostic factors for OS on multivariate analysis.

#### Conclusion

Although FDG-PET is not a standard imaging modality for the treatment of rectal cancers a negative effect of high MTV and TLG on OS was shown in our study. We should consider more intense treatment approaches for tumors with high MTV and TLG values.

#### EP-1450 How smoking status impacts patients undergoing radiochemotherapy for anal canal carcinoma?

L. Grandjean<sup>1</sup>, M. Lamande<sup>1</sup>, E. Gonne<sup>2</sup>, D. Van Daele<sup>3</sup>, J. Collignon<sup>2</sup>, M. Polus<sup>3</sup>, C. Loly<sup>3</sup>, L. Seydel<sup>4</sup>, J. Vanderick<sup>1</sup>, P. Coucke<sup>1</sup>, P. Martinive<sup>5</sup>

<sup>1</sup>CHU de Liege, Radiation therapy, Liege, Belgium ; <sup>2</sup>CHU de Liege, Medical Oncology, Liege, Belgium ; <sup>3</sup>CHU de Liege, Gastroenterology and Digestive Oncology, Liege, Belgium ; <sup>4</sup>CHU de Liege, Biostatistics- SIME, Liege, Belgium ; <sup>5</sup>Institut Jules Bordet, Radiation therapy, Brussels, Belgium

#### Purpose or Objective

Radiochemotherapy (RCT) is the standard of care for Anal Canal Squamous Cell Carcinoma. Although, tobacco consumption during RTC decrease overall survival (OS), cancer specific survival (CSS) and disease-free survival (DFS) in many tumors but it has never been demonstrated in anal cancer. The aim of this study is to compare the results of a tertiary university hospital in terms of colostomy-free survival (CFS), OS, CSS, DFS and to identify prognosis factors in regards to tobacco consumption.

#### Material and Methods

We retrospectively identified 110 patients, with histologically proven SCC of anal canal treated with RCT in our institution between 01/2008 and 12/2017. Patients received 59.4Gy in 33 fractions concomitantly with 5FU and MMC either based on RTOG (45Gy to the pelvic + 14.4Gy for the boost) or EORTC (36Gy to the pelvic + 23.4Gy for the boost) protocol with one week gap before the boost.

#### Results

Most patients presented locally advanced tumor (57.3% of stage III, table 1). Patients benefit from the RTOG and EORTC treatments in 54% and 46 %, respectively. With a median follow-up of 40.6 months (0.3 - 114.7), the 3- and 5-year OS are 73.5% (95% CI, 63.3%-81.2%) and 63.4% (95% CI, 51.6%-73.1%) and for CSS, 81.7% (95% CI, 72.4%-88.1%) and 74.2% (95% CI, 62.7%-82.7%). The 3- and 5-year DFS are 72% (95% CI, 61.9%- 79.8%) and 68.6% (95% CI, 57.8%-77.2%) and for CFS, 81.9% (95% CI, 72.5%- 88.4%) and 79.9% (95% CI, 69.7%-87.1%). Local recurrence (LR) occurred in

20.9% patients, mean and median time to LR was 12.2 and 7.8 months. Males are more likely to have colostomy for LR (HR=3.59, P= 0.014). Tumor stage but not node stage is also associated with higher LR (HR=10.4 for T4 vs T1). There is no correlation between T and N stage with distant metastases. Active smokers at diagnosis/treatment are more likely to undergo a colostomy procedure for LR than former smokers or non-smokers (HR 7.793; P= 0.0053 and HR 2.99; P= 0.2719). Smoking status has no impact on distant failure. Elderly patients have a worse CSS (HR 1.08; P<0.0001) and a significantly higher risk of 90-day mortality after treatment (OR = 1.20; p< 0.0015) with a 26 folds increase risk (p= 0.0031) if patient is older than 71 years.

Characteristics	Number of patients (%)
Age, median (range), y	63.32 (36.4-92.4)
Male/Female	45 (40.9)/65 (59.1)

T2	40 (36.4)
T3	36 (32.7)
T4	18 (16.4)
TX	1 (0.9)
N category	
N0	50 (45.5)
N1	29 (26.4)
N2	14 (12.7)
N3	16 (14.5)
NX	1 (0.9)
Clinical node status	
Positive	50 (45.5)
Negative	60 (54.5)
AJCC stage	
0-I	14 (12.7)
II	33 (30.0)
IIIA	24 (21.8)
IIIB	39 (35.5)

#### Conclusion

For the first time in the SCC of anal cancer, we pointed out tobacco consumption as a negative prognosis factor for LR. We also identified a cut-off of 71 years old for treatment related mortality. Worth noting the homogeneity of the cohort in a retrospective study thanks to institutional treatment protocol. The vast majority of patients presented T3/T4 and positive clinical nodes explaining an OS slightly lower than those observed in clinical trials with less advanced tumors. The CSS and the CFS are in accordance with the literature. To conclude, we should advise patients to stop tobacco consumption during treatment, and we should submit all patients more than 71 years old to an oncologic geriatric evaluation.

#### EP-1451 Impact of tobacco smoking on patient's outcome after (chemo)-radiotherapy for anal cancer

L. Jacques<sup>1</sup>, H. Christophe<sup>1</sup>, E. Isabelle<sup>2</sup>, A. Laurent<sup>3</sup>, G. Gaël<sup>4</sup>, G. Jean-Marc<sup>5</sup>, G. Sophie<sup>1</sup>, A. Thomas<sup>5</sup>, V. Alain<sup>6</sup>, C. Pierre<sup>7</sup>, L. Quero<sup>1</sup>

<sup>1</sup>Saint-Louis Hospital, Radiation Oncology, Paris, France ; <sup>2</sup>Croix Saint Simon Hospital, Proctology, Paris, France ; <sup>3</sup>Bichat Hospital, Proctology, Paris, France ; <sup>4</sup>Bichat Hospital, Gastroenterology, Paris, France ; <sup>5</sup>Saint-Louis Hospital, Gastroenterology, Paris, France ; <sup>6</sup>Croix Saint

*Simon Hospital, Digestive Surgery, Paris, France ; <sup>7</sup>Saint-Louis Hospital, Digestive surgery, Paris, France*

#### **Purpose or Objective**

Squamous cell cancer of the anus is associated with multiple risk factors, including infection with human papillomavirus [HPV] and human immunodeficiency virus, immunosuppression, multiple sex partners, receptive anal sex and tobacco smoking. The aim of our study was to identify prognostic factors associated with poor outcome after radiotherapy for anal cancer.

#### **Material and Methods**

We analysed retrospectively the medical records of 171 patients treated by (chemo)-radiotherapy for a non-metastatic anal cancer in our institution from 2000 to 2015. Patients and tumor characteristics, treatments (chemotherapy (CT), radiotherapy (RT), and surgery) and outcomes were analyzed. Colostomy-free, disease-free and overall survivals at 5 years were studied. Univariate and multivariate analyses were performed by logistic regression in order to determine factors associated with poor progression free survival (PFS).

#### **Results**

Patients characteristics were as follow: median age: 62 years (range 36-89); gender: 45 males (26%) and 126 females (74%); HIV serology: positive 21 patients (12%), negative or unknown 150 patients (88%); tobacco smoking: 86 Pts (50%) among whom 28 Pts and 58 Pts were current and former smokers respectively. Tumors were classified as locally limited (T0-1-2, N0, M0) for 86 pts (50%) and locally advanced (T3-4 or N+, M0) for 85 pts (50%). Median total dose was 64.4 Gy (range 54-76.6), 146 patients were treated by concurrent chemoradiotherapy. Factors associated with poor PFS in univariate analysis were: tumor size >4cm, lymph node involvement; tobacco smoking, no initial surgical excision and anal warts at diagnosis. In multivariate analysis, only tobacco smoking status was significantly associated with poor PFS (HR=2.85 [1.25-6.50], p=0.013). 5-years-PFS for non-smokers, former smokers and current smokers was 88.1%, 76.7% and 73.8% respectively (p=0.038). Tobacco smoking was also associated with poor overall survival (p=0.03) and colostomy free survival (p=0.02).

#### **Conclusion**

Tobacco smoking status is associated with poor overall survival, PFS and colostomy free survival in patients treated for anal cancer by (chemo)-radiotherapy.

#### **EP-1452 Response after neoadjuvant radiochemotherapy as prognostic factor in locally advanced rectum cancer**

S. Couto Gonçalves<sup>1</sup>, A. Ponte<sup>1</sup>, M. Marques<sup>1</sup>, J. Casalta-Lopes<sup>1</sup>, I. Nobre-Góis<sup>1</sup>, T. Teixeira<sup>1</sup>, A. Barros<sup>2</sup>, M. Borrego<sup>1</sup>

<sup>1</sup>Centro Hospitalar e Universitário de Coimbra, Radiation Oncology, Coimbra, Portugal; <sup>2</sup>Centro Hospitalar e Universitário de Coimbra, Oncology, Coimbra, Portugal

#### **Purpose or Objective**

Locally advanced rectal cancer (LARC) treatment includes neoadjuvant (NA) radiotherapy (RT) to achieve downsizing and downstaging and subsequently increase loco-regional (LR) control. The well-known long-course (LC) associates pelvic RT, 45-50.4Gy/25-28F/5-5.5weeks (1,8Gy/F), and radiosensitizing chemotherapy (RTCT). This study aims to evaluate pathological response and survival of patients with LARC after LC.

#### **Material and Methods**

Patients with LARC cT3-4 treated with NA RTCT LC prior to surgery between 2002-2017 were included. Tumor response was evaluated by AJCC staging system; toxicity by CTCAE5.0; survival by Kaplan-Meier;  $\alpha=0.05$ .

#### **Results**

320 patients were included, median age of 65 years, 64.4% male, karnofsky >80% in 94.4%. At diagnosis the median

values for CEA and CA19.9 were 3.5 ng/mL and 8.6 U/mL. Tumors were located at inferior in 47.5% and at medial in 47.5%. Clinical staged cT3N+ in 72.5% and 87.8% was cN+. Acute toxicity was present in 81.6%, G3-4 in 10.0%. The majority was hematologic (44.7%; 1.9% G3-4), cutaneous (44.7%; 4.1% G3-4), diarrhea (24.7%; 3.4% G3-4). Following surgery, positive margins (R+) were obtained in 9.7%, more often in tumors of the inferior (p<0.001); lymphovascular invasion (LVI) was found in 9.7% of pathological specimens. Pathological assessment found ypT0N0 in 15.9%, ypT1-2N0 in 28.4% and ypT3-4 or ypN+ in 55.6%. Lower pre-treatment CEA was related to better response (median of 2.0ng/mL to ypT0N0, 3.05ng/mL to ypT1-2N0, 4.6ng/mL to ypT3-4/N+; p<0.001). Better response was linked to lower rate of R+ and LVI (for both ypT0N0: 0%, ypT1-2N0: 2.2%, ypT3-4/N+: 16.3%; p<0.001). With a median follow-up of 52 months, 5 years LR disease-free survival (LRDFS), disease-free survival (DFS), overall survival (OS) and cancer-specific survival (CSS) were 91.8%, 68.5%, 70.8% and 80.4%, respectively. Pathological response (data in 5 years, ypT0N0 vs ypT1-2N0 vs ypT3-4/N+) related to better LRDFS (100% vs 100% vs 84.9%; p<0.001), DFS (88.9% vs 85.4% vs 54.1%; p<0.001), OS (92.5% vs 82.5% vs 60.3%; p<0.001) and CSS (97.3% vs 88.7% vs 69.7%; p<0.001). Prognostic factors identified at univariate analysis were tumor location on DFS (p=0.012) and CSS (p=0.014), CEA at diagnosis on DFS (p=0.002), OS (p=0.002) and CSS (p=0.001), pre-treatment CA19.9 on LRDFS (p=0.036), DFS (p=0.027), OS (p=0.017) and CSS (p=0.001), LVI on LRDFS (p=0.004), DFS (p<0.001), OS (p=0.004) and CSS (p<0.001), R+ on LRDFS (p<0.001), DFS (p<0.001), OS (p<0.001) and CSS (p<0.001). In multivariate analysis R+ kept prognostic impact on LRDFS (p=0.009); pathological response (p=0.002), LVI (p=0.023) and R+ (p<0.001) on DFS; pathological response (p=0.023 and p=0.010, respectively) and R+ (p<0.001 for both) on OS and CSS.

#### **Conclusion**

RTCT LC in LARC is well-tolerated with manageable toxicities. Better response to treatment was related to better surgical and survival outcomes. Multivariate analysis identified R+, LVI and pathological response as prognostic factors.

#### **EP-1453 Machine learning prediction of early distant progression after SBRT for colorectal cancer**

H. Chung<sup>1</sup>, P. Lang<sup>1</sup>, M. Kayvanrad<sup>2</sup>, R. Thompson<sup>3</sup>, W. Chu<sup>1</sup>, E. Gennatas<sup>4</sup>, G. Valdes<sup>4</sup>, P. Cheung<sup>1</sup>

<sup>1</sup>Odette Cancer Centre- University of Toronto, Radiation Oncology, Toronto, Canada ; <sup>2</sup>University of Toronto, Rotman Research Institute, Toronto, Canada ; <sup>3</sup>Saint John Regional Hospital, Radiation Oncology, Saint John, Canada ; <sup>4</sup>University of California San Francisco, Radiation Oncology, San Francisco, USA

#### **Purpose or Objective**

While SBRT for oligo-metastases (OM) and oligo-progression (OP) has been increasingly utilized, it remains a challenge in identifying patients who would benefit from SBRT, due to complex interactions of patient, tumour and treatment factors. This study examines the ability of machine learning (ML) based classifiers to identify colorectal (CRC) patients who develop early distant progression (DP,  $\leq 90$  days since treatment completion) after completing SBRT for OM and OP, and thus received little benefit.

#### **Material and Methods**

All CRC patients treated with SBRT to any extracranial site at a single institution for OM/OP in 2009 - 2016 were retrospectively reviewed. Clinical characteristics included age, gender, pre-SBRT CEA, RAS status, ECOG performance, treatment indication (OM/OP), primary in situ, SBRT location, disease-free interval (DFI) since last treatment, number of prior lines of systemic of therapy, PTV volume and mean PTV BED. Univariable and

multivariable logistic regression was used to identify predictors of DP. Classification methods included: logistic regression (LR) gradient boosting (GBM), adaptive boosting (ADA), and random forest (RF). Patient characteristics with a high correlation ( $\rho > 0.6$ ) and factors in which missing data  $> 30\%$  were excluded from the models. 10-fold cross validation was used to assess the models. Classifier performance was assessed by receiver operating characteristic curves.

#### Results

113 patients with 226 treated lesions were included; 79 patients and 203 lesions treated for OM and 34 patients and 23 lesions for OP. 31 (27%) of the treated patients had DP within 90 days. 2 patients died within 90 days. In univariable analysis, SBRT location (non-lung/liver), higher CEA, shorter DFI, greater number of prior systemic therapy lines and lower mean PTV BED were significantly associated with early DP ( $p < 0.05$ ). In multivariable analysis, shorter DFI and higher CEA were significant predictors of DP ( $p < 0.05$ ). Performance of the various classifiers is shown in Table 1. All ML classifiers were significantly better at identifying patients with DP compared to the logistic regression model ( $p < 0.05$ ). There was no statistically significant difference in performance between the various ML classifiers.

Table 1. Classifier performance.

	LR	GBM	ADA	RF
Sensitivity	0.55	0.49	0.25	0.48
Specificity	0.73	0.87	0.96	0.92
PPV	0.22	0.31	0.51	0.51
NPV	0.92	0.90	0.93	0.93
AUC	0.61	0.70	0.74	0.76

#### Conclusion

The ability to predict patients at risk of DP would assist clinicians in identifying patients who may benefit minimally from SBRT for OM/OP disease. External validation would be of benefit.

#### EP-1454 Multi-parametric MRI as a biomarker in anal cancer: a prospective trial

M. Jones<sup>1</sup>, G. Hruby<sup>2</sup>, M. Kumar<sup>3</sup>, A. Capp<sup>3</sup>, S. Sridharan<sup>3</sup>, C. Coolens<sup>4</sup>, P. Stanwell<sup>5</sup>, J. Arm<sup>6</sup>, S. Gallagher<sup>3</sup>, C. Holder<sup>7</sup>, C. Oldmeadow<sup>7</sup>, J. Martin<sup>3</sup>

<sup>1</sup>Royal Hobart Hospital, Radiation Oncology, Hobart, Australia ; <sup>2</sup>Royal North Shore Hospital, Radiation Oncology, St Leonards, Australia ; <sup>3</sup>Calvary Mater Newcastle, Radiation Oncology, Waratah, Australia ; <sup>4</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada ; <sup>5</sup>The University of Newcastle, School of Health Sciences, Callaghan, Australia ; <sup>6</sup>Calvary Mater Newcastle, Radiology, Waratah, Australia ; <sup>7</sup>Hunter Medical Research Institute, Statistics, New Lambton Heights, Australia

#### Purpose or Objective

To investigate the role of multi-parametric magnetic resonance imaging (MRI) as a potential biomarker in squamous cell carcinoma of the anal canal (AC).

#### Material and Methods

A multi-centre cohort of 20 patients with non-metastatic AC were enrolled on a prospective clinical trial. Multi-parametric MRIs, incorporating diffusion weighted (DW) and dynamic contrast enhanced (DCE) sequences, were performed at time of staging, during the second and fourth week of chemo-radiotherapy (CRT) and 8 weeks post treatment. MRI parameters were extracted from the primary tumour and correlated with recurrence.

#### Results

With a median follow up of 17 months, 3/20 patients had a local recurrence, and 5/20 had any recurrence. Apparent diffusion coefficient (ADC) skewness ( $p=0.04$ ,

AUC 0.9 and  $p=0.02$ , AUC 0.91) and standard deviation (SD) ( $p=0.2$ , AUC 0.9 and  $p=0.01$ , AUC 0.94) at baseline and week 2, kurtosis ( $p=0.01$ , AUC 0.92) and SD ( $p=0.01$ , AUC 0.96) at week 4 and change in minimum ADC between baseline and week 2 ( $p=0.02$ , AUC 0.94) and baseline and week 4 ( $p=0.02$ , AUC 0.94) significantly predicted for local recurrence. For prediction of any recurrence, ADC min ( $p=0.02$ , AUC 0.87) and SD ( $p=0.01$ , AUC 0.85) at baseline, max ( $p=0.03$ , AUC 0.77) and SD ( $p=0.02$ , AUC 0.81) at week 4 were significant. On LASSO logistic regression, ADC minimum and SD at baseline were retained for any recurrence. No DCE parameters were predictive of recurrence.

#### Conclusion

A number of ADC parameters at various time points appear predictive of local and any recurrence. No DCE parameters correlated with recurrence.

#### EP-1455 Post chemoradiotherapy FDG-PET parameters predict for recurrence in anal cancer: a prospective trial

M. Jones<sup>1</sup>, G. Hruby<sup>2</sup>, U. Metser<sup>3</sup>, S. Sridharan<sup>4</sup>, A. Capp<sup>4</sup>, M. Kumar<sup>4</sup>, S. Gallagher<sup>4</sup>, N. Rutherford<sup>5</sup>, C. Holder<sup>6</sup>, C. Oldmeadow<sup>6</sup>, J. Martin<sup>4</sup>

<sup>1</sup>WP Holman Clinic- Royal Hobart Hospital, Radiation Oncology, Hobart, Australia ; <sup>2</sup>Royal North Shore Hospital, Radiation Oncology, St Leonards, Australia ; <sup>3</sup>Princess Margaret Cancer Centre, Cancer Clinical Research Unit, Toronto, Canada ; <sup>4</sup>Calvary Mater Newcastle, Radiation Oncology, Waratah, Australia ; <sup>5</sup>Calvary Mater Newcastle, Nuclear Medicine, Waratah, Australia ; <sup>6</sup>Hunter Medical Research Institute, Statistics, New Lambton Heights, Australia

#### Purpose or Objective

To investigate the prognostic significance of serial F-18 fluorodeoxyglucose-positron emission tomography (PET) parameters in squamous cell carcinoma of the anal canal (AC).

#### Material and Methods

A multi-centre prospective trial of 19 patients with non-metastatic AC treated per protocol underwent PET imaging before and 12 weeks following chemo-radiotherapy (CRT). PET parameters from the primary tumour were extracted and correlated with recurrence.

#### Results

With a median follow up of 15.8 months, 3/19 patients relapsed locally and 5/19 had any recurrence. On post-CRT PET, the median standard uptake value (SUV) within a volume of interest (VOI) bounded by an SUV of 3 correlated with local recurrence ( $p$  value =  $< 0.01$ , AUC 1.0). The mean SUV 3 did not reach significance ( $p$  value = 0.06, AUC 0.91). On LASSO logistic regression, post-CRT SUVmax was retained on the grouped post model for both local and any recurrence, but not in the final model. No pre-CRT PET parameters reached significance.

#### Conclusion

Patients with a metabolic PET response had a very low risk of recurrence or progression. 12-week post-CRT PET parameters extracted from the primary tumour correlated with local recurrence. Further studies in larger cohorts are warranted to confirm this finding.

#### EP-1456 Clinical impact of re-irradiation with carbon ion radiotherapy for locally recurrent rectal cancer

<sup>4</sup>National Centre of Oncological Hadrontherapy CNAO- University of Pavia, Radiation Oncology- Department of Clinical Surgical- Diagnostic and Pediatric Sciences, Pavia, Italy ; <sup>5</sup>National Centre of Oncological Hadrontherapy CNAO- European Institute of Oncology, Radiation Oncology, Pavia- Milano, Italy

#### Purpose or Objective

The re-irradiation of locally recurrent rectal cancer presents challenges due to the proximity of critical organs such as bowel. Ion beam therapy, specifically carbon ions radiotherapy (CIRT) have some advantages for the favorable relative biological effectiveness and physical dose distribution providing a highly conformal dose distribution while minimizing normal tissue damage. The aim of this study is to report our experience on feasibility and toxicity of carbon-ion radiotherapy (CIRT) in previously irradiated patients with locally recurrent rectal cancer.

#### Material and Methods

Between August 2014 and February 2017, a total of 10 patients (M:F= 8:2) were treated with CIRT as re-irradiation for locally recurrent rectal cancer at National Centre of Oncological Hadrontherapy (CNAO). Patient ages ranged between 46 to 78 years (median 58.5 years). All patients had a history of surgery and pelvic radiotherapy. Specifically, the dose of previous radiotherapy ranged from 45 to 50.4 Gy in 9 patients one of which received a brachytherapy boost up to a total dose of 20Gy. One patient was irradiated with a total dose of 76 Gy for a prostatic cancer. One patient, at time of the first recurrence, underwent to re-irradiation with stereotactic radiotherapy (30 Gy in 6 fractions). They had 7 presacral, 1 perineal, 1 perianal and 1 pre-coccygeal relapses. Three patients received spacer implantation prior to CIRT to secure adequate distance between bowel and tumor. Toxicity was scored according CTCAE 4.0 scale.

#### Results

The median interval between the two courses of radiotherapy was 89.3 months (range: 13.8 - 138.2). Median total dose of CIRT was 60 GyRBE (range: 35-76.8) and was administered in a median number of 16 fractions (range: 15-20) over 4 weeks (from 3 to 4.8 Gy RBE/fraction). The GTV ranged from 7.21 to 300.8 cm<sup>3</sup> with a median of 28.42 cm<sup>3</sup>. The PTV ranged from 53.55 to 742.64 cm<sup>3</sup>. All patients completed the scheduled treatment course. Median follow-up was 13 months. Acute toxicity was mild and mainly neuropathic: grade 2 (G2) neuropathic pain in 1 (10%) and G1 in 2 (20%) patients. The major late toxicities were peripheral neuropathy (20%, G2). No G<sub>≥3</sub> acute/late reaction nor pelvic infections were observed. Four patients were diagnosed with local progression after carbon ion radiotherapy with a median disease free survival of 11.4 months (range: 2.4- 39.7). Three patients experienced systemic progression. The estimated 1-year-local control rate was 80%.

#### Conclusion

In our experience, CIRT for locally recurrent rectal cancer appears to be safe and effective with an acceptable rate of morbidity of normal tissue. More data and longer follow-up are required to investigate the long-term disease control and to determine late effects.

#### EP-1457 Moderate hypofractionation and SIB with volumetric modulated arc therapy (RapidArc) for anal cancer

<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy ; <sup>2</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano, Italy ; <sup>3</sup>Humanitas Research Hospital,

Radiothera and Radiosurgery, Rozzano, Italy ; <sup>4</sup>Humanitas University, Department of Biomedical Sciences, Rozzano, Italy

#### Purpose or Objective

This is a retrospective analysis of patients affected by anal squamous cell carcinoma treated with moderately hypofractionated radiotherapy and concurrent chemotherapy according to the Nigro schedule. End-point of the analysis were the assessment of acute and late toxicity and clinical response

#### Material and Methods

Data of Patients affected by locally advanced anal squamous carcinoma and submitted to exclusive chemoradiation were retrospectively analyzed. Radiotherapy was delivered in 28 daily fractions by Linear accelerators with the VMAT technique in its RapidArc form. Before each radiotherapy fraction a cone -beam CT was performed to verify the patient setup (IGRT). Physical examinations and toxicity assessments were performed during and after RT according to CTCAE v4.0. Tumour response was evaluated on CT-MRI-PET scans using the RECIST modified criteria

#### Results

From 2016 to 2018, 40 patients were treated in our Institution. Median age of patients was 65 years ; 93% had Stage II-III. Dose ranged from 61.6 to the primary tumor and nodes CT-PET positive to 50.4 Gy to the elective nodes. Thirty-eight (95%) patients were submitted to concomitant chemotherapy; two patients were submitted to radiotherapy only, because unfit for chemotherapy. Acute genitourinary toxicity was reported in the form of grade 1 by 11 patients (27.5%) and grade 2 by 3 patients (7.5%). Acute rectal toxicity was observed in 29 patients (72.5 %) as grade 1 and 4 patients (10%) as grade 2. Acute skin toxicity of grade 3 was diagnosed in 3 patients (7.5%). Acute gastrointestinal toxicity was reported by 31 patients (77.5%) as grade 1, 3 patients (7.5%) as grade 2 and 2 patient (5%) as grade 3. Late toxicity was represented by grade 1 genito-urinary toxicity in 4 patients (10%), and grade 1 and 2 rectal toxicity in 17 and 3 patients( 42.5% and 7.5%), respectively. Late skin toxicity was reported by 8 and 3 patients (20% and 7.5%) as grade 1 and 2, respectively. Late gastrointestinal toxicity was reported by 12 patients (40%) as grade 1 ; no late intestinal toxicity of grades 2 and 3 were recorded. At the restaging workup ,34 patients (85%) achieved a complete response and 6 patients (15%) a partial response. No patient had local progression during follow-up while one patients had metastatic progression of disease. All but one patient were alive at time of analysis

#### Conclusion

Moderate hypofractionation with SIB and RapidArc was shown to be safe, with acceptable toxicity. Longer follow-up is needed to assess clinical outcome

#### EP-1458 Acute toxicities comparing VMAT versus 3D-CRT in locally advanced rectal cancer

M. Zimmermann<sup>1</sup>, S. Weick<sup>1</sup>, F. Exner<sup>1</sup>, A. Richter<sup>1</sup>, M. Flentje<sup>1</sup>, B. Polat<sup>1</sup>

<sup>1</sup>University hospital Wuerzburg, Department of radiation oncology, Wuerzburg, Germany

#### Purpose or Objective

In locally advanced rectal cancer multimodal treatment including neoadjuvant radio(chemo)therapy is standard of care. The use of modern radiotherapy treatment techniques like IMRT and IGRT are becoming more common. Here, we analysed the impact of VMAT planning on bladder and small bowel sparing in comparison to conventional treatment planning.

#### Material and Methods

From 08/2015 to 01/2018, 35 patients with rectal cancer with UICC stage II and III were included in this retrospective analysis. All patients received long-term 5-

FU-based radio-chemotherapy with 50.4 Gy in 28 fractions followed by surgery and adjuvant chemotherapy. Radiation dose was delivered using conventional radiotherapy (3D-CRT) with posterior-anterior and opposed lateral field arrangement (with additional segments) in prone treatment position using a belly board. For CT-planning and each treatment fraction, a full bladder was required. Small bowel loops were individually contoured up to 3 cm above the cranial PTV border. The 3D treatment plans were compared to retrospectively calculated VMAT plans with equal dose prescription. Values for Dmean and Dmax for bladder and small bowel were calculated. Additionally the small bowel volume receiving doses between 5 and 50 Gy ( $V_{5-50}$ ) in 5 Gy intervals were recorded. Acute bladder and small bowel toxicities were classified according to CTCAE v4.03. Comparison of mean values was done by using t-test statistics, with p-values < 0.05 regarded as significant.

#### Results

Median patient age was 62.7 years. Nineteen patients were female and 16 male. Tumor stage was T3 100%, N0 3%, N1 14% and N2 83%. Nine patients (26%) developed acute cystitis Grade 1 and 18 patients (51%) acute diarrhea  $\geq 2$ . While occurrence of cystitis did not depend on bladder and PTV volume (p=0.442; p=0.943), there was a significant dependence on higher Dmean values to the bladder (grade 0: 25.2 Gy vs. grade 1: 29.4 Gy; p=0.009). Neither the PTV volume nor the bladder volume correlated with acute diarrhea (p=0.395 and p=0.303). If larger small bowel volumes were close to the PTV, higher grades of diarrhea occurred (grade 0-1: 648.8 ml vs. grade > 2: 846.1 Gy; p=0.021). This relation was also true for almost all dose levels ( $V_{5-50}$ ):  $V_5$  grade 1: 425.5 ml vs. grade 2: 606.6 ml; p=0.017. After re-planning the 3D plans with a VMAT technique dose to bladder and small bowel could be significantly reduced: Dmean bladder 26.3 Gy vs. 21.9 Gy (p<0.01) and Dmean small bowel 11.3 Gy vs. 7.7 Gy (p<0.01). Also, the other small bowel volumes receiving 5 to 45 Gy could be spared by VMAT (p<0.01).

#### Conclusion

Acute cystitis and gastrointestinal toxicities are dose and volume dependent. Irradiated volumes can be sufficiently reduced with VMAT planning compared to 3D-CRT. This effort might reduce urinary and gastrointestinal toxicities.

#### EP-1459 Impact of sentinel lymph-node biopsy and FDG-PET in staging and radiation treatment of anal cancer

N. Slim<sup>1</sup>, P. Passoni<sup>1</sup>, R. Tummineri<sup>1</sup>, C. Gumina<sup>1</sup>, G.M. Cattaneo<sup>2</sup>, P. De Nardi<sup>3</sup>, C. Canevari<sup>4</sup>, M. Ronzoni<sup>5</sup>, C. Fiorino<sup>2</sup>, E. Incerti<sup>4</sup>, A.M. Tamburini<sup>3</sup>, L. Gianolli<sup>4</sup>, L. Gianni<sup>3</sup>, R. Rosati<sup>3</sup>, N. Di Muzio<sup>1</sup>

<sup>1</sup>San Raffaele Scientific Institute- Milano- Italy, Radiation Oncology, Milan, Italy; <sup>2</sup>San Raffaele Scientific Institute- Milano- Italy, Medical physics, Milan, Italy; <sup>3</sup>San Raffaele Scientific Institute- Milano- Italy, Surgery, Milan, Italy; <sup>4</sup>San Raffaele Scientific Institute- Milano- Italy, Nuclear Medecine, Milan, Italy; <sup>5</sup>San Raffaele Scientific Institute- Milano- Italy, Medical Oncology, Milan, Italy

#### Purpose or Objective

To assess the role of sentinel lymph-node biopsy (SLNB) and FDG-PET in staging and radiation treatment (RT) of anal cancer patients (pts).

#### Material and Methods

80 pts (m:32, f:48), median age 61 years (38-87y) with anal squamous cell carcinoma were treated from 3/2008 to 3/2018. Twenty-seven/80 pts (34%) were HIV+. Pts without evident clinical inguinal LN metastases (mts) and/or with discordance between clinical and imaging were considered for SLNB. FDG-PET was performed in 69/80 pts. Pts with negative imaging in inguinal LNs and negative SLNB could avoid RT on groin. CTV included GTV (primary tumour and positive LNs) and pelvic  $\pm$  inguinal

LNs. PTV1 and PTV2 corresponded to GTV and CTV, respectively, adding 0.5 cm. RT dose was 50.4 Gy/28 fractions (fr) to PTV2 and 64.8 Gy/36 fr to PTV1, delivered with 3DCRT, VMAT (RA) or Tomotherapy, concomitant to NIGRO scheme chemotherapy.

#### Results

FDG showed inguinal uptake in 20/69 pts (29%) and in 11/20 pts lymphoscintigraphy was performed: SLNB confirmed inguinal mts in 4/11 (36%) pts, 6/11 (54.5%) pts were false positive and SLN not found in 1 pt. FDG-PET was negative in 49/69 pts (71%) and in 30/49 (61%) lymphoscintigraphy was performed: 6/30 (20%) showed mts, 23/30 (77%) were true negative and SLN not found in 1 pt. PET was false positive in 50% HIV- pts versus no HIV+ pts.

Fifty-four/80 pts (67.5%) received RT on groin (RA: 26 pts, 3DCRT: 14 pts, Tomotherapy: 14 pts); 19/54 pts were HIV+.

Pts treated vs no treated on groin showed more inguinal dermatitis toxicity (G1-G2: 27 (50%) vs 3 pts (11.5%) and G3-G4: 9 pts (17%) vs 0%. HIV+ pts treated on groin had more G3-G4 perineal dermatitis toxicity (9 (33.5%) vs 5 pts (18.5%). All pts treated on groin showed higher G3-G4 hematological toxicity vs not treated pts independently of HIV status.

RA better avoid inguinal region than 3DCRT. Tomotherapy was better than 3DCRT and RA in perineal toxicity (28.5% vs 43% and 42.5%, respectively), and was superior to 3DCRT in inguinal toxicity (14% vs 36%).

All pts were evaluated for responses, at a median follow-up of 36.8 months (5-128 m): 70 pts (87.5%) showed a complete response, 9 pts (11.25%) a partial response, 1 pt (1.25%) a stable disease, while 11 pts (13.75%) had a local relapse (3 with distant mts), median time to local relapse was 9.3 months (6.2-25.5). Twelve pts (5%) had a distant progression, median time to distant progression was 11.16 months (1.4-20.53). No pts treated or not on groin showed inguinal relapse.

#### Conclusion

SLNB improve FDG-PET inguinal LNs staging which has a large false positive and false negative rate, independently of HIV status and guides decision in inguinal RT. Inguinal irradiation could be avoided based on negativity of imaging and SLNB. Advanced RT techniques should better avoid toxicity especially in HIV+ pts.

#### EP-1460 Internal Margin evaluation in prone or supine rectal cancer patients using CBCT

C. Rosa<sup>1</sup>, L. Gasparini<sup>1</sup>, S. Di Biase<sup>1</sup>, C. Di Carlo<sup>1</sup>, A. Allajbej<sup>1</sup>, F. Patani<sup>1</sup>, D. Fasciolo<sup>1</sup>, A. Vinciguerra<sup>1</sup>, L. Caravatta<sup>1</sup>, D. Genovesi<sup>1</sup>

<sup>1</sup>Ospedale Clinicizzato S. S. Annunziata, Department of Radiation Oncology- SS. Annunziata Hospital- "G. D'Annunzio" University- Chieti- Italy, Chieti, Italy

#### Purpose or Objective

Due to a reported dose-response relationship in rectal cancer radiotherapy, a greater interest in dose intensification on small boost volume arises. When conformational techniques, as IMRT and VMAT, are used an accurate delineation of gross tumor volume (GTV) and an appropriate organ motion evaluation are suggested. Our previous study evaluated internal movement (IM) of GTV and mesorectum in patients in prone position on CBCTs. Now, this study aimed to use CBCT for GTV and mesorectal IM evaluation, in rectal cancer patient treated with neoadjuvant radiochemotherapy, examining the differences in prone and supine position.

#### Material and Methods

Thirty-two locally advanced rectal cancer patients (M:22, W:10) underwent CT scan simulation, 16 in prone and 16 in supine position, with controlled bladder filling. Co-registering MRI imaging with CT scan simulation, GTV (tumor site plus corresponded rectum) and mesorectum (from the sacral promontory to the level where the levator

ani muscle inserts into the rectal wall) were delineated. CBCTs were performed once a day during the first 5 fractions, then once or twice a week during all treatment, by Elekta X-Ray volume imaging system (XVI). All CBCTs were co-registered with CT scan simulation and the IM was estimated for GTV. Bladder was also delineated. Co-registrations were performed on RayStation platform (RaySearch Laboratories, Stockholm, Sweden) by bone landmarks and corrected for set-up error. IM evaluation was obtained for both prone and supine position, as mean shift in left and right (L-R), postero-anterior (P-A) and cranio-caudal (Cr-C) directions and volumes variability were calculated by DICE index.

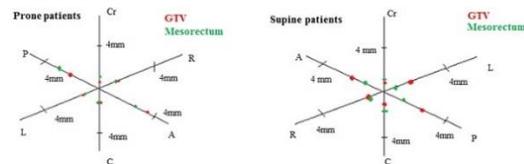

### Results

A total of 296 CBCTs were performed and retrospectively analysed: 147 in prone and 149 in supine position. Mean shift in left and right (L-R), postero-anterior (P-A) and cranio-caudal (Cr-C) directions for GTV and mesorectum were shown in Figure 1. Mean DICE index for GTV, mesorectum and bladder was 0.74, 0.86, 0.65, respectively in prone position, and 0.78, 0.89, 0.69 respectively in supine position. Detailed values are reported in Table 1.

Table 1. Mean shift in left-right (L-R), postero-anterior (P-A) and cranio-caudal (Cr-C) directions, mean volumes and DICE index for GTV, mesorectum and bladder in prone and supine position.

147 CBCT (prone pts)		L-R (cm)	P-A (cm)	Cr-C (cm)	Volume (cm <sup>3</sup> )	DICE index		
GTV	-0.14	0.14	0.23	-0.35	0.10	-0.19	38.45	0.74
Mesorectum	-0.13	0.13	0.29	-0.26	0.19	-0.19	339.46	0.86
Bladder	-0.26	0.22	0.39	-0.52	0.60	-1.00	226	0.65
149 CBCT (supine pts)		R-L (cm)	A-P (cm)	Cr-C (cm)	Volume (cm <sup>3</sup> )	DICE index		
GTV	-0.10	0.17	0.26	-0.23	0.09	-0.10	39.87	0.78

Bladder	-0.15	0.19	0.62	-0.37	0.76	-0.45	236.73	0.69

Figure 1. Mean shift in left-right (L-R), postero-anterior (P-A) and cranio-caudal (Cr-C) directions for GTV (tumor site plus corresponded rectum) and mesorectum

### Conclusion

In our study, GTV and mesorectum IM, evaluated in patients in prone and in supine position, were less than 4mm in all directions. Despite the small number of patients evaluated, we do not observe relevant variation in prone and supine position, even if, in the same deviations, supine position resulted in lesser movement compared to prone position. Our purpose is to increase our evaluation with more patients. Anyway, in both set-up, IM could be obtained with CBCTs and this could be an useful method for appropriate treatment intensification.

### EP-1461 SBRT Pelvic re-irradiation: 2cm "rind" around PTV and small bowel dosimetry of rectal recurrences

S. O'Cathail<sup>1</sup>, T. Smith<sup>2</sup>, Y. Tsang<sup>2</sup>, M. Harrison<sup>2</sup>, M. Hawkins<sup>1</sup>

<sup>1</sup>CRUK/MRC Institute for Radiation Oncology University of Oxford, Oncology, Oxford, United Kingdom ; <sup>2</sup>Mount Vernon Cancer Centre, Oncology, London, United Kingdom

### Purpose or Objective

Management of locally recurrent rectal cancer (LRR) with re-irradiation is challenging. SBRT is an alternative but concerns around small bowel (SB) tolerance remain. We hypothesise the sharp dose gradient of SBRT means that only SB within 2cm of the PTV would be relevant.

### Material and Methods

A prospective nationally maintained database for SBRT re-irradiation was interrogated. Eligibility criteria were

pelvic recurrence in a previously irradiated colorectal cancer, not eligible for exenteration, >6 month disease free survival, >6 month from previous RT, ≤3 metastases, PS 0-1. SBRT dose of 30Gy in 5 fractions in <10 days was specified. Anatomical compartments of site recurrence were mapped using a published atlas. A 2cm 'rind' was added to the PTV and overlapping volume with small bowel was assessed. Clinician reported CTCAE and patient reported Visual Analogue Scale (VAS). Linear regression was used to assess predictive factors of SB D<sub>0.5cc</sub>.

### Results

28 patients with 33 separate pelvic lesions were treated between 10/15 and 06/18. 22 patients had lateral pelvic compartment recurrence. All completed the SBRT. The median age was 64 years (range: 36-84). 27/28 had received 45-50.4Gy in 25-28F with concurrent Capecitabine, 1/28 received 25Gy/5F, all followed by surgery. Including SBRT, the cumulated effective dose received was >100Gy<sub>10</sub>. The median GTV volume was 14.9cc (range 0.47-121.73 cc). 23 lesions had overlap with SB. Median SB overlap volumes in the 2cm rind 12.5 cc (0-179.3). Dose to overlap volumes were median (max) D<sub>0.5cc</sub> =20.6 Gy (36Gy), D<sub>3cc</sub>=16.9Gy (33.6Gy), D<sub>5cc</sub>=17.1Gy (32.4Gy).

With a median FU of 10 months (range 5.4 - 23.4) local control at 1 year was 82.9% (C.I 66% -100%). No grade 3 toxicity was recorded. Median (range) VAS score before radiation was 75 (40-80) and 85 (45-90), a significant improvement (Wilcoxon signed rank, p=0.00861)

GTV volume and non-lateral location were significant predictors of increase overlap SB D<sub>0.5cc</sub> in a linear regression model (GTV p=0.0032, non-lateral, p=0.026; R<sup>2</sup> 0.2872, p=0.0062).

### Conclusion

SBRT in this inoperable re-irradiation cohort of patients produces initial acceptable local control at 1 year. Follow-up is continued for late toxicity events. Lateral pelvic disease, of small size will predicts that D<sub>0.5cc</sub> of small bowel volume within 2 cm of PTV will be lower than for larger non-lateral lesions. We propose limiting dose to 5cc of bowel within 2cm of PTV to 17.1 Gy as new parameter for SBRT re-irradiation.

### EP-1462 Stereotactic body radiation therapy (SBRT) in metastatic colorectal cancer (mCRC)

G.R. Mireia<sup>1</sup>, M.A. Marina<sup>2</sup>, H.M. Ana<sup>3</sup>, S.A. Maria José<sup>2</sup>, L.D.M. Miriam<sup>2</sup>, C.F. Silvia<sup>4</sup>, F.D. Amaya<sup>2</sup>, H.P. Alejandro<sup>5</sup>, L.T. José<sup>6</sup>, C.H. Carlos<sup>7</sup>

<sup>1</sup>Hospital General de Requena /Hopsital General de Valencia, Medical Oncology Department, Requena, Spain ; <sup>2</sup>Hospital General Universitario de Valencia, Medical Oncology, Valencia, Spain ; <sup>3</sup>Eresa Grupo Médico. Hospital General Universitario de Valencia, Radiotherapy, Valencia, Spain ; <sup>4</sup>Hospital General Universitario de Valencia- Universitat de València- Ciberonc, Molecular Oncology Laboratory, Valencia, Spain ; <sup>5</sup>Hospital General Universitario de Valencia- Ciberonc, Molecular Oncology Laboratory, Valencia, Spain ; <sup>6</sup>Eresa Grupo Médico. Hospital General Universitario de Valencia, Head of Radiotherapy, Valencia, Spain ; <sup>7</sup>Hospital General Universitario de Valencia- Universitat de València- Ciberonc, Head of Medical Oncology Department, Valencia, Spain

### Purpose or Objective

It is estimated that 25% of patients with CRC have metastases at diagnosis and up to 50% will develop them during the course of the disease. Although the multidisciplinary treatment in advanced disease has undergone a remarkable improvement in recent years, the median OS of the patients not candidates for surgery is approximately 30 months. Ablative therapies such as SBRT have helped to increase this survival with high local control rates in patients with visceral metastases in retrospective series.

The aim of this study is to analyze the efficacy and safety of treatment with SBRT on metastatic lesions in a cohort of patients with mCRC.

#### Material and Methods

Retrospective study of patients treated with SBRT on metastatic lesions in different locations between February 2012 and August 2016 at the General University Hospital of Valencia. The variables collected in the study were age, sex, location of the primary tumor, date of surgery, stage of the disease, RAS mutational status, location and number of metastases, type of relapse, treatment with SBRT, number of surgeries and previous chemotherapy lines. Statistical analysis was performed using the statistical package SPSS version 20.

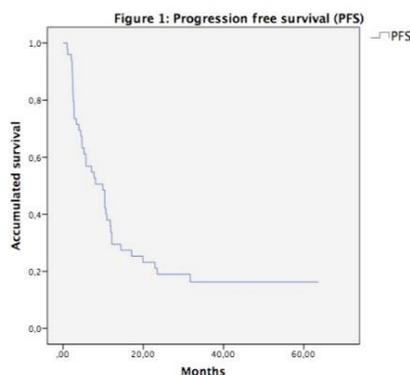

#### Results

A total of 49 patients were included (65.5% men). The average age was 70 years. 89.8% of the primary tumors were located in the left colon. 48% of the cases presented mutation in RAS. The distribution by stage at diagnosis was 10.2% for both stages I and II, 20.4% for III and 59.2% for IV. 83.7% of the metastases were metachronic. 46.9% of the patients were treated with more than 2 chemotherapy lines and 24.5% with  $\geq 2$  surgeries of metastases before the SBRT treatment. 53.1% of metastatic lesions were located in the lung and 30.6% in the liver. 28.6% of lesions treated with SBRT were the first relapse of the disease. 79.6% of the patients had no metastases in other sites at the time of treatment and 44.9% were treated in more than one lesion.

The total dose received in the treatment of SBRT was 45 Gy in 57.4% of the cases (fractionation of 1500cGy/session, 3 sessions, DEB 93.8 Gy) and 22.2% with a dose of 60 Gy. The most frequent adverse events are described in table 1. None of the patients had grade 3-4 events.

The median follow-up was 26.1 months. The PFS after treatment with SBRT was 9.9 months (95% IC 4.6 - 15.1) and the median OS was 28.9 months (95% IC 19.0 - 38.7). No relapses were observed in 20% of the patients after SBRT. Female sex and chemotherapy treatment before SBRT were significantly associated in the multivariate analysis with worse PFS (HR = 3.5,  $p = 0.001$  and HR = 4.81,  $p = 0.002$ ).

Type of toxicity	N (%)
Asthenia	12 (24.5)
Anorexia	4 (8.2)
Pulmonar	0
Cardiac	0
Cutaneous	1 (2)
Digestive	1 (2)

#### Conclusion

Treatment of CRC metastases with SBRT provides a meaningful benefit in PFS with low toxicity. Up to 20% of the patients achieves durable responses. This study supports the implementation of local therapy with SBRT in the multidisciplinary management of mCRC.

#### EP-1463 Radiation dose intensification in rectal cancer: a survey by the AIRO gastrointestinal study group

Gerardo, Department of Radiation Oncology, Monza, Italy; <sup>8</sup>Azienda Provinciale per i Servizi Sanitari- APSS, Proton Therapy Unit- Department of Oncology-, Trento, Italy; <sup>9</sup>Ospedale Belcolle, Department of Radiation Oncology, Viterbo, Italy; <sup>10</sup>Fondazione CNAO, Radiation Oncology Center, Pavia, Italy; <sup>11</sup>Sant'Andrea Hospital- Sapienza University of Rome, Department of Radiation Oncology, Rome, Italy; <sup>12</sup>University of Bologna- S. Orsola-Malpighi Hospital, Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, Bologna, Italy

#### Purpose or Objective

Since a dose-response relationship in rectal cancer has been reported, a boost dose to macroscopic disease could represent a potential strategy to improve oncological outcomes in not responder patients after preoperative long-course radiotherapy (LCRT) or to select patients for which organ-preserving strategies might be possible. The Italian Association of Radiation Oncology (AIRO) study group of gastrointestinal malignancies proposed a national survey to investigate boost volume definition, doses and techniques used for dose intensification in preoperative LCRT for rectal cancer.

#### Material and Methods

In September 2018, an online survey was produced by a restricted group of recognized experts in rectal cancer. Members of AIRO gastrointestinal study group were individually contacted to request their participation to the survey. An expertise in rectal cancer treatment was required on the basis of the professional experience and their involvement in the multidisciplinary team for rectal cancer treatment. The questionnaire had 25 items focused on: center characteristics (5 items), simulation (3 items), imaging (4 items), volumes and doses (5 items), planning and treatment (8 items).

#### Results

Overall, 38 radiation oncologists from different Institutes (north Italy: 25, center: 8, south: 5) joined the study. Twenty-six declared to perform dose intensification preoperative LCRT. The characteristics of patients treated with dose intensification are reported in Table 1. Boost volume is defined as the Gross Tumor Volume (GTV) or as mesorectum area at the level of GTV, with or without additional margins, in 11 (42,31%) and 15 (57,69%) centers, respectively. Boost volume is delineated by

diagnostic imaging as magnetic resonance (MR: 85,71%), computed tomography (CT scan: 39,29%), and/or positron emission tomography (PET-CT: 35.71%). Co-registration with CT simulation is performed in 60.70% of the centers. An isotropic (73%), anisotropic (11,5%) or personalized (15,5%) margin is added for the for planning target volume. Doses are escalated by sequential boost in 6 centres up to 54-55Gy. Concomitant or simultaneous boost is delivered in 20 centers up to 55-60Gy (2.2-2.5Gy/fraction). Intensity-modulated radiotherapy (IMRT) is used in 76,92% of the centers. Intra-operative Radiotherapy or peri-operative Brachytherapy is used in one center. Image-gated RT (IGRT) protocols are used in 22 centers (84,61%). Concomitant chemotherapy based on Capecitabine (57,69%) or 5-FU (42,31%), is administrated in 25 centers (96,15%).

**Table 1.** Characteristics of patients treated with dose intensification preoperative long-course radiotherapy (multiple choice question type).

	N	%
cT4	17	65,38
cT3 MRF+	13	50,00
cN+, extra-mesorectal	9	34,62
cN2	7	26,92
cT3 N0-N+, low rectum	6	23,08
All patients	8	30,77
No-fit patients for surgery and/or CHT	2	7,69

MRF: mesorectal fascia; CHT: chemotherapy

### Conclusion

This survey illustrates the current status of dose intensification in preoperative LCRT in Italy. A high quality of dose escalation treatment was showed as highlighted by volume delineation in the majority of centers based on MR imaging, and on the delivery using IMRT in more than 75%. Future clinical trials are needed to standardize this treatment approach aiming to improve treatment outcomes among locally advanced rectal cancer patients.

### EP-1464 A systematic literature review of rectal re-irradiation: tolerance and outcomes

L. Caravatta<sup>1</sup>, F. Fiorica<sup>2</sup>, A.R. Alitto<sup>3</sup>, C. Rosa<sup>1</sup>, A. Nardangeli<sup>3</sup>, F. Munoz<sup>4</sup>, L. Bianco<sup>4</sup>, L. Giaccherini<sup>5</sup>, G. Timon<sup>5</sup>, F. Dionisi<sup>6</sup>, M. Massacesi<sup>3</sup>  
<sup>1</sup>"SS Annunziata" Hospital- "G. D'Annunzio" University, Radiation Oncology Unit, Chieti, Italy; <sup>2</sup>University Hospital Ferrara, Department of Radiation Oncology, Ferrara, Italy; <sup>3</sup>Fondazione Policlinico Universitario "A. Gemelli"- Catholic University of Sacred Heart, Department of Radiological- Radiotherapy and Hematology Sciences, Rome, Italy; <sup>4</sup>Azienda U. S. L. della Valle d'Aosta, Department of Radiotherapy, Aosta, Italy; <sup>5</sup>Arcispedale Santa Maria Nuova - IRCCS, Radiation Oncology Unit, Reggio Emilia, Italy; <sup>6</sup>Azienda Provinciale per i Servizi Sanitari- APSS, Proton Therapy Unit- Department of Oncology, Trento, Italy

### Purpose or Objective

Standard treatment for locally advanced rectal cancer includes pelvic radiotherapy (RT). Re-irradiation (Re-I) could be required in case of local relapse, that may cause significant morbidity and symptoms impacting quality of life. Unfortunately, Re-I could produce severe normal tissues complications, with variable rate of toxicities. A systematic review, on behalf of the Association of Radiation Oncology (AIRO) study group for the re-irradiation, was conducted aiming to report the toxicity and outcome of pelvic Re-I for rectal cancer recurrences, in terms of local and/or lymph node disease.

### Material and Methods

MEDLINE, EMBASE, OVID, and Cochrane database were used for the systematic search strategy. The computer search was supplemented with hand searches of reference lists. Only studies analyzing outcomes of patients re-treated where Re-I involved overlap with previous RT were taken into consideration. To determine the pooled toxicities rate ( $\geq$ G3), pain relief, overall survival (OS), and local recurrence free survival (LRF5), a meta-analysis technique over single arm study was performed.

### Results

Fourteen studies met the inclusion criteria, published between 2002 and 2017. Only four studies were prospective trials. Overall, 634 patients were analysed in the pelvis for Re-I within the pelvis for rectal cancer recurrences. Median follow-up from Re-I was 18.5 months (4.9 - 40 months). Four studies described the previous irradiation dose, delivered with a median dose of 50.4Gy (45-54 Gy) using a conventional fractionation. The mean time relapsed since previous irradiation was 28.8 months (22 - 47.4 months). Stereotactic RT technique was used for Re-I in 3 studies, carbon ions therapy in 1study, and external beam RT (EBRT) in the remaining studies (10 studies). Variable Re-I doses were prescribed: 25 Gy - 37.5 Gy. A hyper-fractionation schedule was employed in 8 of 10 EBRT studies. Concomitant chemotherapy was given in 501 patients (79%; 10 studies). Overall, 172 episodes of Grade  $\geq$ 3 toxicity were reported; 52 were acute (severe diarrhea, moist desquamation, mucositis) and 120 were late toxicities (chronic severe diarrhea, fistula, small bowel obstructions, pelvic abscess, ureteral stricture, skin ulcerations). Factors influencing toxicities could be identified in surgical resection after Re-I, anterior tumor location, and a shorter retreatment interval of  $\leq$  24months. Pain relief, was evaluated in 10 studies: 88.3% (95% CI: 83.9-92.9%) of patients experienced pain relief. The pooled 2-year OS rate (13 studies) was 54.6% (95%CI:47.8-62.3%). The pooled 2-year LRF5 rate (11 studies) was 49.4% (95% CI: 42.1-57.9%).

### Conclusion

Based on the results of our analysis, rectal Re-I reported moderate rates of acute and late toxicities, although symptoms palliation and local control could be obtained. Prospective studies or large data collections seem to be necessary to define patients selection criteria to ensure maximal benefit of Re-I treatment approach.

### EP-1465 Impact of diabetes on outcome and toxicity of neoadjuvant (chemo)radiation for rectal cancer

D. Bierbaumer<sup>1</sup>, S. Muench<sup>1</sup>, B. Haller<sup>2</sup>, D. Habermehl<sup>1</sup>, P.T. Pfluger<sup>3</sup>, K. Stemmer<sup>3</sup>, S.E. Combs<sup>1</sup>  
<sup>1</sup>Klinikum rechts der Isar- Technical University Munich- Ismaninger Str. 22, Department of Radiation Oncology, 81675 Munich, Germany; <sup>2</sup>Klinikum rechts der Isar- Technical University Munich- Grillparzerstr. 18, Institute of Medical Informatics- Statistics and Epidemiology- Medical School, 81675 Munich, Germany; <sup>3</sup>Helmholtz Zentrum München- Ingolstädter Landstraße 1, Institute for Diabetes and Obesity, 85764 Neuherberg, Germany

### Purpose or Objective

For patients with locally advanced rectal cancer, the German S3- guideline recommends neoadjuvant chemoradiation (nCRT) or short-course neoadjuvant radiotherapy (nRT) with before surgery to improve local control rates. While complete pathologic responses after neoadjuvant treatment are more commonly seen in patients without diabetes, there are conflicting results regarding the impact of diabetes on overall survival. Aim of this study was to compare oncologic outcome and toxicity between diabetic and non-diabetic patients undergoing neoadjuvant (chemo)radiation for rectal cancer.

### Material and Methods

In total, 73 patients with locally advanced rectal cancer who underwent surgery after neoadjuvant chemoradiation

or neoadjuvant short-course radiotherapy, were included in this analysis. Within this cohort, we identified 20 patients with diabetes mellitus type 2 (DMT2) with a median haemoglobin A1c (HbA1c) of 6.2%. Baseline and tumor characteristics, oncologic outcome and toxicity of these patients were compared to 53 patients without diabetes.

#### Results

Patients with DMT2 were significantly older than patients without diabetes (median age 68 vs. 60 years;  $p=0.006$ ). In addition there was a strong trend towards an increased body mass index (BMI) in patients with DMT2 (median BMI 26.8 vs. 24.6 Kg/m<sup>2</sup>,  $p=0.09$ ). After a median follow-up of 49.7 months, there were no significant differences regarding progression-free survival (PFS) between both groups. In contrast, median overall survival (OS) was significantly higher in patients without DMT2 (median OS not reached), compared to patients with DMT2 (45.2 months,  $p=0.006$ ). DMT2 was also confirmed to independently affect OS in a multivariable Cox regression model ( $p=0.029$ ). After nCRT, pathologic complete response was seen in 10% of patients with DMT2 and in 7% of patients without DMT2, ( $p=0.944$ ). Regarding toxicity, diabetic patients had a higher rate of anemia than patients without diabetes ( $\geq 11^\circ$  43% vs. 10%,  $p=0.004$ ). However, no significant differences were seen for the rates of leukopenia ( $\geq 11^\circ$  21% (DMT2) vs. 14% (no DMT2),  $p=0.377$ ) and thrombocytopenia ( $\geq 11^\circ$  0% (DMT2) vs. 0% (no DMT2)).

#### Conclusion

While there were no significant differences for PFS or the rate of complete pathologic remission after nCRT, median OS was significantly higher in patients without DMT2 than in diabetic patients. A significant difference was also seen for the rate of anemia after nCRT, but not for leukopenia or thrombocytopenia.

#### EP-1466 Preoperative chemoradiation with raltitrexid in locally advanced rectal cancer: a systematic review

E. Galofaro<sup>1</sup>, V. Panni<sup>1</sup>, M. Buwenge<sup>1</sup>, A. Guido<sup>1</sup>, G. Macchia<sup>2</sup>, F. Deodato<sup>2</sup>, V. Picardi<sup>2</sup>, M. Boccardi<sup>2</sup>, S. Mignogna<sup>3</sup>, C. Pozzo<sup>3</sup>, F. Di Fabio<sup>4</sup>, A.G. Morganti<sup>1</sup>, S. Cammelli<sup>1</sup>

<sup>1</sup>Policlinico Universitario S. Orsola Malpighi, Radiation Oncology Center- Department of Experimental-Diagnostic and Specialty Medicine - DIMES, Bologna, Italy ; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy ; <sup>3</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Oncology Unit, Campobasso, Italy ; <sup>4</sup>Policlinico Universitario S. Orsola Malpighi, Department of Medical Oncology, Bologna, Italy

#### Purpose or Objective

Neoadjuvant chemoradiotherapy with capecitabine followed by surgery is the standard therapy in patients with locally advanced rectal cancer (LARC). Raltitrexid (RTX) is a specific TS inhibitor with a radiosensitizing effect. No systematic reviews have been performed to analyze the efficacy of RTX based chemoradiotherapy in LARC. The aim of this study was to systematically review available literature to analyze the safety and efficacy of RTX based chemoradiation in terms of pathological CR.

#### Material and Methods

A systematic review of literature published from the earliest date possible to May 2018, using PubMed electronic database was conducted. Only articles reporting at least one of the following patients' outcome: toxicity and/or pathological complete response (pCR) or tumor downstaging were analyzed. Only studies of patients with diagnosis of locally advanced rectal cancer treated with neoadjuvant RTX based chemoradiotherapy alone or combined with other drugs were considered.

#### Results

Fourteen studies were included. All the studies had prospective study design. Median follow up was 40.3 months (range 15-91). Median G3/G4 toxicity and pCR were: 24,8% (range: 16.4-44.4%) and 34.8% (range: 27.7-50.0%), respectively. Moreover, tumor downstaging was reported in nine articles ranging between 53% and 85%.

#### Conclusion

Neoadjuvant chemoradiation with RTX in the preoperative treatment of LARC is reasonably tolerated and able to achieve high pCR rates.

#### EP-1467 KRAS mutation status as predictor factor in locally advanced rectal cancer

M. Campo<sup>1</sup>, S. Flamarique<sup>1</sup>, A. Gemma<sup>1</sup>, L. Alejandra<sup>2</sup>, G. David<sup>3</sup>, M. Fernando<sup>4</sup>, M. Ainara<sup>1</sup>, R. Maitane<sup>1</sup>, R. Lombardo<sup>1</sup>, A. Fernando<sup>1</sup>

<sup>1</sup>Hospital of Navarra, Radiation Oncology, Pamplona, Spain ; <sup>2</sup>Hospital of Navarra, Medical Oncology, Pamplona, Spain ; <sup>3</sup>Hospital of Navarra, Pathology, Pamplona, Spain ; <sup>4</sup>Hospital of Navarra, Physics, Pamplona, Spain

#### Purpose or Objective

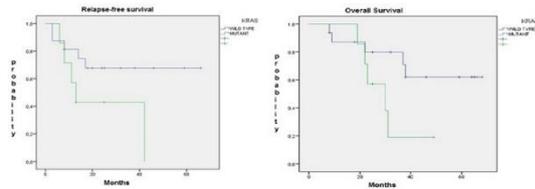

Standard treatment of locally advanced rectal cancer (LARC) includes neoadjuvant chemo-radiotherapy followed by total mesorectal excision (TME). However, some patients have poor tumor response and long-term oncologic outcomes, indicating a lack of benefit from preoperative CRT. The mutation of Kirsten RAS (KRAS) is a molecular transducer and important component of the EGFR pathway and is now widely accepted as a predictor of poor response to anti-EGFR monoclonal antibodies in metastatic colorectal cancer. Nevertheless, few trials have investigated the KRAS status and clinical outcomes in LARC patients treated with neoadjuvant CRT followed by TME. Therefore, we evaluate the Tumor Regression Grade (TRG), Relapse-Free Survival (RFS) and Overall Survival (OS) according to the KRAS oncogene status in LARC.

#### Material and Methods

We evaluated retrospectively 23 patients with LARC treated at our Hospital between January 2013 and August 2018. Tumor DNA was obtained from pretreatment biopsy tissues. Standard polymerase chain reaction analysis was executed to detect specific mutations in KRAS using established primers. All patients received preoperative irradiation of 45Gy in 25 fractions to the whole pelvis at 1.8 Gy/day and 5,4 Gy in 3 fractions to the primary tumor and visible nodes, daily of 5 consecutive days per week. Concurrent chemotherapy was administrated as oral Capecitabine (825mg/m<sup>2</sup> twice daily during radiation time). All patients underwent TME 6-8 weeks after the end of preoperative completion CRT. Tumor regression grade after CRT was classified according to the Mandard grading system; good responders were defined as Mandard TRG1 and TRG2 and bad responders as Mandard TRG3, TRG4 or TRG5. Kaplan-Meier method and the log-rank test were used to compare survival distributions. The significance of correlations between mutation status and tumor regression was assessed by the Chi-square test. All statistical test were 2-sided, and  $p$ -values  $<0.05$  were considered statistically significant.

#### Results

The clinicopathological characteristics of the patients are summarized in *Table1*. KRAS mutation was found in 30,4% of the patients. TRG (1-2) after CRT were 56,2% and 42,8% ( $p= NS$ ), for wild-type and mutant KRAS groups (image1). After a median follow-up of 31 months, there was no difference in RFS (47,7 vs 23,3 months) or OS (51,5 vs 30 months) between wild-type and mutant-type KRAS groups, respectively (image2).

**TABLE 1.** Clinicopathological characteristics of locally advanced rectal cancer patients

Characteristics	No. of patients, %
<b>Gender</b>	
Male	18 (78,3)
Female	5 (21,7)
<b>Age (years)</b>	
Median (range)	63 (49-75)
≤60	11 (47,8)
>60	12 (52,2)
<b>Tumor localization (cm to anal margin)</b>	
High (11-15)	4 (17,4)
Medium (6-10)	13 (56,5)
Low (0-5)	6 (26,1)
<b>Clinical tumor classification</b>	
cT3	19 (82,6)
cT4	4 (17,4)
<b>Clinical nodal classification</b>	
cN0	1 (4,3)
cN1	7 (30,4)
cN2	15 (65,3)
<b>Histologic Grade</b>	
High	9 (39,1)
Moderate	11 (47,8)
Poor	3 (13,1)
<b>CEA level, ng/ml</b>	
≤5	12 (52,2)
>5	11 (47,8)
<b>Tumor regression grade (TRG)</b>	
TRG 1-2	12 (52,2)
TRG 3-4-5	11 (47,8)

**Conclusion**

Clinical trials over the KRAS oncogene status and treatment outcomes in LARC are limited, thus we focused on the potential of KRAS oncogene status as a biological predictive marker. Although KRAS status seems to have slightly better prognosis in patients treated with neoadjuvant CRT followed by curative surgery in LARC, it does not reach significant results (probably due to insufficient sample) in TRG, RFS or OS. It would be interesting to carry out prospective trials with longer follow-up examining KRAS mutation in locally advanced rectal cancer for an increased understanding.

**EP-1468 Radiomics versus volume reduction for rectal cancer response prediction in hybrid MR guided RT**

L. Boldrini<sup>1</sup>, D. Cusumano<sup>1</sup>, J. Lenkowicz<sup>1</sup>, G. Chiloiro<sup>1</sup>, C. Casà<sup>1</sup>, C. Masciocchi<sup>1</sup>, F. Cellini<sup>2</sup>, N. Dinapoli<sup>2</sup>, L. Azario<sup>1</sup>, S. Teodoli<sup>2</sup>, M.A. Gambacorta<sup>1</sup>, M. De Spirito<sup>1</sup>, V. Valentini<sup>1</sup>

<sup>1</sup>Università Cattolica del Sacro Cuore, Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Rome, Italy ; <sup>2</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Roma, Italy

**Purpose or Objective**

Hybrid Magnetic Resonance guided Radiotherapy (MRgRT) represents an innovative therapeutic approach for locally advanced rectal cancer (LARC) patients (pts). Even if daily positioning MR imaging is characterized by low spatial resolution, its superior soft tissue contrast provides better visualization of therapy volumes and allows a direct and reliable visualization of tumor response throughout the treatment. The possibility to apply a radiomics approach to these images is however still under investigation.

Aim of this study was to extract radiomics parameters and compare their performance in complete clinical response (cCR) prediction with tumor volume reduction, known imaging biomarker of response.

**Material and Methods**

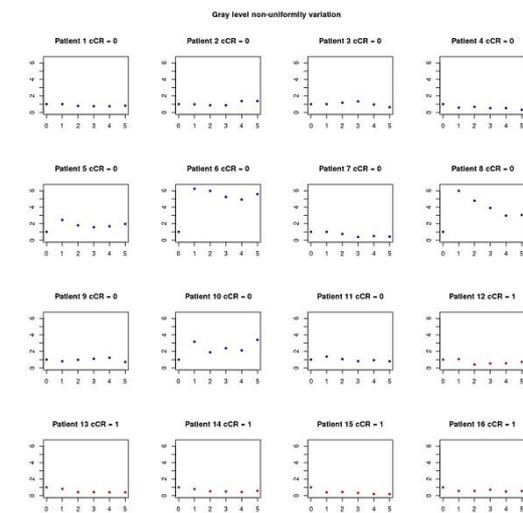

Patients affected by LARC undergoing neoadjuvant chemoradiotherapy on a hybrid 0.35 T MRgRT unit were considered for this analysis.

Prescribed dose was 55 Gy to primary tumor and corresponding mesorectum (PTV1) and 45 Gy to pelvic nodes and mesorectum (PTV2) delivered through a simultaneous integrated boost approach. The cCR was assessed with a MR acquired 6 weeks after chemoradiotherapy and digital examination (DE). An imaging acquisition protocol of 6 true fast imaging with steady state precession (TRUFI) MR scans per pt was performed: the first MR was acquired at first simulation (t0) and the remaining ones at fractions t5,t10,t15,t20 and t25. All the images had a spatial resolution of 1.5x1.5x1.5 mm<sup>3</sup> and an acquisition time of 175 sec. In order to investigate the variation of the radiomics parameters throughout the treatment, all features were normalized respect to the value obtained in simulation (t0).

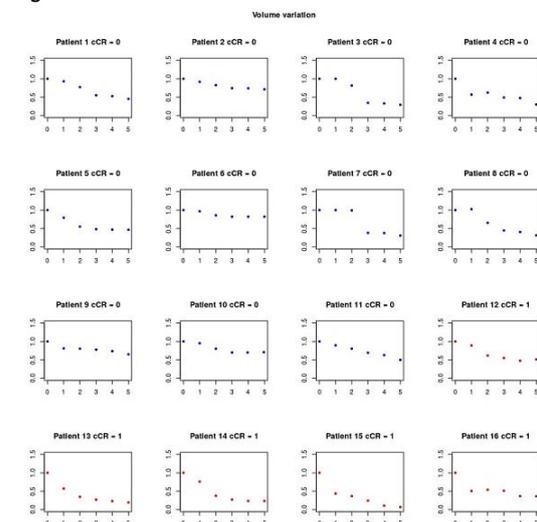

A total of 52 radiomics features (morphological, statistical, textural and fractal) was firstly analyzed, while 254 ratios were calculated.

The Wilcoxon Mann Whitney test was performed to identify the feature whose variation can be more predictive of cCR.

**Fig. 1**

**Fig. 2**

## Results

16 pts (13 male and 3 female) were enrolled, out of which 5 pts (31%) showed cCR.

The most predictive radiomics feature was the “grey level non-uniformity” (*glnu*), whose variation resulted to be always significant in discriminating cCR pts from not responding ones ( $p=0,0375$  at t5;  $0,0005$  at t10;  $0,0133$  at t15;  $0,0032$  at t20;  $0,0380$  at t25).

Volume variation resulted to be significant in 4 of the considered time fractions ( $p=0,0490$  at t5;  $0,0032$  at t10;  $0,0636$  at t15;  $0,0055$  at t20;  $0,0275$  at t25). The trends of *glnu* and volume are reported in figure 1 and 2 respectively for all the pts.

## Conclusion

This hypothesis generating study suggests that hybrid 0.35 T MRgRT images could be suitable for radiomics analyses despite the low spatial resolution and that radiomics parameters may perform better than standard tumor shrinkage measurements in the prediction of cCR.

### EP-1469 Radiation dose to pelvic floor muscles and functional outcome after treatment for anal cancer

C. Kronborg<sup>1</sup>, P. Christensen<sup>2</sup>, B.G. Pedersen<sup>3</sup>, K.G. Spindler<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Oncology, Aarhus C, Denmark ; <sup>2</sup>Aarhus University Hospital, Surgery, Aarhus C, Denmark ; <sup>3</sup>Aarhus University Hospital, Radiology, Aarhus C, Denmark

#### Purpose or Objective

Chemoradiotherapy is the standard treatment for localized anal cancer. However, high dose pelvic radiation is associated with significant both acute and late toxicity. Late and persistent gastrointestinal dysfunction is among the most frequent, debilitating toxicities, with anal incontinence affecting up to 50 %. Radiation dose to the sphincter apparatus, but also to muscles of pelvic floor has been associated to functional gastrointestinal outcome in these patients.

The LARS (lower anterior resection syndrome) questionnaire is a patient reported outcome measure, which evaluates bowel dysfunction after rectal surgery. It consists of five items, all relevant to the late toxicities seen after pelvic radiotherapy: frequent bowel movements, gas and fecal incontinence, fragmentation, and urgency.

We aimed to: i: compare radiation dose to sphincters and pelvic floor muscles in patients with no LARS and major LARS. ii: correlate radiation dose to sphincters and pelvic floor muscles and the 5 individual items in LARS score.

#### Material and Methods

From 2009 to 2015, anal cancer patients were routinely asked to fill out LARS questionnaires at follow-up. For this project all patients with no LARS (score 0-19) were selected from the cohort and an equal number of patients with major LARS (score 30-42).

The Internal and external sphincter (contoured as sphincter complex), levator ani and puborectal muscles were delineated on planning MRI or CT-scans. Dose volume parameters: V50Gy, V60Gy, D90%, Dmean, and Dmax were obtained for each structure and for bowel bag V45Gy and V30Gy.

Differences between patients with no or major LARS were tested by Mann-Whitney U-test, correlations by Spearman’s rank correlation. **Results**

A total of 36 patients were included, 18 patients with no LARS (median 11, range 0-20) and 18 with major LARS (median 37 range 31-39). Gender, age, TNM stage, PTV, chemotherapy, time to LARS score (mean 692 and 749 days) were not statistically different in the two groups. Thirty-three patients were treated with 64 Gy/ 51,2 Gy in 32 fractions, (one with 46 Gy, one 45Gy, and one 54Gy). Thirty patients received therapy with 2 arc VMAT and six with 6-field IMRT.

Dose to sphincter complex (Dmean, V50Gy and D90%) differed significantly between patients with no and major LARS ( $p=0.049$ ,  $0.035$  and  $0.024$  respectively).

There was a significant correlation between D90% to the sphincter complex and the LARS sub-unit “Do you ever have accidental leakage of liquid stool?” (1: yes, 2: no),  $p=0.047$ , with higher risk of incontinence with higher dose. The same applied for V45Gy to the bowel bag and question “How often do you open your bowels?” (1: <1 time per day, 2: 1-3 times per day, 3: 4-7 times per day, 4: >7 times per day),  $p=0.029$ , with higher risk of frequent bowel movements with higher dose. **Conclusion** Specific doses to the sphincter complex could become a useful predictor of anal incontinence and high LARS, and dose to bowl bag a predictor of frequent bowel movements after radiotherapy for anal cancer

### EP-1470 Response assessment in rectal cancer patients treated with MRI-guided RT: preliminary results

Fionda<sup>2</sup>, D. Cusumano<sup>3</sup>, S. Teodoli<sup>3</sup>, V. Valentini<sup>1</sup>, M.A. Gambacorta<sup>1</sup>  
<sup>1</sup>Università Cattolica del Sacro Cuore, Diagnostica per immagini- Radioterapia oncologica ed Ematologia, Roma, Italy ; <sup>2</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS, Diagnostica per immagini- Radioterapia oncologica ed Ematologia, Roma, Italy ; <sup>3</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS, Diagnostica per immagini- Radioterapia oncologica ed Ematologia - U.O.C. Fisica Sanitaria, Roma, Italy

#### Purpose or Objective

To evaluate the efficacy in terms of complete response (CR) of neoadjuvant magnetic resonance-guided radiotherapy (MRgRT) delivered with a hybrid 60Co-MRI unit in locally advanced rectal cancer (LARC) patients (pts).

#### Material and Methods

MRgRT includes daily MRI for setup and real-time cine MRI scans for target tracking.

Pts affected by LARC and clinically eligible for MRgRT were consecutively enrolled.

The clinical target volume (CTV)<sub>1</sub> included the tumor volume and the corresponding mesorectum received 55 Gy/2.2 Gy per fraction and the CTV<sub>2</sub>, including total mesorectum and draining lymph nodes, 45 Gy/1.8 Gy with a simultaneous integrated boost. CTV to PTV margins were 0.5 cm in all directions.

Fluoropyrimidine-based concomitant chemotherapy (CT) was planned, Oxalyplatin was added in selected cases. Acute adverse events were registered according to CTCAE v.4.0 scale.

Surgery was planned at least 8 weeks after the end of chemoradiotherapy (CRT) and pathological complete response (pCR) was defined as ypT0N0.

#### Results

From February 2017 to July 2018 20 LARC pts were enrolled.

Massive lymph nodal involvement (cN1 or cN2) or mesorectal fascia involvement were observed in 30%, 55% and 60% of the cases, respectively. Extra-mesorectal pathological nodes were detected in 30% of pts. Primary lesion was located in low rectum in 40% of the pts. Compliance to CRT was overall good: all pts completed the prescribed treatment.

Fifteen patients (75%) required at least one day of suspension from CRT (average 2,65 days, range 1-10). No patient reported grade 3 or 4 hematological, genitourinary or skin toxicity.

Overall GI adverse events were more commonly reported: 5 pts (25%) showed grade 3 diarrhea during CRT. Two pts (10%) did not undergo surgery as complete clinical response (cCR) was described at restaging exams and confirmed at early follow up assessments and were

addressed to watch and wait. The surgical interval was on average 14 weeks after the end of CRT (range 9-21). Total mesorectal excision was performed in 18 pts (with only 1 abdominal-perineal resection). 22.2% of the pts showed pCR, while the CR overall rate (4 pCR+2 cCR) was 30%. As reported in Tab.1, tumor and nodal downstaging was observed in 65% and 95% of pts, respectively.

Tab1: Tumor and nodal Response according to clinical staging

	ypT0/ycN0	ypT1	ypT2	ypT3	ypT4
cT2			1		
cT3	3	1	2	6	
cT4	3		1	3	
TOT	6	1	4	9	
	ypN0/ycN0	ypN1	ypN2		
cN0	9				
cN1	6				
cN2	8	2	1		
TOT	23	2	1		

All cases in whom there were some kind of response are highlighted

### Conclusion

These preliminary results suggest the possibility to treat LARC pts with MRgRT. Although the limited number, the results seem promising if compared to toxicity data available in literature. MRgRT may potentially support PTV margin reduction and dose-escalation in a tailored and personalized treatment perspective.

### EP-1471 Evaluating the safety and efficacy of neo-adjuvant chemotherapy in locally advanced rectal cancer

K. Saeed<sup>1</sup>, T. Sadaf<sup>1</sup>, A.S. Kazmi<sup>1</sup>, S. Butt<sup>1</sup>, A.A. Syed<sup>2</sup>, M.A. Yusuf<sup>3</sup>

<sup>1</sup>Shaukat Khanum Memorial Cancer Hospital & Research Center., Clinical & Radiation Oncology, Lahore, Pakistan ; <sup>2</sup>Shaukat Khanum Memorial Cancer Hospital & Research Center., Surgical Oncology, Lahore, Pakistan ; <sup>3</sup>Shaukat Khanum Memorial Cancer Hospital & Research Center., Internal Medicine, Lahore, Pakistan

### Purpose or Objective

Standard therapy for locally advanced rectal cancer (LARC) is pre-operative chemo radiotherapy and post-operative chemotherapy. Local recurrence rate for LARC is around 6% while distant recurrence rate is about 25%. Introducing systemic therapy early in the treatment can help control the micrometastasis. Adjuvant chemotherapy is difficult to tolerate due to morbidities of chemoradiation and surgery. We report the safety and efficacy of neo adjuvant chemotherapy before Chemoradiotherapy on tumor downsizing and pathologic complete response (pCR) in Locally advanced rectal cancer.

### Material and Methods

Records of 244 patients treated between April 2007 to November 2014 were retrospectively reviewed, using the hospital information system. Patients were treated by multi-modality approach. Neo adjuvant Chemotherapy used was 3 weekly cycles of Capecitabine 1000mg/m<sup>2</sup> Day 1-14 per oral and Oxaliplatin 130mg/m<sup>2</sup> on Day 1 I/V. Eastern co-operative oncology group (ECOG) performance scale was used to evaluate performance, before chemotherapy. Common terminology criteria for adverse events grades used to measure chemo toxicity.

### Results

226 out of 244 patients received neoadjuvant chemotherapy. Majority of the patients received 4 cycles before the chemoradiation. Patients were reviewed

clinically and via blood tests before each cycle for toxicity of chemotherapy. All of the patients were able to complete the treatment with no major toxicities (Hand-foot syndrome, hematologic, Skin, Neuropathy and diarrhea) of the chemo observed. Pathologic complete response was seen in 41 (23%) of the patients. R0 resection was observed in 70% of patients.

### Conclusion

Neo-adjuvant chemotherapy CapOx can safely be delivered before chemoradiation and planned surgery. It results in tumor regression, a high rate of delivery of planned therapy, and a substantial pathological CR rate. Chemotherapy is well tolerated in the neoadjuvant settings. Further randomized clinical trials are needed to support this evidence.

### EP-1472 Obesity and Colorectal Cancer: Impact of the Gut Microbiota

J. Gomez-Millan Barrachina<sup>1</sup>, L. Sanchez-Alcoholado<sup>2</sup>, A. Otero<sup>1</sup>, R. Ordoñez<sup>1</sup>, D. Castellano-Castillo<sup>2</sup>, Y. Lupiañez-Perez<sup>1</sup>, M.I. Queipo-Ortuño<sup>2</sup>, A. Román<sup>1</sup>

<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology Department, Malaga, Spain ; <sup>2</sup>Hospital Virgen de la Victoria, Clinical Management Unit of Endocrinology and Nutrition- Laboratory of the Biomedical Research Institute of Málaga IBIMA- Virgen de la Victoria University Hospital- Universidad de Málaga- Málaga- Spain CIBER de Fisiopatol,

### Purpose or Objective

Obesity is considered an important factor in the increased risk of colorectal cancer (CRC) (up to 70%), but the role that the intestinal microbial population plays in this link is not well established. The aim of this study was to determine the intestinal microbiota composition in fecal samples from CRC patients with and without obesity compared to the microbiota present in normal-weight healthy controls, in order to unravel the possible association between gut microbiota, the inflammatory level and the intestinal permeability in the context of obesity-associated CRC.

### Material and Methods

The study was conducted over 50 CRC patients (25 patients with BMI < 30 kg/m<sup>2</sup> and 25 patients with BMI > 30 kg/m<sup>2</sup>) who were age and sex paired to 30 normal-weight healthy controls. Fecal bacterial DNA was extracted and analyzed by 16 S rRNA sequencing using an Ion S5 platform and followed by a bioinformatic analysis by QIIME II.

### Results

Patients with CRC had lower bacterial diversity and richness than normal-weight controls, being even lower in CRC subjects with obesity (BMI > 30 kg/m<sup>2</sup>). The microbiota of CRC patients was characterized by a reduction in butyrate and lactate producing bacteria (*Faecalibacterium prausnitzii*, *Roseburia*, *Butyrivibrio* and *Bifidobacterium*) and an increase in opportunistic pathogens (*Streptococcus*, *Fusobacterium nucleatum* and *Escherichia coli*). Moreover, the relative abundance of these opportunistic pathogens was significantly higher in obese CRC patients compared to normal-weight CRC patients and healthy controls. The serum levels of IL-1B (proinflammatory cytokine) and the gut permeability (determined by zonulin levels) were significantly increased in obese CRC patients than in normal-weight CRC patients and healthy controls. Additionally, zonulin levels were significantly correlated with the relative abundance of several microbial groups, being in a positive way with *Prevotella* in normal-weight CRC patients and with *Escherichia coli* in obese CRC patients, while negative associations were found with the relative abundance of *Ruminococcus* and *Faecalibacterium prausnitzii* in normal-weight controls.

### Conclusion

The presence of obesity in CRC patients is related to lower diversity of microbiota, higher gut permeability, higher

presence of opportunistic pathogens such as *Fusobacterium nucleatum*, which in turn could be responsible, at least in part, of the higher levels of inflammation found in these patients. These data point out the importance that gut microbiota could have in the appearance and development of CRC-associated to obesity and could give new clues for the development of new diagnostic tools for CRC prevention.

**EP-1473 Anal adenocarcinoma: a comprehensive review of management practices and clinical outcomes**

Gryfe<sup>5</sup>, E. Kennedy<sup>5</sup>, A. Hosni<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre - University Health Network- University of Toronto, Department of Radiation Oncology, Toronto, Canada ; <sup>2</sup>Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada ; <sup>3</sup>Princess Margaret Cancer Centre - University Health Network- University of Toronto, Department of Medical Oncology, Toronto, Canada ; <sup>4</sup>University Health Network- University of Toronto, Department of Surgical Oncology, Toronto, Canada ; <sup>5</sup>Princess Margaret Cancer Centre - Mount Sinai Hospital- University of Toronto, Department of Surgical Oncology, Toronto, Canada

**Purpose or Objective**

Primary adenocarcinoma of the anal canal (ACC) is rare. There is a lack of consensus regarding the optimal treatment for these patients. The purpose of this retrospective cohort study was to evaluate the multidisciplinary management outcomes of patients with ACC to better define the optimal treatment paradigm.

**Material and Methods**

Patients with anal cancers treated at a tertiary cancer center from Jan 1995 to Dec 2016 were identified. Definitive treatment was either chemoradiation (CRT: 52-63 Gy with concurrent 5-fluorouracil [5FU] and mitomycin-C [MMC]) or trimodality therapy (TMT: abdominoperineal resection [APR] with adjuvant or neoadjuvant CRT [45-50Gy with concurrent 5FU or capecitabine]). Baseline characteristics were compared between the treatment groups. Local (LF) and regional failure (RF), and distant metastasis (DM) cumulative incidences were estimated. The Kaplan-Meier method was used to estimate progression-free survival (PFS) and overall survival (OS). Cumulative incidence and survival outcomes were compared between two treatment groups using the log rank test.

**Results**

There were 1007 cancer patients identified and 89(8.72%) had ACC histology. Eleven (12.4%) had distant metastases, 36(46.2%) were treated with TMT, 23(29.5%) received CRT, 8(8.99%) were treated with wide local excision, 7(7.87%) received palliative care, and 4(4.49%) were treated at outside cancer centers.

The 5-year LF was 9.4% in the TMT group vs 50.8% in the CRT group (p=0.003). (Figure 1a) In the TMT group, 3 patients (2/3 had a positive radial margin) failed locally 3, 8, and 22 months after definitive treatment and were treated palliatively. Out of the 23 patients treated with CRT, 7(30.4%) never achieved a complete response and 9(39.1%) experienced LF. The median time to LF was 4.2 years (CRT) and not reached for patients treated with TMT. Eight of the CRT patients had an isolated local recurrence and were treated with salvage APR. The 5-year cumulative incidence of colostomy was 53.6%. There was no difference in the 5-year RF cumulative incidence (TMT: 10.1% vs. CRT: 21.2%; p=0.231) or DM (TMT: 27% vs. CRT: 25.6%; p=0.734). (Figure 1b,c)

There was no difference in PFS at 5 years (TMT: 48% vs. CRT: 32.2%; p=0.178) and a borderline significant

improvement in OS in patients treated with TMT (TMT: 83.7% vs. CRT: 57.3%; p=0.052). (Figure 2a,b) The median time to death was 5.1 years (range: 0.9 to 15.7 years) in the TMT group and 4.1 years (range: 0.8 to 18.2 years) in the CRT group.

**Conclusion**  
Despite prior reporting, ACC continues to be a therapeutic dilemma for gastrointestinal oncologists. This retrospective cohort suggests a benefit of TMT over non-operative management for ACC although CRT may be considered a reasonable alternative for patients favouring functional organ preservation. The role of adjuvant chemotherapy remains to be elucidated.

**EP-1474 Preoperative RT-CT in locally advanced rectal cancer using different RT doses; our experience**

<sup>1</sup>Ospedale Manzoni di Lecco, Department of Radiotherapy, Lecco, Italy ; <sup>2</sup>Ospedale Manzoni di Lecco, Department of Medical Physics, Lecco, Italy ; <sup>3</sup>Ospedale Manzoni di Lecco, Department of Surgery, Lecco, Italy ; <sup>4</sup>Ospedale Manzoni di Lecco, Department of Clinical Oncology, Lecco, Italy

**Purpose or Objective**

Colorectal cancer (RC) is the most common gastrointestinal (GI) malignancy. More than half patients (pts) affected by RC consist in LARC and preoperative RT-CT followed by total mesorectal excision (TME) is the standard treatment in these pts.. The aim of this study was to evaluate pathological response and toxicities in pts affected by LARC underwent neoadjuvant RT-CT using two different doses.

**Material and Methods**

From January 2014 to September 2018 we analyzed 33 pts affected by LARC treated with neoadjuvant RT-CT followed by surgery. Fifteen pts were female (45,5 %) and 18 pts were male (55,5 %). The median age was 68 years old with a range wide from 36 to 80 years old. Twenty-two pts (Group 1) received 55 Gy in 28 FF (45 Gy to the pelvis and 55 Gy to the T, N+ and mesorectum in SIB technique) + Capecitabine 1650 mg/mq/day; 11 pts (Group 2) received 50.4 Gy to the pelvis in 28 FF + Capecitabina 1650 mg/mq/day. We evaluated clinicopathological characteristics of Tumour (T), Nodal (N), grading, margins, N-down-staging, T-down-staging, tumor regression and sphincter preservation. According to CTCAE vs 5 scale acute and late toxicity was evaluated.

**Results**

After a median follow-up of 38 months (range 3-48 months) the PFS at 2 and 4 years was 93,2% and 82,%, respectively. At histological examination 5 pts (15,2 %) had a T- complete response (CR), 21 pts (63.6%) had N-CR and 4 pts (12.2%) had both T and N-CR. There was no statistically differences between two groups (p-value > 0,05). Tumour down-staging was observed in 23 (66,6%) pts (68 % Group 1 and 63.5 % Group 2; p-value 0,78). Nodal down-staging was reached in 90 % of pts (100 % in Group 1 and 77 % in Group 2; with a trend in favor of Group 1, p-value= 0,082). Four pts had disease progression (2 pts in Group 1 and 2 in Group 2). Of them 3 pts distant metastases and one pt had locally and distant metastases. All pts underwent systemic treatment. Overall sphincter preserving was reached in 79,9 % (90% Group 1 and 65 % Group 2; p-value 0,012). Finally, GI and GU G2/3 acute toxicity was observed in 6 pts (18,2 %): 3/22 (13,6 %) Group 1 and 3/11 (27,2%) Group 2.

**Conclusion**

Neoadjuvant RT-CT with SIB technique and TD of 55 Gy/28ff (45 Gy to the pelvis and 55 Gy to mesorectum, T and N+) showed an advantage regarding N-down-staging and sphincter preserving compared to standard RT treatment (50.4 Gy/28ff). Acute and late toxicity was

acceptable with no statistically differences between two groups. The treatment was well tolerated without statistically differences between two groups. Randomized trials with higher number of pts and longer follow-up are needed to confirm our results

---

**EP-1475 Radiotherapy Is a Safe and Effective Salvage Treatment for Recurrent Cervical Cancer**

H.J. Kim<sup>1</sup>, W.S. Koom<sup>2</sup>, G.E. Kim<sup>3</sup>, Y.B. Kim<sup>2</sup>

<sup>1</sup>Gil Medical Hospital, Department of Radiation Oncology, Incheon, Korea Republic of ; <sup>2</sup>Yonsei Cancer Center, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Jeju National University Hospital, Department of Radiation Oncology, Jeju, Korea Republic of

**Purpose or Objective**

The feasibility of salvage radiotherapy (RT) for patients with recurrent cervical cancer after definitive treatment is contentious. The purpose of this study was to investigate the feasibility and benefit of RT, particularly intensity-modulated RT (IMRT), for salvage treatment in patients with recurrent cervical cancer.

**Material and Methods**

We retrospectively analyzed 125 patients with recurrent cervical cancer treated with RT at Yonsei Cancer Center between January 2007 and December 2016. All patients received salvage RT for the recurred or metastatic tumor mass. Irradiating dose and volume were determined depending on initial treatment. IMRT was selected in challenging cases, such as re-irradiation or for patients for whom implementing a satisfactory 3-dimensional conformal RT plan was challenging.

**Results**

The median follow-up period was 5.5 years (range, 10.8 months to 41 years). The 5-year local failure-free survival (LFFS) and progression-free survival (PFS) rates were 63.9% and 39.6%, respectively. The 5-year overall survival (OS) rate was 66%; 10-year OS reached 51%. The median PFS rates in patients with locoregional failure, distant metastases, or both were 45.4, 29.1, and 14.7 months, respectively (p = 0.005). For the 45 patients that received re-irradiation, 5-year LFFS, PFS, and OS rates were 47.1%, 33.2%, and 66.5%, respectively. Late complications  $\geq$  grade 2 were observed in 12 patients (12/125, 9.6%).

**Conclusion**

Our data suggest that salvage RT is safe and effective against recurrent cervical cancer. IMRT is a safe and effective salvage modality for these patients, including those requiring re-irradiation.

**EP-1476 Validation of a combined PET and MRI radiomics model for prediction of recurrence in cervical cancer**

F. Lucia<sup>1</sup>, D. Visvikis<sup>2</sup>, M. Vallières<sup>2</sup>, M. Desseroit<sup>2</sup>, O. Miranda<sup>1</sup>, P. Robin<sup>3</sup>, P.A. Bonaffini<sup>4</sup>, J. Alfieri<sup>5</sup>, I. Masson<sup>6</sup>, A. Mervoyer<sup>6</sup>, C. Reinhold<sup>4</sup>, O. Pradier<sup>1</sup>, M. Hatt<sup>2</sup>, U. Schick<sup>1</sup>

<sup>1</sup>CHRU Brest, Radiation oncology, Brest, France ; <sup>2</sup>LaTIM-INSEERM- UMR 1101, University of Brest- ISBAM- UBO-UBL- Brest- France, Brest, France ; <sup>3</sup>CHRU Brest, Nuclear Medicine, Brest, France ; <sup>4</sup>McGill University Health Centre MUHC, Department of Radiology, Montreal, Canada ; <sup>5</sup>McGill University Health Centre MUHC, Department of Radiation Oncology, Montreal, Canada ; <sup>6</sup>Institut de Cancerologie de l'Ouest, Radiation Oncology, Nantes, France

**Purpose or Objective**

The aim of this study was to validate previously developed radiomics models relying on just two radiomics features from 18 F-fluorodeoxyglucose positron emission tomography (PET) and magnetic resonance imaging (MRI) images for prediction of disease free survival (DFS) and locoregional control (LRC) in locally advanced cervical cancer (LACC).

**Material and Methods**

Patients with LACC receiving chemoradiotherapy were enrolled in two French and one Canadian centers. Pre-treatment imaging was performed for each patient. Multicentric harmonization of the two radiomics features was performed with the ComBat method. The models for DFS (using the feature from apparent diffusion coefficient (ADC) MRI) and LRC (adding one PET feature to the DFS model) were tuned using one of the French cohorts (n=112) and applied to the other French (n=50) and the Canadian (n=28) external validation cohorts.

**Results**

The DFS model reached an accuracy of 90% (95% CI [79%-98%]) (sensitivity 92-93%, specificity 87-89%) in both the French (figure A) and the Canadian (figure B) cohorts. The LRC model reached an accuracy of 98% (95% CI [90%-99%]) (sensitivity 86%, specificity 100%) in the French cohort and 96% (95% CI [80%-99%]) (sensitivity 83%, specificity 100%) in the Canadian cohort. Accuracy was significantly lower without ComBat harmonization (82-85% and 71-86% for DFS and LRC, respectively). The best prediction using standard clinical variables was 56-60% only.

Figure A

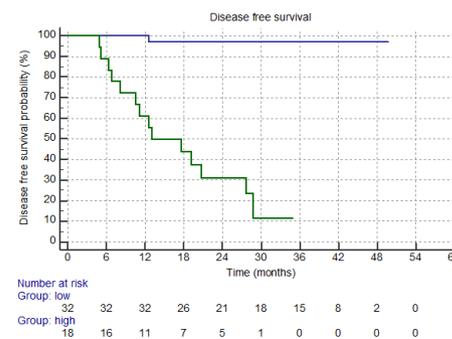

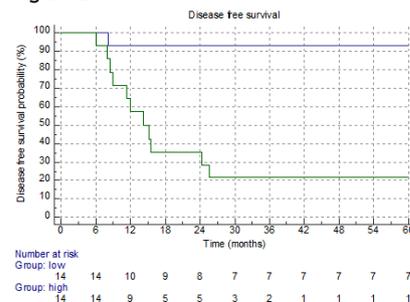

Figure B

**Conclusion**

The previously developed PET/MRI radiomics predictive models were successfully validated in two independent external cohorts. A proposed flowchart for improved management of patients based on these models should now be confirmed in future larger prospective studies.

**EP-1477 Image-guided Intensity Modulated Radiotherapy in cervical cancer: organ motion and geographical miss**

P. Ferrazza<sup>1</sup>, A. Delana<sup>2</sup>, L. Purpura<sup>3</sup>, E. Magri<sup>1</sup>, L. Bandera<sup>1</sup>, V. Vanoni<sup>1</sup>

<sup>1</sup>*Ospedale Santa Chiara di Trento, Radiation Oncology, Trento, Italy*; <sup>2</sup>*Ospedale Santa Chiara di Trento, Medical Physics, Trento, Italy*; <sup>3</sup>*Università degli Studi di Palermo, Radiation Oncology, Palermo, Italy*

**Purpose or Objective**

Volumetric Modulated Radiotherapy (VMAT) is increasingly used in order to minimize toxicity in cervical cancer. However, to prevent geographical misses caused by inter-fraction movement of uterus, the benefit of this approach is detracted by margins applied to Clinical Target Volume (CTV) to obtain Planning Target Volume (PTV). The aim of this retrospective analysis is to verify how variations in bladder filling may cause target miss and unnecessary organs at risk inclusion in high dose regions.

**Material and Methods**

From March 2016 to January 2018 10 patients (pts) with cervical cancer stage FIGO IIB underwent to concurrent radio-chemotherapy (total dose 45-50.4 Gy/25-28 fractions), followed by intrauterine high-dose brachytherapy. Full and empty bladder Computed Tomography (CT) scans were acquired prior the treatment to evaluate uterus, rectal and bowel motion. A VMAT plan based of the CT with full bladder was performed (by Montecarlo algorithm), after image fusion and delineation of the uterus in both CT scans (to create the uterus Internal Target Volume ITV). We applied isotropic margins of 7 and 10 mm respectively to lymph node-cervix and uterus ITV. Daily Cone Beam CT (CBCT) was performed.

We analysed 113 of 273 CBCT, due to the presence of artefacts in images. CBCTs were registered to CT simulation and an operator contoured bladder and uterus on each CBCT.

**Results**

The main cause of uterus motions in our analysis was bladder filling. The uterus shifts are wider in anterior-posterior and superior-inferior directions with larger movements of the fundus and lesser along the endocervical canal. Rectum filling or bowel interposition did not result in uterus motion outside the PTV

88% of CBCTs showed that uterus was included in PTV, especially in pts with correct bladder filling in simulation CT. A further analysis showed that an increase in superior-inferior and antero-posterior margins (anisotropic margins, 1.5 cm vs 1 cm) from uterus ITV, reduces by 9% the risk of target miss (from 12 to 3%). Dose constraints of bowel were respected despite the increase of PTV.

**Conclusion**

Pelvic organ motion is patient specific, and a correct bladder filling in CT simulation seems to reduce geographical misses during radiation treatment. The large CTV-PTV margins can increase gastrointestinal, genitourinary and hematological toxicity, but anisotropic margins in our preliminar analysis improve PTV coverage (respecting dose constraints of bowel and rectum). Due to the small sample size, Further validation of these results is necessary.

**EP-1478 Adjuvant small pelvic field radiotherapy in cervical cancer with intermediate risk factors**

J.A. Solis Campos<sup>1</sup>, B. Tudela Staub<sup>1</sup>, G. Veillon Contreras<sup>1</sup>, I. Perrot rosenberg<sup>2</sup>

<sup>1</sup>*Hospital Carlos Van Buren, oncology, Valparaiso, Chile*; <sup>2</sup>*Universidad de Valparaiso, School of Medicine, Valparaiso, Chile*

**Purpose or Objective**

Adjuvant radiotherapy improves outcomes in surgically treated cervical cancer patients with intermediate risk factors as defined by Sedlis. In our hospital, adjuvant

radiotherapy has been performed using a small pelvic field technique without brachytherapy since 2007. This report aims to analyze the results of those patients in terms of locoregional control, overall survival and acute toxicity.

**Material and Methods**

For this retrospective analysis, all patients treated at the Radiation Oncology Unit of our hospital between 2007 and 2014 were included. Adjuvant radiotherapy without concurrent chemotherapy was administered to FIGO IB1 cervical cancer patients with a combination of  $\geq 2$  of the following intermediate risk factors: lymph-vascular space invasion, deep stromal invasion and/or increased tumor size on pathology. Patients were treated with 3D-conformal radiotherapy, using a small pelvic 4-field box technique, with the upper limit at the inferior border of the sacroiliac joint. Acute genitourinary and gastrointestinal toxicities were classified according to the RTOG grading (G) system. Overall survival and relapse-free survival were analyzed using the Kaplan-Meier method.

**Results**

20 patients treated with small pelvic field radiotherapy were identified. Median follow-up time for the whole group was 37.5 months (IQR 20 - 66.5). Median age was 46 years (IQR 36.5 - 56). Nineteen patients underwent radical hysterectomy and 1 patient underwent radical trachelectomy. Median number of resected lymph nodes was 21.5 (IQR 18-28.5). Reported histologic types were squamous-cell carcinoma (15 patients), adenocarcinoma (2 patients), adenosquamous (2 patients), and clear cell carcinoma (1 patient). Median tumor size was 3 cm (IQR 2.3-3.5). Stromal invasion was 2/3 in 12 patients and 3/3 in 7 patients, and lymph-vascular space invasion was present in 16 patients. The prescribed dose was 50.4 Gy in 19 patients and 45 Gy in one patient. Acute genitourinary toxicity was G0 in 12, G1 in 6, G2 in 1 and G3/4 in 0 patients. Acute gastrointestinal toxicity was G0 in 10, G1 in 4, G2 in 6 and G3/4 in 0 patients.

Three-year relapse-free survival was 84.6%. 3 patients presented relapses; 1 classified as local relapse, 1 located in the retrovesical area, and 1 located lateral to L5 vertebra. Three-year overall survival was 100%.

**Conclusion**

Adjuvant small pelvic field radiotherapy is associated with good oncological outcomes and an excellent toxicity profile in patients with FIGO IB1 cervical cancer with intermediate risk factors. Only one patient experienced a relapse in a region that would have been treated with a standard pelvic field.

**EP-1479 The use of CT texture analysis in cervical cancer to predict response to chemoradiotherapy**

S. Otter<sup>1</sup>, A. Franklin<sup>1</sup>, P. Evans<sup>2</sup>, A. Stewart<sup>1</sup>

<sup>1</sup>*Royal Surrey County Hospital, St Luke's Cancer Centre, Guildford, United Kingdom*; <sup>2</sup>*University of Surrey, Centre for Vision- Speech and Signal Processing, Guildford, United Kingdom*

**Purpose or Objective**

Cervical cancer is the fourth most common cancer worldwide and the 5-year overall survival for stage IIIB disease is only 42%. Treatment for locally advanced cervical cancer (LACC) is chemoradiotherapy (CRT). It would be beneficial to identify at an early stage, patients who may not have a complete response to treatment so that they could have dose escalation or the addition of other systemic agents to improve the chance of cure. Texture analysis (TA) enables the quantification of the spatial heterogeneity of tumours thereby giving more information about a tumour than is available from visual analysis alone. The aim of this study was to apply TA to pre-treatment and brachytherapy CT scans of patients with LACC who were then treated with CRT.

### Material and Methods

46 consecutive LACC patients were included. Patients received CRT, 50.4Gy in 28 fractions and brachytherapy 21Gy in 3 fractions. Pre-treatment radiotherapy planning contrast enhanced CT scans and non-contrast enhanced brachytherapy CT scans (with the tandem and ovoids in situ) were exported from Aria (Varian, USA). The DICOM images were anonymised and imported into the TexRad system (Feedback Medical, UK). The CT slice which corresponded to the most FDG avid part of the tumour on staging PET-CT was used for contouring the region of interest (ROI). Laplacian of a Gaussian filters were applied to the image to highlight features between 2-6mm (labelled SSF 2 to SSF6). Mann-Whitney U test was used to compare TA values for mean, standard deviation (SD), mean positive pixels (MPP), entropy, kurtosis and skewness between a group of patients that achieved a complete response (CR) on the 3-month post-treatment MRI and those patients that achieved a partial response (PR).

### Results

Disease was staged as IB1 in 2%, IB2 in 13%, IIA 2%, IIB 52%, IIIB 13%, IVA 9% and IVB 9%. 33 patients achieved a CR and 13 patients achieved a PR. The TA parameters that yielded significant results from the pre-treatment CT were the SD, entropy and MPP at a spatial scaling factor of 4, 5 and 6 (see figure 1 and table 1) with partial responders having higher values for these parameters than complete responders. 36 patients had brachytherapy scans available which showed significant differences in entropy and skewness at SSF0 ( $p=0.038$  and  $0.017$ ), and in the mean at SSF2 ( $p=0.022$ ) between the patients achieving a CR and those achieving a PR.

TA parameter	SSF	Mean		AUC (95% CI)	P value (Mann-Whitney)
		Complete responders	Partial responders		
SD	4	33.7	42.0	0.69 (0.50-0.88)	0.05
	5	30.9	40.9	0.73 (0.56-0.91)	0.014
	6	28.3	39.9	0.77 (0.62-0.93)	0.005
Entropy	4	4.77	4.96	0.70 (0.51-0.88)	0.042
	5	4.66	4.91	0.75 (0.58-0.92)	0.008
	6	4.54	4.84	0.74 (0.57-0.91)	0.008
MPP	4	27.5	32.8	0.70 (0.52-0.88)	0.037
	5	25.3	32.3	0.75 (0.58-0.93)	0.008
	6	23.6	31.3	0.78 (0.62-0.94)	0.003

### Conclusion

In this cohort, mean values for SD, entropy and MPP from the pre-treatment CT scan were higher in patients who had a partial response compared to those who had a complete response to CRT. TA from the brachytherapy scans was less predictive of response. TA on pre-treatment CT scans could potentially be used in the future to identify patients who need an escalation of treatment. Further work is suggested to examine the correlation of TA parameters with other known prognostic factors for cervical cancer such as stage and nodal status. These results also need to be validated in an independent cohort of patients.

### EP-1480 Radiation therapy for Uterine Cervical Cancer with lung metastases including oligometastases

Y. Mukai<sup>1</sup>, I. Koike<sup>1</sup>, E. Miyagui<sup>2</sup>, M. Hata<sup>1</sup>

<sup>1</sup>Yokohama City University Graduate School of Medicine, Radiation Oncology, Yokohama, Japan; <sup>2</sup>Yokohama City University Graduate School of Medicine, Gynecology, Yokohama, Japan

### Purpose or Objective

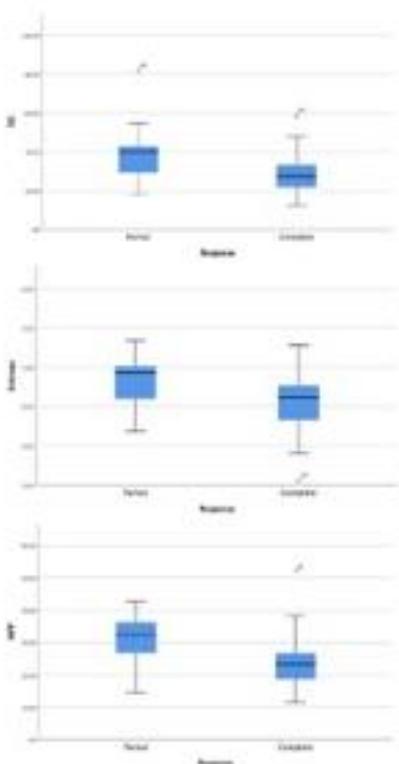

We investigated the role of, and optimal regimen for, radiation therapy (RT) for patients with lung (oligo) metastases from uterine cervical cancer.

### Material and Methods

We enrolled 23 consecutive uterine cervical cancer patients with lung metastases who received pelvic RT between November 2005 and July 2017 (median age: 52 years; range: 39-78 years). All patients had histopathological diagnoses of uterine cervical cancer (squamous cell carcinoma: n=13, 56.5%); 10 had lung metastases only (including 6 with oligometastases, defined as  $\leq 4$  lung metastases); 13 had distant metastases to other sites (para-aortic lymph node, liver, bones, peritoneum and ovary). All patients had bleeding from primary tumors; 5 patients received blood transfusions before RT (median total dose: 59 Gy; 2 Gy per fraction-equivalent dose [ $\alpha/\beta=10$ ], delivered to all patients' uterine cervical cancer tumors). Sixteen patients (69.6%) received concurrent chemotherapy (cisplatin: n=14, 40 mg/m<sup>2</sup> of body surface area; docetaxel/cyclophosphamide: n=2).

### Results

For the 22 patients (95.7%) who completed RT without interruption, 9 (39.1%) had complete response (CR) for primary tumors and 10 (43.5%) had partial responses (PR; initial CR+PR rate: 82.6%). The 1-year primary progression-free rate was 95.2%. Bleeding greatly decreased after treatment (objective hemostatic rate: 100% excluding 2 patients who discontinued RT or who had neuroendocrine carcinoma).

The 1-year overall survival rate was 47.2 % (estimated median survival: 9 months). Five patients were alive, of whom 4 were disease-free at last follow-up. Of 6 patients with oligometastases, 3 were alive and 2 were considered no evidence of disease at last follow-up (median survival time in this group: 31 months).

Significant prognostic factors for survival included <4 lung metastases ( $P = 0.035$ ), unilateral vs. bilateral lung metastases ( $P = 0.039$ ), primary tumor diameter <100 mm ( $P < 0.001$ ), and ECOG performance status <1 at initial treatment ( $P = 0.015$ ).

Lung metastases <10 mm ( $P = 0.14$ ) and concurrent chemotherapy ( $P = 0.07$ ) did not significantly affect survival. No acute or late toxicities > Grade 3 were associated with treatment.

#### Conclusion

RT is safe and effective for patients with lung metastases from uterine cervical cancer. Patients with oligometastases may especially benefit from aggressive treatment.

#### EP-1481 Leukocytosis and Neutrophil to Lymphocyte Ratio: Prognostic Factors in Uterine Cervical Cancer?

S. Garcia<sup>1</sup>, R. Costa Lago<sup>1</sup>, G. Almeida<sup>1</sup>, D. Rodrigues<sup>1</sup>, M.P. Fontes<sup>1</sup>, G. Pinto<sup>1</sup>

<sup>1</sup>Centro Hospitalar de São João, Serviço de Radioterapia, Porto, Portugal

#### Purpose or Objective

Even though the incidence and mortality of invasive uterine cervical cancer have steadily decreased, this disease is still the second most common type of cancer in females worldwide and the leading cause of cancer deaths in women in developing countries. Anemia has long been associated with poor prognosis in patients with cervical cancer. Recently, additional hematological parameters have emerged as potential indicators of a worse outcome in this patient group. In a cohort of cervical cancer patients treated with radiation therapy alone (RT) or concurrent chemoradiation therapy (CCRT) and brachytherapy, we report on prognostic significance of pretreatment hematologic parameters including leukocytosis and neutrophil to lymphocyte ratio (NLR).

#### Material and Methods

Ninety-seven cervical cancer patients were retrospectively identified from a single cancer institution's database (CHSJ - Centro Hospitalar de São João). A database was created with information obtained from patients' clinical records. Hematologic parameters were categorized as: leukocytosis (white blood cells count >  $10 \times 10^9/L$ ) and NLR (high ratio > 5). A demographic analysis of the study sample was performed. The impact of the hematological parameters on progression free survival (PFS) and overall survival (OS) was assessed using the Kaplan-Meier plots and the log rank test for univariate analysis and the Cox regression for multivariate analysis. Statistical analysis was performed with SPSSv24.

#### Results

Of the 97 patients, 10 were in the leukocytosis group and 31 were in the high NLR group. Median age at diagnosis was 58 years and median follow-up time was 56 months. Median PFS was 46 months and median OS was 54 months. Comparing the various groups of patients regarding hematological parameters, the high NLR was significantly associated with worse survival (PFS: 89 vs 118 months,  $p=0.009$ ; OS: 90 vs 118 months,  $p=0.004$ ). Leukocytosis did not show a statistically significant impact on PFS and OS. Multivariate analysis showed that both high NLR and leukocytosis were significant prognostic factors for OS ( $p=0.022$ , CI 95%).

#### Conclusion

Results showed that patients with a high NLR had significantly shorter PFS and OS than those with a low NLR. The leukocytosis and NLR may be promising parameters on which to base the choice of a therapeutic strategy to treat

uterine cervical cancer. This study involved a small sample size of a single institution, so further validation is required prior to incorporating the NLR as a prognostic indicator.

#### EP-1482 Stereotactic rt in ovarian cancer: multicentric retrospective pooled analysis (MITO-RT project)

<sup>11</sup>Fondazione Policlinico Universitario «A. Gemelli»- Università Cattolica del Sacro Cuore-, Department of Women's and Children's health, Rome, Italy

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) represents an interesting opportunity in the treatment of ovarian cancer (OC) isolated recurrences or residual lesions after systemic treatment, and a valid tool to lengthen the free time of re-challenge with platinum. Studies on this topic are sporadic and with few cases. Aim of this multicentric retrospective pooled analysis was to collect the largest unselected real-life dataset of OC patients treated with SBRT in the attempt to define the safety and efficacy. Secondary objectives were to identify the best dose/fractionation regimen in terms of local control as well as to describe acute and late toxicities.

#### Material and Methods

Eight Italian cancer Centers were firstly started the project giving their adhesion to this retrospective pooled analysis. A specific data-set for standardized data collection for ovarian cancer SBRT treatment was developed. Participants were required to fill a data sets including: age, histotype, site of irradiation, previous treatments, best response, toxicity as well as technical/dosimetric data about SBRT treatment.

#### Results

Data on 73 OC patients (median age: 63.5, range 40-83) carrying a total of 120 lesions were considered suitable for analysis. Between 2005 and 2018 all patients underwent SBRT in single or multiple fractions with a median biological equivalent dose (BED<sub>α/β 10</sub>) of 76.8 Gy (range 7.5-262.5). Patient and treatment characteristics as well as acute toxicity are detailed in Table 1. Safety. 52 patients (71.3%) did not experience acute toxicity, the others 21 (28.7%) experienced low grade acute toxicity with no patient showing > grade 2 toxicity. With a median follow-up of 18 months (range: 1 - 120), 68 patients (93.1%) did not experienced late toxicity, the others 5 (6.9%) experienced low grade late toxicity with no patient showing > grade 2 toxicity. Efficacy. On a per-lesion basis, the 12-and 24-months actuarial local control inside SBRT field were 88.3% and

86.2%, respectively. BED10 > 50Gy was correlated with a better 12-months local control (91.7% versus 72.9%, p=0.034).

Table 1. Patients' characteristics, treatment details and acute toxicity

	No. patients (%)	No. lesions (%)
	73	120
Age, years, median (range)	63.5 (40-83)	
Histotype		
Serous		85 (71.0)
Endometrioid		21 (17.5)
Clear cell		5 (4.1)
Mixed epithelial		2 (1.7)
Indifferentiated		5 (4.1)
Mixed malignant Mullerian tumor		1 (0.8)
Other		1 (0.8)
Type of lesion (%)		
Lymph Node metastases		62 (51.7)
Parenchymal lesions		56 (46.6)
Bone metastases		2 (1.7)
Patients treated by previous chemotherapy cycles	48 (95)	
N° of chemotherapy schedules, median (range)		3 (1-7)
Patients treated by previous surgery	73 (100)	
Gross tumor volume (cc), median (range)		3.9 (0.04-88.4)
Planning target volume (cc), median (range)		18.28 (0.04-224)
Median SBRT dose (Gy), range		36 (5-75)
Median SBRT dose BED 10 (Gy), range		78.8 (7.5-282.5)
Median SBRT dose per fraction (Gy), range		7.5 (5-30)
SBRT N° fractions		1-10
Reference dose		
ICRU 52/isocenter		54 (45.0%)
Target mean		51 (42.5%)
Specific isodose		55 (45.5%)
Acute toxicity		
Grade 0	52 (71.3)	
Grade 1: Gastrointestinal (11), pain (2), other (2)	15 (20.5)	
Grade 2: Gastrointestinal (2), pain (2), other (2)	6 (8.2)	

## Conclusion

Preliminary results on a population-level confirm that SBRT delivered in 1-10 consecutive fractions is safe and well tolerated notwithstanding several previous surgical and systemic treatments. Therefore, this treatment can be considered as a further resource in order to lengthen the free time of re-challenge with platinum.

## EP-1483 Stereotactic Body Radiation Therapy Boost for Stage IA - IIB Cancers of the Cervix: 5-Year Results

S. Dalwadi<sup>1</sup>, M. Ludwig<sup>1</sup>, N. Waheed<sup>1</sup>, D. Tran<sup>1</sup>, M. Bonnen<sup>1</sup>, C. Mantz<sup>2</sup>  
<sup>1</sup>Baylor College of Medicine, Radiation Oncology, Houston, USA ; <sup>2</sup>21st Century Oncology, Radiation Oncology, Fort Myers, USA

## Purpose or Objective

SBRT for cancers of the cervix may offer an alternative to brachytherapy for those patients who are not candidates for brachytherapy procedures. SBRT dose-fractionation schedules may be selected to approximate those of HDR in order to achieve similar radiobiologic dosing, while SBRT technique eliminates the need for applicator placement and sedation. Herein, we report health-related quality of life, toxicity and disease control outcomes of a multi-institutional series of SBRT for primary cervical cancers.

## Material and Methods

Eligible patients included those with (1) pathologically confirmed cervical squamous cell carcinoma or adenocarcinoma; (2) FIGO stage IA, IB, IIA or IIB disease; and (3) medical or technical contraindication to brachytherapy or patient refusal of brachytherapy. Prior to SBRT, all patients received pelvic EBRT to a prescribed dose of 45.0-50.4 Gy; pelvic nodal boost (total EBRT dose, 55.9-66.0 Gy) was permitted. All patients received cisplatin-based chemotherapy concurrent with EBRT. SBRT boost treatment planning then followed, and HR-CTV delineation was aided by co-registration of the boost planning CT to a post-EBRT MRI. A boost dose of 14.0-40.0 Gy was prescribed to the post-EBRT HR-CTV and delivered over 4-5 fractions. Assessments included (1) disease response assessed through post-treatment surveillance per institutional protocol; (2) acute and chronic toxicities assessed using the U.S. National Cancer Institute's CTCAE v3 toxicity scales; and (3) quality-of-life scored using FACT-G measurements.

## Results

Sixty-seven patients have been treated since June 2007 and have been followed for a median of 60 months (range, 5-120 months). Forty patients have been followed for a minimum of 5 years. Stage distribution was as follows: 2/67 stage IA, 6/67 stage IB1, 18/67 stage IB2, 3/67 stage

IIA1, 6/67 stage IIA2 and 32/67 stage IIB. Mean SBRT V100 was 95.3% (range, 75.0-99.8%), and mean total equivalent effective doses (EQD2) to 2 cc of bladder and rectum were 72.91 and 64.86 Gy, respectively. Post-SBRT complete response rate was 94.0% at 3 months for all patients based on clinical assessment with or without biopsy; among patients who underwent planned biopsy at 3 months, 52 of 55 demonstrated complete pathologic response. At 5 years, estimated local control at the SBRT boost site is 90.8% for all patients. Estimated failure-free survival and overall survival at 5 years are 83.1% and 74.7%, respectively. Two patients suffered grade 3 toxicities (urinary frequency, vaginal stenosis), and no patient experienced ≥ grade 3 bowel toxicity. Post-treatment FACT-G scores were available for 82% of cases and were statistically superior at 2 and 5 years compared to pre-treatment assessments for the following studied domains: physical, emotional and functional well-being.

## Conclusion

At a median followup of 5 years, SBRT appears to offer an effective and well-tolerated boost modality for selected stage IA-IIB cervix cancer patients who were otherwise contraindicated for brachytherapy.

## EP-1484 Neoadjuvant CT followed by chemoradiation in locally advanced cancer cervix : feasibility and QOL study

S. Singh<sup>1</sup>, S. Sadhan Sarangi<sup>1</sup>, P. Misra<sup>2</sup>, D. Kapoor<sup>3</sup>, A. Rani<sup>3</sup>, N. Rastogi<sup>1</sup>, S. Kumar<sup>4</sup>

<sup>1</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept. of Radiotherapy, Lucknow UP, India ;

<sup>2</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept. of Biostatistics, Lucknow UP, India ;

<sup>3</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept. of Gynecology- General Hospital, Lucknow UP, India ; <sup>4</sup>Sanjay Gandhi Postgraduate Institute of Medical Sciences, Dept. of Radiotherapy-Super Speciality Cancer Institute and Hospital, Lucknow UP, India

## Purpose or Objective

To assess feasibility, response rate and quality of life (QOL) in locally advanced cervical cancer patient treated by 3 weekly neoadjuvant chemotherapy (NACT) followed by chemoradiation (CCRT).

## Material and Methods

Between April 2016 - March 2017, 30 cervical cancer patients, FIGO stage IB2 to IVA, histopathologically proven, eligible and consented for the prospective study were included. Patients received 2 cycles of NACT using Inj. capecitabine 175mg/m<sup>2</sup> and Inj. cisplatin 35mg/m<sup>2</sup> or carboplatin AUC5 as 3 weekly schedule followed by definitive radiation therapy along with concurrent weekly cisplatin 35mg/m<sup>2</sup> or carboplatin AUC2 chemotherapy. The primary end point was to assess feasibility of NACT and overall response at 3 months post NACT-CCRT, toxicities, and QOL (using EORTC C30, CX 24 and OV 28 questionnaires). Analysis were intention to treat.

## Results

The median age was 53 years. 53% had FIGO stage III followed by stage II 40% with >50% having bulky disease. One fifth of patients had both regional and para aortic lymph nodes at presentation based on imaging criteria. 27/30 patients (90%) received planned 2 cycles of NACT while 3 received 1 cycle either due to side effects (n= 2) or administrative error (n=1). The overall clinical response rate post NACT was 76% with complete disappearance of disease seen in 1 patient (3%). 29/30 completed planned radiation treatment with 90% receiving concurrent chemotherapy with a median number of 5 cycles. At 3 months, post completion of all planned treatment 25/30 (84%) of patients had clinically complete disappearance of disease and 3(10%) had partial response using clinical and imaging findings. NACT was well tolerated with only 11% experiencing any grade 3/4 toxicities and no treatment-

related deaths. During CCRT 4% of patients had grade 3/4 hematological while 7% non hematological. With median follow-up of 21 months (Q1-Q3: 15-24 months) the 1 year progression free survival, distant disease survival and overall survival were 80%, 79% and 87% respectively.

The global health score showed moderate increment after treatment and at 6 months follow up (FU) suggesting an improvement in QOL post therapy. In general for both functional and symptom scales, QOL improved during FU from baseline but difference was not significant. Overall symptom experience declined significantly following completion of NACT and CCRT as compared to baseline score. There was trend towards significant difference in sexual activity score over four time period but sexual enjoyment and vaginal function scores could not be analyzed reliably as majority of patients chose not to answer the questions which highlights social stigma related to sex prevalent in society. There was a significant difference in financial difficulty as faced by patient during treatment period as compared to FU period.

#### Conclusion

2 cycles of 3 weekly NACT followed by CCRT in locally advanced cervical cancer had a good response and outcome with acceptable toxicities and without much impact on quality of life

#### EP-1485 Role of PET-CT in patients of recurrent carcinoma cervix treated with definitive chemoradiotherapy

M. Rastogi<sup>1</sup>, A.K. Gandhi<sup>1</sup>, R. Khurana<sup>1</sup>, S.S. Nanda<sup>1</sup>, H.B. Singh<sup>1</sup>, S. Rath<sup>1</sup>, P.C. Rai<sup>1</sup>, S. Kumar<sup>1</sup>, A. Bharati<sup>1</sup>, A.K. Srivastava<sup>1</sup>, S.P. Mishra<sup>1</sup>

<sup>1</sup>Dr. Ram Manohar Lohia Institute of Medical Sciences, Radiation Oncology, Lucknow, India

#### Purpose or Objective

We did this retrospective study to evaluate the role of positron emission tomography (PET-CT) in predicting the clinical outcome of patients with recurrent cervical carcinoma following definitive radiation therapy.

#### Material and Methods

Between July 2015 and June 2017, 40 histo-pathologically proven patients of carcinoma cervix treated with definitive radiotherapy or chemoradiotherapy and declared cured after the completion of their treatment were included. Patients were required to have a diagnosis of recurrent cervical cancer established by histopathology (biopsy or cytology) or clinically evident recurrent disease with a minimum of three months gap between recurrence and completion of radiotherapy. Patients with persistent residual disease and those having distant metastatic disease on conventional imaging (Abdominal CT scan or chest X-ray) were excluded from the study. 18-fluorodeoxyglucose (FDG) PET imaging was performed in each patient before the salvage therapy but was not used for guiding treatment decisions. The maximum standardized uptake value (SUV max) and metabolic tumor volume (MTV) were measured and correlated with cumulative progression free survival (PFS). The MTV was calculated as 60% of the volume covered by the SUV max. SPSS version 20.0 was used for statistical analysis.

#### Results

Median age of the patient was 47 years (Range 30-66 years). 22 patients had stage IIIB, 13 had stage II B, 3 patients had stage III A disease and 2 patients had stage IV disease in the pre-salvage workup. The median recurrence free period was 11 months (Range 3.5-36). 25 patients were treated with Re-irradiation (with EBRT doses of 20-36 Gy ± HDR interstitial brachytherapy of 10-20 Gy in 1-2 sessions), 4 patients underwent surgery (2 Radical hysterectomy and 2 Pelvic exenteration), 6 patients received palliative radiotherapy alone (Dose 5-20 Gray), 4 patient received palliative chemotherapy (with regimen consisting of Paclitaxel and Carboplatin, 3-6 cycles) and 1

patient was put on best supportive care. Median follow up period was 11 months (Range 3-29 months). Median SUVmax was 5.8 (range 2.9-56.2) and median MTV was 43 cm<sup>3</sup> (range 7.8-212). The cumulative PFS for all patients was 30% at 24 months. The one year PFS was 26 % for patients with SUVmax value of >5.8 versus 47 % for those with SUVmax value of <5.8 (P value 0.02). The one year PFS was 41% for patients with MTV of >43cm<sup>3</sup> versus 43% for those with MTV of <43 cm<sup>3</sup> (P value 0.8)

#### Conclusion

Post irradiated recurrent cervical carcinoma patients with SUVmax of <5.8 have a favourable outcome compared with those with SUVmax of >5.8 and should be selected for aggressive salvage therapy. Further prospective studies are needed to validate the findings of our study.

#### EP-1486 Role of HPV DNA testing and its influence on clinical outcomes in Cervical Cancer

P. Jayaprakash<sup>1</sup>, G. Narayanan<sup>1</sup>

<sup>1</sup>Vydehi Institute of Medical Sciences and Research Centre, Radiation Oncology, Bengaluru, India

#### Purpose or Objective

Persistent infection with Human Papillomavirus (HPV) is the major etiological factor for development of cervical cancer. Although the standard treatment of locally advanced cervical cancer includes Definitive Chemo Radiation, little is known about the impact of HPV on the response to chemo radiation and on the clinical outcome. Primary objective was to compare treatment response of cervical carcinoma patients infected with HPV 16 and HPV 18 who are treated with Definitive Chemo Radiation. Secondary Objectives was to find out the HPV positivity rate in diagnosed cervical cancer cases, to estimate the number of HPV high risk genotypes and to compare response between positive and negative cases of HPV in the same study group

#### Material and Methods

96 patients who presented to our institute were included for the study. Inclusion criteria were patients with biopsy proven carcinoma of the uterine cervix considered suitable for curative treatment with definitive radio-chemotherapy with Performance Status 0-2 (ECOG) and International Federation of Gynecology and Obstetrics (FIGO) Stages IB2 to IIIB. HPV testing was done using TRU PCR® HPV 16&18 Real-Time PCR kit. All the patients received External Beam Radiation therapy (EBRT) on Linear Accelerator with 3 Dimensional Conformal Radiotherapy (3DCRT) to a dose of 4600cGy in 23 fractions, 5 fractions per week and weekly Chemotherapy regimen consisted of Cisplatin 40 mg/m<sup>2</sup> during EBRT. Three fractions of High-dose rate Intracavitary Brachytherapy was delivered after completion of EBRT with a fraction dose of 7 Gy at point A. Treatment response assessment was done using Response evaluation criteria in solid tumors (RECIST) criteria. Clinical examination was performed at completion of EBRT and at 3rd month follow up. Radiological response was assessed using MRI at 3rd month follow up

#### Results

96 patients of Cervical Cancer were tested for HPV DNA, of which 79 (82.3%) patients were positive. 73 patients showed HPV genotype 16 and 6 patients were positive for genotype 18. The response was correlated with HPV genotype. There was a significant increase in radiological complete response in HPV16 compared to HPV 18 and HPV negative groups at 3 months, 80.8%, 50% and 52.9% respectively (x<sup>2</sup>=36.5, p<0.001). There was also a significant increase in clinical response at 3 months in HPV 16 group compared to HPV 18 and HPV negative groups, 87.5%, 50% and 50% respectively (x<sup>2</sup>=29.9, p<0.001). The age of the patient, volume of the disease, overall treatment time, and average Hemoglobin level and number of blood transfusions did not have any correlation.

HPV status/Genotype	Complete response	Partial response	Stable disease	Progressive disease	Pearson Chi Square	
<b>Response at completion of EBRT</b>						
HPV Negative	3 (17.6)	13 (76.5)	1 (5.9)		2.54	0.59
HPV 16 positive	13 (17.8)	57 (78.1)	3 (4.1)			
HPV 18 positive	0 (0)	5 (83.3)	1 (16.7)			
<b>Radiological response at 3 months</b>						
HPV Negative	9 (52.9)	8 (47.1)	0	0	36.5	P<0.001
HPV 16 positive	59 (80.8)	14 (19.2)	0	0		
HPV 18 positive	3 (50)	1 (16.7)	1 (16.7)	1 (16.7)		
<b>Clinical response at 3 months</b>						
HPV Negative	8 (50)	7 (43.8)	0	1 (6.2)	29.9	P<0.001
HPV 16 positive	63 (87.5)	9 (12.5)	0	0		
HPV 18 positive	3 (50)	2 (33.3)	1 (16.7)	0		

### Conclusion

HPV genotype 16 positivity shows higher complete response in Cervical Carcinoma patients treated with Definitive Chemo Radiation compared to HPV 18 genotype. Further, HPV genotyping could potentially help to stratify cervical cancer patients for more effective therapeutic regimens

### EP-1487 Prognostic value of 18F-FDG PET/CT parameters in patients with locally advanced cervical carcinoma

S. Cordoba Largo<sup>1</sup>, V. Garcia Jarabo<sup>1</sup>, D. Martinez<sup>1</sup>, M. Ramirez<sup>1</sup>, M. Gaztañaga Boronat<sup>1</sup>, C. De la Fuente<sup>2</sup>, G. Marquina<sup>1</sup>, A. Ortega<sup>1</sup>, R. Mendez<sup>1</sup>

<sup>1</sup>Hospital Clinico San Carlos, radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Universitario Puerta de Hierro, radiation ONcology, Madrid, Spain

### Purpose or Objective

To investigate the value of pretreatment intensity-based 18F-FDG PET/CT parameters as predictors of outcome and para-aortic lymph node involvement in patients with locally advanced cervical carcinoma (LACC) treated with concurrent external beam radiotherapy and chemotherapy (CRT) followed by image-guided brachytherapy (IGBT-MRI).

### Material and Methods

From November 2010 to February 2016 we treated 65 patients with stages IB-III cervical carcinoma. Mean age: 54.6 y (30-88). TNM stage: I: 4 p, II: 54 p and III: 6 p. Histology: epidermoid: 49 p; adenocarcinoma: 15 p. All patients were treated with CRT and 3D-based planning intracavitary/interstitial IGBT, using the GEC-ESTRO recommendations for defining high-risk clinical target volume (HR-CTV). Equieffective doses at 2 Gy (EQD2) were calculated, applying linear quadratic model. In 34 p. (45%) a laparoscopic para-aortic lymphadenectomy was performed before treatment.

In all patients a pretreatment <sup>18</sup>F-FDG PET/CT was performed to determine the metabolic tumoral volume (MTV) and tumor standardized uptake value (SUVmax). In 56 p (87%) a second <sup>18</sup>F-FDG PET/CT before IGBT were used to classify patients as metabolic responders (MR) or non- metabolic responders (nonMR) according to the EORTC criteria.

Statistics: Student's T test for media comparison, chi-square test for comparing proportions and Kaplan Meier for survival analysis and log-rank for curve comparison.

### Results

After median follow-up of 30 months (10-90), 3-year overall survival (OS), 3-year disease-free survival (DFS), local relapse-free survival (LCFS), pelvic relapse-free survival (PRFS) and distant metastases disease-free survival (DMFS) were 83.7%, 58%, 84.2%, 86.3% and 86.8%, respectively.

Only 3/29 p with negative para-aortic PET/CT had pathologically involved nodes (negative predictive value, NPV: 89.6%). Treatment-related factors, D90/D98 HR-CTV and OTT, had no prognostic value. Patients with positive

para-aortic lymph node had a non-significant trend towards worse OS (54.7% vs 91.3%, p=0.06) and DMFS (75% vs 90.8%, p=0.06). Patients with a PET-CT MTV<24 cc had a better 3-y OS when comparing with MTV >24 cc (85% vs 56%, p=0.009). Pretreatment SUVmax did not influence outcome. Early <sup>18</sup>F-FDG PET/CT-based response assessment using the EORTC criteria was not correlated with disease control (3-y OS and LRFS), although patients with SUVmax < 5 had a non-significant trend towards better 3-y LRFS? (91% vs 78%, pNS).

### Conclusion

In our series pretreatment PET-CT MTV was a good predictor of OS. Owing the high NPV observed in our study, a para-aortic lymphadenectomy can be avoided in patients with negative para-aortic <sup>18</sup>F-FDG PET/CT. In our experience, early <sup>18</sup>F-FDG PET/CT-based response assessment before IGBT was not useful in predicting outcome.

### EP-1488 Treatment of early stage intermediate-risk endometrial cancer using MIS and adjuvant radiotherapy

J. Song<sup>1</sup>, T. Le<sup>2</sup>, M. Gaudet<sup>1</sup>, C. Ee<sup>1</sup>, K. Lupe<sup>1</sup>, R. Samant<sup>1</sup>  
<sup>1</sup>The Ottawa Hospital, Radiation Oncology, Ottawa, Canada ; <sup>2</sup>The Ottawa Hospital, Gynecologic Oncology, Ottawa, Canada

### Purpose or Objective

Modern series of technical skills in minimally invasive surgery (MIS) using robotic arm for total abdominal hysterectomy and bilateral salpingo-oophorectomy (TAH-BSO) have resulted in improvement in patient outcome with endometrial cancer. MIS has been increasingly used since its introduction in 2010 at our institution. Randomized prospective studies have shown that adjuvant radiotherapy (RT) following TAH-BSO significantly improves loco-regional control among stage I intermediate-risk patients. Our study aims to elucidate the current use and efficacy of MIS using robotic arm and adjuvant RT among these patients at our institution.

### Material and Methods

A single-center retrospective study was conducted on patients with FIGO stage I endometrioid-type endometrial cancer with intermediate risk factors as defined by PORTEC-1 (<50% myometrial involvement and Grade 2-3, or >50% myometrial involvement Grade 1-2), who have undergone TAH-BSO and adjuvant RT at our institution between 2010 and 2015. Data on surgical and radiation treatments, as well as patient and tumor characteristics were collected and correlated with clinical outcomes. Statistical analysis was carried out using Kaplan-Meier method to compare clinical outcomes to previously reported studies.

### Results

A total of 179 stage I intermediate-risk endometrial cancer patients were identified and 135 (75.4%) patients who received adjuvant RT were selected for study. Median age at diagnosis was 63 years (range 40-89 years) and median follow-up was 4.4 years. Surgical staging was performed with pelvic lymph node dissection on 107 (79.3%) patients, while 94 (69.6%) and 41 (30.4%) patients underwent MIS and traditional laparotomy, respectively. Twenty-eight (20.7%) patients received external beam radiotherapy (EBRT, 45Gy in 25 fractions) in the form of intensity-modulated radiotherapy (IMRT) and 107 (79.3%) patients received vaginal brachytherapy (VBT, 30Gy in 3 fractions). Five-year disease-free survival and overall survival rates were 92.8% and 94.8%, respectively. Estimated 5-year loco-regional relapse rate (vaginal, pelvic, or both) was 2.3%.

### Conclusion

Clinical outcomes for stage I intermediate-risk endometrial cancer at our institution remain excellent with few loco-regional recurrences, and are comparable

to that of previously published randomized studies. Our results confirm that MIS using robotic arm combined with adjuvant RT, especially VBT, should be offered for patients with stage I intermediate-risk endometrial cancer.

**EP-1489 How effective is adjuvant radiotherapy in the management of stage I high-risk endometrial cancer?**

J. Song<sup>1</sup>, T. Le<sup>2</sup>, M. Gaudet<sup>1</sup>, C. Ee<sup>1</sup>, K. Lupe<sup>1</sup>, R. Samant<sup>1</sup>  
<sup>1</sup>The Ottawa Hospital, Radiation Oncology, Ottawa, Canada ; <sup>2</sup>The Ottawa Hospital, Gynecologic Oncology, Ottawa, Canada

**Purpose or Objective**

A recent randomized controlled trial (PORTEC-3) has demonstrated that in endometrial cancer patients with high-risk features, compared to radiotherapy alone, addition of chemotherapy to radiotherapy results in a significant improvement on failure-free survival. However, in the study, the effect of chemotherapy was limited to stage III patients, while the benefit was less pronounced in stage I and II patients. Our study aims to investigate clinical outcome in stage I high-risk endometrial cancer patients who received radiotherapy only, and compare patient outcomes to those from the previous literature.

**Material and Methods**

A single-center retrospective study was conducted on women with high-risk endometrial cancer with FIGO 2009 stage I, endometrioid-type grade 3 with deep myometrial invasion or lymph-vascular space invasion, or both, who have undergone hysterectomy at our institution between 1998 and 2015. Data on surgical and radiation treatments, as well as patient and tumor characteristics were collected and correlated with clinical outcomes. Statistical analysis was carried out using Kaplan-Meier method to compare clinical outcomes to previously reported studies.

**Results**

A total of 46 stage I high-risk endometrial cancer patients were identified. Median age at diagnosis was 63 years (range 49-86 years) and median follow-up was 4.2 years. All patients underwent total abdominal hysterectomy and bilateral salpingo-oophorectomy (TAH-BSO). Surgical staging was performed with pelvic lymph node dissection on 38 (82.6%) patients, while 35 (76.1%) and 11 (23.9%) patients underwent minimally invasive surgery (MIS) and traditional laparotomy, respectively. Thirty-four (80.4%) patients underwent adjuvant radiotherapy alone (31 patients with external beam radiotherapy, EBRT, 45Gy in 25 fractions; and 3 patients with vaginal brachytherapy, 30Gy in 3 fractions), two (4.3%) patients underwent combined chemoradiotherapy (chemotherapy with 6 cycles of intravenous carboplatin and paclitaxel; radiotherapy with EBRT), and 9 (19.6%) patients received no adjuvant treatment. Five-year disease-free survival and overall survival rates were 74.2% and 80.2%, respectively. Five-year disease-specific mortality rate was 14.1%. Among 9 patients with recurrent disease, most disease relapse (89.9%) occurred outside pelvis in 8 patients, while only one patient had regional recurrence (perirectal lymph node). Five-year loco-regional relapse-free survival was 97.8%.

**Conclusion**

Clinical outcomes for stage I endometrial cancer patients with high-risk features in our study are consistent with the published literature. Adjuvant radiotherapy results in high rates of loco-regional disease control, and most recurrences occurred at distant sites. Systemic treatment with chemotherapy may be indicated in stage I endometrial cancer patients with high-risk features to further reduce the risk of distant relapses and improve survival.

**EP-1490 Bone mineral density correlates to pelvic fractures after radiotherapy for cervical cancer**

D. Kurrumeli<sup>1</sup>, B. Weidenbacher<sup>1</sup>, K. Borm<sup>1</sup>, M. Oechsner<sup>1</sup>, S.E. Combs<sup>1</sup>, C. Brams<sup>2</sup>, M. Löffler<sup>3</sup>, M.N. Duma<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- TU München, Department of Radiation Oncology, München, Germany ; <sup>2</sup>Klinikum rechts der Isar- TU München, Department of Gynaecology, München, Germany ; <sup>3</sup>Klinikum rechts der Isar- TU München, Department of Neuroradiology, München, Germany

**Purpose or Objective**

The aim of this study was to investigate the risk factors for pelvic insufficiency fractures (PIF) after radiotherapy for cervical cancer.

**Material and Methods**

Medical records and imaging studies, including CT and MRI of 62 women with cervical cancer who received definitive or adjuvant radio(chemo)therapy between 2013 and 2017 were reviewed. 33 patients were treated with definitive radiochemotherapy, 22 with adjuvant radiochemotherapy and 7 patients were treated with radiotherapy alone. All patients received pelvic MRI during follow-up. The PIF were detected in the follow-up MRI. For each patient we manually contoured the sacrum and analyzed the bone mineral density (BMD) [ $\text{mg}/\text{cm}^3$ ] according to Schwaiger BJ, et al. AJNR Am J Neuroradiol 2014;35:1628-33. The BMD predicts osteoporotic vertebral fractures. We then registered the MRI of the PIF patients to the planning CT and contoured the PIF. Then, on the contralateral side of the fracture, a mirrored structure of the fracture was generated (mPIF). For the sacral bone as well as the fractures we analyzed the BMD, V50Gy, Dmean and Dmax. We also analyzed the BMD of three lumbar spine vertebral bodies (between the 1st and 5th) as well as the S1 and S2 sacral vertebrae for each patient.

**Results**

Out of 62 patients, 6 (9,7%) had a fracture. All of them were insufficiency fractures and all of them in the massa lateralis of the sacral bone. Two out of the 6 patients had a bilateral fracture with only one of them being symptomatic.

PIF patients showed a significantly lower BMD in the sacral bone ( $p < 0.026$ ) as well as in the lumbar vertebrae ( $p < 0.05$ ). The BMD of the PIF was  $70,4 \text{mg}/\text{cm}^3$  and of the mPIF on the contralateral side was  $84,2 \text{mg}/\text{cm}^3$ . However, the difference in the PIF compared to the mPIF was not significant ( $p < 0.49$ ). The Dmean/Dmax of the sacrum in the PIF group was  $40,3 \text{Gy}/55,4 \text{Gy}$  and in the other patients- i.e. without PIF-(OTH)  $39,7 \text{Gy}/53,9 \text{Gy}$ , respectively (with no significant difference between groups). Similarly, the V50Gy of the sacrum in the PIF group compared to OTH as well as the V50Gy of the PIF compared to the mPIF did not reach significance ( $p < 0.43$  and  $p < 0.12$  respectively).

**Conclusion**

PIF were detected in 9,7% of the patients. The dose does not seem to have a relevant impact on the incidence of PIF in our patients. One of the predisposing factors for developing PIF after radiotherapy seems to be the BMD which was significantly lower in the PIF group. For these patients preventive measures to improve BMD should be taken into account.

**EP-1491 Clinical outcome and toxicity of MRI-based vaginal cuff brachytherapy in endometrial cancer**

C. Jaisawang<sup>1</sup>, P. Alisanant<sup>1</sup>, K. Shotelersuk<sup>1</sup>, C. Khorprasert<sup>1</sup>, N. Amornwicheit<sup>1</sup>

<sup>1</sup>King Chulalongkorn Memorial Hospital, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand

**Purpose or Objective**

In the 3-dimensional image-guided brachytherapy era, the determination of vaginal thickness can be optimized for

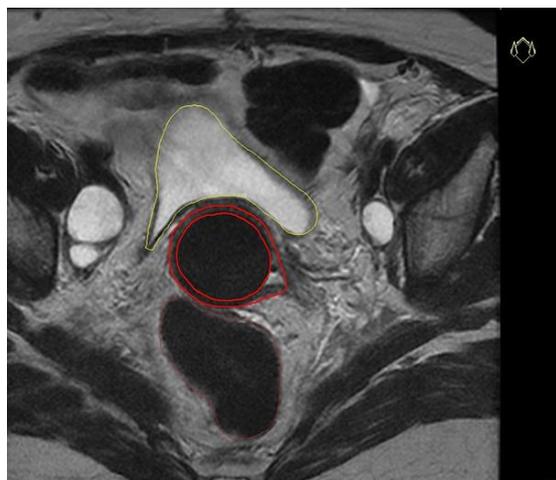

brachytherapy prescription in endometrial cancer. Thus, we conducted a review clinical outcome and toxicity of MRI-based brachytherapy based on post-operative anatomic variation in vaginal cuff (VC) anatomy, which can be visualized using T2W MRI.

#### Material and Methods

Retrospective analysis was done in resectable endometrial cancer patients (FIGO stage I-IV) treated with adjuvant MRI-based brachytherapy with or without external beam radiotherapy (EBRT) from January 2013 to December 2016 in King Chulalongkorn Memorial Hospital (KCMH). All patients in vaginal brachytherapy (VBT) alone group received high dose rate (HDR) brachytherapy with 3 fractions of 7 Gy. And the other group received 45-50.4 Gy of tumor-directed EBRT with 2 fractions of 5-7 Gy brachytherapy. Primary outcome was locoregional relapse free survival (LFRS). Secondary outcomes were toxicity, descriptive vagina doses represented by D90 of whole vaginal thickness in EQD<sub>2.10</sub> and D2cc doses of bladder and rectum in EQD<sub>2.3</sub>.

#### Results

Ninety-five patients and 218 brachytherapy plans were included in the analysis. 22 patients were treated with VBT alone and 73 patients received EBRT with VBT. Median age was 58 years old (IQR 52-72). Atypical forms of vaginal shape in MRI was found in 15 patients (16%). Median follow-up time was 40 months (range 23-50). No locoregional relapse was found in VBT alone group at 3 years. 1-yr, 2-yr and 3-yr LFRS in EBRT with VBT group were 93%, 90% and 88%, respectively. No grade 3-5 gastrointestinal (GI) and genitourinary (GU) toxicity was observed in both groups. Rate of grade 1-2 GI toxicity were significant lower in the VBT alone group than in EBRT with VBT group [0% (0/22) vs 11% (8/73)]. Rate of grade 1-2 GU toxicity was not different in both groups [4.5% (1/22) vs 4.2% (3/73)]. Mean D90 doses of whole vaginal thickness were 32.1 Gy EQD<sub>2.10</sub> for VBT alone and 63.9 Gy EQD<sub>2.10</sub> for EBRT with VBT. In VBT group, mean D2cc doses for bladder and rectum were 29.1 Gy EQD<sub>2.3</sub> and 28.0 Gy EQD<sub>2.3</sub>, respectively. In EBRT with VBT mean D2cc doses were 57.2 Gy EQD<sub>2.3</sub> for bladder and 58.4 Gy EQD<sub>2.3</sub> for rectum. Due to few numbers of events, the D2cc doses were insignificantly related to GI and GU toxicity.

#### Conclusion

The MRI-based brachytherapy for determination vaginal wall thickness provides good dose coverage, even in the atypical vaginal shape group. Additionally, this technique gives better chance to avoid adjacent organs. And the clinical results showed the high rate of tumor control and low gastrointestinal and genitourinary toxicities.

EP-1492 Comparison of 3DCRT and IMRT in endometrial cancer: efficacy, safety, and prognostic analysis

M. Ta<sup>1</sup>, A. Schernberg<sup>1</sup>, P. Giraud<sup>1</sup>, L. Monnier<sup>1</sup>, E. Darai<sup>2</sup>, S. Bendifallah<sup>2</sup>, M. Schlienger<sup>1</sup>, E. Touboul<sup>1</sup>, T. Challand<sup>1</sup>, F. Huguet<sup>1</sup>, E. Rivin Del Campo<sup>1</sup>

<sup>1</sup>Hôpital Tenon, Radiation Oncology, Paris, France ;  
<sup>2</sup>Hôpital Tenon, Gynecology, Paris, France

#### Purpose or Objective

Adjuvant Whole-Pelvic Radiation Therapy (WPRT) improves loco-regional control for stage I high-intermediate risk to stage III endometrial cancer. Nowadays Intensity Modulated Radiation Therapy (IMRT) tends to replace the standard 3D conformal radiation therapy (3DCRT) technique used in benchmark trials. The objective of this study was to compare 3DCRT versus IMRT in patients with endometrial cancer treated with post-operative WPRT.

#### Material and Methods

Patients with FIGO stage I to IIC2 endometrial cancer treated between 2008 and 2014 in our department with post-operative WPRT were included. The impact of the technique on local control, tolerance, and survival was assessed. Toxicity was graded weekly during radiation therapy, according to the Common Terminology Criteria for Adverse Events (CTCAE) version 3.0. The cumulative probabilities of OS and PFS rates were calculated using the Kaplan-Meier method and compared using a log rank test. Univariate and multivariate analyses were performed using Cox's regression

#### Results

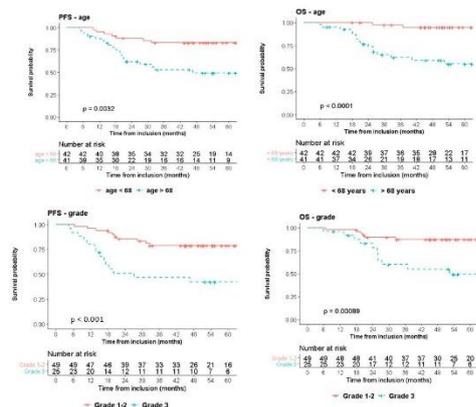

Among the 83 patients included, 47 patients were treated with 3DCRT and 36 with IMRT. There were no differences in patient characteristics between the two groups. Most of the women were menopausal (97.6%) with a median age of 68 years (range: 40-86), a myometrial invasion superior to 50% (66.3%) and no vaginal extension (90.4%). FIGO stage III (54.2%) and grade 1-2 (59%) cancers were the most represented in the population. The median dose was 45 Gy (41.4 - 55 Gy). Twenty-four patients (29%) with vaginal extension underwent Low-Dose Rate (LDR) vaginal brachytherapy after WPRT with a median dose at the reference isodose of 15 Gy (range: 10-20 Gy). Median follow-up was 50 months. The 5-year locoregional control and progression free survival (PFS) rates were 94.5% and 68%, respectively. No significant difference was found between the 3DCRT and IMRT groups in terms of survival, with a 5-year-overall survival (OS) rate of 74.6% and 78%, respectively. All locoregional relapses were associated with distant nodal metastasis, except a vaginal relapse. There was a trend towards lymphadenectomy as a prognostic factor of locoregional control but also in overall survival in univariate analysis (Table 1). The multivariate analysis found age over 68, stage > T1, and grade 3 as factors independently associated with shorter PFS and OS (Table 1, Figure 1). Five patients (10.6%) had grade 3-4 acute gastrointestinal (GI) toxicity in the 3DCRT group and two (5.4%) in the IMRT group. One (1.2%) late grade 3 GI toxicity of was observed.

Table 1. Predictive factors of overall survival.

Factor	n = 83	Deaths n = 20 (%)	5-year OS (%) (95% CI)	p		HR (95% CI)

Abbreviations: HR: Hazard ratio, 95% CI: 95% confidence interval; OS: overall survival; LVSI: lymphovascular space invasion; EBRT: external beam radiotherapy technique.

Figure 1. Subset analysis of progression free survival and overall survival for patients according to age and histological grade.

## Conclusion

These findings support IMRT as a safe technique for the treatment of endometrial cancer with no difference in efficacy and an apparently lower incidence of acute GI toxicities. Results of long-term prospective trials are needed to confirm these results.

## EP-1493 SBRT for oligometastatic gynecological cancer: a single institution experience

C. Iftode<sup>1</sup>, A. Tozzi<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, T. Comito<sup>1</sup>, C. Franzese<sup>1</sup>, F. De Rose<sup>1</sup>, D. Franceshini<sup>1</sup>, L. Di Brina<sup>1</sup>, P. Navarra<sup>1</sup>, E. Clerici<sup>1</sup>, S. Tomatis<sup>1</sup>, M. Scorsetti<sup>1</sup>  
<sup>1</sup>Humanitas Research Hospital, Radiotherapy and Radiosurgery, Rozzano Milan, Italy

## Purpose or Objective

The aim of this study was to evaluate the role of stereotactic body radiotherapy (SBRT) in a series of oligometastatic gynecological malignancies.

## Material and Methods

Clinical records of patients affected by oligometastatic of any gynecological carcinoma treated with SBRT were

reviewed. From 2010 to 2018, a total of 49 patients with single or multiple metastases for a total of 96 lesions were treated in our Center. Primary cancer were 33 ovarian, 10 endometrial, 4 cervical, 1 vulvar and 1 tubal cancer. Toxicities were graded according to Common Terminology Criteria for Adverse Events version 4.0. Tumor response was evaluated by CT/ PET and/or MRI, according to Response Evaluation Criteria in Solid Tumors (version 1.1)

## Results

Median follow-up was 24 months (range 6-100). Most of treated lesions were located in lymph nodal sites 54.2%, lung in 22.9%, liver in 20.8% of cases, and soft tissue in 2.1%. Complete radiologic response, partial response, stable disease and progressive disease were observed in 57.3%, 26%, 10.4% and 6.3% of cases, respectively. The median LC was not reached. One year- and three year- LC were 96.6%. Median distant control was 35.5 months. Median OS was 59.9 months. All of patients completed the prescribed treatment with a low toxicity profile: only 12.5% experienced G2 acute toxicity, most common adverse effect was abdominal pain (5.2%), fatigue (4.2 %) and nausea and vomiting (3.1%). None of the patients had grade 3 or 4 acute or late toxicity.

## Conclusion

SBRT is a feasible and safe approach in selected cases of oligometastatic gynecological cancer with satisfactory results in terms of LC and DFS.

## EP-1494 Quality of life in women treated for gynecologic malignancies and dose-volume parameters correlation

A. Caroli<sup>1</sup>, L. Masini<sup>1</sup>, C. Pisani<sup>1</sup>, E. Gallizia<sup>1</sup>, I. Luciani<sup>1</sup>, M. Brambilla<sup>2</sup>, M. Krengli<sup>1</sup>  
<sup>1</sup>Hospital Maggiore della Carità, Department of Radiotherapy, Novara, Italy; <sup>2</sup>Hospital Maggiore della Carità, Medical Physics, Novara, Italy

## Purpose or Objective

The purpose of this study was to assess self-reported overall QoL and QoL related to genito-urinary and gastroenteric symptoms in patients affected by endometrial and cervical cancer after radiation therapy and in regular follow-up and to analyze a possible correlation with dose-volume parameters of organ at risks (OARs)

## Material and Methods

We administered the anonymous EORTC QLQ-C30 to 182 patients, 141 with endometrial cancer and 41 with cervical cancer, treated with pelvic radiotherapy from 2011 to 2017 and in regular follow-up in our center. The questionnaire was combined with EORT QLQ-EN24, in case of endometrial cancer, or with EORT QLQ-CX 24, in case of cervical cancer. There were no limitations regarding age or performance status. We analyzed overall health and overall quality of life (score from zero (low QoL) to seven (high QoL)), bladder symptoms, dysuria, bladder incontinence and fecal incontinence and their correlation with dose-volume parameters of OARs (whole bladder, bladder trigone, rectum and lumbosacral plexus).

## Results

QoL was very high (score 6-7) in many patients (88.5 % of patients). Relatively few patients referred urinary incontinence (12.6 %) or abdominal discomfort of high grade (7.2 %). We found a significant correlation between bladder V35, i.e., absolute percentage of bladder volume that received a dose of 35 Gy, and urinary incontinence (p<0.05, R=0.27, R<sup>2</sup> = 0.06), and abdominal pain (p<0.05, R= 0.16, R<sup>2</sup> = 0.02). We found also a correlation between urinary urgency and bladder V40, i.e., absolute percentage of bladder volume that received a dose of 40 Gy (p<0.05, R= 0.22, R<sup>2</sup> = 0.06).

## Conclusion

Women treated with surgery and radiotherapy for endometrial and cervical cancers have good QoL with

minimal limitations of daily activities. Parameters related to bladder function may be negatively affected by bladder V40 and V35.

#### EP-1495 Improved Disease-Free Survival with Radiotherapy in Early Stage Endometrial Cancer: 10-year outcome

S. Aytac Arslan<sup>1</sup>, I.P. Aral<sup>2</sup>, G. Altinşik Inan<sup>1</sup>, Y. Tezcan<sup>1</sup>, F. Avsar<sup>3</sup>, Y. Güney<sup>4</sup>

<sup>1</sup>Yildirim Beyazıt University, Radiation Oncology, Ankara, Turkey; <sup>2</sup>Elazığ Fethi Sekin Şehir Hospital, Radiation Oncology, Elazığ, Turkey; <sup>3</sup>Yıldırım Beyazıt University, Obstetric and Gynecology, Ankara, Turkey; <sup>4</sup>Ankara Memorial Hospital, Radiation Oncology, Ankara, Turkey

#### Purpose or Objective

The aim of this study is to evaluate the long term treatment outcomes of patients with early stage endometrial carcinoma.

#### Material and Methods

The data of 311 patients from 2 institutions with the international federation of gynecology and obstetrics (FIGO) stage 1-2 endometrial cancer whom received ±adjuvant treatment following surgery between June 2001 and December 2016 were retrospectively reviewed. Of these, 74 (24%) received no further treatment, 4 (1%) received only chemotherapy (CT), 233 (75%) received radiotherapy (RT) and 24 (7%) received both. RT was administered as pelvic + vaginal brachytherapy (n=128, 54.2%) or vaginal brachytherapy (n=106, 45.8%).

#### Results

The median follow-up was 102 months (range, 3 to 205 months). During this period, 68 (22%) patients died; of which 41 were disease related. Ten-year disease-free survival (DFS) and disease specific survival (DSS) were 73.9% and 82.7% respectively. The univariate analysis showed that nonendometrioid pathology, lymphovascular invasion (LVI) positivity, grad 3 histology, myometrial invasion <sup>3</sup>1/2, cervical stromal invasion (stage 2) and no adjuvant RT had negative significant impact on DSS. Cox multivariate analysis revealed that LVI (p:0.010, HR:2.96, CI:1.5-5.7) and stage (p:0.018, HR:2.1, CI:1.1-4) for DSS; RT (p:0.032, HR: 0.49, CI:0.2-0.9), LVI (p:0.02, HR:1.8, CI:1.09-3.1) and stage (p:0.04, HR: 1.8, CI:1.002-3.15) for DFS are as independent prognostic factors.

#### Conclusion

The findings of our cohort have affirmed the importance of adjuvant RT as a previously identified prognostic variable on long term early-stage endometrial carcinoma progression. RT can be suggested to LVI positive early stage endometrial carcinoma patients even without any other risk factors.

#### EP-1496 Feasibility of carbon ion radiotherapy for the melanoma of the lower genital tract

European Institute of Oncology- Milan- Italy, Radiation Oncology, Pavia, Italy

#### Purpose or Objective

Malignant mucosal melanoma (MMM) of the female genital tract is a rare and aggressive disease with a 5-years overall survival of 37-50% for vulvar (VuM), 13-32% for vaginal (VaM) and 10% for cervical melanoma (CM). MMM has been regarded as radioresistant tumors demonstrating unsatisfactory local control after photon radiotherapy. Based on the promising previous Japanese experience and in light of the well-known biological and therapeutic advantages of carbon ion radiotherapy (CIRT), we were prompted to use CIRT for gynecological MMM. The aim of the present study is to report our preliminary experience with CIRT in the treatment of gynecological MMM at the National Center of Oncological Hadrontherapy (CNAO).

#### Material and Methods

Between January 2016 and September 2018, 8 patients were admitted for CIRT at CNAO. Patient median age was 65 (range: 52-83). They had 6 VaM, 1 CM and 1 VuM. One patient with VaM had been previously irradiated with photons. GTV ranged from 1.13 to 380.96 cm<sup>3</sup> (median: 28.01 cm<sup>3</sup>). Two patients underwent to neoadjuvant and sequential anti-PD-1 immunotherapy. Due to their huge macroscopic diseases, the CM and VuM patients were irradiated with up to a total dose of 28 GyRBE in 3 fractions and 68.8 GyRBE in 16 fractions, respectively, and the CTV was defined as the GTV + uterine cervix and corpus for the CM and GTV + vulva for the VuM. Except one case, in the VaM the small pelvic space including GTV was irradiated with up to a total dose of 43 GyRBE (in 10 fractions) followed by a GTV boost of up to a total dose of 68.8 GyRBE in 16 fractions. One patient underwent to adjuvant CIRT on the small pelvic space up to a dose of 43 GyRBE after a radical surgery without lymphadenectomy. Acute and late toxicities were scored according CTCAE 4.0 scale. Time to event data was calculated from the end of CIRT.

#### Results

The treatment was well tolerated and no interruption was needed. During and at the end of CIRT only a patient experienced G3 erythema and 4 patients grade G1 vaginitis. For the evaluable patients (4) the median local control was 10.23 months for VaM and 7.26 months for CM. All these 4 patients experienced systemic progression. Data is still ongoing for the latest enrolled patients.

#### Conclusion

Because of the low incidence, there are no established guidelines for the management of gynecological MMM. Even if extensive surgery, when feasible, is the standard treatment due to high rate of distant metastases and unsatisfactory survival benefit, more conservative treatment approaches may be warranted. MMM is a radioresistant tumor, an ideal disease to test the biological efficacy of CIRT. Our preliminary results are encouraging, but a longer follow-up and large patient accrual are required. Patients should be encouraged to participate in clinical trials.

#### EP-1497 Particle radiotherapy for re-irradiation of pelvic recurrences of gynecological cancer

A. Barcellini<sup>1</sup>, V. Vitolo<sup>1</sup>, R. Lazzari<sup>2</sup>, M.R. Fiore<sup>1</sup>, A. Iannalifi<sup>1</sup>, B. Vischioni<sup>1</sup>, A. Facchetti<sup>3</sup>, S. <sup>1</sup>National Centre of Oncological Hadrontherapy CNAO, Radiation Oncology, Pavia, Italy; <sup>2</sup>European Institute of Oncology, Radiation Oncology, Milano, Italy; <sup>3</sup>National Centre of Oncological Hadrontherapy CNAO, Radiobiology, Pavia, Italy; <sup>4</sup>National Centre of Oncological Hadrontherapy CNAO, Department of

*Medical Physics, Pavia, Italy ; <sup>5</sup>National Centre of Oncological Hadrontherapy CNAO- University of Pavia, Radiation Oncology- Department of Clinical-Surgical-Diagnostic and Pediatric Sciences, Pavia, Italy ; <sup>6</sup>National Centre of Oncological Hadrontherapy CNAO- European Institute of Oncology, Radiation Oncology, Pavia- Milano, Italy*

#### **Purpose or Objective**

Recurring gynecological tumors of the pelvic area within or at the edge of a previously irradiated field are often in close proximity to the intestinal tract. When surgery is not feasible, re-irradiation can be reasonably used. Re-irradiation presents challenges due to the high cumulative dose and the risk of severe toxicities in normal tissues. Particle therapy (with carbon ions and protons) is a promising alternative for these women.

#### **Material and Methods**

Between May 2014 and October 2018, 8 patients with gynecological recurrent tumor within or at the edge of the previously irradiated field were admitted for particle therapy at National Centre of Oncological Hadrontherapy (CNAO). They had recurrence of cervical (5), endometrial (2) and ovarian (1) cancer. Median age at the time of registration for particle RT was 58 years (range:35-72 years), and median GTV was 79 cm<sup>3</sup> (range: 34.99-172.80). Two patients, with marginal lymph node recurrence, were irradiated with protons up to a total dose of 25 GyRBE and 51 GyRBE respectively. The remaining women underwent to carbon-ion radiotherapy (CIRT) with a median total dose of 50.4 GyRBE (range: 36-57) administered in a median number of 12 fractions. Three patients with pelvic side wall recurrences received surgical spacer placement by open surgery to keep intestinal tracts apart from the tumor, since the distance between tumor and nearest intestinal tracts was not sufficient. Toxicity was scored according CTCAE 4.0 scale.

#### **Results**

All patients completed the planned treatment and no acute toxicities G>1 were observed. For the evaluable patients no grade 2 or higher late toxicities were reported. For the patients with a follow-up > 3 months, we observed 1 local recurrence and 5 patients died for systemic progression. The median local control was 10.26 months. Data is still ongoing.

#### **Conclusion**

Although the study's limitations, particle therapy showed no severe toxicities for recurrence of gynecological cancers after RT. Unfortunately, patients with large volume central or pelvic side wall recurrences have poor prognoses therefore efforts should be made to detect pelvic recurrences early. A strong collaboration between Gynecologic Oncologists and Radiation Oncologists is of utmost importance to make a step forward in the treatment of these diseases. Hence, hadrontherapy for pelvic recurrences should be further investigated in a prospective and multicenter trial.

#### **EP-1498 Reporting vaginal doses for cervical patients receiving external beam radiotherapy and brachytherapy**

T. Chan<sup>1</sup>, P.W. Tan<sup>1</sup>, J.I.H. Tang<sup>1</sup>

<sup>1</sup>The National University Cancer Institute- Singapore NCIS, Radiation Oncology, Singapore, Singapore

#### **EP-1499 The case selection for brachytherapy in cervical cancer patients after radical hysterectomy**

H. Xu<sup>1</sup>, Y. Lai<sup>2</sup>, Y. Jin<sup>1</sup>

<sup>1</sup>Ruijin Hospital- Shanghai Jiaotong University School of Medicine, Radiation Oncology, Shanghai, China ;

<sup>2</sup>XiaoShan Hospital, Oncology, Zhejiang, China

#### **Purpose or Objective**

To explore the suitable cases for brachytherapy as a component of adjuvant radiotherapy, and analyzed the relapse patterns of cervical cancer patients after radical hysterectomy.

#### **Material and Methods**

We retrospectively analyzed the clinical data of 213 cervical cancer patients (aged 28-78 years) with FIGO stage I A to II B admitted to our department who received adjuvant radiotherapy from January 2008 to December 2015. Squamous cell carcinoma (178 cases), adenocarcinoma(25 cases), adenosquamous carcinoma (9 cases) and undifferentiated carcinoma (1 case) were

included. Among them, 149 patients received EBRT (external beam radiation therapy) after radical hysterectomy, 64 received EBRT combined with intracavitary brachytherapy. There was no statistical difference in FIGO stage and pathological type distribution between the two groups. A dose of 45-50.4Gy in 25-28 fractions was prescribed to the planning target volume with IMRT. Those who underwent brachytherapy were supplemented with 18-30Gy/3-5Fx. Survival analyses were performed using Kaplan-Meier method, and Cox model was used to analyze prognostic factors.

#### Results

The median follow-up was 52 months (9-136 months), and 3 years PFS was 77%. Among them, 62 patients had local or distant recurrence, 31 cases in pelvic (including vaginal cuff), 10 cases with metastases to para-aortic or inguinal lymph nodes, and 21 cases with distant metastasis. The types of pathology, large mass, positive lymph node, FIGO stage and depth of invasion were all highly significantly and independently related to risk of recurrences ( $P=0.004$ ,  $0.023$ ,  $0.013$ ,  $0.003$  and  $0.035$ , respectively). However, the adjuvant chemotherapy was not a significant factor influenced PFS ( $P=0.88$ ), which did not reduce the risk of pelvic relapse or distant metastasis ( $P=0.27$ ,  $P=0.40$ ). We found that when the patients received EBRT with dose of 45Gy, 1) if the invasive depth reaching or exceeding the deep muscle layer, the brachytherapy could significantly reduce the recurrence ( $P=0.049$ ); 2) if the tumor size was more 4cm, the brachytherapy could reduce the recurrence (mean PFS,  $58.83\pm 9.28$  months vs.  $35.33\pm 6.78$  months), though the difference was not statistically significant ( $P=0.20$ ).

#### Conclusion

The pathology, stage, mass, lymph node status and depth of invasion were the prognosis factors of cervical cancer patients with radical hysterectomy in our study. Preliminary results showed that adjuvant chemotherapy did not improve the prognosis of these patients. In those who received prescribed dose of 45Gy for the EBRT, high risk factors such as depth of invasion and large tumor size would be the key factors for the case selection to additional intracavitary therapy. And more data is needed for further research.

#### EP-1500 Squamous Cell Carcinoma of unknown primary (CUP) in the Pelvis: A case series and review of literature

E. Connolly<sup>1</sup>, G. Rangaswamy<sup>1</sup>, O. Boycech<sup>1</sup>, C. Gillham<sup>1</sup>, O. McArdle<sup>1</sup>

<sup>1</sup>St Luke's Radiation Oncology Center, Radiation Oncology, Dublin, Ireland

#### Purpose or Objective

The diagnosis and management of Carcinoma of unknown primary (CUP) represents a challenge. Of the 3-5% of invasive cancers that are classified as CUP approximately 5%-10% are squamous cell carcinomas (SCCs), many of which are HPV +ve and are commonly located in the head and neck. HPV +ve SCCs CUP in the pelvis are extremely rare and there is not much known about the aetiology, pathogenesis, or ideal radiation therapy target coverage.

#### Material and Methods

Electronic medical records and patient charts registered as SCC CUP between 2014 and 2018 inclusive were reviewed. Those with a diagnosis of CUP in the Pelvis were included in our study. We also conducted a literature review to identify published data reporting treatment outcomes.

#### Results

Three patients with CUP in the Pelvis were identified at our institution. Case#1: A 62-year-old lady presented with a three-month history of progressive lower back pain. Imaging revealed a left pelvic sidewall mass, confirmed as p16 positive SCC. She was treated with chemoradiotherapy. Case#2: A 33-year-old lady, in her first

trimester presented with a deep vein thrombosis and found to have a right pelvic mass biopsy of which confirmed a SCC. She was treated with chemotherapy, external beam radiotherapy and a single dose of intracavitary brachytherapy. Case#3 A 40-year-old lady with a history of pelvic pain was diagnosed with p16 positive SCC after MRI showed a large infiltrative mass. She was treated with external beam radiotherapy with concomitant chemotherapy. We present treatment outcomes on all three patients and a review of the available literature.

#### Conclusion

Our case series highlights the complexities involved in the management of these rare CUP of the pelvis. Our three cases add to the very small number of previously reported cases in the literature to date. Identification of a primary site is important since therapy is potentially curative. We cannot deduce whether HPV/p16 caused these cancers but it may be that the HPV status can be helpful in identifying mucosal sites. It may thus prove a useful tool in developing a diagnostic and treatment paradigm for such patients.

#### EP-1501 Prognostic value of SCC-Antigen and SUVmax value in locally advanced cervix cancer

S. Pedraza Fernández<sup>1</sup>, P. Sarandeses<sup>2</sup>, D. Lora<sup>3</sup>, J.F. Pérez-Regadera<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de Octubre, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Universitario 12 de Octubre, Nuclear Medicine, Madrid, Spain ; <sup>3</sup>Hospital Universitario 12 de Octubre, CIBER de Epidemiología y Salud Pública imas12-CIBERESP, Madrid, Spain

#### Purpose or Objective

The aim of this study is to combine tumour SUVmax (maximum standardized uptake) value at diagnosis and pretreatment squamous cell carcinoma antigen (SSC-Ag) level to evaluate the impact of both in predicting the response to combined chemoradiotherapy (CCRT) in locally-advanced cervix cancer (LACC).

#### Material and Methods

From March 2009 to October 2015, 114 consecutive patients (pts.) with LACC who underwent a 18F-FDG-PET/CT at diagnosis were enrolled in this retrospective study. Pts. were staged according to FIGO 2008 system. All received definitive radiotherapy in combination with weekly Cisplatin and endocavitary brachytherapy. A follow-up time, in the absence of an event, higher than 2 years (yrs) was required.

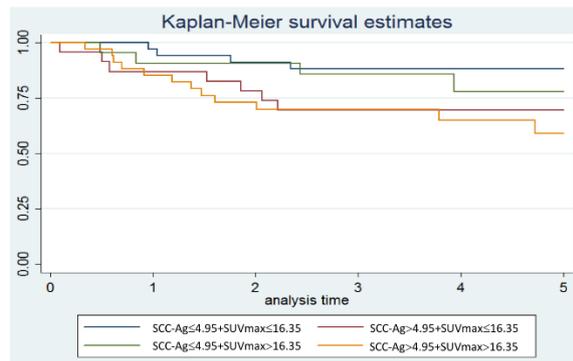

Univariate analysis was performed studying independently the differences in SCC-Ag group and tumor-SUVmax value group and clinic prognostic variables. Kruskal-Wallis test was used;  $p$  value  $\leq 0.05$  was considered statistically significant. Analysis of overall survival (OS) was performed with the Kaplan-Meier method and long-rank test. Statistical studies were performed using program Stata (Version 12, StataCorp, College Station, Texas).

#### Results

The mean age was 52(25-82)yrs. Histology specimens: 86(76%) squamous-cell carcinoma, 27(23.89%) non-squamous-cell carcinoma. FIGO stage: 25(21.93%) IB, 4(4%) IIA, 45(40%) IIB, 1(0.8%) IIIA, 33(29%) IIIB, 5(4.3%) IVA. Hydronephrosis was presented in 13(11.5%)pts. and 80(70%) had parametrial invasion. Pathological uptake in pelvic nodes was evidenced in 56.14%pts. Patients' distribution according to ECOG scale: 94(82.5%) 0 to 1 and 20(17.5%) 2 to 4. Mean follow-up was  $4\text{yrs}\pm 2.16(\text{SD})$ .

The average SSC-Ag pretreatment was  $17.9\text{ng/ml}\pm 36.19(\text{SD})$ . The median was  $4.95\text{ng/ml}$  (range: 0.5-221). There was significant correlation between SSC-Ag level and tumoral histology, FIGO stage, ECOG level and pelvic lymph node affectation ( $p=0.0001$ ,  $p=0.01$ ,  $p=0.01$ ,  $p=0.02$  respectively). No correlation was found with hydronephrosis or parametrial infiltration. Mean SUVmax of primary cervical tumour was  $16.9\pm 8.26$  (SD). The median was  $16.35$ (range: 4.2-48.32). Only pelvis lymph

nodes affectation was found to be statistically significant in prognosis prediction ( $p=0.003$ ). OS at 5yrs. was 73.7%. The 5-yrs OS for pts. with a SCC-Ag  $<4.95$  was higher compared to those with SCC-Ag  $>4.95$ ng/ml (84% Vs 63%,  $p=0.001$ ). Pts. with tumour SUVmax level  $\geq 16.35$  presented worse OS, although it was not statistically significant (80 Vs 66%,  $p=0.21$ ). When stratified pts. in four groups according to SCC-Ag and SUVmax level, the group with SCC-Ag  $>4.95$ ng/ml and SUVmax level  $\geq 16.35$  presented the worst OS at 5yrs ( $p=0.09$ ). Details are shown in figure 1.

### Conclusion

SCC-Ag pretreatment level and tumor SUVmax value can be useful for prognosis prediction in LACC. Further studies are required to establish the role of high level of both and if a more intensive therapy is required to this cohort.

### EP-1502 Endometrial cancer. Relapse free survival rates in our medium/large hospital in the UK

L. Price<sup>1</sup>, R. Allerton<sup>1</sup>

<sup>1</sup>Royal Wolverhampton Hospital, Oncology, Wolverhampton, United Kingdom

### Purpose or Objective

Endometrial cancer (EC) is common in developed countries (N. Colombo et al., 2013) and incidence is increasing in the UK and this is considered to be due to rising obesity rates (NCIN 2015), despite this survival rates have improved since 1990s (NCIN).

Endometrial cancer treatment is guided by the risk of recurrence, low medium or high.

Those with low-Intermediate risk Stage 1 disease have been shown to benefit from Radiotherapy following hysterectomy (PORTEC1). PORTEC2 looked at those with intermediate-high risk EC and demonstrated external radiotherapy is equivalent to vaginal brachytherapy (VT). Adjuvant Chemotherapy can be offered to those with high risk EC with Stage I-III any histology and no residual disease. (NSGO-9501/EORTC 55991 trial and MaNGO ILIAD III-study)

Our objective was to assess local outcomes of relapse free survival for those with low, intermediate and high risk EC treated in our local medium/large district general hospital and compare with published relapse free survival data from large multi-centre clinical trials, PORTEC1, 2 and 3.

### Material and Methods

179 patients with EC discussed at multi-disciplinary meetings (MDT) and actively treated between May 2010 to November 2013 were assessed retrospectively using electronic notes. Patients were followed up for a median of 4 years and 1 month (the minimum follow up was 3 years 3 months with the maximum follow up being 6 years 11 months).

### Results

Our cohort for low risk EC demonstrate a relapse free survival of 95% (62 of 64 patients) which is the same as that quoted by PORTEC1. All relapses were local relapses

within the vaginal vault and all were successfully salvaged with surgery.

Our cohort for intermediate / high risk EC demonstrate a 88% (53 of 60 patients) relapse free survival which is broadly in line with PORTEC2 trial (78 - 83% for endometrioid histology only). Tumour characteristics were broadly comparable by data we collected (See Figure 1). Recently, PORTEC3 reported a 76% failure free survival with chemo-radiotherapy (CRT) and 69% with radiotherapy at 5 years. We looked at 55 patients treated locally with high risk disease and found a 76% (42 of 55 patients) failure free survival rate, those patients were treated with a mixture of CRT, external beam radiotherapy, VT and adjuvant chemotherapy. (See Figure 2 for Kaplan-Meier curves for CRT with or without adjuvant chemotherapy versus radiotherapy alone). However of those with high risk disease only 4 had chemo-radiotherapy per PORTEC3 protocol (two cycles of cisplatin 50 mg/m<sup>2</sup> given during radiotherapy, followed by four cycles of carboplatin AUC5 and paclitaxel 175 mg/m<sup>2</sup>).

### Conclusion

We conclude that broadly our relapse rate for endometrial cancer are in line with those published in the seminal studies.

Importantly, when our cohort of high risk disease was compared to PORTEC3 data (ASCO June 2017), real life data is demonstrated. Only 4 of 55 patients received chemo-radiotherapy as per the PORTEC3 trial protocol because many patients could not be offered toxic CRT due to co-morbidities.

### EP-1503 Brachytherapy versus EBRT boost for cervical cancer: is the standard better?

D. Delgado<sup>1</sup>, A. Figueiredo<sup>1</sup>, J. Leitão Santos<sup>1</sup>, A. Florindo<sup>1</sup>, V. Mendonça<sup>1</sup>, M. Lemos<sup>1</sup>, M. Abdulrehman<sup>1</sup>, M.F. De Pina<sup>1</sup>

<sup>1</sup>Centro Hospitalar Lisboa Norte EPE, Serviço de Radioterapia, Lisbon, Portugal

### Purpose or Objective

Compare the outcomes of intracavity high-dose-rate brachytherapy (IC BT-HDR) boost and external beam radiotherapy (EBRT) boost of patients (pts) treated with concomitant chemoradiotherapy (CCRT) for cervical cancer.

### Material and Methods

Retrospective review of 92 pts with stage IB1-IVA cervical cancer treated with CCRT between 2008 and 2013 with at least 1 year follow-up. All pts received pelvic 3D-conformal EBRT (45-50,4Gy) concomitant with weekly cisplatin (40mg/m<sup>2</sup>) and an IC BT-HDR boost (24Gy/4 fractions prescribed to point A-A') to the tumor or a 3D-conformal EBRT boost (16,2Gy) if the former was not technically feasible. Pts with clinically positive paraaortic (PA) lymph nodes received PA lymph node irradiation. Parametrial EBRT boost was given when appropriate. Pts treated with at least one fraction of BT were included in the IC BT-HDR group. Characteristics of pts treated with and without IC BT-HDR were compared to evaluate for differences. The effect of the IC BT-HDR boost on recurrence free survival (RFS) and overall survival (OS) was examined with univariate and multivariate analyses.

### Results

Median age of all pts was 52 years (24-83). IC BT-HDR boost was given to 37 pts (40,2%) and an EBRT boost to 55 pts (59,8%). Patients treated with EBRT boost had larger tumors (mean 53mm vs 39mm -  $p < 0,001$ ) and more advanced disease at diagnosis (FIGO stage  $>IIB$  38,2% vs 5,4% -  $p < 0,001$ ), however roughly the same number of pts had stage  $\leq IIB$  (34 vs 35pts). There was no difference in age or clinically positive lymph nodes at diagnosis.

Ten pts (10,8%) received PA lymph node irradiation. Parametrial EBRT boost was given to 26 pts (74,6%) treated with IC BT-HDR boost. Median treatment time was

78 days (49-102 days) for IC-BT-HDR boost pts and 56 days (44-114 days) for EBRT boost pts.

The median follow-up time was 67 months (5-129 months) for all pts.

Pelvic failure was detected in 20,7% of pts and distant failure in 12%.

The 3-year RFS rate was 61% for all pts, 45% for EBRT boost pts and 84% for IC BT-HDR boost pts (Log-rank  $p < 0,001$ ). The 3-year OS rate was 76% for all pts, 66% for EBRT boost pts and 89% for IC BT-HDR pts (Log-rank  $p = 0,005$ ).

EBRT vs BT	3,14	0,969	10,171	0,056

Legend: Maximal Tumor Dimension (MTD); External Beam Radiotherapy (EBRT); Brachytherapy (BT)

In multivariate analysis controlling for maximum tumor dimension, lymph node status and FIGO stage (fig.1), EBRT boost was associated with a statistical significant increase in the risk of recurrence (HR 3,56; CI 95% 1,27-10,02  $p = 0,016$ ) and a trend towards an increase in the risk of death (HR 3,14; CI 95% 0,97-10,17  $p = 0,056$ ).

#### Conclusion

IC-BT-HDR boost is considered standard of care combined with CCRT in the treatment of cervical cancer not amenable by surgery.

In some cases IC BT-HDR boost is not technically feasible and department guidelines recommend an EBRT boost up to 66,6Gy.

This retrospective study demonstrates that the EBRT boost is associated with a three fold increase in the risk of recurrence. Better alternatives need to be studied for pts where a BT boost is not possible.

#### EP-1504 Role of PET/CT in assessing treatment response of cervical cancer after definitive RadioChemotherapy

A. Tsikkinis<sup>1</sup>, E. Vlaskou Badra<sup>1</sup>, N. Cihoric<sup>1</sup>, D. Aebersold<sup>1</sup>, K. Lössl<sup>1</sup>

<sup>1</sup>Inselspital- Universität Bern, Radiation-Oncology, Bern, Switzerland

#### Purpose or Objective

To evaluate the value of <sup>18</sup>FDG-PET/CT in the follow-up of patients (pts) with cervical cancer after definitive radio/chemotherapy (RChT).

#### Material and Methods

From 11/2010 to 08/2016, 53 (100%) patients (pts) with cervical cancer (FIGO stage IB1 to IVA) were treated with definitive radio-chemotherapy (RChT).. The median age at the time of diagnosis was 54 (29 -83) years. All pts were staged with a clinical exam and a pre-treatment <sup>18</sup>FDG-PET/CT. 29 (55%) pts were treated in our hospital and 24 (45%) in other referring institutions (n:7). 13 (25%) pts were lymph node (LN) negative and 40 (75%) LN positive. 12 (23%) pts had 1 positive LN, 9 (17%) two, 7 (13%) pts with 3-5 LN and 9 (17%) with >5 positive LN. 17 (32%) pts

had positive paraaortal LN. All pts were treated with image guided RChT. A dose of 50.4 Gy was prescribed to the elective pelvic nodal volume. Primary tumors smaller than 4 cm in diameter received an additional boost of 5.4 Gy, primary tumors larger than 4 cm in diameter received a boost of 9 Gy. Pts with positive LN detected with <sup>18</sup>FDG-PET/CT received a simultaneous integrated boost to a total dose of 64 Gy. Chemotherapy was administered according to institutional standards. After completion of the external beam RChT all pts were referred to our hospital for image guided HDR Brachytherapy in 4 once weekly fractions of 6-7 Gy. Follow up included clinical investigation at 6 weeks and at 3 months after therapy and a <sup>18</sup>FDG-PET/CT at 6 months.

#### Results

Median time to the first <sup>18</sup>FDG-PET/CT after therapy completion was 6 months (1 - 8 months). Pathological findings were found in 21 (40%) pts. 3 pts (6%) showed local tumor persistence and 2 pts (4%) were diagnosed with loco-regional persistence which were later histologically reclassified as benign. In 16 pts (30%) systemic metastasis was diagnosed, of those 12 received palliative systemic treatment and/or palliative radiation, 2 were operated upon and 2 were followed up. In total 19 (36%) pts were diagnosed and confirmed with having malignant disease, to date just 7/19 died as a direct consequence of their disease.

#### Conclusion

<sup>18</sup>FDG-PET/CT conducted 6 months after therapy completion is a valuable imaging tool in assessing treatment response of cervical cancer patients treated with definitive RChT. <sup>18</sup>FDG-PET/CT findings lead to therapeutic consequences in the majority of pts.

#### EP-1505 Is locally advanced cervix adenocarcinoma less radiosensitive than squamous cell carcinoma?

K. Vandecasteele<sup>1</sup>, E. De Jaeghere<sup>2</sup>, P. Tummers<sup>3</sup>, A. Makar<sup>3</sup>, P. De Visschere<sup>4</sup>, K. Van de Vijver<sup>5</sup>, E. Naert<sup>2</sup>, H. Denys<sup>2</sup>

<sup>1</sup>UZ Gent, Radiation Oncology, Gent, Belgium ; <sup>2</sup>UZ Gent, Medical Oncology, Gent, Belgium ; <sup>3</sup>UZ Gent, Gynaecology, Gent, Belgium ; <sup>4</sup>UZ Gent, Radiology, Gent, Belgium ; <sup>5</sup>UZ Gent, Pathology, Gent, Belgium

#### Purpose or Objective

Previous studies on cervical cancer reported a worse outcome for adenocarcinoma (AC) compared with squamous cell carcinoma (SCC). Nevertheless, standard treatment remains identical. Insight in the impact of histological types on biological behavior and pathological complete response rates might result in a treatment paradigm shift.

#### Material and Methods

Since 2006, 114 locally advanced (FIGO IB2-IVA and IVB in case of para-aortic/inguinal lymph nodes metastases only) cervical cancer (LACC) patients were treated consecutively with neo-adjuvant chemoradiation (NA-CRT) and surgery. RT was performed using an Intensity Modulated Arc Technique up to a minimal dose (D98) of 45Gy to the elective lymph nodes and primary target volume and 62/60Gy (SIB) to the tumor/affected lymph nodes. From 1/2/2009 onwards, para-aortic lymph node irradiation was performed in case of positive pelvic lymph nodes. Brachytherapy was applied in case of doubtful or positive margins after surgery or if surgery could not be performed. Chemotherapy was administered concomitantly (cisplatin or 5-FU). Six patients were excluded for analysis due to a synchronous second primary (n=5) or previous liver transplant (n=1). Clinicopathological characteristics, pathological response and survival rates were compared between AC (n=19) and SCC (n=89) LACC patients. Statistics were performed using SPSS vs 25.0.

#### Results

Clinicopathological characteristics before treatment are

described in table 1, only differentiation grade differed significantly between AC and SCC. In 8 SCC patients, surgery was not performed due to remaining unresectable disease after NA-CRT, they were considered as lack of pathological complete response (pCR). Adenocarcinoma patients treated with NA-CRT showed significantly less pCR compared with SCC patients (AC=10.5%, SCC=39%,  $p=0.017$ ) (table 1). Per FIGO stage, 5y OS and DSS was 100%/72%/50%/50% ( $p=0.012$ ) and 100%/85%/57%/50% ( $p=0.005$ ), for stage I/II/III/IV respectively. Per TNM stage, 5y-OS and DSS was 100%/75%/63%/69% ( $p=0.519$ ) and 100%/90%/71%/69% ( $p=0.258$ ) for stage I/II/III/IV respectively. Five-year OS and DSS were 80%/67% ( $p=0.285$ ) and 80%/78% ( $p=0.816$ ) for AC/SCC, respectively. Relapse pattern was not different between AC and SCC (table 1). Five-year locoregional relapse free survival (LRRFS) and DMFS (including distant nodal relapse) were 100%/83% ( $p=0.093$ ) and 52%/81% ( $p=0.024$ ) for AC/SCC, respectively. In AC, 2/6 patients metastasized in an oligometastatic way, 59m and 62m after treatment and were treated according to an oligometastasis protocol.

Table 1

	AC	SCC	p-value
N (%)	19	89	
Median Age, y (range)	53 (28-79)	54 (25-80)	0.800
Median Follow-up, m (range)	57 (5-131)	36 (7-145)	0.401
FIGO stage			
I	5 (26)	9 (10)	
II	11 (58)	52 (58)	
III	2 (10.5)	20 (22.5)	0.208
IV	1 (5)	8 (9)	
TNM-STAGE			
I	1 (5)	3 (3)	
II	8 (42)	34 (38)	
III	8 (42)	40 (45)	0.975
IV	2 (10.5)	12 (13.5)	
Node positive (%)	7 (37)	44 (49)	
Differentiation grade			
Good (%)	3 (16)	5 (6)	
Moderate (%)	6 (32)	37 (42)	
Bad (%)	3 (16)	33 (37)	0.039
Unknown (%)	7 (37)	14 (16)	
Chemotherapy (%)	18 (95)	83 (93)	1
Surgery (%)	19 (100)	81 (91)	0.201
Brachytherapy (%)	2 (10.5)	7 (8)	0.657
Pathological response			
Complete (%)	2 (10.5)	35 (39)	0.017
Incomplete (%)	17 (89.5)	54 (61)	
Locoregional relapse (%)	0 (0)	14 (16)	0.156
Distant Nodal relapse (%)	2 (10.5)	11 (12)	1
Distant Hematogenous (%)	6 (32)	13 (15)	0.098
Cause of Death (%)			
Cancer progression (%)	2 (10.5)	15 (17)	
Cancer related (%)	1 (5)	1 (1)	0.202
Intercurrent (%)	0 (0)	9 (10)	

### Conclusion

Patients with AC responded significantly less to NA-CRT as evidenced by a significantly lower pCR rate. After surgery, however, this did not result in a worse LRRFS for AC. AC patients had a significantly lower DMFS but this did not translate into a worse OS or DSS. These findings imply a need for a paradigm shift in the treatment of AC patients.

### EP-1506 Multi-institutional treatment and management of cervical cancer patients

A. Tsikkinis<sup>1</sup>, N. Cihoric<sup>1</sup>, E. Vlaskou Badra<sup>1</sup>, D. Aebersold<sup>1</sup>, K. Lössl<sup>1</sup>

<sup>1</sup>Inselspital- Universität Bern, Radiation-Oncology, Bern, Switzerland

### Purpose or Objective

Evaluation of treatment outcome, toxicity and patterns of failure in cervical cancer patients (pts) treated with image guided external beam radio(chemo)therapy (IG-EBRT)

and centralized image guided high dose rate brachytherapy (IG-HDR BT).

### Material and Methods

From 01/2012 to 06/2017, 96 (100%) pts with cervical cancer (FIGO IA2 - IVA) were treated with IG-EBRT in 10 national institutions. 74% of pts were diagnosed with positive lymph nodes, 21% after complete or sentinel-lymphadenectomy and 53% via <sup>18</sup>FDG-PET/CT. 81% of pts were diagnosed with tumors larger than 4 cm in diameter. 82% of the tumors were squamous cell carcinomas, 10% adenocarcinomas and 7% other histologies. All pts were treated with IG-EBRT. A dose of 50.4 Gy was prescribed to the elective pelvic nodal volume. Primary tumors smaller than 4 cm in diameter received an additional boost of 5.4 Gy, primary tumors larger than 4 cm in diameter received a boost of 9 Gy. Patients with positive lymph nodes detected with <sup>18</sup>FDG-PET/CT received a simultaneous integrated boost to a total dose of 64 Gy. Chemotherapy was administered according to institutional standards. After completion of IG-EBRT all pts were centrally referred to our hospital for IG-HDR BT treatment (4 x 6-7 Gy). Median EQD2 dose for the primary tumor was 81.6 Gy (62.6 - 93.2 Gy). Adverse events were coded according to the CTCAE version 4.0.

### Results

Survival data were available for 91 pts. During a median follow-up of 22 months (2-77 months) 28 (31%) pts developed disease relapse. 12 (13%) pts had loco-regional relapse, 7 (8%) local relapse and 5 (5%) nodal relapse. 22 (24%) pts developed systemic metastases. 13 (14%) pts died, 9 (10%) from cervical cancer. Median survival time was not reached. In total 89 acute adverse events (AE) were recorded (86 Gr. 1-2; 3 Gr. 3). Data on late AE were available for 83% of the pts. 68 late AE were recorded (37 Gr. 1; 26 Gr. 2; 5 Gr. 3).

### Conclusion

Satisfactory treatment outcomes were achieved while treatment-related toxicities were kept reasonably low.

### EP-1507 Radical radiotherapy/brachytherapy for cervix cancer in Alberta: who are treated, how do they fare?

N. Vawda<sup>1,2</sup>, S. Ghosh<sup>1,3</sup>, S. Menon<sup>4</sup>, A. Duimering<sup>1,2</sup>, J. Cuartero<sup>1,2</sup>, E. Wiebe<sup>1,2</sup>, C. Doll<sup>4,5</sup>, F. Huang<sup>1,2</sup>

<sup>1</sup>University of Alberta, Oncology, Edmonton, Canada ;

<sup>2</sup>Cross Cancer Institute, Radiation Oncology, Edmonton, Canada ;

<sup>3</sup>Cross Cancer Institute, Oncology, Edmonton, Canada ;

<sup>4</sup>University of Calgary, Oncology, Calgary, Canada ;

<sup>5</sup>Tom Baker Cancer Centre, Radiation Oncology, Calgary, Canada

### Purpose or Objective

To explore patterns of disease and outcomes of cervix cancer (CC) patients treated with radical (chemo)radiotherapy (RT), including brachytherapy (BT), in the province of Alberta (AB), Canada.

### Material and Methods

In this retrospective review, all patients with CC who received primary (chemo)RT (including BT) in AB were identified (by consultation date, January 1, 2013 - December 31, 2015). Descriptive statistics were performed on demographic and clinicopathologic data. The Kaplan Meier method was used to determine overall survival (OS) and cause-specific survival (CSS).

### Results

Over 3 years, 146 women received radical RT including BT in AB (2 tertiary cancer centres, 2:1 spread). Annual caseload was 52 and 55 for 2013 and 2014, respectively; less (39) for 2015. Over half (54.5%) lived within 50 km of their treatment centre, with 20 women residing > 350 km (one > 1000 km) away. Among AB residents (n=140), 32.1% lived in areas designated rural and/or remote (AB Health community profile). Mean age at diagnosis was 52.4 years. Only 19.2% reported a routine Pap smear within 2 years of CC diagnosis; 8.2% had never had a Pap and 24.7%, not in

at least 5 years. Half (55.5%) were current or ex-smokers. Squamous carcinoma (76.7%) was the most common histologic type (adenocarcinoma 16.4%, adenosquamous 1.4%). Clinical stage of the primary was distributed as: 30.1% IB, 11.0% IIA, 35.6% IIB, 3.4% IIIA, 15.8% IIIB, 3.4% IVA (n=1 missing). 63% had pelvic and/or para-aortic (PA) nodal involvement; 7.5% had clinical and/or radiological distant disease. Over 10% had another primary cancer diagnosis: n=7 (lymphoma, melanoma, sarcoma, breast, myelodysplastic syndrome) prior to, 2 (vulva, thyroid) concurrent with, and 6 (non-small cell lung, breast, vagina, bladder) after CC treatment. Most (n=125; 85.6%) had conventional chemoRT (pelvic±PA external beam RT with weekly cisplatin, and intracavitary±interstitial BT boost). N=14 received no chemotherapy; n=6, neoadjuvant±concurrent; n=1, concurrent+adjuvant. Four had BT only. Another 4 were treated after curative surgery was abandoned due to disease extent. An additional 11 had pelvic surgery: 1 pre-RT (nodal debulking), 1 post-BT (hysterectomy), 9 during follow-up (FU) (7 for salvage). Median FU was 28.5 months [3 - 54], with 2y-OS of 76.8% and CSS of 77.9%. By clinical stage, 2y-OS was 85.2% (IB), 82.5% (IIA/B), 55.3% (IIIA/B), 44.4% (IVA/B) and was statistically significant (p=0.001); this did not differ by nodal status. Those living < 50 km away fared worse, with 2y-OS of 71.4%, compared to 83.8% for those further away (p=0.054). Age and year of diagnosis had no appreciable effect.

#### Conclusion

In a heterogeneous CC cohort receiving primary RT/BT within a large integrated health system, outcomes are aligned with international reports. Mitigatable risk factors remain, as unrealized opportunities to optimize health outcomes in this population.

#### EP-1508 EQD2 and overall treatment time as prognostic factors in cervical cancer treated with definitive CRT

S.I. Perez Alvarez<sup>1</sup>, G.E. Trejo Durán<sup>1</sup>, J.C. Rodriguez Rosas<sup>1</sup>, C.H. Flores Balcazar<sup>1</sup>, J. Zamora Moreno<sup>1</sup>, G.B. Santiago Concha<sup>1</sup>, A. Mota Garcia<sup>1</sup>  
<sup>1</sup>Instituto Nacional de Cancerología, Radiation Oncology, Mexico City, Mexico

#### Purpose or Objective

Studies in cervical cancer treated with definitive (chemo)radiotherapy (dC(RT)) had reported the prognostic impact of hemoglobin before and during treatment, clinical response (CR), overall treatment time (OTT) and equivalent dose in 2Gy fractions (EQD2). We reported overall (OS) and disease free (DFS) survival by hemoglobin (Hb, cut-off 10 and 12g/dL), CR (complete or persistence), OTT (cut-off 52 and 56 days) and EQD2 (cut-off 75, 80 and 85Gy).

#### Material and Methods

Retrospective analysis of 898 patients with cervical cancer clinical stage I-IVA treated with complete dRT or dCRT from 2013 to 2017 at a single institution. Survival rates were calculated with Kaplan-Meier analysis and groups compared with log rank test.

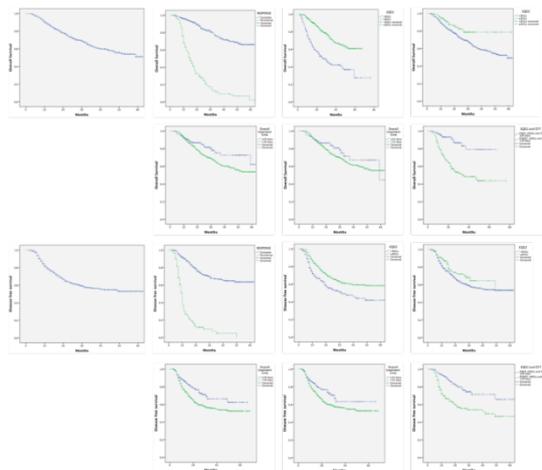

#### Results

More than a half were stage IIB, and 93.8% were treated with CRT (table 1). After treatment, response in 622 patients was complete (69.5%), in 172 stable/partial (19.1%) and in 104 progression (11.6%). With a median follow-up of 22 months (2-76), 317 patients recur or progress (35.3%) with a median time to recurrence of 11 months (1-50). At last follow-up, 69.3% were alive and 30.7% died.

Table 1. Clinico-pathological characteristics	
Median age	51.2 years (19-91 years)
Symptoms at diagnosis	803 (89.4%)
- Median months since symptoms	- 4 months (0-144 months)
Karnofsky performance status ≥90%	838 (96.3%)
Median Hemoglobin	
- On admission	- 12.9g/dL (3.8-16.7)
- Lowest before treatment	- 12.1g/dL (3-16.5)
- Lowest during treatment	- 10.7g/dL (3-15.4)
Clinical stage	
- IB	- 119 (13.3%)
- IIA vs IIB	- 52 (5.8%) vs 463 (51.6%)
- IIIA vs IIIB	- 21 (2.3%) vs 221 (24.6%)
- IVA	- 14 (1.6%)
Histology	
- Squamous cell carcinoma	- 734 (81.7%)
- Adenocarcinoma	- 98 (10.9%)
- Adenosquamous cell carcinoma	- 25 (2.8%)
Table 1. Treatment characteristics	
RT vs CRT	6.2% vs 93.8%
- Median time from admission to RT	- 11 weeks (0-50)
- Median total EQD2	- 82Gy (45-100)
- Median OTT	- 66 days (40-260)
Hemostatic RT	15 (1.7%)
- Median hemostatic radiotherapy dose	- 12Gy (6-24Gy)
Definitive RT	948 (100%)
- Median radiation therapy dose	- 50Gy (30-55.8Gy)
Boost RT	173 (19.3%)
- Median boost radiation therapy dose	- 10Gy (1.8-35Gy)
Brachytherapy	777 (86.5%)
- LDR vs HDR vs LDR and HDR	- 133 (14.8%) vs 655 (72.9%) vs 23 (2.5%)
- Median LDR dose	- 35Gy (15-35Gy)
- Median HDR dose	- 24Gy (5.3-42Gy)
Induction chemotherapy	94 (10.5%)
- Carboplatin / paclitaxel	- 85 (9.5%)
- Median number of cycles	- 6 cycles (1-8)
Concurrent CRT	842 (93.8%)
- Cisplatin vs gemcitabine	- 701 (78.1%) vs 107 (11.9%)
- Median number of cycles	- 5 cycles (1-7)

For all patients included 5-year OS was 51.2%. OS was significantly better within the first 4 years after treatment in patients with Hb before treatment ≥10g/dL (44% vs 30.2%, p<0.001) and ≥12g/dL (58% vs 41.9%, p=0.016). 5-year OS was better with complete CR (66.2% vs 2.3%); EQD2 ≥75Gy (61.5% vs 14.7%, p<0.0001), ≥80Gy (60.8% vs 27.6%, p<0.0001) and ≥85Gy (p=0.011); OTT ≤56 days (62.1% vs 53.7%, p=0.018) and ≤52 days (44.6% vs 50%, p=0.17). Patients with OTT ≤56 days and EQD2 ≥80Gy had a 5-year OS of 78.9% (vs 43.7%, p<0.0001).

For all patients 5-year DFS was 50%. DFS was significantly better within the first 4 years after treatment in patients with Hb before treatment ≥10g/dL (66.7% vs 35.9%, p<0.0001) and ≥12g/dL (65.1% vs 48.1%, p<0.005). 5-year OS was better with complete CR (63.6% vs 0%, p<0.0001); EQD2 ≥75Gy (59.9% vs 24%, p<0.0001), ≥80Gy (58.4% vs 41.7%, p<0.001) and ≥85Gy (54.3% vs 53.8%, p=0.099); OTT ≤56 days (62.3% vs 52.5%, p=0.003) and ≤52 days (63.2% vs 53.6%, p=0.26). Patients with OTT ≤56 days and EQD2 ≥80Gy had a 5-year OS of 65.8% (vs 46.5%, p<0.0001).

In univariate analysis, histological differentiation, Hb (≥10 and ≥12g/dL) before and during treatment, pelvic lymph nodes, concurrent CRT, EQD2 (≥75, ≥80 and ≥85Gy), OTT (≤56 and ≤52 days) and CR showed significance for OS and DFS.

#### Conclusion

Different factors impact negatively the oncologic outcomes. Hemoglobin, OTT and EQD2 are modifiable factors that must be considered for the treatment of patients with cervical cancer to achieve better oncological outcomes. Reducing OTT to ≤52 days and maintaining total

EQD2  $\geq 85$ Gy improves CR, OS and DFS in patients with cervical cancer treated with dCRT independent of other risk factors.

### EP-1509 “Young adult” and “geriatric” locally advanced cervix cancer in Alberta: same but different?

S. Menon<sup>1</sup>, S. Ghosh<sup>2,3</sup>, N. Vawda<sup>3,4</sup>, G. Menon<sup>2,3</sup>, M. Roumeliotis<sup>1,5</sup>, C. Doll<sup>1,5</sup>, E. Wiebe<sup>3,4</sup>, F. Huang<sup>3,4</sup>

<sup>1</sup>University of Calgary, Oncology, Calgary, Canada ;

<sup>2</sup>Cross Cancer Institute, Oncology, Edmonton, Canada ;

<sup>3</sup>University of Alberta, Oncology, Edmonton, Canada ;

<sup>4</sup>Cross Cancer Institute, Radiation Oncology, Edmonton, Canada ;

<sup>5</sup>Tom Baker Cancer Centre, Oncology, Calgary, Canada

#### Purpose or Objective

To review cervix cancer (CC) outcomes after radical (chemo(CH))radiotherapy (RT) including brachytherapy (BT), among women considered, in oncologic terms, younger and older.

#### Material and Methods

Of all CC patients seen in the province of AB (Canada), 01/2013-12/2015, for radical RT, including BT, we identified those aged <40 (young adult, YA) and >65 (geriatric, GA) at diagnosis. We excluded BT-alone cases. Health records were reviewed, abstracting demographic, clinicopathologic, patient-reported, treatment and outcomes data. Statistical analyses, descriptive and actuarial, were undertaken.

#### Results

N=30 YA women (median age 35.7 [23.6-39.1]) and n=26 GA (median age 71.1 [65.2-82.8]), 96% ECOG 0-1, were included. 40% of YA and 69% of GA were within 50 km of their treatment centre. Of the 9 coming from > 350 km away, 8 were YA. Four (all YA) did not live in AB. Age-adjusted Charlson Co-morbidity Index was 0 in all but n=3 YA (score  $\leq 2$ ); median was 3 [1-5] for GA. Most YA (73.3%) and GA (80.8%) had squamous histology, but adenocarcinoma was more common among YA (26.7%, vs. 11.5% for GA, p=0.15; a difference more pronounced between those aged <35 vs.  $\geq 70$ ). Older women had more advanced clinical tumor stage: (YA/GA) 46.7/30.8% IB, 13.3/19.2% IIA, 33.3/19.2% IIB, 0/11.5% IIIA, 6.6/11.5% IIIB, 0/7.7% IVA. YA and GA had similar (60% and 57.7%, respectively) pelvic and/or para-aortic (PA) nodal extent. Clinical/radiological distant metastasis was rare (2 YA, 1 GA). More YA had PET scan workup (76.7%, vs. 57.7%, p=0.13); more GA, EUA (61.5%, vs. 40.0%, p=0.11); MRI rates were similar. 93.3% YA (80.8% GA) received CHRT (pelvic $\pm$ PA external beam (EB)RT with weekly cisplatin, and intracavitary $\pm$ interstitial BT). 2 YA also had neoadjuvant CH. N=5 (all >70 years) had no CH; for those >70 who did, median 4 cycles [2-5]. Few had <3 cycles (3 YA, 2 GA). EBRT (40-50 Gy in 22-25 fractions, extra phase pre/post in 21.4%) preceded HDR-BT (3 fractions; less in n=4) or 1-fraction PDR-BT. BT complications were rare: all GA (3 procedural, 1 stroke). Overall treatment time (CHRT+BT) was 45.5 days median [41.0-84.0] in YA, GA not significantly different (51 [38-112]). Median HR-CTV D90 (Gy EQD2<sub>10</sub>) was 90.2 [53.4-107.1] for YA, 86.0 [54.6-105.5] for GA, p=0.30. Salvage surgery (1 YA, 2 GA) or RT (1 GA) were rare; palliative RT (4 YA, 4 GA) or CH (4 YA, 1 GA) more common. Patient reported outcomes (Table 1) evolved, pre-RT vs. at 6 months post-treatment. For a median 26 months [3-54] follow-up, 2-year overall (OS) for YA was 79.5% and for GA, 57.3% (p=0.473). Two-year cause-specific survival (CSS) was 74.5% for YA and 59.6% for GA (p=0.631) in this small cohort.

**Table 1.** Patient-reported items for YA and GA, from the ESAS-r (Edmonton Symptom Assessment System, revised) and the Canadian Problem Checklist (AB adaptation), administered at baseline and post-treatment (5-8 month visit data are shown).

	Baseline		5-8 months after treatment completion	
	Age < 40 (YA) (26 evaluable)	Age $\geq$ 65 (GA) (22 evaluable)	Age < 40 (YA) (25 evaluable)	Age $\geq$ 65 (GA) (22 evaluable)
<b>ESAS-r</b> (91 symptom items, scored 0 – 10, where 10 = worst possible outcome)				
2 most severe (>7/10) symptoms, ranked by median score	1. Depression, anxiety, well-being (8) 2. Tiredness (7.5)	1. Pain, tiredness, drowsiness, anxiety, well-being (7)	1. Tiredness, depression (8) 2. Drowsiness, anxiety (7.5)	1. Drowsiness (8) 2. Pain, well-being (7.5)
2 most frequent symptoms	1. Anxiety 2. Pain, Tiredness	1. Tiredness, anxiety 2. Well-being	1. Tiredness 2. Well-being	1. Tiredness 2. Pain, well-being

#### Conclusion

CC seems more advanced in older women, who received less intense treatment in our provincial cohort. Patterns of care in primary RT for CC in AB differ in few but important ways among “oncologically” younger and older populations. How cancer outcomes might be improved by addressing the unique needs of each is not known.

### EP-1510 Phase I Trial of Stereotactic MR-guided Online Adaptive Radiotherapy for Ovarian Oligometastases

L. Henke<sup>1</sup>, O. Green<sup>1</sup>, A. Curcuru<sup>1</sup>, S. Mutic<sup>1</sup>, S. Markovina<sup>1</sup>, J. Schwarz<sup>1</sup>, P. Grigsby<sup>1</sup>, C. Robinson<sup>1</sup>, A. Chundury<sup>1</sup>

<sup>1</sup>Washington University/Barnes Jewish Hospital, Radiation Oncology, Saint Louis- MO, USA

#### Purpose or Objective

Delivery of ablative radiation dose using SBRT within the central thorax, abdomen, and pelvis risks toxicity due to target proximity to organs-at-risk (OARs). Stereotactic MR-guided online adaptive radiotherapy (SMART) has been previously shown to improve the therapeutic index of SBRT for abdominal cancers. The feasibility and safety of this approach to treat ovarian oligometastases has not been evaluated. We report the results of a Phase I prospective trial investigating the feasibility and safety of SMART for patients with oligometastatic ovarian cancer.

#### Material and Methods

10 patients with oligometastatic ovarian cancer were enrolled in a phase I trial (NCT02582931) between 9/2016 to 5/2018. All included patients had prior abdominopelvic resection and had received prior chemotherapy, including intraperitoneal chemotherapy in 5/10. Patients were treated with SMART using a 0.35T integrated MR-IGRT unit. 17 lesions were treated, at sites including the central thorax (3), the abdomen (5), and pelvis (9). The prescription was 35 Gy/5 fractions (goal of 95% PTV coverage), with optional dose escalation (DE) up to 50Gy/5 fractions, subject to strict maximum point dose (0.5cc) OAR constraints. During each fraction, physicians re-segmented a daily volumetric setup MRI. Initial plans were applied to daily anatomy to evaluate for OAR constraint violation, or if dose escalation (DE) > 7 Gy/fraction was possible. If either criterion existed, online re-optimization, QA, and delivery of a new plan were performed while the patient remained on-table. Feasibility of SMART was defined as delivery of >80% of planned fractions. Local control was evaluated by RECIST and acute toxicity (within 6 months of treatment) was evaluated by CTCAE v4.3 criteria.

#### Results

100% of SMART fractions were delivered, with a median on-table time of 63 minutes. Each patient received at least 1 adapted fraction and 38/65 (58%) of fractions were adapted, primarily for abdominal and pelvic sites (37/38).

Indications for adaptation included OAR constraint violation (n=32/38 fractions) or DE alone (n=6). 100% of OAR violations were reversed through adaptation. In 16/32 cases where OAR violation reversal was required, target coverage was simultaneously increased. RECIST control of the treated lesion was 100% at 3 months in evaluable patients; one patient did not have imaging at the required time point but had progression on imaging at 4.5 months post-treatment, consistent with 94% short-term lesion control. One treatment-related acute grade 3+ toxicity was observed (duodenal ulcer) with 100% of patients reporting.

#### Conclusion

SMART for patients with ovarian oligometastases is feasible, allowing for dose escalation and/or OAR sparing with low toxicity and promising efficacy. Daily imaging revealed motion primarily of abdominal and pelvic OARs that required frequent re-planning to avoid constraint violations. A phase II trial is planned to further evaluate SMART in this patient subset.

#### EP-1511 Investigation of prognostic factors of cervical squamous cell carcinoma using pre-treatment MRI

C. Tonoiso<sup>1</sup>, A. Haga<sup>2</sup>, A. Kubo<sup>1</sup>, T. Kawanaka<sup>1</sup>, S. Furutani<sup>1</sup>, H. Ikushima<sup>3</sup>, M. Harada<sup>1</sup>

<sup>1</sup>Tokushima University, Radiology, Tokushima, Japan ;

<sup>2</sup>Tokushima University, Medical Image Informatics,

Tokushima, Japan ; <sup>3</sup>Tokushima University, Therapeutic Radiology, Tokushima, Japan

#### Purpose or Objective

Diagnosis and prognostic prediction using features extracted from images have been reported recently. We analyzed MRI images before treatment to investigate prognostic factors of cervical cancer.

#### Material and Methods

100 consecutive patients with cervical squamous cell carcinoma who underwent chemoradiotherapy at Tokushima University Hospital from January 2005 to November 2013 were included in this study. The median age was 59 years old (range 30-79). The FIGO classification was I / II / III / IV in 16/42/34/8 cases, respectively. External irradiation and intracavitary brachytherapy was performed in all cases. The pretreatment T2WI images was transferred to the treatment planning device, and one radiologist defined gross tumor volume (GTV) for all cases. Then the MRI images was standardized with a minimum value of 0 and a maximum value of 1, 3-dimensional wavelet transformation was performed and 476 features were extracted for GTV region. Univariate analysis of prognostic factors was performed by Log-rank test using clinical information and features, and multivariate analysis was performed using Cox proportional hazard model.

#### Results

The median observation period was 55 months (range 2-123), and the 5-year survival rate of all cases was 77.7%. In the univariate analysis, significant differences were observed in the performance state, M factor, 7 features of GTV, and one feature of GTV was a significant factor in multivariate analysis.

#### Conclusion

Analysis using pretreatment MRI may be useful for prognostic prediction of cervical squamous cell carcinoma.

#### EP-1512 Evaluation of target volume margins in prostate dose escalated VMAT by fiducial markers' technique

R. Fawzy<sup>1</sup>, R. Abdel-Malek<sup>1</sup>, M. Metwaly<sup>2</sup>, O. Abdel Aziz<sup>3</sup>, S. Alsirafy<sup>4</sup>, A. Selem<sup>4</sup>

<sup>1</sup>Kasr Al-Ainy Hospitals- Cairo University, Clinical Oncology Dept., Cairo, Egypt ; <sup>2</sup>United Lincolnshire Hospitals- NHS Trust, Department of Dosimetry & Imaging- Radiotherapy physics, Glasgow, United Kingdom ; <sup>3</sup>Kasr Al-Ainy Hospitals-cairo University, Diagnostic & Intervention Radiology Dept., Cairo, Egypt ; <sup>4</sup>Kasr Al-Ainy Hospitals-Cairo University, Clinical oncology Dept., Cairo, Egypt

#### Purpose or Objective

The study aims to investigate sources of errors in radiotherapy that cause uncertainty in the treatment delivery. Measurement of systemic & random errors introduced by the online marker match, the offline marker match & the offline bone match verification and consequently estimating the PTV needed if the verification was done guided by: (i) The fiducial markers match (PTV<sub>marker</sub>), (ii) The bone structure match (PTV<sub>bone</sub>) & (iii) The laser markers on the skin only (PTV<sub>laser</sub>).

#### Material and Methods

Thirty localized prostate cancer patients treated with dose escalated VMAT giving 78 Gy/35# to the whole prostate & 87Gy boost to the focal lesion. Three fiducial markers were inserted US guided; two at the base & the 3rd at the apex. For each patient, two daily MV images were acquired; 1<sup>st</sup> pre-online marker match was utilized for offline bone match, while the 2<sup>nd</sup> post-online marker match used for offline marker match as well. Systematic & random errors were calculated for each verification method to estimate the PTV needed. To composite the PTV<sub>marker</sub>, the online & offline marker matches were compared to check the uncertainty of the marker match, while CT scans were repeated weekly to estimate the marker migration. The PTV<sub>marker</sub> was then added to the evaluated PTV from the online marker match to obtain the PTV<sub>laser</sub>. The offline bone match was used to estimate the PTV due to skin marks migration (PTV<sub>skin marks migration</sub>), which was then deducted from the PTV<sub>laser</sub> to acquire the PTV<sub>bone</sub>.

#### Results

The comparison of the systemic & random errors for the online & offline marker match showed no major difference in the lateral & vertical direction (<0.5mm [p>0.38]), while it was significant with a maximum of 3mm [p=0] in the longitudinal direction. The outcome of the CT study revealed a mean of the maximum marker migration of 2<sub>mm</sub> ± 1.2, this was combined with the mean difference between the offline & the online marker match to produce the PTV<sub>markers</sub> of 2.7±0.6, 3.34±1.1 & 4.44±2.2<sub>mm</sub> in lateral, longitudinal & vertical directions respectively. The resulted PTV margin from the systematic & random errors data of the online marker match was added to the PTV<sub>markers</sub> to yield the PTV<sub>laser</sub> of 13±0.6, 17.7±1.1 & 15.8±2.2<sub>mm</sub> in the same directions respectively. On the other hand, the systemic & random errors equations for the offline bone match shifts revealed PTV<sub>skin marks migration</sub> of 7.1, 9.1 & 8.6<sub>mm</sub>, which implies PTV<sub>bone</sub> of 5.9±0.6, 8.6±1.1 & 7.2±2.2<sub>mm</sub> in the same directions respectively.

#### Conclusion

It was clarified that the PTV needed for fiducial marker image guided verification in dose escalated VMAT to the prostate ranged between 3<sub>mm</sub> and 4<sub>mm</sub> in the lateral, longitudinal & vertical directions; which is about 10<sub>mm</sub> smaller than that is guided by the laser skin marks only and tighter by about 5<sub>mm</sub> relative to that is based on the bone structure image matching only.

#### EP-1513 Patient-reported adverse events following trans-rectal ultrasound-guided prostate marker insertion

T. Rosewall<sup>1</sup>, A. Bayley<sup>1</sup>, P. Chung<sup>1</sup>, C. Catton<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Medicine Program, Toronto, Canada

### Purpose or Objective

Significant improvements in the precision of radiotherapy delivery have been made using radio-opaque intra-prostatic markers (IPM). Despite widespread clinical implementation, there is little information available on the frequency and severity of adverse events associated with IPM insertion. The purpose of this study was to quantify patient-reported adverse events following ultrasound-guided, trans-rectal implantation of IPM and to determine the factors that may influence the frequency and severity of those adverse events.

### Material and Methods

A cohort of 100 prostate cancer patients was prospectively accrued. Procedural parameters that may be associated with the risk of adverse events were documented in a data collection form by the interventional radiologist immediately after the IPM insertion. All patients completed an adverse events questionnaire immediately after IPM insertion and approximately 3 to 5 days later.

### Results

All patients were successfully implanted with 3 IPM following a course of prophylactic antibiotics. Local anaesthetic was used in only 2% of patients, and the radiologist reported that only 4% of patients complained of pain. Conversely, 49% of patients reported that the procedure was as painful as, or worse than, previous biopsies. There was no significant change in AUA prostate symptom score after IPM insertion. 23% to 30% of patients reported hematochezia, hematuria or hematospermia over a few days. Fever was reported by 8% of the patients, requiring a visit to their family doctor (6%) or the emergency department (2%) after which they were admitted to hospital for parenteral antibiotic therapy for Cipro-resistant infection. There were no detectable associations between pain during IPM insertion and pain later on, or between use of anticoagulants and bleeding events.

### Conclusion

IPM are a valuable tool for daily image-guidance during prostate radiotherapy but their utility must be balanced with the clinical safety of their implantation. The trans-rectal ultrasound-guided IPM insertion was well tolerated by most patients. Any bleeding or pain experienced was self-limiting. IPM insertion was however, associated with infrequent, but severe infections.

### EP-1514 Binary exponential model for the PSA fall after IMRT, dependency on initial PSA and Prostate volume

H. Nagano<sup>1</sup>, H. Yokoyama<sup>1</sup>, M. Kato<sup>2</sup>, H. Hashimoto<sup>1</sup>, T. Shimo<sup>2</sup>, M. Watanabe<sup>1</sup>, M. Nakanishi<sup>1</sup>, Y. Kaneko<sup>1</sup>, H. Suzuki<sup>1</sup>, A. Noguchi<sup>1</sup>, K. Kobayashi<sup>1</sup>

<sup>1</sup>Shonan Fujisawa Tokushukai Hospital, Radiation Oncology Department, Fujisawa, Japan; <sup>2</sup>Tokyo-West tokushukai Hp., Radiology, Akishima, Japan

### Purpose or Objective

PSA (prostate-specific antigen) kinetics for patients with localized prostate cancer after radiation therapy has been reported by some authors. These are mainly analysis of nadir or slopes of a certain period. We intended to fit data to binary exponential model mathematically to give away whole course kinetics of PSA after IMRT or VMAT.

### Material and Methods

Twenty one (T1c; 7, T2a; 10, T2b; 2, T2c; 2) patients with mean age 72.4 y. o. (range, 57 - 85 y. o.) and mean GS 6.5 (range, 5 - 8) were treated by IMRT or VMAT (76 Gy / 38 fractions / 8 weeks) without androgen ablation. Their prostate volume before treatment were ranged 13.0 to 68.7 ml with mean value of 39.0 ml. They had mean initial PSA (iPSA) as 7.28 ng/ml (range, 3.58 - 11.85 ng/ml) and had follow-up PSA examinations 2.5 to 8.2 years (mean 4.1 years) with about 3 months interval.

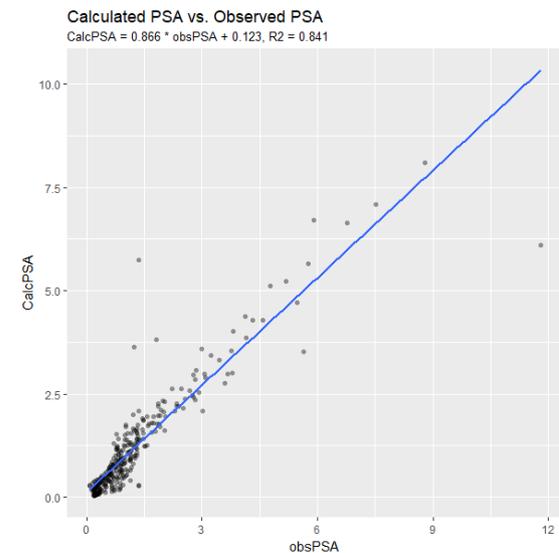

We supposed that PSA fall was composed of two steps, rapid and slow ones. Each fall may fit to exponential decay

with time constant T.rapid [month] or T.slow [month], and initial quantity Amp.rapid [ng/ml] or Amp.slow [ng/ml]. Mathematical expression of PSA at time t month is as this;  $PSA(t) = Amp.rapid * \exp[-t / T.rapid] + Amp.slow * \exp[-t / T.slow]$

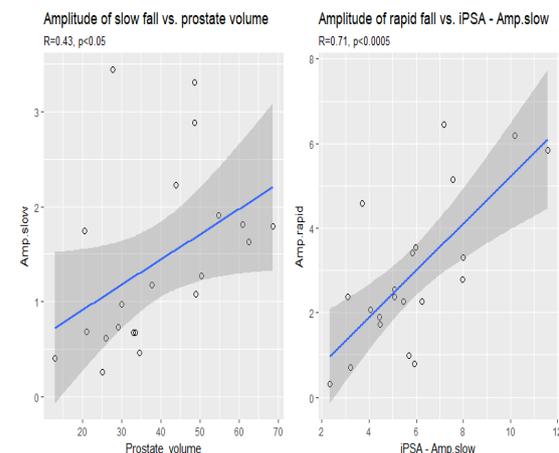

In the assumption that time constant, T.rapid and T.slow might be equal among the all patients, we can also estimate amplitudes of both falls (Amp.rapid and Amp.slow) of each patient using least square method comparing observed and calculated PSA.

### Results

Observed and calculated PSA values were well correlated (R = 0.92). Residuals were almost normally distributed with mean value 0.04 ng/ml and standard deviation 0.29 ng/ml excluding 5 outliers.

T.rapid and T.slow were 0.357 and 3.99 months, respectively. Amp.rapid ranged 0.31 to 6.46 ng/ml and mean was 2.93 ng/ml. Amp.rapid correlated well (R = 0.71) with iPSA - Amp.slow (p < 0.0005). Amp.slow ranged 0.26 - 1.42 ng/ml and mean was 1.42 ng/ml. Amp.slow correlated somewhat well (R = 0.43) with prostate volume (p < 0.05).

### Conclusion

PSA fall after IMRT or VMAT was well fitted to our binary exponential model. Amplitude of rapid fall (Amp.rapid) was related to iPSA - Amp.slow, and that of slow fall (Amp.slow) was relevant to prostate volume. We might speculate that slow fall may mainly related to normal prostate recovery after treatment, and rapid fall may represent elimination of cancer cells by radiation therapy.

**EP-1515 Substantial impact of 68Ga-PSMA-PET/CT on the radiotherapeutic approach for prostate cancer**  
N. Schmidt-Hegemann<sup>1</sup>, C. Eze<sup>1</sup>, M. Li<sup>1</sup>, P. Rogowski<sup>1</sup>, C. Schaefer<sup>1</sup>, C. Stief<sup>2</sup>, U. Ganswindt<sup>3</sup>, P. Bartenstein<sup>4</sup>, C. Belka<sup>1</sup>, H. Ilhan<sup>4</sup>

<sup>1</sup>Department of Radiation Oncology- University Hospital- LMU Munich, Department of Radiation Oncology- University Hospital- LMU Munich, München, Germany ; <sup>2</sup>Klinik und poliklinik für Urologie, Department of Urology - University hospital Munich, München, Germany ; <sup>3</sup>Department of Therapeutic Radiology and Oncology - Medical University Innsbruck, Department of Therapeutic Radiology and Oncology - Medical University Innsbruck, Innsbruck, Austria ; <sup>4</sup>Department of Nuclear Medicine- University Hospital- LMU Munich, Department of Nuclear Medicine- University Hospital- LMU Munich, München, Germany

#### Purpose or Objective

Prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA PET/CT) offers unprecedented accuracy for staging of primary, persistent or recurrent prostate cancer. Thus, we hypothesized that PSMA PET/CT prior to radiotherapy significantly impacts the radiotherapeutic approach.

#### Material and Methods

Between February 2014 and December 2017, a total of 172 patients received PSMA PET/CT and were included in this retrospective analysis. Twenty-two (13%) patients were referred for primary definitive radiotherapy, 51% (88/172) for PSA persistence and 36% (62/172) for PSA recurrence after radical prostatectomy. The potential increase in diagnostic accuracy, and the subsequent change of radiotherapeutic approach was documented separately for PET/CT versus CT.

#### Results

Overall detection rate was 70% (120/172) in 68Ga-PSMA PET/CT. Patients with pre-PSMA PET/CT PSA-level >0.5 ng/ml (98/111; 88%) had significantly more often PET-positive results. Overall, PSMA PET/CT revealed a total of 171 lesions, PET alone 156 and CT alone 85. For all patients a continuous diagnostic increase in positive findings was observed for primary tumor/local recurrence (CT: 18% vs. PET/CT: 37%), pelvic lymph node (CT: 21% vs. PET/CT: 44%) and distant metastases (CT: 7% vs. PET/CT: 19%) when comparing CT vs. PET/CT. Compared to CT, the combination of PET/CT information resulted in a change of treatment in 107/172 (62%) patients, i.e. 8/22 (36%) patients prior to any treatment, 31/62 (50%) with PSA recurrence and 68/88 (77%) with PSA persistence. Comparing the different radiotherapy indications with each other, there was a higher change of management in postoperative patients vs. patients prior to any treatment.

#### Conclusion

Compared to conventional CT, PSMA PET/CT had a remarkable impact on radiotherapeutic approach especially in postoperative patients. Postoperative patients might benefit in particular from an improved staging method, as for patients with persistent or recurrent prostate cancer there are no nomogram-based radiotherapy treatment volumes.

**EP-1516 Macroscopic local relapse from prostate cancer: which role for salvage RT? An update analysis**

A. Bruni<sup>1</sup>, G. Ingrosso<sup>2</sup>, F. Trippa<sup>3</sup>, M. Di Staso<sup>4</sup>, L. Rubino<sup>1</sup>, G. Aluisio<sup>1</sup>, S. Parente<sup>4</sup>, L. Frassinelli<sup>1</sup>, E. Maranzano<sup>3</sup>, R. Santoni<sup>2</sup>, E. Mazzeo<sup>1</sup>, F. Lohr<sup>1</sup>  
<sup>1</sup>Az. Ospedaliero-Universitaria di Modena - Policlinico, Radiation Oncology Department, Modena, Italy ; <sup>2</sup>"Tor Vergata" University General Hospital, Radiotherapy Unit-, Rome, Italy ; <sup>3</sup>"Santa Maria" University Hospital, Radiotherapy Unit, Terni, Italy ; <sup>4</sup>"Nuovo San Salvatore" Hospital, Radiotherapy Unit, L'Aquila, Italy

#### Purpose or Objective

Radical prostatectomy (RP) is an effective and widely used curative treatment for localized prostate cancer while salvage radiotherapy (SRT) is recommended for biochemical relapse (BR) after prostatectomy (RP). Even if several studies showed that biochemical control can be achieved by SRT if it starts as soon as possible several patients (pts) are still referred to Radiation Oncologists when macroscopical recurrence has occurred. This is a final update analysis of a multicenter retrospective study to evaluate SRT efficacy and tolerability in pts with biopsy/imaging proven relapse.

#### Material and Methods

We retrospectively analyzed 105 pts with macroscopic relapse after RP who underwent SRT between 2001 and 2016. We identify subgroups by means of nodal involvement (N0 vs N1) at diagnosis, Gleason Score ( $\leq 7$  Vs  $> 8-10$ ), PSA value at relapse ( $\leq 2.0$  ng/mL Vs  $> 2.0$  ng/mL), restaging (biopsy Vs TC scan/MRI Vs Choline CT-PET) and concomitant hormone therapy (Yes/No). Survival curves were generated using Kaplan-Meier method and relationship with outcome were analyzed using univariate followed by Cox regression analysis.

#### Results

After a median follow up of 52 months, 89 pts were still alive. Total RT dose to macroscopic lesion was  $> 70$  Gy in 58 pts,  $\leq 70$  Gy in 43 pts. Exclusive SRT was used in 42 pts, while 63 received also concomitant ADT. Five and ten-year overall survival was 85,5% and 76,1% while distant metastasis free survival was 86,1% and 73,3% respectively. In 30 pts prophylactic RT was delivered to pelvic nodal stations. Five and 10-year-OS was 85,5% $\pm$ 4,4 Standard Error (SE) and 76,1% $\pm$ 5,9SE while MFS was 86,1% $\pm$ 3,6SE and 73,3% $\pm$ 5,9SE respectively. Five and 10-year-bPFS was 69.7% $\pm$ 5.2SE and 57.7% $\pm$ 6.6SE, respectively. Extrapelvic nodal relapse was found in 5 pts, bone metastasis in 12, both in 2. No grade 4/5 toxicities were found.

#### Conclusion

SRT even in pts with loco-regional macroscopic PCa relapse results in an excellent profile in terms of oncological outcome (OS, BFS, MFS) confirming the role of SRT even in this unfavorable subset of pts. In comparison with available series treated with ADT only, our data suggest that SRT may either postpone ADT or improve results over ADT alone in appropriately selected pts.

**EP-1517 The long-term result of stereotactic body radiotherapy for localized prostate cancer**

Y. Lin<sup>1</sup>, S. Wang<sup>1</sup>

<sup>1</sup>Chi Mei Medical Center, Department of Radiation Oncology, Tainan, Taiwan

#### Purpose or Objective

The understanding of radiobiology for prostate cancer suggested hypofractionation might achieve a higher therapeutic benefit. Stereotactic body radiation therapy (SBRT) is able to deliver a high dose per fraction precisely. SBRT for prostate cancer could escalate biological effective doses while without increasing toxicity. Here, we reported our long-term results of SBRT for localized prostate cancer.

#### Material and Methods

Between November 2008 and May 2018, a total of 232 patients with clinically localized prostate were enrolled for analysis. Patients were low-risk (11%), intermediate-risk (37%), and high-risk (52%). Low- and intermediate-risk patients were treated with SBRT to prostate and half of seminal vesicles (37.5Gy in 5 fractions). High-risk patients were treated with whole pelvic irradiation (45Gy in 25 fractions) and SBRT boost (21Gy in 3 fractions). The intermediate- and high-risk patients received hormone therapy with different duration. The toxicities of gastrointestinal (GI) and genitourinary (GU) tracts were scored by Common Toxicity Criteria Adverse Effect (CTCAE

v3.0). Patterns of prostate-specific antigen (PSA) response were analyzed. Biochemical failure was defined as Phoenix definition.

#### Results

The initial median PSA was 9.4 and 40.8 ng/ml for the low/intermediate-risk and high-risk patients, respectively. After SBRT treatment, median PSA at 60 months level was 0.16 and 0.07 ng/ml for the low/intermediate-risk and high-risk patients, respectively. In the low/intermediate-risk patients, there were four patients with biochemical failures within a median follow-up of 58 months. For the high-risk patients, seven patients with biochemical failure were disclosed in the median 46-month follow up. The estimated 10-year biochemical failure-free survival was 95.1% and 90.2% for low/intermediate-risk, and high-risk patients, respectively. In the low/intermediate-risk patients, late Grade 3 GU and GI toxicities were seen in 2.5% and 0%, respectively. In the high-risk patients, the incidence rate of late Grade 2 GU and GI toxicity were 5% and 2%. There was no late Grade 3 and GI toxicity in the high-risk patients. Most of acute toxicity effects in all the patients resolved within three to six months of treatment completion.

#### Conclusion

This is a 10-year experience of SBRT for localized prostate cancer in a single institution. SBRT with or without whole pelvic irradiation for localized prostate cancer is feasible with minimal toxicity and excellent biochemical failure-free survival. Continued accrual and follow-up would be necessary to confirm this long-term biochemical control and the late toxicity profiles.

#### EP-1518 A dosimetric comparison of treatment plans by using aaa/mc with vmat technique for prostate patients

P. Boydak<sup>1</sup>, K. Temizyurek<sup>2</sup>

<sup>1</sup>Istanbul Aydin University, Medical Physics, Istanbul, Turkey ; <sup>2</sup>Istanbul Aydin University, Medicine, Istanbul, Turkey

#### Purpose or Objective

In this study, it was aimed to compare the performance of two different algorithms on the VMAT technique. Twenty patients with prostate cancer were selected for comparison. Tomography images were scanned with a 3mm slices. Target volume PTV and at-risk organs (OAR) as bladder, rectum, right -left femur heads were defined. Doses of target volumes were prescribed as 70 Gy in 35 fractions for all treatment plans. In Varian technique patient plans are prepared using 6 MV energy, AAA algorithm, and double arc VMAT technique with the Eclipse Treatment Planning System (TPS), then in Elekta for same patients, treatment plans using 6 mV energy, the Monte Carlo algorithm and VMAT technique are made with the Monaco TPS. Dose distributions were obtained for each patient. These two different algorithms were compared in terms of critical organ dose values, target volume maximum dose values, HI, CI and MU values of PTV.

#### Material and Methods

Plans were normalized to cover 95% of the target volume. CI and HI values in Varian Rapidarc are 1.01±0.02 (1), 0.08±0.01 (0.08), respectively. For Elekta-VMAT CI and HI values are 0.96±0.02 (0,95) and 0.1±0.02 (0.09), respectively. Consequently RapidArc gave better result for CI and HI values. The monitor unit value of RapidArc 761,35 ± 94,29 was observed to be lower than that of Elekta-VMAT monitor unit 922,15 ± 93,4. In terms of bladder and rectum doses Elekta-VMAT technique give lower results than results of RapidArc technique. There was no significant difference (p>0.05) in the calculation of PTV Dmax and bladder 50% for each machine. When the critical organ doses were considered, the Elekta-VMAT technique has statistically significant lower values for bladder and rectum doses than those values of the

RapidArc technique. For right and left femurs, the RapidArc technique shows better results.

#### Results

RapidArc MU values are lower than MU values of Elekta-VMAT, so treatment duration was shorter in RapidArc. Clinically both VMAT-techniques for each machine were equally effective in producing acceptable plans.

#### Conclusion

As a result it can be said that these two techniques produce equivalent results by practice.

#### EP-1519 PSMA-PET/CT for guidance and response assessment of SABR for prostate cancer oligometastases

P. Dirix<sup>1</sup>, C. Mercier<sup>1</sup>, C. Billiet<sup>1</sup>, P. Vermeulen<sup>2</sup>, S.

Oeyen<sup>2</sup>, S. Van Laere<sup>2</sup>, P. Huget<sup>1</sup>, D. Verellen<sup>1</sup>

<sup>1</sup>Iridium Cancer Network, Radiation Oncology, Antwerp, Belgium ; <sup>2</sup>Oncologisch Centrum GZA, Translation Cancer Research Unit, Antwerp, Belgium

#### Purpose or Objective

Prostate-specific membrane antigen (PSMA) PET/CT is increasingly used to detect oligometastases in biochemical recurrent prostate cancer and subsequently guide metastasis-directed treatment such as SABR. However, limited prospective evidence is available.

#### Material and Methods

All patients were included in a prospective phase I dose-escalation trial on SABR for non-spine bone and lymph node oligometastases (NCT03486431). According to protocol, a new PMSA-PET/CT was performed at 6 months after treatment. Metabolic response was evaluated according to PERCIST 1.0 criteria. PSA progression was defined as a PSA increase of ≥ 25% and ≥ 2 ng/mL if PSA was ≥ 2 ng/mL at baseline, or a PSA increase of ≥ 25% if PSA was < 2 ng/mL. PSA response was defined as a decline from baseline of ≥ 80%, while complete response was defined as a decline from baseline of ≥ 90%. Toxicity was graded using Common Terminology Criteria for Adverse Event version 4.0.

#### Results

From July 2017 to March 2018, 15 consecutive patients had 1 (n = 12) or 2 (n = 3) metastases detected on PSMA-PET/CT and were prospectively included in the trial. They then received SABR to a total of 18 oligometastases. Four patients had non-spine bone only, 8 had node only, and 3 had mixed disease. The median age was 67 (52-78) years. Four patients received concomitant androgen-deprivation therapy (ADT) for 6 months. Eight patients were included in the first cohort (5x 7.0 Gy) and 4 in the second cohort (3x 10.0 Gy). SABR was feasible and delivered as planned in all cases.

At 6 months after SABR, 5 patients had a complete PSA response, while 7 patients showed PSA progression. Already 8 patients had new metastatic lesions visible on the second PSMA-PET/CT. Interestingly, only 5 of those patients had clear PSA progression at that time. Regarding local control, there was residual PSMA uptake in 6 patients (7 lesions in total). Remarkably, 3 of those 6 patients had a complete PSA response at the same time. All 4 patients who received concomitant ADT presented a complete metabolic response on PSMA-PET/CT as well as a complete PSA response.

Median follow-up was 11 (7 - 14) months. No grade ≥ 3 toxicity was observed. Progression-free survival at 1 year was 100% for patients who had received ADT versus 21% for patients who did not (p = 0.032). In total, 6 of the 11 patients not on ADT had started ADT at the last follow-up (1-year ADT-free survival of 32%).

A further 10 patients were included the second cohort, whose PSMA follow-up will be available at ESTRO.

#### Conclusion

Repeated imaging with PSMA-PET/CT could be incorporated into prospective clinical trials on SABR for prostate cancer oligometastases to evaluate the true

benefit of metastasis-directed therapy. However, specific response criteria for PSMA-PET/CT are urgently needed. Also, an interval of more than 6 months may be required to fully estimate the local efficacy of SABR in control PSMA-PET/CT in some patients.

**EP-1520 Acute and late toxicity of hypofractionated RT for localized prostate cancer: IMRT vs Tomotherapy**  
A. Rese<sup>1</sup>, F. Pastore<sup>1</sup>, G. Panelli<sup>1</sup>, A. Pepe<sup>1</sup>, D. Toledo<sup>1</sup>, F. Francomacaro<sup>1</sup>, V. Iorio<sup>1</sup>

<sup>1</sup>Emicenter, Radiotherapy, Casavatore NA, Italy

#### Purpose or Objective

To evaluate the incidence of acute and late toxicity after hypofractionated radiotherapy using Linac intensity-modulated radiotherapy (IMRT) compared with helical Tomotherapy.

#### Material and Methods

From September 2016 to March 2018, 110 consecutive patients with localized prostate cancer (cT1-2, GS< 8, PSA<10 ng/ml) were randomized to Linac IMRT and to helical Tomotherapy.

55 patients were treated with Linac IMRT and 55 with TOMO.

Patients were monitored before therapy, weekly during therapy, 2 weeks, three and six months after radiotherapy was completed, using RTOG GI and genitourinary toxicity grading scale.

Patients received radiotherapy schedule according to histology reports following international guidelines.

Doses were prescribed to planning target volumes (PTVs) as the followings: 72 Gy (2.4 Gy/fx) to PTV-whole prostate and 64.5 Gy (2.15 Gy/fx) to PTV-prostate and seminal vesicles in 30 fractions with SIB technique. Dose to abdominal cavity, both femoral heads, bladder and rectum were constrained below each tissue tolerance.

#### Results

Median age of the patients was 72.5 (range 55-86 years). At the end of the treatment (6 weeks), 16/55 (29%) patients in the TOMO group vs. 19/55 (34.5%) patients in the Linac IMRT group had G1-G2 grade of GI toxicity (p=0.009), while 2/55 (4%) patients in the TOMO group vs. 4/55 (7.3%) patients in the Linac IMRT group had G3 grade of GI toxicity.

27/55 (49%) patients in the TOMO group vs. 31/55 (56%) patients in the Linac IMRT group had G1-G2 grade of GU toxicity (p=0.04), while 1/55 (1.8%) patients in the TOMO group vs. 3/55 (5.5%) patients in the Linac IMRT group had G3 grade of GU toxicity.

No G4 grade of GI and GU toxicity was showed.

After 6 months from the end of the treatment, no patients in the TOMO group vs. 2/55 (3.6%) patients in the Linac IMRT group had G1-G2 grade of GI toxicity, while 1/55 (1.8%) patients in the TOMO group vs. 2/55 (3.6%) patients in the Linac IMRT group had G3 grade of GU toxicity.

#### Conclusion

Acute toxicity is very low. Most of the recorded symptoms decrease over time.

A small increase in mild toxicity, statistically significant, was observed in the Linac IMRT group when compared with TOMO group. Our study confirmed that Tomotherapy allows for safe moderate hypofractionation, offering a shorter overall treatment time, a lower rate of acute and late toxicities and providing potentially more economic health care.

**EP-1521 IMRT for prostate cancer with seminal vesicle involvement : A multicentric retrospective analysis**  
F. Goupy<sup>1</sup>, S. Supiot<sup>2</sup>, D. Pasquier<sup>3</sup>, I. Latorzeff<sup>4</sup>, U. Schick<sup>5</sup>, E. Monpetit<sup>6</sup>, G. Martinage<sup>3</sup>, C. Hervé<sup>1</sup>, B. Le Proust<sup>7</sup>, J. Castelli<sup>1</sup>, R. De Crevoisier<sup>1</sup>

<sup>1</sup>Centre Eugène Marquis, Radiotherapy, Rennes, France ;

Toulouse, France ; <sup>5</sup>University Hospital Cavale Blanche, Radiotherapy, Brest, France ; <sup>6</sup>Centre Saint-Yves, Radiotherapy, Vannes, France ; <sup>7</sup>Centre Eugène Marquis, Medical Imaging, Rennes, France

#### Purpose or Objective

MRI can detect with high specificity prostate cancer with seminal vesicle involvement (ISV), classifying the tumor stage as T3b. Delivering high curative dose (> 70 Gy) in the ISV is particularly challenging, when respecting the dose constraints in the OARs. No studies have reported data of external beam radiotherapy for specifically T3b prostate cancer. The objective of this study was to analyze the dose distribution and the clinical outcome in a large series of patients having received IMRT for T3b prostate cancer.

#### Material and Methods

This retrospective analysis included all patients having received IMRT and androgen deprivation therapy for T3b prostate cancer, between 2008 and 2017 in six French institutions, with available MRI images and dosimetric data. A dosimetric analysis was performed, in particular regarding the ISV, divided in three thirds in the cranio-spinal axis. Recurrences, survivals and toxicities (CTCAE v4.03) were analyzed.

#### Results

A total of 276 T3b patients was included. The mean follow-up was 35 months. Only the first proximal third of seminal vesicle was involved for 64% of patients, and the entire for 16% of patients. Lymph node involvement was present for 26% of patients. The mean (range) prescribed doses to the prostate and to the ISV were 77 Gy (70-80) and 68 Gy (46-80), respectively. The prescribed doses to the ISV and the not-involved SV were equal to or greater than 70 Gy for 64% and 22% of patients, respectively. The pelvic lymph nodes without lymph node involvement were treated at a prophylactic dose in 90% of cases. The mean prescribed dose to the involved lymph node was 52 Gy (46-74), and equal to or greater than 60 Gy for 30%. The dose constraints recommendations were exceeded in less than 12% of patients for the rectum and the bladder. The 5 year risks of biochemical and clinical recurrences and cancer specific death were 24.8%, 21.7% and 10.3% respectively. The 5 year risks of local, pelvic lymph node and metastatic recurrences were 6.4%, 11.3% and 15%, respectively. Lymph node involvement was the only significant prognostic factor on clinical recurrence (HR 2.90, p=0.005) and cause specific survival (HR 4.45, p=0.017). Grade > 2 acute and 5 year late toxicity rates were 13.2% and 12% for digestive toxicity, and 34% and 31.5% for urinary toxicity. The dose to the pelvic lymph node was predictive of late digestive toxicity (HR 1.13, p=0.002).

#### Conclusion

We reported the most important series of IMRT for T3b prostate cancer. IMRT combined with IGRT allows delivering a high curative dose (> 70 Gy) in the ISV, while rarely exceeding dose constraints. Late digestive toxicity was low but urinary toxicity was slightly increased. Local control appears high and the main pattern of recurrence is metastasis, mostly related to lymph node involvement at diagnosis. More follow-up is needed to confirm the results due to the relative recent use of MRI allowing characterizing ISV. The combined MRI Linac may even more improves the results by a better IGRT targeting.

**EP-1522 Radiotherapy with or without antihormonal therapy for PSMA-positive oligorecurrent prostate cancer**

S. Kroeze<sup>1</sup>, C. Henkenberens<sup>2</sup>, N. Schmidt-Hegemann<sup>3</sup>, M. Vogel<sup>4</sup>, S. Kirste<sup>5</sup>, J. Becker<sup>6</sup>, H. Christiansen<sup>2</sup>, C. Belka<sup>7</sup>, S. Combs<sup>4</sup>, A. Grosu<sup>5</sup>, A. Müller<sup>6</sup>, M. Guckenberger<sup>8</sup>

<sup>1</sup>University Hospital Zürich, Radiation Oncology, Zurich, Switzerland ;

<sup>2</sup>Medical School Hannover, Radiotherapy and Special Oncology, Hannover, Germany ;

<sup>3</sup>University Hospital LMU, Radiation Oncology, Munich, Germany ;

<sup>4</sup>Technical University Munich, Radiation Oncology,

Munich, Germany ; <sup>5</sup>University of Freiburg, Radiation Oncology, Freiburg, Germany ; <sup>6</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany ; <sup>7</sup>University Hospital LMU Munich, Radiation Oncology, Munich, Germany ; <sup>8</sup>University Hospital Zürich, Radiation Oncology, Zürich, Switzerland

### Purpose or Objective

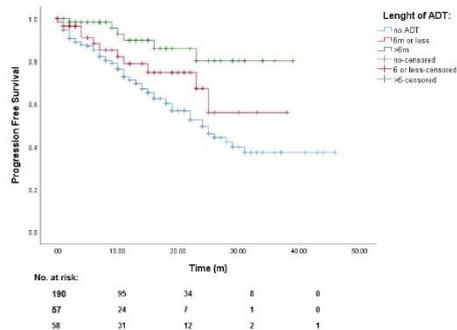

Based on <sup>68</sup>Ga-PSMA-PET imaging, approximately 20-40% of early biochemical recurrent prostate cancer after radical prostatectomy are oligometastatic and located outside the prostate bed, challenging the current standards of care. Definitive radiotherapy (RT) of these recurrences plays an increasingly important role, but it remains unknown whether patients benefit from the addition of antihormonal therapy (ADT) in this situation. This study aims to compare the efficacy of definitive radiotherapy (RT) of <sup>68</sup>Ga-PSMA-positive oligorecurrences (ORT) with or without additive antihormonal therapy (ADT).

### Material and Methods

Retrospectively, data of 305 patients who underwent definitive radiotherapy (RT) of 647 oligorecurrent <sup>68</sup>Ga-PSMA -positive metastatic sites were evaluated. Patients were treated between 04/2013 and 01/2018 in 6 academic centers. All oligorecurrent patients were treatment-naïve. PSA-progression free survival (PFS) and ADT-free survival was analyzed using Kaplan-Meier survival curves and log rank testing. Toxicity were analyzed with the CTCAE v4 score. Uni-, and multivariate analyses were performed to determine patient, disease and treatment factors influencing PFS.

### Results

Median age of patients was 70 (46-95) years, 96% were initially high-, or very high risk. Median PSA at time of <sup>68</sup>Ga-PSMA-PET was 1.05 (0.04-47.5) ng/ml and PSA-DT was 6.3 (1-56) months. A median of 1 (1-19) nodal, and 1 (1-5) distant metastatic lesions were irradiated. Overall, 93% of patients showed a PSA-decrease to median 0.07 (range 0-13.7) ng/ml after median FU of 16 (1-57) months. 37% of patients received additional ADT. Additional ADT resulted in a significantly improved PFS compared to RT alone, which remained significant in multivariate analysis (p=0.0001). However, the addition of ≤6 mo ADT did not significantly improve PFS compared to patients not receiving ADT (fig. 1). Other independent significant factors for better PFS were nodal-only metastases and biochemical recurrence ≥ 1 year. Patients without additional ADT required second salvage therapies more frequently (4% vs. 33%, p<0.001), but 1- and 3y ADT-free survival was 93% and 59%. Grade ≥3 acute toxicity was observed in 0.9% of patients, late toxicity in 2.3%.

### Conclusion

Definitive RT in this large cohort of mainly very high-risk, treatment-naïve oligorecurrent PCa patients was feasible and safe. Immediate addition of ADT improved PFS significantly, but two-third of patients treated with RT

only were spared from ADT for 3 years. Prospective trials with sufficiently long follow-up are needed evaluate the potential of ADT and its duration in addition to radical radiotherapy for PSMA-PET detected oligorecurrent prostate cancer.

### EP-1523 Predictors of severe late urinary toxicity after curative radiotherapy for localised prostate cancer

<sup>3</sup>Tohoku University Hospital, Department of Radiation

Technology, Sendai, Japan ; <sup>4</sup>Tohoku University Graduate School of Medicine, Department of Urology, Sendai, Japan

### Purpose or Objective

We aimed to assess the difference between planned and accumulated doses in prostatic urethra (PU) and bladder and to investigate the relationship between these differences and coexistent clinical status on severe late urinary toxicity following curative radiotherapy for patients with localised prostate cancer (PLPC).

### Material and Methods

Overall, 302 PLPC were treated with image-guided intensity-modulated radiation therapy (IMRT) between 2008 and 2015 in our institution. All PLPC had fiducial markers (FM) implanted in the prostate for daily set-up correction. For each PLPC, urethral catheter (UC) was temporarily used for the PU identification and delineation on planning CT (pCT) images. Moreover, cone-beam CT (CBCT) image was acquired on the first IMRT day and then approximately every 4 days, following daily set-up correction, throughout IMRT course (total 9-10 scans per PLPC). A radiation oncologist (RO) contoured the PU based on UC and the prostate, rectum, bladder, and seminal vesicles on pCT images. Among 302 PLPC, 8 who experienced grade 3 late urinary toxicities (according to the Common Terminology Criteria for Adverse Events version 4.0) within median follow-up period of 53 months (range, 6-118) were enrolled in the present study; the total dose administered was 80Gy in 40 fractions for 6 PLPC and 76Gy in 38 fractions for the remaining 2. Their median age was 65 years (range 59-73). Coexistent clinical status in the eight PLPC included antithrombotic therapy (AT) in four, diabetes mellitus in three, and prior transurethral prostate resection and high intensity focused ultrasound in two. All CBCT images were rigidly registered in the corresponding pCT images via matching FM and were exported to RayStation (version 4.5.1). Thereafter, the RO delineated the bladder on all CBCT images. The PU delineation conducted in each of the eight PLPC was transferred from pCT images to corresponding CBCT images. All CBCT images were then deformed to the corresponding pCT images using deformable image registration. Dose distributions were deformed and summed to estimate the following accumulated dosimetric factors: D<sub>98</sub>, D<sub>95</sub>, D<sub>mean</sub>, D<sub>50</sub>, D<sub>2</sub>, V<sub>75</sub> and D<sub>max</sub> of PU; and D<sub>98</sub>, D<sub>95</sub>, D<sub>mean</sub>, D<sub>50</sub>, D<sub>2</sub>, V<sub>35</sub>, V<sub>55</sub>, V<sub>65</sub>, V<sub>70</sub>, V<sub>75</sub> and V<sub>80</sub> of bladder. Mann-Whitney test was used to evaluate the difference of these dosimetric factors between planned and accumulated doses and to assess relationship between differences of dosimetric variables and coexistent status.

### Results

Marginally significant difference between planned and accumulated doses in D<sub>98</sub> and D<sub>95</sub> of PU were observed (p = 0.05). For PLPC treated with and without AT, the differences between both doses in D<sub>98</sub>, D<sub>95</sub>, D<sub>mean</sub>, D<sub>2</sub> and D<sub>max</sub> of PU were significant (p = 0.029). Differences of the

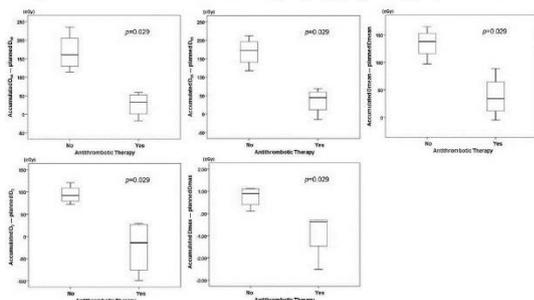

dosimetric factors were smaller in PLPC receiving AT than in PLPC did not undergo AT. Dosimetric factors of the bladder and other coexistent statuses were not significant.

Table. Relationship between the differences of dosimetric variables in  $D_{95}$ ,  $D_{90}$ ,  $D_{mean}$ ,  $D_2$  and  $D_{max}$  and coexistent clinical status in prostatic urethra

Difference of dosimetric parameters	Median (range)	AT (p value)	DM (p value)	Prior TURP and HIFU (p value)
Accumulated $D_{95}$ minus Planned $D_{95}$ (cGy)	86.5 (-18 to 235)	0.029*	0.571	0.286
Accumulated $D_{90}$ minus Planned $D_{90}$ (cGy)	93 (-15 to 212)	0.029*	0.571	0.286
Accumulated $D_{mean}$ minus Planned $D_{mean}$ (cGy)	93 (-5 to 165)	0.029*	0.571	0.286
Accumulated $D_2$ minus Planned $D_2$ (cGy)	107.5 (-8 to 168)	0.057	0.393	0.429
Accumulated $D_{max}$ minus Planned $D_{max}$ (cGy)	50.5 (-99 to 121)	0.029*	1.000	0.143
Accumulated $V_{15}$ minus Planned $V_{15}$ (%)	10.8 (-3.4 to 79)	0.114	0.393	0.071
Accumulated $D_{max}$ minus Planned $D_{max}$ (cGy)	-0.95 (-2.5 to 1.1)	0.029*	0.786	0.286

\* Statistical significance  
Abbreviation AT=antithrombotic therapy, DM=diabetes mellitus, TURP=transurethral resection of the prostate, HIFU=high intensity focused ultrasound.

Figure. For patients with localised prostate cancer treated with and without antithrombotic therapy, the differences between both doses in  $D_{95}$ ,  $D_{90}$ ,  $D_{mean}$ ,  $D_2$  and  $D_{max}$  of prostatic urethra

## Conclusion

PLPC with AT appeared to be more critical than doses in PU on severe late urinary toxicity.

## EP-1524 Differentiation between adenocarcinoma and prostatitis with multi-parametric MRI

S. Ken<sup>1</sup>, R. Aziza<sup>2</sup>, D. Portalez<sup>2</sup>, L. Chaltiel<sup>3</sup>, J. Gilhodes<sup>3</sup>, T. Brun<sup>4</sup>

<sup>1</sup>Institut Universitaire du Cancer - Oncopôle- Institut Claudius Regaud, Department of Engineering and Medical Physics, Toulouse, France ; <sup>2</sup>Institut Universitaire du Cancer - Oncopôle - Institut Claudius Regaud, Department of Medical Imaging, Toulouse, France ; <sup>3</sup>Institut Universitaire du Cancer - Oncopôle - Institut Claudius Regaud, Department of Clinical trial, Toulouse, France ; <sup>4</sup>Institut Universitaire du Cancer - Oncopôle - Institut Claudius Regaud, Department of Engineering and Medical Physics, Toulouse, France

## Purpose or Objective

In our institute, patients with low-to-moderate risk of prostate cancer could benefit from ultra-focal brachytherapy [1] as an alternative treatment to active surveillance. However, radiological diagnosis, which will guide the treatment strategy, remains challenging and still needs confirmed biopsies to distinguish between prostatic adenocarcinoma (PCa) and prostatitis (PT). This study aims at identifying imaging biomarkers derived from multi-parametric MRI (mpMRI) to help for the differentiation between PCa and PT.

## Material and Methods

Nineteen patients with low-to-moderate risk of prostate cancer underwent mpMRI on a 1.5T system (Magnetom Aera, Siemens Healthcare). Anatomical T2-weighted, IVIM diffusion (11b-values 0-800 s/mm<sup>2</sup>) and T1-weighted perfusion series were acquired. Volumes of interest (VOIs, in blue on Figure 1) were contoured on T2 images and reported on KTrans, ADC, D and computed b2000 maps. Distributions of voxel values inside the VOIs were compared to contralateral normal appearing tissue (CONTRO, in green on Figure 1) delineated with careful attention to get equivalent volume size for comparison. Volumes repartitions according to quartiles were compared between the biopsy confirmed groups of PCa

(N=12) and PT (N=7). All parameters values are given as median in the "Results" section.

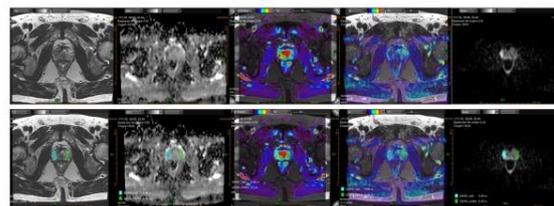

Figure 1: T2-weighted MR images, ADC, KTrans, D and computed b2000 maps (from left to right). Volumes of abnormal T2 are contoured in blue (VOI) and contralateral normal appearing tissues are contoured in green (CONTRO) and reported on ADC, KTrans, D and computed b2000 maps (bottom row).

## Results

Figure 2 presents the violin plots relative to parameters derived from mpMRI. Distributions of ADC, D (10<sup>-3</sup>mm<sup>2</sup>/s), KTrans (min<sup>-1</sup>) and computed b2000 (s/mm<sup>2</sup>) are shown according to the regions of interest (VOI or CONTRO) and the groups (PCa or PT).

For PCa group, ADC and D parameters inside the VOIs were significantly lower than in the CONTRO: 1.23 [0.66-1.62] vs. 1.48 [1.13-1.67] (p=0.0022) and 0.93 [0.59-1.49] vs. 1.33 [0.94-1.57] (p=0.0022), respectively. Voxels intensity of computed b2000 was significantly higher: 37.87 [28.29-87.11] vs. 27.63 [23.04-77.81] (p=0.0037). KTrans values were also significantly higher in the VOIs compared to CONTRO: 0.54 [0.05-1.10] vs. 0.36 [0.06-0.91] (p=0.0414). For PT group, ADC values were significantly lower inside the VOIs compare to CONTRO: 1.30 [0.98-1.43] vs. 1.43 [1.06-1.62] (p=0.0280). Computed b2000 values were significantly higher inside the VOIs: 46.45 [27.32-80.18] vs. 38.75 [25.66-70.20] (p=0.0180). D and KTrans were not significantly different between the VOIs and CONTRO: p=0.0630 and p=0.1282, respectively.

Volume of normal ADC (1<sup>st</sup> and 3<sup>rd</sup> quartile range) inside the VOIs were significantly smaller in the PCa group compared to the PT group: 12.2% [4.3-43.8] vs. 36.7% [8.7-50.9] (p=0.0346). Volume of low ADC (<1<sup>st</sup> quartile) was more important in the PCa group compared to the PT group: 72.7% [52.6-95.4] vs. 51.1% [16.7-84.4] but at the limit of significance (p=0.0519).

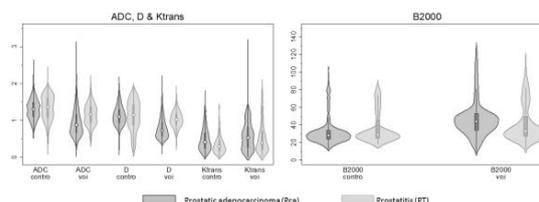

Figure 2: Violin plots of ADC, D, KTrans and computed B2000 parameters of prostatic adenocarcinoma (PCa) group in dark grey and prostatitis (PT) group in light grey. Distribution of these parameters are distinguished between the volume of interest (VOI) contoured according the abnormalities seen on the T2-weighted MR images and the contralateral normal appearing tissue (CONTRO).

## Conclusion

Abnormally low D parameters derived from IVIM and high KTrans parameters derived from perfusion MRI were found in the adenocarcinoma group but not in the prostatitis one. Percentage volumes distribution of ADC was also able to distinguish between the two groups.

## EP-1525 Postoperative radiation therapy following radical prostatectomy in Stockholm County in 2008-2016

J. Falk<sup>1</sup>, M. Aly<sup>2</sup>, T. Nordström<sup>3</sup>, A. Valdman<sup>4</sup>

<sup>1</sup>Karolinska University Hospital, Department of radiation therapy, Stockholm, Sweden ; <sup>2</sup>Karolinska University Hospital, Department of Urology, Stockholm, Sweden ; <sup>3</sup>Danderyd Hospital, Department of Urology, Stockholm, Sweden ; <sup>4</sup>Karolinska University Hospital, Department of Radiation Therapy, Stockholm, Sweden

### Purpose or Objective

This is a large report including 714 consecutive patients who received postoperative radiotherapy following radical prostatectomy in Stockholm, Sweden. The aim of the study was to determine PSA outcomes in this patient cohort in relation of PSA values before radiotherapy.

### Material and Methods

During 2008-2016 all consecutive patients in the Stockholm area treated with postoperative radiotherapy were given 70 Gy to the prostatic bed and included in this study. After radiotherapy (RT) all patients have been monitored for biochemical failure with periodic PSA controls.

### Results

During median follow-up of 48 months, 49% of patients had no signs of biochemical failure (BcF), 13 % experienced BcF and 38 % never reached PSA nadir and subsequently progressed after RT. Five-year biochemical free survival was 47%. Patients who started RT at PSA < 0.28 ng/ml had the best 5-year bPFS of 58%. Patients who started RT at PSA values of 0.28-0.7 ng/ml had bPFS at 39%, and patients who started RT at PSA > 0.7 had the worst biochemical control at 33%.

### Conclusion

Low pre-RT PSA was an independent predictor of biochemical progression-free survival (HR=1.41, p<0.001). Median pre-RT PSA for the entire cohort was 0.28 ng/l (0.2-0.45) indicating the good standard of postoperative radiotherapy process from patient referral to start of postoperative radiotherapy in Stockholm County.

### EP-1526 PSMA-PET/CT validates Roach formula in 280 treatment-naïve prostate cancer patients

S. Koerber<sup>1,2,3</sup>, G. Stach<sup>4</sup>, C. Kratochwil<sup>4</sup>, M. Haefner<sup>1,2,3</sup>, S. Katayama<sup>1,2,3</sup>, H. Rathke<sup>4</sup>, K. Herfarth<sup>1,2,3,5</sup>, T. Holland-Letz<sup>6</sup>, U. Haberkorn<sup>4,7</sup>, J. Debus<sup>1,2,3,5,8,9</sup>, F.L. Giesel<sup>4,7,8</sup>

<sup>1</sup>Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>National Center for Tumor diseases NCT, Radiation Oncology, Heidelberg, Germany ; <sup>3</sup>Heidelberg Institute of Radiation Oncology HIRO, Radiation Oncology, Heidelberg, Germany ; <sup>4</sup>Heidelberg University Hospital, Nuclear Medicine, Heidelberg, Germany ; <sup>5</sup>Heidelberg Ion-Beam Therapy Center HIT, Radiation Oncology, Heidelberg, Germany ; <sup>6</sup>German Cancer Research Center DKFZ, Biostatistics, Heidelberg, Germany ; <sup>7</sup>German Cancer Research Center DKFZ, Clinical Cooperation Unit Nuclear Medicine, Heidelberg, Germany ; <sup>8</sup>German Cancer Consortium DKTK, partner site Heidelberg, Heidelberg, Germany ; <sup>9</sup>German Cancer Research Center DKFZ, Clinical Cooperation Unit Radiation Oncology, Heidelberg, Germany

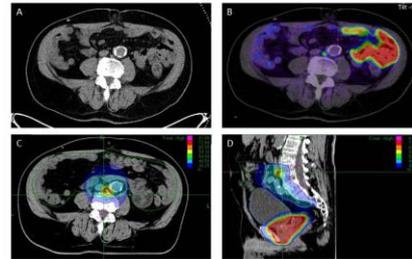

### Purpose or Objective

For radiotherapy planning, the Roach formula is a very useful tool when calculating the risk of lymph node metastases for patients with prostate cancer. However, several trials suggest a risk overestimation of this mathematical approach. Therefore, the present study aimed to evaluate the accuracy of the Roach formula using prostate-specific membrane antigen (PSMA) positron-emission tomography (PET)/computed tomography (CT).

### Material and Methods

Between July 2011 and July 2018, PSMA-PET/CT imaging was performed for almost 2500 patients. 280 patients with treatment-naïve prostate cancer and sufficient clinical data were enrolled in this study. The risk for lymph node metastases was calculated for all patients using Roach formula and PSMA data was analyzed retrospectively regarding lymph node metastases. For statistical analysis, the binary logistic regression was applied in various combinations of prostate-specific antigen (PSA), ln(PSA), Gleason score (GS) or WHO classification, to obtain new calculation methods. Afterwards, a comparison of all formulas was performed using receiver operating curves

(ROC).

**Figure 1:** Personalized irradiation (C + D) of a 69-year old patient with prostate cancer and a risk of lymph node involvement of 20% according to Roach formula. While no suspect lymph node was observed in conventional CT scan (A), PSMA-PET/CT detected one positive lesion just above the bifurcation (B).

### Results

Most lymph node metastases appeared in the extern iliac vessels (28.95%). For patients with a higher GS (>7), there was a higher risk for presacral metastases or a spread outside the pelvis. For classical Roach formula and a cut-off of 20%, the area under the curve (AUC) was 0.781. In contrast, the binary logistic regression formula with ln(PSA) and GS had an AUC of 0.789.

### Conclusion

Although the AUC of the Roach formula is minimally smaller, the Roach formula can still be used for an initial assessment of the risk of lymph node metastases for patients with newly diagnosed prostate cancer undergoing radiotherapy.

### EP-1527 Proton therapy for prostate ca: Comparison of toxicity between mod-hypo and conventional fraction

T. Waki<sup>1</sup>, Y. Tominaga<sup>2</sup>, Y. Niwa<sup>1</sup>, H. Ihara<sup>1</sup>, D. Jin<sup>1</sup>, S. Sugiyama<sup>1</sup>, T. Kawabata<sup>1</sup>, K. Katsui<sup>3</sup>, M. Fujishima<sup>1</sup>, S. Kanazawa<sup>4</sup>

<sup>1</sup>Tsuyama chuo hospital, Radiology, Tsuyama-shi, Japan ; <sup>2</sup>Tsuyama chuo hospital, Radiological technology, Tsuyama-shi, Japan ; <sup>3</sup>Okayama university, Proton beam therapy, Okayama-shi, Japan ; <sup>4</sup>Okayama university, Radiology, Okayama-shi, Japan

### Purpose or Objective

To compare the acute toxicity between moderate hypofractionated (Mod-Hypo: 70 Gy (RBE) / 28 fr) and conventional fractionated (Conv: 74-78 Gy (RBE) / 37-39 fr) proton beam therapy (PBT) in patients with prostate cancer.

### Material and Methods

We evaluated consecutive 53 patients between April 2016 to December 2017. There were 21 Mod-Hypo and 32 Conv PBT cases. Retrospective analysis of the prospectively gathered data concerning gastrointestinal (GI), genitourinary (GU), skin and other toxicity was performed. Toxicity symptoms were scored weekly during treatment period and at 3 month after the completion of treatment by 1 radiation oncologist and 1 nurse. We compared the difference in the rate of acute adverse effect score between Mod-hypo and Conv cohorts using CTCAE.ver.4.03.

### Results

There was no severe (grade 3-4) acute toxicity. The rate of grade 1 / 2 GI toxicity in Mod-Hypo and Conv cohorts were 4.8 / 0.0% and 9.4 / 0.0%, respectively (p=0.82). The rate of grade 1 / 2 GU toxicity in Mod-Hypo and Conv cohorts were 57.1 / 9.5% and 50.0 / 25.0%, respectively (p=0.81). The rate of grade 1 / 2 skin toxicity in Mod-Hypo and Conv cohorts were 76.2 / 9.5% and 78.1 / 12.5%, respectively (p=0.87). The rate of grade 1 / 2 other toxicity in Mod-Hypo and Conv cohorts were 9.5 / 9.5% and

12.5 / 3.1%, respectively (p=0.94). There was no statistical difference between 2 cohorts for each toxicity.

#### Conclusion

Moderate hypofractionated proton beam therapy for prostate cancer is feasible. Further follow-up is needed to evaluate late toxicity.

#### EP-1528 Feasibility and toxicity of focal dose escalation on multimodally defined GTVs in prostate cancer

E. Haehl<sup>1</sup>, C. Zamboglou<sup>1</sup>, H.C. Rischke<sup>1</sup>, M. Bock<sup>2</sup>, S. Kirste<sup>1</sup>, M. Mix<sup>3</sup>, P.T. Meyer<sup>3</sup>, D. Baltas<sup>1</sup>, A.L. Grosu<sup>1</sup>  
<sup>1</sup>Medical Center - University of Freiburg, Department of Radiation Oncology, Freiburg, Germany ; <sup>2</sup>Medical Center - University of Freiburg, Department of Radiology, Freiburg, Germany ; <sup>3</sup>Medical Center - University of Freiburg, Department of Nuclear Medicine, Freiburg, Germany

#### Purpose or Objective

Introduction: The combination of MRI and PSMA PET/CT is a highly sensitive method to identify intraprostatic gross tumour volumes (GTV) in patients with prostate cancer (PCa). In silico studies already showed an improved tumour control for dose escalation through an intensity-modulated radiation therapy (IMRT) on multimodally defined GTV's. The present retrospective and monocentric analysis investigates the feasibility and acute toxicity of a focal IMRT dose escalation on multimodally defined target volumes.

#### Material and Methods

Methods: 31 patients with histologically ascertained PCa underwent insertion of intraprostatic gold markers followed by MRI imaging and a PSMA PET/CT planning scan. After image fusion target volumes were contoured based on MRI (GTV-MRI) and PET (GTV-PET defined as 30% of prostatic SUVmax) images. MRI and PET GTVs were merged (GTV-union) and the planning target volume for dose escalation (PTV-boost) was created by isotropic expansion with 4 mm. The clinical target volume (CTV) for the entire prostatic gland and the seminal vesicles was created according to the ESTRO guidelines and expanded isotropically with 6 mm to create the respective PTV. RT was performed using rapid-Arc and image guided RT (IGRT). During RT the doses applied to the target volumes and organs at risk were adapted considering cone beam CT scans. 6 patients received androgen deprivation therapy.

#### Results

Results: According to NCCN guidelines 18 respectively 13 patients have been classified as intermediate and high risk. A focal dose escalation could be realised in 21 patients (68%). Impending reasons were multifocal tumour lesions (>3), prolonged rectum contact and extensive tumour volume. Median volumes of GTV-MRI, GTV-PET, GTV-union and whole prostate were 2.1 ml (0-16,7 ml), 3.9 ml (0-11.13 ml), 5.5 ml (1-20.5 ml), and 58,2 ml (33-98 ml). Thereby GTV-union showed to be significantly larger than GTV-MRI (p<0.05).

Patients undergoing dose escalation received a mean dose of 74Gy on the PTV and 80Gy on the PTV-boost, both in 40 fractions. Acute grade 2 GI-toxicity occurred in 3 patients and acute grade 2 GU-toxicity in 4 patients, following CTCAE 5.0. One patient developed an acute grade 3 GU-toxicity most probably due to fiducial insertion, which was resolved completely.

#### Conclusion

Conclusion: Dose escalation to 80Gy based on multimodally defined target volumes could be performed in 68% of patients. Acute GI- and GU-toxicity seems to be tolerable. Further prospective studies are necessary to investigate this promising treatment regime.

#### EP-1529 Dosimetric parameters of radical radiotherapy for prostatic cancer: Targeting based on CT vs MRI

K. Nishiyama<sup>1</sup>, T. Toyofuku<sup>1</sup>

*This abstract is part of the media programme and will be released on the day of its presentation*

**EP-1530 Prostate volume reduction with neo-adjuvant hormones and its relation with bladder and rectal volume**

M. Sivanandan<sup>1</sup>, C. Vivekananthan<sup>1</sup>, Z. Ali<sup>1</sup>, S. Sundar<sup>1</sup>  
<sup>1</sup>Nottingham University Hospitals NHS Trust, Oncology and Radiotherapy, Nottingham, United Kingdom

**Purpose or Objective**

Androgen deprivation therapy (ADT) is routinely used in association with radical radiotherapy (RT) for intermediate and high risk prostate cancer. Neoadjuvant ADT has been shown to reduce the size of the prostate and hence target volume, thereby reducing the volume of normal tissue exposed to high radiation doses.

The purpose of our review was to examine whether prostate volume was associated with bladder and rectal volume as a surrogate of whether ADT-induced prostate volume reduction contributed to reduced normal tissue doses through changes in normal tissue volumes.

**Material and Methods**

Patients having radical prostate RT between January and May 2016 were identified from the hospital's RT database. Respective prostate volumes were calculated from diagnostic and planning MRI scans for each patient. Bladder and rectal volumes were calculated from each patient's planning CT scan. Statistical analysis was performed using the paired T-test and Pearson correlation.

**Results**

68 patients were identified. All patients had neoadjuvant ADT with median duration of ADT prior to planning MRI scan of 95 days. Mean reduction in prostate volume from diagnostic to planning MRI scan was 35.6% (95% CI: 32.0-39.3%) which was statistically significant ( $p < 0.01$ ). No correlation was seen between planning scan prostate volume and bladder volume ( $r = 0.0$ ;  $p = 0.97$ ) or rectal volume ( $r = 0.04$ ;  $p = 0.75$ ). Furthermore, no correlation was identified between percentage change in prostate volume and bladder volume ( $r = -0.07$ ;  $p = 0.60$ ) or rectal volume ( $r = 0.06$ ;  $p = 0.65$ ).

**Conclusion**

Our study confirms neoadjuvant ADT leads to a significant reduction in prostate volume. The reduction in high radiotherapy dose to bladder and rectum with ADT appears to be due to reduction in target volume alone rather than its interaction with normal tissue volumes. This work suggests that transurethral resection of the prostate (TURP) for patients with large prostate volumes before prostate RT with a view to specifically reducing bladder volumes would be of negligible benefit.

**EP-1531 SBRT for Prostate Cancer in 3 fractions: Acute Toxicity Rates from a Prospective Multicenter Study**

G. Sanguineti<sup>1</sup>, A. Farneti<sup>1</sup>, M. Trovò<sup>2</sup>, V. Landoni<sup>3</sup>, E. Moretti<sup>4</sup>, M. Ferriero<sup>5</sup>, F. Spasiano<sup>1</sup>, U. De Paula<sup>6</sup>, S. Gomellini<sup>6</sup>, A. Magli<sup>2</sup>

<sup>1</sup>irccs - Regina Elena National Cancer Institute, Radiotherapy, Rome, Italy ; <sup>2</sup>asiud, Radiotherapy, Udine, Italy ; <sup>3</sup>irccs - Regina Elena National Cancer Institute, Medical Physics, Rome, Italy ; <sup>4</sup>asiud, Medical Physics, Udine, Italy ; <sup>5</sup>irccs - Regina Elena National Cancer Institute, Urology, Rome, Italy ; <sup>6</sup>san Giovanni-Addolorata Hospital, Radiotherapy, Rome, Italy

**Purpose or Objective**

Five-fraction hypo-fractionated SBRT is an acceptable option for low/favorable intermediate risk prostate cancer (NCCN 2018). The aim of the present study was to further reduce the number of treatment sessions to 3. Here we report acute toxicity rates on the patients treated so far

**Material and Methods**

This phase I-II prospective study is enrolling patients with low/fav int risk prostate cancer at 3 Institutions since November 2015. The prescribed dose to the target (prostate+4 mm isotropic) is 40 Gy in 3 fractions while prioritizing a 30 Gy Dmax limit to the rectum (1cc), the bladder trigone (1cc) and the urethra (0.1cc). A gel spacer (along with gold fiducials) is placed before simulation to dislocate the rectum. Patients are simulated and treated with a urethral catheter and controlled bladder filling. Prostate had to be < 80 cc at diagnosis or after 3 months of androgen deprivation and IPSS < 16. Toxicity was graded according to the CTCAE v4.0 scale at the 3<sup>rd</sup> fraction and every 3 months afterwards. Toxicity developing within 3 months from treatment end is considered 'acute'.

**Results**

Twenty-eight patients (19, 7, 2 at each Institution) have been treated and have a 3-month minimum follow up. All patients had low (n=20) or intermediate risk (n=8) prostate cancer; mean (SD) age was 73 (5.2) years and mean (SD) PSA at diagnosis was 6.9 (2.8) ng/ml. At planning, average (SD) prostate volume (CTV) was 51.4 (17.8) cc, 3 patients after 3-month neoadjuvant androgen deprivation. On average (SD) 95% of the PTV was covered by the isodose 85.4 (4.7)% while the isodose 38 Gy covered 61.8 (19.0)% of the PTV. Mean (SD) Dmax to rectum (1cc), bladder trigone (1cc) and urethra (0.1cc) were 28.9 (1.9) Gy, 22.1 (9.0) Gy and 30.8 (1.6) Gy, respectively.

Peak acute GR0,GR1,GR2,GR3 gastrointestinal (GI) and genitourinary (GU) toxicity rates developed in 18,7,3,0 and 19,6,2,1 patients, respectively. Overall, 4 GR2+ GU events (2 urinary tract pain, 2 cystitis and 1 urinary retention) were recorded in 3 patients. The only grade 3 event consisted in urinary retention requiring transurethral resection 3 months after treatment completion. All three GR2 GI events consisted in mild proctitis. No GR4-5 GU or GI events were recorded as well as no other GR2+ event was observed.

**Conclusion**

Under the technical and dosimetric conditions set here, prostate SBRT in 3 fractions is associated with a favorable acute toxicity profile.

**EP-1532 Metastases directed SBRT using Ga68-PSMA for oligometastatic prostate cancer: TROD 09-002 Study**

G. Ozyigit<sup>1</sup>, S. Igdem<sup>2</sup>, B. Atalar<sup>3</sup>, H.B. Ozkok<sup>4</sup>, P. Hurmuz<sup>1</sup>, F. Akyol<sup>1</sup>

<sup>1</sup>Hacettepe University- Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey ; <sup>2</sup>Istanbul Bilim University, Department of Radiation Oncology, Istanbul, Turkey ; <sup>3</sup>Acibadem University, Department of Radiation Oncology, Istanbul, Turkey ; <sup>4</sup>Anadolu Medical Center, Department of Radiation Oncology, Istanbul, Turkey

**Purpose or Objective**

To evaluate the role of stereotactic body radiotherapy (SBRT) for oligometastatic prostate cancer (oPC).

**Material and Methods**

In current Turkish Radiation Oncology Group (TROD) study clinical data of 43 patients receiving metastases-directed SBRT between July 2014 and March 2017 from 4 institutions was retrospectively evaluated. Prior therapy was radical prostatectomy (RP) alone (30%), RP followed by adjuvant radiotherapy (28%) or definitive radiotherapy (RT) (42%). All of the patients should have biopsy proven prostate cancer with 5 or less metastases shown by Ga68-PSMA (Prostate Specific Membrane Antigen) PET-CT. SBRT was delivered in median 3 fractions (range, 1-5 fractions) to a total dose of median 27 Gy (range, 15-35 Gy).

**Results**

Median age was 64 years (range, 42-79 years). Median initial PSA was 21.5 ng/dL (range, 5-160 ng/dL) and Gleason score was 8 (range, 6-10). At the time of initial diagnosis, 18 patients had T3a, 12 patients had T3b disease and 7 patients were metastatic. Median 1 metastatic lesion located in regional lymph nodes (41%), bone (46%) and both lymph node plus bone (13%) was treated. Thirty three patients received androgen deprivation treatment (ADT). With a median follow up of 14.5 months (range, 1-45 months), 13 patients (30%) had progressive disease and 54% of them were oligometastatic progression. None of the patients had relapse in the treated region. Time to progression was median 13 months. One and two year progression free survival rates were 76% and 59%, respectively. No patients reported grade 3 or more acute or late radiation related gastrointestinal or genitourinary side effects.

**Conclusion**

This multi-institutional study shows that SBRT for oPCa seems to be safe and effective. Most of the relapses are oligometastatic, thus retreatment with SBRT might be an option for properly selected patients to avoid early ADT and its complications. Further prospective clinical studies should be done to evaluate this treatment option.

**EP-1533 Stereotactic Body Radiotherapy in Prostate Cancer: A Single Center Experience**

F. Akyol<sup>1</sup>, P. Hurmuz<sup>1</sup>, S. Sari<sup>1</sup>, A.E. Dogan<sup>1</sup>, D. Yuce<sup>2</sup>, S. Yazici<sup>3</sup>, B. Akdogan<sup>3</sup>, G. Ozyigit<sup>1</sup>

<sup>1</sup>Hacettepe University Ankara, Radiation Oncology, Ankara, Turkey; <sup>2</sup>Hacettepe University Ankara, Preventive Oncology, Ankara, Turkey; <sup>3</sup>Hacettepe University Ankara, Urology, Ankara, Turkey

**Purpose or Objective**

To evaluate our treatment results in patients with prostate cancer receiving definitive robotic stereotactic body radiotherapy (rSBRT).

**Material and Methods**

Between July 2007 and November 2016 135 patients were treated with CyberKnife® robotic radiosurgery treatment machine. According to our institutional treatment protocol we delivered 36.5 Gy in 5 fractions to prostate. According to D'Amico risk classification system 74 patients were in low-risk group and 61 patients were in intermediate-risk group. 'Phoenix definition' was used for biochemical relapse and Cavanagh definition was used for PSA bounce, respectively.

**Results**

Median follow-up time was 34 months (range, 3-111 months). Biochemical relapse was detected in 6 patients between the 26th and 56th months. PSA bounce was observed in 38 (29%) patients, and 30 of these patients had low-risk disease. Biochemical relapse was observed in 3 patients who experienced PSA bounce during the follow-up. For the whole group, 3-year biochemical relapse-free

survival (BRFS) and overall survival (OS) rates were 95% and 92%, respectively. Presence of PSA bounce did not have an effect on BRFS rates; however, OS rate was significantly higher in patients with PSA bounce, independent from the risk group (p=0.025). Treatment was well tolerated with no grade 3 or more acute toxicities. Late grade III gastrointestinal system and grade III genitourinary system toxicity was observed in 4 and 11 patients, respectively.

**Conclusion**

Prostate rSBRT is an effective and safe treatment for patients with low-intermediate risk prostate cancer with acceptable toxicity rates.

**EP-1534 Clinical Outcomes for Patients with Gleason Score 10 Prostate Adenocarcinoma: TROD 09-004 Study**

G. Ozyigit<sup>1</sup>, H.C. Onal<sup>2</sup>, P. Hurmuz<sup>1</sup>, A. Iribas<sup>3</sup>, I. Cetin<sup>4</sup>, I.B. Gorken<sup>5</sup>, D. Yalman<sup>6</sup>, F. Akyol<sup>1</sup>

<sup>1</sup>Hacettepe University- Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey; <sup>2</sup>Baskent University, Radiation Oncology, Adana, Turkey; <sup>3</sup>Istanbul University, Radiation Oncology, Istanbul, Turkey; <sup>4</sup>Marmara University, Radiation Oncology, Istanbul, Turkey; <sup>5</sup>Dokuz Eylul University, Radiation Oncology, Izmir, Turkey; <sup>6</sup>Ege University, Radiation Oncology, Izmir, Turkey

**Purpose or Objective**

Gleason score (GS) 10 disease is a rare and an aggressive form of prostate adenocarcinoma (PCa). In this national multi-institutional study we evaluated the treatment outcomes for this subgroup of patients.

**Material and Methods**

The clinical data of 30 patients receiving definitive radiotherapy (RT) plus androgen deprivation therapy (ADT) between January 2001 and March 2015 from 6 institutions was retrospectively evaluated in current Turkish Radiation Oncology Group (TROD) study. All of the patients had biopsy proven disease. Follow up duration of at least 24 months was mandatory. ASTRO Phoenix definition was used for biochemical relapse.

**Results**

Median age was 65 years (range, 58-78 years). Median initial PSA was 25 ng/dL (range, 4.5-150 ng/dL). Median RT dose was 75 Gy (range, 70-78 Gy) and 12 patients received pelvic radiation as a part of treatment protocol. All patients received ADT with median duration of 24 months (range, 9-48 months). With a median follow up time of 66.5 months, 13 patients (43%) had biochemical relapse, 2 patients (7%) had local relapse and 8 patients (27%) had distant metastases. Five-10 year overall survival (OS) and biochemical relapse free survival (BRFS) rates were 78%-66% and 56%-42%, respectively.

**Conclusion**

To our knowledge this is the first study to give BRFS in GS=10 prostate cancer patients treated with RT and long term ADT. Regarding the rarity of the disease multi-institutional studies are valuable in the further evaluation of this group of patients.

**EP-1535 Vessel-sparing prostate V-MAT with simultaneous integrated boost to dominant intraprostatic lesion**

#### Purpose or Objective

New evidences suggested a vascular etiology for sexual impotence after prostate radiotherapy. Internal pudendal arteries (IPA), corpora cavernosa (CC) and penile bulb (PB) were identified as critical structures related to erectile function. We explored the potential of VMAT to spare the critical erectile structures with a SIB to the dominant intraprostatic lesion (DIL)

#### Material and Methods

Twelve patients were selected for this study. DILs were defined using T2-weighted, dynamic contrast-enhanced and diffusion-weighted MRI (multiparametric MRI). Vascular structures were contoured and expanded by a uniform 2 mm margin. The seminal vesicles, the prostate and DIL were expanded uniformly by 5 mm to create the planning target volumes (PTVsv, PTVpr and PTVdil, respectively). PTVsv, PTVpr and PTVdil dose prescription was 56.25, 67.50 and 75 Gy, respectively, in 25 fractions. The doses were prescribed to cover >95% of PTVs. All VMAT plans were generated in a dual-arc modality for a VersaHD linac. Original clinical plans (ST-VMAT) were created to fulfil targets coverage and Quantec constraints for non vascular OARs (NV\_OARs: rectum, bladder and femoral heads). For each patient, a new plan (SS-VMAT) based on the approved ST-VMAT plan was created. IPA, CC and PB were considered OARs related to sexual impotence (V\_OARs). All objectives for PTVs coverage and NV\_OARs sparing were left unchanged. New objectives were added for V\_OARs, with priority to minimize mean doses to IPA, CC and PB. A Wilcoxon signed-rank test was used to compare the two optimization techniques.

#### Results

For all plans, targets coverage was well within the predefined objectives for all metrics (D95, D98, Dmean). In particular, D98% was >95% of prescribed doses for all targets, patients and techniques. No significant differences were found in sparing rectum, bladder and femoral heads for all considered metrics (Dmean, V50, V60, V70). With regard to V\_OARs sparing, SS\_VMAT plans provided a major reduction of dose irradiation. Mean doses for IPA, CC and PB were reduced by 32.4% (11.2 Gy, p=0.002), 22.5% (4.1 Gy, p=0.006) and 10.0% (4.6 Gy, p=0.010), respectively. V30 decreased from 61.1% to 21.4% (p=0.02) for IPA and from 27.2% to 14.8% (p=0.04) for CC.

#### Conclusion

We showed that a significant dose sparing for IPA, CC and PB using VMAT-SIB strategy is feasible, allowing vessel-sparing and highly conformal plans, dose escalation to DIL and fast treatment delivery.

#### EP-1536 Influence of obesity in treatment outcomes in prostate cancer patients

J.L. Munoz Garcia<sup>1</sup>, F. Ropero Carmona<sup>1</sup>, M. Gonzalez Ruiz<sup>2</sup>, P. Simon Silva<sup>1</sup>, J. Quiros Rivero<sup>1</sup>, Y. Rios Kavadoy<sup>1</sup>, M.C. Cruz Muñoz<sup>1</sup>, J. Cabrera Rodriguez<sup>1</sup>  
<sup>1</sup>Badajoz University Hospital, Radiation Oncology, Badajoz, Spain ; <sup>2</sup>Punta de Europa Hospital, Radiation Oncology, Algeciras, Spain

#### Purpose or Objective

**Purpose/Objective:** obesity is related to worst pronostic factors after prostatectomy and lower prostate cancer specific survival (PCSS) after radiotherapy with low doses of external beam radiation (EBRT). Our objective is to

analyse the influence of obesity in treatment outcomes with high doses of external beam radiation therapy (HDEBRT) plus androgen deprivation therapy (ADT) in patients (pts) with prostate cancer (PC) treated with radical intention.

#### Material and Methods

**Material/methods:** Retrospective comparative study of 297 out of 531 pts with PC treated with EBRT+ADT in our hospitals from October 2001 to December 2011 with height and weight data available at baseline (56%). 168 were non-obese (57%) and 129 obese (43%). Baseline characteristics non-differed significantly between treatment groups in PSA level, tumour stage, risk group, percentage of positive cylinder, ADT duration and total dose of RT but more obese pts had cardiovascular events, high blood pressure and metabolic alterations. All pts were treated with 3DCRT at a median total dose of 78 Gy (range 74-78). Phoenix definition was used for biochemical failure. Survival rates were estimated with Kaplan-Meier and compared with Log Rank test. Prognostic factors such as age, primary tumour stage, Risk group, Gleason, percentage of positive cylinder, radiotherapy total dose and ADT duration have been related to BDFS, OS and PCSS using Cox regression.

#### Results

**Results:** The median follow-up was 84 months (range 11-175) in non-obese pts and 91 months (range 29-188) in obese pts. The 7-year BDFS, OS and PCSS in non-obese pts were 92.4%, 91.6%, and 99.9% respectively and in obese were 88.2% (p=0.147), 90.1% (p=0.384), and 96.6% (p=0.330) respectively. In the multivariate analysis, obesity was not a significant prognostic factor of BDFS, OS neither PCSS.

#### Conclusion

**Conclusion:** Regarding to our results, obesity in prostate cancer treated with high doses of EBRT did not have significantly influence in BDFS, OS and CSS. Studies with large sample of pts are recommended

#### EP-1537 Local Relapse after Radiotherapy for prostate cancer: is a second local treatment worthwhile?

C. Hennequin<sup>1</sup>, M. Pierre<sup>2</sup>, D.K. Eric<sup>3</sup>, V. Laetitia<sup>4</sup>, D. François<sup>2</sup>, C. Stéphane<sup>5</sup>, Q. Laurent<sup>1</sup>

<sup>1</sup>Hôpital Saint-Louis- AP-HP, Radiation Oncology, Paris, France ; <sup>2</sup>Hôpital Saint-Louis- AP-HP, Urology, Paris, France ; <sup>3</sup>Hôpital Saint-Louis- AP-HP, Radiology, Paris, France ; <sup>4</sup>Hôpital Saint-Louis- AP-HP, Nuclear Medicine, Paris, France ; <sup>5</sup>Hôpital Saint-Louis- AP-HP, Medical Oncology, Paris, France

#### Purpose or Objective

To compare the outcome of patients with an isolated local relapse (LR) after radiotherapy (RT) of prostate cancer treated with a salvage local treatment (SLT) with those only monitored

#### Material and Methods

Between January 2011 and December 2016, all consecutive patients presenting a biochemical relapse (BR: nadir+2ng/ml) after RT (external beam radiotherapy or brachytherapy) who had a staging including a 18-fluorocholine-PET-CT (FCH-PET/CT) were prospectively registered. Patients with an isolated LR had systematically a multiparametric magnetic resonance imaging (mpMRI) to confirm LR. After evaluation of comorbidities, life expectancy, functional status and discussion with the patient, a SLT (cryotherapy, stereotactic RT: SBRT or High-Intensity Focused Ultrasounds: HIFU) or a simple surveillance could be proposed. A salvage androgen deprivation therapy (ADT) was given in case of a PSA doubling-time ≤ 12 months or a PSA level higher than 10 ng/ml or if distant metastases are detected.

#### Results

Among the 134 patients with a BR, 67 had an isolated LR on FCH-PET/CT and mpMRI. Mean age was 67 yrs (53-86). Initial prognostic groups was: favourable: 20;

Intermediate: 28; High risk: 19. Mean PSA at the time of relapse was 6.3 ng/ml. Twenty-five had a SLT (cryotherapy: 23; SBRT:1; HIFU:1) and 42 a simple monitoring. Mean follow-up was 48 months. Three-year overall survival (OS: 93%) and distant metastasis-free survival (DMFS: 85%) were similar in both groups. But SLT postponed the use of ADT: at 3 year, 71% of the patients treated with SLT did not receive ADT versus 37% in the other group (p=0.001). We observed 24% of grade 3-4 side effects after cryotherapy, mainly incontinence, with two patients receiving an artificial urinary sphincter.

#### Conclusion

we did not observed an improvement in 3-year OS or DMFS after SLT for LR after RT. But it could delay the use of ADT. Due to the potential side effects of salvage treatments, a stringent selection of the patients based on imaging, analysis of prognostic factors and life expectancy must be recommended.

#### EP-1538 Where fail PC patients treated with limited RT to prostate and sv with 76-80 Gy +/- hormonotherapy?

J. Lopez Torrecilla<sup>1</sup>, P.P. J<sup>1</sup>, V. A<sup>2</sup>, G.H. T<sup>2</sup>, G.S. D<sup>1</sup>, A. P<sup>1</sup>, H.M. A<sup>1</sup>, G.M. E<sup>1</sup>, G.P. Jc<sup>1</sup>, B. L<sup>2</sup>, G. D<sup>2</sup>, R.F. J<sup>2</sup>

<sup>1</sup>H. General Univ Valencia, Radiation Oncology-ERESA, Valencia, Spain ; <sup>2</sup>H. General Univ Valencia, Radiofísica-ERESA, Valencia, Spain

#### Purpose or Objective

To analyse where they fail and what are the causes of death of patients treated with an "optimal" dose of radiotherapy.

#### Material and Methods

Between November 1997 and July 2007, 302 patients were treated with external radiotherapy +/- hormone therapy (29 with RTC-3D, 227 with IMRT and 52 with IMRT-IGRT). The average age of the series was 70.15 years (range of 51-87 years). Average follow-up 117.49 months, with a median of 130 months. The patients who died at the time of the analysis, the mean follow-up was 87.19 months, with a median of 87.5 months. Distribution by TNM: T: T1c: 80 (26.5%); T2a: 90 (29.8%); T2b: 36 (11.9%); T2c: 12 (4.0%); T3a: 42 (13.9%); T3b 38 (12.6%); T4: 2 (0.7%); Tx: 2 (0.7%). N: N0: 250 (82.7%); Nx: 52 (17.2%). M: M0: 233 (77.2%) ptes. Mx: 69 patients. Initial PSA <10 ng/ml: 177 (58.6%); 10-20: 87 (28.8%); > 20: 32 (10.6%), in 6 patients we do not know the PSA before any treatment. Gleason was <7: 225 (74.5%); 7:58 (19.2%); 8-10: 17 (5.6%). 2 patients unknown. Distribution by groups of risk (NCCN 2018 classification): Low risk 80 (26.55%), Intermediate risk: 86 (28.5%); high risk: 77 (25.5%), Very high risk 49 (16.2%), Unknown 10 (3.3%). The dose in prostate was 76 Gy in 119 (39.4%) patients and 80 Gy in 183 (60.6%). The dose in seminal vesicles was 50 Gy in 145 (47.9%) of the patients and 58 Gy in 152 (50.4%) patients. Patients were treated with 15 MV photons by 6 incidences with a rate of 200 cGy per session, 5 times per week. They did not receive hormone therapy 65 (21.5%) patients.

#### Results

**Survival at 5 and 10 years:** Global 84.4% and 65.0%. Free of biochemical failure (BQF): 89.1% and 82.0%. Free of metastasis: 96.4% and 94.3%, respectively. At the time of the analysis 143 (47.4%) patients are alive, 158 (52.3%) have died and one is lost. **BQF** has presented 54 (17.9%) patients, of them 30 (9.9%) have not developed clinical disease, 11 (3.6%) presented **local failure (LF)**, 4 (1.3%) **regional failure (RF)** and 17 (5.6%) **metastasis**. The cause of death was 106 (67.1%) intercurrent disease, 28 (17.7%) a second tumour, 24 (15.2%) due to prostate cancer. Of the 143 living patients 121 (84.6%) are disease-free, 22 (15.4%) with BQF (5 of them with associated LF, 1 LF + metastasis and 1 single metastasis). Of this group 5 patients (3.7%) are alive with a second tumour. **Late Complications (RTOG):** GU: G0: 40 (13.2%); G1: 134 (44.4%); G2: 98 (32.5%); G3: 27 (8.9%); G4: 3 (1.0%). GI:

G0: 237 (78.5%); G1: 45 (14.9%); G2: 10 (3.3%); G3: 8 (2.6%); G4: 2 (0.7%); Maximum haematuria in follow-up: G0: 257 (85.1%); G1: 16 (5.3%); G2: 18 (6.0%); G3: 11 (3.6%). Maximum rectal bleeding in follow-up: G0: 251 (83.1%); G1: 30 (9.9%); G2: 8 (2.6%); G3: 13 (4.3%).

#### Conclusion

**Conclusions:** Optimal dose of radiotherapy +/- Hormonotherapy in prostate cancer achieves a local control of the disease that translates into a low probability of death from cancer. The risk of regional failure has been extremely low (1.3%) despite not treating the pelvic lymph nodes.

#### EP-1539 Early experience and quality of life in SBRT prostate cancer boost of 9 Gy in a phase II trial.

#### Purpose or Objective

Extracranial stereotactic body radiation therapy (SBRT) allows delivering high doses per fraction with high accuracy to the prostatic gland in a low number of fractions. Dose escalation in normofractionated radiation prostate cancer trials showed an increased toxicity. In order to evaluate the feasibility and toxicity of a regimen of a single dose hypofractionated prostate stereotactic boost a phase II study was undertaken. Self-reported quality of life (QOL) measures were also obtained in order to better define the possible deleterious effect of treatment.

#### Material and Methods

Patients included were diagnosed of prostate cancer with T3aNOMO Gleason score 8 or less (N+risk<25%) and IPSS 0-12. Hormonal-therapy was prescribed according to risk classification. Image Guided RT with Cone Beam CT was mandatory. Dose SBRT was delivered at a prescribed planning target volume (PTV) 9 Gy after 60 Gy 2 Gy per fraction in 30 days, using with RapidArc VMAT, with 6 MV FFF photons. Equivalence of dose at 2 Gy per fraction, using Linear Quadratic Model is round 87Gy. RTOG-EORTC and CTCAE v4.0 morbidity scores were used to assess toxicities. Health-related quality of life questionnaire was administered centrally by telephone interview before treatment and during follow-up (at 3, 6 and 12 months). Study was planned following a Simon's 2-stage design. Due to a low recruitment rate firsts 22 evaluable patients were studied.

#### Results

First's 22 patients included were analyzed. Mean age was 69.6 years old. Median follow-up was 9 months (2-50) with more than 60% having at least 6 months of follow-up.

According to D'Amico risk classification for trial and inclusion criteria all of them were high risk. All patients completed the treatment as programmed with good tolerance. No toxicity greater than grade 2 was observed. EPIC urinary values were 81.26 and 80.49 at 6 and 12 months respectively. EPIC hormonal was 63.83 and 64.09 at 6 and 12 months respectively. EPIC bowel values for these points in time were 93.30 and 92.50. Non PSA relapse was seen during this short follow-up. Acute GI grade 2 toxicities were 9.2% for a week after treatment. At the 1<sup>st</sup> month GI Grade 2 toxicity showed the same percentage. At the 3<sup>rd</sup> month GI Grade 2 was reduced to 4.5%. Acute GU grade 2 toxicity was 31.8%. At the 1<sup>st</sup> month GU Grade 2 toxicity decrease to 9.1%. One patient showed late GU Grade 2 at 6 months.

#### Conclusion

SBRT regime of 9 Gy to the prostate after normofractionated 60 Gy for high risk prostate cancer is feasible and well tolerated in selected patients. Decline in QoL values are seen EPIC hormonal QLQ measures are related to prolonged hormonal treatment in high-risk patients. Long-term follow-up is needed for assessment of late toxicity and outcomes.

#### EP-1540 A bowel pathway for patients undergoing radiotherapy for prostate cancer

C. Perna<sup>1</sup>, C. Williamson<sup>1</sup>, S. Khaksar<sup>1</sup>

<sup>1</sup>Royal Surrey County Hospital, St Lukes cancer centre, Guildford, United Kingdom

#### Purpose or Objective

To investigate whether the introduction of a new bowel pathway, in patients undergoing radiotherapy to prostate (PRT), whole pelvis (WPRT) and prostate bed (PBRT), could improve the rate of repeated planning CT scans caused by faecal loading and rectal gas.

#### Material and Methods

Data were collected retrospectively from patient's notes and electronic records. From January 2015 until January 2016, 23% of patients underwent rescan due to faecal loading and rectal gas.

Patients underwent PBRT, traditionally did not receive bowel preparation, on the contrary, those underwent PRT and WPRT used micro enemas prescribed at the time of the fiducial markers insertion.

We introduced a new radiographer led clinic for all patients to discuss bowel habit and identify patients that needed additional laxatives. Patients underwent PBRT also received micro enemas routinely.

All patients received a bowel chart to record their bowel movement and type of stools. Sodium Docusate 100mg TDS was our laxative of choice. In addition, a record of off-line review was kept.

#### Results

A total of 195 patients were treated (18 PBRT and 177 between PRT and WPRT) from January 2017 until April 2017. They all received, a bowel chart and the prescription of micro enemas. 32 patients also received additional prescription of Sodium Docusate.

Sodium Docusate was well tolerated in all cases and therefore continued during the whole treatment helping in reducing faecal loading and rectal gas.

32 (16.4%) required a re-scan, because poor hydration, micro enema compliance and patient position. However, only 14 (7.1%) had large rectum with antero-posterior diameter >4 cm.

Of the 18 PBRT patients, 15 were assessed in the radiographer led clinic and did not require a second planning scan. The 3 patients who missed the clinic underwent re-scan.

The off-line review didn't show significant differences during the course of the treatment, but data are still too small.

#### Conclusion

The addition of a radiographer led clinic, with bowel habit assessment and prescription of laxatives, helped reducing the rate of planning rescan from 23% to 16.4% with only a 7.1% of rescan rate due to large rectum. This consequently reduced unnecessary radiation exposure to the patients and additional workload for the department.

#### EP-1541 Intention to treat analysis of 68Ga-PSMA/11C-choline PET/CT vs. CT for prostate cancer recurrences

A. Müller<sup>1</sup>, S. Olthof<sup>2</sup>, C. Pfannenber<sup>2</sup>, D. Wegener<sup>1</sup>, J. Marzec<sup>1</sup>, J. Bedke<sup>3</sup>, A. Stenzl<sup>3</sup>, C. La Fougère<sup>4</sup>, K. Nikolaou<sup>2</sup>, D. Zips<sup>1</sup>, J. Schwenck<sup>4</sup>

<sup>1</sup>Eberhard Karls University Tübingen, Department of Radiation Oncology, Tübingen, Germany; <sup>2</sup>Eberhard Karls University Tübingen, Department of Diagnostic and Interventional Radiology, Tübingen, Germany; <sup>3</sup>Eberhard Karls University Tübingen, Department of Urology, Tübingen, Germany; <sup>4</sup>Eberhard Karls University Tübingen, Department of Nuclear Medicine and Clinical Molecular Imaging, Tübingen, Germany

#### Purpose or Objective

Biochemical recurrence (BCR) after prostate cancer (PC) surgery is very common, even after additional salvage radiotherapy (SRT). This might be explained by target miss. Improved diagnostic accuracy provided by PET could potentially circumvent this therapeutic gap. Therefore, we evaluated the impact of simultaneous <sup>11</sup>C-choline and <sup>68</sup>Ga-PSMA PET/CT compared to standard CT imaging after surgery +/- SRT with regard to curative radiotherapy (RT) options including stereotactic body radiotherapy (SBRT) for oligometastases.

#### Material and Methods

The prospective register database (064 / 2013 BO1) was searched for patients receiving both <sup>68</sup>Ga-PSMA and <sup>11</sup>C-choline PET/CT within the same day. Inclusion in this analysis was restricted to patients after radical prostatectomy +/-SRT at time of BCR. <sup>11</sup>C-choline PET/CT was acquired with a contrast-enhanced CT and <sup>68</sup>Ga-PSMA was combined with a low-dose CT. TNM-stage was assessed by two blinded investigators (JS, SCO). Ten curative treatment routines were defined including SBRT for up to 5 oligometastases. Imaging-related changes of treatment and treatment intent as well as related costs depending on stage shift after imaging were analysed. Cost calculation for in-/correct treatment was performed using the German reimbursement catalogue ("Einheitlicher Bewertungsmaßstab"; EBM) and the German medicines compendium ("Rote Liste").

#### Results

Eighty-three patients were eligible (median PSA-level 1.9 ng/ml). Both PET-examinations led to concordant results in 72.3% of patients, while concordance of TNM-staging between <sup>68</sup>Ga-PSMA-PET and diagnostic CT was only 36.1%. Incorrect staging would lead to "wrong" treatment and therefore to additional treatment costs. A <sup>68</sup>Ga-PSMA-PET would be cost-effective if additional costs do not exceed 3,843 € (vs. CT). According to the "number needed to treat" we calculated the "number needed to image (NNI)" to avoid one "wrong" treatment for a patient. The NNI<sub><sup>11</sup>C-choline</sub> equals 4 and the NNI<sub>contrast enhanced CT</sub> equals 2 compared to <sup>68</sup>Ga-PSMA-PET to avoid one incorrect treatment. <sup>68</sup>Ga-PSMA-PET-staging enabled new curative options in half of the patients with previous SRT who otherwise always receive palliative ADT.

#### Conclusion

In this prospective analysis we compared the impact of three simultaneously performed imaging modalities on treatment of PC recurrences after surgery. Main findings include cost-efficacy of <sup>68</sup>Ga-PSMA-PET by calculating the additional costs of "wrong" intended treatment occurring in approximately 2/3 of patients after conventional staging. In addition, we were able to demonstrate that <sup>68</sup>Ga-PSMA-PET gave a high chance of curative treatment

for patients without previous RT (>90%) and new curative options in half of patients after SRT who usually would otherwise receive palliative ADT. Cost efficacy is further substantiated by the new measure NNI. Therefore, <sup>68</sup>Ga-PSMA PET/CT staging should become the standard method for staging of high risk prostate cancer patients with BCR, also after initial salvage therapy.

#### EP-1542 Long-term results and PSA kinetics after robotic SBRT for prostate cancer

Y. Park<sup>1</sup>, H.J. Park<sup>2</sup>, W.I. Jang<sup>3</sup>, B.K. Jeong<sup>4</sup>, H. Kim<sup>5</sup>, A.R. Chang<sup>1</sup>

<sup>1</sup>Soonchunhyang University Seoul Hospital, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Hanyang University College of Medicine, Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Korea Institute of Radiological and Medical Sciences, Radiation Oncology, Seoul, Korea Republic of ; <sup>4</sup>Gyeongsang National University School of Medicine, Radiation Oncology, Jinju, Korea Republic of ; <sup>5</sup>Inha University Hospital, Radiation Oncology, Incheon, Korea Republic of

#### Purpose or Objective

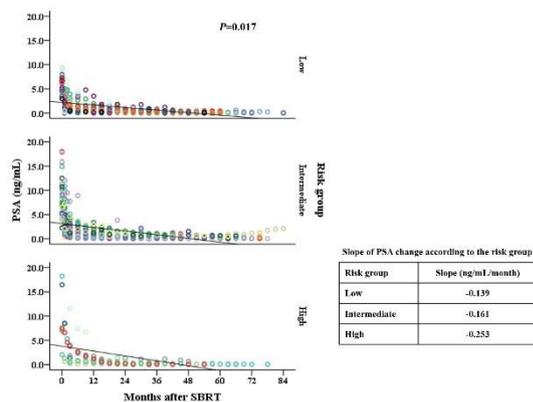

To evaluate the treatment outcome and prostate-specific antigen (PSA) change after stereotactic body radiotherapy (SBRT) for localized prostate cancer.

#### Material and Methods

Patients with localized prostate cancer treated with SBRT at three academic hospitals were enrolled. Treatment was delivered using Cyberknife with dose range from 35 to 37.5 Gy in 5 fractions. Biochemical failure (BCF) was assessed with Phoenix definition and toxicities were scored with Radiation Therapy Oncology Group (RTOG) toxicity criteria. The PSA kinetics were analyzed in patients who received no androgen deprivation therapy (ADT) and showed no recurrence.

#### Results

Of the total 88 patients, 14 patients (15.9%) received ADT. After median follow-up of 63.8 months, the 5-year BCF free survival (BCFFS) was 94.7%. Two patients experienced late grade  $\geq 3$  GI toxicities (2.2%). The median nadir PSA was 0.12 ng/mL and the median time to nadir was 44.8 months. Patients who reached nadir before 24 months showed poorer BCFFS than the others. The rate of PSA decline was maximum in the first year after treatment and gradually decreased with time. The pattern of PSA change was significantly different according to the risk groups ( $p=0.011$ ) with the slope of -0.139, -0.161 and -0.253 ng/mL/month in low-, intermediate- and high-risk groups, respectively (Figure)

#### Conclusion

SBRT for localized prostate cancer showed favorable efficacy with minimal toxicities. The time to PSA nadir was significantly associated with treatment outcome. PSA revealed rapid initial decline and slower decrease with

longer follow-up and the patterns of PSA changes were different according to the risk groups.

#### EP-1543 Early Results of a Phase 2 Multicentre Study of Linac-based Stereotactic Boost for Prostate Cancer

D. Pryor<sup>1</sup>, M. Sidhom<sup>2</sup>, S. Arumugam<sup>2</sup>, J. Buccicci<sup>3</sup>, J. Smart<sup>4</sup>, M. Grand<sup>2</sup>, P. Greer<sup>4</sup>, S. Keats<sup>2</sup>, L. Wilton<sup>4</sup>, M. O'Neill<sup>4</sup>, J. Martin<sup>4</sup>

<sup>1</sup>Princess Alexandra Hospital, Radiation Oncology, Brisbane, Australia ; <sup>2</sup>Liverpool Hospital, South Western Sydney Radiation Oncology, Sydney, Australia ; <sup>3</sup>St George Hospital, Radiation Oncology, Sydney, Australia ; <sup>4</sup>Calvary Mater Newcastle, Radiation Oncology, Newcastle- NSW, Australia

#### Purpose or Objective

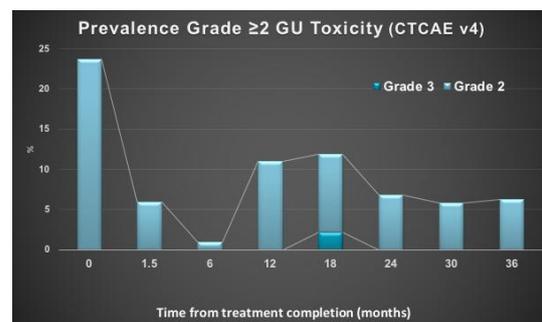

To report early toxicity and PSA kinetics following a novel, linac-based, stereotactic radiotherapy (SBRT) boost for a prospective multicentre phase 2 study (PROMETHEUS ACTRN12615000223538).

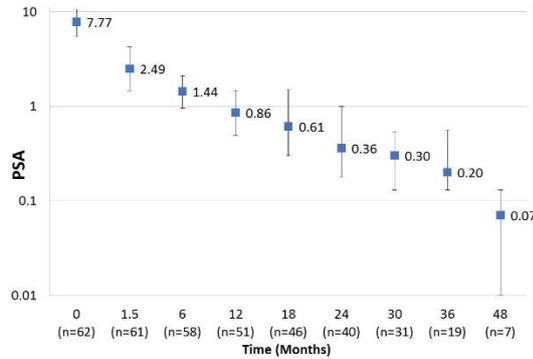

#### Material and Methods

Patients were treated with linac-based SBRT, 19-20 Gy in 2 fractions delivered one week apart, followed by conventionally fractionated IMRT/VMAT (46 Gy in 23 or 36 Gy in 12 fractions). MRI fusion for RT planning was mandated, as was rectal displacement during SBRT. Toxicity was prospectively graded using the Common Terminology Criteria for Adverse Events version 4.0 (CTCAE v4).

#### Results

Between 3/2014 and 10/2018, 134 patients (76% intermediate, 24% high-risk) with a median age of 70 years (range 53-85) have been treated across 5 centres. Short course ( $\leq 6$  m) ADT was used in 37%, long course in 17%. Rectal displacement method was SpaceOAR in 59% and Rectafix in 41%. 42 and 92 patients were treated at the 19 Gy and 20 Gy dose levels respectively. Median follow-up is 24 months. Acute G2 GI and GU toxicity occurred in 3% and 24% with no cases of acute G3 toxicity. Late  $\geq 2$  GI toxicity was 3%, 1% and 0% at 12, 24 and 36 months respectively. Only one G3 GI toxicity occurred (18 months post-RT). Late  $\geq 2$  GU toxicity at 6, 12, 18, 24 and 36 months was 1%, 11%, 12%, 7% and 6% respectively with only two G3 events (18 months post RT - figure 1). For patients not receiving ADT the median PSA value pre-treatment was 7.8 ug/L (range 1.1-20) and at 12, 24, 36 and 48 months post-treatment was 0.86, 0.36, 0.2 and 0.07 ug/L (figure 2).

### Conclusion

Delivery of linac-based SBRT boost is feasible and well tolerated with low rates of early toxicity and promising PSA responses. A second transient peak in moderate irritative GU toxicity was observed at 18 months. No urethral strictures have been reported to date. Longer term follow-up is required to document late toxicity and tumour control with this approach. A randomized trial comparing this approach with SBRT monotherapy is under development.

### EP-1544 Focal Linac-based SBRT Re-treatment for local recurrence of Ca P following previous definitive RT

G. Hruby<sup>1</sup>, A. Kneebone<sup>1</sup>, T. Eade<sup>1</sup>, A. Le<sup>1</sup>, J. Booth<sup>1</sup>, J. Hunter<sup>1</sup>, C. Kwong<sup>1</sup>, C. Brown<sup>1</sup>

<sup>1</sup>Royal North Shore Hospital, Radiation Oncology, Sydney, Australia

#### Purpose or Objective

to determine the safety and tolerability of focal linac based SBRT re-treatment with real time imaging for local only recurrence of prostate cancer after definitive RT

#### Material and Methods

A prospective, ethics approved feasibility and toxicity trial with nested sequential dose escalation component. In order to be eligible, men had to have biopsy proven recurrence limited to both PSMA-PET and mp-MRI region of suspicion and disease confined to less than half a lobe. We mandated a disease free interval of at least 4 years from initial RT and a PSA < 15 prior to enrolment.

#### Results

Between March 2016 and October 2018, 20 men were treated with 36 or 38Gy in 6 2nd to 3rd daily fractions. Two men had received LDR monotherapy and 2 HDR boost brachytherapy, the rest (16) EBRT. Median time from initial RT was 8 years (range 4.5-12). Original tumour details are presented in Table 1.

At focal SBRT, median age and PSA were 73 and 5.6 respectively. All 20 completed SBRT; 5, 3 and 2 men with grade 1 fatigue, GU and GI toxicity, respectively. All toxicity was self-limiting and to date there has been no late toxicity. 19 of 20 patients are biochemically controlled with PSA response. Nine men have undergone per-protocol repeat PSMA-PET at 12 months, only one (also with BF = PSA nadir +2) has failed within the prostate. Eight of 9 have demonstrated metabolic PSMA response to focal SBRT (see Figure 1).

Table 1: Tumour Features at original RT  
T stage NPSANGSNT190-10963T2910-204713T3220 or more783 91

Figure 1

16/11/2015 2 months before SBRT - local recurrence R lobe

3/6/2017: 12 months after SBRT re-treat

#### Conclusion

Our patients have tolerated treatment better than expected with no sub-acute or late toxicity. Biochemical and PSMA responses are promising. We continue to accrue patients at dose level 2 (38Gy in 6#).

### EP-1545 Prostate cancer EBRT: adaptive strategy and use of robust optimization for geometrical uncertainties

E. Ferrara<sup>1</sup>, D. Beldi<sup>1</sup>, J. Yin<sup>2</sup>, G. Loi<sup>3</sup>, M. Krengli<sup>1,4</sup>

<sup>1</sup>University Hospital "Maggiore della Carità", Radiotherapy, Novara, Italy; <sup>2</sup>Sichuan Cancer Center, Radiotherapy, Chengdu, China; <sup>3</sup>University Hospital "Maggiore della Carità", Medical Physics, Novara, Italy; <sup>4</sup>University of "Piemonte Orientale", Translational Medicine, Novara, Italy

#### Purpose or Objective

Intensity modulated radiotherapy is sensitive to errors, mainly due to steep beam dose gradients and organ motion. Conventional margins are often insufficient to ensure robustness of treatment plans. The aim of this work is to develop and validate a new adaptive treatment method for prostate cancer (PCa) radiotherapy (RT), using an off-line strategy to design a patient-specific internal target volume (ITV) based on the study of organ motion obtained by serial Cone-Beam CT (CBCT) images and management of the geometrical uncertainties with min-max robust optimization.

#### Material and Methods

20 patients (pts) with intermediate-high PCa treated with radical RT were enrolled in this study. The prescribed dose was 78 Gy to prostate (CTV78) and 60 Gy to prostate plus seminal vesicles (CTV60) delivering 2 Gy/fraction (fx). The CBCTs were acquired during the first 5 fxs, then once a week for the remaining treatment. The CBCTs were imported in the Raystation treatment planning system (TPS) and co-registered with the planning CT using the on-line match rigid transformations provided by the OBI system on the treatment unit (Varian Trilogy TX). Then the deformable image registration (DIR) algorithm ANACONDA was applied to propagate the CTV78 and CTV60 volumes from the reference planning CT to the first 5 CBCTs. The reliability of the DIR mapped ROIs was assessed by radiation oncologists and the contours were used to generate the ITV. The original plan was re-optimized using a min-max robust algorithm based on the worst scenario optimization assuming an isotropic 5 mm maximum setup error. Then CTV coverage and OARs sparing achieved with the robust plan (RP) were analyzed and compared with the original standard plan (SP) calculating the dose distributions on the residual CBCTs. For each isocenter perturbation of 1 mm, the dose was recalculated and the following parameters were acquired: D99, D98 and D95 to evaluate target volume coverage and mean dose and D2 to evaluate OARs doses.

#### Results

Our adaptive strategy and RP showed to achieve optimal coverage of CTV also in the worst scenario (geometric error up to 5 mm) with D99>95% of prescribed dose and significant less dose to rectum and bladder. The analysis on all the residual CBCT acquired during the treatment showed that CTV coverage of RP was statistically better than SP in terms of D99 and D98 (p=0.008 and p=0.02, Wilcoxon test). Statistically (T-student test) significant mean dose reduction and D2 reduction was noted for rectum (p<0.05) and for bladder (p<0.009). Moreover, RP appeared to be less sensitive to bladder and rectal filling.

#### Conclusion

Robust optimization is a feasible and safe approach in prostate treatment. It may be successfully used to adapt the treatment with better target coverage and OARs sparing than standard PTV based planning during the treatment course.

**EP-1546 Stereotactic radiotherapy for prostate bed recurrence after prostatectomy, a multicentric series**  
 G. Francolini<sup>1</sup>, B.A. Jereczek-Fossa<sup>2,3</sup>, V. Di Cataldo<sup>4</sup>, G. Simontacchi<sup>1</sup>, G. Marvaso<sup>3</sup>, M.A. Zerella<sup>2,3</sup>, C.I. Fodor<sup>3</sup>, L. Masi<sup>4</sup>, L. Livi<sup>5</sup>

<sup>1</sup>Azienda Ospedaliero Universitaria Careggi, Radiotherapy, Florence, Italy ; <sup>2</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy ; <sup>3</sup>IEO European Institute of Oncology- IRCCS, Division of Radiotherapy, Milan, Italy ; <sup>4</sup>Istituto Fiorentino di Cura ed Assistenza, CyberKnife Center, Florence, Italy ; <sup>5</sup>Department of Experimental and Clinical Biomedical Sciences- University of Florence, Radiotherapy Unit, Florence, Italy

#### Purpose or Objective

Rate of biochemical recurrences in men affected by localized prostate cancer after radical prostatectomy (RP) ranges between 20 and 50%. Risk is particularly high for positive margins and poorly differentiated disease. Biochemical recurrence can be managed with curative purpose through salvage radiation therapy (SRT). However, Progression-free survival after conventional SRT approach, without concomitant androgen deprivation therapy (ADT), is 56% at 5 years. Moreover, likelihood of treatment failure in patients with pre-RT PSA values greater than 1.5 ng/ml is high, with PFS at 5 years of 18%. Positive metabolic imaging detecting local recurrence negatively impacts outcomes after SRT in this setting. Data from literature suggest that higher relapse-free survival is achieved by increasing radiation dose in patients undergoing SRT. Thus, when macroscopic recurrence is detected in prostatic bed through diagnostic imaging (MRI or CT-PET scan) improved local control may be achieved by extremely hypofractionated regimens. Here we present results from a multicentric retrospective experience including patients affected by macroscopic prostate bed recurrence and treated with stereotactic radiotherapy

#### Material and Methods

Data of 71 patients with prostate bed macroscopic recurrence treated in two institutions in Italy were reviewed. Recurrences were detected by MRI or CT-PET. Patients underwent stereotactic radiotherapy on prostate bed recurrence with a mean dose of 34.4 Gy (32.5-35 Gy) in 5 fractions, using Brainlab Veror<sup>®</sup> or Cyberknife<sup>®</sup> systems. Patients features, clinical outcomes and adverse events were reported. Biochemical failure after treatment was defined as increase of PSA levels of >10% if compared to pre-treatment value. Complete biochemical response after treatment was defined as PSA nadir <0.2 ng/ml. Univariate and multivariate analysis was performed through Cox regression model to explore the association between prognostic factors (Gleason score <7, Concomitant ADT, Time to recurrence <36 months and PSA at recurrence <1) and biochemical relapse-free survival (BRFS). Toxicity was reported according to CTCAE v

Mean age (years)	67,7
Gleason score at diagnosis	<7: 50 (70,4%)
	>7:19(26,8%)
pT Stage	N/A: 2 (2,8%)
	pT2: 37(52,2%)
	pT3: 32(45%)
	pT3a:20 pT3b:12 N/A: 2(2,8%)
pN Stage	N0/x: 64 (90,2%)
	N+: 5 (7%)
	N/A: 2 (2,8%)
Average PSA	Pre-RT: 2,3 ng/ml (0,14-16)
Concomitant ADT	Yes:12 (16,9%)*
	No:59 (83,1%)
TOTAL	71 (100%)

Table 1. Baseline population features

\*5 patients started ADT at SBRT, 7 patients had already ongoing ADT

#### 5.0

#### Results

71 patients were included, 16.9% were under ADT during treatment. Gleason score >7 and stage pT3 at diagnosis were reported in 26,8 and 45% of patients, respectively. Mean PSA at recurrence was 2,3 ng/ml, mean time to recurrence after RP was 98,6 months. Average volume of GTV was 10,8 cc (0,7-34,6). After an average follow up of 21.5 months 73

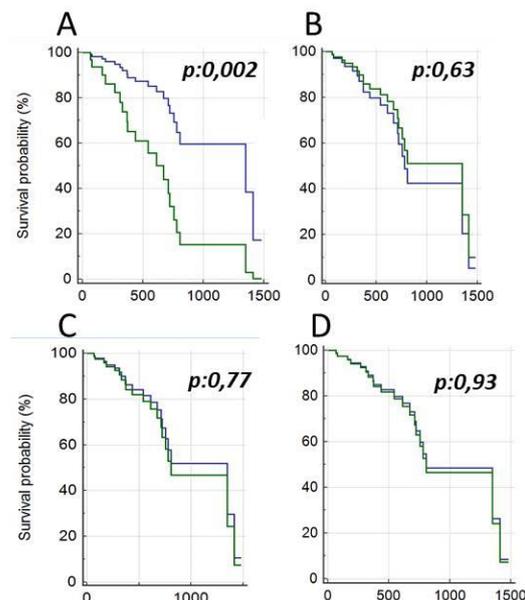

Fig.1: Multivariate analysis results. BRFS (days) in patients with Gleason score ≤/≥ 7(A), Time to macroscopic recurrence ≤/≥36 months (B), PSA at recurrence ≤/≥1 (C) and Concomitant ADT (D)

.1% of patients were free from recurrence and 49.3 % had complete biochemical response. Median BRF5 was 26 months (95% CI 23-46), Gleason score was the only prognostic independent factor associated with BRF5. Only 1 acute and 2 late G2 rectal and vesical toxicities were reported.

#### Conclusion

Stereotactic radiotherapy for prostate bed recurrence is safe and effective, regardless concomitant use of ADT and adverse prognostic factors. Prospective studies are needed to compare outcomes of conventional SRT to this technique

#### EP-1547 Developing an empirical nomogram for clinical visualization of DFS/OS for prostate cancer patients

R.M. Abdul<sup>1</sup>, E.P.P. Pang<sup>1</sup>, Y.S. Koh<sup>1</sup>, S.A. Gan<sup>1</sup>, J.K.L. Tuan<sup>1,2</sup>

<sup>1</sup>National Cancer Centre Singapore, Division of Radiation Oncology, Singapore, Singapore ; <sup>2</sup>Duke-NUS, Graduate Medical School, Singapore, Singapore

#### Purpose or Objective

To develop a predictive nomogram to provide clinical visualization on the probability of treatment outcomes [i.e. disease-free survival (DFS) and overall survival (OS)] for prostate cancer.

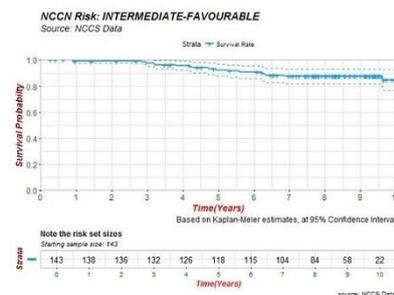

#### Material and Methods

This is a pilot longitudinal cohort study that analyzed 549 patients (enrolled in the DRO Cancer Registry) diagnosed with prostate cancer between 1998 and 2010. All the patients were stratified based on NCCN guidelines and have received radiotherapy up to 74Gy in 37# (+/- pelvic nodes irradiation). A multivariate analysis was conducted to predict DFS and OS as primary endpoints. Baseline prostate-specific antigen (PSA) level, T and N staging, Gleason scores (primary, secondary and total) were collected as independent prognostic factors in the building of this nomogram. Incidence of biochemical failure and death, along with its respective time from date of diagnosis to date of incidence, were tabulated to provide a binary predictor (SSMS, Microsoft). This is then input into a script utilizing R (survival), by using the Kaplan-Meier (K-M) survival estimate model. The resulting data output are then published on SQL Server Reporting Services (SSRS, Microsoft) to provide a visual representation of the model.

#### Results

Output from R provides a 95% Confidence Interval on DFS and OS based on input of the independent variables. A K-M survival curve (Figure 1), as well as a visual presentation based on a sample size of 100 patients of 5-year or 2-year survival estimates are displayed for facilitation of patients' meaningful understanding of the results (Figure 2). However, there were wide confidence variances for certain stratified groups with small sample size.

This graph is an estimation of survival rates up to 10 years after diagnosis. Results are based on selected inputs.

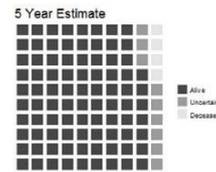

Probability of disease-free survival upon diagnosis, based on 143 patients:

At 2 years: ~98.5% (96.5% to 100.0%)

At 5 years: ~91.7% (87.0% to 96.4%)

At 10 years: ~More data required (Insufficient Data to compute accurately)

In a group of 100 patients with the same characteristics as selected, 87 to 96 of them are likely to not experience Biochemical Failure 5 years from their diagnosis.

These estimates are based on the real world outcome of patients treated in our institutions. Your exact experience may differ within the limits of this prediction. Survival estimates can be unreliable the further into the future prediction is made as there are less patients to base this estimate on

Report Generated on 15 Oct 2018, 08:16 AM

#### Conclusion

We have developed a cohort-based nomogram that served as a tool to facilitate the shared-decision making discussion between clinicians and patients on the management options.

#### EP-1548 Patterns of progression in metastatic prostate cancer: who might benefit from targeted radiotherapy? P. Patel<sup>1</sup>, N. Tunariu<sup>2</sup>, A. Tree<sup>1</sup>

<sup>1</sup>Royal Marsden NHS Foundation Trust- London and the Institute of Cancer Research, Clinical Oncology, London, United Kingdom ; <sup>2</sup>Royal Marsden NHS Foundation Trust- London and the Institute of Cancer Research, Radiology, London, United Kingdom

#### Purpose or Objective

Treatment for metastatic castrate-resistant prostate cancer (mCRPC) patients has rapidly changed since the introduction of androgen receptor targeted therapies (ART) such as Abiraterone and Enzalutamide. These treatments are better tolerated and have less toxicities compared to chemotherapies used. Therefore, methods of maintaining patients on these oral medications are of great interest. The aim of this study was to document patterns of progression of patients on ART and to identify the number of patients potentially amenable to Stereotactic body radiotherapy (SBRT) for oligo-progressive disease (OPD). OPD is a relatively newly described disease state whereby 1-3 metastatic lesions are progressing/new whilst all other sites of disease are well-controlled by a systemic agent. Theoretically SBRT to OPD lesions could allow continued therapeutic benefit of these oral treatments.

#### Material and Methods

This is a single centre retrospective cohort study. Data was collected from electronic patient records from the first 50 patients treated with ART for mCRPC between April 2015 - 2017. Data including patient demographics, tumour staging, radiological and symptomatic response to ART, PSA trend, and progression pattern on serial imaging were collected.

#### Results

This study analysed 50 patient records. The median age of patients was 81 years. Median PSA at presentation was 26. At the time of analysis 37 patients had progressed on ART, and 5 remained in remission. Four patients stopped treatment due to toxicity, 1 patient transferred care and 3 patients died due to other causes. Of those patients who had progressed 6 patients (12%) demonstrated OPD. Further details of the patients demonstrating OPD is represented in Table 1. Patient no.1 was treated with SBRT twice for OPD occurring 3 years apart. Patient no. 4 demonstrated further OPD 6 months later. The majority of patients remained asymptomatic at the time of OPD, 2 patients presented with related pain not requiring intervention. OPD lesions were detected by multiple different imaging modalities including CT, Whole body diffusion weighted MRI (WBDWMRI) and PET/CT.

Patient number	No. of sites of OPD	Sites of OPD	Type of scan detecting OPD	Suitability for SBRT	Treatment of OPD
1	1	Retroperitoneal lymph node	CT	Yes	SBRT 30Gy/5#
2	3	Thoracic vertebra T1, T6 Lumbar vertebra L1	WBDWMRI	Yes	Continuation of abiraterone + dexamethasone
3	1	Retroperitoneal lymph node	CT	Yes	Continuation of abiraterone
4	1	Prostate	Choline PET/CT	No-previous EBRT	Continuation of abiraterone + prednisolone
5	1	Pelvic lymph node	Choline PET/CT	Yes	Switched to abiraterone + dexamethasone
6	1	Inguinal lymph node	CT	Yes	Stopped systemic treatment

**Conclusion**

OPD is prevalent in mCRPC patients on Abiraterone/Enzalutamide. The majority of OPD occurred in non-bone metastases and a range of imaging techniques can be used to identify OPD. Most patients were asymptomatic at the time of OPD and had disease suitable for SBRT. The TRAP trial (NCT03644303) is currently testing the role of SBRT to sites of OPD in mCRPC.

**EP-1549 Clinical outcomes of image-guided radiotherapy in intermediate to high risk prostate cancer**

C. Chen<sup>1</sup>, H. Chuang<sup>2</sup>, M. Huang<sup>3</sup>

<sup>1</sup>Kaohsiung Medical University, Graduate Institute of Medicine- College of Medicine, Kaohsiung City, Taiwan ; <sup>2</sup>Kaohsiung Medical University, Faculty of Department of Public Health- College of Health Science, Kaohsiung City, Taiwan ; <sup>3</sup>Kaohsiung Medical University, Radiation Oncology, Kaohsiung City, Taiwan

**Purpose or Objective**

To report the long-term survival outcomes and late toxicities resulted from curative image-guided radiotherapy (IGRT) for prostate cancer patients with and without androgen deprivation therapy (ADT).

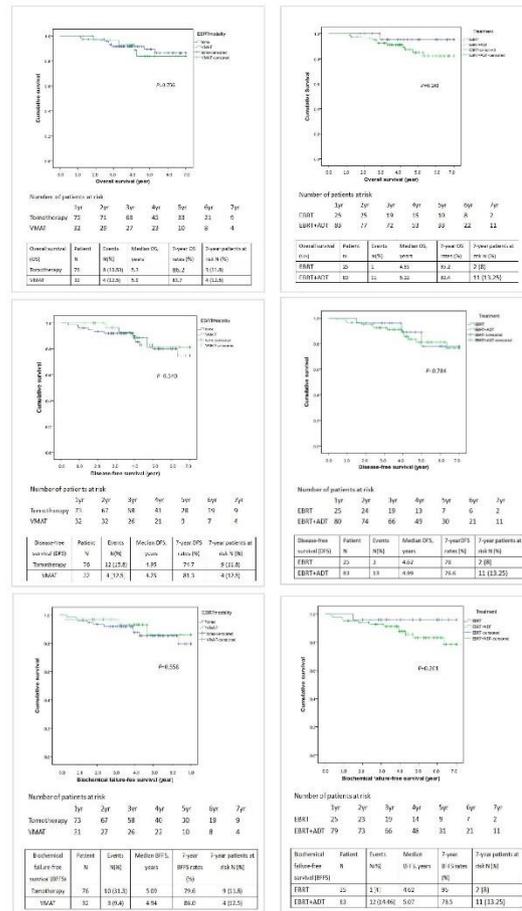

**Material and Methods**

The study included 108 patients with pathologically proven prostate adenocarcinoma who underwent IGRT between 2008 and 2014. Age ranged from 54 to 89 with a median age of 75 years. Twenty-nine patients were in the intermediate-risk group and 79 were in the high-risk group. The biochemical failure was defined by a rise of 2 ng/mL or more above the nadir PSA. The nadir was defined as lowest PSA value preceding a given threshold of 0.2 ng/mL or as absolutely lowest PSA before the transient bounce. Gastrointestinal (GI) and genitourinary (GU) toxicities were assessed and documented in agreement with the Common Toxicity Criteria Adverse Events version 3 (CTCAE v.3.0). Cox regression model and Kaplan-Meier curves were calculated, and the log-rank test was used to evaluate the differences of overall (OS), biochemical failure free (BFFS), disease free (DFS), locoregional failure free (LRFS) and distant metastases-failure free (DMFS) rates between two different modalities of radiotherapy.

**Results**

Among 108 patients, 32 patients (29.6%) were treated with RapidArc and 76 patients with Helical Tomotherapy. The mean radiation dose was 75 Gy. The median follow-up was 4.43 years (range, 417-3330 days). Two patients (2.8%, 2/72) in the EBRT-ADT group developed late GI complication 20 months after EBRT. There was no late GU complication. All patients tolerated the IGRT without any interruption. The 5-year OS, DFS, BFFS, LRFS and DMFS rates were 83.7%, 81.3%, 86.0%, 92.4% and 100.0% for the RapidArc group while 89.2% (P = 0.635), 80.1% (P = 0.747),

85.3% (P = 0.681), 95.5% (P = 0.338) and 91.7% (P = 0.129) for the Tomotherapy group.

**Conclusion**

There exists no statistically significant difference in the rates of locoregional recurrence, distant metastasis, biochemical control and overall survival when comparing RapidArc with Tomotherapy. IGRT was well tolerated with small late GU and GI toxicity.

**EP-1550 Give-me-five trial: toxicity assessment in ultra-hypofractionated prostate cancer radiotherapy**

Rojas<sup>1</sup>, G. Petralia<sup>4</sup>, R. Cambria<sup>5</sup>, R. Orecchia<sup>6</sup>, B.A. Jereczek-Fossa<sup>1,3</sup>

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Department of Radiation Oncology, Milan, Italy ; <sup>2</sup>IEO- European Institute of Oncology IRCCS, Division of Epidemiology and Biostatistics, Milan, Italy ; <sup>3</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy ; <sup>4</sup>IEO- European Institute of Oncology IRCCS, Department of Radiology, Milan, Italy ; <sup>5</sup>IEO- European Institute of Oncology IRCCS, Unit of Medical Physics, Milan, Italy ; <sup>6</sup>IEO- European Institute of Oncology IRCCS, Scientific Direction, Milan, Italy

**Purpose or Objective**

To evaluate genitourinary (GU) and gastrointestinal (GI) toxicity after ultra-hypofractionated prostate cancer (PCa) radiotherapy.

**Material and Methods**

As a part of the prospective phase II Give-me-five trial, 65 PCa patients underwent volumetric modulated arc therapy with simultaneous integrated boost to the dominant

intraprostatic lesion (DIL). The treatment scheme was 36.25-37.5 Gy/5 fractions to the whole prostate gland and to the DIL, respectively.

Univariate and multivariate logistic regression models were applied to identify independent factors associated with toxicity adjusting for confounding factors. The systematic analysis of urinary bladder and rectum dose-volume histograms (DVHs) was performed with Fisher exact test. The correlation between the relative volume receiving a given absolute dose and acute toxicity was investigated, with cutoffs at grade G>0 and G>1.

**Results**

Sixty-five patients fulfilled the inclusion criteria. At 1-month after the end of radiotherapy, 42 patients (65%) had no GU toxicity, whereas 18 (28%), 4 (6%) and 1 (1%) patients had G1, G2 and G3 GU toxicity. As concerning GI toxicity, 54 (83%) patients had no toxicity, whereas 11 (17%) reported G1 toxicity.

IPSS changed significantly (P<0.05) from baseline to 1 month and changes during time are significantly different by symptomatic score at first month (mild, moderate and severe, P<0.0001).

At univariate analysis (Table 1), no relationship was found between the prostate volume and acute GU (P=0.97) or GI toxicity (P=0.83), nor between the urinary bladder volume and any grade of acute GU toxicity (P=0.60) whereas the correlation between the rectum volume and any grade of acute GI toxicity was at the boundary of statistical significance (P=0.05).

At multivariate analysis adjusting for age and the presence of severe concomitant disease, IPSS at 1 month is positively significantly associated with acute GU G≥1 toxicity (P=0.03), whereas rectum volume is only borderline significantly associated with GI G≥1 toxicity (P=0.06). Prostate volume is not significantly associated with any toxicity (P=0.78).

For urinary bladder, the area of DVH between 17-24 Gy vs. volume 12-22% was correlated with any acute GU toxicity and the region between 25-35 Gy vs. volume 2-6% was correlated with acute G>1 GU toxicity. As concerning the relation between rectum DVH and GI toxicity, the portion between 18-34 Gy was correlated with any acute GI toxicity (Figure 1).

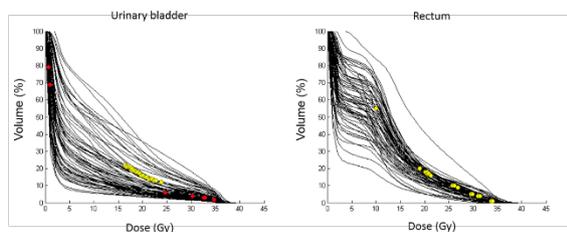

Figure 1 – Dose volume histograms of urinary bladder (left panel) and rectum (right panel) for all patients. Coloured points represent dose-volume combinations that statistically significantly correlate with acute genito-urinary (left panel) and gastro-intestinal (right panel) toxicity at Fisher's Exact Test. In particular, yellow points refer to any-grade toxicity (G>0) and red points refer to grade G>1 toxicity.

Table 1 - Univariate logistic regression evaluating the probability of acute genito-urinary (GU) and gastro-intestinal (GI) toxicity for urinary bladder and rectum, respectively. Values in table represent median and interquartile range, in brackets.

		All	No GU toxicity (n = 42)	Any GU toxicity (n = 23)	P-value
Urinary bladder	V <sub>18Gy</sub> (%)	12.4 (7.6, 18)	12.1 (7.6, 20.9)	12.4 (7.3, 17.4)	0.366
	V <sub>29Gy</sub> (%)	0.8 (0.36, 1.3)	0.8 (0.3, 1.3)	0.7 (0.36, 1.3)	0.269
	Bladder volume (cm <sup>3</sup> )	341 (226, 485)	354 (211, 470)	331 (242, 579)	0.602
	Prostate volume (cm <sup>3</sup> )	43 (33, 56)	41 (33, 53)	44 (33, 58)	0.828
Rectum	All		No GI toxicity (n = 54)	Any GI toxicity (n = 11)	P-value
	V <sub>18Gy</sub> (%)	20.9 (16.4, 23.5)	21 (16.4, 23.9)	19.6 (14.9, 21.2)	0.466
	V <sub>29Gy</sub> (%)	5.6 (4.0, 6.7)	5.8 (4.5, 7)	4.9 (3.7, 5.6)	0.164
	V <sub>35Gy</sub> (%)	1.5 (0.85, 2.9)	1.6 (0.9, 3)	1.1 (0.6, 1.6)	0.132
	V <sub>36Gy</sub> (%)	0.01 (0.0, 0.2)	0.02 (0.0, 0.3)	0.0 (0.0, 0.0)	0.146
	Rectum volume (cm <sup>3</sup> )	62 (50, 82)	56 (48, 81)	77 (69, 94)	0.051
	Prostate volume (cm <sup>3</sup> )	43 (33, 56)	43 (35, 53)	47 (26, 58)	0.969

Abbreviations: V<sub>18Gy</sub> = volume receiving 18 Gy; V<sub>29Gy</sub> = volume receiving 29 Gy; V<sub>35Gy</sub> = volume receiving 35 Gy; V<sub>36Gy</sub> = volume receiving 36 Gy; GI = genitourinary toxicity; GU = gastrointestinal toxicity.

**Conclusion**

The acute toxicity profile after ultra-hypofractionated radiotherapy for PCa is satisfactory. Prostate volume does not affect the toxicity probability.

The analysis will be extended to early and late toxicity (1-year minimum follow-up) and the systematic analysis of DVHs will be used to infer exploratory constraints for ultra-hypofractionated PCa radiotherapy.

**EP-1551 Interpretation of T3 found after MRI in low-intermediate risk patients with prostate adenocarcinoma.**

C. García Torres<sup>1</sup>, L.A. Glaría Enríquez<sup>1</sup>, A. Escribano Uzcudum<sup>1</sup>, R. Morera López<sup>1</sup>

<sup>1</sup>Hospital Universitario La Paz, Radiotherapy Oncology, Madrid, Spain

**Purpose or Objective**

Multiparametric magnetic resonance (mpMR) is the best imaging technique to achieve precise delimitation of disease-affected areas in PCa.

Urological guidelines do not systematically recommend MRI at low risk stage of prostate cancer, because of its low sensitivity to detect focal extra-prostatic extension (EPE) disease and cost.

After mpMR of low risk PCa patients, EPE data could be found (rmT3).

The finding of rmT3 upgrades the patient to high-risk group, which should change the type of treatment. This change of decision also implies exposing the patient to a greater risk of adverse events (AEs) related to the treatment. However in this group 85-95% is free of biochemical recurrence at 10 years, with any standard treatment.

Objective:

- 1- Determinate the percentage of low-risk patients studied with mpMR have EPE disease (T3)
- 2- Determinate factors associated to upstage of T after mpMR.

**Material and Methods**

We have retrospectively analyzed 58 patients diagnosed of low-risk prostate adenocarcinoma or favorable-intermediate risk, with PSA <20ng/ml and studied with mpMR.

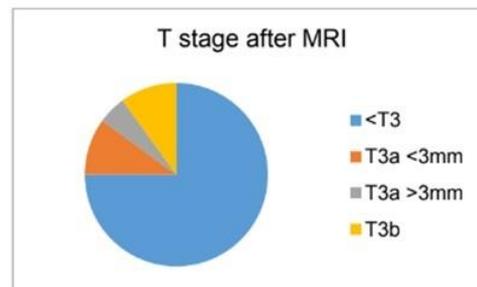

We use risk group classification according to NCCN 2018. Those with very low risk (VLR), low risk (LR) and favorable-intermediate (FI) were grouped as low risk. The definition of grade group (GG) according to AJCC 2010 was used.

Related to stage, we will group patients in <T3 (when none EPE is found after MRI), and T3 when there is some grade of EPE. The rmT3a was classified in focal T3a (<3mm of EPE) and extended T3a (>3mm of EPE) and T3b when seminal vesicle invasion is found.

**Results**

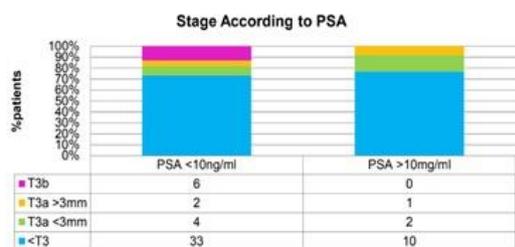

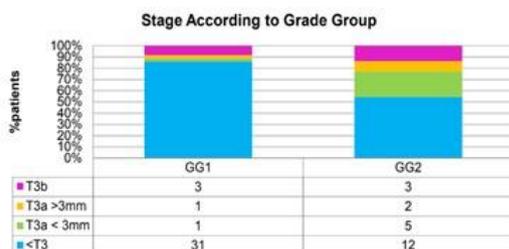

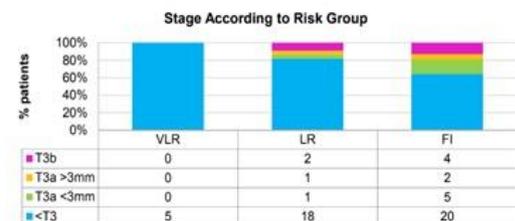

The mean age was 68.9 years (+/- 8.47 years). Among these patients, 36 (62.1%) belonged to GG1 and 22 (37.9%) corresponded to GG2.

After mpMR was performed 25% of patients presented some grade of EPE, becoming a locally advanced stage (T3a-T3b).

Patients were analyzed according to Risk Group: very low, low or intermediate. None very-low-risk patients (5 in total) increased their stage after mpMR. In low-risk

patients and in favorable-intermediate risk, 18.2% and 35.5% patients after mpMR upgrade to T3, respectively. We observe that among GG1 patients, 14 % and GG2 45.5% increased their stage. In patients with PSA <10ng/ml, 13.3% had an increase in stage. Between patients with PSA >10ng/ml, 23% upgrade to T3 after mpMR.

## Conclusion

According to the results obtained, we observed that 25% of patients diagnosed of localized prostate cancer with low-intermediate risk upgrade T stage after MRI. Switching to T3 stage of any type after MRI is more frequent in Grade 2 patients and favorable-intermediate risk groups. Grouping extended T3a and T3b we obtain 15.52.% (n=9). This percentage of more extended occult disease is close to historically reported recurrence (15- 25%). That is, with high reliability 15% of low- risk patients upgrade to high-risk groups. Without MRI, these patients could be undertreated according to a poor initial stage with the usual methods, which could be the cause of recurrence and subsequent metastasis.

## EP-1552 Impact of MRI on prostate cancer risk classification: game changer for therapeutic decision making?

C. Draulans<sup>1,2</sup>, W. Everaerts<sup>3,4</sup>, S. Isebaert<sup>1,2</sup>, G. Thomas<sup>4</sup>, R. Oyen<sup>5,6</sup>, S. Joniau<sup>3,4</sup>, E. Lerut<sup>6,7</sup>, L. De Wever<sup>5</sup>, B. Weynand<sup>6,7</sup>, E. Vanhoutte<sup>5</sup>, G. De Meerleer<sup>1,2</sup>, K. Haustermans<sup>1,2</sup>

<sup>1</sup>University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium ; <sup>2</sup>KU Leuven, Department of Oncology, Leuven, Belgium ; <sup>3</sup>University Hospitals Leuven, Department of Urology, Leuven, Belgium ; <sup>4</sup>KU Leuven, Department of Development and Regeneration, Leuven, Belgium ; <sup>5</sup>University Hospitals Leuven, Department of Radiology, Leuven, Belgium ; <sup>6</sup>KU Leuven, Department of Imaging and Pathology, Leuven, Belgium ; <sup>7</sup>University Hospitals Leuven, Department of Histopathology, Leuven, Belgium

## Purpose or Objective

To investigate the impact of magnetic resonance imaging (MRI) information on clinical staging, risk stratification and treatment recommendations for prostate cancer (PCa) according to the European Association of Urology (EAU) guidelines.

## Material and Methods

We performed a single-centre analysis of 180 men with PCa, undergoing clinical staging by digital rectal examination (DRE) as well as MRI before their robot-assisted radical prostatectomy between April 2016 and December 2017. Patients were stratified according to the EAU guidelines based on their clinical T-stage assessed by either DRE or MRI, initial prostate specific antigen (iPSA) value and Gleason score. Furthermore, to combine the best of both world, we created a combined clinical T-stage definition and investigated its accuracy. This combined clinical T-stage takes into account the DRE-based clinical staging for peripheral zone tumours, except for anterior located tumours not detected by DRE (cT1c). In this case, as well as for tumours with a transitional zone tumour component, the combined clinical T-stage is determined by MRI-based clinical T-staging. Differences in risk classification and recommended optimal duration of concomitant androgen deprivation therapy (ADT) between DRE- and MRI-staging were analysed using a paired-samples sign test. In all analysis of differences, a statistical significance level of p<0.05 was used.

## Results

Use of MRI information instead of DRE information leads to significant upstaging of clinical T-stage (33%) and EAU risk grouping (31%). When comparing these results with the pT-stage after histopathological evaluation, MRI showed a significantly higher sensitivity than DRE to detect non-organ-confined PCa (59% vs. 41%; p<0.01). In contrast the specificity of MRI was significantly worse than DRE (69% vs. 95%; p<0.01). The combined clinical T-stage approach (DRE-MRI) showed a sensitivity of 58% and a specificity of 79% to detect non-organ-confined PCa. Incorporation of MRI only information in the treatment decision process based on the EAU guidelines would alter the choice of surgical treatment in 49/180 patients (27%) with in most cases less nerve-sparing surgery (46/180 patients (26 %)). When we focus on radiation treatment with concomitant ADT, the treatment would be intensified in 46/180 patients (26%) with ADT prolongation as a result of upstaging by MRI. When the combined clinical T-stage approach (DRE-MRI) would be used, treatment would be intensified in 36/180 patients (20%).

## Conclusion

The incorporation of MRI information substantially affects the treatment choice in PCa patients as compared to using the current available EAU guidelines based on DRE information. More specifically, treatment intensification would be recommended in 1 out of 4 patients. Hence, there is a clear need for contemporary, updated MRI-based stratification tools and treatment guidelines to avoid overtreatment. Currently, a combined DRE-MRI-based assesment could be a pragmatic approach for cT-staging of PCa tumours.

## EP-1553 High-dose hypofractionated helical IG-IMRT in high-risk prostate cancer patients

N.G. Di Muzio<sup>1</sup>, C.L. Deantoni<sup>1</sup>, F. Zerbetto<sup>1</sup>, C. Cozzarini<sup>1</sup>, S. Broggi<sup>2</sup>, P. Mangili<sup>2</sup>, A. Chiara<sup>1</sup>, I. Dell'Oca<sup>1</sup>, A.M. Deli<sup>1</sup>, R. Calandrino<sup>2</sup>, C. Fiorino<sup>2</sup>, A. Fodor<sup>1</sup>  
<sup>1</sup>San Raffaele Scientific Institute, Department of Radiotherapy, Milan, Italy ; <sup>2</sup>San Raffaele Scientific Institute, Medical Physics, Milan, Italy

## Purpose or Objective

Recently Kishan and co-workers (JAMA 2018) demonstrated that high-risk prostate cancer patients treated with dose-escalated external beam radiotherapy and more than 24 months of androgen deprivation have

better outcomes than surgical patients. Here we report the results of our experience with high-dose hypofractionated helical Image Guided-Intensity Modulated Radiotherapy (IG-IMRT) (Tomotherapy, Accuray, Wisconsin) in high-risk prostate cancer (HR PCA) patients (pts).

#### Material and Methods

One hundred thirty-three HR PCA pts treated with hypofractionated helical IG-IMRT from April 2006 to July 2015 were included in this analysis. HR PCA was defined as the presence of one or more of the following characteristics: Gleason Score  $\geq 8$ , and/or initial PSA  $\geq 20$  ng/ml, and/or clinical stage  $\geq$  T3b. Seventeen pts had radiologically positive nodes (N1). The median age of the patients was 75 (range: 57-90) years. They were treated on pelvic lymph nodes (including common iliac chain) to a total dose of 51.8 Gy, with simultaneous integrated boost (SIB) on prostate and seminal vesicles to 74.2 Gy in 28 fractions, delivered in 5 ½ weeks. The 2 Gy equivalent dose, considering the accepted a/b ratio of 1.5 for prostate cancer, is 88 Gy. Androgen deprivation therapy (ADT) was prescribed to 121/133 pts for a median of 38 (0-120) months (pts with biochemical failure during ADT continued the hormonal treatment). In NO pts ADT was prescribed for median of 32 months. Median initial PSA was 16 (1.41-826.00) ng/mL.

#### Results

With a median follow up of 60 (11.8-145.2) months, biochemical relapse free survival (bRFS) was 79.7% and distant metastasis free survival (DMFS) was 86.5%. Overall survival was 69.2%, and cancer specific survival (CSS) was 91.7%. Important differences were registered between NO and N1 pts (see Table 1). Gastro-Enteric (GE) acute grading (G)  $\geq 2$  toxicity was 6 %, G3 only 0.8%. Genito-Urinary (GU) acute G $\geq 2$  toxicity was 30.1%, G3 only 0.8%. Late toxicity was as follows: GE $\geq$  G2 12.8%, G3 3%; GU $\geq$  G2 21.1%, G3 9%, but with spontaneous or therapeutic resolution, thus only 3.8% of pts presented G3 GU toxicity at the last follow up.

Patients	bRFS	DMFS	CSS
High Risk, NO	82.8%	89.7%	94.8%
N1	52.9%	58.8%	70.6%

#### Conclusion

Our results confirm that high-risk prostate cancer patients, most of them not suitable for surgery due to comorbidities, irradiated on pelvic lymph nodes with dose-escalation on prostate, associated to androgen deprivation, obtain good 5-year biochemical control, with acceptable acute and late toxicity. Positive lymph nodes pts present worse outcomes.

#### EP-1554 Twice vs thrice-weekly moderate hypofractionated EBRT for PCa: does overall treatment time matter?

V. Achar<sup>1</sup>, S. Jorcano<sup>2</sup>, M. Rouzaud<sup>1</sup>, L. Escude<sup>2</sup>, R. Miralbell<sup>1</sup>, T. Zilli<sup>1</sup>

<sup>1</sup>Hopitaux Universitaires Geneve, Radio-oncology, Geneva, Switzerland ; <sup>2</sup>Teknon Oncologic Institute, Radiation Oncology, Barcelona, Spain

#### Purpose or Objective

For prostate cancer the influence of overall treatment time (OTT) remains a controversial issue. Although a protracted OTT may have a detrimental effect on long-term disease control with standard fractionation, its impact on outcome has never been explored in moderate hypofractionation. Furthermore, changes in dose per fraction and OTT can impact tolerance and treatment-related side-effects.

This study is aiming to evaluate the influence of OTT in disease control, acute, and long-term side effects with

moderate hypofractionated external beam radiotherapy (RT) for prostate cancer delivered either twice or thrice a week.

#### Material and Methods

From 2003 to 2017, 157 patients with localized prostate cancer and an estimated risk of nodal metastases of  $\leq 20\%$  were treated consecutively on the prostate  $\pm$  seminal vesicles with 56 Gy in 4 Gy-fractions delivered either twice (86 patients, from 2003 to 2010, group-1) or thrice (71 patients, from 2010 to 2017, group-2) a week using IMRT or VMAT techniques. Median OTT for group-1 and group-2 were 46 (range, 38-90) and 30 (range, 29 to 40) days, respectively. Sixty-one patients (39%) received, in addition, neoadjuvant and concomitant androgen deprivation (median duration of 6 months). Gastrointestinal (GI) and genitourinary (GU) toxicities were scored according to the Common Terminology Criteria for Adverse Events version 3.0 grading scale. Biochemical relapse-free survival (bRFS) was assessed using the Phoenix definition. The median follow-up time was 110 and 56 months for group 1 and 2, respectively.

#### Results

At 6 weeks, patients treated thrice-a-week experienced higher acute  $\geq$  grade-2 GU toxicity compared to those treated twice-a-week (25.4% vs 5.8%,  $p=0.001$ ) even though none presented  $\geq$  grade-3 GU or GI toxicity in the thrice-a-week group. Although, 5-year  $\geq$  grade-2 late GU toxicity-free survival was higher in group-1 (95.9% $\pm$ 2.3%) than in group-2 (81.5 $\pm$ 4.9%,  $p=0.003$ ), the long range GU toxicity was not different between both groups. Furthermore, no differences in  $\geq$  grade-2 late GI toxicity-free survival were observed between both groups (97.5 $\pm$ 1.7% vs. 97 $\pm$ 2.1% for groups1 and 2, respectively). The 5-year bRFS was not different for patients treated twice compared to those treated thrice-a-week (80.6 $\pm$ 4.5% vs. 85.3 $\pm$ 4.8%, respectively  $p=0.441$ ), as much as for patients treated in  $>5$  weeks vs. those treated in  $\leq 5$  weeks (81.3 $\pm$ 4.4% vs. 84.4 $\pm$ 5.1%, respectively  $p=0.584$ ).

#### Conclusion

Less vs. more than 5 weeks OTT may increase acute and late GU side effects without significantly improving bRFS in patients treated to high effective doses ( $>80$  Gy) with moderate hypofractionated RT for prostate cancer. However, the similar prevalence of side effects in the long range for both groups of patients may favor that patients find more convenient to be treated in 5 rather than 7 weeks. The role of OTT on long-term outcome and toxicity of prostate cancer patients treated with hypofractionation deserves further prospective evaluation.

#### EP-1555 Precision of deformable image registration for high-field MR-Linac treatment of prostate cancer

R.L. Christiansen<sup>1,2</sup>, L. Dysager<sup>3</sup>, O. Hansen<sup>2,3</sup>, C. Brink<sup>1,2</sup>, B. Uffe<sup>1,2</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark ; <sup>2</sup>University of Southern Denmark, Department of Clinical Research, Odense, Denmark ; <sup>3</sup>Odense University Hospital, Department of Oncology, Odense, Denmark

#### Purpose or Objective

Online radiotherapy (RT) plan adaption requires re-delineation of target and organs at risk (OAR), while the patient is on the treatment couch. Automated deformable image registration (DIR) resulting in deformation of the planned target and OAR delineations will potentially minimize time spent on re-planning if deformation of these structures is sufficiently accurate for clinical use. This study investigates the precision of automatically deformed structures with manually defined structures in high-risk prostate cancer patients.

#### Material and Methods

The study includes six high-risk prostate patients referred for curative RT and prescribed 78 Gy to the prostate and the proximal 2 cm of the seminal vesicles (SV) and 56 Gy

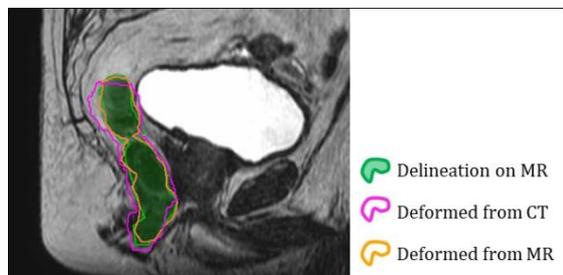

to the elective lymph node region (CTV56) in 39 fractions. The patients were CT- and MR-scanned (T2 weighted 3D sequence) for treatment planning and additionally MR scanned at the 10<sup>th</sup>, 20<sup>th</sup> and 30<sup>th</sup> treatment fraction. On each scan, target structures were defined by an experienced oncologist who also validated the OARs defined by an experienced RTT. For evaluation of intra-observer variability, all structures were re-delineated on one MR image set per patient at least 30 days after the initial delineations were performed.

Delineations and DIRs were performed in Monaco v 5.40 (Elekta AB, Sweden) treatment planning system (TPS) dedicated to the high field MR-Linac treatment. Structures defined on the planning CT and MR were deformed to the additional MR scans resulting in total 18 CT-MR and 18 MR-MR DIRs.

Agreement of deformed structures with the gold standard manual delineations was evaluated by mean surface distance (MSD) and Dice similarity coefficients (DSC). Differences between mean DSC and MSD of CT-MR and MR-MR deformation, respectively, were tested with paired t-tests for each structure set.

### Results

An example of a rectum structure delineation as well as CT- and MR-based deformation is shown in the figure. In total, 285 structures were deformed successfully, while three bladder structures were not created because the TPS' inability to deform ring structures. All mean DSC between deformed and manually delineated structures were better for MR-MR than CT-MR DIR, as seen in the table. Also, MSD was 0.6 - 1.3 mm lower for all deformed structures based on MR relative to CT. Overall, CT-MR deformed structures showed lesser DSC and higher MSD than the intra-observer variation. MR-MR deformed structures showed DSC and MSD of similar magnitude to those of intra-observer variations.

The figure shows the delineation of rectum made on an MR scan made at the 10<sup>th</sup> fraction along with deformed delineations originating from planning MR and CT scans.

Structure	DSC			MSD			Intra-obs. var.		
	Unit	CT-MR [index]	MR-MR [index]	p-value	CT-MR [mm]	MR-MR [mm]	p-value	DSC	MSD
Prostate		0.84	0.91	< 0.001	1.82	1.09	< 0.001	0.91	0.96
SV		0.63	0.77	0.02	2.01	1.00	0.06	0.78	1.06
CTV56		0.78	0.84	0.04	3.29	2.11	0.06	0.85	1.71
Rectum		0.73	0.86	0.005	3.06	1.80	0.006	0.93	0.85
Bladder		0.87	0.91	0.11	2.19	1.36	0.01	0.96	0.80
Femoral head R		0.90	0.94	0.03	1.46	0.91	0.03	0.93	1.06
Femoral head L		0.90	0.93	0.06	1.62	1.06	0.07	0.91	1.41
Penile bulb		0.61	0.76	0.23	1.75	1.07	0.33	0.80	1.02

DSC and MSD are given as the mean for all deformations within all patients for each structure. Resulting p-values for test of difference between CT-MR and MR-MR deformation are listed for DSC and MSD. DSC and MSD of each structure is given to evaluate intra-observer variation in delineation on MR.

### Conclusion

Intra-modally deformed OAR and target structures for daily plan adaptation in prostate cancer patients matched manually delineated structures more precisely than inter-modal deformations. Agreement of intra-modal deformations corresponded in magnitude to the intra-observer variation and is recommended for clinical use. However, some manual corrections of deformed structures should be expected.

### EP-1556 The effect of an endorectal balloon on GI toxicity after EBRT for localized prostate cancer

V. Groen<sup>1</sup>, L. Kerkmeijer<sup>1</sup>, E. Monnikhof<sup>2</sup>, M. Van Schie<sup>3</sup>, M. Kunze-Busch<sup>4</sup>, H. De Boer<sup>1</sup>, U. Van der Heide<sup>3</sup>, F. Pos<sup>3</sup>, K. Haustermans<sup>5</sup>, R.J. Smeenk<sup>4</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>UMC Utrecht, Epidemiology, Utrecht, The Netherlands ; <sup>3</sup>The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands ; <sup>4</sup>Radboud University Nijmegen Medical Centre, Radiation Oncology, Nijmegen, The Netherlands ; <sup>5</sup>University Hospitals, Radiation Oncology, Leuven, Belgium

### Purpose or Objective

Gastro-intestinal (GI) toxicity is a common side effect following external beam radiation therapy (EBRT) in patients with localized and locally advanced prostate cancer. The introduction of IMRT and IGRT with subsequent margin reduction has shown to reduce the risk of GI toxicity. However, further reducing toxicity remains a challenge. Endorectal balloons (ERB) are applications initially developed to reduce intrafraction variations of the prostate during EBRT. In addition, studies have suggested the potential ability of an ERB to reduce EBRT related GI toxicity. The aim of this study was to compare GI toxicity in patients with and without an ERB after EBRT for localized prostate cancer.

### Material and Methods

We included 568 patients with intermediate and high risk prostate cancer of the phase 3 multicenter FLAME RCT in this observational analysis. The primary purpose of the FLAME trial is to compare EBRT in a standard treatment arm (n=284) of 77 Gy to the entire prostate + seminal vesicles in 35 fractions and a dose-escalation arm (n=284) consisting of an additional integrated boost up to 95 Gy to the macroscopic visible tumour on mpMRI. One of the participating centers applied an ERB during all radiation sessions (n=49). The ERB was filled with 100cc air.

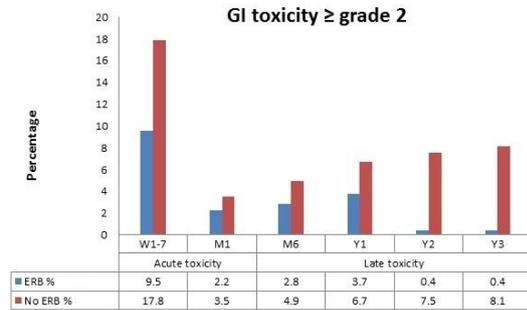

GI toxicity was scored by a physician using the CTCAE version 3.0 in all patients. The effect of the ERB in comparison to no ERB on cumulative GI toxicity  $\geq$  grade 2 was assessed by using a binary logistic regression model using the total study cohort irrespective of randomization. The model was adjusted for age, cardiovascular disease (CVD), diabetes mellitus (DM), T stage of prostate cancer, baseline toxicity, hormonal therapy and radiation dose received in 2cc of the rectum (D2cc). To account for missing data, multiple imputation was used. Furthermore, the prevalence of GI toxicity  $\geq$  grade 2 per follow-up moment was analyzed.

### Results

The incidence of cumulative GI toxicity  $\geq$  grade 2 within 3 years after treatment was lower in the ERB group compared to the group without ERB. After imputation the percentage of cumulative GI toxicity  $\geq$  grade 2 was 29.0% in the no ERB group versus 12.6% in the ERB group, p < 0.001. With adjustment for age, CVD, DM, T stage, baseline toxicity, hormonal therapy and rectum D2cc the daily application of an ERB showed a decreased risk of cumulative GI toxicity  $\geq$  grade 2 with an odds ratio of 0.35 (0.27 - 0.46 95% CI p < 0.001) (table 1). In figure 1 the prevalence of GI toxicity  $\geq$  grade 2 per FU moment is shown.

Imputed data	OR	95% CI
Without adjustment	0.353	0.272 - 0.459
Adjustment for baseline toxicity	0.361	0.277 - 0.470
Adjustment for all	0.353	0.271 - 0.461

Table 1. Binary logistic regression model imputed data. Adjusted for age, CVD, DM, T stage, baseline toxicity, hormonal therapy and rectum D2cc.

### Conclusion

Daily ERB application during EBRT for the treatment of localized prostate cancer may reduce GI toxicity  $\geq$  grade 2. However, the results above must be interpreted cautiously since the group of patients treated with ERB were all treated in the same center. Additional local protocol variations could have been confounders in the relation between ERB and GI toxicity. Further evaluation of the dosimetric parameters is necessary.

### EP-1557 Do metformin and statins play a role in localized high-risk prostate cancer?

G. Cadeddu<sup>1</sup>, F. López Campos<sup>1</sup>, M. Martín Martín<sup>1</sup>, L. Pelari Mici<sup>1</sup>, K. Ytuza Charahua de Kirschner<sup>1</sup>, A. Hernández Corrales<sup>1</sup>, E. Carrasco Esteban<sup>2</sup>, S. Sastre Gallego<sup>3</sup>, I. Císcar García<sup>1</sup>, S. Sancho García<sup>1</sup>, A. Hervás Morón<sup>1</sup>

<sup>1</sup>Hospital Ramón y Cajal, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Central de la Defensa "Gómez Ulla", Radiation Oncology, Madrid, Spain ; <sup>3</sup>Hospital Beata María Ana, Radiation Oncology, Madrid, Spain

### Purpose or Objective

There is increasing evidence that statins and oral anti-diabetic drugs, such as metformin, can have a favourable role in the treatment of advanced prostate cancer. This study analyses the impact of metformin and/or statins on biochemical failure-free survival (BFFS) and on distant failure-free survival (DFFS) in high-risk prostate cancer treated with radiotherapy.

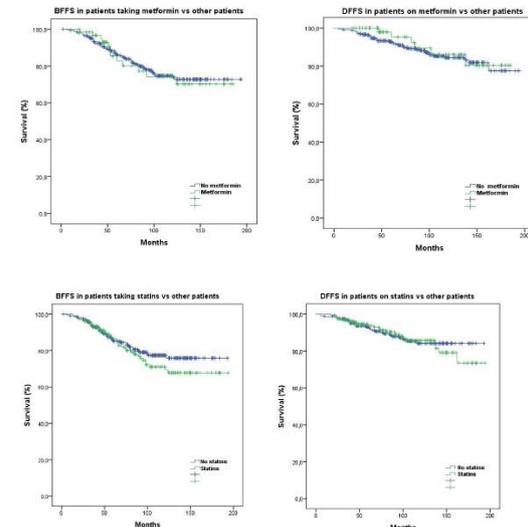

### Material and Methods

From 2002 to 2016, 393 patients with histologically confirmed high-risk prostate cancer defined by National Comprehensive Cancer Network (NCCN) risk group were retrospectively evaluated. All patients assumed androgen deprivation therapy and were treated with radiotherapy according to the institution protocol. Biochemical recurrence was determined by Phoenix criteria defined as a PSA rise of 2 ng/mL or more above the nadir PSA, metastatic patients were defined by the presence of radiological documented metastasis (CT scan, MRI, Choline-PET or bone scintigraphy) in nodes, bones, or visceral disease according to RECIST 1.0 criteria. Association with BFFS and DFFS was analysed using Kaplan and Meier method.

### Results

393 patients with a median age of 70 years (46-83) and median PSA at diagnosis of 34ng/ml (0.6-766) were studied. Of the patients included in this study, 40% (N=158) were treated with statins (64.6% with a dose  $\leq$  20mg/day) and 16% of patients (N=63) were treated with metformin (77.4% with a dose  $\leq$  1700mg/day). With a median follow-up of 97 months, no statistically significant differences were found in BFFS and DFFS between patients treated with metformin versus non-metformin treated patients: 74% versus 77% (p=0.92) and 89% versus 87% (p=0.52), respectively. BFFS and DFFS in patients receiving  $\leq$  1700mg/day versus  $\geq$  1700mg/day of metformin was 78% versus 56% (p=0.10) and 93% versus 71% (p=0.12), respectively. Regarding patients treated with

statins versus non-statins treated patients BFFS at 97 months was 74.6% versus 79% (p=0.31) and DFFS was 88% versus 87.2% (p=0.90). BFFS and DFFS in patients receiving  $\leq$  20mg/day vs  $\geq$  20mg/day of statins was 69.4% versus 77.8% (p=0.28) and 87.2% versus 88.3% (p=0.82), respectively.

### Conclusion

Metformin and statins treatments were not associated with an improvement of BFFS and DFFS in our analysis. Prospective studies are needed to define the role of metformin and statins in localized prostate cancer patients

### EP-1558 Updated results of a Phase II study on 5 fractions FFF SBRT for low and intermediate prostate cancer

F. Alongi<sup>1</sup>, L. Nicosia<sup>1</sup>, R. Mazzola<sup>1</sup>, N. Giaj-Levra<sup>1</sup>, F. Ricchetti<sup>1</sup>, V. Figlia<sup>1</sup>, M. Rigo<sup>1</sup>, G. Sicignano<sup>1</sup>, S. Naccarato<sup>1</sup>, R. Ruggieri<sup>1</sup>

<sup>1</sup>Ospedale Sacro Cuore "Don Calabria", Radiation Oncology, Negrar, Italy

### Purpose or Objective

SBRT had been shown to be a potential treatment option for localized prostate cancer (PC) in selected population. Usually, prostate SBRT has been delivered every other day in order to favour normal tissues recovery, minimizing side effects. Flattening Filter Free (FFF) delivery is a treatment modality able to reduce treatment beam-on time, decreasing patient positioning uncertainties. We reported feasibility, side effects and biochemical control of FFF SBRT delivered in 5 consecutive days in a cohort of patients affected by localized PC.

### Material and Methods

The study, approved by Ethical Committee, started on January 2014. Inclusion criteria were: age  $\leq$  80 years, World Health Organization performance status  $\leq$  2, histologically proven prostate adenocarcinoma, low-to-intermediate risk according to D'Amico criteria, no distant metastases, no previous surgery other than TURP, no other malignant tumor in the previous 5 years, a pre-SBRT International Prostatic Symptoms Score (IPSS) ranged between 0 and 7.

The SBRT-schedules were: 35Gy for low risk and 37.5Gy for intermediate risk PC in 5 fractions, delivered in 5 consecutive days. SBRT was delivered with volumetric modulated radiation therapy (VMAT). Toxicity assessment was performed according to CTCAE v4.0 scale. Neoadjuvant/concomitant hormonal-therapy was prescribed according to risk classification.

### Results

Fifty-two patients were enrolled at the time of analysis. Median age was 73 years (55-83), Median follow-up was 33 months (range: 6-55 months). Thirty-four (65.3%) had a low-risk PC and 18 (34.6%) an intermediate-risk PC. Median initial PSA was 5.9 ng/ml (range, 1.8-15.7 ng/ml). Median Gleason score was 6 (6-7). Median IPSS pre-SBRT was 4.5 (range, 0 - 7). All patients completed the treatment as planned.

Acute G1-2 toxicity occurred in 18 (34.6%) patients and was distributed as follows: 8 (15.3%) cases of G1 gastrointestinal toxicity, 1 (1.9%) patients had G2 gastrointestinal toxicity, 5 (9.6%) patients reported G2 genitourinary toxicity and 11 (21.1%) G1 genitourinary toxicity. Patients may have experienced more than one toxicity. Late G1 gastrointestinal toxicity occurred in 5 (9.6%) patients. No G3 toxicities occurred.

At the last follow-up median IPSS was 3 (1-19) and median PSA was 0.315 ng/ml (range 0.04-7.965 ng/ml). Biochemical control was 98%.

#### Conclusion

The results of our study showed that FFF SBRT in 5 fractions for low-to-intermediate PC is feasible and well tolerated. Longer follow-up is necessary to assess late toxicity and long-term effectiveness.

#### EP-1559 SBRT for lymph node metastases from prostate cancer: a multi-institutional retrospective analysis

F. Alongi<sup>1</sup>, L. Nicosia<sup>1</sup>, C. Francese<sup>2</sup>, G. D'Agostino<sup>2</sup>, L. Di Brina<sup>2</sup>, V. Figlia<sup>1</sup>, R. Mazzola<sup>1</sup>, S. Tomatis<sup>2</sup>, M. Scorsetti<sup>2</sup>  
<sup>1</sup>*Ospedale Sacro Cuore "Don Calabria", Radiation Oncology, Negrar, Italy*; <sup>2</sup>*Humanitas Clinical and Research Hospital, Radiotherapy and Radiosurgery Department, Milan, Italy*

#### Purpose or Objective

Metastases directed treatment is an emerging strategy for oligometastatic/oligorecurrent/oligoprogressive lymph node metastases from prostate adenocarcinoma. Aim of the present study was to evaluate outcome of patients treated with stereotactic body radiation therapy (SBRT) on lymph node metastases.

#### Material and Methods

This is a multi-institutional retrospective analysis, including patients affected by lymph node metastases from prostate adenocarcinoma treated with SBRT. Patients with a maximum of 5 lymph node metastases were included. Concomitant treatment with systemic therapy was allowed. End-points of the analysis were local control (LC), out-of-field progression-free survival (OFPFS), overall progression-free survival (PFS) and overall survival (OS).

#### Results

80 patients and 157 lymph node metastases, treated from 2009 to 2018 were evaluated. Median age was 70.2 years and median PSA before SBRT was 1.88 ng/ml. Median diameter of treated lesion was 37 mm (range 7 - 40 mm). Dose delivered ranged from 25 to 48 Gy in 5 to 12 Gy per fractions (median BED<sub>3Gy</sub> 116.67, range 66.67-240). Androgen deprivation therapy was administered concomitantly in 72 lesions. With a median follow-up of 16 months, LC rates at 1- and 3-years were 93% and 86%. In-field progression of disease was observed in 11 (7%) lesions. One and 3-years OFPFS were 59% and 29% while PFS were 49 % and 20%. Median values of OFPFS and PFS were 15 and 11 months, respectively. Rates of OS at 1- and 3-years were 100% and 95%.

#### Conclusion

SBRT in the management of lymph node metastases from prostate cancer seems to be an effective approach with high rates of in-field control. Prospective trials are necessary to better select patients who can benefit the most from this ablative focal treatment.

#### EP-1560 Quality of life after focal salvage high-dose-rate brachytherapy for radiorecurrent prostate cancer

M. Van Son<sup>1</sup>, E. Monnikhof<sup>2</sup>, M. Peters<sup>1</sup>, J. Van der Voort van Zyp<sup>1</sup>

<sup>1</sup>*UMC Utrecht, Radiotherapy, Utrecht, The Netherlands*; <sup>2</sup>*UMC Utrecht, Epidemiology, Utrecht, The Netherlands*

#### Purpose or Objective

Despite developments in radiotherapy, prostate cancer recurrences are common. Radiorecurrent disease is usually palliatively treated with androgen deprivation therapy (ADT), exposing patients to harmful side-effects and deterioration of quality of life (QoL). Focal ablative therapy is an emerging curative treatment option aiming to reduce toxicity and preserve QoL. Here, we present our longitudinal analysis of prospectively collected QoL data from recurrent prostate cancer patients treated with focal salvage high-dose-rate brachytherapy (HDR-BT).

#### Material and Methods

We included the first consecutive 100 patients who were treated with focal salvage HDR-BT at our institution. QoL was measured with the validated questionnaire EORTC QLQ-PR25, covering the domains urinary symptoms, bowel symptoms and sexual functioning (scoring scale from 0 - 100). Questionnaires were completed at baseline and after 1, 3, 6, 9, 12, 18 and 24 months, and yearly thereafter. All patients had completed at least 3 questionnaires at the time of analysis. A linear mixed effects model for repeated measures was used to assess the course of QoL over time. Furthermore, we assessed potential risk factors for QoL deterioration. For every domain, a separate model was built.

#### Results

Median follow-up time was 19.5 months (range 6-62). The mean questionnaire response rate was 86% (range 72-100% between follow-up time points). Median baseline QoL scores were 12 (urinary symptoms), 0 (bowel symptoms) and 50 (sexual functioning). Urinary symptoms and sexual functioning demonstrated clinically relevant changes over time with maximum score differences of 13 and 12 points respectively (>10 points generally being considered relevant change). Bowel symptoms showed small changes over time (<5 points). Figure 1 illustrates the modelled QoL trends per domain, without adjustment for covariates. Urinary symptoms increased in the first month, normalised afterwards and temporarily increased again after two years. Sexual functioning deteriorated in the first six months, but seemed to recover afterwards. Assessment of potential risk factors related to QoL deterioration was only performed for urinary symptoms and sexual functioning, since these domains showed relevant change over time. Urinary symptoms were related to the administered dose to the urethra, genitourinary toxicity (as graded by the CTCAE 4.0), baseline QoL score and biochemical failure after treatment. Sexual functioning was associated with age, size of the irradiated tumour volume, T-stage of the tumour, erectile dysfunction (as graded by the CTCAE 4.0), baseline QoL score and previous use of ADT.

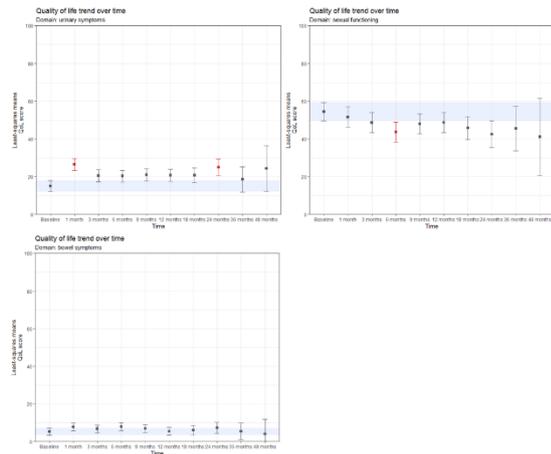

Figure 1: Modelled quality of life trends over time. Least-squares means are displayed with their 95% confidence intervals at each follow-up time point. As a reference, the estimated baseline score is highlighted in blue.

### Conclusion

Compared to baseline QoL, a transient increase of urinary symptoms was seen in the acute and late phase, and sexual function temporarily deteriorated in the first six months. Bowel symptoms did not increase after focal salvage HDR-BT. In contrast with the side-effects associated with ADT, this treatment has very low impact on QoL of recurrent prostate cancer patients.

### EP-1561 Prostate cancer radiotherapy: a systematic review about boost on the dominant intraprostatic lesion

S. Cammelli<sup>1</sup>, M. Buwenge<sup>1</sup>, S. Giambattista<sup>1</sup>, A. Zamagni<sup>1</sup>, E. Galafaro<sup>1</sup>, P. Valeria<sup>1</sup>, M. Ntreta<sup>1</sup>, E. Alexopoulou<sup>2</sup>, M. Ferro<sup>3</sup>, E. Arena<sup>3</sup>, G. Macchia<sup>3</sup>, F. Deodato<sup>3</sup>, S. Cilla<sup>4</sup>, I. Djan<sup>5</sup>, G.P. Frezza<sup>6</sup>, A.G. Morganti<sup>1</sup>  
<sup>1</sup>Radiation Oncology Center, Dept. of Experimental-Diagnostic and Specialty Medicine - DIMES- University of Bologna- S.Orsola-Malpighi Hospital, Bologna, Italy ; <sup>2</sup>Department of Radiation Oncology, University of Patras Medical School, Patras, Greece ; <sup>3</sup>Radiotherapy Unit, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy ; <sup>4</sup>Medical Physics Unit, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy ; <sup>5</sup>Institute of Oncology Vojvodina, Medical Faculty-University of Novi Sad, Novi Sad, Serbia ; <sup>6</sup>Radiation Oncology Unit, Bellaria Hospital, Bologna, Italy

### Purpose or Objective

Local recurrence has been shown to originate within the initial tumor in prostate cancer (PCa). Modern imaging allows identification of dominant intra-prostatic lesions (DIL). Evidence suggests that higher radiotherapy (RT) doses result in increased biochemical control, but dose escalation to the whole prostate is limited by the surrounding normal tissues tolerance. Therefore, a systematic review was conducted to analyse the current evidence of RT boost to DIL and assess toxicity and biochemical outcome.

### Material and Methods

PubMed Electronic database was searched through 9th April 2018 for clinical studies on DIL boost irradiation published in English. Established inclusion criteria were:  $\geq 15$  number of patients, localized PCa, and only clinical studies with planned boost to the DIL.

### Results

Thirteen studies with a total of 1044 patients (range: 15-239) reported on a boost to DIL. In all studies, functional imaging was used in DIL delineation to correlate with the histopathological findings. Boost RT to DIL-PTV was delivered using hypofractionated image-guided RT techniques. In series where boost RT was delivered by IMRT-SIB, median dose to DIL was 82.0 Gy (range: 74.0 -

83.2 Gy), while in series with BRT boost, median total dose was 78.0 Gy (range: 56.0-96.0 Gy). Median acute  $G \geq 3$  GU and GI toxicities were 2.0% (range: 0.0-7.0%) and 0.0% (0.0-5.0%), respectively. Median Late  $G \geq 2$  GU and GI toxicities reported were 7.5% (0.0-39.0%) and 6.3% (0.0-21.0%), respectively. Median 5-year bDFS was 94.0% (range: 70.5-98.0%).

### Conclusion

Based on our analysis, the strategy of boosting the DIL is correlated with reasonable toxicity and excellent results in terms of bDFS.

### EP-1562 CyberKnife or HDR Brachytherapy Alone for the Treatment of Prostate Cancer: A Matched Pair Analysis

P. Wojcieszek<sup>1</sup>, G. Głowacki<sup>2</sup>, T. Krzysztofciak<sup>1</sup>, P. Lelek<sup>1</sup>, M. Szlag<sup>3</sup>, A. Cholewka<sup>3</sup>, M. Fijałkowski<sup>1</sup>, S. Kellas-Ślęczka<sup>1</sup>, K. Krysiak<sup>1</sup>, L. Miszczyk<sup>4</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Brachytherapy Department, Gliwice, Poland ; <sup>2</sup>COiDO, Radiotherapy, Tomaszów Mazowiecki, Poland ; <sup>3</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Planning Department, Gliwice, Poland ; <sup>4</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland

### Purpose or Objective

To evaluate the efficacy and morbidity of CyberKnife (CK) compared to high-dose-rate (HDR) brachytherapy alone.

### Material and Methods

Two independent prospective trials were conducted in our cancer centre between 2008 and 2015. Outcome blinded patients from both trials exceeding six months of the follow-up were matched 1:1 with following criteria: Gleason score, maximum PSA, T stage, D'Amico risk, Age. No high-risk patients were allowed in this analysis. Wilcoxon rank test was used to assess the differences among the groups. Kaplan-Meier method, log-rank test and Cox regression model were used to analyse the biochemical recurrence-free survival.

### Results

One hundred ninety patients were enrolled in this study. There were no statistically significant differences among the two cohorts except for the age. Median follow-up for HDR and CK was 48 months (16-120 mo) and 52 months (9-74 mo), respectively. HDR was linked with higher mild genitourinary toxicity (p=0.03), while CK was associated with higher gastrointestinal morbidity (p=0.002). There was no difference in the time to achieve nadir PSA. Biochemical relapse-free survival was higher in the HDR cohort with no statistical significance (94% vs 88%; p=0.11). There were no differences in the overall survival.

### Conclusion

HDR alone and CK are safe with comparable outcomes. Less invasive treatment may be considered for older patients with good prognosis. A randomised controlled study should be designed to consider the best options for different groups of prostate cancer patients.

### EP-1563 PSMA-ligand based radiotherapy for lymph node relapsed prostate cancer after radical prostatectomy

C. Henkenberens<sup>1</sup>, N. Schmidt-Hegemann<sup>2</sup>, M.M.E. Vogel<sup>3</sup>, S. Kirste<sup>4</sup>, J. Becker<sup>5</sup>, C. Belka<sup>2</sup>, S.E. Coombs<sup>3</sup>, A. Grosu<sup>4</sup>, M. Arndt-Christian<sup>5</sup>, S.G.C. Kroeze<sup>6</sup>, M. Guckenberger<sup>6</sup>, H. Christiansen<sup>1</sup>, D. Walacides<sup>1</sup>

<sup>1</sup>Medical School Hannover, Department of Radiotherapy and Special Oncology, Hannover, Germany ; <sup>2</sup>University Hospital LMU, Department of Radiation Oncology, Munich, Germany ; <sup>3</sup>Technical University Munich, Department of Radiation Oncology, Munich, Germany ; <sup>4</sup>University of Freiburg, Department of Radiation Oncology, Freiburg, Germany ; <sup>5</sup>University Hospital Tübingen, Department of Radiation Oncology, Tübingen,

Germany ; <sup>6</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland

#### Purpose or Objective

After initial curative treatment of prostate cancer with radical prostatectomy (RP) and salvage radiotherapy (sRT), a substantial number of patients develop lymph node metastases. The standard of care for these patients is the initiation of androgen deprivation therapy (ADT). PSMA-ligand PET imaging allows for individualizing the treatment concept. Radiotherapy (RT) of lymph node metastases aims to delay the initiation of ADT by improving the PSA-progression free survival (PSA-PFS). This study assessed the impact of RT on the PSA-PFS for lymph node recurrences after RP and sRT.

#### Material and Methods

Based on a multi-institutional databank of 379 patients from six academic radiation oncology departments, we performed a subgroup analysis of 41 patients who developed an isolated lymph node relapse after RP and sRT. All patients had a PSMA-ligand PET imaging for staging purposes. Patients were treated between 04/2013 and 01/2018 in six academic centers with definitive radiotherapy of all PSMA-ligand positive lymph node metastases.

PSA-PFS was analyzed using Kaplan-Meier survival curves and factors influencing PSA-PFS with cox regression Analysis.

#### Results

Median age of patients was 70 (52-79) years, median PSA at PSMA-ligand PET was 2.12 (0.12-22.08) ng/ml and PSA-DT was 8.0 (0-27) months. A median of 1 (1-10) lymph node metastases per patient was irradiated. After a median follow-up of 12 (2-31) months, 21 (51.2%) patients had biochemically progressive disease and 19 (46.3%) patients had no PSA progression. One (2.4%) patient was lost to follow-up. The median PSA-PFS was 15.0 months (95% CI 11.8-18.2). The median PSA-level prior to RT decreased significantly from 2.12 ng/ml to a median PSA-Nadir of 0.45 (<0.00-12.25; p=0.02). In 11 of 40 patients (27.5%) the PSA level decreased to 0.07 ng/ml or less. In multivariate cox-regression analysis no predictive factors for PSA-PFS were found.

#### Conclusion

Radiotherapy as a metastasis-directed therapy for PSMA-ligand positive lymph node metastases after RP and sRT improved PSA-PFS and is a considerably option in well-selected patients. Prospective trials are warranted to investigate which patients will benefit the most from and which RT technique, dose and field size are needed.

#### EP-1564 Evaluation of Quality of Life in men with prostate cancer after radiation therapy

B. Florenò<sup>1</sup>, C.G. Rinaldi<sup>1</sup>, P. Trecca<sup>1</sup>, P. Zuccoli<sup>1</sup>, M. Miele<sup>1</sup>, B. Santo<sup>1</sup>, G.M. Petrianni<sup>1</sup>, S. Gentile<sup>1</sup>, S. Palizzi<sup>1</sup>, L. Trodella<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, S. Ramella<sup>1</sup>  
<sup>1</sup>Campus-Bio Medico University, Radiotherapy Unit, Rome, Italy

#### Purpose or Objective

To evaluate health-related quality-of-life (QOL) outcomes in patients with prostate carcinoma after radiotherapy (RT) at a time-point during follow-up.

#### Material and Methods

QOL outcomes were assessed using the FACT-P QOL questionnaire administered during a whole month at a time-point during follow up. Mean scores of individual domains/scales were compared between different categories of patients (men in hormonal therapy or not, men who had undergone to radical prostatectomy and adjuvant RT or RT alone, men who had undergone to RT to pelvic nodes and men after RT to prostate or prostatic bed alone) using 't' test.

#### Results

60 patients (mean age 65.2 years) were included in the analysis. The median follow up was 46 months (range 3-134). 16 patients (25.8%) were taking hormonal therapy at the time of the examination, 26 patients (42.6%) underwent surgery before RT and 35 patients (57.4%) RT alone, and in 22 patients (36.1%) RT was delivered also to the pelvic lymph nodes. Several general (emotional functioning, role functioning, social contact) as well as prostate cancer-specific (sexuality, bowel and bladder function) QOL domains were analysed. Importantly, all the QOL domains were worse in patients in hormonal therapy, but only the functioning QOL domains in a significant way (p<0.05). Prostatectomy patients reported worse outcomes in bladder function and emotional well-being, but the difference wasn't statistically significant. There were no differences in the level of sexual activity between patients undergoing surgery and not, even if 16 patients (26.6%) didn't answer the question. Moreover, we didn't find QOL discrepancies between patients who had undergone to RT to pelvic nodes and men after RT to prostate or prostatic bed alone. There were no differences in all QOL domains in patients with > 75 years, even if emotional well being is worse in the younger group with a trend towards statistically significant. Patients with a follow up longer than 6 years didn't report worse QOL scores than those with a follow up of 6 years or less.

#### Conclusion

At a time point during follow up we didn't find significant discrepancies for all the QOL domains in the different categories of patients except for patients in hormonal therapy, who reported worse score in the functioning QOL domains. An analysis on a larger sample of patients is needed to confirm these preliminary data.

#### EP-1565 Quality of online information about radiotherapy for prostate cancer

L. Käsmann<sup>1</sup>, S. Janssen<sup>2</sup>, F. Fahlbusch<sup>3</sup>, D. Vordermark<sup>4</sup>, D. Rades<sup>2</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>University of Luebeck, Department of Radiation Oncology, Luebeck, Germany ; <sup>3</sup>Friedrich-Alexander-University of Erlangen-Nuernberg, Department of Pediatrics and Adolescent Medicine, Erlangen-Nuernberg, Germany ; <sup>4</sup>University Hospital Halle Saale, Department of Radiation Oncology, Halle Saale, Germany

#### Purpose or Objective

Prostate cancer represents the most common cancer in men. Radiotherapy is a major treatment option. It can either be used curatively in localized disease, adjuvant after radical prostatectomy or as an effective option in palliative setting. As patients increasingly seek medical information on the Internet, our goal was to evaluate the quality of websites regarding radiotherapy for prostate cancer.

#### Material and Methods

A simulated patients' search for the terms "prostate cancer" and "radiotherapy" was carried out in a time-staggered manner using the three most popular search-engines Google, Bing and Yahoo. The first 20 search results of each were evaluated using the validated DISCERN Plus instrument, the HON code certification, the JAMA benchmark criteria and the ALEXA global traffic rank.

#### Results

The quality of information on websites about prostate cancer and radiotherapy was good, with a mean DISCERN Plus score of 55.1 ± 10.0, 51.8 ± 10.3 and 50.7 ± 10.1 for Google, Yahoo and Bing, respectively. The scores ranged from a minimum of 34 to a maximum of 74. 13% of all websites were rated as excellent, 31%, 48% and 8% as good, fair and poor, respectively. The overall quality of websites was neither dependent on the choice of search engines nor did we observe a significant temporal change in quality. The main categories of websites retrieved from

the first search were charity/NGO sites (46%), followed by sponsored medical news sites (28%), hospital/university sites (20%) and governmental sites (6%). Websites operated by charity organizations had significantly higher DISCERN Plus scores (mean score:  $55.5 \pm 9.3$ ) compared to hospital sites (mean score:  $47.3 \pm 9.6$ ,  $p < 0.042$ ) and medical news sites (mean score:  $46.1 \pm 6.1$ ,  $p < 0.009$ ), respectively. The JAMA benchmark criteria were fulfilled for all four sections in 13%, for three, two and one in 13%, 31% and 40%, respectively. Only 13% of all websites were HON code certified. All analyzed websites had a focus on curative teletherapy, 76%, 51% and 22% of all websites mentioned brachytherapy, active surveillance and palliative radiotherapy, respectively. In 57% the procedure of radiotherapy was described in detail. Special radiation techniques like “hypo-fractionation”, “Intensity modulated Radiotherapy (IMRT)”, “Image guided Radiotherapy (IGRT)” and “proton therapy” were mentioned in 37%, 72%, 27% and 31% of all analyzed websites, respectively.

#### Conclusion

The quality of websites on radiotherapy and prostate cancer directed at laypersons is promising. The fact that we were unable to find a simple strategy for the identification of high quality websites (i.e. HON code certification, JAMA benchmark criteria, ALEXA ranking or different search engines) emphasizes the responsibility of the treating physicians to interpret and rank the vast quantity of information and value of personal contact with the treating radio-oncologist in order to integrate and interpret the information found online.

#### EP-1566 MR-guided online adaptive radiotherapy: First experience in the UK

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, Sutton, United Kingdom ; <sup>2</sup>Royal Marsden Hospital NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom ; <sup>3</sup>Institute of Cancer Research, Clinical Trials and Statistics Unit, London, United Kingdom ; <sup>4</sup>Royal Marsden Hospital NHS Foundation Trust and the Institute Cancer Research, Radiotherapy and Imaging, London, United Kingdom

#### Purpose or Objective

The Elekta Unity<sup>1</sup> (Elekta AB, Stockholm, Sweden) combines a linear accelerator and 1.5T magnetic resonance imaging (MRI) scanner, allowing daily and real-time imaging for online adaptive radiotherapy (RT)<sup>2</sup>. Here we describe the first experience of MR-guided RT in the United Kingdom (UK).

#### Material and Methods

A 65 year-old man with localised prostate cancer on androgen deprivation therapy was recruited to the PRISM trial (Prostate Radiotherapy Integrated with Simultaneous MRI) NCT03658525, a non-randomised R-IDEAL phase I/IIa study<sup>3</sup>, to receive radical RT to the prostate and seminal vesicles (SV).

A week prior to imaging for reference planning, three gold fiducial markers (FM) were implanted. Planning computed tomography (CT) and MRI (standard T2-weighted and T2\*-weighted for FM visualisation) were registered using FM. Rectal preparation with micro-enemas and bladder filling were used prior to simulation imaging and each treatment as per trial protocol.

RT was planned using Monaco 5.4 treatment planning system (Elekta) to a standard UK dose of 60 Gy in 20 fractions with 7-field intensity modulated RT. Clinical target volume 1 (CTV1) was defined as the prostate and proximal 1 cm SV, planning target volume 1 (PTV1) was created by addition of a 5 mm isotropic margin, except 3

mm posteriorly. CTV2 was defined as the prostate plus proximal 2 cm SV with a 5 mm isotropic margin for PTV2. PTV1 and PTV2 were covered by 95% and 77% of the prescription dose respectively. Organ at risk constraints were defined as per institutional guidelines.

For each fraction, a daily session T2W MRI was acquired. CTV1/2 were re-contoured by a clinician each day for the ‘adapt to shape’ (ATS) workflow, whereby a new daily online plan was created with reoptimisation based on the anatomy of the day. Following plan adaptation and checking, a verification MRI was acquired before treatment to assess whether any additional adaptation was required to adjust for patient movement.

#### Results

A clinically acceptable reference CT-based plan was generated that achieved all mandatory and optimal dose constraints. Patient-specific electron densities were extracted for the daily MR-based adapted plans. (Figure 1). The patient received his first treatment on 18<sup>th</sup> September 2018 and completed all 20 fractions on the MR-Linac using the ATS online workflow. Prostate motion was visually monitored during treatment delivery using cine-MR.

Time taken for each stage of the adaptive workflow is summarised in Table 1. Over the treatment course, toxicity was assessed using RTOG and CTCAE criteria. Highest genitourinary toxicity was Grade 2 urinary frequency and cystitis (CTCAE). Highest gastrointestinal toxicity was Grade 2 diarrhoea (RTOG). Treatment was tolerated without any unexpected toxicity compared to standard treatment delivery.

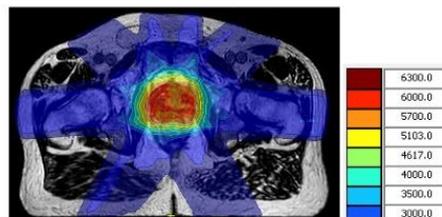

Figure 1: Example of a new daily online MR plan, 7-field IMRT prostate radiotherapy. This is created by adapting a CT-based reference plan, using the anatomy of the day. Red line- Prostate CTV.

Stage of online re-planning	Mean (standard deviation) time in minutes
Patient set-up time	4.9 (0.8)
Scan acquisition and image fusion	7.3 (1.4)
Clinician re-contouring	8.7 (0.8)
Plan adaptation	9.0 (1.2)
Physics checking	3.6 (0.9)
Verification imaging and review	7.3 (1.3)
Treatment delivery	5.1 (0.7)
<b>Total time from patient entering room to end of treatment delivery</b>	<b>45.9 (4.3)</b>

Table 1: Summary of the different stages of daily online adaptive radiotherapy for the prostate. Values reported here are for the first patient- mean (standard deviation) time in minutes over twenty fractions, reported to 1 decimal place.

#### Conclusion

Daily online adaptive RT for the prostate with MRI is feasible and well tolerated. The PRISM trial will recruit 30 patients, with a safety analysis after the first 10 patients.

### Purpose or Objective

To study the evolution of quality of life (QoL) in the first 5 years after IMRT for prostate cancer and to determine possible association with clinical/treatment data: age, presence and type of hormonal therapy, prescribed dose, acute intestinal (GI) and urinary (GU) toxicity

### Material and Methods

Patients were enrolled in a prospective multicentre observational trial in 2010-2014. They were treated at different prescription doses with conventional (74-80Gy-1.8-2Gy/fr) or moderately hypofractionated IMRT (65-75.2Gy-2.2-2.7Gy/fr) in 5 fractions/week. QoL was evaluated using the European Organization for Research and Treatment of Cancer (EORTC) QoL questionnaire (EORTC QLQ-C30) at baseline, at RT end and every 6 months up to 5 years after IMRT.

14 QoL dimensions were investigated separately: global health/QoL, physical functioning (func), role func, social func, emotional func, cognitive func, appetite loss, diarrhoea, fatigue, insomnia, dyspnoea, pain, constipation, nausea.

Longitudinal evaluation of QoL was analysed by means of ANOVA for multiple measures. Differences between groups were evaluated through Mann-Whitney test

### Results

281 patients with complete set of questionnaires across 5 years were available.

Figure 1 reports results from ANOVA in Table format, while Figure 2 presents longitudinal results for the 14 investigated QoL dimensions. A general trend toward significant worsening of QoL at RT end was detected for global health, physical and role func, fatigue, appetite loss, diarrhoea and pain. This worsening usually recovered within 6 months, with the only exception of

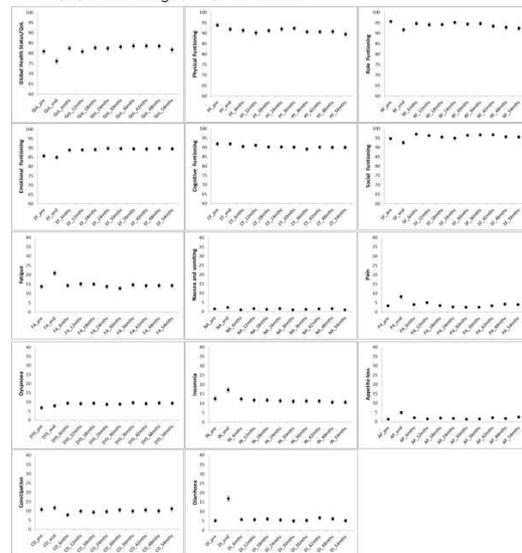

physical func which exhibited a further worsening at 5-year follow-up.

Detailed analysis was carried out for QoL dimension at RT end, which from ANOVA resulted as the most impaired time point. Acute Grade $\geq$ 2 GI toxicity significantly impacted global health, physical and role func, fatigue, appetite loss, diarrhoea and pain (p range: 0.02-0.0003, worsening range: 3-9 points). Pelvic irradiation resulted in significantly lower QoL for global health, fatigue, appetite loss and diarrhoea (p range: 0.05-0.0001, worsening range: 5-14 points). Acute Grade $\geq$ 2 GU toxicity resulted in lower role func and higher pain (p=0.03 and 0.002 respectively, worsening of 5 and 10 points). Prescription dose was associated to diarrhoea (cutoff at 81 2Gy-equivalent, p=0.0001, 23.9 vs 13 points). Use of any neoadjuvant/concomitant hormonal therapy was associated to lower pain (6.7 vs 11, p=0.01), while the use of anti-androgen was associated to lower fatigue (19.2 vs 24.8, p=0.01)

Figure 1: result of ANOVA analysis (over 5 years after the end of IMRT) on the 14 QoL dimensions investigated by EORTC QLQ C30 questionnaire

QoL dimension	significant trend with time from ANOVA	p-value	time and size	of significant variation
global health/QoL	quadratic	0.05	5 point worsening at RT end with respect to baseline, then recover	
physical functioning	cubic	0.04	4 point worsening at RT end with respect to baseline, then recover, further 4 point worsening at 5 years	
role functioning	cubic	0.04	5 point worsening at RT end with respect to baseline, then recover, further 5 point worsening at 5 years	
social functioning	linear	0.04	2 point increase in the 5 year period	
emotional functioning	linear	0.01	3 point increase in the 5 year period	
cognitive functioning	no significant trend			
appetite loss	quadratic	0.004	5 point worsening at RT end with respect to baseline, then recover	
diarrhoea	quadratic + linear decrease	0.05	14 point worsening at RT end with respect to baseline, then recover and at 5 years 1.5 points better with respect to baseline	
fatigue	quadratic	0.03	7 point worsening at RT end with respect to baseline, then recover	
insomnia	no significant trend			
dyspnoea	no significant trend			
pain	quadratic	0.03	5 point worsening at RT end with respect to baseline, then recover	
constipation	no significant trend			
nausea	no significant trend			

Figure 2: Longitudinal evolution (5-year time frame) of the EORTC QLQ C-30 investigated QoL dimensions.

### Conclusion

Modern IMRT delivered in conventional or hypofractionated regimens, at high dose, represents a modality that doesn't affect the long term QoL. A transient worsening of some QoL dimensions is associated to the presence of acute GI/GU toxicity, pelvic irradiation and higher prescribed doses. However, these detrimental effects are solved in the short term after RT end, within 6 months

<sup>1</sup>Azienda Ospedaliero Universitaria Pisana, Oncology, Pisa, Italy ; <sup>2</sup>Azienda Ospedaliero Universitaria Pisana, Radiotherapy, Pisa, Italy ; <sup>3</sup>University of Pisa, Radiotherapy, Pisa, Italy ; <sup>4</sup>Casa di Cura Sanrossore, Radiotherapy, Pisa, Italy ; <sup>5</sup>University of Pisa, Nuclear Medicine, Pisa, Italy ; <sup>6</sup>Humanitas Cancer Centre, Nuclear Medicine, Milan, Italy

#### Purpose or Objective

**Aim:** In the last years, functional imaging has given a significant contribution to the clinical decision making of biochemical relapsed prostate cancer (PCa), allowing early diagnosis of metastatic disease with a limited tumor burden, the so-called oligometastatic patients, and driving local therapies like stereotactic body radiotherapy (SBRT). Herby, we present a prospective study aiming to validate the role of [<sup>18</sup>F]Fluoro-Methyl Choline ([<sup>18</sup>F]FMCH) PET/CT in the selection of PCa patients suitable for SBRT.

#### Material and Methods

**Materials and Methods:** Patients with biochemical recurrence were screened. Eligible patients were imaged with Endo-rectal Magnetic Resonance to exclude local recurrence inside the prostate bed and [<sup>18</sup>F]FMCH PET/CT to assess tumor burden. Patients with up to three synchronous active lesions identified by [<sup>18</sup>F]FMCH PET/CT were enrolled in the present study. All patients were treated with SBRT on all active lesions revealed by [<sup>18</sup>F]FMCH PET/CT. Systemic therapy free-survival since the [<sup>18</sup>F]FMCH PET/CT was considered as the primary endpoint.

#### Results

**Results:** 50 patients were included in the present study. Forty-five patients with oligometastatic PCa (castration sensitive in 34 patients, castration-resistant in 11) for a total of 66 lesions (lymph node and bone lesions, in 44 and 22 cases, respectively) were considered evaluable for the present analysis. After SBRT, five patients were lost at follow-up since they started ADT for personal reason. Patients' median age at the time of study entry was 70 years (range 50-81). The median length between PCA diagnosis and study enrollment was 69 months (range, 2-180 months). At the time of study entry, Median PSA value was 2,69 ng/mL (range 0.9-27,40). In-field progression was observed in 3 out of 66 irradiated lesions. After the detection of oligorecurrent disease following SBRT, 6 patients underwent further courses of SBRT on the active lesions revealed by [<sup>18</sup>F]FMCH-PET/CT (two, three, four, five courses respectively in 3,1,1,1 patients). Toxicity higher than grade 2 was not recorded. After a median follow-up of 22.3 months, systemic therapy was started in 24 patients (53,3%). Median systemic therapy free survival was 39.1 months (95%CI6.5-68.6) whereas systemic free survival ratios at 6, 12 and 24-month were 93.5%, 73.9%, and 63.1 %, respectively. At univariate Cox regression analysis, Delta PSA and Gleason Score (GS) demonstrated an impact on systemic therapy free survival (p=0.03 and p<0.001, respectively), being GS higher than 6 related to longer systemic therapy free survival. The Delta PSA remained statistically significant on multivariate analyses while the Gleason Score shows a trend to a statistically significant association (p<0.001 and p=0.18, respectively).

#### Conclusion

**Conclusion:** Based on our findings, [<sup>18</sup>F]FMCH PET/CT can identify oligometastatic patients suitable for SBRT, resulting in a systemic therapy free survival of 39.1 months.

**EP-1569 High-dose-rate brachytherapy boost in high-risk prostate cancer: results of two different schemes**

L. Pelari<sup>1</sup>, F. López<sup>1</sup>, G. Caddedu<sup>1</sup>, K. Ytuza<sup>1</sup>, A. Hernández<sup>1</sup>, I. Ciscar<sup>1</sup>, C. Vallejo<sup>1</sup>, M. Martín<sup>1</sup>, S. Sancho<sup>1</sup>, A. Hervás<sup>1</sup>  
<sup>1</sup>Ramón y Cajal Hospital, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

To evaluate preliminary clinical results, acute and chronic genitourinary (GU) and gastrointestinal (GI) toxicity of a retrospective cohort of high-risk prostate cancer patients treated with External Beam Radiation Therapy (EBRT) and a boost of High-Dose-Rate Brachytherapy (HDR-BT).

#### Material and Methods

Patients with histologically confirmed high risk prostate cancer defined by National Comprehensive Cancer Network (NCCN) risk group were included. Patients received hypofractionated and image-guided EBRT by volumetric IMRT technique to a dose of 37.5 Gy in 15 fractions combined with a single 15 Gy HDR-BT (<sup>60</sup>Co multi-source) dose (Arm-1) or 60 Gy in 30 fractions combined with a single 9 Gy HDR-BT (<sup>60</sup>Co multi-source) dose (Arm-2). All patients assumed androgen deprivation therapy for two years. Biochemical recurrence was defined by Phoenix criteria (PSA concentration superior than nadir plus 2 ng/ml). Acute and chronic toxicity (according to the CTCAE Version 4.0) were collected. Toxicity was considered "acute" if occurred until 3 months after the treatment and "chronic" if occurred after 6 months of the end of the treatment.

#### Results

From February 2008 to July 2015, 78 patients were treated by the reported schedules. Median age was 72 years (range 42-83 years). With a median follow-up of 49 months (range 23 -126 months) the median biochemical progression-free survival rates were 91,5% for the 15 Gy HDR group (Arm 1) and 93,8% for the scheme of treatment of 9 Gy HDR (Arm 2). No post-HDR procedure complications were detected in all patients.

**Arm-1:** Acute GU toxicity grade I occurred in 8 patients (50%). No patients developed acute GI toxicity. Chronic GU toxicity grade I occurred in 2 patients (12,5 %). Chronic GI toxicity grade I was observed in 2 patients (12,5 %). No patients developed GU or GI acute or chronic toxicity ≥ GII.

**Arm-2:** Acute GU toxicity grade I occurred in 25 patients (40,3%), grade II in 7 patients (11,3 %) and grade III in 3 patients (4,8 %). Acute GI toxicity grade I were observed in 16 patients (25,8 %). No patient developed GI toxicity ≥ GII. Chronic GU toxicity occurred as follows: grade I in 13 patients (20,9 %), grade II in 4 patients (6,45 %) and grade III in 2 patients (3,22 %). Chronic GI toxicity grade I was observed in 4 patients (6,45%) and grade II in 1 patient (1,6 %). No late gradeIV GU or GI toxicity was detected.

#### Conclusion

Hypo-RT combined with HDR-BT produces acceptable acute and chronic toxicity rates with promising outcomes of biochemical control for high risk prostate cancer. Longer term follow-up should be analysed to confirm these data and to compare possible differences between both arms.

**EP-1570 Stereotactic body radiation therapy for oligometastatic prostate cancer. Our experience.**

### Purpose or Objective

To analyze the survival and toxicity in patients with oligometastatic prostate cancer treated in our center with stereotactic body radiation therapy (SBRT).

### Material and Methods

We retrospectively reviewed 51 patients with oligometastatic prostate cancer that received SBRT to treat malignant adenopathies and bone metastasis between March 2014 and August 2018. We analyzed metastasis control (MC), disease-free survival (DFS), biochemical progression-free survival (BPFS), distant progression-free survival (DPFS), and overall survival (OS).

#### Patient and disease characteristics (n=51)

Characteristics	Value (%)
Age at diagnosis in years (median)	68,59

RT	7 (13,73)
RP+RT	7 (13,73)
BT	3 (5,88)
HT	1 (1,96)
Hormonal treatment	37 (72,55)
Yes	14 (27,45)
No	

Abbreviations: PSA = prostate-specific antigen; RP = radical prostatectomy; RT = radiation therapy; LP=lymphadenectomy; BT = Brachytherapy; HT = Hormonal treatment.

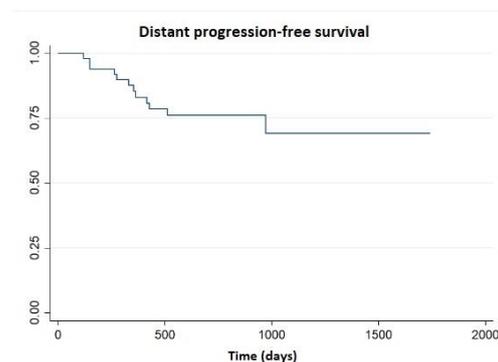

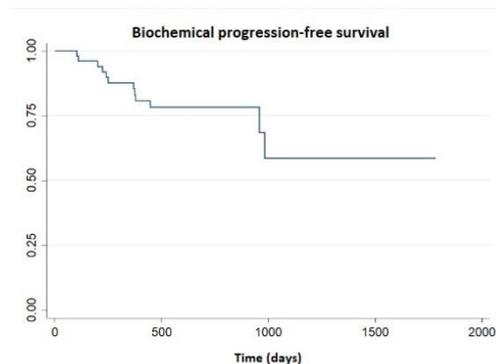

### Results

We included 51 patients with 69 lesions, of which 100% were hormone-sensitive. 72% were being treated with hormone therapy (analogue LHRH). 11.76% became castrate resistant during follow-up. The number of lesions treated was 22 bone metastasis and 47 malignant lymphadenopathies. The treatment was administered with intensity-modulated radiotherapy guided by daily image by cone-beam and simmetry device for respiratory control. The patients were immobilized by Body Fix system and the treatment dose used was 45Gy in 6 fractions of 7.5Gy, twice a week for lymph nodes and 16Gy single session for bone lesions.

Estimated Metastasis control at 2 years was 86.27%. Disease-free survival, biochemical progression-free

survival and distance-free relapse-free survival were 52,95%, 78,26%, 76,10% respectively, counting on a overall survival of 98,04%.

We used CTCAE 4.0 scale to measure toxicity. 46 patients (90.20%) had no acute gastrointestinal toxicity, 4 (7.84%) had acute grade 1 gastrointestinal toxicity. In case of acute genitourinary toxicity, 41 patients (80.39%) did not experience any toxicity while 8 (15.69%) had grade 1 toxicity. Only one patient suffered late toxicity, a pathological fracture, one year after administration of SBRT.

### Conclusion

Stereotactic body radiation therapy used in oligometastatic prostate cancer patients provided optimal control of metastasis and acceptable toxicity. It is a good therapy for bone and lymph nodes lesions.

<sup>1</sup>Instituto Zunino - Fundacion Marie Curie, Radiation Oncology, Cordoba, Argentina

### Purpose or Objective

To analyze urinary and rectal toxicity in patients with prostate cancer undergoing combination treatment with High Rate Dose Prostate Brachytherapy (HDR-B) plus External Beam Radiation Therapy IMRT + IGRT in 15 fractions, with pelvic lymph nodes irradiation.

### Material and Methods

Between June '15 and August '18, 38 patients with positive prostate cancer biopsy were treated. The average initial PSA was 22.34 ng/ml [4.19-84]. The average prostate volume was 40.5 g [15-75]. The distribution of patients by risk groups was: Low risk 0% (0), Intermediate risk 10.5% (4), High risk 73.7% (28), Locally advanced 13% and Metastatic 2%.

100% of the patients received neoadjuvant, concomitant and adjuvant hormonal treatment. All the patients were

irradiated with combined treatment, first with HDR Brachytherapy = 15 Gy in a single fraction, with Ir-192, Microselectron v2 Nucletron-Elekta. In that same act, 4 fiducial markers of intra-prostatic titanium were implanted for posterior IGRT. Two weeks later, IMRT+IGRT was performed on 15 fractions of the Novalis Tx linear accelerator (BrainLab-Varian), high resolution multilane collimator (HDMLC) with 2.5 mm wide slices. IGRT (intra and interfraction) were based on ExacTrac (BrainLab) localization system. The CTscan was performed every 2.5 mm at the prostate level. Drawing volumes and dosimetry planning were performed in the Eclipse (Varian system). Prescribed dose at 95% PTV-prostate + seminal vesicles and Pelvic Lymph nodes was = 39 Gy. Genitourinary toxicity (GU) was assessed using the IPSS (International Prostate Symptom Score) and gastrointestinal (GI) scale according to the RTOG criteria. The PSA was recorded systematically during the follow-up.

#### Results

The mean age was 66.7 years [47.1-76.7]. Average follow-up of 9 months [0.0-37.4]. The mean IPSS pre HDR-B was 7.4 [0-28]. Post IMRT + IGRT = 6.9 [1-25]; 6.4 [1-22] and 5.4 [1-22] for 2; 6 and 12 months respectively. The rate and degree of rectal toxicity after HDR-BQT + IMRT-IGRT was at 2 months G0 = 0%; G1 = 100%; G2 = 5.4% and G3 = 0%; G4 = 0% At 6 months: G0 = 0%; G1 = 100%, G2 = 0%; G3 = 0% and G4 = 0%. At 12 months: G0 = 0%; G1 = 100%; G2 = 0%, G3 = 0% and G4 = 0%. The mean PSA at 6 months was 0.28 ng / ml [0-1.2] and at 12 months 0.15 ng / ml [0-1.1]

#### Conclusion

According to the results presented, we didn't see any moderate or severe urinary nor rectal toxicity. Related to these results, lymph nodes irradiation in a hypofractionation schedule, could be a safe option for patients. Due to the limitations of these report, related to low patient volume and short follow up, these results should be confirmed in a prospective trial.

#### EP-1572 How multiparametric magnetic resonance changes the staging and treatment of prostate cancer

S. Fernandez Alonso<sup>1</sup>, S. Guardado González<sup>1</sup>, J. Durá Esteve<sup>1</sup>, A. Rodríguez Antolín<sup>2</sup>, M.J. Buj Pradilla<sup>3</sup>, I. Alda Bravo<sup>1</sup>, M. Alarza Cano<sup>1</sup>, J.F. Pérez-Regadera Gómez<sup>1</sup>, M.Á. Cabeza Rodríguez<sup>1</sup>

<sup>1</sup>Hospital Universitario 12 de octubre, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Universitario 12 de Octubre, Urology, Madrid, Spain ; <sup>3</sup>Hospital Universitario 12 de Octubre, Radiodiagnosis, Madrid, Spain

#### Purpose or Objective

To determine the implication of multiparametric magnetic resonance (mpMRI) in the management of localized prostate cancer (PCa) and the correlation between PIRADS and histological grade.

#### Material and Methods

A retrospective study and a correlation statistical analysis were carried out in 149 patients diagnosed with localized PCa who underwent mpMRI +/- MR-guided biopsy (MRGB) before receiving treatment between 2015 and 2018.

#### Results

The mean age was 66 years and the mean PSA was 10.02 ng/ml. The mean time interval between diagnosis and mpMRI was 14 weeks.

The indication for mpMRI was staging in 73% cases, diagnostic in 16% and follow - up in 10%.

Rectal examination, transrectal ultrasound (TRUS) and transrectal biopsy did not found disease in 22 cases (14%). In cases where illness was found, 67% were T1c, 21% T2a, 10% T2b-c and 2% T3a. After MpMRI 15% were T1c, 15% T2a, 20% T2b-c and 40% T3-4. Spearman's correlation coefficient was 0.33.

Regarding GS, before MRGB 22 cases had not got histological confirmation; 60% were GS6, 19% GS7 and 7% GS8-10. MpMRI detected more clinically significant

prostate cancer, being after MRGB 57% GS6, 26% GS7 and 17% GS8-10. Kendall's correlation coefficient was 0.8.

MRGB gave the diagnosis of the 22 initially negative patients; 2 of them were GS6, 6 GS7, 13 GS8-9; about patients initially GS6, 5 of them were finally GS7 and 2 GS8.

Also, it confirmed histological suspicious lesions located on the anterior and transitional zone (considered as higher risk) seen in mpMRI but not in TRUS in 17 patients (11%). Grades GS8-9 were related to stages T3a, T3b and T4 by mpMRI with a Spearman's correlation coefficient of 0.42. Correlated with PIRADS classification, 16% of GS 6 were PIRADS 2-3, 63% PIRADS-4 and 20% PIRADS-5. Among GS7, 8% were PIRADS2-3, 33% PIRADS-4 and 58% PIRADS-5.

Of the GS8-9, 44% were PIRADS-4 and 56% PIRADS-5.

The GS 8-9 values were associated with higher PIRADS, with a Spearman correlation coefficient of 0.287.

Regarding the risk group, after mpMRI +/- MRGB, 52% belonged to high risk, to medium risk 27.5% and to low risk 20.5 %, while initially 14% did not have diagnosis, 11% belonged to high risk, 36 % to intermediate and 39% to low risk group. Spearman's correlation coefficient was 0.5.

As a result, mpMRI changed the treatment in 54% patients; 41% left active surveillance, brachytherapy was rejected in 5% and surgery in 8%, being finally treated with radiotherapy plus hormone therapy.

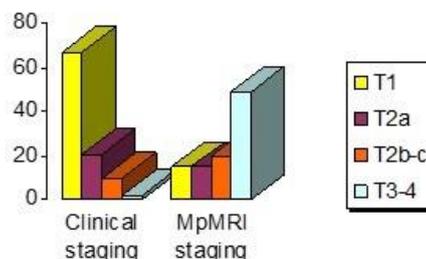

Figure 1: Prostate cancer staging.

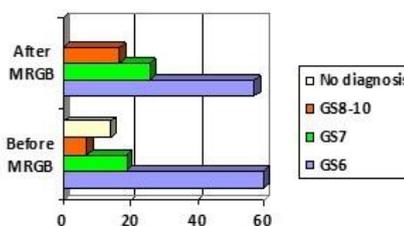

Figure 2: Gleason score.

#### Conclusion

Through clinical staging with TRUS and TRUS-guided biopsy, histological grade and staging of a part of tumors may be underestimated

In our experience, mpMRI modified histological grade in a third of patients, risk group in 50% and treatment decision in 54% cases.

Therefore, we recommend the use of mpMRI in PCa staging to carry out an adequate management of the disease according to its characteristics.

#### EP-1573 Is there an optimal OAR-filling protocol reducing G2+-toxicity for prostate IMRT?

J. Marzec<sup>1</sup>, F. Paulsen<sup>1</sup>, S. Westbomke<sup>1</sup>, Z. Outaggarts<sup>1</sup>, D. Wegener<sup>1</sup>, D. Thorwarth<sup>2</sup>, D. Zips<sup>1</sup>, A. Müller<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology, University Hospital, Tübingen, Germany ; <sup>2</sup>Section for Biomedical Physics Department of Radiation Oncology, University Hospital, Tübingen, Germany

#### Purpose or Objective

Prediction of genitourinary (GU) and gastrointestinal (GI) toxicity after prostate cancer intensity modulated radiotherapy (IMRT) based on organs at risk (OAR) prescriptions is limited. Therefore, we investigated the potential impact of bladder-, rectal- and target volumes on acute side-effects of patients treated in a prospective study.

#### Material and Methods

Twenty-eight patients received a dose-escalated IMRT of localized prostate cancer (257/2007B01). Radiotherapy was performed using the coverage probability concept to a total dose of 78Gy in 39 fractions. All patients underwent at least three planning CTs and were instructed according to a bladder-rectal filling protocol (aim: bladder volume of 250-500ml, empty rectum). Contouring of OARs and target volumes was performed in each CT and three OAR-volumes per patient were measured. Incidence of acute GU/GI-toxicities (RTOG) was correlated with bladder-, rectal- and PTV-volumes. The volumes of 28 patients were descriptively evaluated by SPSS and subdivided in 4 quartiles (i.e. 7 patients per quartile).

#### Results

Acute toxicity was predominately detected in patients with small bladder volume, large or small rectal volume and large target volume.

**GU-toxicity** (G0/G1/G2: 5/15/8): Patients with the smallest bladder volume quartile (<188.41ml) represented with G2 (n=3) and G0/1 (n=1/3) toxicity. This equals 37.5% of G2-toxicities and 20% of G0- and G1-toxicities. The largest target volume quartile (>271.17ml) was connected to toxicity of grade G2 (4/7), G1 (2/7) and G0 (1/7) accounting for 50% (G2), 20% (G1) and 13% (G0) of GU-toxicities. Combination of adverse factors i.e. small bladder volume (<188.41ml) and large target volume (>271.17ml) was only present in 33% of patients experiencing G2 toxicity.

**GI-toxicity** (G0/G1/G2: 6/16/6): Considering the lowest (<63.36ml) and highest quartile (>166.87ml) of rectal volume 66% of patients experiencing G2-toxicity were in these quartiles compared to G1 with 50% and G0 with 33%. The largest quartile of PTV (>271.17ml) was always connected to GI-toxicity of at least G1 (n=5) and higher (G2=2). Presence of even small rectal maxima exceeding 80Gy (rectal V80>0.26ml) were related to G2-toxicity (83%, n=5/6). Combination of adverse factors i.e. small/large rectal volume and rectal V80>0.26ml were associated with increased toxicity (G1=31%, G2=50%).

#### Conclusion

GU-toxicity was reduced in case of a minimal bladder volume  $\geq 188.41$ ml and a target volume <271.17ml. GI-toxicity was less apparent in patients with intermediate rectal volumes between 63.36-166.87ml and absence of rectal hot spots >80Gy. Combination of these adverse factors was always connected to toxicity (no G0) and should therefore be avoided during treatment planning. These findings need to be substantiated in a larger cohort.

#### EP-1574 Four-year outcomes of hypofractionated proton therapy for localized prostate cancer

A. Grewal<sup>1</sup>, C. Schonewold<sup>1</sup>, S. Both<sup>2</sup>, S. Lam<sup>1</sup>, S. Mazzoni<sup>1</sup>, J. Bekelman<sup>1</sup>, J. Christodouleas<sup>1</sup>, N. Vapiwala<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA ; <sup>2</sup>University Medical Center of Groningen, Department of Radiation Oncology, Groningen, The Netherlands

#### Purpose or Objective

Moderately hypofractionated radiation therapy represents an effective treatment for localized prostate cancer.

Hypofractionated proton therapy (HFPT) has not been extensively studied. The purpose of this study was to determine the toxicity profile and biochemical-clinical failure (BCF) rates for patients with localized prostate cancer treated with HFPT.

#### Material and Methods

Between 2010 and 2017, 184 men were enrolled on a prospective trial of 70Gy in 28 fractions of proton therapy for localized low- to intermediate-risk prostate cancer. Short-term androgen suppression (AS) was allowed, per institutional practice. Acute and late toxicity was evaluated using the Common Terminology Criteria for Adverse Events, version 4.0 (CTCAEv.4.0). Patient-reported urinary quality-of-life changes and erectile changes were captured using the International Prostate Symptom Score (IPSS) and the International Index of Erectile Function (IIEF-5) Questionnaire, respectively.

#### Results

Median follow-up was 49.2 months. Enrolled patients had low-risk [LR] (n=18), favorable intermediate-risk [FIR] (n=78), and unfavorable intermediate-risk [UIR] (n=88) disease. Twenty-six percent of patients received neoadjuvant and concurrent AS, with a median duration of 6 months.

Four-year rates of BCF free survival were 95.7%, 94.4%, 98.7%, and 93.2% in the overall group and the LR, FIR, and UIR cohorts, respectively (p=.21). Overall survival at 4 years was 97.3%. All 5 deaths were unrelated to prostate cancer.

Median IPSS before treatment and at 1 year after treatment were 6 and 7 for LR patients, 6 and 6 for FIR patients, and 8 and 7 for UIR patients. Median IIEF-5 before treatment and at 1 year after treatment were 21 and 18 for LR patients, 18 and 16.5 for FIR patients, and 15 and 10.5 for UIR patients.

The incidence of acute CTCAE v4.0 grade 2 or higher gastrointestinal (GI) and urologic toxicities were 3.8% (7 events) and 12.5% (23 events), respectively. Only one acute grade 3 GI toxicity was reported. The estimated cumulative 4-year incidence of late grade 2 or higher urologic toxicity was 7.6% (14 events), with no grade 3 or 4 events reported. The estimated cumulative 4-year incidence of late grade 2 or higher GI toxicity was 13.6% (25 events), with one grade 3 event and no grade 4 events. The predominant late grade 2 GI toxicity was rectal bleeding, and late grade 2 urologic toxicity was urinary frequency, accounting for 79% and 57% events, respectively. All late grade 2 and 3 events were transient. There were no associations between risk group, anticoagulation use, or history of transurethral resection of the prostate and incidence of acute or late toxicity.

#### Conclusion

HFPT for the treatment of prostate cancer is associated with low rates of urologic and GI toxicity, and low rates of patient-reported urinary bother post-treatment. Further analyses are warranted to assess long-term toxicity and understand differences between proton and photon hypofractionated radiation therapy in the treatment of prostate cancer.

#### EP-1575 Stereotactic Body Radiotherapy in bone oligometastatic prostate cancer patients

F. Trippa<sup>1</sup>, F. Arcidiacono<sup>1</sup>, A. Di Marzo<sup>1</sup>, L. Draghini<sup>1</sup>, P. Anselmo<sup>1</sup>, S. Terenzi<sup>1</sup>, M. Casale<sup>1</sup>, S. Fabiani<sup>1</sup>, E. Maranzano<sup>1</sup>

<sup>1</sup>Radiotherapy Oncology Centre, Santa Maria Hospital, Terni, Italy

#### Purpose or Objective

The first line treatment of metastatic prostate cancer (PC) is androgen-deprivation therapy (ADT). A subgroup of patients (pts) with disease progression can present few lesions (i.e., oligometastases). Stereotactic body radiotherapy (SBRT) delivers high ablative doses of radiotherapy while sparing adjacent tissues. We used SBRT

in selected PC oligometastatic pts with bone metastases (BM) to improve local control and delay the start of ADT or pharmacologic second-line therapy.

#### Material and Methods

Between October 2010 and July 2018, in 17 oligometastatic PC pts with a total of 20 BM local control (LC) rate, biochemical progression free-survival (b-PFS) and time to beginning of ADT were evaluated. Median age was 72 years (range, 57-87), median Gleason score at the primary diagnosis was 7 (range, 5-9). Median time from primary treatment to SBRT was 53 months (range 2-134 months). Diagnosis of BM was documented by Choline-PET/CT. Median PSA value before SBRT was 2.25 ng/ml (range, 0-46.8). Ten (59%) oligometastatic ADT-free pts underwent SBRT alone, while the other 7 (41%) oligometastatic castration-resistant prostate cancer (CR-PC) pts, continued ADT. Three (18%) pts underwent SBRT for two synchronous BM. The BM sites were: pelvis in 12 (60%), spine and ribs in 6 (30%), and in 2 (10%) cases, respectively. Gross tumor volume (GTV) was delineated using Choline-uptake and planning target volume was defined as the GTV plus a 5 mm isotropic margin. Radiotherapy schedules adopted were 5 × 5-8Gy in 13 (65%) BM and 3 × 9-10Gy in 7 (35%) BM. Response was assessed with PSA evaluation every 3 months during the first year and then every 6 months. Pts with a reduction or a stability of PSA level were considered responders, Choline-PET-CT was done in case of an increase of PSA level.

#### Results

The median follow-up was 10 months (range 3-96). All (100%) patients had a decrease of PSA level after SBRT. Nine (53%) pts remained b-PFS, while 8/17 (47%) pts had new PSA increase after a median time of 8 months (2-48). Among biochemical progression pts, Choline-PET/TC showed LC in 100% of the treated lesions and a disease progression in other sites. At last follow-up one (6%) patient has died for PC, the other 16 (94%) were alive. Of note, 7 CR-PC pts before SBRT continued ADT but they did not have to start second-line therapy; 2/10 (20%) ADT-free pts before SBRT had to start ADT due to disease progression for an ADT-free survival of 9 months (3-96). No SBRT related acute or late toxicities were observed.

#### Conclusion

Our experience showed that SBRT of BM was highly effective with an excellent risk-benefit profile. SBRT in PC bone oligometastases pts should be evaluated to improve response rate and delay ADT or pharmacologic second-line therapy.

#### EP-1576 Middle Half Body Radiotherapy in bone metastases from prostate cancer: a phase I study

A. Zamagni<sup>1</sup>, M. Buwenge<sup>1</sup>, G. Siepe<sup>1</sup>, A. Arcelli<sup>1</sup>, C.M. Donati<sup>1</sup>, S. Bisello<sup>1</sup>, G. Macchia<sup>2</sup>, F. Deodato<sup>2</sup>, S. Woldemariam<sup>5</sup>, T. Wondemagegnhu<sup>5</sup>, G.P. Frezza<sup>6</sup>, A.G. Morganti<sup>1</sup>, S. Cammelli<sup>1</sup>

<sup>1</sup>Radiation Oncology Center- Department of Experimental- Diagnostic and Specialty Medicine - DIMES, University of Bologna- Sant'Orsola-Malpighi Hospital, Bologna, Italy ; <sup>2</sup>Radiotherapy Unit, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy ; <sup>3</sup>Medical Physics Unit, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy ; <sup>4</sup>Medical Oncology Unit, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy ; <sup>5</sup>Department of Radiotherapy, Black Lion Hospital, Addis-Ababa, Ethiopia ; <sup>6</sup>Radiation Oncology Unit, Bellaria Hospital, Bologna, Italy

#### Purpose or Objective

In 2001 a clinical randomized trial from IAEA tested 2D Half Body Irradiation (HBI) for palliative treatment of multiple bone metastases demonstrating that a dose of 12

Gy in 4 fractions, twice a day, had the same effectiveness and tolerability of a total dose of 15 Gy in 5 daily fractions. However, the 2-days treatment was more comfortable and time-saving for patients (pts), in a variety of metastatic malignancies, with the exception of prostate cancer. In fact, in metastatic prostate disease, better outcome and lower toxicity were observed with a longer therapeutic schedule. Aim of our study was to evaluate the possibility to deliver the higher dose (15 Gy) in 4 fractions twice a day, in the specific setting of HBI defined as middle half body (MHB: pelvis, femurs and lumbar spine) by using a multiple field 3D-conformal technique to reduce toxicity.

#### Material and Methods

A phase I trial in 3-dose escalation steps was designed: 13 Gy (3.25 Gy-fractions), 14 Gy (3.5 Gy-fractions), and 15 Gy (3.75 Gy-fractions). The eligibility criteria included prostate cancer with painful bone metastatic disease in MHB fields, ECOG performance status ≤ 3, life expectancy > 3 months, no severe bone marrow dysfunction. Treatment was delivered in 2 days with twice-daily fractionation and at least 6 hours interval. Pts were treated in cohorts of 6-12 to define the maximum tolerated dose (MTD). The dose-limiting toxicity (DLT) was defined as any acute toxicity of grade 3 or greater, using the RTOG scale. Pain was recorded using a visual analogue scale. IAEA pain and drug score were also registered.

#### Results

25 patients were enrolled. Only grade 1-2 acute toxicity was recorded. No pts experienced DLT. With a median follow-up of 7.4 months, only two cases of G1 skin late toxicity were observed. The overall (complete plus partial) response rate for pain was 84% (21/25 pts): 9 pts had complete pain relief (VAS=0), 10 pts showed at least 30% VAS reduction, 2 pts showed an improvement in pain score and drug score with 20 and 25% VAS reduction respectively.

#### Conclusion

The MTD of short course MHB radiotherapy in patients with bone metastases is 15 Gy. Preliminary data on palliative efficacy are promising.

#### EP-1577 Prostate SBRT with Gantry-based LINAC without ConeBeam. Toxicity outcomes of 205 patients

P. Castro Peña<sup>1</sup>, A. Henao<sup>1</sup>, P. Murina<sup>1</sup>, O. Muriano<sup>1</sup>, L. Suarez Villasmil<sup>1</sup>, A. Giraudo<sup>1</sup>, J.C. Archilla<sup>1</sup>, D. Venencia<sup>1</sup>, S. Zunino<sup>1</sup>

<sup>1</sup>Instituto Zunino - Fundacion Marie Curie, Radiation Oncology, Cordoba, Argentina

#### Purpose or Objective

To describe the technique of SBRT in 5 fractions, with IGRT ExacTrac only based, in patients with prostate cancer. Analyze of toxicity and biochemical response, in patients with age of 6 months of follow-up

#### Material and Methods

Between Nov / 13 and Jun / 15, 223 patients with a positive prostate cancer biopsy were treated; Mean initial PSA = 25 ng / ml [0.42-1890] and mean prostate volume = 52.8 g [18.1-134]. All were irradiated with SBRT technique in 5 fractions (alternate days), following the institutional protocol. For IGRT (intra and interfraction) based on ExacTrac, 4 intraprostatic fiducial markers were implanted 2 weeks before. Virtual simulation based on CT with 1mm cuts at the prostate level. Drawing of volumes and dosimetry with planning system iPLAN-Net (BrainLab) and Eclipse (Varian). Prescribed dose in 95% PTV-prostate = 40 Gy (95.6%) and 36.25 Gy (4.4%), according to institutional medical criteria. The patients were irradiated with Novalis Tx technology (BrainLab-Varian), high resolution multilamellar collimator (HDMLC) with 2.5mm plates. They were planned and irradiated with IMRT-dynamics technique, using 9 beams of 6 MV. Genitourinary toxicity (GU) was evaluated using the IPSS (International Prostate Symptom Score) (0-35 points) and

gastrointestinal (GI) scale according to the RTOG criteria (Grade 0-5). The PSA was systematically registered.

#### Results

We analyzed 205 patients with follow-up longer than 6 months. The average age was 69 years [48-86.6]. The distribution by risk group was: 12.6%, 62.2%, 23.3% and 1.9% for low, medium, high and metastatic respectively. Average follow-up: 24.7 months [5.7-46.3]. The mean of the IPSS prior to SBRT was = 6.1 [0-35]. After SBRT: 5.1 [0-31], 5.5 [0-30], 4.7 [0-22], 4.7 [0-19] and 5.5 [0-26] to 6, 12, 18, 30 and 42 months respectively. The rate and degree of rectal toxicity at the end of SBRT was: G0 = 96.6%; G1 = 2.4% and G2 = 1%. At 6 months: G0 = 84.2%; G1 = 9.2%, G2 = 5.1% and G3 = 1.5%. At 12 months: G0 = 89.3%; G1 = 5.3%; G2 = 2.4%, G3 = 1.8% and G4 = 1.2%. At 18 months: G0 = 90.8%; G1 = 6.8%; G2 = 0.8% and G4 = 0.8%. At 30 months: G0 = 90.7%, G1 = 8.5 and G4 = 0.8%. At 42 months: G0 = 99.2%, G4 = 0.8%. The mean PSA value in ng / ml, Pre-SBRT was = 16.54 [0.01-1890] and after 24 months = 5.32 [0.03-115].

#### Conclusion

According to the presented results we can suggest that SBRT Prostate based on a Novalis platform with IGRT ExacTrac based, is convenient for the patient, has acceptable toxicity rate, without significant difference with the Cone-Beam results published. The assessment of the impact on disease control deserves longer follow-up.

All patients underwent treatment with IMRT up to a total dose of 62.5Gy/2.5Gy/day in 25 fractions (EQD2Gy for a/b=1.5 of 70 Gy). Daily verification was performed with IGRT. Eight p (10%) received androgen deprivation. Acute Toxicity was assessed according to CTCAE 5.0. Late toxicity was scored with RTOG/EORTC criteria. Biochemical relapse was defined as PSA increase of 0,2 ng/mL or greater from the post-RT nadir (confirmed with a second increase). Institution review board approved this study

#### Results

All patients received complete treatment. There were no complications during marker placement. Follow-up: 17 months (range 3-39 months). Of the 80 patients, 68 demonstrated a continuous biochemical response after treatment. Three patients had regional lymph nodes and 3 p distant metastasis. Only one patient died for lung cancer. All remaining patients were alive at the last follow up visit. The cancer specific survival is 100%. The estimated actuarial SLRB rate at 1, 2 and 3 years was 88%, 78% and 72% respectively. A pre salvage PSA level no significant prognostic factor for biochemical control (Breslow p = 0.075), log-rank (p=0.251). Maximal acute urinary (GU) toxicity: G2 in 4% (3 p) of patients. Maximal acute gastrointestinal (GI) toxicity: G2 in 1% of patients (1p). There was no grade 3, 4 or 5 acute toxicity. Neither urinary stress nor incontinence was influenced by radiation therapy. Late toxicities were evaluated in all patients. No G3 or greater late toxicities were observed. Late G2-GU: 2%; G2-GI: 0. No relationship was found between acute and late GU or GI adverse effects and any of the analyzed parameter> age, androgen deprivation or urinary incontinence pre/treatment.

#### Conclusion

Hypo-IMRT with IGRT for postoperative PC is feasible and well tolerated showing encouraging rates of BRFS although longer follow up is required.

#### EP-1579 Prior prostatectomy MRI improves target coverage of adjuvant radiotherapy for pT3bNo prostate cancer

G. Kacsó<sup>1</sup>, T. Popescu<sup>2</sup>, P. DAniel<sup>2</sup>, C. Iacob<sup>3</sup>, R. Zahu<sup>3</sup>, A. Eva<sup>4</sup>, D. Dordai<sup>4</sup>

<sup>1</sup>Radiotherapy Center AMETHYST- UMF Iuliu Hatieganu Cluj, Radiotherapy, Cluj, Romania ; <sup>2</sup>The Institute of Oncology "Prof Dr Ion Chiricuta" Cluj-NAPOCA, Radiotherapy, Cluj-Napoca, Romania ; <sup>3</sup>Radiotherapy Center AMETHYST, Radiotherapy, Cluj, Romania ; <sup>4</sup>Radiotherapy Center AMETHYST, Radiotherapy- Physics, Cluj, Romania

#### Purpose or Objective

Seminal vesicle (SV) invasion (pT3b) is accepted by all guidelines as criteria for adjuvant radiotherapy (aRT) after radical prostatectomy (RP). Our hypothesis was that the delineation of the tumour bed as per ESTRO guidelines might be improved by MRI fusion into the planning.

#### Material and Methods

Twelve pT3bNo, cM0 prostate adenocarcinoma patients (50 % with peri-vesicular extension) having received aRT in our institution during 2016-2017 were retrospectively contoured by fusing the preoperative prostate MRI into the treatment planning. The treated (postoperative) CTV and PTV (+5 mm) were according to the ESTRO delineation guidelines; 66Gy/33 fr IMRT/VMAT with daily IGRT were delivered. The preoperative MRI SV length was divided in 3 levels (lower, middle and upper third), expanded to PTV with the same margin as in the actual plan (5mm). We analysed the "geographic miss" of the postoperative dosimetry applied to the "preoperative SV adapted" delineation.

#### Results

Assuming all of them would have had peri-vesicular extension, the coverage of the SV bed was suboptimal for 8.3 % of the lower third, 25 % of the middle third and 16.6 % of the upper third of the SV, leaving only 50 % accurate PTV coverage!

#### Conclusion

Integrating the preoperative MRI into the RT planning might improve the target coverage in a substantial number of pT3b cases. We suggest that future ESTRO guidelines shall consider fusion of the prior prostatectomy prostate MRI into the treatment planning for adjuvant or salvage RT.

#### EP-1580 Adjuvant radiotherapy in prostate cancer patients-bRFS and toxicity using adaptive IMRT technique

P. Toncheva<sup>1</sup>, N. Volegova - Neher<sup>1</sup>, K. Henne<sup>1</sup>, A. Grosu<sup>1</sup>, S. Kirste<sup>1</sup>

<sup>1</sup>Uniklinik Freiburg, Radiation Oncology, Freiburg, Germany

#### Purpose or Objective

In this retrospective study we assessed local tumor control and biochemical recurrence free survival (bRFS) in a single center cohort of prostate cancer patients who underwent postoperative radiation therapy in adaptive IMRT technique. Furthermore we investigated acute and long - term genitourinary and gastrointestinal toxicities.

#### Material and Methods

We evaluated 140 high risk prostate cancer patients who were treated between 2010 and 2014 within 6 months after radical prostatectomy. Depending on bladder and rectum volumes the planning target volume (PTV) was adapted. Median prescription dose applied to the prostate bed was 66,6 Gy in 37 fractions. 39 out of 62 node positive patients received up to 54 Gy to the pelvic lymph nodes. Descriptive statistics as well as uni- and multivariate analysis were performed.

#### Results

Median follow up was 48 months (2 - 86 months). The 4 - year overall survival rate was 94%. 4 - year bRFS was 55%. 51 out of 140 patients developed a recurrence. Biochemical recurrence was observed in 15 patients, 30 patients developed a recurrence outside the treatment field and 6 patients had a recurrence inside the treatment field. Acute grade 3 genitourinary toxicity occurred in 3

patients (2%) and late grade 3 genitourinary toxicity was observed in 2 patients (1%). Acute and late grade 3 gastrointestinal toxicities occurred in 5 patients (4%) and 2 patients (1%). Lymph node status, pelvic lymph node irradiation, Gleason score, neoadjuvant and concomitant hormonal therapy were significant variables in univariate analysis for bRFS (p<0,05). Multivariate cox regression analysis identified lymph node status as having significant influence on bRFS.

#### Conclusion

Postoperative radiotherapy is able to deliver long - term biochemical disease free survival in a substantial number of patients with prostate cancer and high risks features. The majority of recurrences occur outside the treatment field. Modern radiotherapy techniques including IMRT and plan adaptation can reduce toxicity to < 4% in the postoperative setting.

#### EP-1581 Good tolerability of hypofractionated radiation therapy for localized prostate cancer

I. Navarro<sup>1</sup>, R. Correa<sup>1</sup>, A. Otero<sup>1</sup>, A. Roman<sup>1</sup>, I. Zapata<sup>1</sup>, A. Fernandez<sup>1</sup>, P. Prieto<sup>1</sup>, S. Segado<sup>1</sup>, C. Jodar<sup>1</sup>, C. Garrido<sup>1</sup>, J.A. Medina<sup>1</sup>, J. Gomez<sup>1</sup>

<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology, Malaga, Spain

#### Purpose or Objective

Radiobiological models have determined a low  $\alpha/\beta$  value for prostate cancer (1.5Gy), which suggests a good response with fewer and larger fractions. Some randomized studies of hypofractionation in prostate cancer have been published, reported a high differences in patients selection and in the risk, dose and technical groups used; unable to establish as standard treatment. To analyze the efficacy and toxicities of localized prostate cancer (LPC) patients treated with curative hypofractionated radiotherapy, with a long follow up. These patients were treated outside of a clinical trial. We also evaluate the results in subgroups of patients to determine possible prognostic factors.

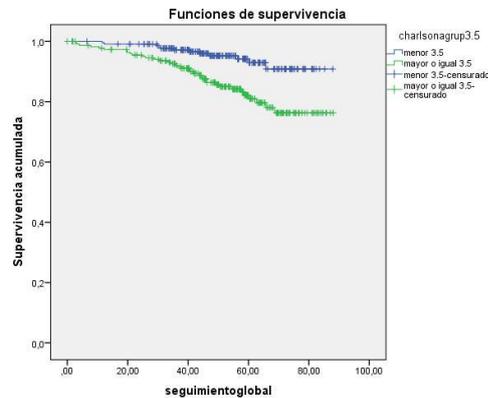

#### Material and Methods

Retrospective study of 451 patients with LPC treated with hypofractionated radiotherapy, in our institution, between January 2011 and May 2016. The scheme used was 60Gy to 3Gy/fraction, using 3D and volumetric arc therapy techniques (VMAT). We analyzed the Charlson Comorbidity Index (CCI) as a predictor of survival at 10 years. We also analyzed the age, Gleason score, stage and NCCN risk factors, as well the use of androgen deprivation therapy. Toxicity was evaluated using Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0. The overall survival (OS) was defined as the time from the last day of radiotherapy until the date of last revision. We considered biochemical progression (BP) as Phoenix's definition of more 2ng/dl of PSA nadir; and clinical recurrence (CR) as progression to locoregional lymph-nodes or distant metastases.

#### Results

With a median follow-up of 51 months (1.6-88 months), only 1.6% (7 patients) died due to the disease, 89.6% remained alive, 8.4% with biochemical disease, and 3.3% with clinical disease. We observed a high rate of any grade of acute genitourinary toxicity (72.7%), most of them grade 1. But only 20% of chronic genitourinary toxicity was observed. The acute and chronic rectal toxicity showed a low rate, 19.1% and 2.7%, respectively. The radiotherapy technique was significantly associated with acute rectal toxicity. Thus, patients treated with VMAT presented toxicity in 23.9% versus 13.5% with RT3D (p=0.005). The OS at 2, 5 and 7 years was 97%, 88% and 83% respectively. Disease-free survival until BP was 96%, 83.8% and 77.9%. And for the CR, it was 99%, 94% and 92%, respectively. Regarding the survival analysis, the CCI was the only factor with statistical significance for OS (p = 0.00), with a greater number of events being observed in

the patients with CCI  $\geq$  to 3.5 (Image 1). Moreover, those patients with high or very high risk, presented a lower survival ( $p=0.032$ ), as well as patients with higher Gleason ( $p=0.04$ ).

### Conclusion

Hypofractionated radiotherapy with escalated doses in prostate cancer is a well-tolerated treatment, with a low rate of chronic toxicity and with a high efficacy. The hypofractionation benefits allow reducing the number of sessions thus improving the quality of life, the use of resources and decreases the cost of treatment.

### EP-1582 Differences between 3d and vmat in hypofractionated radiation therapy for localized prostate cancer

I. Navarro<sup>1</sup>, R. Correa<sup>1</sup>, A. Roman<sup>1</sup>, A. Otero<sup>1</sup>, A. Fernandez<sup>1</sup>, P. Prieto<sup>1</sup>, M.J. Garcia<sup>1</sup>, I. Garcia<sup>1</sup>, R. Ordoñez<sup>1</sup>, I. Jerez<sup>1</sup>, J.A. Medina<sup>1</sup>, J. Gomez<sup>1</sup>  
<sup>1</sup>Hospital Virgen de la Victoria, Radiation Oncology, Malaga, Spain

### Purpose or Objective

External beam radiotherapy (RT) is an appropriate treatment option for patients with localized prostate cancer. Some studies have shown superiority of dose escalation in the control of the disease. However, an increase in toxicity has been described with these regimens. The use of intensity modulated radiotherapy (IMRT) with volumetric arc therapy (VMAT) and image-guided radiotherapy (IGRT) makes possible to carry out the treatment without increasing side effects. The objective is to analyze the differences between 3D and VMAT techniques in the toxicity profile, biochemical failure and clinical recurrence.

### Material and Methods

Retrospective study of a large number of patients with localized prostate cancer treated with hypofractionated radiotherapy (60Gy to 3Gy per fraction) with radical intention using 3D and VMAT techniques, both with daily image verification with cone beam CT (XVI), in our institution, between January 2011 and May 2016. After analyzing dose-volume histogram (DVH), those cases with satisfactory coverage of planning target volume (PTV) and dose constraints for organ at risk, were treated with 3D technique. More complex cases were treated performing VMAT. From May 2015, due to the better conformation treatment planning, translated into better DVH results and a shorter treatment time, all patients were treated with VMAT. The variables analyzed were the age, stage, Gleason score, NCCN risk group and seminal vesicles treatment, using univariate and multivariate analysis.  $P$  values  $< .05$  were considered statistically significant.

### Results

We analyzed 451 men with prostate cancer with a range of age between 45 and 81 (median 68 years). 208 patients (46.1%) were treated with 3D radiotherapy, and 243

patients (53.9%) with VMAT. The median follow-up was 51 months (maximum 88 months). The volume and the mean rectal and bladder doses were slightly higher in VMAT compared to 3D (Table 1). Regarding toxicity, we found differences between both groups. An increased acute rectal toxicity (any grade) was seen in 58 patients (23.9%) in VMAT group, compared to the group of 3D-RT with 28 patients (13.5%) ( $p = 0.005$ ). No statically difference was found in the rest of parameters analyzed, and no difference in chronic toxicity between both techniques (Table 2). The percentage of patients in the VMAT group had higher risk factors with significant differences (age  $> 68$  years, seminal vesicles included, Gleason score  $> 7$ , stage and NCCN group risk), in univariate and multivariate test. No difference in biochemical and clinical failure were observed.

Table 1.

		VMAT	3D
RECTUM	VOLUME	54.13 cc	55.16 cc
	MEAN DOSES	35.65 Gy	28.60 Gy
	V40	43.73%	25.10%
	V50	15.28%	11.85%
	V60	0.88%	1.15%
BLADDER	VOLUME	83.02 cc	86.75 cc
	MEAN DOSES	40.38 Gy	31.41 Gy
	V40	53.86%	36.10%
	V50	40.26%	25.85%
	V60	17.27%	5.60%

Table 2.

		RADIOTHERAPY TECHNIQUE		
		VMAT	3D	P
BIOCHEMICAL FAILURE	YES	27 (11.1%)	33 (15.9%)	0.13
	NO	216 (88.9%)	175 (84.1%)	
CLINICAL RECURRENCE	YES	7 (2.9%)	12 (5.8%)	0.12
	NO	236 (97.1%)	196 (94.2%)	
RECTAL ACUTE TOXICITY	NO	185 (76.1%)	180 (86.5%)	0.005
	YES	58 (23.9%)	28 (13.5%)	
GENITOURINARY ACUTE TOXICITY	NO	67 (27.6%)	56 (26.9%)	0.87
	YES	176 (72.4%)	152 (73.1%)	
RECTAL CHRONIC TOXICITY	NO	238 (98.3%)	199 (96.1%)	0.14
	YES	4 (1.7%)	8 (3.9%)	
GENITOURINARY CHRONIC TOXICITY	NO	192 (79.3%)	166 (80.2%)	0.82
	YES	50 (20.7%)	41 (19.8%)	

### Conclusion

We did not find significant differences between the two techniques used, except in acute rectal toxicity. This apparent difference may be due to the fact that the VMAT technique was considered to be the choice in those cases that required a greater volume of irradiation, when including the seminal vesicles, so that this increased toxicity could be more related to the total volume rather than to the technique employed.

### EP-1583 Feasibility of postprostatectomy dose escalated salvage radiotherapy by reduction of bladder dose

G. Sancho Pardo<sup>1</sup>, E. Acosta<sup>1</sup>, L. Tilea<sup>1</sup>, A. Soto<sup>1</sup>, A. Nuria<sup>1</sup>, G. Gómez de Segura<sup>1</sup>, J. Craven-Bartle<sup>1</sup>  
<sup>1</sup>Hospital de la Santa Creu i Sant Pau, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

After radical prostatectomy, salvage RT with doses over 66 Gy to the prostate bed may confer a benefit but also an increased risk of genitourinary (GU) toxicity. In this setting, we analyse the acute and late GU toxicity and their association with dosimetric parameters.

### Material and Methods

We performed a retrospective study in 190 patients (pt) with prostate cancer who had biochemical failure after radical prostatectomy. Since June 2011, all patients underwent a multiparametric-MRI to investigate the site of recurrence before planning the radiation treatment. Clinical and planning target volumes (CTV and PTV) were contoured according to the EORTC guidelines. Elective pelvic irradiation was indicated in patients without

lymphadenectomy. We have progressively increased the dose delivered to the prostate bed from 66 to 71 Gy. In patients with visible recurrence, we registered the mpMRI and the simulation CT images to define a recurrence and to intensify the dose on it. The series include the first 25 pt treated with IMRT and moderate hypofractionation (2.1 to 2.35 Gy per fraction). For the analyses, total doses were converted into 2Gy-equivalent doses (EQD2) according to the linear quadratic model taking  $\alpha/\beta=1.5$  for the tumor and  $\alpha/\beta=3$  for bladder. Acute and late toxicity were scored according to the RTOG and CTCAE v4.0 scales. We have investigated the association among the dosimetric parameters and toxicity.

### Results

The multiparametric-MRI was positive in 79 pt (41.5%). Local recurrences were mostly located at the perianastomotic site. Lymph node recurrence occurred in 22 pt (11.5%). Median radiation doses (Gy) for pt treated with normofractionation were: 70.2 (64-71) in prostate bed, 73.8 (71-76) on local recurrence location, and 60.90 (56-75.2) on positive lymph nodes. The doses for hypofractionation were: 65 (63.8-70.2) in prostate bed, 68.5 (63.8-70.2) on local recurrence location and 60.9 (58.8-62.35) on positive lymph nodes. With a median follow-up of 40 months (2-75 months) 75% of pt showed biochemical and clinical control. We observed acute grade 2-3 GU toxicity in 3pt (3.2%). Grade 2, 3 and 4 GU late toxicity (mainly haematuria) was observed in 9 (5.1%), 7 (3.9%) and 1 (0.5%) pt respectively. Late haematuria grade  $\geq 2$  was higher in those patients with mean bladder dose > 50 Gy (10.8% vs 1.4%;  $p=0.017$ ) and/or bladder V70 > 30 Gy (20.8% vs 2.3%;  $p < 0.001$ ). None of the patients treated with IMRT showed late grade  $\geq 2$  haematuria.

### Conclusion

We recommend a very strict evaluation of bladder dose-volume histogram to decide whether or not to intensify the radiation dose after prostatectomy.

### EP-1584 Radium-223 treatment in Metastatic Prostate Cancer: Prognostic Factors: Real-world Outcome

R. Pearson<sup>1</sup>, X. Jiang<sup>1</sup>, S. Atkinson<sup>2</sup>, S. Cumming<sup>1</sup>, A. Burns<sup>3</sup>, J. Frew<sup>1</sup>, R. McMenemin<sup>1</sup>, I. Pedley<sup>1</sup>, A. Azzabi<sup>1</sup>  
<sup>1</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Northern Centre for Cancer Care, Newcastle upon tyne, United Kingdom ; <sup>2</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Dept of Nuclear Medicine, Newcastle upon tyne, United Kingdom ; <sup>3</sup>Newcastle upon Tyne Hospitals NHS Foundation Trust, Dept of Radiotherapy Information Technology, Newcastle upon Tyne, United Kingdom

### Purpose or Objective

Radium 223 (Ra-223) is a radiopharmaceutical used to treat men with metastatic castrate resistant prostate cancer (mCRPC) with symptomatic bone metastases. We aim to evaluate factors impacting survival outcomes from a heterogeneous cohort of 228 patients treated in a single UK centre.

### Material and Methods

We prospectively collected data from 228 men underwent Ra-223 therapy for mCRPC between April 2014 and August 2018. Survival outcomes were analysed and prognostic factors were extracted.

### Results

Medium age = 72 (51-87) years. Most patients (90.3%) whose baseline haemoglobin > 10g/dl (n=160) managed to complete 5-6 cycles of treatment in contrast to 13.2% if it was 8-10 g/dl (n=19) or 0% if < 8 g/dl (n=4). Key findings are summarised in table below.

Variables	Patient No (%)	Median Survival (mths)	p-value (log rank)	HR (log rank)	95% CI
Overall	228	11.1	n/a	n/a	n/a

PS 0-1	160 (70.2%)	15.7	<0.0001	0.38	0.24 - 0.6
PS >2	53 (23.2%)	7.8	<0.0001		
No of mets <6	32 (14%)	28	<0.0001		
No of mets 6-20	64 (28.1%)	5.9	<0.0001		
No of mets >20	67 (29.4%)	5.4	<0.0001		
Baseline ALP <220	107 (46.9%)	13.5	0.0014	0.57	0.39 - 0.83
Baseline ALP >220	80 (35.1%)	8.4	0.0014		
Baseline Hb >/= 10	161 (70.6%)	13	<0.0001	0.32	0.15 - 0.7
Baseline Hb <10	22 (9.6%)	5	<0.001		
Baseline PSA <50	49 (21.5%)	19.5	0.006		
Baseline PSA 50-100	27 (11.8%)	15.8	0.006		
Baseline PSA >100	112 (49.1%)	8.9	0.006		
Cycles completed 5-6	144 (63.2%)	15.8	<0.0001	0.25	0.15 - 0.4
Cycles completed 1-4	62 (27.2%)	4.7	<0.0001		
PSA fall /= 30%	33 (14.5%)	25.1	0.0066	0.51	0.34 - 0.77
PSA other	152 (66.7%)	10.5	0.0066		
Neutrophil/lymphocyte ratio post Ra223 <3.89	84 (36.8%)	17.5	0.0005	0.52	0.35 - 0.75
Neutrophil/lymphocyte ratio post Ra223 >/= 3.89	85 (37.3%)	8.6	0.0005		

### Conclusion

Our data showed patients with fewer metastases, completion of 5-6 cycles of Ra-223 and those who had PSA reduction of 30% or more at the end survive significantly longer. Fitness but not age was significant. Lower baseline ALP, PSA, neutrophil/lymphocyte ratio and higher baseline haemoglobin are positive prognostic biomarkers for survival.

### Electronic Poster: Clinical track: Urology-non-prostate

### EP-1585 Modified BEP chemotherapy regimen in testicular germ cell tumors: Outcome and toxicity

N. Thakur<sup>1</sup>  
<sup>1</sup>Post Graduate Institute of Medical Education and Research, Radiotherapy and Oncology, Chandigarh, India

### Purpose or Objective

Bleomycin, Cisplatin and Etoposide (BEP) is established as standard treatment for Testicular Germ cell Tumours. Standard BEP regimen consist of Bleomycin 30 IU DAY 1,8 and 15, cisplatin 20 mg/m2 day1-5 and etoposide 100 mg/m2 day1-5. As these tumours are highly curable, so management is crucial in terms of long term toxicity particularly lung toxicity. With standard BEP there is increased toxicity which leads to poor compliance so we at a tertiary care centre assessed modified BEP regimen in such patients and evaluated its effectiveness in terms of response and toxicity as compared to standard BEP. The original intent is to explore the cost-effectiveness and improved patient compliance of this modified protocol without losing efficacy in treatment.

### Material and Methods

Forty nine patients of testicular tumours were enrolled in this study from January 2012 to December 2016. Of them, 43 patients were of non-seminomatous germ cell tumor

(NSGCT) and 5 patients were of pure seminoma. The mean age at diagnosis was 30 years. Pretreatment staging consisted of physical examination, determination of serum tumor marker levels and radiological examination. The modified BEP regimen consisted of bleomycin 30 IU Day 1, Cisplatin 20 mg/m<sup>2</sup> Day 1-5 and Etoposide 100mg/m<sup>2</sup> Day 1 to 5, given every three weeks. Therefore, the planned drug intensities were 33.3 mg/m<sup>2</sup>/week for cisplatin, 166.7 mg/m<sup>2</sup>/week for etoposide and 10 IU/body/week for bleomycin. The schedule for chemotherapy was as follows: four courses of modified BEP for stage I patients and six courses of modified BEP for stage I S, II and III patients.

#### Results

Out of 48 patients, 16 (33.3%) patients had complete response and 23 (47.9%) patients had partial response. Overall Response rate in our study was seen to be 81.2% which was comparable with the available evidence. The complete biochemical response was seen in 35 (72.9%) patients. Only 5 (10.4%) patients had febrile neutropenia and only two (4.1%) patients showed clinically evident Bleomycin induced pulmonary toxicity during chemotherapy. In this study no clinically evident neuropathy was seen. Lower toxicity seen in these patients led to better overall compliance as 40 (83.3%) patients completed 6 cycles within a stipulated overall treatment time of 16 weeks.

#### Conclusion

Modified BEP protocol is a good alternative to standard BEP with comparable efficacy, reduced toxicity and better compliance. We strongly believe that this modified BEP regimen improving the quality of life of these patients during chemotherapy will replace the conventional mode of administration if randomized trials will validate that this is achieved without jeopardizing the excellent response rates of the standard regimen.

#### EP-1586 FDG PET-CT based risk-adapted radiotherapy for post-chemotherapy residual mass in advanced seminoma

V. Murthy<sup>1</sup>, C. Johnny<sup>1</sup>, R. Krishnatry<sup>1</sup>, A. Joshi<sup>2</sup>, G. Prakash<sup>3</sup>, M. Pal<sup>3</sup>, G. Bakshi<sup>3</sup>, S. Menon<sup>4</sup>, A. Agarwal<sup>5</sup>, V. Rangarajan<sup>5</sup>, V. Noronha<sup>2</sup>, K. Prabhaskar<sup>2</sup>

<sup>1</sup>Tata Memorial Hospital, Radiation oncology, Mumbai, India; <sup>2</sup>Tata Memorial Hospital, Medical Oncology, Mumbai, India; <sup>3</sup>Tata Memorial Hospital, Surgical Oncology, Mumbai, India; <sup>4</sup>Tata Memorial Hospital, Pathology, Mumbai, India; <sup>5</sup>Tata Memorial Hospital, Nuclear Medicine, Mumbai, India

#### Purpose or Objective

There is a lack of consensus regarding the management of postchemotherapy residual mass in advanced seminoma. Surgery for these masses is technically challenging and often morbid. FDG PET CT has aided in identifying viable disease based on size and SUVmax values. The aim of this study is to evaluate if risk stratification based in FDG PET CT residual mass size and SUV uptake can help in identifying patients who would benefit with locoregional radiotherapy in advanced seminoma.

#### Material and Methods

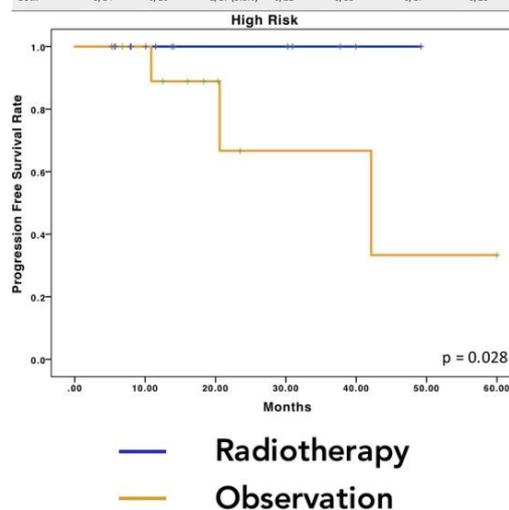

This is a retrospective study of patients with advanced classical seminoma primarily treated with platinum-based first-line chemotherapy. All patients had routine response assessment FDG PET CT after chemotherapy. Patients were stratified into three subgroups based on FDG PET-CT residual nodal size and SUV max. The low-risk group (LR) consisted of SUV max  $\leq 3$  and size  $\leq 3$ cm, intermediate and high-risk groups (HR) consisted of patients with SUV max  $\geq 3$  or size  $\geq 3$ cm and SUV max  $\geq 3$  and size  $\geq 3$ cm respectively. There were 2 intermediate risk groups (based on Size  $> 3$ cm with any SUV (IR-Size) and SUV $>3$  with any size (IR-SUV)). Patients were either kept on observation after chemotherapy or received radiotherapy to the PET positive nodal mass in the intermediate and

high-risk groups. Low-risk group patients did not receive radiotherapy. Patients who underwent surgery were excluded. Locoregional control, overall survival, and patterns of failure were compared between the two groups.

#### Results

Seventy-three patients were included in the study, 51 patients were observed and 22 patients received radiotherapy after chemotherapy. The median pre-chemotherapy node size between the radiotherapy and observation cohort was 8.9cm (IQR 7.6-11.6) and 8.6cm (IQR 5.6-11). Median post-chemotherapy node size in the radiotherapy and observation cohort was 4 cm (IQR:2.7-5.5) and 2.5 cm (IQR:1.4-5.5) respectively while the post-chemotherapy SUVmax in the 2 groups was 4.1 (IQR 3.2-5.8) and 0 (IQR 0-3.6) respectively. Median time to PET CT was 7 weeks (IQR 4-10). Locoregional failures in the radiotherapy and observation cohort were 0% and 30% in the HR (p = 0.028), 0% and 18% (p = 0.295) in IR-Size and 5.5% and 29% (p = 0.076) in IR-SUV respectively. The benefit of loco regional control failed to translate into overall survival benefit. The patterns of failure and failure rates by risk group are shown in table 1.

	SUV > 3 and size > 3cm (High Risk)		Any SUV and size > 3cm (Intermediate Risk, IR Size)		SUV > 3 and any size (Intermediate Risk, IR-SUV)		SUV < 3 and size < 3cm (Low Risk)	
	RT	No RT	RT	No RT	RT	No RT	RT	No RT
All failures	1/14 (7%)	4/10 (40%)	2/17 (12%)	6/22 (27%)	3/18 (16.6%)	6/17 (35%)	2/25 (8%)	
		p=0.05		p=0.176		p=0.14		
Loco regional failure only	0/14	3/10 (30%)	0/17	4/22 (18%)	1/18 (5.5%)	5/17 (29%)	2/25 (8%)	
		p=0.028		p=0.295		p=0.076		
Distant failure only	1/14 (7%)	1/10 (10%)	1/17 (5.8%)	2/22 (9%)	2/18 (11%)	1/17 (6%)	0/25	
Both	0/14	0/10	1/17 (5.8%)	0/22	0/18	0/17	0/25	

#### Conclusion

FDG PET CT can help in stratifying postchemotherapy masses based on size, SUVmax and hence can help in tailoring treatment appropriately. Residual masses  $\geq 3$ cm and SUVmax  $\geq 3$  (high-risk group) are likely to benefit the most with radiotherapy. A prospective study to address this question is planned.

#### EP-1587 Conservative strategy with concomitant chemoradiation for bladder cancer: analysis of a 313 patients

E. Fabiano<sup>1</sup>, H. Martin<sup>1</sup>, M. Arnaud<sup>2</sup>, G. Philippe<sup>1</sup>, K. Sarah<sup>1</sup>, T. Hélène<sup>1</sup>, B. Jean Emmanuel<sup>1</sup>, S. Antoine<sup>1</sup>, D. Catherine<sup>1</sup>

<sup>1</sup>Hôpital Européen Georges Pompidou, Radiation Department, Paris, France; <sup>2</sup>Hôpital Européen Georges Pompidou, Urology Department, Paris, France

#### Purpose or Objective

To evaluate trimodal conservative treatment as an alternative to radical surgery for urothelial invasive bladder carcinoma (IBC).

### Material and Methods

This retrospective study reported the carcinologic and functional results of patients (pts) presenting a cT2/T3 NOMO operable IBC, treated by a conservative strategy. Treatment consisted of a transurethral resection, as complete as possible, followed by concomitant bifractionated split-course chemoradiation (CCR) with 5FU-Cisplatin chemotherapy. A control cystoscopy was performed 6 weeks after the first part CCR (eq45Gy) with systematic biopsies. Pts with complete histologic response achieved CCR protocol. Salvage surgery was proposed to pts with persistent tumor.

### Results

313 patients (83% cT2, 17% cT3) treated between 1988 and 2013 were included in this study, with a median follow-up of 59 months and 67 year mean age. After the first part of CCR histologic response rate was 83%. After 5 years, overall, disease-free, metastasis-free and functional bladder-intact survival rates were respectively 69%, 61%, 78% and 69%, significantly better for patients in complete response after induction CCR ( 77% vs 32%, p= 0,001 for 5 years OS). Late urinary and digestive toxicities were limited, with respective rates of 3.2% and 1.3% of grade 3 toxicity.

### Conclusion

Chemoradiation after transurethral resection is a good treatment option, especially for older or frail pts.

### EP-1588 The preliminary result of combination of chemoradiotherapy and arterial infusion for bladder cancer

H. Yoshioka<sup>1</sup>, T. Shimbo<sup>1</sup>, Y. Tanaka<sup>1</sup>, A. Hori<sup>1</sup>, M. Nakata<sup>1</sup>, N. Yoshikawa<sup>1</sup>, K. Yoshida<sup>1</sup>, Y. Uesugi<sup>2</sup>, K. Yamamoto<sup>1</sup>

<sup>1</sup>Osaka Medical College, Department of Radiology, Takatsuki, Japan ; <sup>2</sup>Kansai University of Welfare Sciences, Rehabilitation, Kashiwara, Japan

### Purpose or Objective

We present the preliminary results from our clinical study evaluating the effectiveness of combination of chemoradiotherapy with balloon-occluded arterial infusion (BOAI) and hemodialysis (HD) for bladder cancer

### Material and Methods

We investigated 200 patients and the median age was 66 (range; 32-85) . According to the UICC classification, 4 patients were at clinical stage Tis, 19 at T1, 120 at T2, 40 at T3, and 17 at T4. About N stage, 167 patients had no lymph node metastasis. All patients received external beam radiation therapy (EBRT) of 40- 50 Gy to the whole pelvis with 10 Gy to the bladder as a boost. During EBRT, combination chemotherapy of gemcitabine (GEM) and cisplatin (CDDP) was described. After chemoradiotherapy, BOAI of CDDP was administered from bilateral internal iliac arteries with simultaneous HD to prevent back-flow of CDDP into the systemic circulation.

### Results

The median follow-up time was 38 months(range; 4-58). Complete response (CR) rate was 78% after 2 months of treatment. Three-year local control (LC) and overall survival (OS) rates were 72% and 87%, respectively, and 3-year bladder preservation rate was 99%.Grade 3 acute complication occurred in 25 patients (13%) (genitourinary: 9; gastrointestinal: 17) and Grade 4 acute complication was not observed.

### Conclusion

Combination of chemoradiotherapy with BOAI and HD may be regarded as a curative therapy for patients with bladder cancer.

### EP-1589 Establishing international variation in target delineation using MRI for bladder radiotherapy.

### Purpose or Objective

MRI has an established diagnostic role in local staging of muscle invasive bladder cancer (MIBC). Improved soft tissue definition with MRI compared to CT should facilitate radiotherapy target definition. However, experience of MRI in bladder radiotherapy planning is limited, with no current guidance available on its use. This multicentre, international study aims to establish current inter-observer variability of target delineation for MIBC using MRI in order to develop future consensus.

### Material and Methods

24 participants with a specialist interest in MIBC (19 radiation oncologists, 2 radiologists and 3 treatment radiographers) from 15 institutions (11 UK, 1 Danish, 2 Australian, 1 Canadian) were provided with MRI scans of 3 patients with MIBC. One CT based case was also included. Consultant radiation oncologists also completed a questionnaire on their MIBC radiotherapy experience and MRI use. Case vignettes were given but participants were not coached on MRI or CT interpretation. CTV and GTV delineation was performed on T2W images and outer bladder wall (BW) delineation completed on T1W images. Diffusion weighted images were also available for reference. For the CT benchmark case, only CTV and GTV were defined. Delineation was carried out on the MONACO treatment planning system research version v5.10 (Elekta AB, Stockholm, Sweden).

On completion of all contours a Simultaneous Truth and Performance Level Estimate (STAPLE) was created for each structure set. Individual contours were compared to this, enabling inter-observer comparisons. Four variability tests were performed using ADMIRE research version v2.0 (Elekta AB, Stockholm, Sweden).

### Results

Participating consultant radiation oncologists had a median 10 years of experience (IQR 7-15) in MIBC radiotherapy. Use of MRI in the radiation pathway was mixed, 53% (9/17) of clinicians had access to diagnostic MRIs, 18% had access to radiotherapy planning MRs, while 41% did not routinely use MR in their radiotherapy pathway.

In total, 264 contours were completed, of which 2 could not be analysed due to technical reasons.

Table 1 shows the combined median variability indices across the MRI based cases with the CT based case as a comparator.

Variability Index	MRI GTV	MRI CTV	MRI Bladder Wall	CT GTV	CT CTV
Median DICE coefficient (IQR)	0.69 (0.59-0.76)	0.94 (0.94-0.95)	0.95 (0.93-0.96)	0.70 (0.6-0.8)	0.97 (0.97-0.97)
Median Cohen Kappa (IQR)	0.65 (0.54-0.73)	0.91 (0.90-0.92)	0.91 (0.89-0.93)	0.67 (0.57-0.78)	0.95 (0.94-0.95)
Median Hausdorff Distance (mm)	15.04 (11.99-30.3)	7.70 (6.27-11.22)	7.95 (6.39-10.29)	12.12 (9.83-14.47)	4.02 (3.51-5.19)
Median mean distance (mm)	3.08 (1.80-6.38)	1.22 (1.07-1.43)	1.43 (1.06-1.75)	2.21 (1.13-2.98)	0.60 (0.57-0.71)

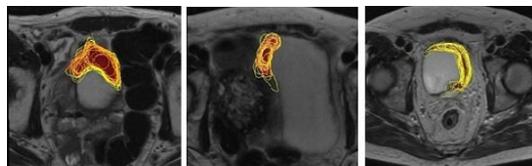

Figure 1 GTV inter-observer variation on T2 image. L-R cases 1-3, STAPLE in red colourwash, participants yellow contour

## Conclusion

Current use of MRI in MIBC radiotherapy is mixed. Some institutions have access to MRI for the majority of their patients, others have restricted or no access to these scans.

Despite this, MRI delineated volumes on average show reasonable concordance between participants, this is similar to CT where there is greater experience. Greatest variance was seen in GTV delineation with a median DICE of 0.69.

Further work will now include an education/consensus meeting followed by the production of guidance for the proposed use of MRI in MIBC radiotherapy target delineation with particular attention paid to GTV boost volume delineation.

## EP-1590 Hyperthermia-radiotherapy in frail bladder cancer patients unfit for cystectomy or chemoradiotherapy

E. Stutz<sup>1,2</sup>, B. Eberle<sup>1</sup>, E. Puric<sup>1</sup>, A. Meister<sup>1</sup>, O. Timm<sup>1</sup>, D. Marder<sup>1</sup>, S. Rogers<sup>1</sup>, S. Wyler<sup>3</sup>, N.R. Datta<sup>1</sup>, S. Bodis<sup>1</sup>  
<sup>1</sup>Center for Radiation-Oncology KSA-KSB, Kantonsspital Aarau, Aarau, Switzerland ; <sup>2</sup>Department of Radiation Oncology, Inselspital- Bern University Hospital, Bern, Switzerland ; <sup>3</sup>Department of Urology, Kantonsspital Aarau, Aarau, Switzerland

### Purpose or Objective

Radiotherapy (RT) combined with radiosensitizers such as chemotherapy (CRT) or hyperthermia (HTRT) with curative intent shows superior local tumour control (LC) compared with RT alone in muscle-invasive bladder cancer (MIBC). We aimed to evaluate the LC rate, overall survival, MIBC-specific survival, acute and late toxicity of RT with concomitant deep hyperthermia (HT) in MIBC patients who are too frail for or decline radical cystectomy (RC) or CRT.

### Material and Methods

From 12/2012 to 03/2018 we treated 17 patients with unifocal or multifocal MIBC (T1-4, cN0-1, cM0, G3) with HTRT after maximal TURBT. Multifocal MIBCs received 50 Gy/20 fx (5x/week) to the whole bladder. Unifocal MIBCs were treated with 36 Gy/12 fx (3x/week) to the full bladder and a 12 Gy/4 fx boost (once a week) to the resected tumour region to a total of 48 Gy/16 fx (4x/week). HT was delivered weekly over 60 minutes with a mean temperature of 41.3°C using a BSD-2000 applicator. LC was assessed by cystoscopy every 3 months if possible.

### Results

One patient did not tolerate HTRT and was excluded from the analysis. Thus 16/17 patients (94.1%) completed HTRT

as per protocol. The median age in these 16 patients (6 unifocal, 10 multifocal) was 81 years (range, 52 - 88 years) while the median age-adjusted Charlson comorbidity index was 5 (range 1 - 9). LC was achieved in 100% (12/12) of patients at 3 months and in 87.5% (7/8) of patients at 12 months (Tab. 1). Median cystoscopic follow-up was 7.5 months (range, 2 - 59 months). Two local recurrences were detected. One local relapse was a noninvasive papillary carcinoma (pTa) at 9.5 months, which was successfully salvaged by TURBT. The other relapse presented at 17 months with lymph node and bone metastases. MIBC-specific survival during follow-up was 100%. Overall survival at 1 year was 71.4% (95% CI 47.7% - 95.1%) (Fig. 1). Grade 3 gastrointestinal (GI) and genitourinary (GU) toxicity (CTCAE v4.0) was evident in 12.5% (2/16) patients while none had grade 4 toxicity. During follow-up, only one grade 3 (CTCAE v4.0) late toxicity occurred. This was a transient episode of macrohematuria under anticoagulation due to bladder telangiectasia and was locally treated by coagulation. Bladder function was well preserved in all patients.

### Assessed at 3 months

<b>Patients available:</b>	12/16 (75%)
<b>not available due to:</b>	<ul style="list-style-type: none"> <li>• 2/16; not yet reached follow-up timepoint</li> <li>• 2/16; unable for cystoscopy due to health deterioration</li> </ul>
<b>Local control:</b>	12/12 (100%)

### Assessed at 12 months

<b>Patients available:</b>	8/16 (50%)
<b>not available due to:</b>	<ul style="list-style-type: none"> <li>• 3/16; not yet reached follow-up timepoint</li> <li>• 1/16; declined further cystoscopic follow-up</li> <li>• 4/16; died (not MIBC-related)</li> </ul>
<b>Local control:</b>	7/8 (87.5%)
	• 1/8 with recurrence at 9.5 months

Tab. 1. Cystoscopic local disease control

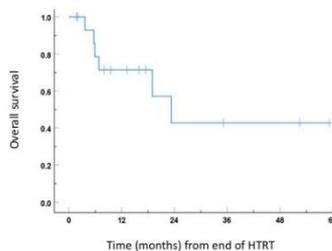

Fig. 1. Kaplan-Meier plot for rates of overall survival

## Conclusion

Elderly, polymorbid patients with MIBC have limited therapeutic options. To preserve quality of life, treatment achieving LC with a minimum of adverse effects is required. Several hypofractionated RT schedules have been reported for this population group, but this is the first report of RT combined with HT as radiosensitizer. Our results showed good tolerance of HTRT, minimal late toxicity and an excellent LC. These data are comparable or even better than those from hypofractionated RT alone in this population of frail patients unfit for definitive surgery or CRT.

## EP-1591 Dose mapping local failure following radical image guided bladder radiotherapy

S. Hafeez<sup>1</sup>, H. Abdel-Aty<sup>1</sup>, K. Warren-Oseni<sup>2</sup>, A. Dunlop<sup>2</sup>, K. Chan<sup>3</sup>, D. McQuaid<sup>2</sup>, K. Jones<sup>1</sup>, V. Harris<sup>4</sup>, M. Tan<sup>1</sup>, V. Hansen<sup>5</sup>, R. Huddart<sup>1</sup>, S. Hafeez<sup>1</sup>

<sup>1</sup>Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London,

United Kingdom ; <sup>2</sup>Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom ; <sup>3</sup>The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom ; <sup>4</sup>Guys and St Thomas' Hospital NHS Foundation Trust, Radiotherapy, London, United Kingdom ; <sup>5</sup>Odense University Hospital, Radiotherapy and Medical Physics, Odense, Denmark

### Purpose or Objective

Recurrences after radical bladder radiotherapy occur predominantly within the bladder. Accurate dose mapping is important to determine whether cause of local failure is due to geographical miss, and or insufficient dose. To assess the success of image guided bladder radiotherapy strategies and margin reduction, we aim to determine the dose prescribed and received by the volume that harboured the local failure.

### Material and Methods

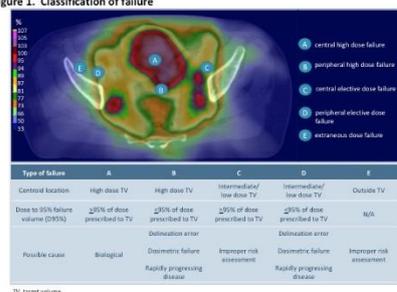

Thirty-eight patients with T2 (high risk pathology) or T3-4N0-3M0 bladder cancer recruited prospectively to an ethics approved phase II radiotherapy protocol treating whole bladder and pelvic lymph nodes with IMRT were retrospectively evaluated. Expansions to create the PTVs are shown Table 1. Soft tissue imaging was acquired prior to treatment with CBCT and registered to bony anatomy followed by soft tissue registration to whole bladder if necessary. Use of neo-adjuvant and concurrent chemotherapy was recommended.

Diagnostic imaging (CT/MRI) identifying the site of local recurrence was used to reconstruct the relapse volume (GTV<sub>relapse</sub>). This was co-registered with the planning CT. GTV<sub>relapse</sub> was compared dosimetrically and spatially to the PTV using centroid based approach. Patterns of failure were classified as in Figure 1. Time to local failure was defined from the start of radiotherapy to pathological confirmation of relapse, and was estimated using Kaplan Meier method.

Table 1. Applied expansions

Structure	Applied expansion to create corresponding PTV (cm)					PTV	Planned dose (Gy)
	Superior	Inferior	Lateral	Anterior	Posterior		
Bladder tumour	1.0	1.0	1.0	1.0	1.0	PTV <sub>Tumour bed</sub>	64
Whole bladder	1.5	0.5	0.5	1.5	1.0	PTV <sub>Whole bladder</sub>	52
Involved nodes	0.5	0.5	0.5	0.5	0.5	PTV <sub>Involved LN</sub>	60
Uninvolved nodes	0.5	0.5	0.5	0.5	0.5	PTV <sub>Pelvic LN</sub>	52

Figure 1. Classification of failure

### Results

27/38 (71%) of all patients had disease recurrence. 18/38 (47%) patients experienced first relapse within the bladder following radiotherapy. Median time to local relapse was 9.0 months (95% CI, 6.3-11.7 months). 15/18 (83%) of these patients received neo-adjuvant chemotherapy and 10/18 (57%) had received concurrent chemotherapy. 9/18 (50%) patients relapsed with  $\geq$ T2 local disease, and 7/18 (28%) with  $<$ pT1 disease. Based on endoscopic evaluation alone, 13/18 (72%) patients were reported to

have relapsed clinically at the original tumour site.

2 patients were excluded from further analysis because no axial imaging identifying relapse was available. Median volume of GTV<sub>relapse</sub> was 33.9cc (range 7.5-142.5). Median GTV<sub>relapse</sub> D<sub>95%</sub> was 56.4Gy (range 50.1-63.8Gy), 88.1% (78.3-99.6) of the prescribed dose (64Gy). Six patients (38%) were classified as experiencing type A failure, 9 patients (56%) as type B failure, and 1 (6%) as type C failure. No other types of local failure were identified.

### Conclusion

Relapse patterns following bladder radiotherapy suggest local failure occurs at or within close proximity of the original tumour (PTV<sub>Tumour bed</sub>). Work is on-going to expand the patient numbers and to determine actual radiotherapy dose delivered to GTV<sub>relapse</sub> from on-line CBCT data using the deformable registration techniques. This will inform whether dose escalation, and or margin modification could improve reported outcomes.

### EP-1592 Consolidative radiotherapy after loco regional relapse in muscle invasive bladder cancer

D. Santamaria Vasquez<sup>1</sup>, X. Maldonado<sup>2</sup>, M. Altibas<sup>2</sup>, D. Moreno<sup>2</sup>, S. Micó<sup>2</sup>, C. Raventós<sup>3</sup>, F. Lozano<sup>3</sup>, R. Morales<sup>4</sup>, J. Giralt<sup>2</sup>

<sup>1</sup>Vall D'Hebron hospital, Radiation Oncology, Barcelona, Spain ; <sup>2</sup>Hospital Universitario Vall d'Hebron, Radiotherapy, Barcelona, Spain ; <sup>3</sup>Hospital Universitario Vall d'Hebron, Urology, Barcelona, Spain ; <sup>4</sup>Hospital Universitario Vall d'Hebron, Medical Oncology, Barcelona, Spain

### Purpose or Objective

The aim of this study is to report the outcomes of consolidative radiotherapy after cystectomy in locoregional relapse of muscle invasive bladder cancer (MIBC) patients.

### Material and Methods

We performed a retrospective analysis of eighty-eight patients with MIBC that had been treated at our institution from January 1999 to August 2018.

Forty-nine patients underwent radical cystectomy followed by platinum-based chemotherapy (cisplatin / carboplatin). We identified 31 patients that had loco-regional relapse that received consolidative radiotherapy. These patients are the subject of our study.

Overall survival (OS) was calculated using the Kaplan-Meier method. OS was defined as the time from the start of radiotherapy to death.

The toxicity was evaluated according to the RTOG toxicity criteria.

### Results

In the select group of 31 patients with loco-regional relapse treated with consolidative radiotherapy, 25 were men, the median age was 65.3 years (range 44-87). Eight patients had local recurrence, 12 patients had regional recurrence, and 11 patients both.

All patients completed their radiotherapy course. Treatment volume was local recurrence or positive lymph nodes and regional pelvis. The mean dose of radiotherapy was 54.4 Gy (range 37.5 Gy - 64.8 Gy). No patient received concurrent chemotherapy.

Two patients (6%) developed grade 3 gastrointestinal toxicity. No grade 4 toxicity has been reported.

No grade  $\geq$ 2 genitourinary toxicity has been reported.

With a median follow-up of 27 months, there was no evidence of disease in 14 patients (45%) after consolidative radiotherapy. Seventeen patients presented metastatic distant progression: 5 hepatic, 4 bone and 4 pleuropulmonary.

One patient had local relapse, one patient had nodal relapse and one patient had loco-regional and metastatic relapse.

Overall survival was 21.8m (3-149m)

### Conclusion

These data suggest that consolidative radiotherapy after loco-regional relapse is feasible and could contribute to the long-term control in up to half of the treatments, with acceptable toxicity rates.

---

#### EP-1593 The impact of Radiotherapy combined with immunotherapy on local control in mucosal melanoma patients

H.J. Kim<sup>1</sup>, S.J. Shin<sup>2</sup>, K. Woong Sub<sup>3</sup>

<sup>1</sup>Gil Medical Hospital, Department of Radiation Oncology, Incheon, Korea Republic of ; <sup>2</sup>Yonsei Cancer Center, Division of Medical Oncology- Department of Internal Medicine, Seoul, Korea Republic of ; <sup>3</sup>Yonsei Cancer Center, Department of Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

Mucosal melanoma is an aggressive malignancy with a poor response to conventional therapies. The efficacy of immunotherapy (IMT), especially combined with radiotherapy (RT), has not been reported in this rare subtype. We investigated the impact of RT combined with IMT in mucosal melanoma patients.

#### Material and Methods

Forty-two patients with mucosal melanoma who were treated with RT at Yonsei Cancer Center between Jul 2008 and Feb 2017 were identified from our database. Patients who received postoperative RT, had no response evaluation, and expired during RT were excluded. A total of 18 patients with 22 lesions were included in this analysis. All patients received RT for primary or metastatic gross tumor mass. The median dose of radiation was 45 Gy (range, 20-69 Gy) with a median fractional dose of 3 Gy (range, 1.8-7.5 Gy). Eleven patients with 14 lesions were treated with RT alone, while 7 patients with 8 lesions were administered IMT sequentially or concurrently; pembrolizumab in 6 patients and nivolumab in 1. The local control (LC) rate, infield failure-free survival (IFFS), and outfield failure-free survival (OFFS) were compared between two groups (no-IMT vs. IMT group). IFFS and OFFS was determined from the date of RT finish, while overall survival (OS) was calculated from the date of diagnosis.

#### Results

Common anatomic sites of primary tumors were the head and neck (59%), anorectal region (31.8%), and female genital tract (9.1%). Patient characteristics including sex, age, primary site, tumor stage, BRAF mutation, adjuvant interferon, and RT site (primary vs. metastatic mass) were not significantly different between two groups. The median OS was 50.2 months with a median follow-up of 39.7 months (range, 7.3-102.1 months) for all patients. The LC rate was 59.1% for 22 lesions and the median time to local progression was 4.8 months (range, 0.5-20.3 months). Although RT dose was not significantly different between two groups, the LC rate was better in the IMT group than no-IMT group. (57.1% versus 12.5%; P = 0.074). The outfield failure rate was 87.5% in IMT group and 100% in no-IMT group (P = 0.364). Dividing lesions according to RT dose in terms of EQD2 ( $\alpha/\beta=10$ ), higher dose group (> 45 Gy) showed better tumor control; the LC rates were 53.8% vs. 22.2% and the median IFFSs were 20.3 vs. 7.3 months for >45 Gy vs. ≤45 Gy group, respectively. The OFFS was not significantly different between the IMT and no-IMT group.

#### Conclusion

RT combined with IMT improved local tumor control compared to RT alone. Combination treatment with RT and IMT can be an effective treatment option in patients with mucosal melanoma.

#### EP-1594 Two years' experience of electronic brachytherapy for basal cell carcinomas in selected patients

H. Westenberg<sup>1</sup>, R. Keus<sup>1</sup>, M. Van Hezewijk<sup>1</sup>, B. Oosterveld<sup>2</sup>

<sup>1</sup>Radiotherapiegroep, radiotherapy, Arnhem, The Netherlands ; <sup>2</sup>Radiotherapiegroep, medical physics, Arnhem, The Netherlands

#### Purpose or Objective

In 2016 electronic brachytherapy (EB) by low kilovoltage energy (69,5 kV Esteya®/Elekta, Sweden) was introduced in our department as addition to our radiation facilities for treating basal cell skin cancer. Due to the maximum applicator diameter of 3 cm, only small lesions are eligible. Maximum depth for dose prescription is 4 mm. After 2 years we evaluated toxicity, outcome and patient comfort.

#### Material and Methods

Patients with basal cell carcinoma referred for radiotherapy with curative intent were selected for EB. From March 2016 to September 2018 56 patients with 66 lesions were treated with electronic brachytherapy. All lesions received 6 fractions, twice a week, of 7 Gy prescribed to a depth of 3 mm (in 92% of the lesions) from the skin surface. In 2 patients the dose was prescribed to a depth of 4 mm, because of the tumour thickness, and in 3 patients to 2 mm because of superficial growth of the tumour. Before the first fraction the lesion (gross tumour volume GTV) and the treatment margin (GTV was expanded by 5- 10 mm to clinical target volume CTV, depending on size and histology) was delineated on the skin by the radiation oncologist. Dermatoscopy was used for precise GTV delineation. Photographs were routinely taken before the 1<sup>st</sup>, 4<sup>th</sup> and 6<sup>th</sup> fraction and during follow-up.

#### Results

One patient, in poor medical condition, was treated with palliative intent and one patient discontinued treatment because of a pneumonia. The remaining 54 patients with 64 lesions were evaluated. All lesions were ≤ 20 mm and 90% were histologically confirmed basal cell carcinoma, either of solid (67%), morpheaform (17%) or superficial growing (5%) type. Mean age was 75.7 years and despite high age and comorbidities, the treatment was well tolerated. Most lesions were localised in the head and neck area, with the majority on the nose (in 65% of the patients). The most common acute toxicity was a mild erythema and nasal mucositis, both self-limiting. In one patient, with a lesion on the tibia, delayed wound healing for several months occurred. Follow-up ranges from 0.5-26 months with an average FU of 5 months. There were 2 recurrences, one in and therefore a true recurrence, and one recurrence close to the radiation field.

#### Conclusion

In our two years' experience electronic brachytherapy offers an effective, comfortable and simple method for the curative treatment of small basal cell skin cancers in elderly patients with lesions in areas where surgery is complicated or mutilating. Our preliminary results are comparable to the published results with EB.

#### EP-1595 In operable SSSC, radiotherapy schedules could be chosen using dermoscopic features?

F. Pastore<sup>1</sup>, A. Rese<sup>1</sup>, G. Panelli<sup>1</sup>, A. Pepe<sup>1</sup>, D. Toledo<sup>1</sup>, V. Iorio<sup>1</sup>

<sup>1</sup>Emicenter, Radiation Oncology, Casavatore, Italy

#### Purpose or Objective

Radiotherapy is an optimal option for unoperable SSCC (Skin Squamous Cell Cancer) with excellent local control and good cosmetic outcomes. A lot of different fractionation and total doses had been used to treat SSCC, according to several clinical and histological parameters. Dermoscopically, these kind of lesion are characterized, by atypical vascular pattern and/or deep ulceration that some authors correlate with the severity of the neoplasm. In our study, we decide to use different radiotherapy schedules for our patients with SSCC, performing a “dose escalation” in those who had negative dermoscopic features.

#### Material and Methods

28 patients (age > 60yo) with unoperable SSCC were enrolled in this study. Based on negative dermoscopic features (ulceration, bleeding, irregular vessels), signed by a skilled dermatologist, we divided them in two groups: those with no negative dermoscopic features (15 patients) and those with negative one (13 patients). All the lesions were on the trunk or on upper/lower limbs. None of these lesions had nodal involvement (N0). No lesions were >4cm. In the first group we use an electron beam schedule of 2 Gy/30fx (60Gy) while in the second group we prescribe 2Gy/33fx (66Gy).

#### Results

All the patients ended treatment. In the group A (standard) the LC was observed (at 1 year follow up) in 13 patients (86%) and in 11 patients (73%) at 2 years follow up. Skin toxicity > grade 3 was not seen in these patients. No late toxicity was registered, with good cosmetic outcome. In the group B (negative features) the LC was observed in 12 patients (92%) at 1 year follow up and in 10 patients (77%) at 2 years follow up. 3 patients had grade 3 skin toxicity in this group with 2 cases of hypopigmentation.

#### Conclusion

Dermoscopic examination could be used to perform a dose escalation schedule in unoperable SSCC, with similar LC and acceptable toxicity. More patients and a longer follow up are the main future topics to enhance this kind of approach.

#### EP-1596 Radiotherapy and Ipilimumab as first-line immunotherapy: A comparative study on 63 patients

N. Benziane<sup>1</sup>, V. Atallah<sup>1</sup>, F. Amestoy<sup>1</sup>, E. Gerard<sup>2</sup>, N. Leduc<sup>1</sup>, A. Huchet<sup>1</sup>, M. Beylot Barry<sup>2</sup>, C. Dupin<sup>1</sup>, S. <sup>1</sup>University Hospital Bordeaux, Radiation Oncology, Bordeaux, France ; <sup>2</sup>University Hospital Bordeaux, Dermatology, Bordeaux, France

#### Purpose or Objective

A combination of immune-checkpoint inhibitors and radiation therapy (RT) represents a promising therapeutic strategy in part mediated by the abscopal effect, but clinical experience related to this combination remains scarce (1). Abscopal effects have been observed with association of radiotherapy concomitantly to Ipilimumab (2). Shaverdian *et al.* showed that patients receiving radiotherapy before immunotherapy presented better survival rates (3). Radiotherapy used concomitantly to immunotherapy showed better survival outcomes. But all of series pooled heterogeneous cancer types or lines of treatment (1). Our study evaluated clinical outcomes for patients treated by radiotherapy or not concomitantly to cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) inhibitor ipilimumab in a homogeneous cohort of patients.

#### Material and Methods

Clinical data and patterns of treatment were retrospectively collected from all consecutive patients with metastatic melanoma and receiving ipilimumab after one line of chemotherapy exclusively. Patients receiving Tyrosine Kinase inhibitor or other immunotherapies before Ipilimumab were excluded. Survival data and toxicities

were compared between patients receiving concurrent RT (CIR) or no concurrent irradiation (NCIR). Patients who received RT before immunotherapy were secondly pooled in the analysis.

#### Results

Sixty-three patients received Ipilimumab between June 2007 and May 2017 at our institution. Among these, 50.8% (n=32) received RT before immunotherapy (at least four weeks before immunotherapy) and 20.6% (n=13) received RT concurrently to immunotherapy. Sixty-six % (n=42) received RT both before and/or concurrently to immunotherapy (RT group). RT schedules were heterogeneous. After a 12.0 months median follow-up, median Progression-free survival (PFS) after initiation of immunotherapy for the NCIR group was 3.2 months versus 3.1 months for the CIR group (P=0.863). Overall Survival (OS) was also non-significant between these groups (P=0.141). For RT group (n=42), median PFS were 3.2 months compare to 3.0 months for unirradiated patients (P= 0,802). OS was also non-significant between RT group and unirradiated patients (P=0.080). Acute and late “in-field” or “out-of-field” immunologic toxicity profiles were similar in the two groups.

#### Conclusion

Despite the homogeneity of our series (we selected exclusively all patients receiving Ipilimumab as first-line immunotherapy after chemotherapy), we failed to show that combination of RT and Ipilimumab increase PFS or OS. These results could be explained by the heterogeneity of the RT schedules in our series. However, combination of RT and Ipilimumab were well tolerated and did not increase toxicities rates within and outside the irradiated field.

#### EP-1597 Radiotherapy of monstrous squamous cell carcinoma of the head and scalp in elderly: our series

G. Lazzari<sup>1</sup>, A. Terlizzi<sup>2</sup>, G. Silvano<sup>1</sup>

<sup>1</sup>Azienda Ospedaliera SS. Annunziata Presidio Osped, Radiology, Taranto, Italy ; <sup>2</sup>Azienda Ospedaliera SS. Annunziata Presidio Osped, Physics, Taranto, Italy

#### Purpose or Objective

Squamous cell carcinoma of scalp and skin head is a common clinical tumor in elderly population, mainly complicated by bleeding, necrotic masses with tissue loss. Most of them are very difficult to treat and little has been documented regarding treatment or outcomes due to low survival of these patients (pts). Herein we present our retrospective cases treated with customized electron beam radiotherapy analyzing factors impacting on local control .

#### Material and Methods

Fifty pts entered into this analysis. Elderly pts treated for giant and necrotic T3-T4 squamous skin lesions of the scalp and other skin regions of the head (occipital, face, nasal, retroauricular) between 2005-2015 were retrospectively studied. Age, sex, comorbidity, extension of the lesions, site , deep tissue involvement, necrosis, electron energies and radiation doses were analysed with t-test for univariate analysis assuming p< 0.05 for statistical significance. The Pearsons covariance test was adopted for multivariate analyses. The patients were primarily male (60%) with a median age of 83 years (75-93 years). A total of 60 lesions were treated. There were an high proportion of tumours of the scalp ( 55 %) and lesions with a maximum diameter over mean 6 cm (5- 9 cm) mainly showing a deep tissue involvement with bleeding (40%). Treatment consisted of one field with a customized electron beam. Energies ranged within 8- 15 MeV with or without a customized bolus according to deep involvement which was assessed by a simulation CT scan. The clinical target volume (CTV) was created adding 10 to 20 mm margins around the lesions. The dose schedules were 60 Gy in 30 fractions for lesions over 8 cm maximum diameter and 50 Gy in 20 fractions for the others.

## Results

Median follow up from treatment was 5 years. Bleeding control was obtained in all symptomatic lesions (100%). Local control consisted of a partial regression or resolution of necrotic skin cavities in 70 % of the lesions . A durable ( over 2 years) complete resolution was obtained in 40% of the treated lesions . The 5-year cumulative incidence of local relapse and local progression were 15% and 30% respectively . At univariate analysis statistically significant prognostic factors for local relapse were diabetes, age over 80 years, diameter > 5 cm, necrosis , deep invasion with a tissue loss and site; the scalp was the most significant site for a good and durable local control ( $p < 0.03$ ) ; fractionations and energies were not significant. At Pearson's multivariate the diameter , necrosis and the site were confirmed the most significant poor prognostic factors.

## Conclusion

Customized electron beam radiotherapy for head skin and scalp lesions is effective for palliation as bleeding or resolution with a good local control appearing an easy modality to treat monstrous and complicated lesions of very old population ameliorating quality of life.

### EP-1598 Efficient use of a modified Stanford TSEBT technique in the treatment of MF patients

E. Csiki<sup>1</sup>, M. Simon<sup>1,2</sup>, J. Papp<sup>1,2</sup>, P. Árkosy<sup>3</sup>, Á. Kovács<sup>1,2</sup>  
<sup>1</sup>University of Debrecen Med. and Health Science Centre- Clinic of Oncology, Department of Radiotherapy, Debrecen, Hungary ; <sup>2</sup>University of Pécs- Faculty of Health Sciences, Doctoral School of Health Sciences, Pécs, Hungary ; <sup>3</sup>University of Debrecen Med. and Health Science Centre- Clinic of Oncology, Department of Oncology, Debrecen, Hungary

## Purpose or Objective

Mycosis fungoides (MF) has the highest incidence in cutaneous T-Cell lymphomas, although it is a very rare entity amongst lymphomas. TSEBT is one of the most effective skin directed therapy for MF and can be used after other type of therapies (PUVA, topical steroids, etc.). In early stage disease (IIB) the intent of therapy is curative, at later stages (stage IV) it is mostly palliative to mitigate skin symptoms. We have treated two patients with modified Stanford Total Skin Electron Body Radiotherapy (TSEBT) technique. As a result of their condition these patients are barely suitable to hold the treatment position during treatment. We have developed a method to easily move, treat and re-position the patients during radiotherapy to ensure the effective and safe treatments.

## Material and Methods

During TSEBT entire skin homogeneous radiotherapy is carried out. Patients are irradiated with a nominal 6 MeV energy beam in High Dose Rate mode with a special applicator. In the treatment plane the beam energy decreased to 3.5 MeV, but it was sufficient to treat the skin surface and the underlying tissues. The beam size allowed by the special applicator in the plane of the isocenter was 40X40 cm. Patients were positioned in a special treatment frame, which had a rotating base plate, allowing the staff to easily re-position the patients between positions without removing them from the frame. An 8 mm thick Perspex had been attached to the frame to ensure the desired homogeneity of the electron beam in the treatment plane. The distance between the source and the Perspex was 360 cm, therefore a single beam was not sufficient. We matched two beams horizontally to perform the treatments. Geometrical matching was not plausible because of the extremely wide penumbra, a dosimetrical analysis was necessary to ensure the homogeneous border. The necessary angle to tilt the head was 18.5 °. Both dosimetrical and geometrical

parameters of the matched beams found to be fulfilling the recommendations.

## Results

Between February 2017 and July 2018 we have treated two patients. The first case was a young male patient with Stage IV. MF with erythroderma, Sezary syndrome. The second case was a Stage III. male patient with mental retardation, this circumstance made the treatments even more difficult. Prescribed dose was: 30-36 Gy/1,8-2 Gy at  $D_{max}$ . None of the patients have developed severe (grade III-IV) side effects during or following treatment. We perceived a grade II radio dermatitis in one of the cases, but treatment brake insertion was not necessary. Additional fields were used to complement the soles and perineal regions.

## Conclusion

At 3 months follow-up both patients were in a remission regarding the skin symptoms, no late side effects were observed. The method we implemented in the clinic was suitable to manage and treat both patients with dementia and severe skin symptoms.

### EP-1599 Electronic brachytherapy for non-melanoma skin cancers: preliminary results of a pilot trial

F. Maurizi<sup>1</sup>, G. Capezzali<sup>1</sup>, M. Mazza<sup>1</sup>, C. Blasi<sup>1</sup>, G.L. Moroni<sup>1</sup>, M. La Macchia<sup>1</sup>, A. Ciarmatori<sup>2</sup>, F. Palleri<sup>2</sup>, E. Argazzi<sup>2</sup>, S. Giancaterino<sup>2</sup>, M. Bono<sup>2</sup>, F. Bunkheila<sup>1</sup>  
<sup>1</sup>A.O. Ospedali Riuniti Marche Nord, Radiotherapy, Pesaro, Italy ; <sup>2</sup>A.O. Ospedali Riuniti Marche Nord, Medical Physics, Pesaro, Italy

## Purpose or Objective

Surface electronic brachytherapy (EBT) is an emerging alternative radiotherapy (RT) solution to external beam electron RT and high-dose-rate radionuclide-based brachytherapy for non-melanoma skin cancers. It can also be used as an alternative treatment to surgery for selected patients (pts). This prospective, single-center, non-randomized, pilot trial shows the clinical implementation of a new EBT system named Esteya® evaluating dosimetric features, the clinical safety and efficacy of this approach. Preliminary results are presented.

## Material and Methods

Flatness and symmetry of X-Ray beams have been evaluated using a high definition 2D array equipped of liquid filled ionization chambers. Half Value Layer (HVL), PDD and absolute dose have been measured for each applicator with a soft x-ray parallel plate chamber and solid water. Dose distributions have been compared with the ones calculated for conventional electron treatments (Fig.1). Between November 2016 and August 2018, 47 lesions of 36 consecutive pts (mean age: 78 years, range: 55-96) with non-melanoma malignant skin cancer have been enrolled and analyzed. Fifteen pts presented primary squamous cell carcinomas (SCC) of eyelids and scalp and 12.8 % recurrent SCC of the scalp and nose, 10.6 % showed recurrent basal cell carcinomas (BCC) of the nose and forehead, 44.7 % BCC of nose and temporal area. Only lesions with a maximum diameter < 2,5 cm were treated with radiation dose of 40 Gy (5 Gy fraction, 2/week). Acute toxicity has been measured according to CTCAE (Common Terminology Criteria for Adverse Events) v4.03 scales and RTOG-EORTC scales were used to assess cosmetic results.

## Results

All pts underwent clinical examination and photographs during RT, 4 weeks, 8 weeks, 3 months, and 6 months after treatment. Toxicity started after the 4<sup>th</sup> fraction and worsened between the end and 4-6 weeks after RT. All pts presented erythema: moderate to brisk grade was scored in 66% cases (G2 CTCAE). Moist desquamation and crusting were shown by 6 pts, 2 patient presented moderate edema. Late toxicity was scored in 42.4 % pts: 10 pts showed slight pigmentation changes (G1 Late RTOG-EORTC) and 4 pts presented moderate telangiectasia (G2).

No residual pain has been scored at the site of irradiation. A clinical complete response was observed in 95.7% of cases at 3 months, 2 patient presented residual disease at 3 months. After a median follow up of 6 months (1-21 months), local control rate is 95.6%: 1 patient experienced in-field recurrence at 6 months and one patient marginal recurrence at 4 months.

#### Conclusion

Our preliminary results show that EBT is an effective, simple, safe, and comfortable treatment associated with good cosmetic outcomes for non-melanoma skin cancers. Even if a longer follow-up and a bigger sample size are needed to confirm these preliminary findings, EBT can be an alternative solution for elderly pts, for pts refusing or presenting contraindications for surgery or when surgical treatment would result in a more disfiguring outcome.

**EP-1600 Implementing TG100: an FMEA for superficial radiotherapy at Wellington Blood and Cancer Centre**  
 A. Williams<sup>1</sup>, B. Steer<sup>1</sup>, D. Paterson<sup>1</sup>, J. Evans<sup>1</sup>, R. Dew<sup>1</sup>  
<sup>1</sup>Wellington Blood and Cancer Centre, Radiation Oncology, Wellington, New Zealand

#### Purpose or Objective

Prospective risk analysis is recommended in radiotherapy to identify high risks and implement safety interventions before adverse events occur [1-4]. In this project, a multidisciplinary team (MDT) conducted a Failure Modes and Effects Analysis (FMEA) for superficial radiotherapy (SXR) with the aim to identify risks in our SXR process and to recommend safety interventions for the highest risks. The process for SXR treatments has marked differences to that for MV photon treatments, for example, patient immobilisation is limited, there is no computerised planning on CT datasets, and there is no on-board imaging during treatment, so the results of the FMEA were expected to differ considerably from those of an advance linac-based technique such as IMRT as presented in TG 100 [1].

#### Material and Methods

We followed our department's own FMEA procedure, closely based on that of Ford [5]. It was planned that the MDT meet six times to perform the FMEA: 1) a general FMEA education session, 2) generate the SXR process map, 3) identify possible failure modes (FMs), 4) generate risk priority number (RPN) scores for identified FMs (all FMs were scored twice by different team members), 5) group review of FM scoring, 6) develop safety recommendations.

#### Results

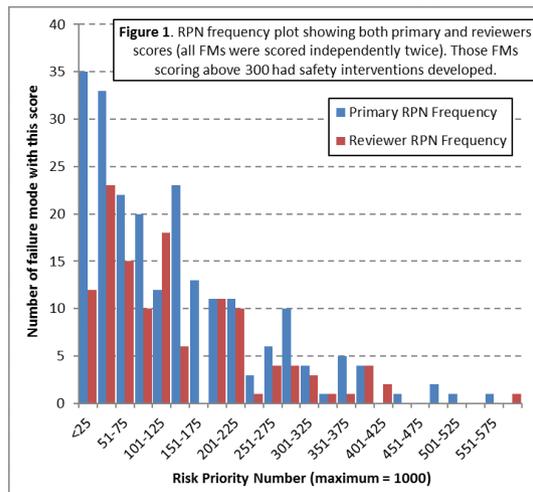

In total, 220 FMs were identified, of which 24 had an RPN greater than 300 (Figure 1) for which the team recommended 27 safety interventions. The recommendations were grouped according to TG100's Table III, *Ranking of QM tools based on effectiveness* as shown in table 1. The top three scoring FMs were 1) Lesion extends into hairline and difficulty seeing the margin, 2) plan parameters and treatment time checked incorrectly and 3) shielding not in place when marking up GTV e.g. under lip, so wrong GTV delineated. The recommended safety interventions for these FMs were 1) hair to be removed from lesion, 2) replace one manual treatment time calculation with a Radcalc QC check, do a reverse treatment time calculation, and scan-in the contour of irregularly shaped cut-outs to a computer for automated equivalent square calculation, and 3) mark-up GTV with shielding / cut-out / applicator in place.

Table 1. Number of interventions grouped according to effectiveness as per TG 100 Table III

QM Tools	Number of interventions (FMs)
1 - Forcing functions	0
2 - Automation and computerisation	5 (9)
3 - Protocols, standards and information	13 (18)
4 - Independent double check systems	1 (3)

5 - Rules and policies  
 6 - Education and information

6 (6)  
 2 (2)

#### Conclusion

The FMEA has facilitated a better understanding of the risks in the SXR process, however, it was time-consuming, requiring around ten hours of meetings (with four more meetings than planned) and many hours of supplementary work outside of the meetings. Listing FMs was challenging and their scoring highly subjective, and some of the recommended interventions e.g. a move to electronic prescribing, will affect our whole radiotherapy service, not just the SXR process.

The recommended interventions for failure modes scoring greater than 300 are now being reviewed by senior management with a view to their implementation.

#### Electronic Poster: Clinical track: Sarcoma

##### EP-1601 Radiotherapy in resectable Intrathoracic Sarcomas. A Rare Cancer Network Study

C. Solé<sup>1</sup>, F. Larsen<sup>2</sup>, M. Terlizzi<sup>3</sup>, P. Sargos<sup>3</sup>, V. Linacre<sup>4</sup>, F. Suarez<sup>5</sup>, Y. Kirova<sup>6</sup>, P. Van Houtte<sup>7</sup>, D. Lerouge<sup>8</sup>, T. Zilli<sup>9</sup>

<sup>1</sup>Instituto de Radiaciones Médicas, Radiotherapy, Santiago, Chile ; <sup>2</sup>Clinica IRAM, Santiago, Chile ; <sup>3</sup>Institut Bergonie, Bordeaux, France ; <sup>4</sup>Instituto Nacional del Torax, Thoracic Surgery, Santiago, Chile ; <sup>5</sup>Clinica Santa Maria, Thoracic Surgery, Santiago, Chile ; <sup>6</sup>Institut Curie, Paris, France ; <sup>7</sup>Institut Bordet, Bruxelles, Belgium ; <sup>8</sup>Centre Baclesse, Caen, France ; <sup>9</sup>Hôpitaux Universitaires de Genève, Geneva, Switzerland

#### Purpose or Objective

Intrathoracic sarcomas (ITS) are considered rare tumors and have a dismal prognosis. We investigated outcomes and risk factors for local control (LC), disease free survival (DFS) and overall survival (OS) in patients with resected non-metastatic ITS treated with or without adjuvant radiotherapy (RT) and or chemotherapy (CT).

#### Material and Methods

Patients from the Rare Cancer Network database were studied. Kaplan Meier estimate was used to assess survival curves and Cox proportional hazards regression was used to assess risk factors for LC, DFS and OS.

#### Results

Between 2000 and 2017, 121 patients met inclusion criteria. Primary site was lung in 30%, mediastinum 34% and pleura in 36%. 39 % and 32% received RT and CT. Median follow-up was 34 months (range, 2-141). Local control, DFS and OS at 10 years was 52%, 18.7% and 7.2%, respectively. In multivariate analysis RT (P=0.003) and R1 margin status (P=0.041) retained a significant association with local control. Only R1 resection (P=0.002) remained associated with a decreased risk of death in multivariate analysis. Overall, 7 patients (6%) developed grade 3 treatment-related chronic toxicity events

#### Conclusion

This joint analysis revealed that OS remains modest in this group of patients, mainly given by the high risk of local and distant failure. Our results suggest that resected ITS can benefit from adjuvant RT.

#### EP-1602 Role of clinical networks in sarcomas: The Scottish Sarcoma Network(SSN)Experience

J. Nixon<sup>1</sup>, F. Cowie<sup>1</sup>, J. White<sup>2</sup>, P. Chong<sup>3</sup>, S. Lo<sup>4</sup>, D. Bodie<sup>5</sup>, L. Hayward<sup>6</sup>, M. Ferguson<sup>7</sup>, L. Campbell<sup>8</sup>

<sup>1</sup>the beatson west of scotland cancer centre, Oncology, glasgow, United Kingdom ; <sup>2</sup>the beatson west of scotland cancer center, oncology, glasgow, United Kingdom ; <sup>3</sup>gartnaval hospital, surgery, glasgow, United Kingdom ; <sup>4</sup>glasgow royal infirmary, plastic surgery, glasgow, United Kingdom ; <sup>5</sup>aberdeen royal infirmary, surgery, aberdeen, United Kingdom ; <sup>6</sup>edinburgh cancer center, oncology, edinburgh, United Kingdom ; <sup>7</sup>nhs tayside, oncology, dundee, United Kingdom ; <sup>8</sup>national health services, nsd, glasgow, United Kingdom

#### Purpose or Objective

The Scottish Sarcoma Network(SSN) is one of the few National Managed Clinical Networks (MCNs) in Scotland. It was established in November 2004 with its core aim being to improve communication and collaboration between treating centres and promote patient care for sarcoma patients across Scotland. MCNs are virtual entities designed to drive upwards the standards of patient care through integration of services and collaboration. They are defined as "linked groups of health professionals and organisations from primary, secondary and tertiary care, working in a co-ordinated manner, unconstrained by existing professional and Health Board boundaries, to ensure equitable provision of high quality clinically effective services throughout Scotland." We aim to share our experience to achieve better care for sarcoma patients across Scotland.

#### Material and Methods

The National Network Lead rotates across centres and works closely with the National Manager, Subspecialty Leads and sub-groups, NHS staff, patients, carers, charities, Universities and Local Authorities to enhance patient care.

Ambition and Action (2016) details a commitment to delivering the national cancer quality programme across NHS Scotland, with a recognised need for national cancer Quality Performance Indicators(QPIs) to support a culture of continuous quality improvement. The sarcoma QPIs were implemented for patients diagnosed in 2014/15, refined based on the first year's results and reported for years two and three, reviewed after three years and will be reported for year four in December 2018. A weekly National Sarcoma MDT hosted by the SSN is ensuring same standards of care for all sarcoma patients. SSN plays a pivotal role in the QPI process and decision making regarding steps towards continuous improvements. In addition, three education days are organised by the network and are hosted in each of the

three regions treating sarcoma patients across Scotland. Medical Education is used by the network to promote clinical excellence, share clinical practice in transparency and learn through mistakes. A Mortality and Morbidity session is introduced into each of the education days to enable all members of the network to share their practices and share key learning points with peers.

#### Results

The data on QPIs is collected locally by each NHS Board and the analysis is performed locally, regionally and nationally with the resultant actions being assigned to the local NHS Board, the sarcoma specialist centre (there are five) or the Scottish Sarcoma Network. Education sarcoma days are well attended and based on evaluation are connecting specialists and health care professionals with patients, carers, charities, universities and local authorities, all working along the lines of promoting care and raising awareness for sarcomas.

#### Conclusion

SSN is an example that successful networking, which is enhanced through the education days can utilise limited resources by coordination and collaboration to provide best possible and uniform services closer to patient's home in challenging geographical circumstances.

#### EP-1603 Survival after adjuvant radiotherapy for aggressive fibromatosis depend upon time and B-catenin

J.S. Kim<sup>1</sup>, H.J. Kim<sup>1</sup>, M. Lee<sup>2</sup>, K.C. Moon<sup>3</sup>, S.G. Song<sup>3</sup>, H. Kim<sup>4</sup>, I. Han<sup>4</sup>, I.H. Kim<sup>1</sup>

<sup>1</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>Hallym University College of Medicine, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Seoul National University Hospital, Department of Pathology, Seoul, Korea Republic of ; <sup>4</sup>Seoul National University Hospital, Department of Orthopaedic Surgery, Seoul, Korea Republic of

#### Purpose or Objective

We identified the prognostic factors influencing progression-free survival (PFS) of patients with aggressive fibromatosis (AF) after postoperative radiotherapy (PORT). We also assessed the correlation between immunohistochemistry (IHC) features of B-catenin/SMA and PFS.

#### Material and Methods

The records of 37 patients with biopsy-proven AF treated by PORT from 1984 to 2015 were retrospectively reviewed. Fifteen patients underwent wide excision for AF and 22 patients received debulking operation. The median total dose of PORT was 59.4 Gy. IHC of B-catenin and SMA were evaluated in available 11 and 12 patients, respectively. IHC staining intensity was graded and compared between low and high intensity. Log-rank test and Cox proportional hazard model were performed.

#### Results

The median follow up duration was 105.9 months. The 5-year PFS rate was 70.9%. The tumor size and margin status were not related to PFS in univariate analysis (p=0.197; p=0.716, respectively). Multivariate analysis showed that increased interval from surgery to PORT was independent risk factors for PFS (HR 1.303, 95% CI 1.023-1.650, p=0.032). PORT after recurrence had marginal significance (HR 7.550, 95% CI 0.964-59.110, p=0.054). Patient with 2 risk factors, AF recurrence and interval from surgery to PORT >5 weeks, had significantly lower 5-year PFS than patients with no risk factor (43.8% vs. 100.0%, p=0.022). Nuclear B-catenin intensity had a tendency to inversely correlate with 5-year PFS, although it did not have statistically significance (low intensity, 44.4% vs. high intensity, 100.0%, p=0.260). SMA intensity was not related to PFS (p=0.700).

#### Conclusion

PORT should be performed immediately after surgery as initial treatment of choice, irrespective of margin status and tumor size. B-catenin staining intensity of IHC might correlate with local recurrence. Further investigations to validate its prognostic value are needed.

**EP-1604 Feasibility of preoperative radiotherapy in localized sarcoma of the limb: a single center experience**

B. Durand<sup>1</sup>, G. Decanter<sup>2</sup>, M. Jafari<sup>2</sup>, W. Tessier<sup>2</sup>, Y. Robin<sup>3</sup>, A. Renaud<sup>4</sup>, M. Ben Haj Amor<sup>4</sup>, L. Basson<sup>5</sup>, D. Pannier<sup>6</sup>, T. Ryckewaert<sup>6</sup>, N. Penel<sup>6</sup>, A. Córdoba Largo<sup>7</sup>  
<sup>1</sup>Centre Oscar Lambret, Department of Radiotherapy, Lille, France ; <sup>2</sup>Centre Oscar Lambret, Surgery Department, Lille, France ; <sup>3</sup>Centre Oscar Lambret, Pathology department, Lille, France ; <sup>4</sup>Centre Oscar Lambret, Imaging department, Lille, France ; <sup>5</sup>Centre Oscar Lambret, Academic Radiation Department, Lille, France ; <sup>6</sup>Centre Oscar Lambret, Medical Oncology department, Lille, France ; <sup>7</sup>Centre Oscar Lambret, Department of Radiation Oncology, Lille, France

**Purpose or Objective**

To report feasibility and first clinical and toxicity data from a retrospective series of patients treated with the association of preoperative radiotherapy and radical surgery for a localized sarcoma in the limbs in our referenced center.

**Material and Methods**

All patients with soft tissue sarcoma of the limbs treated consecutively in our institution by preoperative radiotherapy and surgery combination. The combined treatment of preoperative radiotherapy and surgery was decided in a multidisciplinary consultation meeting depending on the histological type, the relationship of the tumor to the blood vessels and the size of the tumor. Principal objective: Feasibility of pre-operative radiotherapy followed by surgery at 4-6 weeks; Secondary: Resection quality (R0, R1, R2), Post-operative complication rate, Survival without local recurrence, Histological response (necrosis rate) to preoperative radiotherapy.

**Results**

31 patients were enrolled on a 4-year period. In 25 patients (80.6%) tumor was in lower limb. Vascular relation < 5mm on MRI was observed in 19 patients (61.3%), 27 patients (87.1%) were classed T2b and the median largest axis was initially 12 cm (1.7-30), the median depth was 7cm. Initial biopsy was performed in our center in 22 patients (71%). Histology based on biopsy was: sarcoma indifferenced in 11 patients (35.5%), adipocytic tumor in 10 patients (32.3%) and autre in 10 patients (32.3%). Preoperative radiotherapy delivered 45 to 50,4 Gy at 1,8 Gy fractions; IMRT for 26 patients (83,9%) and 3D-CRT for 5 (16.1%) patients. All patients were operated with a conservative intent with 49 days (24-83) median after the end of the radiotherapy. In 28 patients, (90.3%) we performed image, MRI in 25 (89.3%) patients or CT (9.7%) in 3 patients, before surgery. In 25 patients (80.6%) surgery was R0 and in the other six patients (19.4%) was R1. Histology after surgery was: sarcoma indifferenced in 13 patients (41.9%), adipocytic tumor in 9 patients (29%) and autre in 9 patients (29%). Flap was needed in 11 patients (35.5%), 5 (16.1%) immediately and 6 (19.4%) remote flap because delayed healing. Bone fracture was observed in 3 patients (9.7%). Three patients presented chronic pain (1 patient grade 1 and 2 patients grade 2). At the end of our median follow-up of 18 months, there were 6 relapses, 5 metastatic and 1 local), 2 of them died of the disease evolution.

**Conclusion**

Preoperative radiotherapy in locally advanced sarcoma of the limb is feasible, when achieved in a reference center, with a satisfactory early clinical and toxicity data.

**EP-1605 Adjuvant RT for soft tissue sarcomas: volumetric modulated arc therapy vs 3D conformal radiotherapy**

L. Di Brina<sup>1</sup>, P. Navarria<sup>1</sup>, G.R. D'Agostino<sup>1</sup>, F. De Rose<sup>1</sup>, C. Iftode<sup>1</sup>, E. Clerici<sup>1</sup>, F. Lobefalo<sup>1</sup>, A. Bertuzzi<sup>2</sup>, V. Quagliuolo<sup>3</sup>, M. Scorsetti<sup>4</sup>

<sup>1</sup>Humanitas Clinical and Research Center, Radiotherapy and Radiosurgery, Rozzano, Italy ; <sup>2</sup>Humanitas Clinical and Research Center, Medical Oncology, Rozzano, Italy ; <sup>3</sup>Humanitas Clinical and Research Center, Surgical Oncology, Rozzano, Italy ; <sup>4</sup>Humanitas University, Biomedical Sciences, Rozzano, Italy

**Purpose or Objective**

Soft tissue sarcomas (STS) represent rare tumors of mesenchymal origin, frequently detected to the extremities. Nowadays limb-sparing surgical resection followed by radiation therapy (RT) is considered the standard treatment in large, high-grade sarcomas. Recent RT technological advances allow to improve the tumor coverage with maximum sparing of normal tissues. Aim of this study is to assess the impact of VMAT compared with 3DCRT in patients with diagnosis of STS of the extremities and treated with surgery and adjuvant RT in terms of toxicity, local control (LC), disease free survival (DFS) and overall survival (OS).

**Material and Methods**

This analysis included patients with diagnosis of STS of the extremity treated with limb-sparing surgery and submitted to adjuvant RT for one or more of the following risk factors: deeply located tumors, grade II-III, maximum diameter larger than 5 cm and marginal surgical resection. From 2004 to 2010 plans were processed using 3DCRT. Starting from 2011 to 2016, all patients were treated with VMAT. Response was recorded with contrast-enhanced MRI and thoracic and abdominal CT scan every 3 months. Toxicity was evaluated with Common Terminology Criteria for Adverse Events (CTCAE) scale version 4.3.

**Results**

From 2005 to 2016, 109 patients were treated in our center and included in the analysis. Median age was 55 years (range 15-84 years). The majority of patients had disease of the lower extremity (95 patients, 87%). The most frequent histotype was liposarcoma (57,7%). Fifty-three patients received chemotherapy (CT). Radical surgical resection was performed in 76% of patients, 24 patients received R1 resection and 2 patients R2. 3DCRT was performed in 38 cases and VMAT in 71 cases. The administered total dose was 66 Gy in 33 fractions. Median follow-up was 70 months for the entire cohort, 121 months for the 3DCRT group, 61 months for the VMAT group. Actuarial LC at 3 years were 83.0% in 3DCRT group and 92.7% for patients in VMAT group. Actuarial DFS at 3 years were 74.0 % and 79.2% for patients who underwent 3DCRT and VMAT respectively. Actuarial OS at 3 years were 70.0% for patients who underwent 3DCRT, and 79.2% for VMAT group. Grade 1-2 acute skin toxicity occurred in 58% of the patients in 3DCRT group and 48% of VMAT group. One patient in each group presented grade 3 acute skin toxicity. Late toxicity was recorded in 38 patients (35%): nine patients treated with 3DCRT had grade 1 toxicity while in VMAT group 17 patients and 1 patients had G1-G2 and grade 4 skin toxicity respectively. Between VMAT patients 4 of them had G1 joint toxicity. Only margins and grade were significant factors for LR after univariate analysis (p=0.002). The technique influenced significantly OS both at univariate and multivariate analysis (p=0.006).

**Conclusion**

The availability of modern RT technique permit a better conformity on the target with maximum sparing of normal tissue and acceptable side effects. Results on local control and survival of VMAT are encouraging. More perspective

studies are needed to better define the use of arc therapy in this setting of patients.

#### EP-1606 Stereotactic Ablative Radiotherapy for oligometastatic soft tissue sarcoma patients

D. Greto<sup>1</sup>, M. Loi<sup>1</sup>, D. Pezzulla<sup>1</sup>, M. Lo Russo<sup>1</sup>, M.A. Teriaca<sup>1</sup>, V. Maragna<sup>1</sup>, S. Lucidi<sup>1</sup>, D.A. Campanacci<sup>2</sup>, G. Beltrami<sup>2</sup>, G. Scoccianti<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence-Azienda Ospedaliera Universitaria Careggi AOUC, Department of Biomedical- Experimental- and Clinical Sciences, Firenze, Italy ; <sup>2</sup>Azienda Ospedaliera Universitaria Careggi- University of Florence, Department of Orthopaedic Oncology and Reconstructive Surgery, Florence, Italy

#### Purpose or Objective

Stereotactic Body Radiotherapy (SBRT) is emerging as a novel treatment option in oligometastatic cancer patients ( $\leq 3$  synchronous lesions), but it is unclear whether this treatment option could be applied to bone and soft tissue sarcoma due to theoretical intrinsic radioresistance. The aim of our study was to evaluate the effectiveness and safety of SBRT in oligometastatic sarcoma.

#### Material and Methods

We collected data from a consecutive cohort of oligometastatic sarcoma patients treated in our Institution. Toxicity, Local Control (LC) rates and prognostic role of clinical and treatment-related characteristics (primary tumor type and location, synchronous or metachronous onset, SBRT site, dose delivered expressed as Biologically Effective Dose [BED], use of concurrent systemic treatment) were assessed.

#### Results

Thirty-four consecutive patients, accounting for 56 metastases (including 38 lung, 16 bone and 2 lymph node metastases), were treated at our institution with SBRT. Eight (23.5%) patients had metastatic disease at diagnosis. Nine (26.5%) patients in treatment with chemotherapy for metastatic disease received associated SBRT in case of oligoprogression. Median follow-up from first SBRT was 10 months (range 1-112). Median number of metastases treated per radiation course was 2 (range 1-3). Median number of SBRT fractions was 4.5 (range:3-12). Median prescribed dose was 40 Gy (range: 25-54 Gy) and median BED was 75 Gy (range 48-151). LC at 6 months, 1 year and 2 years was 85.4% [CI95% 73.8-92.4], 82.3 [CI95% 69.1-90.6], and 73.6% [CI95% 56.8-86.5] respectively. At statistical analysis, only trunk primary tumor identified patients with poorer LC ( $p=0.02$ ). Fifteen patients received 2 courses of SBRT while 1 patient received 3 courses of SBRT. No acute or chronic grade  $\geq 3$  toxicity was observed in the treated site, only 2 patients experienced minor toxicity consisting of 1 acute grade 1 skin reaction and 1 grade 1 late fibrosis, respectively.

#### Conclusion

In patients with oligometastatic sarcoma, SBRT yields satisfying LC with minimal toxicity regardless of concurrent treatment, metastasis timing location, and dose schedule. Repeated SBRT is feasible and may be considered to extend disease-free interval.

#### EP-1607 Preoperative Radiation Therapy and IORT in Retroperitoneal Soft Tissue Sarcomas. Long Term Outcome

Aviano, Italy ; <sup>5</sup>Centro di Riferimento Oncologico CRO - IRCCS- Aviano- Italy, Medical Oncology, Aviano, Italy ; <sup>6</sup>Centro di Riferimento Oncologico CRO - IRCCS- Aviano-Italy, Pathology, Aviano, Italy ; <sup>7</sup>Centro di Riferimento Oncologico CRO - IRCCS- Aviano- Italy, Cancer Epidemiology, Aviano, Italy

#### Purpose or Objective

Local control in patients (pts) with RPS is still challenging. Local recurrence after gross total resection remain the major issue. To improve local control radiation therapy (RT) was used. Post-op RT was not successful due to limited dose-tolerance of surrounding normal structure. Pre-op RT and IORT, allowing dose-escalation to high risk areas after resection, could overcome such limitations. Their use has been evaluated at our Institution.

#### Material and Methods

Long-term outcome of a consecutive series of 93pts(M/F ratio 50/40, median age 60yrs range 24-81) treated with preop RT +/-IORT at our Institute, from February 1999 to December 2017, is reported. Three pts had R2 resection and were excluded from this analysis. Fifty-five had primary 35 had recurrent disease. Pre-op RT consisted of 45-50.4 Gy in 25-28 frs after through-cut biopsy or initial operation. Conformal 3D-RT was used to include the tumor with a 3-5 cm margin (PTV1) with 45 Gy, followed by a reduced volume with a 2 cm margin (PTV2) up to 50.4 Gy. Concurrent chemotherapy (CT) with 3 cycles of c.i. Ifosfamide (1 gr/mq for 14 days, q 4 wks) was given to 31pts From 2012, IMRT with 45Gy/25frs and a SIB up to 52.5 Gy to posterior area at high risk, was used to optimize RT program. Pre-op RT ( $\pm$  CT) was followed by surgical resection after 4-6 weeks. A IORT boost was given to high risk area, if applicable, with a dose ranging from 10-18 Gy based on the completeness of surgical margins. Median tumor size was 16 cm (3-33 cm) and the most common histotypes were Liposarcoma (55%) and Leiomyosarcoma (21%). Tumor grade was G1:28.8%, G2: 27.7% and G3: 43.5%.

#### Results

All pts completed the planned pre-op RT at the median dose of 50.4 Gy (range 45-52.5Gy). Tolerance to pre-op RT was acceptable with G3 toxicity (15%) only in pts who received concurrent CT. Surgical operation was performed in all 90 with complete gross total resection in all operated pts. IORT at the median dose of 12 Gy (10-15Gy) was given to 79 of 90 resected pts. IORT was not given to 11 pts, in 3 because of wide complete resection and in 8pts for IORT technical reasons. At a median follow-up of 3.5 years (02-18 years) the cancer specific survival (CSS), LDFS and DFS were 57.1%, 54.6% and 41.1% respectively. Status of surgical margins, R0 vs R1, resulted of borderline significant for LDFS (71.4% vs 41.4% and 65% vs 37.3% at 5 and 10 yrs, respectively,  $p=0.047$ ). In the subset of 11 no-IORT pts, no difference in LDFS was reported. Complications occurred in 2 pts (3%) who had bowel perforation after pre-op RT  $\pm$  CT; 4 pts (10%) developed G2-3 IORT related neuropathy and 3 pts (3.3%) IORT urethral injury.

#### Conclusion

Pre-op RT and IORT in RPS was feasible with an acceptable toxicity profile. This approach allows a favourable complete resection rate and long-term outcome in disease control and survival with low rate of complications. IORT allows dose escalation to high-risk areas and in pts with R0 resection yields excellent local tumor control.

#### EP-1608 Results of an aggressive local strategy after R1 or R2 unplanned surgery for soft tissue sarcomas

P. Paul<sup>1</sup>, M. Laurence<sup>2</sup>, V. Gualter<sup>3</sup>, R.C. Isabelle<sup>4</sup>, M. Pierre<sup>3</sup>, B. Jean Yves<sup>4</sup>, P. Patrice<sup>3</sup>, B. Mehdi<sup>4</sup>, K. Marie<sup>5</sup>, D. Armelle<sup>4</sup>, S. Marie Pierre<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiation Oncology, Lyon, France ;

<sup>2</sup>CHRU Besançon, Radiation Oncology, Besançon, France ;  
<sup>3</sup>Centre Léon Bérard, Surgery, Lyon, France ; <sup>4</sup>Centre  
 Léon Bérard, Medical Oncology, Lyon, France ; <sup>5</sup>Centre  
 Léon Bérard, Pathology, Lyon, France

#### Purpose or Objective

To compare outcomes of soft tissue sarcomas (STS) with and without residual disease subsequent to re-excision in our institution after primary unplanned surgery.

#### Material and Methods

Between 1996 and 2015, 180 patients with extremities or trunk wall STS were referred to our center after unplanned R1 or R2 surgery for local treatment including re-excision with or without post-operative irradiation. Cutaneous and lipoma-like sarcomas were excluded. Re-excision was considered R0 if margins were  $\geq 1$  mm and R1 when margins were closer. Re-excision found microscopic residual disease in 93 patients, and no residual disease in 87 patients. Median time between unplanned surgery and re-excision was 2 months (range 1-8). Adjuvant radiotherapy was performed for 133 patients (74%) with a median delivered dose of 50 Grays in 25 fractions.

#### Results

Median follow-up was 78 months (range 3-244). Median age was 62 years old. In the group of patients with residual disease (R group), STS were more likely to be of higher grade ( $p=0.043$ ) and larger volume ( $p<0.01$ ) than the group of patients without residue (No-R group). Radiotherapy was more frequently performed in R group (74/93 patients) than No-R group (59/87 patients) ( $p=0.045$ ). In R-group, re-excision was R1 for 65% of patients and R0 for 35%. Achieving R0 margins was associated with better LRFs, MFS, DSS and OS on univariate ( $p=0.024$  for LRFs) and multivariate analysis ( $p=0.027$  for LRFs); grade 3 sarcomas were associated with worse MFS on multivariate analysis ( $p=0.044$ ).

Whether or not residual disease was remaining at the time of re-excision did not impact local-recurrence-free survival (LRFs), which was similar in the 2 groups : 62.4 months in R-group vs 73.4 months in No-R group ( $p=0.092$ ). In an analogous way, metastasis-free survival (MFS), overall and disease-specific survival (OS and DSS) were not different in the 2 compared groups.

In No-R group, radiotherapy was associated with better LRFs on univariate analysis ( $p=0.014$ ); tendency to better LRFs was observed on multivariate analysis ( $p=0.08$ ); grade 3 sarcomas had worse MFS on univariate analysis ( $p=0.014$ ).

#### Conclusion

Achieving R0 re-excision after primary unplanned surgery is essential. Our results suggest that radiotherapy should be performed after re-excision even if no residual disease is observed.

#### Purpose or Objective

In pediatric patients, permanent alopecia occurred in a grave late complication of multi-drug chemotherapy (CTx) plus cranial irradiation, reducing both patient self-esteem and quality of life. To prevent permanent alopecia, we started to use craniospinal irradiation (CSI) using the volumetric-modulated arc whole-brain radiotherapy (VMAT-WBRT) for pediatric patients, and their hair had fully recovered without disease progression. As the threshold to prevent permanent alopecia is still unknown, we evaluated the dose distribution of VMAT-WBRT and compared the dosimetric parameters between VMAT-WBRT and conventional whole-brain radiotherapy (WBRT).

#### Material and Methods

Four consecutive patients (4-11 years old) who received CSI using VMAT-WBRT from June 2015 to December 2016 were included. One patient with embryonic carcinoma received radiotherapy (RT) with concurrent CTx; three patients with medulloblastoma (two patients with standard risk, and one patient with high risk) received RT followed by CTx. The prescribed doses of CSI were 23.4-35.2 Gy in 13-22 fractions, respectively. 5 mm thickness of the hair follicles bearing scalp was created (Fig. A). VMAT-WBRT was delivered with double arcs, and optimization was performed to reduce doses to the hair follicles with keeping the dose coverage to the planning target volume. For the dosimetric study, the conventional WBRT plans were retrospectively created, and the dose distributions were compared between VMAT-WBRT and conventional WBRT. Doses to the planning target volume for whole brain [PTV(WB)] and organs at risk (OARs), including hair follicles, cochlea, lacrimal glands, lens, eyes, parotid glands, oral cavity, hypopharynx, and thyroid, were evaluated.

#### Results

Although all patients experienced temporary alopecia, their hair fully recovered over the whole scalp within 8 months after finishing RT. None had disease progression at least 23.9 months after completing CTx or RT. In the dosimetric study, the mean doses to the hair follicles, parotid glands, and left lacrimal glands were lower in the VMAT-WBRT group. On the other hand, the mean doses to the oral cavity, hypopharynx, and thyroid were higher in the VMAT-WBRT group than in the conventional WBRT group. The average mean equivalent doses in 2-Gy fractions (EQD2) to the hair follicles were 19.5 and 13.3 Gy in the conventional WBRT and VMAT-WBRT groups, respectively. In this study, the mean EQD2 to the hair follicles of all patients who received VMAT-WBRT were lower than 15.1 Gy. The D2 of other OARs and the D2, D98, D50, mean doses, V90, V95, and V107 of PTV(WB) were similar between the two groups.

Rt. parotid gland	mean (%)	93.6 ± 5.8	50.2 ± 8.7	0.002
Lt. parotid gland	mean (%)	93.7 ± 5.8	50.1 ± 11.3	0.006
Bilateral parotid gland	mean (%)	93.7 ± 5.8	50.1 ± 9.8	0.003
Rt. lacrimal gland	mean (%)	93.8 ± 7.3	64.4 ± 6.2	0.125
Lt. lacrimal gland	mean (%)	91.9 ± 5.8	60.3 ± 9.0	0.002

Abbreviations: WBRT, whole brain radiotherapy; VMAT-WBRT, volumetric-modulated arc whole brain radiotherapy; SD, standard deviation; DX (%) means the relative dose to the X % of the PTV or the organs at risk; VX (%) means the relative volume of the PTV receiving X % of the prescribed dose; Rt., right; Lt., left.

## Conclusion

Our study showed that the mean EQD2 to the hair follicles lower than 15.1 Gy seemed to be associated with prevention of permanent alopecia. More cases are needed to verify the efficacy and more accurate threshold to prevent permanent alopecia for pediatric patients who receive multi-drug CTx and cranial irradiation.

## EP-1610 Cranio Spinal Axis irradiations using Pencil Beam Scanning: the PSI experience

D. Siewert<sup>1</sup>, F. Belosi<sup>1</sup>, R. Gonzalo Gleyzes<sup>1</sup>, L. Mikroutsikos<sup>1</sup>, D. Correia<sup>2</sup>, A. Pica<sup>1</sup>, F. Albertini<sup>1</sup>, A.J. Lomax<sup>1</sup>, D.C. Weber<sup>1</sup>, A. Bolsi<sup>1</sup>

<sup>1</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland ; <sup>2</sup>Bern University Hospital, Department of Radiation Oncology- University of Bern, Bern, Switzerland

## Purpose or Objective

Cranio Spinal Irradiation (CSI) is a promising indication for pencil beam scanning (PBS) proton therapy. In this study we present the clinical and dosimetric evaluation of CSI treatments delivered at PSI, with special focus on tumour recurrences.

## Material and Methods

20 CSI patients, treated between 2004 and 2017, have been included in this study. 17/20 were positioned prone (Gantry1), and 3 supine (Gantry 2). The primary tumors were: medulloblastoma (10pts), PNET (4pts), anaplastic ependymoma (3pts), choroid plexus carcinoma (1pt) and others (2pts). 3 of 20 patients received CSI for local failure after a first course of local fractionated RT, thus requiring accurate sparing of pre-irradiated brain tissue. Daily imaging was performed based on orthogonal topograms acquired once along the full length of the spine before delivery, and a single positioning correction vector for the entire CSI PTV applied. Dose delivery on the other hand consists of a number of patched subfields. As such, inaccuracies of couch movements between sub-fields during delivery might result in under- or over-dosage. For all cases we analysed: i) planning approach; ii) target coverage (V95, D98) and OAR sparing; iii) dose averaged LET distributions and iv) robustness (range errors and set-up scaling for fractionation). Accuracy of prone (G1) vs. supine (G2) setup was evaluated. During follow-up, 6 patients (30%) presented with tumor recurrences, of which 5 (25%) could be considered high risk patients at diagnosis - 3 with leptomeningeal dissemination at the time of CSI, 1 with a recurrent PNET at the time of irradiation and one case where the tumor was an "in-field" relapse of an anaplastic ependymoma after re-irradiation. For all 6 relapsing patients, a detailed localization of the recurrence and any spatial relationship with field patching was performed.

## Results

Clinical dosimetric data are summarized in Table 1. Supine positioning resulted in lower systematic and random errors as compared to prone (systematic residual errors < 0.1mm for supine as compared to 0.5mm for prone; random errors in PA direction were reduced from 1.7mm for prone to 1.1mm for supine). For the relapsing patients, the recurrences did not overlap with patch lines and were not correlated with setup or range error. Indeed, all recurrences were either located in the high risk PTV or were leptomeningeal dissemination. We observed two vascular radiation induced toxicities: one with Moya-Moya syndrome and one with multiple cerebral cavernomas. These observed vascular toxicities were not related to high-LET areas.

## Conclusion

PBS CSI treatments can be safely delivered, as the plans are robust considering range and setup uncertainties. The pattern of recurrences was not correlated with potential dose inaccuracies in the patch lines or lack of robustness, and no correlation of toxicities to enhanced LET have been observed.

### EP-1611 Experience of uninterrupted radiotherapy for pediatric hodgkin's disease in a developing country

B.M. Qureshi<sup>1</sup>, Y. Ahmed<sup>1</sup>, F. Shaikat<sup>1</sup>, A.N. Abbasi<sup>1</sup>, M.R. Khan<sup>2</sup>, M.A. Mansha<sup>1</sup>, M.U. Karim<sup>1</sup>, A. Hafiz<sup>1</sup>, A.M.H. Khan<sup>1</sup>, B. Mir Khan<sup>1</sup>, N. Ali<sup>1</sup>, M.S. Ashraf<sup>3</sup>

<sup>1</sup>The Aga Khan University, Radiation Oncology Section- Department of Oncology, Karachi, Pakistan ; <sup>2</sup>The Indus Hospital, Department of Pediatric Oncology- Indus Children Cancer Hospital, Karachi, Pakistan ; <sup>3</sup>The Indus Hospital-, Department of Pediatric Oncology- Indus Children Cancer Hospital, Karachi, Pakistan

#### Purpose or Objective

Radiation therapy is an essential component of patients treated on Euronet protocol who have not responded to initial chemotherapy. The Purpose of the study is to report the planning and delivery experience of radiation therapy for pediatric Hodgkin's disease patients at our tertiary care university hospital in Pakistan.

#### Material and Methods

All the patients with Hodgkin's disease are discussed in site specific pediatric leukemia / lymphoma tumor board meeting. Patients having residual disease on interim evaluation after initial cycles of chemotherapy are treated with radiation therapy after the completion of appropriate chemotherapy according to treatment group. Radiation therapy is planned and delivered according to radiotherapy guidelines of Euronet PHL-C1 study treatment protocol. Children requiring radiation therapy are treated with a dose of 19.8 Gy in 11 fractions to the initial involved site with 1.8 Gy per fraction. A boost of 10 Gy in 5 fractions with 2 Gy per fraction is given to the residual disease seen on interim scan.

#### Results

From January 2017 till October 2018, a total of 18 patients of Hodgkin's disease were identified who required

radiotherapy according to the protocol. Out of 18 children, 14 (78%) were male and 4 (22%) were females. Mean age of the children was 11 years (6 - 17years).

All the patients were discussed in departmental peer review meeting with at least two radiation oncologists and a team of residents before starting radiotherapy. A total of 14 patients (77.8%) received both supra and infra diaphragmatic radiotherapy while two patients each had supra diaphragmatic and infra diaphragmatic radiation alone in phase I with total dose of 19.8Gy.

Out of 14 patients who received radiation to both supra and infra-diaphragmatic regions, 9 (64%) patients received simultaneous supra & infra diaphragmatic radiation whereas 5 (35.7%) received sequential radiotherapy to the other region.

Neck was irradiated in 16 (88.9%) patients, among them 9 patients received bilateral neck radiation. RT to axilla was given in 13 (72.2%) patients out of which bilateral axilla was treated in 9 patients. Spleen was treated in 12 (66.7%) patients. A phase II boost of 10 Gy was given to the regions of neck in 8 patients, axilla to 3 patients and spleen to 3 patients.

None of these patients had a treatment gap during the course of radiation therapy. Also, no severe acute hematologic toxicity was observed after completion of treatment.

#### Conclusion

Radiation therapy for children with Hodgkin's disease was planned by peer reviewed team and delivered according to the protocol without any treatment interruption. Long term toxicity needs to be evaluated, possibly in a larger prospective study.

### EP-1612 Radiation induced hypothyroidism in pediatric tumours of central nervous system

<sup>1</sup>University of Genoa and San Martino Hospital, Health Science Department DISSAL and Radiation Oncology, Genoa, Italy ; <sup>2</sup>San Martino Hospital, Radiation Oncology, Genoa, Italy ; <sup>3</sup>Istituto Giannina Gaslini, Department of Pediatrics, Genoa, Italy ; <sup>4</sup>Istituto Giannina Gaslini, Department of Neurooncology, Genoa, Italy ; <sup>5</sup>Istituto Giannina Gaslini, Epidemiology and Biostatistics Unit, Genoa, Italy

#### Purpose or Objective

To investigate primary and secondary hypothyroidism in pediatric patients affected by central nervous system (CNS) tumors.

#### Material and Methods

From January 1999 to September 2015 we retrospectively analyzed all patients with CNS tumors treated by IMRT or 3D-CRT. We analyzed hypothyroidism from direct thyroid damage (primary hypothyroidism) with FT4 value and hypothyroidism from direct damage to the pituitary gland and hypothalamus (considering them as a single organ at risk - central hypothyroidism) with TSH detection.

#### Results

Sixty-four consecutive pts with a median age of 10 years (range: 2 to 17) were identified. Nineteen (29,7%) and 45 (70,3%) pts received IMRT and 3DCRT respectively. 39 (60.9%) patients underwent craniospinal irradiation (CSRT) ± boost; all other patients were treated with involved field radiation therapy (IFRT) ± boost (39.1%). Histology was represented by medulloblastoma, gliomas, germinoma, ependymomas and others in 50%, 26.5%, 11%, 4.6% and 7.8% of patients, respectively. Sixty-one (95,3%) patients received chemotherapy (CT) and 42 (65,6%) patients surgery. Thyroid dose evaluation was possible in 20 of 39 patients who received CSRT, whereas a documented pituitary gland dose was available in 64 pts. 19/64 pts presented a TSH deficit and 6/64 FT4 deficit. Sixteen of 19 patients with TSH deficiency were treated with CSRT (dose

range: 23.4 to 39.0 Gy)  $\pm$  boost, and 3/19 with IFRT (dose range: 21.0 to 54.0 Gy)  $\pm$  boost. All patients with central and peripheral hypothyroidism underwent CSRT (dose range: 23.40 to 39.0 Gy)  $\pm$  boost. Three of 6 patients with FT4 deficiency were treated with CSRT (dose range: 23.40 to 36.00 Gy)  $\pm$  boost, 3/12 with IFRT (dose range: 50.40 to 60, 00 Gy)  $\pm$  boost.

#### Conclusion

Our data confirm the frequency of hypothyroidism post-RT in pediatric patients; the relationship between dose to pituitary gland and to thyroid and damage is ongoing.

#### EP-1613 A dosimetric comparison of Proton and VMAT for Pediatric Ewing sarcoma of pelvis and spine

F. Meniai-Merzouki<sup>1,2</sup>, M. Vigan<sup>3</sup>, F. Goudjil<sup>4</sup>, S. Helfre<sup>1,2</sup>  
<sup>1</sup>Institut Curie, Radiation oncology Department, Paris, France ; <sup>2</sup>centre de protontherapie, Radiation oncology Department, Orsay, France ; <sup>3</sup>Biostatistic Department, , France ; <sup>4</sup>Physics department, Orsay, France

#### Purpose or Objective

To compare the dosimetric results of proton radiation with volumetric modulated arc therapy (VMAT) for pediatric Ewing Sarcoma of pelvis and spine. The goal was to assess the potential advantage of proton over VMAT planning in pelvis and spine Ewing's sarcoma.

#### Material and Methods

Ten patients with Ewing sarcoma of the pelvis and spine treated with proton beam at Protontherapy center (CPO) at Institut Curie. VMAT plans had generated and analyzed. To facilitate dosimetric comparisons, clinical target volumes and normal tissue volumes were held constant. Plans were optimized for target volume coverage and normal tissue sparing.

#### Results

The average dose coverage values for CTV were comparable in PROTON and VMAT plans. Whereas the Proton plans achieved a higher conformity index compared to the VMAT plans (conformity index  $1.2 \pm 0.2$  vs. 1,  $p=0.009$ ), The index of homogeneity (IH) did not differ significantly. For the bladder, Kidney, head femoral and testis Dmean were significantly reduced in Proton plans. For the bowel and rectum, there was no significant difference in Dmean. The volume of normal tissue receiving at least 5 Gy (V5) was significantly higher in VMAT plans compared with Proton, whereas at high dose levels (V30) it was significantly lower.

#### Conclusion

Compared to VMAT, Proton showed significantly better results regarding dose conformity ( $p=0.009$ ) and mean Dose of bladder ( $p=0.004$ ), kidney ( $p=0.01$ ). Proton delivered a lower healthy tissue dose than VMAT. Thus, dose escalation in the radiotherapy of pelvic and spine Ewing's sarcoma can be more easily achieved using proton.

#### EP-1614 Incidence of second malignancies among pediatric patients treated with helical Tomotherapy

E. Coassin<sup>1</sup>, A. Drigo<sup>2</sup>, L. Barresi<sup>2</sup>, G. Fanetti<sup>3</sup>, C. Elia<sup>1</sup>, G. Sartor<sup>2</sup>, G. Franchini<sup>3</sup>, M. Mascarin<sup>1</sup>  
<sup>1</sup>IRCCS Centro di Riferimento Oncologico CRO di Aviano, Pediatric Radiotherapy and AYA Unit, Aviano, Italy ; <sup>2</sup>IRCCS Centro di Riferimento Oncologico CRO di Aviano, Medical Physics, Aviano, Italy ; <sup>3</sup>IRCCS Centro di Riferimento Oncologico CRO di Aviano, Radiation Oncology, Aviano, Italy

#### Purpose or Objective

Intensity modulated radiation therapy (IMRT) delivered with helical Tomotherapy (HT) has been increasingly applied in young patients with cancer. Concerns about a potential increase of radiation-induced malignancies (SMN) exist. The purpose of this study was to determine the incidence of SMN among pediatric patients treated with HT.

#### Material and Methods

We performed a retrospective study of 146 patients less than 24 years of age treated with HT since its introduction in 2006 to September 2013 at Centro di Riferimento Oncologico CRO in Aviano, Italy. The main outcome measure was the incidence of SMN after radiation.

#### Results

Seventy-eight patients with a follow-up of at least 5 years after the end of radiotherapy were included in the analysis. The median follow-up was 7.6 years (range, 5-12.2). Forty-seven and 14 patients were followed for at least 7 and 10 years, respectively. The median age at treatment was 13.5 years (range, 1.5-24). Forty-five patients were males and 33 were females. Patients were irradiated with HT alone or in combination with other radiation techniques for CNS tumors (n=33), lymphomas (n=21), sarcomas (n=17), H&N carcinomas (n=4), or other histologies (n=3). Treatment sites were brain (n=21, 2 whole ventricular), mediastinum (n=20), craniospinal (n=12), H&N (n=6), pelvis (n=6), thorax (n=5, 2 total pleural), limbs (n=4), abdomen (n=3, 1 whole abdomen), spine (n=1). Median prescribed doses were 54 Gy (range, 8-59.4) for CNS tumors, 25.2 Gy (range, 9-50) for lymphomas, 50.4 Gy (range, 41.4-66) for sarcomas, 66 Gy (range, 63-70) for H&N carcinomas, and 15-21 Gy for the remaining cases. At a median follow-up of 7.3 years (range, 5-12.2), 57 patients (73%) were alive in complete remission. Among these long-term survivors, a 17.5-year-old female affected by Hodgkin lymphoma developed a recurrent fibromatosis of the soft tissues of the breast region close to the central venous catheter insertion site within the irradiated area 5 years after HT (prescribed dose, 14.4 Gy in 8 fractions). At a median follow-up of 7.2 years (range, 5-8.9), 10 patients (13%) were died of disease. One patient died because of esophageal cancer 7 years after total pleural irradiation delivered for an Ewing sarcoma of the right thoracic wall (prescribed dose, 36 Gy in 20 fractions). The tumor arose in the high-dose radiation volume and was considered a SMN. No other SMN occurred. Eleven patients (14%) were alive with disease without evidence of SMN at the time of the study. A 6-year-old girl affected by Li-Fraumeni syndrome irradiated to a dose of 50.4 Gy in 28 fractions for an anaplastic rhabdomyosarcoma of the right masticator space was alive in first complete remission without SMN 9.6 years after HT.

#### Conclusion

At a median follow-up of more than 7 years, IMRT delivered with HT resulted not associated with an increased risk of SMN due to low-dose irradiation to normal tissues as previously reported. Longer follow-up is needed to confirm this finding.

#### Electronic Poster: Clinical track: Palliation

---

#### EP-1615 Impact of pretreatment imaging modality on the response to palliative radiation for bone metastases

Y. Wada<sup>1</sup>, E. Okuyama<sup>1</sup>, S. Kumagai<sup>1</sup>, M. Sasajima<sup>1</sup>, T. Tozawa<sup>1</sup>, N. Takagi<sup>1</sup>, A. Anbai<sup>1</sup>, M. Hashimoto<sup>1</sup>  
<sup>1</sup>Akita University Graduate School of Medicine, Radiology, Akita, Japan

#### Purpose or Objective

MRI, bone scintigraphy, and 2-deoxy-2-(<sup>18</sup>F)-fluoro-D-glucose positron emission tomography (<sup>18</sup>FDG-PET) have been reported to be more sensitive than CT for detecting malignant bone lesions. Therefore, it was thought that gross tumor volume (GTV) contoured on MRI, bone scintigraphy, or <sup>18</sup>FDG-PET is more accurate than that on CT. The aim of the present study was to evaluate whether the imaging modality before irradiation affects the

response to palliative radiation therapy of painful bone metastases from solid malignant carcinomas.

#### Material and Methods

Consecutive patients with painful bone metastases treated with palliative radiation between 2013 and 2017 in our institution were enrolled. Patients without pain and those with vertebral bone metastases were excluded. The reason for excluding vertebral bone metastases was that it was usual to contour the whole body of metastatic vertebra as the clinical target volume (CTV), and, thus, the effect of how to contour GTV for vertebral bone metastases was thought to be much less than that for long or flat bone metastases. The imaging modality used between one month before and the start of palliative radiation, primary sight of carcinoma, histological type, metastatic lesion type (osteolytic, osteoblastic, or mixed) and the biological equivalent dose of  $\alpha/\beta=10$  (BED10) were retrospectively investigated, and the relationships between these factors and treatment response were evaluated. "Response" was defined as the condition in which patients achieved pain relief or reduced their use of analgesic medications. All radiation plans were three-dimensional conformal radiation therapy based on simulation CT images according to the guideline of the Japanese Society for Radiation Oncology. Briefly, GTV was defined as the bone metastatic lesion according to physical and any imaging examinations. CTV was defined as GTV plus about 1 cm, and planning target volume (PTV) was defined as CTV plus about 0.5-2 cm.

#### Results

Forty-three patients were included in the present study (median age 67 years; age range 37-85 years; 27 males, 16 females). Prescribed doses were 8-50 Gy/1-25 fractions with 2-8 Gy/fraction. Response was seen in 36 (response rate, 84%). The number of each imaging modality before irradiation was 43 CT scans (all patients, including simulation CT for radiation planning), 10 MRI scans, 17 bone scintigraphies, and 6 <sup>18</sup>FDG-PET images. Welch's *t*-test, Mann-Whitney test and the chi-squared test showed that only BED10 was significantly related to treatment response ( $p<.01$ ) (Table 1), and multiple logistic regression analysis also showed that only BED10 was a significant predictor ( $p=.02$ ) (Table 2). No significant relationship was observed with imaging modality before irradiation.

Table 1. Predictive factors; univariate analysis

	Response	Non-response	P value
Age	Median 67 (range: 37-85)	Median 67 (range: 57-73)	0.82
Sex (Male: Female)	22:14	5:2	0.93
Primary Sight (Lung: Uro: GI: HN: Thyroid: Gyne: Unknown)	6:10:11:3:2:2:2	3:2:2:0:0:0:0	0.88
Histology (SCC: Adeno: Small: CC: others: unknown)	2:19:0:6:8:1	1:4:0:1:1:0	0.58
Bone metastases type (Osteolytic: Osteoblastic: Mixed)	26:6:4	5:2:0	0.92
BED10	Median 39 (range: 24.7-61.2)	Median 39 (range: 14.4-39)	<0.01
MRI	7 (19%)	3 (43%)	0.18
Bone scintigraphy	13 (36%)	4 (57%)	0.30
<sup>18</sup> FDG-PET	5 (14%)	1 (14%)	0.98

Uro: urology, GI: gastrointestinal, HN: head and neck, Gyne: gynecology, SCC: squamous cell carcinoma, Adeno: adenocarcinoma, Small: small cell carcinoma, CC: clear cell carcinoma, BED10: biological effective dose ( $\alpha/\beta=10$ )

Table 2. Predictive factors; multivariate analysis

	Odds ratio	95% CI	P value
BED10	1.187	1.007-1.399	0.02
MRI	0.131	0.015-1.108	0.19
Bone scintigraphy	0.555	0.081-3.792	0.31
<sup>18</sup> FDG-PET	1.000	0.060-16.578	0.98

BED10: biological effective dose ( $\alpha/\beta=10$ ), CI: confidence interval

#### Conclusion

The results of the present study suggest that appropriate radiation field setting according to CT images and physical assessment could avoid further imaging before palliative radiation for painful bone metastases.

#### EP-1616 Population-based Phase II Trial of Stereotactic Radiotherapy for up to 5 Oligometastases: SABR-5

R. Olson<sup>1</sup>, M. Liu<sup>2</sup>, A. Bergman<sup>3</sup>, S. Lam<sup>4</sup>, F. Hsu<sup>5</sup>, B. Mou<sup>6</sup>, T. Berrang<sup>7</sup>, A. Mestrovic<sup>8</sup>, N. Chng<sup>9</sup>, D. Tyldesley<sup>2</sup>, D. Schellenberg<sup>11</sup>  
<sup>1</sup>BC Cancer Agency - Centre for the North, Radiation Oncology, Prince George, Canada ; <sup>2</sup>BC Cancer, Radiation Oncology, Vancouver, Canada ; <sup>3</sup>BC Cancer, Medical Physics, Vancouver, Canada ; <sup>4</sup>BC Cancer, Clinical Trials, Vancouver, Canada ; <sup>5</sup>BC Cancer, Radiation Oncology, Abbotsford, Canada ; <sup>6</sup>BC Cancer, Radiation Oncology, Kelowna, Canada ; <sup>7</sup>BC Cancer, Radiation Oncology, Victoria, Canada ; <sup>8</sup>BC Cancer, Medical Physics, Victoria, Canada ; <sup>9</sup>BC Cancer, Medical Physics, Prince George, Canada ; <sup>10</sup>BC Cancer, Medical Physics, Kelowna, Canada ; <sup>11</sup>BC Cancer, Radiation Oncology, Surrey, Canada ; <sup>12</sup>BC Cancer, Radiation Oncology, Prince George, Canada

#### Purpose or Objective

Oligometastases refer to a state of disease where cancer has spread beyond the primary site, but is not yet widely metastatic, often defined as 1-3 or 1-5 metastases in number. Stereotactic ablative radiotherapy (SABR) is an emerging radiotherapy technique to treat oligometastases that require further prospective population-based toxicity estimates.

#### Material and Methods

This is a non-randomized phase II trial in a setting where SABR for oligometastases is not available off clinical trial. All participants receive SABR treatment to all sites of newly diagnosed or progressing oligometastatic disease. We have accrued 150 of a planned 200 patients to assess toxicity associated with this experimental treatment. The study was powered to give a 95% confidence on the risk of late grade 4 toxicity, anticipating a < 5% rate of grade 4 toxicity.

#### Results

We have accrued 150 patients within 18 months, and anticipate completion of study accrual by December 2018. The majority (65%) had a solitary metastasis, followed by 26%, 7%, and only 2% who had 2,3, or 4-5 metastases, respectively. Within the 150 patients, 220 metastases were treated, with the most common locations being lung (35%), non-spine bone (24%), spine (21%), lymph nodes (9%), and liver (7%). The majority of primary tumour sites were prostate (27%), colorectal (21%), breast (11%), renal cell carcinoma (11%), and head and neck cancer (9%). To date, no SABR related deaths have occurred, but there has been 1 grade 4 serious adverse event related to SABR reported (biliary duct stenosis resulting in jaundice). Updated adverse event rates will be presented.

#### Conclusion

SABR treatment of oligometastases is occurring off-trial at a high rate, without sufficient evidence of its efficacy or toxicity. We will present toxicity data from this population-based cohort, using standardized doses and organ at risk constraints.

#### EP-1617 Palliative radiotherapy for lung cancer from patients' perspective: a quality of life (QoL) study W. Majewski<sup>1</sup>, M. Wyduba<sup>2</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Department, Gliwice, Poland ; <sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Anaesthesiology Department, Gliwice, Poland

### Purpose or Objective

To evaluate the results of palliative radiotherapy for lung cancer with prospective assessment of quality of life (QoL).

### Material and Methods

The study group comprises 162 patients with lung cancer undergoing palliative radiotherapy in 2014-2016. The mean patients' age was 66 years (46-89 years). There were 43 female (27%) and 27 male (73%) patients. A total of 115 patients (71%) were in a good performance status ZUBROD 0-1, whereas the rest was in a poor general condition: 36 (22%) ZUBROD-2 and 11 patients (7%) ZUBROD-3. Stage IIIA was diagnosed in 27 patients (17%), Stage IIIB in 17 (10%) and stage IV in 40 patients (73%). Radiotherapy was performed with 6 or 20 MV photons, using 2D technique and two opposed AP-PA fields in 131 patients (81%), whereas 3DCRT technique with 3- or 4- fields was utilized in remaining patients. The radiation schedules were as follows: 20 Gy with 4 Gy per fraction- 96 patients (59%), 20-30 Gy with 2 Gy per fraction- 34 patients (21%), 30 Gy with 3 Gy per fraction- 27 patients (17%) and 5 patients did not completed the planned RT. The prospective evaluation was based on QLQC30, RSCL and Pain questionnaires filled by each patient before, at the completion of radiotherapy and 3-4 months post-treatment.

In this study the evaluation of changes of pain intensity (NRS scale 0-10), global QoL (scored 0-100) and dyspnea was performed. With NRS scale- the higher point means more pronounced pain. With general QoL scale the higher point means better QoL. The intensity of dyspnea is scored on a 4-point scale (never, sometimes, often, very often), with higher score meaning more pronounced symptom. The comparison was performed with non-parametric Wilcoxon test.

### Results

The mean intensity of pain before treatment was 3.3 points. At the completion of radiotherapy it was 5.7 points. At the last measurement 3-4 months post-treatment it was 2.8 points. The differences with respect to the pre-treatment value were significant ( $p=0.0002$  and  $p=0.009$ ).

The mean global QoL was scored 56 points before treatment. At the completion of radiotherapy it was 35 points, at the last measurement 3-4 months post-treatment it was 62 points. The differences as compared to the pre-treatment value were significant ( $p=0.000$  and  $p=0.000$ ).

The mean dyspnea score before radiotherapy was 2.4 points. At the completion of radiotherapy it was 3.3 points, at the last measurement 3-4 months post-treatment it was 2.3 points. The difference between pre-treatment and post-treatment value was significant, and there was a trend to improvement between pre-treatment and 3-4 month post-treatment value ( $p=0.000$  and  $p=0.06$ ).

### Conclusion

Shortly after palliative radiotherapy for lung cancer a decrease in general status and increase in existing symptoms may be expected. At longer follow-up an improvement as compared to the pre-treatment status is reported. Patients with expected survival of at least 3-4 months seem to benefit from palliative radiotherapy.

### EP-1618 Early clinical results and feasibility of amplitude-gated DIBH for SBRT: A multi-centre experience

K. Chufal<sup>1</sup>, I. Ahmed<sup>1</sup>, C.P. Bhatt<sup>2</sup>, R. Chowdhary<sup>1</sup>, R. Singh<sup>1</sup>, A. Pahuja<sup>1</sup>

<sup>1</sup>Rajiv Gandhi Cancer Institute & Research Centre, Radiation Oncology, Delhi, India ; <sup>2</sup>Sarvodaya Hospital & Research Centre, Department of Radiation Oncology, Faridabad, India

### Purpose or Objective

This analysis reports our initial experience with amplitude-gated DIBH technique for SBRT in patients with oligometastases treated on an institutional review board approved prospective protocol.

### Material and Methods

Between 2016 and 2018, 21 consecutive patients with oligometastatic disease to lung and liver were treated with SBRT utilizing amplitude-gated DIBH technique and were included in this analysis. After being coached for 3-4 days to achieve a reproducible breath hold in terms of amplitude and duration, simulation CT scans and orthogonal fluoroscopy images were acquired in free breathing and DIBH phases. The gated amplitude was set at +/- 2mm from the recorded baseline DIBH pattern. Target delineation and plan evaluation was performed in accordance with the ongoing RTOG BR001 protocol. Treatment planning was performed with co-planar 6MV FFF 2-3 Arc VMAT technique on Eclipse v13.5. The dose was escalated in consecutive patients from BED<sub>10</sub> of 75 Gy<sub>10</sub> up to 132 Gy<sub>10</sub>. Patient-specific pre-treatment QA was performed for all patients. Pre- and intra-treatment positioning verification was performed with DIBH CBCT for all patients for each treatment fraction and corrected on a 6D treatment couch. The primary endpoints of the analysis were local control (LC) and time to local progression (TTLP).

### Results

**Results:** A total of 21 metastatic sites were treated, with 90.6% sites being located in lung and liver. 1 year LC rate was 88.9% ( $\pm 2$  SD = 0.148) and mean TTLP was 16.8 months (95% CI = 15.5 to 18 months). The median overall survival was 16.0 months (95% CI: 15.1 to 16.8 months). Breath-hold duration across all patients varied from 25 to 45 seconds. Maximum measured tumor motion during fluoroscopy in free breathing varied from 8-15 mm (Mean, 95% CI = 10.5 mm, 9.3 to 11.8 mm) and in DIBH it reduced to 1-2 mm (Mean, 95% CI = 1.7 mm, 1.6 to 2 mm), which permitted a reduction in PTV margins from 5mm to 3mm. DIBH CBCT acquisition was time-consuming, as it required two consecutive breath-holds within a short duration. We noted a significant degradation in image quality with three consecutive breath-holds or two breath-holds with a long gap in between. The Dose Gradient Index for all DIBH SBRT plans varied from 0.73 to 1.49 cm (Mean, 95% CI = 0.998, 0.883 to 1.112 mm). Total MU's varied from 1794 to 4765 (Mean, 95% CI = 3168 MU, 2651 to 3685 MU), with beam-on time varying from 120 to 537 seconds (Mean, 95% CI = 334 sec, 263 to 407 sec). Implementation time for the first treatment session (including imaging and verification) varied from 693 to 2488 seconds (Mean, 95% CI = 1464 sec, 1184 to 1744 sec).

### Conclusion

**Conclusions:** Amplitude-gated DIBH technique for SBRT in oligometastatic disease yielded equivalent results to reports previously published in the literature. Reduced target motion with DIBH resulted in reduction of PTV margins. The main limitation of this technique is long patient-on-table time, which is directly dependent on the patient's breath-hold duration.

### EP-1619 SBRT and the treatment of adrenal gland metastasis

D. Georgiev<sup>1</sup>, N. Gesheva-Atanasova<sup>1</sup>, S. Lalova<sup>1</sup>, A. Balabanova<sup>1</sup>, I. Mihaylova<sup>1</sup>, B. Antonov<sup>1</sup>, K. Ormankova<sup>1</sup>  
<sup>1</sup>National Oncological Center Hospital, Radiotherapy, Sofia, Bulgaria

### Purpose or Objective

The purpose of the study is to evaluate our experience in the use of stereotactic body radiation therapy (SBRT) for treatment of adrenal glands metastasis and in particular the dosimetry planning, clinical outcomes and toxicity.

### Material and Methods

From 6/2016 to 6/2018, 8 patients were treated with 10 lesions of the adrenal gland - 7 of the lesions were located

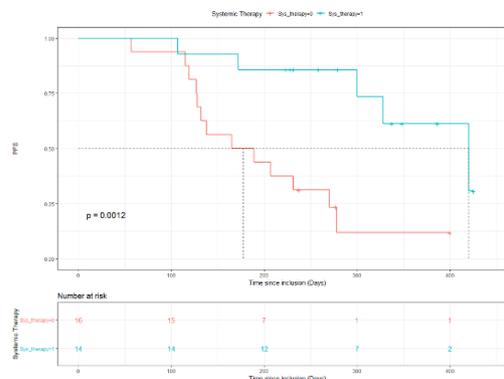

previously irradiated area). Twelve patients had non-spine bone lesions only, 16 had lymph node metastases, and two had mixed disease. Patient and tumor characteristics are presented in table 1.

Characteristics	n (%)	
<b>Mean age (range)</b>	<b>69 (48-86) years</b>	
<b>Gender</b>	<b>30</b>	<b>100%</b>
Male	24	80%
Female	6	20%
<b>Metastatic site</b>	<b>32</b>	<b>100%</b>
Non-spine bone	14	44%
Lymph node	18	56%
<b>Primary cancer</b>	<b>30</b>	<b>100%</b>
Prostate (AdenoCa)	18	60%
RCC	2	7%
NSCLC	2	7%
Breast (IDA)	2	7%
Ovarium	2	7%
Melanoma	1	3%
Cholangiocarcinoma	1	3%
Stomach (AdenoCa)	1	3%
Ureter (TCC)	1	3%
<b>Timing</b>	<b>30</b>	<b>100%</b>
Synchronous	3	10%
Metachronous	27	90%
<b>Concomitant systemic treatment</b>	<b>30</b>	<b>100%</b>
None	16	53%
Hormonal Therapy	11	37%
Chemotherapy	1	3%
Immunotherapy	2	7%
<b>Treatment characteristics</b>		
PTV_D50% (Gy); mean (range)	37,75	34,42-43,86
PTV_D2% (Gy); mean (range)	40,48	36,22-48,07
PTV_D98% (Gy); mean (range)	31,51	20,66-35,5

**Table 1.** Patient, tumor and treatment characteristics  
**NOTE.** Data presented as No. (%) unless otherwise indicated.  
**Abbreviations:** AdenoCa, adenocarcinoma; RCC, renal cell carcinoma; NSCLC, non-small cell lung carcinoma; IDA, invasive ductal adenocarcinoma; TCC, transitional cell carcinoma; PTV, planning target volume; D50%, median absorbed dose; D2%, near-maximum absorbed dose; D98%, near-minimum absorbed dose;

Median follow-up after SBRT was 9 (2 - 14) months. LC at 6 months was 100%. At 12 months, 2 local relapses were observed, both in lesions >4cm. The median PFS was 8 months. There was a significant difference between PFS in patients who received concomitant systemic treatment and those who did not (median 5.8 vs 13.8 months, p = 0.0012) (figure1). No significant difference in PFS between patients with bone and lymph node metastases was observed. There was no grade ≥ 3 toxicity observed. During follow-up, QoL scores didn't change significantly.

Limitations include small sample size, limited duration of follow-up, and lack of a control arm. **Conclusion** SABR in 5 fractions appears extremely safe and feasible, resulting in excellent local control but rather limited progression-free survival. Consequently, 30 more patients were included in the second cohort (3 fractions of 10 Gy), now including translational research to tailor future patient selection. Patients with oligometastases should probably not be withheld systemic treatment.

#### EP-1622 Stereotactic Body Radiation Therapy for Oligometastatic Disease: A single-institution experience

L.P. Guzman Gomez<sup>1</sup>, J. Luna Tirado<sup>1</sup>, D. Gonsalves Pieretti<sup>1</sup>, A. Ilundain Idoate<sup>1</sup>, M. Montero Feijoo<sup>1</sup>, W.A. Vasquez Rivas<sup>1</sup>, E. Lopez Ramirez<sup>1</sup>  
<sup>1</sup>Hospital Universitario Fundación Jiménez Díaz, Radiation Oncology Department, Madrid, Spain

#### Purpose or Objective

To report clinical outcome and treatment-related toxicity of SBRT in the treatment of oligometastatic disease in patients no suitable for surgery or unresectable metastases.

#### Material and Methods

Between May 2015 and December 2017, 68 patients with 1-3 inoperable metastases were treated with SBRT. Medical records were retrospectively reviewed. Patients with liver/abdominal lesions were immobilized with Vac-Q-Fix™ Cushions including BodyFix Diaphragm™ for abdominal compression to minimize respiratory organ motion. No abdominal compression was applied to lung patients, in these cases, 4D planning was required. Dose prescription ranged from 27 to 60 Gy in 3 - 8 fractions. In particular, 27 Gy in 3 fractions was prescribed to bone metastases, 60 Gy in 8 fractions to liver lesions, 50-60 Gy in 4 - 6 fractions to lungs lesions and 40-45 Gy in 4 - 6 fractions to adrenal metastases and abdominal lymph nodes. Dose reductions were allowed if judged necessary to cope with organs at risk (OAR) sparing. Treatment was delivered on Elekta Beam Modulator™ linear accelerator, using volumetric modulated arc therapy (VMAT) with 6-10 MV photon beam energy. Daily image guidance (IGRT) was performed by means of CBCT acquisitions prior to each treatment. After conclusion of SBRT, all patients were assessed at 1.5 months and every 3 months during the first year and every 6 months after 1 follow-up year, with a CT scan and/or RM at each follow up. The primary end points were local control (LC) and treatment-related toxicity.

#### Results

Sixty-eight patients with 82 total metastases were treated. Median age at treatment was 64 years (ranged, 28-87 years). 67% were men. 82% of patients presented an ECOG performance status 0-1. Primary tumors were 30 GI, 12 lungs, 10 breasts, 7 prostates, 4 gynecological, 2 melanomas, 2 sarcomas and 1 unknown tumor. 52 patients (76%) had a single lesion; the remaining patients had 2-3 lesions. 48% of the lesions were localized in bones; 28.7%

in the lungs; 16.3% in the liver; 5% in lymph nodes and 2% in adrenal glands. Median diameter of the lesions was 8 mm for bone lesions, 14 mm for lung, 24 mm for liver, 12 mm for adrenal and 13 mm for lymph nodes metastases. Median follow-up was 12.1 months (ranged 2 - 35 months). Local control at 1-year (inclusive of complete, partial and stable response) was achieved in 86.5% of the treated lesions. Treatment-related grade 2-3 toxicity was observed in 4.2% of patients; grade 1 toxicity in 10.8% and no toxicity was observed in 85% of the cases.

#### Conclusion

SBRT is a safe and effective therapeutic option for the treatment of oligometastatic patients not suitable for surgery or unresectable metastases, with high local control rates, good tolerance and low treatment-related toxicity.

#### EP-1623 KORTUC for lytic bone metastasis

S. Obata<sup>1</sup>, O. Yukihiro<sup>1</sup>, T. Tatsuya<sup>1</sup>, M. Shigeki<sup>1</sup>, O. Yohiaki<sup>1</sup>, K. Tsunehiko<sup>1</sup>, K. Shinya<sup>1</sup>, I. Yohta<sup>1</sup>, K. Akira<sup>1</sup>, I. Kayo<sup>1</sup>, W. Kumiko<sup>1</sup>, O. Hitomi<sup>1</sup>

<sup>1</sup>Nagasaki Prefecture Shimabara Hospital, Department of Radiology and Radiotherapy, Shimabara, Japan

#### Purpose or Objective

To improve the effects of radiation for lytic bone metastasis, we directly injected a new radio-sensitizer into the lesion (KORTUC) under image guidance after obtaining approval from our ethics committee and informed consent. We herein report the retrospective clinical data from 25 consenting patients since 2010.

#### Material and Methods

We selected 20 eligible patients our hospital followed up. Patient age was 42-83 years, the ratio of men to women was 12: 8. As for the primary lesion, lung was 12 cases, 3 rectums, 2 esophaguses, and others. Uncontrolled primary lesion was 16 cases. 16 cases accompanied other metastasis. Affected bone was 9 pelvic bones, extremities bone 5, thorax 2, and others. Performance status 3-4 was 7 cases, uncontrollable pain was recognized in 18 cases. We performed KORTUC in all cases. In half of the patients, chemotherapy, molecular targeted drug or immunotherapy was administered.

#### Results

Radiation dose was 8-54 Gy and the number of times of radio-sensitizer injection was 1-12 times. The palliative rate was 94%. 95% of the targets did not enlarge in size and half of the cases presented bone re-formation. The treatment took effect after 1-17 days and it continued for 7-630 days. The survival time was 30-1680 days. There was no severe adverse event. Neither univariate nor multivariate analysis of the local control recognized significant difference.

#### Conclusion

KORTUC for lytic bone metastasis was thought safe and effective. And a further accumulation of many cases is needed for recognition of a clinical option.

#### EP-1624 First clinical experiences with SBRT on the 1.5 T MR-linac for pelvic lymph node oligometastases

A.M. Werensteijn-Honingh<sup>1</sup>, P.S. Kroon<sup>1</sup>, D. Winkel<sup>1</sup>, E.M. Aalbers<sup>1</sup>, B. Van Asselen<sup>1</sup>, G.H. Bol<sup>1</sup>, K.J. Brown<sup>2</sup>, W.S.C. Eppinga<sup>1</sup>, M. Glitzner<sup>1</sup>, E.N. De Groot-van Breugel<sup>1</sup>, S.L. Hackett<sup>1</sup>, M. Intven<sup>1</sup>, J.G.M. Kok<sup>1</sup>, A.N. Kotte<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, M.E.P. Philippens<sup>1</sup>, R.H.N. Tijssen<sup>1</sup>, J.W.H. Wolthaus<sup>1</sup>, S.J. Woodings<sup>1</sup>, B.W. Raaymakers<sup>1</sup>, I.M. Jürgenliemk-Schulz<sup>1</sup>

<sup>1</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands; <sup>2</sup>Elekta AB, Scientific Research, Stockholm, Sweden

#### Purpose or Objective

The 1.5 Tesla (T) MR-linac (Unity, Elekta AB, Stockholm, Sweden) has been available for clinical use at our institute since August 2018. Our aim is to present the first clinical

experience with the onboard workflow as provided in the system including daily contour adaptation and online treatment planning based on the daily anatomy as visualized on online MRI.

#### Material and Methods

Starting August 2018, we have been treating on average 2 patients per month for pelvic and low abdominal lymph node oligometastases. Seven-beam step-and-shoot IMRT (FFF 7 MV) was used to deliver 35 Gy in 5 fractions, with a maximum of 3 fractions per week.

The pre-treatment workup and actual online workflow for these treatments is illustrated in Figure 1 and consists of the following steps:

- 1) Pre-treatment preparation consists of CT and MR imaging, contouring based on CT and MRI, treatment planning, patient QA including film measurement and independent 3D dose calculation for the pre-treatment plan;
  - 2) Treatment session consists of online MRI, deformable registration from pre-treatment CT to the online MRI scan, manual adaptation of GTV and organs at risk (OAR) from deformed contours if needed, full online re-planning ('adapt to shape' workflow with most extensive re-planning option), position verification MRI, independent 3D dose calculation, radiation delivery with intra-fraction MRI and post-fraction MRI;
  - 3) Post treatment steps are patient QA and dose reconstruction on the intra- and post-fraction MRIs.
- All patients are asked to participate in a prospective observational study that investigates treatment issues and clinical outcome data, including acute toxicity and patient-reported quality of life.

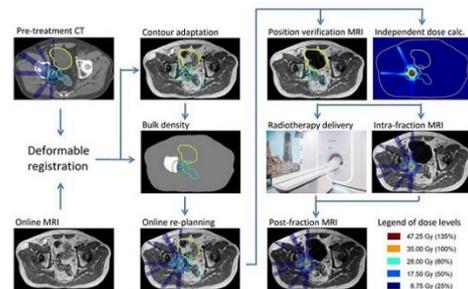

Figure 1: flow chart of online MR-linac workflow

Anatomical contours: yellow: bladder; light blue: sigmoid; pink: ureter; light green: GTV; dark blue: PTV; green circle: PTV + 2 cm. Images are shown for the first fraction of the second patient.

#### Results

As of October 2018, three patients have completed their full treatment course with Unity and two are currently being treated. The average daily online session duration was 41 minutes (range 33-49) including an average 34 minutes on-couch time (range 27-39). Time to completion for individual workflow items is shown in Figure 2.

Target lymph nodes and surrounding tissues and organs were well visible at each treatment session allowing for contour adaptation of GTV and OAR and full online re-planning to the daily anatomy. All online treatment plans satisfied the predefined target and OAR constraints. The online independent dose calculations resulted in an average Gamma pass rate (3%/3 mm) of 97.5% (range 90.4-99.2%). For all treatment fractions, the entire GTV received 100% of the prescribed dose (35 Gy) based on reconstruction on all online MRI scans (position verification, intra- and post-fraction).

Clinical outcome data including acute toxicity and patient-reported quality of life are being collected.

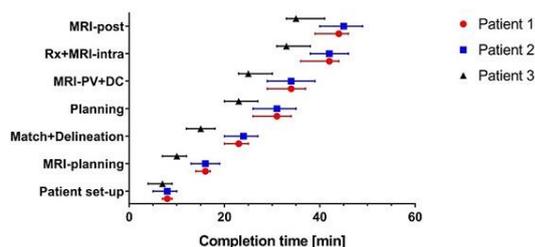

Figure 2: visualization of online session duration  
Average and range of time to completion (from session start) for the different workflow items.  
Rx: radiotherapy delivery; PV: position verification; DC: independent dose check.

## Conclusion

The onboard clinical workflow of the 1.5 T MR-linac, with daily contour adaptation and full online re-planning, can successfully be used to treat patients with pelvic and low abdominal lymph node oligometastases using an SBRT approach.

## EP-1625 Patterns-of-care and outcome-analysis of the stereotactic body RT (SBRT) of adrenal-gland-metastases

T. Voglhuber<sup>1</sup>, S.E. Combs<sup>1</sup>, K.A. Kessel<sup>1</sup>, M. Oechsner<sup>1</sup>  
<sup>1</sup>Technical University of Munich TUM, Department of Radiation Oncology, München, Germany

### Purpose or Objective

High-precision stereotactic body radiotherapy (SBRT) has proven to be a valuable method in the curative and palliative treatment of different tumor entities and is meanwhile an established keystone in the field of neoadjuvant tumor-therapy.

In this study, we evaluate the effect of SBRT in patients with metastases in the adrenal gland focused on progression-free-survival (PFS), overall survival (OS), and acute as well as late toxicity.

### Material and Methods

A cohort of 24 patients was analyzed treated with SBRT for metastases in the adrenal gland between 2006 and 2018. Treatment-planning was performed through contrast-enhanced CT followed by the image-guided radiation therapy (IGRT) using Cone-beam-CT (CBCT). SBRT was applied with a cumulative median dose of 35 Gy (range: 25-40 Gy) and a single dose of 5 Gy in five fractions per week.

### Results

The evaluation is still ongoing. Primary tumors of the patients were: NSCLC 45.8 %, Mamma-Ca 12.5 %, Melanoma 12.5 %, Sarcoma 8.3 %, and others 20.9 %. At the time of analysis, 7 patients (29.2 %) experienced local failure (LF) of the neoplasia in the adrenal gland (mean LF: 52.0 months, 95%-KI: 26.2-77.8 months, median not reached), 19 (79.2 %) faced a distant progression (median-PFS: 2.2 months, 95%-KI: 1.8-2.6 months). 12 patients were still alive (50 %), 5 of them without LF (41.7 %), 4 of them (33.3 %) without any tumor progression (median OS: 12.9 months, 95%-KI: 6.3-19.5 months).

Our results showed that there occurred no treatment-related side-effects  $\geq$  grade 2, which reflects the overall low-grade-toxicity of SBRT used for adrenal-gland-metastases.

Toxicity rates  $\geq$  grade 2 were as follows: 41.7 % suffered from acute ( $\leq$  6 months) gastrointestinal disorders like nausea (29.2 %), vomiting (8.3%), and abdominal pain (4.2 %); 29.2 % also reported acute fatigue, constipation, throbbing pain in the renal area and increase of the retention parameters. Only 20.8 % of the patients faced late-toxicities like loss of weight (4.2 %), fatigue (4.2 %) and gastrointestinal medical conditions (12.5 %) persisting or appearing after the 6-month-period.

### Conclusion

SBRT is a safe and effective method for treating metastases in the adrenal gland. None of the patients had treatment-related acute or late toxicities  $\geq$  grade 2, and 70.8% of the patients were progression-free after RT.

## EP-1626 "TEACHH MODEL" as a tool for decision-making in palliative patients: Our experience

A. Miranda Burgos<sup>1</sup>, C. Escuin Troncho<sup>1</sup>, G. Molina Osorio<sup>1</sup>, C. García Aguilera<sup>1</sup>, L. Alled Comín<sup>1</sup>, J.M. Ponce Ortega<sup>1</sup>, R. Ibáñez Carreras<sup>1</sup>

<sup>1</sup>Hospital Universitario Miguel Servet, Radiation Oncology, Zaragoza, Spain

### Purpose or Objective

Radiotherapy is an effective and cost-effective treatment when patients have symptoms such as metastatic bone pain, hemorrhages or cerebral edema. Up to 16% of planned patients do not receive treatment for causes such as clinical worsening or death. It is important to estimate the life expectancy to make appropriate decisions according to radiotherapy treatment. Our objective is to introduce in our clinical practice a scale of prognostic assessment that will help us decide on the relevance of palliative radiotherapy indication and thus reduce the rate of untreated planned patients below 10%.

### Material and Methods

After the review of literature, we considered the TEACHH model suitable as a support tool for decision making in palliative radiotherapy. The TEACHH model divides patients into three life expectancy groups (1.7, 5, and 19.9 months) based on the score obtained according to the patient's clinical characteristics (type of cancer, Eastern Cooperative Oncology Group performance status, age, prior palliative chemotherapy, prior hospitalizations, and hepatic metastases).

We decided to use the TEACHH model in all the patients that were hospitalized and needed palliative radiotherapy.

### Results

We selected 147 patients candidates for palliative radiotherapy. We administered radiotherapy for metastatic bone pain in 42% of the patients, with hemostatic intention in 10%, for brain metastases in 28% and finally, for spinal cord compression in 20% of the patients.

Of the total of treated patients, 22% were in the life expectancy group of 1.7 months; 74% in 5 months and 4% in 19.9 months. The use of the model allowed us to reject the treatment in 33 (22.5%) patients (18 in the group 1.7 months, 14 in 5 months and 1 in 19.9 months). We planned 21 (14%) patients who were not treated for death (3 in 1.7 months and 18 in 5 months).

### Conclusion

It is a tool that allows us to administer a palliative treatment or dismiss it individually to each patient considering their life expectancy and thus reduce the rate of planned patients not treated by improving the use of resources of our Service.

## EP-1627 Impact of body morphology on survival in patients with bone metastases: A prospective cohort study

B. Pielkenrood<sup>1</sup>, P. Van Urk<sup>2</sup>, J. Van der Velden<sup>1</sup>, N. Kasperts<sup>1</sup>, J. Verhoeff<sup>1</sup>, G. Bol<sup>1</sup>, L. Verkooijen<sup>1</sup>, J. Verlaan<sup>2</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands ;

<sup>2</sup>UMC Utrecht, Orthopedic Surgery, Utrecht, The Netherlands

### Purpose or Objective

An increasing number of patients is diagnosed with spinal metastases due to more effective treatment and better survival of cancer. Patients with painful spinal metastases are treated with radiotherapy, combined with surgical

stabilization in case of spinal instability or neurological deficit. Patients with a life expectancy less than 3 months are deemed unfit for surgery because quality of life is considered to be hampered too much by surgery and revalidation to justify the procedure. Therefore, adequate assessment of expected survival is necessary. The aim of this study was to evaluate whether abdominal fat and muscle distribution, and muscle attenuation are associated with overall survival.

#### Material and Methods

Within the UMC Utrecht PRospective Evaluation of interventional StudiEs on bone meTastases (PRESENT) cohort, we identified all 310 patients who received radiotherapy for thoracic or lumbar spinal metastases. Using an in-house developed delineation tool (VolumeTool), a single transverse slice at the L3 vertebra was used to (semi automatically) segment the visceral fat area, subcutaneous fat area, total muscle area and muscle attenuation (figure 1). Muscle attenuation was defined as the density of the muscle, which decreases with increased lipid content. Subsequently the ratio between visceral and subcutaneous fat was calculated. Cox regression analyses was performed to determine the association between the variables of interest and survival at 90 and 365 days, adjusted for potential confounders (age, sex, primary tumor, Karnofsky performance scale, number of bone metastases, non-bone metastases and neurological symptoms).

#### Results

Patients had a median age of 67 years, and 63% were male. The most common primary tumors were lung (28%), prostate (27%) and breast (18%). Median follow-up was 197 days, overall survival rates at 90 and 365 days were 71% and 36% respectively. In univariable analysis, subcutaneous fat area, fat ratio and muscle attenuation were significantly associated with survival at 90 and 365 days. After adjustment, only muscle attenuation was significantly associated with 90 and 365 days survival, HR: 0.89 (95% CI 0.84-0.94) and HR: 0.93 (95% CI 0.89-0.97) respectively.

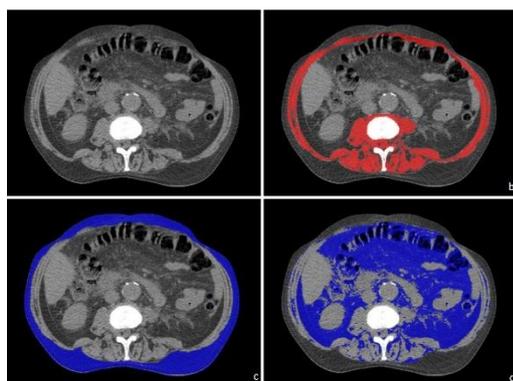

Figure 1. Example of a CT-analysis. a) base CT-scan b) total muscle area measurement c) subcutaneous fat area measurement d) visceral fat area measurement.

#### Conclusion

This study showed that muscle attenuation was significantly associated with the overall survival of patient with spinal metastases. CT-scans, which are routinely available in the majority of patients with spinal metastases, contain useful information and can contribute to better selection of patients for surgical stabilization of spinal metastases.

#### EP-1628 Stereotactic Ablative Radiotherapy for non-spinal bone metastasis. A single institution experience

A. Acosta Rojas<sup>1</sup>, M. Nuñez<sup>1</sup>, A. Montero-Luis<sup>1</sup>, E. Sanchez-Saugar<sup>1</sup>, O. Hernando-Requejo<sup>1</sup>, R. Ciervide-Jurio<sup>1</sup>, M. Lopez-Gonzalez<sup>1</sup>, M. Garcia-Aranda<sup>1</sup>, J. Valero-Albarran<sup>1</sup>, M.C. Rubio-Rodriguez<sup>1</sup>

<sup>1</sup>University Hospital Madrid Sanchinarro, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

To evaluate the effectiveness and toxicity of stereotactic ablative radiation therapy (SART) for non-spinal bone metastases.

#### Material and Methods

From May 2013 to August 2017, 48 non-spinal bone metastasis of 43 patients were treated with SART, 47 metastasis underwent 30 Gy in 3 fractions and 2 lesions received 35 Gy in 5 fractions, delivered every single day in a Linear Accelerator Novalis with inter and intra-fraction orthogonal X-ray imaging guidance (IGRT). Intensity-modulated radiotherapy (IMRT) was performed in 44 lesions (90%) and 3D-conformal radiotherapy in 5 treatments (10%).

Patients were reviewed at the end of treatment and one, three and six months afterward. Pain control was documented with the Visual Analogue Scale (VAS) and the radiological response was determined with the MD Anderson Cancer Center Criteria (MDA criteria).

#### Clinical features of irradiated patients.

Characteristics		Cases	%
<b>Primary tumor n=43</b>			
- Breast	Infiltrating ductal carcinoma	11	25.58
	Infiltrating lobular carcinoma	1	2.33
- Lung	Adenocarcinoma	7	16.28
	Atypical carcinoid	1	2.33
	Prostate adenocarcinoma	14	32.56
- Urothelial	Renal	2	4.65
	Kidney	1	2.33
	Ureter	4	9.30
- Thyroid papillary		1	2.33
- Cholangiocarcinoma		1	2.33
<b>Location of the Metastasis n=48</b>			
- Sacrum		1	2.33
- Sacroiliac		6	13.95
- Iliac crest		13	30.23
- Ischium		3	6.98
- Pubis		2	4.65
- Acetabulum		5	11.63
- Femoral head		4	9.30
- Femoral diaphysis		5	11.63
- Acromion		1	2.33
- Ribs		6	13.95
- Sternum		1	2.33
- Skull		1	2.33
<b>MDA radiological response criteria</b>			
1 <sup>st</sup> control N=38	Stable disease	19	50
	Partial response	10	26.32
	Complete response	8	21.05
	Progression disease	1	2.63
2 <sup>nd</sup> control N=26	Stable disease	16	61.54
	Partial response	3	11.54
	Complete response	5	19.23
3 <sup>rd</sup> control N=19	Progression disease	2	7.69
	Stable disease	9	47.37
	Partial response	1	5.26
	Complete response	5	26.32
	Progression disease	4	21.05

#### Results

With a median follow-up of 14.5 months (1-64 month) 27 patients (56.25%) are alive, 20 patients (41.6%) death for progression of the disease and 1 patient (2.33%) death related to comorbidity.

Complete local pain control was reported in vast majority of patients (graphic 1).

38 lesions (79.17%), 26 lesions (54.17%) and 19 lesions (39.58%) were radiologically evaluated with MDA criteria at 3, 6 and 9 months respectively (table 1).

Local progression free survival was 92.1% at 12 months; 83.3% at 24 and 36 months.

The software is accessed remotely via Citrix and includes Pinnacle treatment planning system (TPS) V14 (Philips), Mosaic Record and Verify (R&V) System V2.62 (Elekta) together with RADCALC (RC) V 6.3 (Lifeline software Inc) and PerFRACTION™ 3D from SunNuclearCorporation.

**Plan production, Plan quality assessment and Plan metrics using Dose Volume Protocol (DVP) and Quality Checks(QC)**- A suite of scripts run within TPS based on the institutes clinical protocols and planning guidelines.

**Plan production** - Palliative Scripted class solution

**DVP** - reports the plan and DVH dose metrics independently extracted in a tabular format enables the planner to review OAR and PTV constraints using a visual traffic light system. Once plan is locked the report is auto generated and attached into the correct patient in R&V.

**QC**-Checks plan integrity against planning guidelines such as beam energy, normalisation and calculation grid which can be configured. QC interrogate R&V for information such as patient demographics and compare to TPS.

**RadCalc®** - independent MU check and creates a configurable QA reports which is auto loaded into R&V for approval if it meets the tolerance.

**RadCalc® Reconciler** - Ensures accurate reconciliation between the planning data in TPS and R&V. Comparison occurs in RC. prerequisites require data export of the final Clinical plan from TPS to RC and R&V to RC. The RTP-Filter informs the user of any differences and the report can be configured to display discrepancies only.

**PerFRACTION™3D** - independent automated phantom-less end to end QA solution for all patient plans and fractions. A report is automatically compiled and accessed via the web user interface. A traffic light system efficiently flags any issues with the option of viewing more information if needed.

## Results

Learning from the trial period from November 2018 to be presented together with detailed process map as well as Clinical case studies.

Activity Name	Activity	Comments
08:00-09:00	Patient preferences and finance details	Consent and book any patient experience appointments or preferences for day (including taxi, therapy table, appointment times, and patient finance details)
09:00-09:30	Checklist review	Appointment must be booked for open the day before to PAO
09:30-10:00	Checklist review	Appointment time to be communicated to patient at the point of arrival (email or text) to the patient - communication any delay
10:00-10:30	Checklist review	Appointment time to be communicated to patient at the point of arrival (email or text) to the patient - communication any delay
10:30-11:00	Checklist review	Appointment time to be communicated to patient at the point of arrival (email or text) to the patient - communication any delay

## Purpose or Objective

Palliative Radiotherapy (PR) for bone metastases is a possible treatment for metastatic patients but often clinical practice and absence of shared guidelines can limit choice of correct regimen. Prognostic scores can help clinician to tailor time, dose and volume in PR. In this study we investigate about decision variance after application of Mizumoto Prognostic Score (MPS) to different clinical cases

## Material and Methods

Nine clinical cases were selected with a complete indication of MPS parameters: 3 cases were of A class (prognosis > 6 months), 3 of B class (prognosis between 6 and 12 months) and 3 of C class (prognosis between 12 and 24 months). Radiotherapy Oncologists (ROs) with different grade of experience [in training RO (IT), Junior RO (JRO), Senior RO(SRO), Junior RO Team Palliative member (JRPO), Senior RO Team Palliative member (SP)] underwent a questionnaire to explore what RT regimen would choose before and after MPS application. The questionnaire were administered on blind by phone. Results were recorded on CRF Excel format and analyzed on RStudio. Descriptive statistical analysis and concordance Fleiss' kappa test were used to discriminate variance of answers between groups.

## Results

The questionnaire was administered to 75 ROs (12 IT; 13 JRPO; 17 JRO; 25 SRO; 8 SP). Median conversion rate of RT dose prescription after MPS application was 9.3% (1.3-18.6%). In particular median conversion rate was: 13.8% for IT; 11.1% for JRPO; 8.5% for JRO; 10.2% for SRO; 15% for 15%. According to Fleiss' kappa parameters, evaluation of agreement in dose prescription showed an improving in 5.18% at the overall analysis after MPS application. Analytical case evaluation of agreement showed a basal good level of concordance between ROs in C class cases (46.8-66.6%), with an implement of agreement between 5.6 and 15.6%. A and B class cases showed a poor level of basal agreement (25-35.2%), that after MPS rise since to 38.6%. MPS score application resulted in increase of the agreement in the choice of pattern of care, beyond clinician's experience and actual patient's prognosis.

## Conclusion

This preliminary investigation about prognostic score used in palliative radiotherapy has showed that MPS application can change RT prescription in 9.3% of participant with different grade of experience in palliative care. Globally, there was also an increase of the agreement in final dose prescription, although only of 5.18%. Further analysis on subgroups, experience in palliation and clinical cases stratification would be reported in extensive publication, together with more questionnaire results.

## EP-1632 Response prediction of palliative radiotherapy to painful spinal bone metastases

J. Akhgar<sup>1</sup>, J.C. Peeken<sup>2</sup>, S.U. Pigorsch<sup>3</sup>, S.E. Combs<sup>2</sup>  
<sup>1</sup>Klinikum rechts der Isar - Technical University of Munich TUM, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>Klinikum rechts der Isar - Technical

University of Munich TUM - Institute of Innovative Radiotherapy iRT - Department of Radiation Sciences DRS - Helmholtz Zentrum München - Deutsches Konsortium für Translationale Krebsforschung DKTK - Partner Site Munich, ; <sup>3</sup>Klinikum rechts der Isar - Technical University of Munich TUM - Deutsches Konsortium für Translationale Krebsforschung DKTK - Partner Site Munich, Department of Radiation Oncology, Munich, Germany

### Purpose or Objective

Palliative radiation therapy of painful spinal bone metastases (SBM) triggers a pain response in only two-thirds of treated patients. A reliable prediction model of pain may help to personalize the decision for radiation therapy. In this retrospective study, we investigated the relationship between several pretherapeutic data and pain response in SBM patients.

### Material and Methods

A cohort of 190 patients with SBM treated with radiation was analyzed. Patients with non-solid tumors and previous invasive procedures were excluded. Pretherapeutic information about basic patient characteristics, staging information, treatment modalities, radiation-specific regimens, Karnofsky Performance Index (KI) and Spinal Instability Neoplastic Score (SINS) was collected. SINS was determined using radiotherapy planning CT scans. Pain response was categorized as complete pain response, partial pain response, indeterminate pain response or progression of pain according to previous studies. For statistical analysis, binary variables were created: complete response and any response (complete or partial pain response). Patients with indeterminate pain response were excluded. Univariate and multivariate binary logistic regression (IBM SPSS Statistics 20) was used to test for associations.

### Results

Univariate logistic regression revealed significant associations between complete response and multiple pretherapeutic parameters: SINS (Odds-Ratio [OR] 0.879; 95% confidence interval [CI] 0.784-0.985;  $p < 0.027$ ), KI (OR 1.032; 95% CI 1.006-1.058;  $p < 0.014$ ), neurological dysfunction (OR 0.459; 95% CI 0.232-0.909;  $p < 0.025$ ), tumor type (prostate or mammary carcinoma [OR 0.411; 95% CI 0.235-0.720;  $p < 0.002$ ] vs lung cancer [no significance (ns)] vs others [reference category;  $p < 0.008$ ]), tumor histology (adenocarcinoma [OR 0.127; 95% CI 0.024-0.672;  $p < 0.015$ ], squamous cell carcinoma [ns] and others [ns]), simultaneous systemic therapy (chemotherapy [ns], hormone therapy [ns], targeted [OR 0.344; 95% CI 0.154-0.767;  $p < 0.009$ ], no therapy [reference category;  $p < 0.002$ ]). There was no significant association between complete response and age, gender, grading, localization, spinal cord compression, soft tissue involvement, metastasis type (blastic/lytic/mixed), opioid/steroid medication and radiation dose. KI (OR 1.053; 95% CI 1.014-1.094;  $p < 0.008$ ) and neurological dysfunction (OR 0.320; 95% CI 0.103-0.997;  $p < 0.049$ ) were also significantly associated with complete response in multivariate logistic regression. Only age (OR 0.974; 95% CI 0.949-0.999;  $p < 0.043$ ) and steroid medication (OR 3.314, 95% CI 1.254-8.757;  $p < 0.016$ ) were significantly associated with any response in univariate and multivariate logistic regression.

### Conclusion

Our results indicate that spinal stability, higher KI, no simultaneous therapy, no neurological dysfunction, specific tumor histologies, and tumor types may be associated with pain response in patients with spinal bone metastases treated with radiation.

<sup>1</sup>Vall D`Hebron Hospital, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

The role of radiotherapy as a supportive treatment in the palliative care of patients with advanced stages of cancer is well known. However, the decision to carry out these treatments is influenced by the benefit that could be obtained in the last days of life. The aim of this study was to analyze the factors that could influence death within 30 days after a palliative radiotherapy (RT) treatment was initiated.

### Material and Methods

We retrospectively collected data from patients treated with palliative intention radiotherapy in our department between January and June of 2018 in order to identify factors related to mortality in the first 30 days after start of the treatment. Clinical features of gender, age, Eastern Cooperative Oncology Group performance status (PS), Karnofsky index, presence of visceral metastases, the indication of radiotherapy treatment (antalgic, haemostatic, whole brain radiotherapy [WBRT], spinal cord compression or any other) and the prescribed doses. Follow-up was made up to 3 months after the RT was performed, but we decided to set our cut-off point in 30 days.

### Results

A total of 353 palliative treatments were performed in 284 patients. The main characteristic of our population are describe in table 1. The mean age was 64 years (5-90). At the end of the follow up period, 27 patients (9.5%) receiving 120 different treatments during the follow up, died within 30 days after the last treatment was performed, with a median of 16 days (13-22 days) after the start of the treatment. In the 27 deaths, single doses were administered in 37% of the cases (10), 9 with antalgic intentions. Typical fractionation schemes as 20Gy in 5 fractions and 30Gy in 10 fractions occurred in 7 patients (25.9%) in both cases, being 60% for pain control and 60% for WBRT, respectively. A higher mortality rate was observed in those who had worse performance status (ECOG 0= 18% vs ECOG 3= 69%  $p < 0.005$ ; KPS > 70= 24.2% vs KPS < 70= 49.3%  $p < 0.005$ ). Likewise, a difference was observed between the group with visceral metastasis and those that did not have it. Regarding the primary tumour, the lowest mortality was observed in the patients with breast, prostate, gynecologist and myeloma without finding a statistical significance. Greater mortality was found in WBRT and the cases of spinal cord compression (46.8% and 51.8% respectively,  $p$  NS) and in those who received single dose RT (44.8%  $p < 0.005$ ). Of these patients, 57.5% had a partial or completed response to treatment ( $p < 0.005$ ).

EP-1633 Profile of patients who die in the first 30 days after palliative radiotherapy in our center

	No	8 (2,3)	9 (2,5)	

Quantitative variables expressed in median (percentile 25<sup>th</sup>, percentile 75<sup>th</sup>). Qualitative variables expressed in total amount and percentages. \*Whole brain radiotherapy. \*\*p>0.05, <sup>1</sup>Karnofsky performance status, <sup>2</sup>Eastern cooperative oncology group.

## Conclusion

As expected, the highest mortality incidence at 30 days was found in patients with worse PS, which in the majority of cases were treated with single doses, and in those with presence of visceral metastases. The largest fractionation schemes included in this group were prescribed in patients with WBRT intention.

Knowing these data is useful for treatment decision making as well as selection of dose-fractionation prescription. This could help to avoid futility and non-beneficial treatment during the end of life.

## EP-1634 Stereotactic Body Radiotherapy (SBRT) for bone metastases: Preliminary experience

E. González Del Portillo<sup>1</sup>, O. Alonso-Rodríguez<sup>1</sup>, A. Nieto-Palacios<sup>1</sup>, C. Martín-Rincón<sup>1</sup>, L.A. Pérez-Romasanta<sup>1</sup>

<sup>1</sup>Complejo Asistencial Universitario de Salamanca, Radiation Oncology, Salamanca, Spain

### Purpose or Objective

Bone metastases (BM) are common in patients with advanced solid tumours causing pain, disability, increased fracture risk, and having a negative impact on patient's quality of life. Stereotactic body radiotherapy (SBRT), also referred to as stereotactic ablative radiotherapy (SABR), is an emerging option of treatment for these metastases. It is characterized by either a single or limited number of dose fractions, and a high biological effective dose, often above 100 Gy. Its effects are higher cell death, lower DNA repair mechanisms, damage to tumour vasculature, and activation of immune system. Our goal is to evaluate local control, survival, pain control and complications.

### Material and Methods

This is a prospective study from 2014 to 2018. We included 31 oligometastatic patients and 44 BM treated with SBRT. Patients received a total dose of 20-35 Gy, typically in 5 consecutive fractions. Most treatments included an extended volume with simultaneous integrated boost on the macroscopic tumor, following standardized consensus for volume definition. Daily 3D imaging for verification purposes was done before treatment. The endpoints were radiological response and local control (control included complete response, partial response and stable disease), survival rate by Kaplan-Meier method, and pain control

evaluated with visual analogic scale (VAS) (0-3: light; 4-6: moderate; 7-10: intense).

## Results

Mean age at the bone metastases diagnoses was 56 years (range: 32-85 years). The most common primary tumour was breast cancer (58%), followed by lung cancer (16%), renal cell carcinoma (9%) and prostate cancer (6%). For metachronous metastases the mean interval between primary tumour diagnoses and bone metastasis diagnoses was 4,5 years (range: 0-18 years). Synchronous primaries and metastases appeared in 30% of patients. Most metastases (80%) were located in the spine, especially thoracic and lumbar vertebrae. Others sites were pelvis, breastbone, ribs and femur. Radiologically, 52% were sclerotic, 30% were lytic and 18% were mixed metastases. The maximum number of treated lesions per patient was 4. The mean total dose for macroscopic tumour was 29 Gy (range: 18-35 Gy) and for adjacent bone was 22 Gy (range: 20-30 Gy). Local control rate, including complete response, partial response and stable disease was 75%. Two year overall survival was 73,7%. The mean following time was 386 days. Four patients died during the follow-up. Before treatment, 16% suffered moderate pain and 30% intense pain. After treatment, 8 patients achieved complete control (VAS 0); 7 presented partial control (lower VAS); 12 kept stable; 4 patients did not achieve symptomatic control. The mean reduction of VAS after SBRT was 2 points. Forty-two percent achieved reduction of VAS ≥3 (range 3-8). No spinal cord toxicity was observed.

## Conclusion

SBRT is a treatment option for BM because local control and pain control without toxicity are achievable in most of cases.

## EP-1635 Stereotactic ablative radiation therapy for non-spine bone metastases

K.S. Kim<sup>1</sup>, C. Choi<sup>1</sup>

<sup>1</sup>Dongnam Institute of Radiological and Medical Sciences, Radiation Oncology, Busan, Korea Republic of

### Purpose or Objective

To report the treatment outcome of stereotactic ablative radiation therapy (SABR) for non-spine bone metastases in a single institution

### Material and Methods

From Jul. 2011 to Jan. 2017, thirty-three patients with non-spine bone metastatic disease were treated with SABR. Treatment intent were categorized as follows (1) Single metastasis or oligometastases, for which the goal was to irradiate all sites of disease; (2) Oligoprogression, for which the goal was to irradiate only those tumors that were progressing while a systemic therapy was controlling all other sites of disease; (3) Dominant areas of progression, for which the goal was to irradiate dominant tumors usually for palliation. A total of 38 lesions were treated and responses were evaluated according to University of Texas MD Anderson (MDA) cancer center criteria.

### Results

The most common primary cancer was non-small cell lung cancer (n=12) following breast cancer (n=8), hepatocellular carcinoma (n=3) and renal cell carcinoma (n=3). Twenty-five lesions (66%) were located in the pelvis following femur (n=5) and ribs (n=5). Majority of the lesions were lytic bone metastases (n=25, 66%). Prescribed radiation doses and fractions were 18 Gy/1 fraction (Fx) to 3 lesions, 24-60 Gy/3 Fx to 16 lesions, 28-48Gy/4 Fx to 15 lesions and 40-50 Gy/5 Fx to 4 lesions. Median follow up periods was 10.4 months (2.5-47.4). One-year local control rate was 94.2%. Median overall survival was 25.1 months (95% CI 14.7-35.5 month) for single metastasis or oligometastasis (n=24), 25.7 months (95% CI 0-54.2) for oligoprogression (n=3) and 5.8 months (95% CI 2.0-9.6) for

dominant areas of progression (n=6). No grade 3 or greater toxicity was reported.

#### Conclusion

Although heterogeneous patients populations, SABR to non-spine bone metastases showed high local control rate with acceptable toxicity. Appropriate treatment indication and unified response evaluation are important for the future clinical trials and wide application of SABR to non-spine bone metastases in the clinic.

#### EP-1636 Linac-based radiosurgery in elderly patients: mono-institutional experience on 110 brain metastases

F. Gregucci<sup>1</sup>, A. Fiorentino<sup>1</sup>, S. Corradini<sup>2</sup>, V. Figlia<sup>1</sup>, R. Mazzola<sup>1</sup>, F. Ricchetti<sup>1</sup>, R. Ruggeri<sup>1</sup>, F. Alongi<sup>1,3</sup>

<sup>1</sup>Hospital Sacro Cuore Don Calabria- Cancer Care Center, Radiation Oncology, Negrar, Italy ; <sup>2</sup>LMU University Hospital, Radiation Oncology, Munich, Germany ;

<sup>3</sup>University of Brescia, Radiation Oncology, Brescia, Italy

#### Purpose or Objective

To analyze the feasibility and clinical results of linac-based stereotactic radiosurgery (SRS) or fractionated stereotactic radiotherapy (SFRT) with Flattening Filter Free (FFF) volumetric modulated arc therapy (VMAT) in elderly patients affected by Brain Metastases (BMs) with the idea of improving patients' compliance at treatment and their quality of life.

#### Material and Methods

Patients selected for the present analysis were > 65 years old with a life expectancy of > 3 months, good performance status, a controlled or synchronous primary tumor, a number of BMs <10 with a diameter <3 cm. All patients were treated with FFF Linac-based SRS/SFRT. The prescribed total dose (15-30Gy/1-5 fractions) was based on BMs size, proximity to organs at risk and intent of treatment. Acute and late toxicity was assessed according to CTCAE v4.0. A retrospective analysis of patients, BMs, treatment characteristics and outcomes included toxicity, local control (LC), overall survival (OS) and intracranial progression free survival (iPFS), were performed. MedCalc v18.2 was utilized for statistical analysis.

#### Results

From April 2014 to December 2017, 40 elderly patients with 110 BMs were treated by FFF-VMAT Linac-based SRS/SFRT. Median age was 70 years (range 65-83). The median number of BMs was 2 (range 1-10). The median PTV was 1 cc (0.1-42) and the median diameter of BMs was 1 cm (0.6-3). In case of multiple BMs, the median cumulative PTV was 10.3 cc (range 0.9-65.9 cc). Median biologically effective dose (BED) calculated with an alfa/beta value of 12 Gy was 47.2 Gy, with 87% of BMs receiving an efficacy dose  $\geq$  40 Gy. The median beam on time was 2 min (range 1,5-4) for lone lesion, while for multiple BMs, the treatment time was 11 min (range 9-15). With a median follow-up time of 28 months (range 6-50), median and 1-year OS were 9 months and 39%, respectively; median iPFS was 6 months. No difference in terms of outcomes were observed between patients under or over the age of 70 years ( $p=0.2$  and  $p=0.18$ ). At the time of the analysis, LC was reported in 109/110 BMs (99.1%): 12 BMs had a complete response; 51 a partial response; 46 a stable disease. One BM (0.9%) progressed after 2 months. The analysis of LC profile stratified by clinical and treatment variables has shown that BM volume (<1cc) and higher SRS/SFRT dose ( $\geq$  40 Gy) correlated to positive treatment local response ( $p=0.01$ ;  $p=0.0017$ ). No adverse events more than grade 2 were observed.

#### Conclusion

The present findings highlight the feasibility, safety and effectiveness of FFF Linac-based SRS/SFRT in elderly patients with BMs.

#### EP-1637 Validation of a predictive model for survival in elderly patients treated with radiotherapy

H. Park<sup>1</sup>

<sup>1</sup>Dankook University Hospital, Radiation Oncology, Cheonan, Korea Republic of

#### Purpose or Objective

Elderly patients are more likely to have poor performance status and comorbidities. There is a reluctance to extensively investigate and treat elderly patients. Patient selection based on prognosis is necessary to provide appropriate treatment. This study was conducted to validate a predictive model for survival of elderly patients treated with palliative radiotherapy.

#### Material and Methods

From February 2015 to February 2018, a total 41 patients aged 80 and older underwent palliative radiotherapy. Prognosis in Palliative care study predictor (PiPS), Palliative prognostic index (PPI) and Delirium-Palliative prognostic score (D-PaP) were used for prediction of survival. The Clinical prediction of survival (CPS) was excluded from the D-PaP score. The median biologically effective dose (BED) was 39 Gy<sub>10</sub> (range, 28-75 Gy<sub>10</sub>) with dose-per-fraction of 2.5-7.0 Gy.

#### Results

Among 41 patients, 1 patient didn't receive the scheduled treatment. During the median follow-up duration of 1.8 months (range, 0.2-27.5 months), 20 patients referred to hospice care center and 6 patients died. The 1- and 6-months overall survival (OS) rates were 97.0% and 87.3%, respectively. The 1- and 6-months OS of patients who were predicted to live more than a month according to PiPS were 100% and 90.7%, respectively. Patients with PPI and D-PaP without CPS less than 4 points, the 1- and 6-months OS were 100% and 93.8% each. The 1- and 6-month OS were 80.0% and 0% in the patients with D-PaP without CPS 4 points or more ( $p<0.001$ ). D-PaP without CPS score showed significant correlation with survival ( $p=0.033$ ).

#### Conclusion

The prognostic prediction models can be used to predict prognosis in elderly patients who need palliative radiotherapy. These models can be used to guide clinical decisions, including patient selection, total dose and schedule of radiotherapy. Further studies are needed to develop a more appropriate prediction models for elderly patients.

#### **Purpose or Objective**

In USA 53% of new cancer cases are diagnosed in people over 65 years, and in the next decade the incidence of cancer in elderly people will continue to grow up. Radiotherapy (RT), chemotherapy and more recently immunotherapy have favorably changed the outcome of various cancers. Nevertheless, elderly people are under-represented in clinical trials. Aim of the present review is to assess the present data about the use of the association of Radiotherapy and immunotherapy in elderly people.

#### **Material and Methods**

PubMed database was searched for English literature published up to December 2017 using keywords "radiotherapy" combined with "immunotherapy" and "ipilimumab" or "pembrolizumab" or "nivolumab". Studies performing radiotherapy and immunotherapy in people aged > 65 years were evaluated focusing on safety, toxicity and, if possible, efficacy. Studies eligible for inclusion in this review were: (a) case reports, retrospective or prospective studies in which RT and new drugs were used concomitantly or sequentially; (b) studies in which the evaluation of elderly sub-group was reported.

#### **Results**

The systematic search identified 363 records from PubMed. After exclusion of duplicates, full-text review, cross-referencing and paper that do not respect the inclusion criteria, 20 studies were included in this review. As regard Ipilimumab, data seems to indicate a longer OS in patients with metastatic melanoma treated with ipilimumab +RT vs those treated with ipilimumab alone, suggesting a possible RT role in enhancing ipilimumab-induced immune response (Stokes WA et al 2017, Tazi K et al 2015). In NSCLC a prospective phase II trial of neoadjuvant ipilimumab followed by radical or post operative surgery demonstrated excellent tolerance with no observed G3 or more side effects (Boyer MJ et al 2016) and in prostate cancer ipilimumab + palliative RT seems to improve OS in subgroups of pts (high risk) (Kwon ED et al 2015). As regards Pembrolizumab it seems to improve PFS and OS in NSCLC previous treated with RT without increasing in side effects (Shaverdian N et al 2017). On the other hand there are some data on immunotherapy related pneumonitis during anti PD1 treatment combined to RT, reported both for pembrolizumab and for nivolumab with development also later after RT end (Lu CS et al 2017, Manapov F et al 2018, Yoshida Tet al 2017).

#### **Conclusion**

Immunotherapies in association of RT seems to be safe, but in elderly patients data concerning safety and toxicity are limited. The tolerance of combined RT and immunotherapy seems similar among older and younger people. To date many data underline the immune stimulation of RT, so it might be interesting evaluate if the two combined treatment might improve the response also in elderly patients. Specific clinical trials on this population are encouraged.

#### **EP-1639 Socioeconomic Status and Mortality in Elderly Cancer Patients:A National Elderly Sample Cohort Study**

B. Jang<sup>1</sup>, J.H. Chang<sup>2</sup>

<sup>1</sup>Seoul National University Hospital, Radiation Oncology, Seoul, Korea Republic of ; <sup>2</sup>SNU-SMG Boramae Medical Center, Radiation Oncology, Seoul, Korea Republic of

#### **Purpose or Objective**

We hypothesized that lower socioeconomic status (SES) was associated with higher all-cause mortality in patients newly diagnosed with cancer, particularly with respect to the elderly (age  $\geq$  60 years). There are no previous studies evaluating the relationship between individual/regional-level SES and all-cause mortality in cancer patients more than 60 years in the context of national health care coverage.

#### **Material and Methods**

We collected study patients from the stratified random sample of Korean National Health Insurance Elderly Cohort (2002-2015). Patients who were newly diagnosed with cancer between 2003 and 2015 were included. Those living in a newly created city ('Sejong' city) or with other/ill-defined/sex-specific cancer at diagnosis were excluded. A total of 108,626 patients were collected. Cox's proportional hazard regression model was used to investigate risk factors of mortality. Individual SES position (insurance type, income level) and regional-level SES from composite deprivation index (CDI) 2010 were derived. The comorbidities were measured using Charlson Comorbidity Index score.

#### **Results**

Patients with disability or residing in a deprived region were found more in the low-income level group. In patients  $\leq$ 80 years, multivariate Cox hazard regression model revealed that low-income status was associated with higher risk of mortality compared to high-income status (HR 1.08, 95% CI 1.05-1.11,  $P < 0.001$ ). Contrary to patients > 80 years, those  $\leq$ 80 years and living in a deprived region at diagnosis showed worse survival (HR 1.10, 95% CI 1.08-1.12,  $P < 0.001$ ). Male, lowest insurance

#### **Conclusion**

Low individual/regional SES at the time of cancer diagnosis is associated with increased mortality in elderly patients. Further understanding causes of the phenomena and accordingly providing support for elderly cancer patients with low SES or residing in deprived regions would be necessary.

#### **EP-1640 Radical radiotherapy in elderly prostate cancer patients: a monoinstitutional experience**

C.L. Deantonj<sup>1</sup>, A. Fodor<sup>1</sup>, C. Fiorino<sup>2</sup>, C. Cozzarini<sup>1</sup>, F. Zerbetto<sup>1</sup>, P. Mangili<sup>2</sup>, C. Calandrino<sup>2</sup>, N.G. Di Muzio<sup>1</sup>  
<sup>1</sup>San Raffaele Scientific Institute- Milano- Italy, Department of Radiotherapy, Milano, Italy ; <sup>2</sup>San Raffaele Scientific Institute- Milano- Italy, Medical Physics, Milano, Italy

#### **Purpose or Objective**

Continuous or intermittent androgen deprivation therapy (ADT) is generally prescribed in elderly prostate cancer (PCa) patients (pts) with under 10 years life expectancy. Unfortunately, 18-24 months later many pts become castration resistant and only palliative therapies are available. Here we report toxicity and outcomes obtained in elderly ( $\geq$ 80 years old at diagnosis) PCa (pts) treated with radical radiotherapy in a monoinstitutional experience

#### **Material and Methods**

From December 2006 to July 2014, 34 elderly PCa pts underwent radiotherapy with radical intent. Three pts, affected by a low risk cancer, were treated on prostate and seminal vesicles only, to 71.4 Gy in 28 fractions (EQD2 80.8 Gy, considering  $\alpha/\beta=1.5$  for prostate cancer). Intermediate and high-risk PCa pts underwent prophylactic irradiation on pelvic nodes to 51.8 Gy in 28 fractions (EQD2 52.2 Gy), with simultaneous integrated boost to seminal vesicles up to 65.5 Gy (77.7 Gy EQD2) and to prostate up to 74.2 Gy (88 Gy EQD2). Neoadjuvant and/or adjuvant androgen deprivation therapy (ADT) was prescribed in 25/34 pts for a median of 27.9 months (2-79 months). All patients were treated with helical IMRT

(Tomotherapy®, Accuray, Wisconsin) and daily IGRT (MVCT). Patients' characteristics are reported in Table 1.

Median ( range) age at diagnosis	82 (80-90) years
Median (range) iPSA	10.09 (3.74-300.0) ng/ml
	6: 9
	7: 11
Median ( range) Gleason Score	8: 6
	9: 9
	cT1c: 16
	cT2a: 3
	cT2b: 2
T Stage	cT2c: 10
	cT3: 2
	cT4: 1

## Results

Median follow up was 61 (13.3-128.6) months. Acute and late toxicity were mild, with only one late G3 rectal toxicity (2.94%) registered, eventually solved by Argon Plasma applications, and 1 G3 urinary stenosis (2.94%), solved with temporary catheterization. Late G2 toxicity were 14.7% (5 pts) for urinary tract and 5.88% (2 pts) for the rectum.

Five-year biochemical relapse-free survival (bRFS) was 73.5% (25/34 pts) and clinical relapse-free survival was 79.4% (27/34 pts). Median bRFS and distant progression-free survival (calculated from the last day of RT) were 56.3 and 61.1 months respectively Eighteen pts were dead at the last follow up, six of whom with a prostate cancer progression.

## Conclusion

Radical radiotherapy with a curative intent even in elderly pts demonstrated good results in terms of both biochemical control and progression-free survival, with a good toxicity profile. In our opinion, radical treatment in elderly pts could improve their life expectation and quality of life.

### EP-1641 Radiotherapy for prostate cancer patients over 80 years: 95 patients treated in a single institution

P. Méré<sup>1</sup>, C. Dalban<sup>2</sup>, E. Peynet<sup>2</sup>, A. Guignot<sup>1</sup>, J. Droz<sup>3</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Department of Radiation Oncology, Lyon, France ; <sup>2</sup>Centre Léon Bérard, Department of Research and Innovation, Lyon, France ; <sup>3</sup>Centre Léon Bérard, Department of Medical Oncology, Lyon, France

## Purpose or Objective

The benefit of radiotherapy alone or associated with hormonal treatment is still debated in men aged 80 years or more, due to competitive risk of death and the fear to induce more often severe acute or late toxicities than younger men. The objectives were to assess if the standard of care could be applied in that population

## Material and Methods

A retrospective study has been conducted in all consecutive patients (pts) aged 80 years or more, treated with a curative intent from January 2003 to December 2013 in a single radiotherapy center for a non-metastatic prostate adenocarcinoma (prostatectomy excluded). All patients received external beam radiotherapy (EBRT) or brachytherapy (BT) with or without associated hormonal therapy (HT) according to the cancer status, co-morbidities, and physician decision.

95 pts aged from 80 à 91 Years (median 81.9 Years) have been included. The majority of patients (92.2%) were in the 80 to 85 years age group.

The Performance Status was 0 in 84% and 1 in 16%. The majority of patients had 1 or 2 co-morbidities, but most were rated CIRS-G-1 or 2 and therefore not severe. All patients had an assessment of their overall health based on medical record data according to Balducci classification and G8 oncology and item distribution. 83.2% were considered as "fit elderly" according to

Balducci classification, and the G8 score was > 14 in 56.8 %.

The distribution according to d'Amico and Zumsteg Score was: low (4 pts), favorable intermediate (10 pts), unfavorable intermediate (28pts) and high risk (53 pts).

91 pts were treated with EBRT and 4pts with Iodine seeds BT. 21 pts previously receive a palliative HT before the decision to propose radiotherapy with a curative intent. HT was used concomitantly with EBRT in 36 pts.

Regarding EBRT techniques, a conformational 3D was used for the first 50pts, before the technique moved to IMRT (standard in 10; VMAT in 31 pts). The mean and median dose delivered to the prostate were respectively 69.7 and 74 Gy (Range 24 - 78) to the prostate volume. Pelvic nodes were irradiated in 15 patients.

## Results

The median follow-up time was 5.1 years (CI95%:4.6- 5.9). EBRT was prematurely stopped in 8 pts because of a grade >=3 acute toxicity in 5 (urinary in 4; diarrhea in 1), a fall at home in 2 and a breakdown in 1 pt. Three patients experienced a grade 3 late toxicity: Bladder in 2 pts; Rectal in 1pt. No grade 4 was reported. The median overall survival was 9.9 years. Event Free Survival according to d'Amico and Zumsteg classification are presented in figure 1.

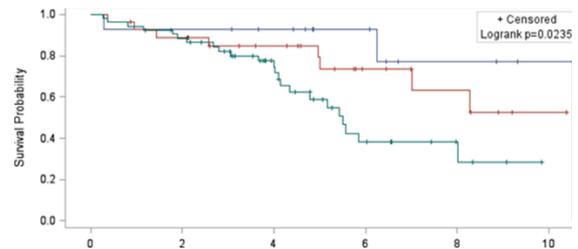

Figure 1: Event free survival (death, recurrence) according to D'Amico/Zumsteg classification 1: Low and Favorable Intermediate risk ; 2: Unfavorable Intermediate risk; 3: High risk

## Conclusion

Radiotherapy with a curative intent may be proposed in selected patients of 80 years or more, providing an accurate geriatric oncology evaluation to evaluate the benefit of this treatment in term of overall survival and quality of life.

### EP-1642 Short-course accelerated palliative EBRT for advanced head and neck cancer in elderly patients

M. Ferro<sup>1</sup>, G. Macchia<sup>1</sup>, S. Cilla<sup>2</sup>, A. Ianiro<sup>2</sup>, V. Picardi<sup>1</sup>, M. Boccardi<sup>1</sup>, E. Arena<sup>1</sup>, M. Ferro<sup>1</sup>, S. Cammelli<sup>3</sup>, F. Romani<sup>4</sup>, S. Riga<sup>4</sup>, E. Farina<sup>3,5</sup>, M. Buwenge<sup>3</sup>, M.A. Sumon<sup>6</sup>, A. Kamal Uddin<sup>6</sup>, P. Assalone<sup>7</sup>, V. Valentini<sup>8</sup>, A.G. Morganti<sup>3</sup>, F. Deodato<sup>1</sup>

Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

## Purpose or Objective

To assess the safety and efficacy of a Short-course Accelerated Radiation therapy (SHARON) regimen in the

palliative treatment of H&N locally advanced or metastatic cancer in elderly patients.

#### Material and Methods

Eligibility criteria for the analysis were: 1) histological confirmed H&N cancers, 2) age  $\geq$  80 years, 3) expected survival  $>$  3 months and 4) Eastern Cooperative Oncology Group (ECOG) performance status of  $\leq$  3. A total dose of 20 Gy was delivered in 2 consecutive days with a twice daily fractionation (5 Gy per fraction) and at least 6-8 hour interval. Primary endpoint was the symptoms response rate.

#### Results

Thirty-four patients (male/female: 18/16; median age: 85.0 years; range: 80-98) were included in the analysis. ECOG performance status was  $<$  3 in 17 patients (50%). Patients with different cancer types were included in the analysis, in particular the primary were: oral cavity (N<sup>o</sup>=13; 38.2%), larynx (N<sup>o</sup>=5; 14.7%), oropharynx (N<sup>o</sup>=4; 11.7%), salivary gland (N<sup>o</sup>=3; 8.8%), lip (N<sup>o</sup>=3; 8.8%), nasal cavity (N<sup>o</sup>=2; 5.8%), maxillary sinus (N<sup>o</sup>=3; 8.8%) and ethmoid sinus cancer (N<sup>o</sup>=1; 2.9%). With a median follow-up time of 4.5 months (range 1 to 28 months), two patients (5.9%) developed  $\geq$ G3 acute toxicities: one patient had a G3 mucositis and one had a G3 dysphagia requiring N-G feeding tube and G4 dyspnoea requiring tracheostomy. Moreover, 9 (26.4%) G1-G2 acute pharyngeal toxicities, 8 (23.5%) G1-G2 acute skin toxicities and 9 (26.4%) G1-2 mucositis were recorded. Overall palliative response rate was 76.5%. Moreover, among 24 symptomatic patients for pain, 21 showed an improvement or resolution with an overall pain response rate of 87%. No detrimental effects in terms of quality of life (CLAS 1,2,3) were observed after the treatment. The median survival time was 9 months, with a median palliative progression free survival of 8 months.

#### Conclusion

Short-course accelerated radiotherapy in palliative setting of Head & Neck cancers is effective in terms of symptom relief and well tolerated even in elderly patients.

#### EP-1643 Short-course accelerated palliative radiotherapy for advanced lung cancer in elderly patients

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy; <sup>3</sup>Radiation Oncology Center, Dept. of Experimental- Diagnostic and Specialty Medicine - DIMES- S.Orsola-Malpighi Hospital, Bologna, Italy; <sup>4</sup>Maria Cecilia Hospital- GVM Care & Research, Radiation Oncology Unit, Cotignola RA, Italy; <sup>5</sup>Veneziale Hospital, Oncology Unit, Isernia, Italy; <sup>6</sup>Black Lion Hospital, Department of Radiotherapy, Addis-Ababa, Ethiopia; <sup>7</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

#### Purpose or Objective

To assess the safety and efficacy of a Short-course Accelerated Radiation therapy (SHARON) regimen in the palliative treatment of locally advanced or metastatic lung cancer in elderly patients.

#### Material and Methods

Eligibility criteria for the analysis were: 1) histological confirmed lung cancers, 2) age  $\geq$  80 years, 3) expected survival  $>$  3 months and 4) Eastern Cooperative Oncology Group (ECOG) performance status of  $\leq$  3. A total dose of 20 Gy was delivered in 2 consecutive days with a twice daily fractionation (5 Gy per fraction) and at least 8 hour

interval. Primary endpoint was the symptom response rate.

#### Results

Forty patients (male/female: 29/11; median age: 84.0 years; range: 80-96) were included in the analysis. ECOG performance status was  $<$  3 in 36 patients (90%). Patients with different cancer histology were included in the analysis, in particular: adenocarcinomas (N<sup>o</sup>=22; 55%), squamous cells (N<sup>o</sup>=15; 37.5%), small cell lung cancer (N<sup>o</sup>=3; 7%). With a median follow-up time of 1.2 months (range, 1 to 20 months), no G3 acute toxicities were observed, 2 (5%) G2 acute lung toxicity, 2 (5%) G1-G2 acute skin toxicities and 2 (5%) G1 esophagus toxicities were recorded. Among overall 26 symptomatic patients, 25 showed an improvement or resolution of baseline symptoms (overall palliative response rate: 96%). With a median survival time of 6 months, the median symptom free survival was 4 months. No differences in terms of quality of life was recorded after the treatment. Two of 40 (5%) patients required a retreatment that was performed in median after 5 months (range: 3-7 months) from the previous one.

#### Conclusion

Short-course accelerated radiotherapy in palliative setting of lung cancers is effective in terms of symptom relief and well tolerated even in elderly patients.

#### EP-1644 Elderly patients with non-melanoma skin cancer: results of accelerated hypofractionated treatment

M. Ferro<sup>1</sup>, G. Macchia<sup>1</sup>, E. Arena<sup>1</sup>, S. Cilla<sup>2</sup>, A. Ianiro<sup>2</sup>, V. Picardi<sup>1</sup>, M. Boccardi<sup>1</sup>, S. Cammelli<sup>3</sup>, A. Morganti<sup>3</sup>, F. Deodato<sup>1</sup>, M. Ferro<sup>1</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy; <sup>3</sup>Radiation Oncology Center, Dept. of Experimental- Diagnostic and Specialty Medicine - DIMES- University of Bologna- S.Orsola-Malpighi Hospital, Bologna, Italy; <sup>4</sup>United Hospital Limited, Radiation Oncology Department, Gulshan- Dhaka, Bangladesh; <sup>5</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

#### Purpose or Objective

To assess the safety and efficacy of an accelerated radiotherapy schedule (Short Skin) in elderly patients with early stage non-melanoma skin cancer (NMSC).

#### Material and Methods

Eligibility criteria for the analysis were: 1) Patients with NMSC  $\leq$  3 cm, without infiltration of deep structures; 2) aged  $\geq$ 80 years; 3) Eastern Cooperative Oncology Group (ECOG) performance status of  $\leq$  3. Exclusion criteria were as follows: T3-T4 disease stage, prior RT on the same anatomical site, and poor compliance. Radiotherapy was delivered using electrons (6-9-12 MeV) or megavoltage photons (6MV) depending on tumor site and characteristics. The field size choice depended on the lesion size and location. For basal cell tumors of stage T1, the field size included a 1.5-cm normal tissue margin, while for stage T2 and/or squamous cell carcinomas, a 2.5-3-cm margin was included. A total dose of 30 Gy was delivered in 5 Gy fractions throughout six consecutive days. Primary endpoint was the local control rate.

#### Results

Forty patients (male/female: 24/16; median age: 87.0 years; range: 80-98) were included in the analysis. ECOG performance status was  $<$  3 in 37 patients (92.5%). The histology of skin cancer was squamous cell in 19 (47.5%) and basal cell in 19 (47.5%) patients, while 2 patients had mixed histology (5%). With a median follow-up time of 10 months (range, 2-63 months), no G3 acute skin toxicity

was recorded, while G2 skin toxicity was recorded in 20 patients (50%) and G2 mucositis was recorded in one patient (2,5%). The complete response of lesion was obtained in 18 (45%) patients, with a partial response in 9 (22,5%) patients. In 7 (17,5%) patients the response was not evaluable and in 6 (15%) patients was registered a stable disease. The 1-year actuarial local control was 82,5% with median local control not reached.

#### Conclusion

Short-course RT in elderly patients affected by early stage NMSC is able to produce more than 80% disease local control with excellent tolerability

#### EP-1645 Short-course accelerated palliative radiotherapy for advanced skin cancer in elderly patients

M. Ferro<sup>1</sup>, F. Deodato<sup>1</sup>, S. Cilla<sup>2</sup>, A. Ianiro<sup>2</sup>, V. Picardi<sup>1</sup>, M. Boccardi<sup>1</sup>, E. Arena<sup>1</sup>, S. Cammelli<sup>3</sup>, E. Galofaro<sup>3</sup>, V. Panni<sup>3</sup>, A. Arcelli<sup>3</sup>, M. Buwenge<sup>3</sup>, M.A. Sumon<sup>4</sup>, A. Kamal Uddin<sup>4</sup>, A.L. Angelini<sup>5</sup>, S. Riga<sup>5</sup>, V. Valentini<sup>6</sup>, A.G. Morganti<sup>3</sup>, G. Macchia<sup>1</sup>

<sup>1</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Radiotherapy Unit, Campobasso, Italy ; <sup>2</sup>Fondazione di Ricerca e Cura "Giovanni Paolo II", Medical Physics Unit, Campobasso, Italy ; <sup>3</sup>Dept. of Experimental- Diagnostic and Specialty Medicine - DIMES- University of Bologna- S.Orsola-Malpighi Hospital, Radiation Oncology Center, Bologna, Italy ; <sup>4</sup>United Hospital Limited- Gulshan, Radiation Oncology Department-, Dhaka, Bangladesh ; <sup>5</sup>Dept. of Experimental- Diagnostic and Specialty Medicine - DIMES- University of Bologna- S.Orsola-Malpighi Hospital, Medical Physics Unit, Bologna, Italy ; <sup>6</sup>Policlinico Universitario "A. Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

#### Purpose or Objective

To assess the efficacy and safety of a Short-course Accelerated Radiation therapy (SHARON) regimen in the palliative treatment of non-melanoma skin cancers in elderly patients.

#### Material and Methods

Patients with histological confirmed non-melanoma skin cancers, age  $\geq$  80 years, expected survival  $>$  3 months and Eastern Cooperative Oncology Group (ECOG) performance status of  $\leq$  3 were considered eligible for this analysis. The primary endpoint was to evaluate the symptom response rate. Radiotherapy regimen was based on the delivery of 4 radiotherapy fractions (5 Gy per fraction) with a twice daily fractionation in two consecutive days. Three different level of dose were administered according to organ at risk constraints: 20 Gy (1 cycle), 40 Gy (2 cycles) and 60 Gy (3 cycles).

#### Results

Twenty-seven patients (male/female: 13/14; median age: 87.0 years; range: 80-98) were included in this analysis. ECOG performance status was  $<$  3 in 18 patients (66.6%).

Histology were squamous cell carcinoma (N<sup>o</sup>=21, 77.8%), basal cell carcinoma (N<sup>o</sup>=3, 11.1%), baso-squamous carcinoma (N<sup>o</sup>=2, 7.4%) and Bowen's Disease (N<sup>o</sup>=1, 3.7%). Among 14 patients who completed the 1 cycle, only one (7%) experimented acute G3 skin toxicity; two (14%) G2 skin toxicities were observed. Nine patients reported an improvement or resolution of baseline symptoms (overall palliative response rate: 64%). When more cycles were administered, mean time between cycles was 28 days. Six patients underwent to 2 RT cycles: of these, no G3 toxicities were recorded; four patients (66%) showed G2 mucosal toxicity and G2 skin toxicity. In this subset of patients the overall response rate was 100%. Six patients received 3 RT cycles: none of them experienced G3, but all of them showed G2 skin toxicity. Even in this case, overall response rate was 100%. With a median survival

time of 15 months, the median symptom free survival was 10 months.

#### Conclusion

Short-course accelerated radiotherapy in palliative setting of non-melanoma skin cancers is effective in terms of symptom relief and well tolerated even in elderly patients. High doses seem to be more effective in terms of response rate against a reasonable toxicity profile.

#### EP-1646 Radiation Oncology for the Older Person: Defining international standards for trainee education

L. Morris<sup>1,2</sup>, S. Turner<sup>1</sup>, N. Thiruthaneeswaran<sup>3</sup>, A. O'Donovan<sup>4</sup>, M. Agar<sup>2</sup>, R. Simcock<sup>5</sup>

<sup>1</sup>Crown Princess Mary Cancer Centre, Radiation Oncology, Westmead, Australia ; <sup>2</sup>IMPACCT Centre Improving Palliative- Chronic and Aged Care through Clinical Research and Translation, University of Technology Sydney, Sydney, Australia ; <sup>3</sup>University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom ; <sup>4</sup>Applied Radiation Therapy Trinity, Trinity College Dublin, Dublin, Ireland ; <sup>5</sup>Brighton and Sussex University Hospitals NHS Trust Department, Sussex Cancer Centre, Sussex, United Kingdom

#### Purpose or Objective

To define an internationally applicable geriatric radiation oncology curriculum competency set for radiation and clinical oncology training. The purpose of developing a curriculum in geriatric radiation oncology is to address the gap in education in this increasingly important area of oncology practice.

#### Material and Methods

Stage 1 (completed): An Expert Reference Panel comprised of inter-professional experts in geriatric and radiation oncology was formed. Members of the panel performed an initial needs assessment by reviewing the literature. The candidate competency set was then developed via a comprehensive review of geriatric oncology literature, related international guidelines and consultation with international experts. Items were grouped into key learning themes.

Stage 2 (results pending): A modified Delphi Consensus methodology will be employed to further refine the ideal geriatric oncology competency set for radiation and clinical oncology trainees worldwide. Two formal Delphi rounds delivered online will be conducted with an intervening Expert Reference Panel Round (n = 9). Participants (n = 40) will review and rank potential curriculum competencies as well as providing free text comments.

Medical specialists looking after elderly patients from radiation oncology, geriatrics, surgery, medical oncology and palliative care will be invited to participate, as well as radiation and clinical oncology trainees, radiation therapists, specialist nurses and consumers. Rounds will commence in November 2018.

Geographic spread of participants aims at widespread relevance of the final competency set. This study is an international collaboration supported by the Global Radiation Oncology Collaboration in Education in conjunction with the Faculty of Radiation Oncology (RANZCR) and the UK Macmillan ER (Expert Reference Group) for the Older Person with Cancer.

#### Results

Stage 1: The Expert Reference Panel identified 70 potential knowledge & skill-based 'candidate' competencies across 12 domains. Concepts range from the epidemiology and biology of ageing and cancer, general geriatric medicine, geriatric assessment in oncology, approaches to planning and delivery of radiation therapy in the older person with cancer and special considerations regarding the role of systemic therapy, surgery and palliative care. Skills in communication, research, education and health advocacy are also included.

Stage 2: Modified expert Delphi Consensus results are pending. **Conclusion**

Development of the first international dedicated geriatric radiation oncology curriculum is underway. This educational framework will support radiation oncology training bodies around the world in ensuring future radiation and clinical oncologists are able to provide high quality and appropriate care to the rapidly increasing numbers of elderly people with cancer.

#### EP-1647 Neoadjuvant chemoradiotherapy in elderly rectal cancer patients in a mono-institutional experience

L. Gasparini<sup>1</sup>, C. Rosa<sup>1</sup>, S. Di Biase<sup>1</sup>, C. Di Carlo<sup>1</sup>, A. Allajbej<sup>1</sup>, F. Patani<sup>1</sup>, D. Fasciolo<sup>1</sup>, A. Porreca<sup>2</sup>, M. Di Nicola<sup>2</sup>, L. Caravatta<sup>1</sup>, D. Genovesi<sup>1</sup>  
<sup>1</sup>SS. Annunziata Hospital- "G. D'Annunzio" University, Department of Radiation Oncology-, Chieti, Italy ; <sup>2</sup>"G. D'Annunzio" University, Laboratorio di Biostatistica-Dipartimento di Scienze Biomediche, Chieti, Italy

#### Purpose or Objective

Colorectal cancer affects similarly both young and elderly patients. The improving mean life expectancy increases the number of rectal cancer patients in good performance status (PS), permitting to achieve a curative intent. Furthermore, modern radiotherapy (RT) allows a better coverage to the tumor, preserving the adjacent organs at risk, decreasing acute and late toxicities. The aim of this study was to evaluate the impact of neoadjuvant chemoradiotherapy (CRT) in elderly patients.

#### Material and Methods

Between 2000 and 2018, 117 (M:80;W:37) locally advanced rectal cancer patients, with  $\geq 70$  years, were treated in our Radiotherapy Department and retrospectively analysed. They received concurrent fluoropyrimidine based chemotherapy. RT was performed by 3D conformal technique, with a dose of 4500 cGy, on the pelvic nodes, followed by a sequential boost or a concomitant boost. Mandard tumor regression grade (TRG) score was used to evaluate the pathologic response. The evaluation of anal sphincter function was obtained according to the Memorial Sloan-Kettering Cancer Center (MSKCC) score. Acute and late toxicities were assessed using the Radiation Therapy Oncology Group (RTOG) scale and the RTOG/European Organization for Research and Treatment of Cancer (EORTC) late radiation scoring system. The 3-year and 5-year local control (LC), disease-free survival (DFS) and overall survival (OS) rates were calculated using the Kaplan-Meier method.

#### Results

Median follow-up was 45 months (range:1-163). The median age was 75 (range: 70-88). One hundred and three (88%) patients had ECOG PS 0. Sixty (51.3%) patients were staged as T3-T4 and/or N+. Eighty-three (70.9%) patients were treated with a sequential boost, with a total dose of 5040 cGy, whereas 34 (29.1%) received a concomitant boost of 1000 cGy (100 cGy/die, 2 times/week, total dose 5500 cGy). A pathological complete response (TRG 1) was obtained in 23 patients (19.7%). Acute toxicities were reported in Table 1. Twenty-four patients (20.5%) were lost to the follow-up. Ninety-four (80.3%) patients were evaluated for late toxicities. Overall sphincter function resulted excellent in 23 (24.5%) patients, good in 3 (3.2%), fair in 6 (6.4%) and poor (incontinence) in 11 (11.7%) patients. Twenty-three (24.5%) patients presented stoma. One patient presented late skin toxicity  $\geq G3$  and 2 late GI toxicity  $\geq G3$ . The 3-year DFS and OS rates were  $82.8\pm 4.2\%$  and  $86.5\pm 3.8\%$ , respectively. The 5-year LC, DFS and OS rates were  $89.5\pm 3.9\%$ ,  $73.3\pm 5.2\%$  and  $78.1\pm 5.0\%$ , respectively.

Table 1. Acute Toxicities

Acute Toxicities	G0	G1	G2	G3
Skin Toxicity	63 (53.8%)	22 (18.8%)	31 (26.5%)	1 (0.9%)
GI Toxicity	37 (31.6%)	39 (33.3%)	39 (33.3%)	2 (1.8%)
GU Toxicity	88 (75.2%)	26 (22.2%)	3 (2.6%)	0 (0%)
Hematologic Toxicity	94 (80.4%)	10 (8.5%)	10 (8.5%)	3 (2.6%)

#### Conclusion

Our results reported good tolerability, in terms of acute and late toxicities and clinical outcomes, of neoadjuvant CRT in patients 70 years. Based on our analyses, elderly patients with good PS can be also considered to be treated with a concomitant boost intensification in presence of very unfavourable prognostic factors.

#### EP-1648 Radio-chemotherapy with temozolomide in elderly patients with glioblastoma: our experience

A. Molinari<sup>1</sup>, F. Pasqualetti<sup>1</sup>, A. Gonnelli<sup>1</sup>, M. Cantarella<sup>2</sup>, S. Montrone<sup>1</sup>, F. Paleari<sup>1</sup>  
<sup>1</sup>University Hospital of Pisa, Radiotherapy Unit, Pisa, Italy ; <sup>2</sup>Casa di Cura San Rossore, Radiotherapy, Pisa, Italy

#### Purpose or Objective

Glioblastoma multiforme (GBM) is the most aggressive brain tumor in adults and the second most common brain cancer after meningioma with a peak of incidence on the fifty decades of life. Due to the progressive ageing of the developed country population, more than a half of new cases occurs in patients older than 65 years. The aim of the present study was to evaluate the clinical outcome of radio-chemotherapy with temozolomide in patients with glioblastoma aged more than 65 years.

#### Material and Methods

Sixty-three patients treated with radiotherapy and chemotherapy at Pisa University Hospital between September 2004 and November 2017 were enrolled in this retrospective analysis. All patients had a proven diagnosis of glioblastoma grade IV WHO, ECOG PS 0-2, age  $\geq 65$ . Radiotherapy was delivered in daily fractions of 2 Gy given 5 days per week for 6 weeks, for a total of 60 Gy. During radiotherapy, temozolomide was administered at a dose of 75 mg per square meter of body-surface area per day from the first to the last day of radiotherapy. 5-6 weeks after the end of radiotherapy, adjuvant temozolomide was administered at 150-200 mg per square meter for five consecutive days, every 28 days. A maximum of 12 cycles were prescribed if MRI showed no disease progression and temozolomide was well tolerated.

#### Results

Data analysis was performed in April 2018. The present study was performed in 37 male and 26 female patients with a median age at diagnosis of 72,5 years (range=65-89). Fifty-seven patients underwent surgical resection, four patients stereotactic diagnostic biopsy, two patients had a radiologic diagnosis only. During follow up, we recorded 46 cases of disease progression with a median progression-free survival (PFS) of 12 months (range 1-88 months). Median overall survival (OS) were 25 months (range 1-107 months); at data analysis, 65 patients were died. After disease recurrence, based on ECOG, tumor burden and age, patients were treated with surgery (15 cases), chemotherapy (30 cases) and re-irradiation (11 cases).

#### Conclusion

In our experience, progression free survival and overall survival were similar to those reported in literature for younger patients. We think that radiochemotherapy is a good option for older patients with a good performance status in glioblastoma treatment.

### EP-1649 Patterns of care and survival in elderly patients with advanced soft-tissue sarcoma

D. Greto<sup>1</sup>, S. Calogero<sup>2</sup>, M. Lo Russo<sup>1</sup>, D. Pezzulla<sup>1</sup>, M. Loi<sup>1</sup>, M.A. Teriaca<sup>1</sup>, V. Maragna<sup>1</sup>, S. Lucidi<sup>1</sup>, D.A. Campanacci<sup>3</sup>, G. Beltrami<sup>3</sup>, G. Scocianti<sup>3</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence-Azienda Ospedaliera Universitaria Careggi AOUC, Department of Biomedical-Experimental- and Clinical Sciences, Firenze, Italy ;  
<sup>2</sup>Molecular and Nutritional Epidemiology Unit, Cancer Research and Prevention Institute ISPO, Florence, Italy ;  
<sup>3</sup>University of Florence-Azienda Ospedaliera Universitaria Careggi AOUC, Department of Orthopaedic Oncology and Reconstructive Surgery, Firenze, Italy

#### Purpose or Objective

Elderly people represent more than 50% of sarcoma patients and they often present many differences compared to younger patients. In fact, older patients experience increased cancer-related morbidity and mortality compared to younger patients: this is shown in several studies pointing out that older age is associated to poorer outcomes. Nowadays, there are no data regarding the management of advanced soft-tissue sarcoma (STS) in elderly patients. The aim of this study is to analyze clinical outcome and treatment related toxicity of elderly STS patients in a single Institution.

#### Material and Methods

We retrospectively collected data of patients  $\geq 65$  years old diagnosed with localized advanced STS between 1998 and 2017 in a single institution.

#### Results

The study included 111 patients. Mean Charlson Index was 7.5 (2-12). One hundred five (94.6%) patients underwent surgery, ninety-one patients (82%) received radiotherapy, 23 (20.7%) patients received concurrent radiochemotherapy and 20 (18.1%) patients received chemotherapy alone. Grade  $>3$  acute skin toxicity was recorded in 38 (52.8%) patients out of 72 patients who received postoperative radiotherapy, age  $> 80$  years correlated with higher incidence of toxicity compared to younger patients (63.6% vs 33.3%,  $p=0.02$ ). Late fibrosis, late edema and joint stiffness occurred in 10.4%, 11.8% and 4% of patients, respectively. Age did not correlate to late toxicity incidence. At a mean follow up of 4.1 years (0.1-17.7) twenty-four (22%) patients recurred, 3- and 5-year local recurrence free survival was 80.3% and 75.7%, respectively. At statistical analysis no treatments and patients characteristics affected local recurrence. Fifty-five (52.9%) patients developed distant metastasis, 3- and 5-year distant metastasis free survival (DMFS) was 59.6% and 44.6%, respectively. At univariate analysis no delivered of adjuvant radiotherapy and no surgery correlated with higher local recurrence ( $p=0.043$  and  $p=0.002$ ). On multivariate analysis, undifferentiated pleomorphic sarcoma histology was the only independent factors associated with DMFS ( $p=0.026$ ). Overall survival (OS) was 62% and 46.6% at 3 and 5 years, respectively. On multivariate analysis, surgery was the only independent factor associated with OS ( $p=0.006$ ).

#### Conclusion

Older patients have worse outcomes because they tend to present with worse tumors and are treated less aggressively. In this study elderly STS patients were treated with a tailored treatment comprising surgery, radiotherapy and/or chemotherapy resulted in a good efficacy and safe.

### EP-1650 Elderly glioblastoma patients:role of multidimensional assessment of frailty in predicting outcomes

L. Giaccherini<sup>1</sup>, P. Ciammella<sup>1</sup>, M. Galaverni<sup>1</sup>, M. Manicone<sup>1</sup>, I. Renna<sup>1</sup>, M. Galeandro<sup>1</sup>, G. Timon<sup>1</sup>, F. Bellafiore<sup>1</sup>, D. Ramundo<sup>1</sup>, F. Vigo<sup>1</sup>, A. Rosca<sup>1</sup>, T. Palmieri<sup>1</sup>, M.P. Ruggieri<sup>1</sup>, A. Botti<sup>2</sup>, R. Sghedoni<sup>2</sup>, E. Cagni<sup>2</sup>, M. Orlandi<sup>2</sup>, M. Iori<sup>2</sup>, M. Russo<sup>3</sup>, C. Iotti<sup>1</sup>

<sup>1</sup>Radiation Oncology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy ; <sup>2</sup>Medical Physics Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy ; <sup>3</sup>Clinical Neurology, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

#### Purpose or Objective

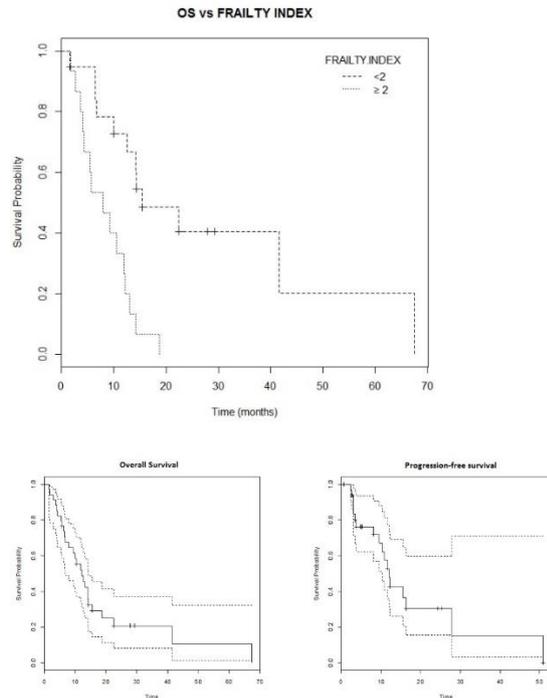

To evaluate the impact of comorbidities, clinical and biological factors on outcomes in elderly glioblastoma (GBM) patients (pts) treated with surgery followed by concurrent radiation (RT) and Temozolomide (TMZ).

#### Material and Methods

Elderly pts with GBM treated from January 2013 to December 2017 were included in the study. We collected data regarding age, extension of surgery, use of current medications, Karnofsky Performance Status (KPS), presenting symptoms, Prognostic Nutritional Index (PNI), Charlson Co-morbidity Index (CCI) and Frailty Index (FI). All of these parameters, measured before the start of RT-TMZ, were linked to clinical outcomes.

#### Results

Thirty four pts (male/female: 23/11; median age: 70 years), were retrospectively analysed. After a median follow-up of 9.7 months (range 2.0 - 30.6), the median OS was 12.1 months (range 6.7-14.3), and 1-year OS was 50% (range 31-64%). Median PFS was 12.1 months (range 10.3 + NA), 1-year PFS was 48% (range 30-73%). Four pts (11,76%) experienced G1-2 neurological symptoms during RT. No pts showed G3 events. At univariate analysis high KPS and total surgery were significantly associated with better OS ( $p=0.0339$  and  $p=0.00782$ ) and only the type of surgery with PFS ( $p=0.0182$ ). Using log rank test we identified as the optimal PNI cut-off level the value of 42; the best cut-off value of CCI was 2 for OS and 3 for PFS. Univariate analysis showed that 14 pts with a PNI  $< 42$  had a median survival of 13.10 months versus 8.38 months for those pts with a PNI  $\geq 42$  ( $p=0.63$ ). The 1 year OS rate for pts with a PNI  $< 42$  was 25% while the corresponding value for pts with PNI  $> 42$  was 54%. Univariate analysis showed that pts with a CCI  $>2$  had a median OS of 8 months versus 14.2 months for pts with CCI  $<2$  ( $p= 0.076$ ). The 1-year OS rate was 33% and 54% for pts with CCI  $<2$  and  $\geq 2$ , respectively. Pts with CCI  $\geq 3$  showed a median PFS of 5.9 months versus 12.3 months for those with CCI  $<3$  ( $p=0.0113$ ). The 1-year PFS rate for pts with a CCI  $<3$  was 52%, while no pts with CCI  $> 3$  was alive at one year. At the multivariate analysis FI alone remained significant in predicting OS: presenting with a FI  $>2$  compared with FI  $<2$  was significantly associated with an increased risk of death [( $p= 0.023$ , HR = 3.330 (1.96 - 5.66)]. At multivariate analysis KPS, type of surgery and FI remained a significant predictors of OS and, based on these parameters, we generated a prognostic score that, dividing pts into three risk categories, has proven to be a survival predictor, with an increase of the risk of death by 2.2 times for each increment of the score (HR 2.2,  $p=0.0004$ ).

### Conclusion

The appropriate management of elderly cancer pts with GBM is an important concern in oncology. Our data suggest that in elderly pts in good clinical conditions and with a low FI score, extensive surgery, when feasible without adding neurological impairment, followed by adjuvant RT-TMZ, should be considered.

### EP-1651 Geriatric oncology for decision-making in women over 75 years with breast cancer

M.D. De las Peñas-Cabrera<sup>1</sup>, J. Martínez Peromínguez<sup>2</sup>, P.M. Samper Ots<sup>1</sup>, E. Amaya Escobar<sup>1</sup>, M. Hernández Miguel<sup>1</sup>, C. Oñoro Algar<sup>2</sup>, M.E. Baeza Monedero<sup>2</sup>, C. González de Villambrosia<sup>2</sup>, J. Zapatero Ortuño<sup>1</sup>, S. Hoyos Simón<sup>3</sup>, M.R. Noguero Meseguer<sup>4</sup>, E. Abreu Griego<sup>4</sup>, M. De Matias Martínez<sup>4</sup>, R. Fernández Huertas<sup>4</sup>, A.B. Cuesta Cuesta<sup>4</sup>  
<sup>1</sup>Hospital Rey Juan Carlos, Radiation Oncology, Mostoles - Madrid, Spain ; <sup>2</sup>Hospital Rey Juan Carlos, Geriatric Oncology, Mostoles - Madrid, Spain ; <sup>3</sup>Hospital Rey Juan Carlos, Clinical Oncologist, Mostoles - Madrid, Spain ; <sup>4</sup>Hospital Rey Juan Carlos, Oncology Gynecology, Mostoles - Madrid, Spain

### Purpose or Objective

Geriatric Oncology Unit helps us to make oncological decision making, through a Comprehensive Geriatric Assessment (CGA). The objective of the present study is to describe how our patients are categorized, decisions made and the impact on oncological treatments.

### Material and Methods

It's a retrospective study on data prospectively recorded. From January 2017 to September 2018, 114 oncology patients, older than 75 years, were diagnosed in the University Hospital Rey Juan Carlos, Mostoles, Spain. Of them 42 patients (37.5%, 42/112) had breast cancer. All of them received a Comprehensive Geriatric Assessment. Data are shown as number and percentages and chi-squared was used for comparisons.

### Results

Age was  $83.90 \pm 4.83$  (range 75-94). Histology was invasive ductal carcinoma 81.0% (34/42). Immunophenotype was: Luminal A and B in 28 cases, 66.6%. Clinical stages were: I-II in 28 cases and IV, only in 11.9%. Comprehensive Geriatric Assessment was as follows: **Functional reservation**, with Barthel scale, only 31% were

independent; minor dependents, 31%. A high comorbidity according to Charlson score: 47.6% was present. **Polypharmacy** (> 5 drugs), was present in 64.3%. According to **Frail Frailty Questionnaire**: Non fragile 64.3% and fragile 35.7%. The **SPPB**: serious limitation, 33.3% Criteria for malnutrition according to the **MNA scale**: 54.8%, normal nutritional status; risk of malnutrition 40.5% and were only malnutrition 4.8%. And according to the body mass index, normal 42.9%. The presence of cognitive impairment on the **Pfeiffer scale**: normal were 54.8% and severe only 5 patients, 11.9%. Classification of patients, clinical decisions and main outcomes according to CGA were: **Robust**: 35.7% (15/42), decided: Endocrine therapy (ET): 40%, alive with disease. All of patients, were Luminal A or B. Full-oncological treatment: 60% (Surgery+/-CT+/-RT), alive without disease. Of them, 44.44%, (4/9) were triple negatives. One patient received chemotherapy neoadjuvant and 3, surgery was initial treatment. **Frail patients**: 50% patients, Refused[CdS1] treatment[B2] , 23.8%. Of them, 80% were triple negatives ET: 42.85%, alive with disease. **Bad prognostic patients**: 28.57%, of them, refused treatment 1 patient, 16.6%, palliative treatment with ET, 66.66%. The period of **follow up** was  $19.43 \pm 26.09$  months (Range 0.10-129.97). The 54.66% (23/42) were alive with disease. After the recommendation of the CGA, the proportion of patients in whom a curative treatment was decided was higher in the group of robust patients. This difference was statistically significant ( $p = 0.03$ ) when comparing robust patients with both poor prognosis and fragile groups considering these together.

### Conclusion

The CGA, the Immunophenotype and the participation of the patient and their families were determinants of the oncological treatment decision. Exclusive endocrine therapy was the most recommended treatment, in 45.23%. Comprehensive Oncogeriatric Assessment allows oncological treatments to be personalized without reducing the quality of life.

### EP-1652 Stability and survival of elderly patients after palliative radiotherapy of spinal bone metastases

T. Bostel<sup>1,2,3</sup>, R. Förster<sup>1,4</sup>, I. Schlamp<sup>1</sup>, T. Sprave<sup>1</sup>, S. Akkaba<sup>1</sup>, D. Wollschläger<sup>5</sup>, J. Debus<sup>1,3</sup>, H. Schmidberger<sup>2</sup>, H. Rief<sup>1</sup>, N.H. Nicolay<sup>1,3,6</sup>

<sup>1</sup>University Hospital of Heidelberg, Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>University Medical Center Mainz, Radiation Oncology, Mainz, Germany ; <sup>3</sup>German Cancer Research Center DKFZ, Clinical Cooperation Unit Radiation Oncology, Heidelberg, Germany ; <sup>4</sup>University Hospital of Zurich, Radiation Oncology, Zurich, Switzerland ; <sup>5</sup>University Medical Center Mainz, Medical Biostatistics- Epidemiology and Informatics IMBEI, Mainz, Germany ; <sup>6</sup>University Hospital of Freiburg, Radiation Oncology, Freiburg, Germany

### Purpose or Objective

This retrospective study aimed to evaluate the stability of spinal bone metastases (SBM) in elderly patients resulting from various solid tumors following palliative radiotherapy (RT).

### Material and Methods

A total of 322 patients aged at least 70 years received palliative RT at two major University Hospitals. Stability assessment was based on the validated Taneichi score based on CT-imaging acquired prior to RT as well as at 3 and 6 months after RT. Furthermore, the survival time after RT (bone survival, BS) and prognostic factors for stability and survival were assessed.

### Results

Prior to RT, 183 patients (57%) exhibited unstable SBM. Among the surviving patients, significant re-calcification and stabilization were evident in 19% (23/118) and 40% (31/78) at the follow-up examinations at 3 and 6 months after RT. In breast cancer patients, the stabilization rates

were significantly higher than in patients with SBM derived from other histologies such as lung cancer, malignant melanoma or urothelial cancer. The median survival time and 6-months-survival rates following RT were 5.4 months (95% CL 4.4 - 7.2 months) and 48%, respectively. To predict BS, the Karnofsky performance status (KPS) was the strongest predictive factor in our study; further statistically significant factors were the application of chemotherapy, number of SBM and primary tumor classification.

#### Conclusion

Prognostic assessment of elderly patients with SBM should be at least based on the primary tumor classification and the KPS. In the event of palliative RT, more hypofractionated radiation schedules are advisable for patients with a very poor prognosis to reduce hospitalization times and to maintain the residual quality of life.

#### EP-1653 Evaluation of Italian Radiotherapy research: preliminary analysis

A. Fiorentino<sup>1</sup>, R. Mazzola<sup>2</sup>, V. Lancellotta<sup>3</sup>, S. Saldi<sup>3</sup>, S. Chierchini<sup>3</sup>, A.R. Alitto<sup>4</sup>, P. Borghetti<sup>5</sup>, F. Gregucci<sup>2</sup>, M. Fiore<sup>6</sup>, I. Desideri<sup>7</sup>, L. Marino<sup>8</sup>, D. Greto<sup>7</sup>  
<sup>1</sup>General regional Hospital "F. Miulli", Radiation Oncology Department, Acquaviva delle fonti BA, Italy ; <sup>2</sup>Ospedale Sacro Cuore Don Calabria, Radiation Oncology, Negrar, Italy ; <sup>3</sup>University of Perugia, Radiation Oncology, Perugia, Italy ; <sup>4</sup>Fondazione Policlinico Universitario A. Gemelli IRCCS, Radiation Oncology, Roma, Italy ; <sup>5</sup>University and Spedali Civili, Radiation Oncology, Brescia, Italy ; <sup>6</sup>Campus Bio-Medico University, Radiation Oncology, Rome, Italy ; <sup>7</sup>University of Florence, Radiation Oncology, Firenze, Italy ; <sup>8</sup>REM- Viagrande, radiation Oncology, Catania, Italy

#### Purpose or Objective

The difficulty in conducting meaningful clinical research is a multifactorial issue, involving political, financial and cultural problems, which can lead to unexpected negative long-term consequences, in terms of knowledge advancement and impact on patient care. Aims of the present review were to evaluate the publications of Italian Radiotherapy (RT) groups during a 20-year period and to verify if research is still appealing to young radiation oncologists (RO) in Italy.

#### Material and Methods

PubMed database was searched for English-language articles published by Italian groups by 2 independent RO, from January 1985 to December 2015 using as keywords "radiotherapy" combined with "Italy" [(radiotherapy) AND (Italy)]. Studies eligible for inclusion in this analysis were: case reports, radiobiological studies, clinical and dosimetric retrospective or prospective studies (Phase I-II-III) in which RT was used, systematic or not reviews and meta-analyses. Exclusion criteria were: study not conducted in Italy, study in which RT was not used or was not investigated, study in which no Italian RO was in the authors list. Analyzed variables were: publication/year, kind of study, geographic area and age of the first Author.

#### Results

The systematic review identified 3291 articles: 1207 papers fulfilled the inclusion criteria. The number of Italian published papers increased during the examined period. Retrospective analyses, prospective Phase I-II trials and literature reviews were 44%, 20% and 14.5% of all published manuscripts, respectively. Randomized trials showed a mild increase from 2000 to 2005, but their absolute number remained low respect to other type of

studies (4%). Northern Italy produced the very most of Italian research papers (58.7%). The age of the first/second Author was evaluated on 716 papers: in more than 50% of cases, the first author was younger than 40.

#### Conclusion

Despite a general gradual improvement, RT clinical research suffers in Italy (as elsewhere) from insufficient funding, with a negative impact on evidence production. It is worth noticing that clinical research is still appealing and accessible to junior Italian RO.

#### EP-1654 Hypofractionation in breast cancer: possible advantages and logistical implications

I. Meaglia<sup>1</sup>, M. Paolini<sup>1</sup>, C. Bocci<sup>1</sup>, G.B. Ivaldi<sup>1</sup>, M. Liotta<sup>2</sup>, P. Tabarelli de Fatis<sup>2</sup>

<sup>1</sup>ICS Maugeri Società Benefit SpA, Servizio di Radioterapia, Pavia, Italy ; <sup>2</sup>ICS Maugeri Società Benefit Spa, Servizio di Fisica Sanitaria, Pavia, Italy

#### Purpose or Objective

In the last three decades, hypofractionation has been an interesting and promising field of investigation. The primary and most important benefit of treating, for instance, breast and prostate cancer with a hypofractionated regimen is the improved therapeutic index that can be obtained; moreover, there are other advantages in terms of logistics, patient convenience and resource allocation. Here, we present our speculations about a routinely use of a hypofractionated regimen in breast after conserving surgery, and how its introduction in our Department has had an impact on our waiting list.

#### Material and Methods

From 2010 to 2017 we used a hypofractionated regimen of 20 fractions, 5 fractions a week, with a weekly concomitant boost. In February 2018, we started a new 15 fractions regimen (5 fractions a week, and weekly concomitant boost), reducing overall treatment time to 3 weeks. In both cases the weekly concomitant boost follows whole breast irradiation immediately. Considering that we scheduled to keep 13 daily slot for breast radiotherapy in a dedicated linear accelerator, we estimated how many patients could be treated with the 15 fractions regimen in one year, assuming 250 working days. Then, we calculated the expected reimbursement (according to the current rates used in the Lombardy social reimbursement based Health System) and compared with the old 20 fractions schedule. We also checked if our waiting list changed during the six months since the introduction of the new fractionation regimen, comparing with historic data from our scheduling activity.

#### Results

In one year we estimate to treat 217 patients using the 15 fractions schedule compared to 162 patients that can be irradiated with the 20 fractions regimen in the same time. The expected reimbursement for each patient is 3200 euro for the 20 fractions schedule and 2750 for the 15 fractions regimen. With almost the same number of daily treatments performed, in the first 6 months of the 15 fractions schedule, we registered an average waiting time to start radiotherapy ranging from 16,3 to 30,1 days (median 24 days) for breast cancer patients. Previously, these patients had to wait at least one month in most of the cases (range: 24,6 - 37,5 days, median 29 days). The introduction of the 15 fractions regimen also affected the waiting list for other clinical scenario such as palliative treatments: in 2016 we calculated an average waiting time of 20,2 days (more than twice than the 10 days suggested by ISTISAN). From February to July 2018 palliative patients had a waiting time less than 10 days for 3 out of 6 months.

#### Conclusion

A hypofractionated regimen allows to treat more patients in the same interval of time with a reduction of the cost for each treatment. The potential increase in number of treated patients can affect the waiting list in a positive

way. These improvements should be additional justification for clinical implementation.

#### EP-1655 Cost-effectiveness analysis of stereotactic radiotherapy in colorectal cancer brain metastases

A. Paix<sup>1</sup>, F. Thillays<sup>2</sup>, J. Biau<sup>3</sup>, N. Vulquin<sup>4</sup>, I. Pop<sup>5</sup>, K. Debbi<sup>6</sup>, A.L. Grosu<sup>5</sup>, E.A. Sauleau<sup>7</sup>, G. Noël<sup>1</sup>

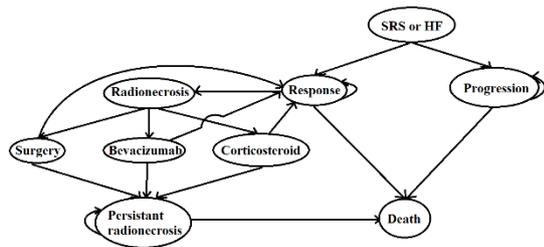

<sup>1</sup>Centre Paul Strauss, Radiothérapie, Strasbourg, France ; <sup>2</sup>Institut Cancérologique de l'ouest, Radiothérapie, Saint Herblain, France ; <sup>3</sup>Centre Jean Perrin, Radiothérapie, Clermont-Ferrand, France ; <sup>4</sup>Centre Georges-François Leclerc, Radiothérapie, Dijon, France ; <sup>5</sup>Universitätsklinikum Freiburg, Klinik für Strahlenheilkunde, Freiburg, Germany ; <sup>6</sup>Centre Henry Kaplan - CHU Tours, Radiothérapie, Tours, France ; <sup>7</sup>CHU Strasbourg, Methodological and clinical research group, Strasbourg, France

#### Purpose or Objective

Colorectal cancer (CRC) is the third most common cancer in developed countries and brain metastases only occur in 1% of CRC patients, however this rate is likely to raise due to the increase of the overall survival as new systemic drugs became available. Stereotactic radiosurgery (SRS) and hypofractionated stereotactic radiotherapy (HFSRT) are treatment options. We developed a Markov model to evaluate the cost-effectiveness of SRS and HFSRT in patients with CRC brain metastases.

#### Material and Methods

We designed a Markov model, reported Figure 1, to simulate the clinical trajectory of a patient with a single CRC brain metastasis using data retrospectively collected in 6 hospitals in France and Germany.

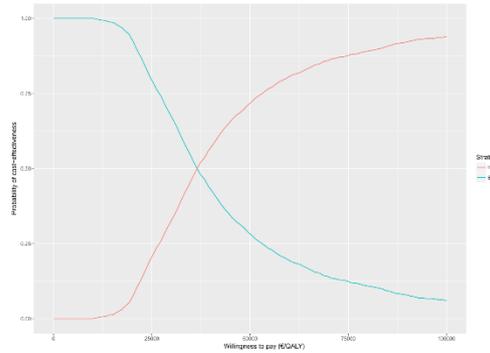

This analysis was conducted in a French payer perspective on a lifetime horizon. Utility values, recurrence risks, and costs were adapted from the literature. Deterministic (DSA) and probabilistic (PSA) sensitivity analyses were performed to assess the influence of the assumptions made.

#### Results

In the base case analysis, SRS and HFSRT total costs were 4,404.76€, and 5,921.34€ and the quality-adjusted life expectancies were 1.2545 and 1.2589.

In the probabilistic sensitivity analysis, SRS and HFSRT were associated with a mean total cost of 4,407.80 € and 5,817.33€, and quality-adjusted life expectancies 1.2597 and 1.2987 QALYs, respectively. SRS appeared to be 1,409.53€ cheaper than HFSRT with a decrease of quality-adjusted life expectancy of 0.039 QALYs. HFSRT had a probability of cost-effectiveness for the willingness-to-pay threshold of 30,000€ and 100,000€ of 33.2% and 94% respectively, as reported on the acceptability curves in Figure 2.

#### Conclusion

This is the first medico-economic evaluation of SRS and HFSRT in CRC brain metastases, and its results suggest that HFSRT is cost-effective compared to SRS, in the French payer perspective.

#### EP-1656 Prevention of heterotopic ossification after total hip replacement: a cost-effectiveness analysis

A. Paix<sup>1</sup>, T. Stévignon<sup>2</sup>, N. Baudrier<sup>3</sup>, G. Noël<sup>1</sup>

<sup>1</sup>Centre Paul Strauss, Radiothérapie, Strasbourg, France ; <sup>2</sup>Hôpital Saint Joseph, Orthopedic surgery, Paris, France ; <sup>3</sup>Centre chirurgical Emile Gallé, Orthopedic surgery, Nancy, France

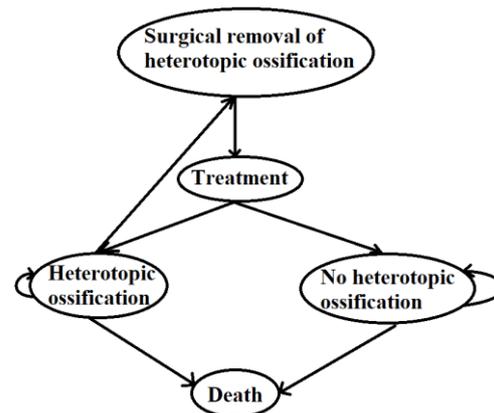

#### Purpose or Objective

Heterotopic ossifications (HO) following total hip replacement can severely impact the quality of life of patients. While there are no guidelines for HO prophylaxis, non-steroidal anti-inflammatory drugs (NSAIDs) are widely used. However, radiotherapy delivered in a single fraction has also proven its efficacy.

We conducted a medico-economic evaluation of NSAIDs and radiotherapy in the prevention of HO following total hip replacement.

#### Material and Methods

We designed a Markov model to simulate the clinical trajectory of a patient at risk for HO following total hip replacement. Two prevention strategies were compared: 3 x 25 mg per day for three weeks and a single radiation dose of 7 Gy. Patients treated with NSAIDs could experience upper digestive bleeding. In both cases, HO could occur despite prophylaxis and be treated with painkiller and physical therapy or surgery.

Our study was conducted from a French payer perspective, using payment data applicable in public hospitals in 2017. All the costs used are expressed in 2017 euros, and costs and Quality Adjusted Life Years (QALYs) were discounted at an annual rate of 4%.

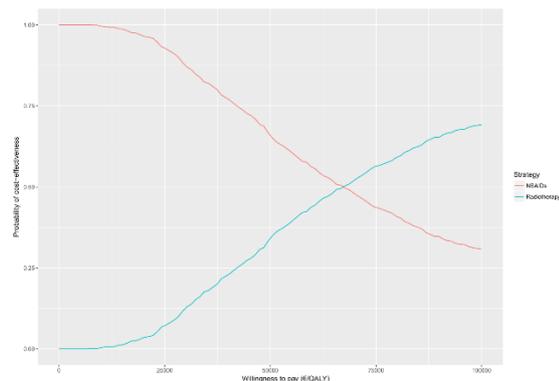

## Results

In the base case analysis total cost for the NSAIDs and the radiotherapy, strategies were 258.81€ and 702.01€ respectively. Utilities for the NSAIDs and radiotherapy strategies were 12.42332 QALY and 12.43608 QALY respectively. The ICER of radiotherapy compared to NSAIDs was 65,545€/QALY.

The deterministic sensitivity analysis reveals that the incremental cost-effectiveness ratio (ICER) is mainly sensitive to the probability of surgery in case of HO, to the relative risk of HO between NSAIDs and radiotherapy, to the probability of HO following radiotherapy, to the probability of upper digestive bleeding for NSAIDs and to the cost of surgery in case of HO.

In the probabilistic sensitivity analysis, the total cost for the NSAIDs and the radiotherapy strategies were 356.87€ and 777.36€ respectively. The utilities related to the NSAIDs and radiotherapy strategies were 14.58905 QALY and 14.59614 QALY respectively. The ICER of radiotherapy compared to NSAIDs was 59,286.17€/QALY. Most of the simulations were in the north-east quarter.

For a willingness to pay threshold of 30,000€/QALY, and 100,000€/QALY, the probability of cost-effectiveness of NSAIDs was 87.3%, and 30.8% respectively.

## Conclusion

We report the results of the first medico-economics evaluation of NSAIDs and radiotherapy in HO prophylaxis. Our analysis suggests that from a French payer perspective, radiotherapy is cost-effective for HO prophylaxis following total hip replacement.

### EP-1657 Overcoming appointment delay in radiotherapy: a single institution experience

M. Ait Erraïsse<sup>1</sup>, O. Masbah<sup>1</sup>, T. Bouhafa<sup>1</sup>, K. Hassouni<sup>1</sup>  
<sup>1</sup>CHU Hassan II, Radiothérapie, Fez, Morocco

#### Purpose or Objective

Delay to access to radiation therapy in developing countries is challenging and compromising the cancer prognosis. In our department there was one linear accelerator for a whole region in the country. 50 to 60 patient a day were treated and appointments were for more than 3 months. The medical and psychological impact on patients was important. Our objective was to shorten this delay.

#### Material and Methods

The radiotherapy department goal was to treat 50 to 60 patients from Monday to Friday as the majority of radiation therapy departments. Treatments started at 8 AM to finish at about 7 to 8 PM. The idea was to treat more patients and efficiently. Therefore, actions were taken on three axes : 1st Before radiotherapy, we had to shorten the time from first consultation to first radiotherapy fraction. 2nd during radiation, we extended treatment period to above 8 PM. and 3rd axis concerns fractionation regimens.

## Results

The hospital executive decided to transform the oncology hospital to an emergency hospital with the possibility to treat 24/7. In this way, we could treat up to 100 patient a day or more. we also treat on weekends especially palliative patients. Concerning the patient workflow, patients were seen immediately when they arrive at the department, and if medical file is complete and ready to radiation, CT scan simulation was done within a week, countouring, dosimetry, and validation with safety checks were done within 3 days. and finally, when possible, we chose hypo-fractionated regimens (Breast, rectum, single fraction for palliative, etc ...).

The appointment time started to drop from more than 3 months to almost 2 weeks.

## Conclusion

In developing countries, access to radiotherapy is a real problem. The number of linear accelerators per capita is very low. Therefore delays are very long. This kind of approach, if sufficient human resources, could solve the problem while waiting for a second and maybe other machines.

### EP-1658 Stereotactic Ablative Body Radiotherapy:UK implementation and current practices.Progress since 2012

G. Distefano<sup>1</sup>, S. Garikipati<sup>2</sup>, H. Grimes<sup>3</sup>, M. Hatton<sup>2</sup>  
<sup>1</sup>University of Surrey, Centre for Vision- Speech and Signal Processing, Guildford, United Kingdom ; <sup>2</sup>Weston Park Hospital, Oncology, Sheffield, United Kingdom ; <sup>3</sup>University College London Hospitals, Radiotherapy Physics, London, United Kingdom

#### Purpose or Objective

In 2012 a UK SABR Consortium survey reviewed the implementation of SABR treatment programmes in the UK, obtaining details of practice and varying techniques used in centres with an active treatment programme, evaluating the workload and assessing projected future provision<sup>1</sup>. A second survey was designed and implemented to update those results aiming to continue to drive forwards techniques, aid standardisation and assist in highlighting issues to be addressed within the NHS to improve access to SABR services and trials in the UK.

#### Material and Methods

An online questionnaire was sent by the UK SABR Consortium to over 65 UK radiotherapy institutions. The questionnaire covered current service provision and collected data on patient numbers, clinical sites, immobilisation, motion management, CT scanning protocols, target and OAR delineation, treatment planning, image-guidance, treatment protocols, QA methods and expected service development over the next couple of years.

#### Results

48 centres responded to the questionnaire. The number of centres with an active SABR program has doubled since 2012 (36 vs 15) with a further 12 centres indicating the intention of starting SABR in the next couple of years. 28 treating centres deliver SABR to non-lung sites, with 17 centres able to offer the range of sites required for treating oligometastatic disease. The number of patients treated has significantly increased since 2012 with 25 centres now treating above the minimum UK recommended level (25 patients per year).

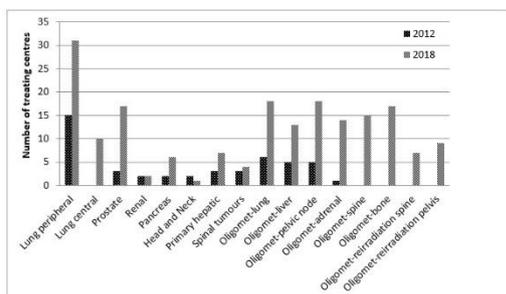

Figure 1: Results from survey in 2012 and 2018 indicating the number of centres treating a variety of sites with an active SABR program.

The survey indicates that treatment techniques remain reasonably standard across the UK with all centres using 4D-CT and 85% delineating their ITV to contain respiratory-induced tumour motion. The most popular immobilisation devices in the UK remain the wing board, vacuum bag and knee support in use by 70% of centres. 90% use inverse planning solutions together with VMAT delivery and > 80% of treating centres are still performing patient specific QA for all patients.

	Mode (2012)	Mode (2018)
4D-CT	30-40mins	50-60mins
Target and OAR delineation	30-60mins	30-60mins
Treatment planning	>91mins	>120mins
Patient-specific plan QA <sup>a</sup>	30-45mins	30-45mins
Daily treatment delivery	21-30mins	Lung 21-30mins Other 31-40mins

Table 1 Summary of the most frequent time at each stage of the SABR process in the UK (<sup>a</sup>quicker if several plans batched together).

Documented changes in practice since 2012 include the development of Linac delivered SABR to non-lung sites and notable increase in number of centres using abdominal compression as part of the immobilisation process (14 vs 2 centres). An increase in time spent at some stages of the SABR process (table 1) was also seen which is likely to be a reflection on the increased complexity of cases treated.

#### Conclusion

The 2018 survey shows a welcome increase in SABR provision across the UK with an ongoing commitment to Quality Assurance within centres. However, with emerging data it is clear that the UK SABR program need to continue its expansion to ensure that patients with oligometastatic disease have access and SABR for early stage lung is deliverable in all centres.

#### EP-1659 Trends in industry payments to radiation oncologists from 2014-2017

D. Marshall<sup>1</sup>

<sup>1</sup>Mount Sinai Hospital, Radiation Oncology, New York, USA

#### Purpose or Objective

Physician-industry relationships are common and introduce conflicts of interest. This study investigates recent trends in industry payments to radiation oncologists in a population-based national sample.

#### Material and Methods

Open Payments records of general payments to radiation oncologists in the United States were included. We describe the number of payments, total amount of payments and annual percent change over 2014 to

2017. This excludes research payments and ownership interest.

#### Results

Radiation oncologists received 91,804 payments totaling \$25.6 million (USD) over the four-year period, representing 0.31% of payments to oncology specialties (46.4 million payments totaling \$8.3 billion USD). For radiation oncologists, the number of payments grew 6.9% over the period and the total number of payments grew 9.1%, while these numbers decreased by about 1% for all oncology specialties.

#### Conclusion

Industry-physician financial relationships are substantial and have grown over time. Further research is needed to determine the effect of these relationships on physician decision making.

General industry payments to physicians in Open Payments, 2014-2017

Specialty	Measure	Year				Total
		2014	2015	2016	2017	
Radiation oncology	number of payments	18,534	23,329	25,779	24,162	91,804
	total amount (USD)	\$ 4,676,365	\$ 7,228,094	\$ 7,069,081	\$ 6,620,594	\$ 25,594,134
All oncology specialties	number of payments	11,755,185	11,717,589	11,823,905	11,135,359	46,432,038
	total amount (USD)	\$ 2,093,715,892	\$ 2,077,188,495	\$ 2,117,974,615	\$ 2,060,608,391	\$ 8,349,487,394

#### EP-1660 Patterns of acute brain metastases related admissions: Opportunity amongst recurring themes

R. Bentley<sup>1</sup>, M. O'Cathail<sup>1</sup>, L. Aznar-Garcia<sup>1</sup>, V. Crosby<sup>2</sup>, A. Wilcock<sup>2</sup>, J. Christian<sup>1</sup>

<sup>1</sup>Nottingham University Hospitals NHS trust, Oncology and Radiotherapy, Nottingham, United Kingdom ;

<sup>2</sup>Nottingham University Hospitals NHS trust, Palliative Care, Nottingham, United Kingdom

#### Purpose or Objective

Brain metastases (BM) affect up to 40% of patients with metastatic disease. They are associated with a wide range of symptoms and significant morbidity. Though the symptoms are known the health care provider burden is not. We aim to describe the patterns of BM related admissions in a large oncology centre.

#### Material and Methods

Over a two year period (1<sup>st</sup> Jan 2016 - 31<sup>st</sup> Dec 2017), adult patients with a new radiologically confirmed diagnosis of BM were identified by retrieving all MRI and CT head scans that contained the words 'metastases', 'metastasis' or 'met' in the on-line scan report. Only patients with a confirmed primary cancer were included. Information recorded included patient demographics, primary cancer site, treatment received and survival. Number, duration of and reasons for hospital admissions were recorded if they were attributable to BM.

#### Results

236 cases of newly diagnosed BM identified. The median age at diagnosis was 65 years (range 30-87). The median survival across all groups was 115 days (range 1-829). There were more females (58%) than males (42%). Lung cancer represented the most common primary site (49%), followed by breast (20%) and melanoma (13%). Median survival varied by primary site with lung carrying the worst prognosis (95 days) and breast (202 days) the best. Sixty-nine percent of patients had a BM related admission. There were 305 admissions accounting for 2318 bed days. The first diagnosis of BM occurred as a direct result of an admission in 63 patients (27%). The median length of stay was 7 days. The most common reasons for admission were seizures (18%) headaches, (17%) confusion (16%) and weakness (14%). Patients with lung primaries had the longest median stay (12 days) and the largest number of admissions (50% of all admissions)

Bed days varied depending on the treatment received. Patients who received Stereotactic Radiosurgery (SRS) had the fewest bed days as a proportion of total follow up days. They had 63 admissions and 491 bed days, which represented 3% of the total follow up days.

	SRS	Whole Radiotherapy	Brain Surgery	BSC
Number	50	50	27	118
Median Survival	NR	202	210	55
Follow days up	16,107	11,111	7,218	10,058
Admissions	63	80	67	113
Bed Days	491	584	459	899
Bed days: follow up	3%	5.3%	6.4%	8.9%

The estimated cost of the bed day varies from £306 for an excess stay bed day to £1609 for an emergency admission. Based on these figures the cost range for admissions is between £709,308 at the low end and £3,729,662 at the top.

#### Conclusion

The four most common reasons for admission were seizure, confusion, weakness and headaches. Knowing this, it may be possible to better educate patients on the symptoms and, with proper support, avoid admission. Fifty-two admissions (17%) were related to headaches: patient education with telephone support may help avoid many of these admissions. We suggest there is scope to avoid unnecessary admissions and make significant cost savings with a dedicated BM nurse specialist supporting patients and we recently have appointed one.

##### EP-1661 Teleconsultations: Bringing specialist radiotherapy services to patients

M. O'Cathail<sup>1</sup>, L. Aznar-Garcia<sup>1</sup>, R. Bentley<sup>1</sup>, P. Patel<sup>1</sup>, J. Christian<sup>1</sup>

<sup>1</sup>Nottingham University hospital NHS trust, oncology and radiotherapy, Nottingham, United Kingdom

#### Purpose or Objective

As part of its 'Five year forward view' in 2014, NHS England recognised the changing needs of patients and the need to capitalise on the opportunities new technologies present. Teleconsultations have the ability to deliver greater access to specialist care and advice. Our centre provides a regional stereotactic radiosurgery (SRS) service to treat patients with brain metastases. These patients are prohibited from driving thus potentially limiting access to this service. We have established a teleconsultation service to support the management and follow-up of patients with brain metastases. We aim to assess the feasibility and acceptability of this service. Here we present the results of a pilot. Patients had a choice of teleconsultation or face to face (FTF) appointment for assessment

#### Material and Methods

Participants provided feedback via a previously validated set of questions which assesses clarity of audio-visual connection, ease of communication, perception of privacy, overall satisfaction, patient preference for future appointments and patient reported expense. Data is also collected on round trip distance and predicted travel time saved. A baseline survey of face-to-face consultations acts as a control. The pilot ran for 6 months.

#### Results

There were 123 attendances to the brain metastases clinic, of which 45 (36.5%) were teleconsultations. Twenty-four (11 female & 8 male) individual patients have participated with feedback received on 28 separate teleconsultations. Feedback from FTF clinics was received from 14 patients. The median age was 59 years (Range 32-

88) compared with 65 (range 23-84) in the FTF group. Participants avoided travelling 2520 miles (61.5 per consult) and 70 hours of travel time (1hr 42 mins per consult). FTF patients travelled 2362 miles (30.5 per consult) and spent 86 hours travelling (1hr 6mins per consult). Satisfaction, ease of communication and privacy measured on a Likert scale was universally high or very high in both surveys. 95% of respondents wished to continue further follow up via teleconsultation with 4/13 respondents wishing to try teleconsultations for future appointments. All respondents felt they received satisfactory care. Most common reasons for preferring video clinics were that it was less disruptive to daily life and saved time.

#### Conclusion

Teleconsultations are feasible means of assessing and following up patients for SRS and is acceptable to patients as a means of accessing specialist care although patient choice appears to be driven by distance and travel considerations. This clinic model has worked well in a patient cohort with distance and transport restrictions.

##### EP-1662 Multicentric structured medical data production on an OIS for modeling of radiotherapy effects

J. Clavier<sup>1</sup>, R. Eugene<sup>2</sup>, J. Thariat<sup>3</sup>, D. Antoni<sup>1</sup>, V. Beneyton<sup>4</sup>, L. Claude<sup>4</sup>, J. Fontbonne<sup>5</sup>, N. Gaillot<sup>6</sup>, V. Ganansia<sup>1</sup>, C. Jamain<sup>7</sup>, A. Lepinoy<sup>8</sup>, C. Laude<sup>4</sup>, C. Mazzara<sup>1</sup>, C. Noblet<sup>1</sup>, S. Racadot<sup>4</sup>, A. Ruffier<sup>9</sup>, S. Servagi<sup>6</sup>, P. Truntzer<sup>1</sup>, S. Guihard<sup>1</sup>

<sup>1</sup>Cancer Center Paul Strauss, Radiation oncology, Strasbourg, France ; <sup>2</sup>Elekta, Consultancy Services Specialist, Boulogne Billancourt, France ; <sup>3</sup>Cancer Center François Baclesse / Archade, Radiation Oncology, Caen, France ; <sup>4</sup>Cancer center Léon Bérard, Radiation Oncology, Lyon, France ; <sup>5</sup>Laboratoire de Physique Corpusculaire, Research - Industrial and medical applications, Caen, France ; <sup>6</sup>Cancer center Jean Godinot, Radiation oncology, Reim, France ; <sup>7</sup>Unicancer, Basic and pre clinical research, Paris, France ; <sup>8</sup>Institut de Cancérologie de Bourgogne, Radiation Oncology, Dijon, France ; <sup>9</sup>Cancer center Gustave Roussy, Radiation Oncology, Villejuif, France

#### Purpose or Objective

We developed a model of structured medical charts. Three objectives were defined: collection of structured data during consultations, real-time production of medical letters and massive data extraction for clinical analysis feedback on a daily-basis.

#### Material and Methods

Twenty-three forms were created in MOSAIQ® oncology information system (OIS) related to the phase of patient journey (pretherapeutic, during irradiation and post-irradiation) and localization (brain, head and neck, breast etc.). Three hundred features were defined based on international scales (CTCAE, TNM, ICD-10 code, histology code, etc.), classical endpoints (date of local relapse), tumor-specific needs (use of gastrotomy, etc.) or case report forms of ongoing clinical trials. Ergonomics were adapted for fast entry during consultations without decreasing social contact. Consensus on the content of forms was reached between 17 radiation oncologists from 4 centers of the French national comprehensive cancer center network. Automatic medical letter production from collected data was implemented for time-saving. The software allows massive export of patient, tumor and radiation treatments (dose, fractionation, etc.) data.

## Results

Sixty per cent of radiation oncologists at initiating center used the forms. From January 2016 to May 2018, 411 134 structured data were collected with a monthly median of 15 197 (811-24 015). The forms and tables were synchronized between two MOSAIQ® systems in different institution. Daily use was easy and produced 14 864 data between May and June 2018. Prospective evaluations were performed (dermatitis rate by physicians, by technique etc.). Post processing of data allowed development of algorithms that enabled early detection of unexpected toxicity patterns in patient populations.

## Conclusion

Such massive production of data, integrated in daily care offers great opportunities for improvement of the quality of data and large scale of exploitation to produce levels of evidence from routine practice. Modeling of radiation treatment (tumor control and toxicity) and creation of more automatic alerts is ongoing. The concept and format used in MOSAIQ® OIS (Elekta) can be implemented in other software (OIS and hospital-based electronic patient charts). On October 2018, three other departments will integrate the structured medical record system.

### EP-1663 REQUITE multicentre study of patients undergoing radiotherapy for breast, lung or prostate cancer

## Purpose or Objective

REQUITE aimed to establish a resource for multi-national validation of models and biomarkers that predict a patient's risk of late toxicity and quality-of-life following radiotherapy. The purpose here is to provide an overview of the data available.

## Material and Methods

An international, prospective cohort study recruited patients in 26 hospitals in eight countries between April 2014 and March 2017. Target recruitment was 5,300 patients. Eligible patients had breast, lung or prostate cancer and planned potentially-curable radiotherapy. Radiotherapy was prescribed according to local regimens, but centres used standardised data collection forms including patient reported outcome measures available in multiple languages. Pre-treatment blood samples were collected. Patients were followed for a minimum of 12 (lung) or 24 (breast/prostate) months and summary descriptive statistics generated.

## Results

Between 2014 and 2017, the study recruited 2,069 breast (98% of target), 1,808 prostate (86%) and 561 lung (51%) cancer patients. 383 lung cancer patients from external cohorts were included for genotyping. The centralised, accessible database includes: physician- (45,881 forms) and patient- (52,691) reported outcomes; 11,383 breast photos; 17,107 DICOM and 12,684 DVH files. Raw genotype data are available for 4,634 and imputed data for 4,304 patients with European ancestry (1,948 breast, 1,728 prostate, 628 lung) patients. Baseline demographics tended to vary per tumour site, e.g., the percentages of current smokers were 18% (365 breast patients), 14% (249 prostate) and 43% (227 lung). Respective figure for diabetes were 6% (126 breast), 7% (136 prostate) and 17% (92 lung); for heart disease 7% (143 breast), 21% (371 prostate) and 31% (166 lung); and for a BMI>30 kg/m<sup>2</sup> 22% (454 breast), 23% (399 prostate) and 22% (118 lung). Radiation induced lymphocyte apoptosis (RILA) assay data are available for 1,290 patients. DNA (n=4,434 REQUITE patients) and Paxgene tubes (n=3,039) are stored in the centralised biobank. Example 2-year prevalences (1-year for lung) of ≥grade 3 toxicities are: 13% atrophy (breast), 26% dyspnea (lung), and 3% rectal bleeding (prostate).

## Conclusion

The comprehensive centralised database and linked biobank is a valuable resource for the radiotherapy community for validating models and biomarkers that predict for risk of the late effects that most effect long-term quality-of-life. Most cancer patients gave consent to share their data and samples with external researchers, and a formal process for requesting data access for specific research questions is in operation (32 projects approved). A data discovery platform to search on numbers of patients with various attributes collected by the consortium is available at [www.requite.eu](http://www.requite.eu).

### EP-1664 Inter-fractional urinary bladder filling variation during IGRT in pelvic malignancies

M. Shah<sup>1</sup>, S. Agarwal<sup>2</sup>, R. Agarwal<sup>2</sup>, B. Subramanian<sup>2</sup>, S. Gupta<sup>3</sup>, S. De<sup>1</sup>, S. Mishra<sup>2</sup>, S. Srinivasan<sup>4</sup>, P. Chaudhary<sup>2</sup>, A. Chabra<sup>2</sup>, R. Chandra<sup>2</sup>  
<sup>1</sup>Jaypee Hospital- Noida, Radiation Oncology, Noida, India ; <sup>2</sup>Max Hospital- Delhi, Radiation Oncology, New Delhi, India ; <sup>3</sup>All India Institute of Medical Science- Rishikesh, Radiation Oncology, Rishikesh, India ; <sup>4</sup>Tata Institute of Medical Science, Radiation Oncology, Mumbai, India

## Purpose or Objective

Organ motion is an important factor that limits the precision of radiation treatment. Bladder filling variation has a significant impact on the position of target volumes in pelvic malignancies. One of the approach to reduce the bladder motion influence on the target location is by controlling the bladder volume, a protocol instructing the patient to drink a certain amount of water before starting the treatment. This study was an effort to maintain a consistent bladder volume after following a bladder protocol, which was then analyzed by in-room CBCT imaging. The bladder volumes and bladder wall dimension were Image-guided comprehensively thus adding considerable understanding to the bladder wall motions.

## Material and Methods

This study was conducted on patients of pelvic malignancies excluding urinary bladder carcinoma. It was a single institution, non-randomised, prospective study and the duration of the study was of 6 months. All patients of pelvic malignancies undergoing IGRT (Image guided radiotherapy) with curative intent having urine holding capacity of at least half an hour were included in the study. In Bladder protocol patients were instructed to void the bladder 40 minutes prior to treatment and to drink 600 ml of water within 10 minutes. The patients were scanned after 30 minutes of taking the last glass of water. Time of

last glass of water and CBCT was noted. The bladder protocol was followed from the planning day and then on daily basis before treatment. The CBCT data set was fused to the planning CT and was used to characterize the bladder each day. Bladder contouring was done on all planning CTs and treatment CBCT images by the same oncologist. The volumetric changes of the bladder were measured to analyze the inter-fractional filling variation. Total 274 CBCT was contoured in 26 patients and were compared with the 26 planning CT to see the average bladder filling variation and standard deviation in transverse, anteroposterior and longitudinal diameter.

#### Results

The mean bladder volumes in-room 183.07 cc (range, 62-475cc) and SD were 90.43cc. Similarly, the mean time was 40.12 minutes with SD of 2.15 min and p-value 0.059 which was non-significant. Bladder wall motion of these patients was analyzed in transverse, anteroposterior and longitudinal diameter shown in Table-1.

Urinary bladder movements	N	Mean	Standard Deviation	p-Value	Significance
Transverse (in cm)	26	8.35	1.039	0.064	NS
Antero-posterior (in cm)	26	6.69	1.05	0.108	NS
Longitudinal (in cm)	26	5.59	1.798	0.973	NS

Table 1- Mean± SD of bladder wall movements

#### Conclusion

This study finds a possible answer to a very pertinent question on bladder wall motion and bladder volume variations during radiation therapy. Image-guided radiotherapy (IGRT) with verification of the organ position before the daily treatment after following bladder filling protocol has allowed for lessening of inter-fraction bladder wall motion and showed considerable benefits in terms of margin reduction on lateral side as there is less displacement on transverse diameter and more liberal margins should anteroposterior in anteroposterior dimension and longitudinal dimension.

#### EP-1665 Extra-pulmonary Neuroendocrine Carcinoma. Rarity of Brain Metastases

L. FERRO<sup>1</sup>, I. Golomb<sup>2</sup>, H. Ligumsky<sup>3</sup>, O. Gutfeld<sup>1</sup>, I. Wolf<sup>3</sup>, V. Soyfer<sup>1</sup>

<sup>1</sup>Sourasky Medical Center, Radiation oncology- Oncology Division, Tel Aviv, Israel ; <sup>2</sup>Tel Aviv University, Sackler school of medicine- Tel Aviv University, Tel Aviv, Israel ; <sup>3</sup>Sourasky Medical Center, Oncology Division, Tel Aviv, Israel

#### Purpose or Objective

Extra-pulmonary small cell carcinoma (EPSCC) is a rare clinical entity and while its management is usually extrapolated from small cell lung cancer (SCLC), this approach is controversial and is not evidence-based. Specifically, the current clinical practice in the management of SCLC involves prophylactic cranial irradiation (PCI). The PCI proved the decrease in incidence of brain metastases both in limited and extensive disease. We aimed to analyze the clinical characteristics of a relatively large cohort of patients treated at single tertiary center.

#### Material and Methods

A search of the entire database of the Center, consisting of over 25,000 patients, yielded 24 patients diagnosed with EPSCC or high-grade neuroendocrine carcinoma between 2015 and 2018. Clinical characteristics were obtained from the medical files. The overall median survival, response rate, and the incidence of local and distant progression were calculated.

#### Results

The primary sites were 17 (71%) gastrointestinal including seven (41%) pancreatic, genitourinary (5, 21%), or unknown primary sites (2, 8%). The median Ki67 was 90% for all patients.

Five patients were diagnosed with limited disease and operated, one received neoadjuvant treatment and is still free of disease 10 years later, while one patient received adjuvant treatment and had a DFS of 4.7 months.

Nineteen patients were diagnosed with extensive disease, 14 of them received Platinum based chemotherapy as first line of treatment, mostly (13, 93%) with Etoposide, same treatment protocol as in SCLC. 6 (31.6%) and 3 (15.7%) patients received second or more lines of systemic treatment respectively. Of the 10 patients we have an imaging test after first course of treatment we can determine that 3 (30%) had a partial response and 4 (40%) had a stable disease. For the total of patients with extensive disease the median survival was 8.2 months.

While no patient received prophylactic cranial irradiation, only one patient (4%), presenting with pancreatic SCC developed brain metastasis, compared to the 40-50% known in SCLC.

#### Conclusion

We report herein a relatively large number of patients. Our data demonstrates a relative efficacy for the classic platinum based treatment. While treatment of EPSCC is often extrapolated from SCLC, the rarity of brain metastasis in this cohort suggest that PCI should not be incorporated in the treatment protocol of these patients.

#### EP-1666 ARENA: Improving training in target volume delineation for radiotherapy

E. Evans<sup>1</sup>, C. Piazzese<sup>2</sup>, E. Spezi<sup>2</sup>, J. Staffurth<sup>1</sup>, S. Gwynne<sup>3</sup>

<sup>1</sup>Velindre Cancer Centre, Clinical Oncology, Cardiff, United Kingdom ; <sup>2</sup>Cardiff University, School of Engineering, Cardiff, United Kingdom ; <sup>3</sup>South West Wales Cancer Centre, Clinical Oncology, Swansea, United Kingdom

#### Purpose or Objective

Inter-observer variation radiotherapy (RT) Target Volume Delineation (TVD) may be considered the 'weakest link' in the RT planning process. Accurate outlining is imperative to ensure patients receive optimal outcomes with minimal toxicity. In response to this the ARENA project has been launched by clinical oncologists in South Wales to facilitate a standardised approach to TVD training. The project will develop tumour site-specific TVD instructional modules with corresponding outlining modules, offering test cases for trainees to outline, upload and receive semi-automated feedback on through software developed by Cardiff University. Experience has been drawn from the team's involvement with National Radiotherapy Trials Quality Assurance (RTTQA) group, providing feedback for submitted pre-trial RT outlining.

#### Material and Methods

To ascertain TVD training needs of clinical oncology trainees, 406 UK clinical oncology trainees were surveyed regarding TVD training quality and preferential format for TVD modules. Using the survey results, a TVD instructional module and corresponding series of cases of varying difficulty with semi-automated feedback have been developed using oesophageal cancer as a pilot site. 6 UK UGI oncologists outlined 6 oesophagus cases to develop a reference volume for each case. Software was developed in MATLAB to provide semi-automated on the cases outlined by trainees on their training centre's planning software. Feedback developed included trainee outline against a reference volume, over /under contoured regions, minimum and maximum acceptable volumes, a conformity score and a 'red flag' when volumes contoured inappropriately include normal tissue. The latter module with semi-automated feedback was piloted locally with 3 clinical oncology trainees.

## Results

131 trainees at different stages of training responded to the survey. The most common method of TVD training for trainees was consultant led (94%) followed by self-directed learning (83%). RT trial protocols were the most common self-directed used tool (89%). Most trainees (54%) report their supervising consultants spend only 1 hour per week reviewing their TVD. 20% of trainees felt highly competent in TVD for a recently completed tumour site, 55% of trainees reasonably confident and 20% insufficiently competent. Most trainees (61%) preferred step-by-step instructions for TVD modules with qualitative feedback for the cases outlined (51%). Trainees testing the model allocated each feedback method a usefulness score out of 10, with the 'red flag' tool deemed most useful (mean score 9.2) and over/under contoured regions least useful (mean score 7).

## Conclusion

Given current reliance upon self-directed learning, ARENA aims to support consultant-led TVD teaching through site-specific TVD modules. Software developed for outlining feedback will be further developed to reflect trainee opinion. Further site-specific modules are in development.

### EP-1667 Safety and efficacy of fiducial marker implantation for robotic SBRT with fiducial tracking

N. Scher<sup>1</sup>, G. Bouilhol<sup>1</sup>, R. Tannouri<sup>1</sup>, I. Khemiri<sup>1</sup>, A. Vouillaume<sup>1</sup>, N. Sellami<sup>1</sup>, R. Von Eyben<sup>2</sup>, L. Rotenberg<sup>3</sup>, H. Lamallem<sup>1</sup>, O. Bauduceau<sup>1</sup>, M. Bollet<sup>1</sup>, D. Foster<sup>3</sup>, A. Toledano<sup>1</sup>

<sup>1</sup>Hartmann Institute of Radiotherapy, Hauts de Seine, Levallois Perret, France ; <sup>2</sup>Stanford Cancer Center, California, Palo Alto, USA ; <sup>3</sup>American Hospital of Paris, Hauts de seine, Neuilly sur seine, France

## Purpose or Objective

The purpose of this study was to assess the feasibility, efficacy and toxicity of fiducial marker implantation and tracking in CyberKnife® stereotactic radiation therapy (SBRT) applied to extracranial locations.

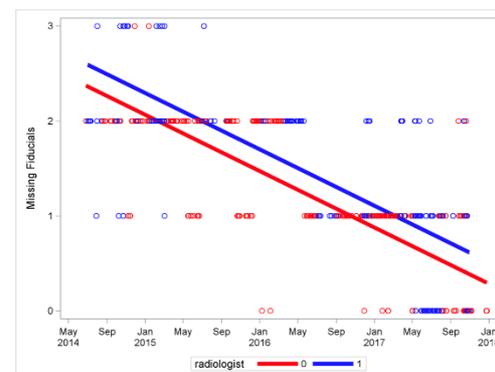

## Material and Methods

This was a retrospective, single-centre, observational study to collect the data of all patients treated by stereotactic radiation therapy with fiducial marker tracking at extracranial locations, conducted between June 2014 and November 2017 at the Hartmann Radiosurgery Institute. Information regarding the implantation procedure, the types of toxicity related to marker implantation and the number of markers implanted/tracked during treatment were collected. Complication rates were evaluated using the CTCAE [Common Terminology Criteria for Adverse Events] scale, version 4. The technical success rate was based on the ability to optimally track the tumour (during translation and/or rotation, depending on the type of target movement) throughout all treatment fractions.

## Results

2,505 patients were treated by stereotactic radiation therapy, 25% of whom received treatment with fiducial marker tracking. The total number of implantation procedures was 616, and 1,543 fiducial markers were implanted. The implantation-related complication rate was 3%, with 16 Grade 1 events and 4 Grade 2 events. The number of treated patients and the number of implanted markers has gradually increased since the technique was first implemented. The median treatment time was 27 minutes. 1,295 fiducials were actually tracked throughout all treatment fractions, representing a technical success rate of 84%. The difference between the number of fiducials implanted and those tracked during treatment decreased significantly as the site's experience increased.

Localization and number of patient (n)	Fiducial markers implanted Median, SD, range	Fiducial markers tracked Median, SD, range
Lung n=89	1 0.3 [1 ; 2]	1 0.3 [1 ; 2]
Prostate n=150	4 0.8 [2 ; 5]	3 0.5 [2 ; 4]
Liver n=151	4 1.3 [1 ; 6]	3 1 [1 ; 5]
Nodes n=85	1 0.6 [1 ; 3]	1 0.6 [1 ; 3]
Pancreas n=18	3 1.1 [1 ; 5]	3 0.5 [1 ; 3]
Bones n=57	1 0 1	1 0 1
Adrenal n=23	2 0.9 [1 ; 4]	2 0.9 [1 ; 4]

## Conclusion

Fiducial marker implantation and tracking is feasible, well-tolerated, and technically effective technique in SBRT for extracranial tumours.

### EP-1668 Creation and pilot-test of virtual cases for learning oncologic emergency management

Z.S. Fawaz<sup>1</sup>, P. Nancy<sup>1</sup>, J. Alfieri<sup>1</sup>

<sup>1</sup>McGill University Health Center, Radiation Oncology, Montreal, Canada

## Purpose or Objective

Management of radiation oncologic emergencies becomes critical at the start of the second year of a radiation oncology residency. Considering the limited exposure to oncology in the medical school curriculum, this knowledge gap needs to be filled prior to managing real patients. The aim of this project was to create virtual cases to ease this transition, improve readiness for managing oncologic emergencies on call, and to create viable alternatives to fulfill accreditation standards based on the Association of Faculties of Medicine of Canada (AFMC).

## Material and Methods

A curriculum mapping exercise was done to identify gaps. The main oncologic emergencies that needed to be addressed were selected for development of the modules. Review of the key concepts for management were

elucidated and validated. The learning concepts included history, physical examination, imaging interpretation, staging, as well as anatomy, epidemiology, pertinent literature, differential diagnosis, prognostication, radiation treatment planning, summarizing, and patient and peer communication skills.

Clinical vignettes were then designed, in collaboration with a virtual patient education expert, to mimic the clinical presentation and evolution of a typical patient for three common oncologic emergencies: spinal cord compression, superior vena cava syndrome, and hemorrhage.

#### Results

3 virtual cases were developed: spinal cord compression, superior vena cava syndrome, and tumour-induced hemorrhage. Each case includes 25 to 30 screens to progress through, with a total estimated completion time of 30 to 45 minutes. Each node branches out to provide a detailed answer and explanation of the key concept. Figures were included to mimic real patients and provide a more authentic learning environment.

The modules also included quantitative pre- and post-testing with multiple choice questions, true or false, fill in the blank, and text response. The cases were then transcribed onto a virtual patient simulation platform. The platform is accessible to the learner through his or her own personal sign-on. Following completion of the module, a report is generated for each individual learner to track all responses and can be used as an assessment tool. Qualitative data will also be collected regarding user-friendliness and learner satisfaction.

The pilot test showed an increase of 27% in the pre-to-post-test results in a cohort of 9 residents. The mean pre-test result of 64% increased to a mean post-test result of 91% (range: 70-100%) after completing the three modules.

#### Conclusion

Virtual patient cases can be used for the management of oncologic emergencies and can be done on a simulation-based learning platform. The modules can be used as an assessment and learning tool for junior residents. The preliminary results of the pilot-test show a significant improvement in competence after completion of the three modules.

#### EP-1669 Evaluation of Healthcare Quality Concepts in Radiation Oncology PG Training Programs

M. Uddin Karim<sup>1</sup>, A.N. Abbasi<sup>2</sup>, B.M. Qureshi<sup>2</sup>, N. Ali<sup>2</sup>, A. Hafiz<sup>2</sup>, B. Mir Khan<sup>2</sup>

<sup>1</sup>Aga Khan University Hospital, Oncology, Karachi, Pakistan ; <sup>2</sup>Aga Khan University, Oncology, Karachi, Pakistan

#### Purpose or Objective

Radiation Oncology (RO) Trainees (Post graduate Residents, Trainee medical physicists, Trainee Radiation Therapy Technologists RTTs) face ongoing challenges associated with the everyday reality of having demanding clinical workloads. They are expected to contribute to patient safety and quality improvement in RO, but prior studies suggest that training for this may be inadequate. In order to inculcate the basic concepts of healthcare quality in all three training programs, an evaluation of awareness was performed in our department. As per our team's deliberations, this evaluation will allow treatment idea sharing of quality systems and processes after training. As healthcare providers, these future carers will be looking after their professional development needs. It is important to identify weaker links and to learn core concepts of quality.

#### Material and Methods

An orientation lecture was designed to give a practical overview of quality RO practice concepts. The content was streamlined to fit into a single day activity and delivered through a lecture followed by interactive group discussion of the concepts.

A pre and post-test was developed comprising of 12 questions in order to assess the trainee's understanding of the knowledge of basic quality concepts deliberated in the lecture. The intent of tests was to provide qualitative feedback about the trainee's knowledge and understanding of these processes.

A total of 25 trainees (8 post graduate residents, 9 trainee medical physicists, 8 RTTs) participated. The class was led by a senior faculty who delivered a lecture and moderated the interactive discussion.

#### Results

There was an open and constructive interaction among the trainees during all four phases of this evaluation. Changes in trainee's knowledge and understanding was positive. The pretest scores of all 12 questions varied from 8% to 72%. This trend was positively changed to a score ranging from 84-100%.

#### Conclusion

The pretest survey results showed that most trainees have less than expected practical knowledge of healthcare quality concepts. Our team would recommend introduction of a well-constructed module for inclusion in these three training programs which can fill this knowledge gap.

#### EP-1670 Painful osteoarthritis responds to low-dose radiotherapy

B. Álvarez Rodríguez<sup>1</sup>, Á. Montero<sup>1</sup>, F. Calvo<sup>2</sup>, J. Valero<sup>1</sup>, F. Aramburu<sup>2</sup>, J. García<sup>3</sup>, R. Ciérvide<sup>1</sup>, M. López<sup>1</sup>, M.Á. De la Casa<sup>3</sup>, J. Martí<sup>3</sup>, E. Sánchez<sup>1</sup>, M. García-Aranda<sup>1</sup>, X. Chen<sup>4</sup>, O. Hernando<sup>4</sup>, R. Alonso<sup>4</sup>, S. Rodríguez<sup>2</sup>, P. García de la Peña<sup>2</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>Hospital Universitario HM Sanchinarro, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Universitario HM Sanchinarro, Rheumatology, Madrid, Spain ; <sup>3</sup>Hospital Universitario HM Sanchinarro, Radiophysics, Madrid, Spain ; <sup>4</sup>Hospital Universitario HM Puerta de Sur, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

Evaluation of painful osteoarthritis response to low-dose irradiation based on previous positive evidence.

#### Material and Methods

With a median age of 67 years (range 45-89 years), 69 patients (56 women and 13 men) were enrolled in a prospective analysis between April 2015 and March 2018. 111 treatments were performed due to enrollment of patients affected with more than one location. Patients analyzed presented finger joints osteoarthritis, rhizarthrosis, wrist osteoarthritis, gonarthrosis, shoulder and hip arthritis or spondyloarthrosis. All patients underwent CT-based simulation. Planning target volume (PTV) contoured on CT scan included painful joint. Treatment was delivered in a LINAC and daily verified with orthogonal X-ray. 6 Gy were delivered in single fractions of 1 Gy every other day, however, if complete response wasn't reached, a second course of identical characteristics was delivered 6-8 weeks after finishing the first course. Pain was measured before and after radiotherapy using the visual analogue scale (VAS). Long term response was also evaluated with the functional scale proposed by von Pannewitz and determining the variation in the daily analgesic drugs intake.

#### Results

Most prevalent locations were fingers (47%), knees (30%), and shoulders (14%). With a median follow-up of 7 months (1-28 months), 52% of patients referred improvement, however, objectively, 74% of treated patients experienced pain relief in different degrees. According to the VAS scale, pain reported was greater or equal to 7 in 82% of the patients before treatment and 88% of this group showed response. After treatment, half of all patients showed grade 3 or less of pain even though, 86% of these patients had pain greater than 7 before treatment. 42% of the patients needed to take less analgesia after

treatment.

In 51 cases, a second course was needed to achieve better response, accomplishing it in 44 of them with a stable response in all except 2 cases. 55% of the cases were followed for more than 6 months and 90% of these patients maintained partial or total response after long follow-up.

#### Conclusion

Low doses of radiotherapy achieve significant pain relief in patients with osteoarthritis disorders, as well as subjective functional improvement and decrease in daily requirements of analgesia. All in all, this improvement can be translated in a better quality of life accomplished.

#### EP-1671 Radiotherapy: promising alternative treatment for painful enthesopathies and inflammatory diseases

B. Álvarez Rodríguez<sup>1</sup>, Á. Montero<sup>1</sup>, F. Aramburu<sup>2</sup>, E. Calvo<sup>2</sup>, J. Palma<sup>1</sup>, J. Valero<sup>1</sup>, J. García<sup>3</sup>, J. Martí<sup>3</sup>, R. Ciérvide<sup>1</sup>, E. Sánchez<sup>1</sup>, S. Rodríguez<sup>2</sup>, M.Á. De la Casa<sup>3</sup>, M. García-Aranda<sup>1</sup>, X. Chen<sup>4</sup>, O. Hernando<sup>4</sup>, R. Alonso<sup>4</sup>, M. López<sup>1</sup>, P. García de la Peña<sup>2</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>Hospital Universitario HM Sanchinarro, Radiation Oncology, Madrid, Spain ; <sup>2</sup>Hospital Universitario HM Sanchinarro, Rheumatology, Madrid, Spain ; <sup>3</sup>Hospital Universitario HM Sanchinarro, Radiophysics, Madrid, Spain ; <sup>4</sup>Hospital Universitario HM Puerta del Sur, Radiation Oncology, Madrid, Spain

#### Purpose or Objective

Efficacy of low-dose radiotherapy for periarticular inflammatory diseases has been largely probed. We present the results after analyzing a series of patients enrolled in our protocol consisting of a prospective non-randomized study.

#### Material and Methods

From April 2015 to May 2018, 44 patients were enrolled in our protocol, including 32 women (70%) and 12 men (30%), with a median age of 59 y/o (range 30-89 y/o). The analysis was based on the number of treatments delivered, which were 70 because some patients referred pain at different locations. Most patients (77%) presented with bursitis, specifically trochanteritis (70.5%), followed by sacroiliitis (13%) and epicondylitis (6%).

Pre-treatment and post-treatment evaluation of the pain was based on the visual analogue pain scale (VAS), requirements of oral analgesic intake and the modified von Pannewitz pain score (MVPPS). Clinical response was evaluated 6 weeks after treatment and each 3 months thereafter. If less than major response was achieved, a second course was delivered 6-8 weeks after finishing the first course.

Treatment comprised low-dose radiation up to a total dose of 6 Gy (1 Gy/fraction) every other day. All patients underwent CT-based simulation. This was, sometimes, fused with the corresponding magnetic resonance image if available. Planning target volume (PTV) was contoured on CT scan including the painful periarticular soft tissue. Treatment was delivered in a LINAC and daily verified with orthogonal X-ray.

#### Results

Before treatment, 81% of the patients referred VAS equal or greater than 7, while only 7% of the patients maintained this VAS after treatment. On the other hand, no patients referred VAS equal or under 3 before treatment, but 66% of the patients did achieved it after radiotherapy; what is more, 13% of all cases referred complete response (VAS 0) after treatment.

The median follow-up was 8 months (range 1-29), and 54% of the patients were monitored for more than 6 months. In these cases, 89% maintained VAS < 7 and 37% showed VAS < 3 after long follow-up. Regarding functionality, 87% of the cases referred MVPPS 1-3 and 44% of patients referred less intake of analgesia.

A second course of radiotherapy was required in 44 cases (63%), obtaining response in 36 cases (81%) in the early analysis and response was maintained in 28 cases (77%) after 3 or more months.

#### Conclusion

Low-dose radiotherapy is an effective and well-tolerated approach for painful inflammatory periarticular disorders, achieving acceptable rates of pain control that seem to be maintained during follow-up and thus contributing to improve the quality of life of these patients. Further follow-up is required for ensuring these promising results.

#### EP-1672 Multimodality treatment in thymic tumors: a retrospective analysis and accordance with ESMO guidelines

A. Carnevale<sup>1</sup>, C. Greco<sup>1</sup>, M. Fiore<sup>1</sup>, E. Ippolito<sup>1</sup>, S. Silipigni<sup>1</sup>, C.G. Rinaldi<sup>1</sup>, A. Di Donato<sup>1</sup>, S. Gentile<sup>1</sup>, P. Trecca<sup>1</sup>, P. Zuccoli<sup>1</sup>, G. Petrianni<sup>1</sup>, S. Palizzi<sup>1</sup>, R.M. D'Angelillo<sup>1</sup>, L. Trodella<sup>1</sup>, S. Ramella<sup>1</sup>

<sup>1</sup>University Campus BioMedico of Rome, Radiation Oncology, Rome, Italy

#### Purpose or Objective

Surgery represents the mainstay treatment for Thymic Epithelial Tumors. Due to the lack of prospective randomized studies, the role of postoperative radiotherapy (PORT) is not supported by high levels of evidence. We retrospectively assessed whether the decision regarding the postoperative radiotherapy at Campus Bio-Medico University has been taken according to the new ESMO guidelines.

#### Material and Methods

All consecutive patients with Thymic Tumors from 2005 to 2018 were analyzed and a complete review of medical records was performed.

#### Results

51 patients underwent surgery up-front. Median age at diagnosis was 64 years (range 33-82). Tumors histology was thymoma (A-AB-B3) in 47 (92%) patients or thymic carcinoma in 4 (8%) patients. Complete resection (R0) was achieved in 35 (67%) patients. Other patients had R1 resection. Applying 8<sup>th</sup> TNM system edition, 1 patients with Masaoka stage III was reclassified to stage II and I stage and one IV A. Decision of delivering PORT was in accordance with ESMO guidelines in 94% of the 51 patients. Two patients with R1 resection, with B1 and B2 thymoma and negative postoperative CT scan, did not receive radiotherapy for excessive delay after surgery. Median total dose was 46 Gy and was variable depending of radical resection: median total dose was 45 Gy after R0 resection and 54 Gy after R1 resection. Only G1-2 acute esophageal and G1 acute lung toxicities were reported. No in-field local recurrences were reported; four patients had pleural and distance metastases. With a median follow up of 47 months (range 7.2-155 months), median overall survival was 9.7 years.

#### Conclusion

Our data suggest that PORT is a safe and effective treatment for Thymic Epithelial Tumors in patients with stage II (B2-B3), Stage III Masaoka-Koga, R1 resection and Thymic carcinoma, in accordance with ESMO guidelines.

#### EP-1673 Implementation of a Collaborative Fast Access Radiotherapy Program for Benign Disease

M. Rolfo<sup>1</sup>, R. Shaffer<sup>1</sup>

<sup>1</sup>Genesiscare Uk, Radiation Oncology, Berkshire, United Kingdom

#### Purpose or Objective

Benign diseases and non-malignant conditions may cause pain, loss of function and other symptoms that can impact on quality of life. Radiation may not be sought as first line treatment for benign conditions, but some studies have suggested the efficacy of RT as a valid treatment option for specific patient cohorts. Genesis Care Australia, Spain

and United Kingdom currently provide a benign RT service. A project was undertaken at GenesisCare UK to review all aspects of the patient pathway and to standardise RT delivery for Dupuytren's Disease, Ledderhose's Disease and Plantar Fasciitis across 12 centres with postulated endpoints to improve access, increase awareness and optimise clinical practice of the service to prospective patient and potential referrers.

#### Material and Methods

The project team was formed from a multi-disciplinary group consisting of a Medical Oncologist, Radiographers, Medical Physicist, Patient Experience Coordinator and a Referrer/Marketing Liaison Officer. A literature review was to be performed, and a clinical analysis of current practice initiated to identify potential quality improvement and efficiency gains. The efficacy of a dedicated heel pain clinic hypothesising a joint consulting model of a Medical Oncologist and a Musculoskeletal (MSK) Consultant, with access to multi-modality imaging and treatment to diagnose and treat Plantar Fasciitis (PF) and Achilles Tendonitis was investigated.

#### Results

The evaluation demonstrated that clinical quality improvement and efficiencies were warranted to improve service delivery

#### Findings included:

1. The patient pathway from consult to RT treatment was reduced from 10 to 14 days to 24 hours.
2. A fully electronic workflow was introduced
3. Evidence based clinical protocols were written for DD, LD, PF, AT.
4. Improved and standardised patient stabilisation for RT and Surface Guidance Radiotherapy was implemented for all benign treatments.
5. Introduction of a completed acrylic coated less toxic electron insert by sourcing an external supplier
6. Tattoo-less treatment was implemented for all benign RT treatment across all 12 centres
7. Extracorporeal Shockwave Treatments (EST) for newly diagnosed PF and AT and external beam for persistent and recurrent AT was introduced.
8. The Heel Pain clinic was implemented with a Medical Oncologist consulting with multimodality imaging available at the time of consult

#### Conclusion

The project resulted in i service delivery efficiencies, in reducing consult to treatment start time, through a collaborative and coordinated approach. Initiating mechanisms to develop external relationships with prospective patients and referrers have been implemented. Further investigation will continue evaluating the Benign Service and collect metrics on all aspects of the patient pathway. A joint consulting model for the heel pain clinic is anticipated to start in early 2018. Future goals are to initiate a centralised data base with an automated data transfer system for patient recorded outcomes measures and to expand the service

#### EP-1674 Early toxicity and outcome of 258 consecutive patients treated with CyberKnife in an Indian centre

D. Dutta<sup>1</sup>, R. Das<sup>1</sup>, A. Gupta<sup>1</sup>, K. Katakai<sup>1</sup>, T. Tarani<sup>1</sup>, A. Krishnan<sup>1</sup>, C. Oc<sup>2</sup>, R. Holla<sup>2</sup>

<sup>1</sup>Amrita Institute of Medical Science- Kochi, Radiation Oncology, Kochi, India ; <sup>2</sup>Amrita Institute of Medical Science- Kochi, Medical Physics, Kochi, India

#### Purpose or Objective

Demographic profile, patient parameters, early toxicity and response to treatment assessment of all consecutive patients treated with CyberKnife radiosurgery.

#### Material and Methods

258 consecutive patients [male 56%, mean age 52 (7-87 yrs)] treated with CK in an Indian dedicated radiosurgery unit. Brain tumour, GI tumour, oligo-metastasis, lung cancer and GU tumour patients were 146 (56%), 43 (17%), 41 (16%), 9 (4%) and 8 (3%) respectively. In brain tumour, 36 (14%) was meningioma, 26 (10%) AN, 23 (9%) AVM and 34 (12%) brain metastasis. 36 (14%) was HCC, 9 (4%) glomus tumour and only 6 (2%) were prostate cancer patient. In rare tumours, 6 (2%) were brainstem cavernoma, 2 patient each eye tumours, cholangiocarcinoma and pancreatic cancer. AVM dose 18-24Gy/1fr, meningioma & AN 12Gy/1fr. Lung cancer dose 45Gy/3fr, HCC 45Gy/5fr, prostate 36.25Gy/5fr. Four large AVM patients were treated in 'staged' SRS.

#### Results

Among 23 AVMs, 2 patient had acute oedema requiring admission and recovered with supportive care, 6 patients were on more than 1 month steroid after CK. Among 23 AN patients, 4 required steroid >3 months. One pituitary tumour patient had acute steroid insufficiency. 4% (7/146) of brain tumour patients required admission after CK. No treatment related death or permanent neurodeficit. Among 34 brain metastasis, 15 (44%) had controlled disease at last follow up [Estimated OS 284 days (95%CI: 234-328; SEM: 22.5); >6 month actuarial OS 89%]. 29.4% (10/34) had intra-cranial progression, 18% (6/34) patients had new lesions and 12% (4/34) had recurrence within high dose region. 27 HCC with PVT treated with CK [mean age 59 yrs, 94% male; CP A 63%; KPS>80: 81%]. 16% underwent TACE before SBRT. Mean follow up was 7 months (range 1.7-17.6 months). Mean actuarial OS was 10.8 months (SEM: 1.48; 95%CI: 7.8-13.7). At last follow up, 16/27(59%) were alive and 11/27(41%) expired. 22% (6/27) had complete PVT response, 11% had stable disease with partial PVT response. 30% had local progression & 27% had metastasis. No death due RILD. Post-CK, 2 patient underwent TACE and 1 had TARE. Mild GI toxicities (Gr I-II) in 40%, fatigue (Gr II-III) 28%. One (4%) patient had Gr III GI toxicity and one (4%) patient had decompensation (<4wk) after treatment. 36 patients (Male 92%, mean age 60.2 yrs, ECOG 0-1 92%, Child-Pugh A 89%) with HCCs underwent fiducial placement. Three patients (8%) had gross displacement (2 in lung, 1 in abdomen) immediate after placement. Poor post-fiducial pain score (3-4) was in 6% patients. 1/34(4%) patient expired after fiducial placement (<72 hours) with decompensation. Five patients (15%) had minor complications (pain abdomen 2, pneumothorax 2).

#### Conclusion

Early symptomatic toxicities after CK is less than 5%. Post-CK edema requiring long-term steroid is in 8%, procedure related mortality in 0.7% and admission required 4% patient. Recurrence rate after brain metastasis SRS is 29% at 6 month follow up. HCC with PVT response is in 27%. Acute toxicity and early outcome is acceptable with CK.

#### EP-1675 Club100 (student organization of DEGRO e.V.) - Current activities and future perspectives

L. Käsmann<sup>1</sup>, L. Bolm<sup>2</sup>, S. Knoedler<sup>3</sup>, T. Hoelscher<sup>4</sup>, F. Prött<sup>5</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>University Medical Center Schleswig-Holstein- Campus Luebeck, Department of Surgery, Luebeck, Germany ; <sup>3</sup>University Hospital Ulm, Department of Radiation Oncology, Ulm, Germany ; <sup>4</sup>University Hospital of Cologne, Department of Radiation Oncology, Cologne, Germany ; <sup>5</sup>St. Josefs-Hospital, Department of Radiation Oncology, Wiesbaden, Germany

#### Purpose or Objective

The Club 100 is an integral part of the German society of radiation oncology (DEGRO e.V.). The main goal of this subgroup is to actively support medical students as well as

biology and physics students in the field of radiation oncology. Several activities spread over the year are organized for students: special student program during the annual congress of the German society of radiation oncology, several training seminars as well as a "Journal Club". The Club 100 supports students in publishing their scientific work, gives advice for MD/PhD thesis, offers a mentorship as well as financial support for stays abroad. The aim of this survey was to characterize the Club 100, reveal students' interests as well as to gather ideas for future projects and activities to support the interest in the field of radiation oncology.

#### Material and Methods

We surveyed all members of the Club 100 (n=144), who joined the working group between 2015 and 2017 via an anonymous online questionnaire sent by e-mail. The questionnaire was based on 12 questions with a total of 42 items.

#### Results

The survey was sent to 144 members of the Club 100. A total of 44 responses (response rate: 31%) were completed and returned, and hence were eligible for further evaluation. A total of 36 (77.3%) students study medicine, 6 (13.6%) physics and 4 (9.1%) biology enrolled at 17 different universities. All medical students were all in an advanced stage of their studies. 15 (42%) medical students were in their final year. 39 (89%) of medical students reported participation in lectures during their study as previous experience, 27 (61%) undertook an elective, 22 (50%) chose a topic for their MD/PhD thesis in the field of radiation oncology, 17 (39%) undertook an internship (<6 weeks) during their studies and 9 (21%) had a rotation (2-4 months) during their final year. The majority of medical students were made aware of radiotherapy and the Club 100 during lectures (48%) or in conjunction with MD/PhD thesis. >90% of all students rate the activity and training seminars of the Club 100 as 'good' or 'very good'. For future projects, the students are interested in more information and opportunity of stays abroad, more interdisciplinary lectures and the organisation of an exclusive poster session during the annual meeting of the German society of radiation oncology.

#### Conclusion

Medical students represent the majority (77.3%) of all members in the Club 100 (subgroup of the German society of radiation oncology). The satisfaction of the Club 100 members is high concerning training seminars and the student programs at the annual meeting of the German society of radiation oncology. The ideas for future projects and improvements show that the students are interested in presentation of their scientific work as well as obtaining more information about internships and education opportunities abroad.

#### EP-1676 Importance of work-life balance among German students interested in the field of radiation oncology

L. Käsmann<sup>1</sup>, L. Bolm<sup>2</sup>, S. Knoedler<sup>3</sup>, T. Hoelscher<sup>4</sup>, F. Prött<sup>5</sup>

<sup>1</sup>LMU University Hospital Grosshadern, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>University Medical Center Schleswig-Holstein- Campus Luebeck, Department of Surgery, Luebeck, Germany ; <sup>3</sup>University Hospital Ulm, Department of Radiation Oncology, Ulm, Germany ; <sup>4</sup>University Hospital of Cologne, Department of Radiation Oncology, Cologne, Germany ; <sup>5</sup>St. Josefs-Hospital, Department of Radiation Oncology, Wiesbaden, Germany

#### Purpose or Objective

The Club 100 is an integral part of the German society of radiation oncology (DEGRO e.V.). The main goal of this subgroup is to actively support medical students as well as biology and physics students in the field of radiation oncology. Several activities spread over the year are

organized for students: special student program during the annual congress of the German society of radiation oncology, several training seminars as well as a "Journal Club". The Club 100 supports students in publishing their scientific work, gives advice for MD/PhD thesis, offers a mentorship as well as financial support for stays abroad. The aim of this survey was to reveal the importance of work-life balance as well as career and research ambitions of students interested in the field of radiation oncology.

#### Material and Methods

We surveyed all members of the Club 100 (n=144), who joined the working group between 2015 and 2017 via an anonymous online questionnaire sent by e-mail. The questionnaire was based on 10 questions with a total of 22 items.

#### Results

The survey was sent to 144 members of the Club 100. A total of 44 responses (response rate: 31%) were completed and returned, and hence were eligible for further evaluation. A total of 36 (77.3%) students study medicine, 6 (13.6%) physics and 4 (9.1%) biology enrolled at 17 different universities. All medical students were all in an advanced stage of their studies. 15 (42%) medical students were in their final year. 96% of all responders can imagine to work in the field of radiation oncology (physician, physicist or biologist). 71% of all students plan to work in the clinical field as well as to work in clinical or experimental research. 14% of all responders want to work fulltime in research and another 14% want to work fulltime in clinical field. Radiation oncology caught attention due to a good work-life-balance by 59% of all responders. The perspective to work in a private practise, in a clinic or university hospital is rates as 'very good' by 12%, 30% and 39% of all students. The opportunity to have a family with children and a career is seen as possible by 45%. The family situation is more important than a career by >90% of all responders.

#### Conclusion

The results of this survey show that >95% of all Club 100 members can imagine to start a career in radiation oncology and 71% of all responders want to work in the clinical field as well as in research. The work-life balance appears to be an important factor to start in radiation oncology. The family situation is an important part of career planning. Radiation oncology is perceived as family-friendly from a student perspective.

#### EP-1677 Low dose radiotherapy for painful joint and tendon disorders in elderly and risk for malignancies

R. Buecker<sup>1</sup>, R. Muecke<sup>2</sup>, U. Schaefer<sup>1</sup>

<sup>1</sup>Klinikum Lippe GmbH, Strahlentherapie / Radioonkologie, Lemgo, Germany ; <sup>2</sup>Strahlentherapie RheinMainNahe, Strahlentherapie / Radioonkologie, Bad Kreuznach, Germany

#### Purpose or Objective

Low-dose megavoltage or orthovoltage x-rays treatment for painful benign conditions in the locomotor system as arthrosis and chronic tendinopathy is still widespread in Germany, despite the theoretical risk of radiation-induced malignancies. The aim of this study was to investigate the rate of hematological malignancies, i.e. leukemia, non-Hodgkin's lymphoma, Hodgkin's disease and myeloma in patients treated with low dose x-rays

#### Material and Methods

A cohort of 3017 such patients (mean age 67 years, range 20 - 97 years), treated from 1995 -2007 at the General Hospital of Lippe (northern Germany) was analyzed with regard to the risk of hematologic malignancies suspected of emanating from red bone marrow. Therapy was applied on a conventional radiotherapy treatment with 200 kVorthovoltage x-rays in single fraction of 1 Gy to a total dose of 6 Gy in 6 fractions. Depending on the treated region, the absorbed red marrow dose was determined to be almost zero (elbow, hand, knee, foot; n= 1839),

intermediate (shoulder; n= 930), and high (mostly trochanteric bursa and hip, occasionally spine and sacroiliac joint; n= 248). The endpoints (hematological malignancies) were searched for by computer linkage with the hospital information system (the General Hospital of Lippe is the only oncological center for more than 350 0000 inhabitants). The rate of hematological malignancies has been assigned to the different dose groups.

#### Results

Median follow-up was 8.8 years (range: 0 - 22.7 years). In the zero dose group, the rates for all hematological malignancies, only leukemia, and only leukemia except chronic lymphocytic leukemia were 4 / 1839 (0.8%), 5 / 1839 (0.3%), and 4 / 1839 (0.2%). In the intermediate dose group (n= 929), the corresponding values were 11 / 930 (1.2%), 3 / 930 (0.3%), and 2 / 930 (0.2%). In the highest dose group (n= 248), corresponding values were 4 / 248 (1.6%), 2 / 248 (0.8%), and 1 / 248 (0.4%). The differences between the dose groups were not significantly different (chi-squared test). 332 (11 %) solid malignancies were detected.

#### Conclusion

No statistical evidence was provided in this cohort that a higher x-ray dose in the red bone marrow increases hematologic malignancies after low-dose radiotherapy of benign disease in middle-aged and older adults. However, in a larger number of patients, the differences between the dosage groups could reach the level of significance. Therefore, the extension of the cohort will be continued.

#### EP-1678 Modern radiotherapy learning: a scoping review of the literature

G. Walls<sup>1</sup>, S. McAleer<sup>2</sup>, G. Hanna<sup>1</sup>

<sup>1</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom ; <sup>2</sup>Queen's University Belfast, Centre for Medical Education, Belfast, United Kingdom

#### Purpose or Objective

The last two decades have seen revolutionary developments in both radiotherapy technology and postgraduate medical training. Trainees are expected to attain the required competencies over a period of five years using a mix of experiential learning, formal postgraduate teaching, self-directed learning and peer learning. Developing skills in radiotherapy relies on workplace-based learning in particular, and Radiation/Clinical Oncology is a recognised craft specialty where the apprenticeship model of education is applicable. The process of learning radiotherapy in its current form has not been comprehensively described.

#### Material and Methods

A systematic search of MEDLINE and EMBASE was undertaken to identify published studies of trainee and/or trainer experience of radiotherapy learning 1999-2018. Keywords used in the search included "radiotherapy", "radiation oncology", "postgraduate training", "postgraduate education" and "apprenticeship". Results pertaining to medical oncology, workforce trends, undergraduate radiotherapy exposure, academic training, global health, gender issues, non-medical staff, health service infrastructure and recruitment to training programmes were not included as they were out-with the focus of the research.

Publication Type	Freq (%)	Publication Timeframe	Freq (%)	Country	Freq (%)
Surveys	62	2015 - 2018	58	USA	59
Interventional	41	2011 - 2014	55	UK	21
Reports	28	2007 - 2010	21	Collaboration	20
Editorials	15	2003 - 2006	10	Canada	19
Pure research	8	1999 - 2002	2	Others	27
Interviews	3				

#### Results

Of 269 search results, 87 met the inclusion criteria. A further 59 publications cited in the search results were included in the synthesis. Only abstracts existed for 5

results. See table 1 below for a results summary. Surveys formed the greatest proportion of relevant manuscripts identified (n=62). The surveys were of trainees (n=32), trainers (n=11), both trainees and trainers (n=16) or were multidisciplinary (n=3).

#### Conclusion

Although studied since the emergence of Oncology as a specialty in the 1950s, there is a paucity of qualitative and quantitative research examining radiotherapy learning. Medical education is becoming a more popular focus in radiation oncology but no study has been designed to comprehensively assess the current status. A majority of the literature identified reports results of observational, local or national surveys with a tightly defined scope. The results of the search results indicate that variation has a major impact between different curriculum areas, within hospitals, within and between countries and over time. The important contributing factors were captured, as was the impact of suboptimal training. Emerging educational approaches to radiotherapy training were also proposed.

#### EP-1679 Modern radiotherapy learning: a qualitative study of trainer and trainee views

G. Walls<sup>1</sup>, G. Hanna<sup>1</sup>, S. McAleer<sup>2</sup>

<sup>1</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom ; <sup>2</sup>Queen's University Belfast, Centre for Medical Education, Belfast, United Kingdom

#### Purpose or Objective

Radiotherapy technology and postgraduate medical training have benefitted from considerable advances in recent decades. Trainees are expected to attain the required competencies over a period of five years using a mix of experiential learning, formal postgraduate teaching, self-directed learning and peer learning. Developing skills in radiotherapy relies on workplace-based learning in particular, and Radiation/Clinical Oncology is a recognised craft specialty where the apprenticeship model of education is applicable. The process of learning radiotherapy in its current form has not been comprehensively described, and it was postulated that a more accurate insight would be gained by including both stakeholders involved in the radiotherapy learning process.

#### Material and Methods

Five Clinical Oncology trainers and five Clinical Oncology trainees at a regional Cancer Centre were invited to undertake semi-structured interviews regarding their personal accounts of modern radiotherapy learning. All participants were treated as equal co-investors in the process of radiotherapy learning with the common ultimate aim of passing radiotherapy skills from trainers to trainees. Interviews lasted between 13 and 32 minutes. Following transcription, interpretative phenomenological analysis was performed.

#### Results

Trainee subjects had completed a median of 3 years of training, trainers had completed training for a median of 9 years, and 60% study participants female. With the increasing maturity of Clinical Oncology as a discipline, treatments are becoming more complex and cancer centres are becoming more busy, to the detriment of the apprenticeship model of learning. There is more onus on the trainee to navigate more advanced techniques in today's more rigorously structured training programme, whilst adapting to the increasingly time-pressured working environment. Moreover, insufficient confidence restricts new trainees. Despite this task, standardised, intra-centre factors are under-represented in the mandatory training requirements and owing to poor compatibility, the interface with the curriculum, ePortfolio, has not been fully engaged. The feedback on which competency-based training relies could be optimised, and increased both trainer and trainee commitment to radiotherapy learning

were insightfully suggested. A multitude of additional mechanisms were proposed to counter the challenges identified, not limited to enhanced induction, interdisciplinary teaching, trainee empowerment and mindfulness of collegiality. Both trainers and trainees offered tailored novel measures, illustrating the co-operative responsibility perceived in relation to RL, many of which would go some length to restoring a sense of apprenticeship in Clinical Oncology training.

#### Conclusion

It would be prudent for Clinical Oncologists with an interest in medical education to engage with both trainees and trainers to establish local challenges and opportunities.

#### EP-1680 The effectiveness and safety evaluation of radiotherapy for painful humeroscapular periarthritis (PHS)

T. Latusek<sup>1</sup>, G. Wozniak<sup>1</sup>, L. Miszczyk<sup>1</sup>

<sup>1</sup>Centrum Onkologii-Instytut im.M.Sklodowskiej-Curie Gliwice Branch, Radiotherapy, Gliwice, Poland

#### Purpose or Objective

Painful humeroscapular periarthritis (PHS) is a painful, degenerative skeletal disorder of unknown etiology. Among a large variety of treatment options, the radiotherapy (RT) represents a relevant method.

The aim of the study was to evaluate the efficacy and safety of radiotherapy for periarthritis of the shoulder.

#### Material and Methods

The research included a group of 60 patients with the Periarthritis of the shoulder irradiated in the Department of Radiotherapy in the Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology Gliwice Branch. Patients' medical records have been analyzed retrospectively and a telephone survey has been carried out.

The following variables were assessed: pain duration before radiotherapy, shoulder function and pain evaluated using modified Constant- Murley and UCLA (University of California at Los Angeles) scales at the beginning of the therapy and during follow-up visits, the side effects after the irradiation in RTOG scale, duration of pain relief, the need for further treatment and necessity of analgesics use.

All patients were irradiated to a total dose of 6 Gy given in 6 fractions five times weekly. Cochran's Q test was used to assess the response to the therapy.

#### Results

The mean duration of follow-up was 3 years [range 2-6 years]. In 2012-2016, 60 patients were treated. 37% of the patients reported pain for months and 63% for years before radiotherapy. Nearly all patients had taken analgesics and had undergone physiotherapy.

During the first follow-up examination at the end of radiotherapy 60% of the patients reported pain relief and improvement of motility ( $p < 0.001$ ). In the telephone survey, 59% of the patients with pain relief stated that it had lasted for "years", in further 41% at least for "months". Necessity of analgesic use after radiotherapy was 10%. No radiation toxicity or secondary malignancies were observed.

#### Conclusion

The obtained results allow the conclusion that the low-dose radiotherapy for painful humeroscapular periarthritis may be an effective method of treatment; one that is often characterized by a long-lasting relief of pain and does not produce side effects.

#### EP-1681 Modern radiotherapy learning: a quantitative study of trainer and trainee views

G. Walls<sup>1</sup>, S. McAleer<sup>2</sup>, G. Hanna<sup>3</sup>

<sup>1</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom ; <sup>2</sup>Queen's University Belfast, Centre for Medical Education,

Belfast, United Kingdom ; <sup>3</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom

#### Purpose or Objective

Trainees in Clinical/Radiation Oncology previously learned radiotherapy skill in an apprenticeship model with their trainers. The last two decades have seen revolutionary developments in both radiotherapy technology and postgraduate medical training and therefore the current training landscape is different from that that current trainers experienced. The current state of radiotherapy training following this progress has not been explored comprehensively. As co-investors in the process of radiotherapy learning, passing radiotherapy skill from trainer to trainee, both the perspectives of trainers and trainees are important for this assessment.

#### Material and Methods

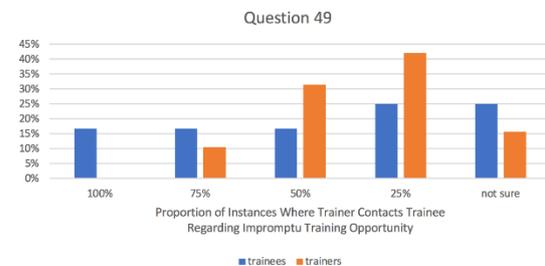

Clinical Oncology trainees and trainers at a regional Cancer Centre (n=34) were invited to undertake the same purpose-built questionnaire (69 questions). Four trainers (including two Educational Supervisors) and four trainees piloted the questionnaire, and input was sought from national leads in training Clinical Oncology training surveys. Significance testing was performed on pre-defined questions, and thematic analysis was performed on white space questions.

#### Results

Responses were received from 13 trainees and 19 trainers (96% invitees). The responses indicate that the training programme connects trainees to the necessary expertise and technology but several components could be optimised.

Discordance exists between some trainer and trainee views eg trainer and trainee responses were not aligned on how robust the programme induction is ( $p=0.005$ ), how encouraged trainees are to prioritise radiotherapy learning ( $p=0.009$ ) or how adequately equipped the First FRCR course prepares trainees for the physics ( $p=0.001$ ). Furthermore, trainees and trainers agreed on many points, such as Consultant observation of trainee volume delineation on a regular basis would optimise radiotherapy learning ( $p=0.182$ ) and peer teaching sessions increase trainee 'on the job' learning in the radiotherapy department ( $p=0.088$ ).

Additional differences between trainers and trainees were apparent from graphical representation of results eg graph 1 for 'proportion of instances where trainer contacts trainee regarding impromptu training opportunities'. Trainees are shown to have limited insight into the amount of plan analysis that occurs, and of the total components required for professional activity as a Consultant. Trainers on the other hand have poor awareness regarding trainee induction, general radiotherapy learning access outside their subspecialty, frequency of peer teaching and radiological anatomy teaching. A degree of validation of the bespoke questionnaire was achieved through comparison with RCR survey results.

#### Conclusion

The study demonstrated incomplete mutual understanding. Significant differences exist between the

perspective of trainers and trainees in radiation oncology and input from both stakeholders is needed for development. The survey tool should be validated in an external and large cohort for further evaluation.

### EP-1682 Fetal dose from head and neck tomotherapy versus 3D conformal radiotherapy

S.H. Park<sup>1</sup>, J. Choi<sup>1</sup>, Y.S. Kim<sup>1</sup>, J. Yoon<sup>2</sup>, S. Ahn<sup>3</sup>, W.H. Choi<sup>4</sup>

<sup>1</sup>Jeju National University Hospital, Department of Radiation Oncology, Jeju, Korea Republic of ; <sup>2</sup>Seoul National University Hospital, Department of Radiation Oncology, Seoul, Korea Republic of ; <sup>3</sup>Kangwon National University Hospital, Department of Radiation Oncology, Chuncheon, Korea Republic of ; <sup>4</sup>Gangnam Severance Hospital, Department of Radiation Oncology, Seoul, Korea Republic of

#### Purpose or Objective

To compare the dose of radiation received by the fetus in a pregnant patient irradiated for head and neck cancer using helical tomotherapy and 3-dimensional conformal radiation therapy (3DCRT).

#### Material and Methods

The patient was modeled with a humanoid phantom to mimic a gestation of 26 weeks. Radiotherapy with a total dose of 2 Gy in 20 fractions was delivered with both tomotherapy (2.5- and 5.0-cm jaw size) and 3DCRT. The position of the fetus was predicted to be 45 cm from the field edge at the time of treatment. The delivered dose was measured according to the distance from the field edge and the fetus using optically simulated luminescence dosimeters.

#### Results

The accumulated dose to the fetus was 1.6 cGy by 3DCRT and 2.0 and 2.3 cGy by the 2.5-and 5.0 cm jaw tomotherapy plans. For tomotherapy, the fetal dose with the 2.5-cm jaw was lower than that with the 5.0-cm jaw, although the radiation leakage was greater for 2.5-cm jaw plan due to the 1.5-fold longer beam-on time. At the uterine fundus, tomotherapy with a 5.0-cm jaw delivered the highest dose of 2.4 cGy. Considering that the fetus moves up to 35 cm at the 29th week of gestation, the resultant fetal doses for 3DCRT and tomotherapy with 2.5- and 5.0-cm jaws were estimated as 2.1, 2.7, and 3.9 cGy, respectively.

#### Conclusion

Fetal radiation dose was about 30% higher with tomotherapy than with 3DCRT, but this observed difference was tiny in absolute terms. For tomotherapy, scattering radiation was more important due to the high monitor unit values. Therefore, selecting a smaller jaw size for tomotherapy may reduce the fetal dose; however, evaluation of risk should be individually performed for each patient.

### EP-1683 Monte Carlo evaluation of organ doses from a proton gantry-mounted CBCT system

T. Henry<sup>1</sup>, O. Ardenfors<sup>1</sup>, I. Gudowska<sup>1</sup>, G. Poludniowski<sup>2</sup>, A. Dasu<sup>3</sup>

<sup>1</sup>Stockholm University, Medical Radiation Physics Department of Physics, Stockholm, Sweden ; <sup>2</sup>Karolinska University Hospital, Medical Radiation Physics and

Nuclear Medicine, Stockholm, Sweden ; <sup>3</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden

#### Purpose or Objective

To simulate organ doses delivered by a proton gantry-mounted cone-beam computed tomography (CBCT) system using two Monte Carlo codes.

#### Material and Methods

The CBCT system at the Skandion Clinic, Uppsala, Sweden, was modelled using MCNP6 and GATE from measurements of depth doses in water and spatial profiles in air. The beam models were subsequently validated against absolute dose measurements in a CTDI phantom. Organ doses in a whole-body phantom from different CBCT scan modes (360° full scan, 190° posterior/anterior scans) and different protocols (Head, Thorax, Pelvis) were then evaluated with the validated Monte Carlo beam models. The influence of repeated imaging on organ doses was also investigated, taking into account different imaging schedules (weekly/daily imaging, based on a standard treatment schedule of 30 fractions).

#### Results

An agreement within 4% was observed between MCNP6, GATE and the measurements with regard to depth doses and beam profiles for all protocols. The resultant average agreement in absolute dose validation was 4%. In-field absorbed organ doses after a single 360° scan ranged between 6-8 mGy (Head protocol), 15-17 mGy (Thorax) and 24-54 mGy (Pelvis). The highest absorbed organ dose after a single scan (54 mGy) was deposited in the femoral heads for the Pelvis protocol. Total organ doses after repeated CBCT imaging ranged between 0.04 and 0.32 Gy for weekly imaging and 0.2-1.6 Gy for daily imaging, depending on the organ and protocol considered. An average increase of 24% in dose per mAs to the organs of interest was observed for the anterior scans in comparison to the 360° scans, while the posterior scans showed a 37% decrease.

#### Conclusion

An accurate model of a proton gantry-mounted CBCT system was implemented in the MCNP6 and GATE Monte Carlo codes and used to calculate organ doses in a whole-body phantom following CBCT acquisitions. Various protocols and acquisition modes were evaluated. Organ doses varied greatly depending on acquisition mode, favouring posterior scans.

### EP-1684 Radiation isocontour levels for shielding considerations of the Varian Halcyon linear accelerator

K. Caravani<sup>1</sup>, T. Jarema<sup>1</sup>, A. Kazi<sup>1</sup>, R. Murry<sup>1</sup>, G. Godwin<sup>2</sup>

<sup>1</sup>Radiation Oncology Centres, Physics, Toowoomba, Australia ; <sup>2</sup>Radiation Oncology Centres, Physics, Brisbane, Australia

#### Purpose or Objective

The purpose of this study was to create a radiation isocontour plot of the Varian Halcyon linear accelerator (Halcyon), within the bunker, with the aim of creating a Halcyon specific shielding design for future installations.

#### Material and Methods

A PTW 30013 Farmer chamber (with the manufacturer's supplied build-up cap) was positioned at predefined points in 15° increments around the room, in a horizontal plane at the height of the isocentre and at various radial distances. Static cardinal gantry angles were used, with collimator angle 45°, maximum field size 28 cm x 28 cm, 6 MV FFF beam, maximum dose rate 800 MU/minute and 1000 MU/reading. Room angles were defined as per Figure 1.

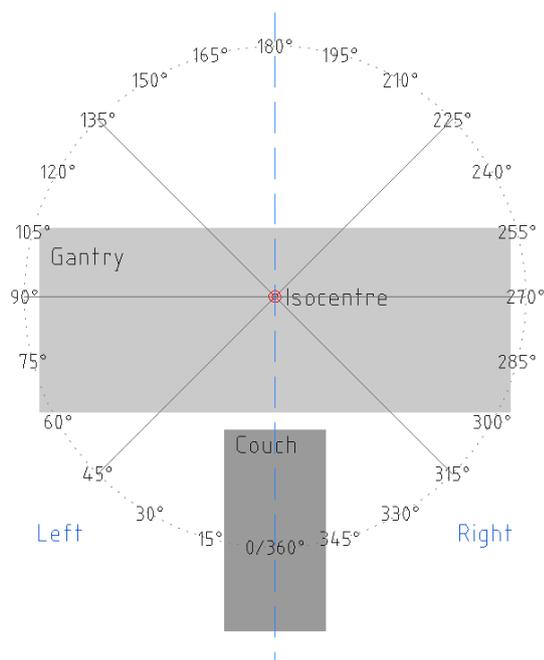

Figure 1: Illustration defining the room angles used for measurements.

Central axis (CAX) measurements in solid water, at depth of dose maximum, 100 cm SSD, for a 10 cm x 10 cm field, corrected for daily output variation, were used as a reference to give the relative reading [%]. Transmission through the beam stopper was measured for gantry 90° and 270° with the chamber at 1.5 m from the isocentre.

Head leakage measurements were made at 1 m behind the target, with closed MLC, collimator angle 0°, 1000 MU/reading, at room angles 90° and 270°.

#### Results

Initial horizontal plane measurement results at 1.5 m from the isocentre are shown in Figure 2.

The transmission through the beam stopper at a distance of 1.5 m from the isocentre was 0.003%. The inverse square law was used to calculate transmission at 1 m from the isocentre (0.007%). This agrees with the Varian Designers' Desk Reference, Halcyon Accelerator Edition (2017) which states that the transmission 1 m from the isocentre is < 0.1%.

The highest measurements were 0.28% and 0.27% at room angles 90° and 270° respectively, at 1.5 m from the isocentre. The average result of the head leakage measurements was 0.05%. Head leakage is required to be less than 0.1% as per IEC standard 60601-2-1. Gantry angles 0° and 180° provided similar results for the left and right (Figure 1) of the Halcyon, while Gantry angles 90° and 270° provided mirrored results.

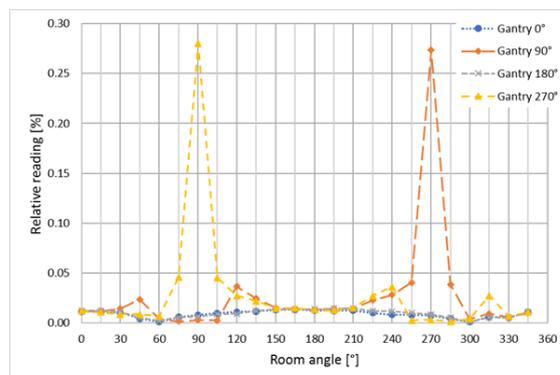

Figure 2: Relative readings [%] measured at a horizontal radial distance of 1.5 m from the isocentre at 15° increments.

Results at 2 m from isocentre follow the same trend as the results at 1.5 m.

Relative measurements in full scatter conditions are currently under investigation.

#### Conclusion

The relative radiation measurements in a horizontal plane throughout the bunker were plotted as a function of room angle for various distances from the Halcyon isocentre. Measurement results reported above fall within quoted reference values. These suggest that a primary barrier may not be required when designing a bunker for the Halcyon as the primary transmission through the primary beam stopper is negligible. This agrees with the Varian Designers' Desk Reference, Halcyon Accelerator Edition (2017) which states that a primary shielding wall is not required for the bunker.

#### EP-1685 Impact of acquisition mode of CBCT scans on size-specific dose estimates (SSDE) conversion factors

A. Abuhaimeid<sup>1</sup>, C. Martin<sup>2</sup>, O. Demirkaya<sup>3</sup>  
<sup>1</sup>King Abdulaziz City for Science and Technology, The National Centre for Applied Physics, Riyadh, Saudi Arabia ; <sup>2</sup>University of Glasgow, Department of Clinical Physics and Bioengineering, Glasgow, United Kingdom ; <sup>3</sup>King Faisal Specialist Hospital & Research Centre, Department of Biomedical Physics, Riyadh, Saudi Arabia

#### Purpose or Objective

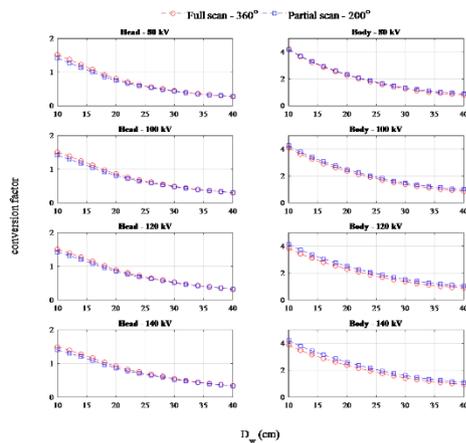

This study aimed to investigate influence of an acquisition mode, namely the partial scan, which is used for cone-beam CT (CBCT) scans to image patients partially over 200°, on size conversion factors of size-specific dose estimates (SSDE), which were derived with the full 360° scan mode.

#### Material and Methods

The SSDE factors are used to account for patient size by converting a dose index that is measured in phantoms of reference sizes known as CTDI head and body phantoms. For a CBCT scan of nominal beam width > 40 mm, one of the dose indices, recommended by IEC, is called CTDI<sub>IEC</sub>. It is based on dose measurements at central and peripheral positions of the CTDI phantoms with a reference beam width of ≤ 40 mm, and free-in-air dose measurements for the beam of interest and the reference beam. SSDE factors for a Varian kV imaging system, namely on-board imaging (OBI), were derived to convert CTDI<sub>IEC</sub> values using Monte Carlo simulations with BEAMnrc and Cavity user codes under different conditions. SSDE factors were assessed in water phantoms of diameters ranging from 10 to 40 cm. The diameters range was selected to match the patient size that is given as a water equivalent diameter. Two clinical scan protocols, head and body, similar to those used in the clinic were employed. Four tube potentials of 80 - 140 kV and the full and partial scan modes were used to derive SSDE factors.

## Results

SSDE factors for the full scan mode were greater than those for the partial mode over all tube potentials studied using the head scan protocol (Fig.1). The full mode factors were higher by up to 7% for small sizes, and the differences were decreased as the phantom size increase reaching  $\pm 2\%$  for large sizes. The tube potential, however, was found to play a major role on factors of the body scan protocol (Fig. 1). For 80 kV, factors of the full and partial scan modes were comparable over all sizes, all being within  $\pm 1\%$ . However, for higher potentials, factors of the partial scan mode were greater than those for the full mode by (4 - 14%), (8 - 17%), and (9 - 17%) for 100, 120, and 140 kV, respectively. The body variations were also affected by the phantom size as the variations were raised by the size increase.

**Figure 1:** SSDE conversion factors for the head and body scan protocols using four tube potentials and the full and partial acquisition modes. The factors were derived for patients of sizes equivalent to a water phantom diameter ( $D_w$ ) in the range of 10 to 40 cm.

## Conclusion

Results of this study show that the SSDE factors derived for the full scan mode using the head scan protocol can be utilized for the partial mode with an over/underestimation reaching up to 7% over all sizes and for the tube potentials studied. For the body, negligible differences found for the lower tube potential, 80 kV, but attention to the differences should be paid if one uses the full mode factors for the partial mode at higher potentials. Moreover, influence of start point on CTDI measurements for partial scan should be taken into consideration.

## EP-1686 Assessment of patient size for size-specific dose estimates using two methods: a comparative study

A. Abuhaimed<sup>1</sup>, C. Martin<sup>2</sup>, O. Demirkaya<sup>3</sup>

<sup>1</sup>King Abdulaziz City for Science and Technology, The National Centre for Applied Physics, Riyadh, Saudi Arabia ; <sup>2</sup>University of Glasgow, Department of Clinical Physics and Bioengineering, Glasgow, United Kingdom ; <sup>3</sup>King Faisal Specialist Hospital & Research Centre, Department of Biomedical Physics, Riyadh, Saudi Arabia

## Purpose or Objective

Volume CT dose index ( $CTDI_{vol}$ ), which is assessed in cylindrical phantoms of reference sizes, is one of the main dose indices utilized for CT dosimetry. Since  $CTDI_{vol}$  is assessed in standard phantoms, it does not give the user an accurate indication of the dose absorbed by a patient of a specific size, which is different from the reference ones. As a result, the concept of size-specific dose estimates (SSDE) has been developed to overcome this limitation. SSDE is based mainly on determination of the

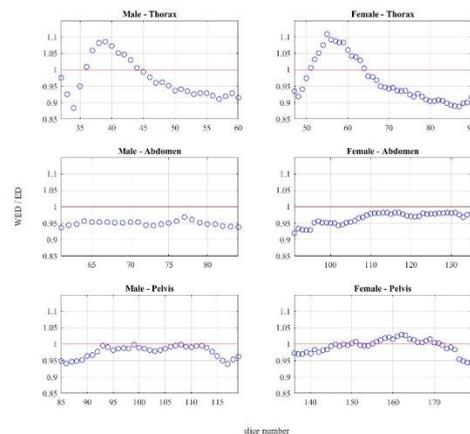

patient size. Aim of this study was to compare between two methods used to evaluate the patient size.

## Material and Methods

The first method is based on determination of the patient's dimensions for the region of interest (ROI). This includes anterior-posterior dimension and lateral dimension, from which effective diameter (ED) of the patient is calculated as suggested by AAPM TG-204. However, this method is limited as it does not distinguish between low and high attenuated regions. Therefore, an alternative method was suggested by AAPM TG-220 to account for attenuation of the ROI. It requires evaluating the mean CT number of the ROI, and number and area of pixels located in the same region. This allows estimation of the patient size as a water equivalent diameter (WED), from which a conversion factor can be applied to  $CTDI_{vol}$ . A MATLAB-based code was developed in house to import the ICRP reference adult phantoms, and to assess ED and WED for each slice of the two reference phantoms that represent an average male and female. Only the trunk was considered, and divided to three regions: thorax, abdomen, and pelvis.

## Results

Figure 1 shows variations between the methods studied for each slice. The variations were found to be comparable for both phantoms. WED values were higher than those for ED by 11% at the upper part of the thorax at most slices due to the higher attenuated area resulting from the shoulder. However, for the slices of the lower part, ED values became higher by up to 12% due to soft tissues existing in this part, e.g. lung and heart. Soft tissues were also spread largely over the abdomen region, which resulted in obtaining ED values that were higher. For the male phantom, ED values were higher by  $\sim 5\%$  over most of the slices, but the variations were reduced for the female phantom from 8 to 2% when the slices were moved down. WED values of the male phantom were lower over all the pelvic region by up to 6%. For the female phantom, however, WED values were within  $\pm 3\%$  of those for ED at most slices.

**Figure 1:** Variations between the ED and WED methods on the ICRP phantoms. Slice number is increased as the slice moves down of the body.

## Conclusion

The comparison shows that the variations between the methods investigated were within  $\pm 12\%$ ,  $\pm 8\%$ , and  $\pm 6\%$  for the thorax, abdomen, and pelvic regions, respectively. Since evaluation of the ED is relatively easier than that for the WED, one may use the ED method to obtain an approximate estimation for the patient dose, taking into consideration the uncertainty associated with this method, and that the WED is the accurate method to assess the dose.

### EP-1687 Variation of size-specific dose estimates (SSDE) of cone-beam CT (CBCT) scans with the scan length

A. Abuhaimeed<sup>1</sup>, C. Martin<sup>2</sup>, O. Demirkaya<sup>3</sup>

<sup>1</sup>King Abdulaziz City for Science and Technology, The National Centre for Applied Physics, Riyadh, Saudi Arabia ; <sup>2</sup>University of Glasgow, Department of Clinical Physics and Bioengineering, Glasgow, United Kingdom ; <sup>3</sup>King Faisal Specialist Hospital & Research Centre, Department of Biomedical Physics, Riyadh, Saudi Arabia

#### Purpose or Objective

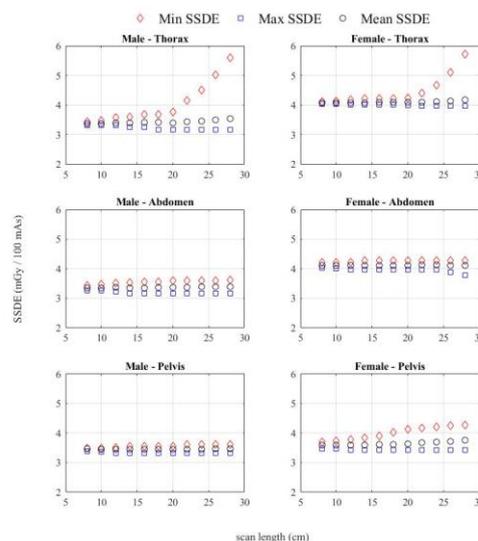

Length of a cone-beam CT (CBCT) scan is defined mainly by the clinical need. Recently, size-specific dose estimates (SSDE) has been recommended to estimate the imaging dose received by a specific patient from a given scan. SSDE is based on determination of size of the area of interest for the patient, i.e. region being scanned. Since length of this area is varied by the scan length, this investigation aimed to study impact of the scan length on SSDE values for CBCT scans.

#### Material and Methods

Monte Carlo simulations with user codes, BEAMnrc and Cavity, that were based on EGSnrc system, were employed to model a Varian on-board imager (OBI) kV system integrated into a linear accelerator (Truebeam), and to assess doses in water phantoms of diameters ranging from 10 - 40 cm. This allowed derivation of size conversion factors required to assess SSDE. The factors were derived in water phantoms to be linked to the patient size, which is reported in terms of a water equivalent diameter ( $D_w$ ). SSDE of CBCT scans were assessed by applying the conversion factors to the dose index  $CTDI_{IEC}$ , which is recommended by IEC as a dose index for CBCT scans. A MATLAB-based code developed in house to calculate  $D_w$  of the region of interest was utilized. The ICRP adult male and female reference phantoms were used in this study to represent average sizes for adult patients. Impact of the scan length was investigated in the trunk, which was divided to three regions, thorax, abdomen, and pelvis. Eleven scan lengths ranging from 80 - 280 mm, with increments of 20 mm, were used for each region, and centers of each scan was set at middle of these regions. The protocol used in the clinic to scan the body was applied, and the beam widths in the z-axis for CBCT scans were set the scan lengths studied.

#### Results

Minimum, maximum, and mean values of  $D_w$  for the region of interest were assessed for each scan.  $CTDI_{IEC}$  of the body scan was evaluated to be 2.46 mGy/100 mAs, and this value was converted to SSDE using the different values of  $D_w$  as shown in Figure 1. Use of the mean and maximum values of  $D_w$  to assess SSDE indicated less dependency on the scan length, where SSDE values were only varied by up to  $\pm 5\%$  over all the scan lengths studied. However, SSDE values based on the minimum values of  $D_w$  were affected by the scan length, particularly for the thorax region, where extension of the scan length from middle of the region to the upper part included the shoulder that had a higher attenuation area. The lower variations in SSDE values based on the mean  $D_w$  values were found for the abdomen region, all being within  $\pm 1\%$ , as the attenuation values for the tissues in this region are comparable.

**Figure 1:** Influence of the scan length on SSDE values based on minimum, maximum, and mean values of  $D_w$  for the regions of interest.

#### Conclusion

Estimation of SSDE values based on the mean  $D_w$  for the regions of interest showed to give a good indication for the patient dose as the scan length had a minimal influence on SSDE values as well as it took into account the minimum and maximum values of  $D_w$ .

### EP-1688 Monte Carlo simulations to quantify out-of-field doses due to the electron streaming effect

V.N. Malkov<sup>1</sup>, S.L. Hackett<sup>1</sup>, J.W.H. Wolthaus<sup>1</sup>, B.W. Raaijmakers<sup>1</sup>, B. Van Asselen<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

#### Purpose or Objective

In the context of magnetic resonance guided radiation therapy (MRgRT), the influence of the magnetic field on surface doses has been an ongoing area of research. The electron return effect (ERE) can contribute to a significant increase in surface doses at boundaries (Raaijmakers et al.). In addition to the ERE, in orthogonal magnetic field orientations, electrons are swept out of the irradiated air volume. This leads to a reduction of in-field entry surface doses, but contaminant streaming electrons can contribute up to about 5.4% to out of field doses (Hackett et al., 2018). Further, Park et al. (2018) studied treatment accelerated partial breast plans with either a 0 or 0.35 T perpendicular magnetic field and found that the presence of the magnetic field induced out-of-field doses as large as 15% of the prescription dose to extend in the air along the magnetic field. In this work, the out-of-field surface doses contribution due to backscattered or ejected electrons, focused by the magnetic field, is studied. This electron streaming effect (ESE) can contribute to substantial out-of-field doses and requires detail study.

#### Material and Methods

The EGSnrc Monte Carlo package is used to simulate a water phantom with an incident  $10 \times 10 \text{ cm}^2$  7MV FFF beam. As shown in Figure 1, the phantom entry or exit surface is inclined with respect to the magnetic field, and an out-of-field water panel is positioned 10cm away from, and centered, on the isocenter. The surface dose profiles in the water panel are calculated with either a 0, 0.35, or 1.5 T magnetic field and inclines of 10, 30, or 45°.

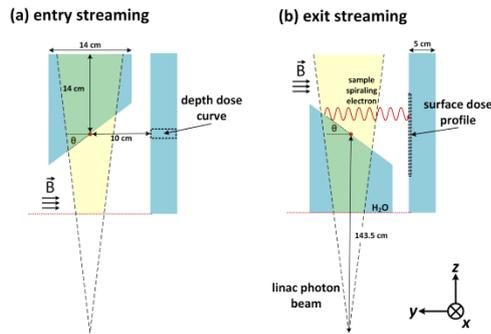

Figure 1: Schematic of EGSnrc simulation set-up of the (a) entry and (b) exit inclined phantoms.

## Results

As the magnetic field increases, in the entry and exit simulations, the dose distributions become sharper, as shown in Figure 2 for the exit streaming case. The maximum doses for the 0.35T exit simulations are 22.9%, 38.0%, and 42.8% for the respective 10, 30, and 45° simulations. For 1.5T, for the same angles, the maximum values are 16.7%, 29.6%, and 36.4%. Dose values drop to below 2% within the first 1cm of the out-of-field water phantom. For the entry simulation, the largest ESE doses were observed for the 45° simulation and were 4.5% and 8.0% for the 0.35 and 1.5T magnetic fields, respectively. Percentages are with respect to the maximum deliverable dose by the beam to a large water phantom.

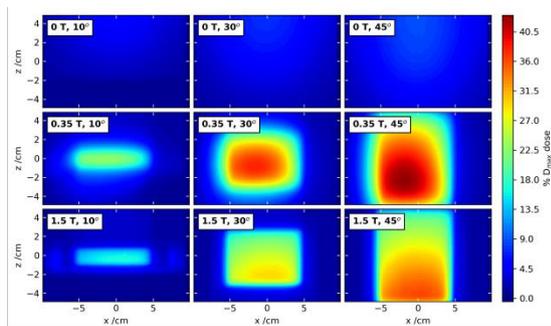

Figure 2: Surface dose profiles in the out-of-field for the exit streaming simulation

## Conclusion

The ESE can contribute to notable out-of-field doses and should be considered during treatment planning for MRgRT systems. Treatments often include several beams which will spread out the overall effect. In situation where ESE doses are unavoidable, a 1cm bolus or the already mounted RF coils would greatly reduce the effect. Further exploration is required into the capabilities of the treatment planning system to capture this effect.

### EP-1689 Implementation of ultra-low dose CBCT for children using an optimised bowtie filter

A. Bryce-Atkinson<sup>1</sup>, M.C. Aznar<sup>1</sup>, G. Whitfield<sup>2</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>The University of Manchester, Division of Cancer Sciences- School of Medical Sciences- Faculty of Biology Medicine and Health, Manchester, United Kingdom ; <sup>2</sup>The University of Manchester, Manchester Academic Health Science Centre- The Christie NHS Foundation Trust, Manchester, United Kingdom

### Purpose or Objective

Cone beam CT (CBCT) image guidance can lead to excessive doses to children undergoing radiotherapy due to incorrect use of imaging protocols designed for adults. But even with correct protocols, there are concerns of late effects due to imaging dose, affecting the use of image

guidance in children (e.g. choice of imaging modality and frequency of acquisition). The aim of this work is to implement ultra-low dose CBCT through use of a bowtie filter specifically designed for paediatric CBCT: it provides additional attenuation to reduce exposure and is shaped to fit the smaller body size of children. Here, we quantitatively evaluate the effect of implementing such a filter on image quality, registration accuracy and dose.

### Material and Methods

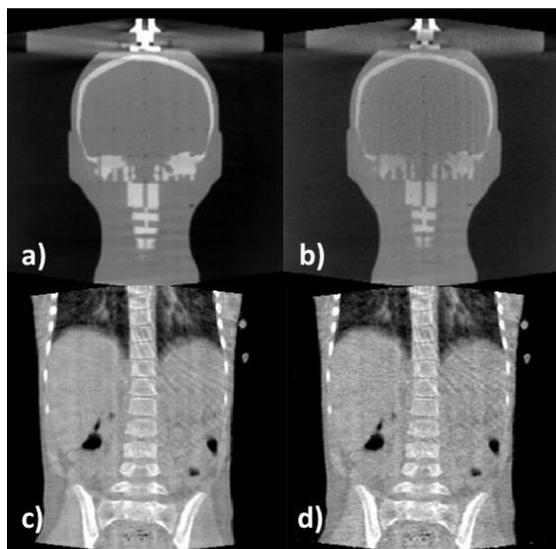

The paediatric bowtie filter (Fig.1) provides additional attenuation compared to the standard (adult) Elekta XVI bowtie filter and produces uniform X-ray intensity across the average paediatric patient in the lateral direction, as derived from 15 paediatric CBCT scans. This bowtie filter was used to scan an ATOM 10-year-old paediatric phantom at the lowest dose in the brain, thorax and abdominal regions. Registration accuracy was recorded as a measure of image quality and its suitability for IGRT. Each CBCT was automatically registered to the planning CT, matching on bony anatomy. The couch shift derived from the low dose scans was compared to that for the standard dose scans (100kV, 0.16mAs per frame, 200 frames). In addition, CBCT scans with the paediatric bowtie filter were simulated for 23 paediatric patients using a noise addition method, and the registration results were compared to that of the original acquisition.

Fig 1: The paediatric bowtie filter. The thick central part of the filter reduced exposure fivefold.

### Results

The lowest exposure acquired was equivalent to 15.6% of the standard low dose exposure used for children (0.8mGy to 0.13mGy). This dose level is well below the leakage dose of head and MLC. Bone-equivalent material in the phantom scans and bony anatomy in the simulated paediatric scans remained clearly visible, although increased noise was apparent in the images (Fig. 2). All acquired phantom scans and simulated patient scans had registration discrepancies of less than 1mm compared to the standard paediatric exposure. The filter can also be used at higher exposures, giving a greater range of ultra-low dose imaging protocols than is currently clinically available, such that optimised paediatric imaging protocols can be developed for different age groups.

**Fig 2:** Comparison of image quality of a) A typical paediatric exposure scan of the ATOM 10 year old phantom. b) The lowest dose phantom scan at 15% of this exposure (0.13 mGy). c) A typical paediatric patient scan (100kV, 0.16mAs). d) Same as c but with the new bowtie filter simulated by adding non-uniform noise.

### Conclusion

A bowtie filter optimised for children has been implemented and evaluated in phantom scans and simulated in patient CBCT data. Even at the lowest exposure setting, registration accuracy and image quality were sufficient, i.e., the filter provided considerable dose reduction to paediatric patients without affecting image guidance.

The authors are grateful to Elekta Oncology Systems for manufacture of the bowtie filter.

### EP-1690 Induced radioactivity as a (un)helpful effect of particle therapy

P. Sekowski<sup>1</sup>, I. Skwira-Chalot<sup>1</sup>, T. Matulewicz<sup>1</sup>

<sup>1</sup>University of Warsaw, Faculty of Physics, Warsaw, Poland

### Purpose or Objective

Particle therapy is a rapidly developing form of radiation therapy of tumours, but it still has many secrets which are continually discovered. The main purpose of our project is to measure radioactivity induced in the human body during hadron therapy tumour treatment and assessment of its influence on therapy effects and causation of secondary tumours.

### Material and Methods

In order to find the sources of induced radioactivity in the patient's body, the targets, which are very similar to humans tissues, have irradiated with commonly used beams in hadrontherapy. For that, the pig liver and bone meal were chosen and as projectiles, the proton beam of 60 MeV and neutron beam obtained from the neutron source were used. After irradiation, the samples measured using the low-background spectrometer, at INP PAS in Kraków. Based on Geant4, the Monte Carlo simulations were simultaneously performed. In our experiments, the proton beam of 60 MeV and neutron beam obtained from the neutron source were used.

### Results

Table 1 presents the list of isotopes which were identified after bone tissue irradiation of 60 MeV proton beam. One can see that the total dose from induced radioactivity for prescribed dose as 80 Gy in 100 c.c. tumour volume is approximately 30 µGy.

### Isotope Dose [pGy c.c. /Gy\_therapy]

Cl-34m 546 +/- 95

K-42 145.7 +/- 6.3

Sc-44 99.5 +/- 3.7

K-43 6.3 +/- 5.4

Sc-47 10.70 +/- 0.49

K-38 3100 +/- 1500

Sc-43 42.2 +/- 2.7

### Conclusion

As we can see above the additional dose using a low energetic proton beam is not significant. But for bigger tumours and highly energetic beams, the contribution of induced radioactivity could be higher. Moreover, as we can see in case of Proton Boron Cancer Therapy that even a small amount of specific element (in the case of PBCT - B-8) can significantly change the therapy effects. That is why the effect of induced radioactivity cannot be omitted and have to be estimated and taken into consideration during treatment planning.

### EP-1691 IORT and stray radiation: comparison of 2 commercial linacs

P. Stevens<sup>1</sup>, F. Van Hoof<sup>1</sup>, M. Holvoet<sup>1</sup>, E. Messens<sup>1</sup>, L. Grasso<sup>2</sup>, S. De Stefano<sup>2</sup>, G. Felici<sup>2</sup>, D. Verellen<sup>1</sup>

<sup>1</sup>GZA- Ziekenhuizen - St. Augustinus, Radiation Physics, Wilrijk, Belgium ; <sup>2</sup>SIT, Physics, Aprilia, Italy

### Purpose or Objective

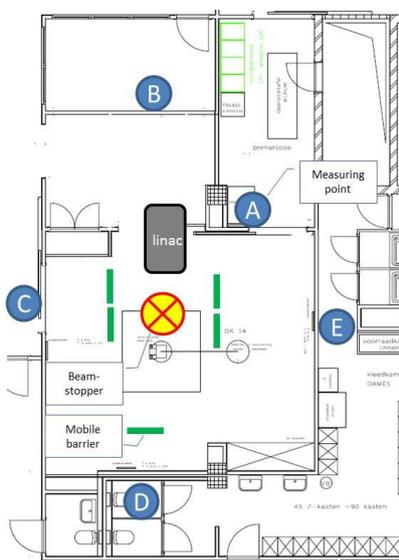

Intraoperative Radiation Therapy (IORT) is performed with a linear accelerator in a standard operating room mainly constructed with 7 cm drywall walls. An important safety issue of IORT is radiation protection and stray radiation. This stray radiation is mainly produced by the accelerator itself (leakage radiation) and the patient (Patient Stray Radiation), as per NCRP 151. Two IORT dedicated electron linacs (IntraOp Mobetron 1000 and SIT Liac HWL) have been installed in the same operating room in our institute, providing a unique opportunity to benchmark both with regard to radiation protection performances.

### Material and Methods

The 2 linacs were positioned in the center of the Operating Room; measurements have been performed with a reference applicator (100 mm applicator with bevel 0°) positioned on a 15 cm thick RW3 phantom, at a height of 100 cm above the floor with their beamstopper. Both linacs were set up at an energy of 12 MeV and a dose rate (DR) of 1000 MU/min or 550 MU/min. Measurements for the Liac HWL were performed with and without mobile barriers provided by the manufacturer. Instantaneous dose rate (IDR) was measured at 5 points against the wall of the surrounding rooms in the patient plane and at the hotspot at groundlevel beneath the OR with 3 survey meters: Canberra Babyline 81, Canberra Babyline 81\*, Fluke 451 P. Additional surveys were performed in the rooms surrounding the OR and personnel InLight dosimeters were placed at critical locations to assess the weekly dose equivalent during clinical use.

## Results

Device and set up	measuring point	Instant dose rate ( $\mu\text{Sv/h}$ )		
		Canberra babyline 81	Canberra babyline 81*	Fluke 451 P
MOBETRON	A	2000	200	/
DR 1000	B	300	50	/
12 MeV	C	1500	800	/
Without mobile barriers	D	300	100	/
	E	100	100	/
	downstairs	/	600	/
LIAC HWL for preliminary testing	A	200	150	200
DR 1000	B	60	30	60
12 MeV	C	200	200	200
with mobile barriers	D	40	100	40
beamstopper 70 cm	E	80	50	80
	downstairs	20	50	20
LIAC HWL 54	A	90	/	95

DR 1000	B	/	35	/
12 MeV	C	/	150	/
without mobile barriers	D	/	90	/
beamstopper 90 cm	E	/	100	/
	downstairs	/	20	/

The personnel dosimeters didn't register a monthly dose exceeding the minimal reporting limit (50  $\mu\text{Sv}$ ) for the treatment of 44 patients (480 Gy) over 5 months with the Liac HWL.

## Conclusion

In terms of stray radiation Liac HWL outperforms Mobetron 1000 both in the patient plane and the room beneath the OR. The Liac HWL produces an equal amount of stray radiation at a dose rate of 10 Gy/min or 5.5 Gy/min. The beamstopper was redesigned to reduce stray radiation below the limit of 10  $\mu\text{Sv/h}$  in the room under the OR. The mobile barriers reduce the stray radiation in patient plane. The personnel dosimeters confirm the survey measurements.

#### EP-1692 Flatbed scanner stability for radiochromic film dosimetry

C. Laosa<sup>1</sup>, J.F. Calvo Ortega<sup>2</sup>, S. Moragues Femenia<sup>2</sup>, J. Casals<sup>2</sup>

<sup>1</sup>Hospital Quirónsalud, Radioterapia, 08035, Spain ;

<sup>2</sup>Hospital Quirónsalud Barcelona, Radiotherapy, Barcelona, Spain

## Purpose or Objective

To investigate the stability of a flatbed scanner used for radiochromic film dosimetry.

## Material and Methods

An Epson Pro V750 flatbed scanner and EBT3 films of a same batch were used. A piece of film exposed to 1 Gy was aged for 4 months so that its post-exposure change was considered as zero. The aged film and an unexposed film piece were simultaneously scanned in the center of the bed scanner. A 1 mm-thick glass sheet was used to avoid film curling. Transmission mode, RGB-48 bits and 72 dpi resolution were used. The scanner was warmed-up for at least 30 min before the scanning. For each scanning session, five empty scans were taken to stabilize the scanner lamp. After that, five consecutive scans were made. The first scan was discarded and the resulting image was the average of the remaining four. The film image was converted into a dose image using the triple-channel method implemented in Radiochromic.com software (<https://radiochromic.com>). The unexposed film piece was used to apply the inter-scan correction option of Radiochromic.com. Two approaches were considered to investigate the stability of the scanner: 1) the scanner was uninterruptedly powered on during 45 days. For each day, several scanning sessions were performed at different times. A total of 88 sessions were recorded. 2) During a period of 13 consecutive days, the scanner was powered on every day before the scanning session, and after finished, it was powered off. For each day, several scanning sessions were performed at different times. A total of 67 sessions were recorded. Average dose in a specific ROI over the aged film (DROI) was monitored over all scanning sessions for the two approaches. Fluctuation (SD to average ratio) of DROI was analyzed for each approach.

## Results

Fluctuations of 1.4% and 2.6% for  $D_{ROI}$  were observed for the approaches 1 and 2, respectively. 95<sup>th</sup> percentiles of 2.3% and 4.8% were respectively found for the deviation of  $D_{ROI}$  with respect to the average  $D_{ROI}$  over all scanning sessions.

## Conclusion

According to the results, keeping the scanner powered on improved its stability.

#### EP-1693 Determination of the angular dependence of a CC04 ion chamber

A. Prado<sup>1</sup>, Á. Gaitán<sup>2</sup>, M. Manzano<sup>2</sup>, M. Leonor<sup>2</sup>

<sup>1</sup>Hospital Universitario 12 de octubre, Oncología Radioterápica. Sección de Radiofísica., Madrid, Spain ;

<sup>2</sup>Hospital Universitario 12 de octubre, Radiofísica y Protección Radiológica., Madrid, Spain

## Purpose or Objective

Due to the specific geometry and design of each type of detector, its response when exposed to a radiation beam might vary with the angle of incidence. In the present work this angular dependence is quantified for a CC04 (IBA Dosimetry) ion chamber.

Due to the specific geometry and design of each type of detector, its response when exposed to a radiation beam might vary with the angle of incidence. In the present work this angular dependence is quantified for a CC04 (IBA Dosimetry) ion chamber. **Material and Methods**

Measurements were performed on a Varian Clinac iX using a 6MV beam energy. A CC04 ion chamber and a Bahnhofstrasse 5 (IBA Dosimetry) electrometer were utilized. A home-made phantom made of high-density

polyethylene with a cavity adapted to the size of the ion chamber used was employed (fig. 1). This cavity was constructed so as to make the center of the phantom coincide with the reference point of the chamber. The phantom is comprised of a half sphere joined to a cylindrical region. The center of the phantom was located at 10 cm depth from the spherical region surface. The phantom center was positioned at the unit isocenter. The phantom spherical region pointed upwards, being the chamber perpendicular to the couch plane. In this way, it was possible to rotate the gantry between 90° and 270° without moving the couch. In each measurement 200 MU were delivered using a 600 MU/min dose rate and a 4x4 cm<sup>2</sup> field size. Gantry angles between 90° and 270° in 10° steps were used, performing three measurements per angle and calculating the average and the standard deviation for each position. Results were normalized to the value obtained at 0° (ion chamber parallel to the radiation beam).

Figure 1: Home-made phantom used with a cavity adapted to the CC04 ion chamber size.

Gantry angles between 90° and 270° in 10° steps were used, performing three measurements per angle and calculating the average and the standard deviation for each position. Results were normalized to the value obtained at 0° (ion chamber parallel to the radiation beam). Figure 1: Home-made phantom used with a cavity adapted to the CC04 ion chamber size. **Results** Results agree with the IEC 60731 document, which states that the angular dependence of an ion chamber should not exceed a 1% deviation in the angular interval comprised between ±40° (maximum deviation was 0.45% at -40°). However, for gantry angles greater than 40° an increasing angular dependence was found. In figure 2 the percent deviations of the normalized values as a function of the gantry angle is depicted. Some symmetry with respect to 0° is observed mainly due to the cylindrical geometry of the chamber as well as due to the irradiation geometry. Deviations up to 3.6% with respect to the 0° value were observed (at -90°). For each angle the standard deviation did not exceed 0.1%, so it was decided not to perform a higher number of measurements per gantry position.

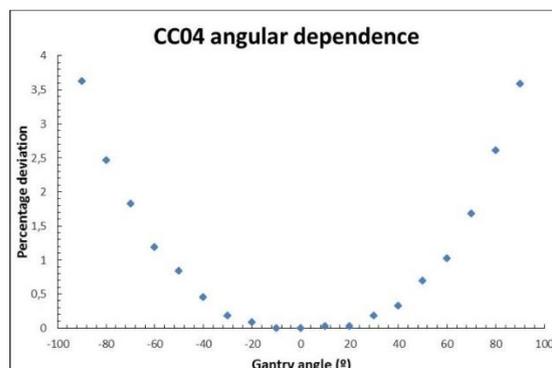

Figure 2: CC04 angular dependence in percentage deviation with respect to 0° value as a function of gantry angle.

Results agree with the IEC 60731 document, which states that the angular dependence of an ion chamber should not exceed a 1% deviation in the angular interval comprised between ±40° (maximum deviation was 0.45% at -40°). However, for gantry angles greater than 40° an increasing angular dependence was found. In figure 2 the percent deviations of the normalized values as a function of the gantry angle is depicted. Some symmetry with respect to 0° is observed mainly due to the cylindrical geometry of the chamber as well as due to the irradiation geometry. Deviations up to 3.6% with respect to the 0° value were observed (at -90°). For each angle the standard deviation did not exceed 0.1%, so it was decided not to perform a higher number of measurements per gantry position. Figure 2: CC04 angular dependence in percentage deviation with respect to 0° value as a function of gantry angle. **Conclusion**

The angular dependence of a CC04 ion chamber was obtained for an angular interval between 90° and 270°. This dependence is in accordance with the IEC 60731 document, but it increases as the angle deviates from 0° up to 3.6% at -90°. Considering these results it is recommended that the angular dependence of the detectors used be known by the user, being this data provided by the manufacturer or measured by the user itself. A proper characterization of this dependence could be employed to calculate correction factors to be applied when using an ion chamber.

#### EP-1694 Evaluation of a new portal dosimetry solution for dose quality control of Elekta and Varian linacs

S. Couespel<sup>1</sup>, N. Delaby<sup>1</sup>, S. Sorel<sup>1</sup>, C. Boutry<sup>2,3</sup>, C. Lafond<sup>1,4</sup>

<sup>1</sup>Centre Eugène Marquis, Ille-et-Vilaine, Rennes, France ;

<sup>2</sup>Groupe Oncorad Garonne, Tarn-et-Garonne, Montauban, France ; <sup>3</sup>Dream SAS, Haute-Garonne, Toulouse, France ;

<sup>4</sup>Univ Rennes- CLCC Eugène Marquis- Inserm- LTSI-UMR 1099, Ille-et-Vilaine, Rennes, France

#### Purpose or Objective

The aim of this study is to evaluate a new portal dosimetry solution (ARTISCAN Beam QA, AQUILAB - France) for independent QA of photon and electron beams on Elekta and Varian linacs.

## Material and Methods

ARTISCAN Beam QA software is based on EpiDream method (Boutry et al, Med Phys 2017) converting EPID signal in air into absorbed dose in reference conditions. The product is developed to perform dose quality control of photon and electron beams using EPID.

Our study was performed on 6 MV and 6 MV FFF photon beams from Elekta linac (Versa HD with iViewGT v3.4.1) and on 6 MV photon beam and 6 MeV electron beam from Varian linac (Clinac 2100C with EPID AS500). Intrinsic characteristics of the solution were first evaluated, including repeatability, reproducibility, dose linearity and dose consistency over the time. Then, we performed tests of our current internal QA program: daily X-Ray and electron output constancy, beam profiles constancy, wedge transmission factor constancy, monitor chamber linearity. Results were compared to those obtained with ionization chamber (0.6 cc, PTW) or with ionization chamber 2D-matrix (StarCheck, PTW).

## Results

The reproducibility of 10 EPID measurements was 0.09% for 6 MV (Elekta). Dose linearity for photon and electron beams for the Varian linac was better than 1% for MUs higher than 20 with EPID solution. From 3 to 15 MUs, dose linearity was between 1.3% and 2.4% for photon beam and 0.7% and 1.9% for electron beam EPID solution. A 4 months analysis showed a dose deviation for a square field between +0.05% and -1.25% for 6 MV beam and between +0.39% and -1% for 6 MV FFF beam (Elekta). For the daily output constancy on Elekta linac, the mean difference obtained for 32 QAs between EPID dosimetry and ionization chamber was -0.1% ( $\sigma=0.3\%$ ) for 6 MV and -0.6% ( $\sigma=0.3\%$ ) for 6 MV FFF beam. Beam profiles obtained with ARTISCAN Beam QA software and the StarCheck were plotted for 6 MV, 6 MV FFF and 6 MeV beams in Fig 1. The difference on wedge transmission factor obtained with EPID solution and ionization chamber was 0.2% for 6 MV (Varian). The maximal difference on monitor chamber linearity for 6 MV beam (Varian) between EPID solution and ionization chamber was 1.4% for MUs higher than 3, reaching 5% for 1 MU.

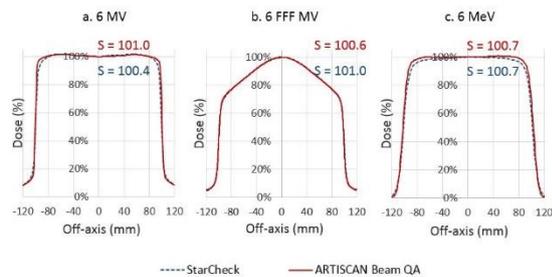

Fig 1: Inplane profiles for 6 MV (a), 6 FFF MV (b), photon beams and 6 MeV (c), electron beam, obtained with the StarCheck matrix (blue dashed curves) and with ARTISCAN Beam QA (red solid curves). The symmetry  $S$  is computed as  $S = 100 \times \left( \frac{D(x)}{D(-x)} \right)_{\max}$ ,  $D(x)$  and  $D(-x)$  being the symmetric points in the 80% isodose for the photon beams and in the 90% isodose -1 cm for the electron beam.

## Conclusion

Our results showed that the EPID dosimetry solution proposed by AQUILAB seems to be promising to perform QA programs on Elekta and Varian linacs for both photon and electron beams.

## Reference

A simple algorithm to convert EPID gray values into absorbed dose to water without prior knowledge. Boutry C, Sors A, Fontaine J, Delaby N, Delpon G. Med Phys. 2017 Dec; 44(12):6647-6653.

## EP-1695 Determining the dose per pulse dependence of a commercial synthetic diamond detector

D. O'Doherty<sup>1</sup>, J. Cross<sup>1</sup>, R. Plaistow<sup>1</sup>, K. Fathi<sup>1</sup>, S.J. Thomas<sup>1</sup>

<sup>1</sup>Addenbrooke's Hospital - Oncology Centre, Medical Physics Box 152, Cambridge, United Kingdom

## Purpose or Objective

When measuring percentage depth doses (PDD) using a radiation detector in a plotting tank, the dose per pulse decreases with depth in water. Since the recombination correction to be applied to the detector varies with dose per pulse, this requires corrections to be made to the PDD. At the small doses per pulse observed in conventional flattened field, these corrections are small (typically less than 0.2%); however with the larger doses per pulse seen in Flattening Filter Free (FFF) beams, corrections of up to 1.3% can be required, depending on the detector used (Budgell et al 2016). The PTW 60019 micro diamond (PTW, Freiburg, Germany) is a commercially available synthetic diamond detector, designed for the dosimetry of small radiotherapy fields. As there is a lack of consistent published data on the dose per pulse dependence of the Micro Diamond the purpose of the measurements described below is to determine whether a dose per pulse correction is needed for this detector.

## Material and Methods

We have performed measurements on two PTW 60019 Micro Diamond detectors to determine whether such a correction is necessary. Depth doses for a 10MV FFF beam were measured with the Micro Diamond, and compared with depth doses measured with an A1SL ion chamber which had been corrected for ion recombination.

## Results

For depths from 30mm to 300mm, the ratio of the depth dose to the corrected A1SL ion chamber depth dose was  $1.0005 \pm 0.001$  for one of the Micro Diamonds, and  $1.0001 \pm 0.001$  for the other. Both of these values are consistent with unity.

## Conclusion

For the measurement of depth doses on FFF beams with large dose per pulse, no correction for the variation with depth of dose per pulse is required when measuring with a PTW 60019 micro diamond.

## EP-1696 Microdosimetry assessment in cyclotron proton beamline with new 3D-microdetectors

Ville, France ; <sup>6</sup>Universidad de Sevilla, Dpto. Física Atómica- Molecular y Nuclear, Sevilla, Spain

## Purpose or Objective

Protontherapy achieves very high dose conformity around the target, allowing a better protection of the organs at risk (decreasing radiation side effect) [1]. The determination of the relative biological effectiveness (RBE) of protons depends on several factors, being the particle LET one of them. Therefore the use of devices that help to reduce any uncertainty is essential. Likewise, there is a rising interest in the medical-physics community in placing the enhanced LET of the beam within the tumor or removing it from the most sensitive normal structures around [2]. Nevertheless, there is no instrument to quantify the LET in clinical scenarios, but as the one we show herein. In this work we present direct microdosimetric measurements of 18 MeV proton beams

using novel silicon 3D-microdetectors [3]. Results were verified with both Geant4 and FLUKA simulations.

#### Material and Methods

The new 3D-microdetectors used are a type of diode with a 3D-cylindrical electrode etching (15  $\mu\text{m}$  diameter, 5  $\mu\text{m}$  depth) with an inner volume that matches a sensitive volume that simulates a subcellular structure. Details are described elsewhere [3,4]. The 18 MeV proton beams were generated in a Cyclone 18/9 cyclotron at flux rates of  $10^8$  p/cm<sup>2</sup>s. The proton beam average energy was modulated with an in-house wedge system formed by two equal 10° angle wedges made of 1.19 g/cm<sup>3</sup> Lucite that provides a continuously variable thickness from 3 mm up to 30 mm with an uncertainty of 30  $\mu\text{m}$  [5]. The cyclotron proton beamline was simulated with Geant4.10.4. The so simulated outgoing energy spectrum was used as input-file within Geant4 and FLUKA simulations of the 3D-microdetector performance.

#### Results

Fig. 1 shows the most probable lineal energy through the Bragg curve and measured microdosimetry spectra. The experimental silicon microdosimetric spectra showed clearly the variations of the lineal energy frequency distribution along the Bragg curve.

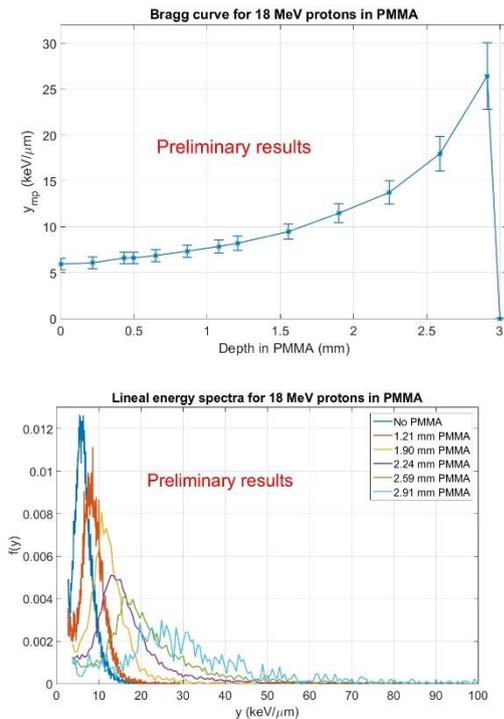

Figure 1: Left: Most probable lineal energy versus PMMA depth curve for the 18 MeV protons measured with the novel 3D-microdetector. Right: Measured microdosimetry spectra as a function of the PMMA thickness.

#### Conclusion

Measurements at various depths along the Bragg curve of a 18 MeV proton beam were performed at high fluence rate with a novel 3D-microdetector and both microdosimetric spectra and Bragg curves were obtained. The results show that this new device is useful to microdosimetry characterization of clinical proton beams.

#### EP-1697 Real time small animal irradiator dosimetry using Radioluminescence imaging

A. Spinelli<sup>1</sup>, E. D'Agostino<sup>2</sup>, S. Broggi<sup>3</sup>, C. Fiorino<sup>3</sup>, F. Boschi<sup>4</sup>

<sup>1</sup>San Raffaele Scientific Institute, Experimental Imaging Centre, Milano, Italy ; <sup>2</sup>DoseVue NV, Research and Development, Turnhout, Belgium ; <sup>3</sup>San Raffaele Scientific Institute, Medical Physics, Milano, Italy ; <sup>4</sup>University of Verona, Department of Computer Science, Verona, Italy

#### Purpose or Objective

The main objective of this work was the development of a novel real-time 2D dosimetry approach for small animal external radiotherapy using radioluminescence imaging (RLI) with a commercial CMOS detector. Radioluminescence light is generated by a flexible and thin scintillator composed of green-emitting rare earth phosphors.

#### Material and Methods

A CMOS detector was mounted on a photographic tripod and coupled with a F=1.4, 8 mm C-mount lens (Edmund Optics) facing the scintillator screen taped on the back side of the animal stage. Measurements were performed on the small animal image-guided platform SmART (Precision X-Ray Inc.). As shown in figure 1 the CMOS was inserted in the XRAD225Cx SmART cabinet, 40 cm away from the animal stage. The SmART cabinet was light-tight and, thus, allowed to investigate RLI with different lighting conditions by switching on/off the internal led during image acquisition.

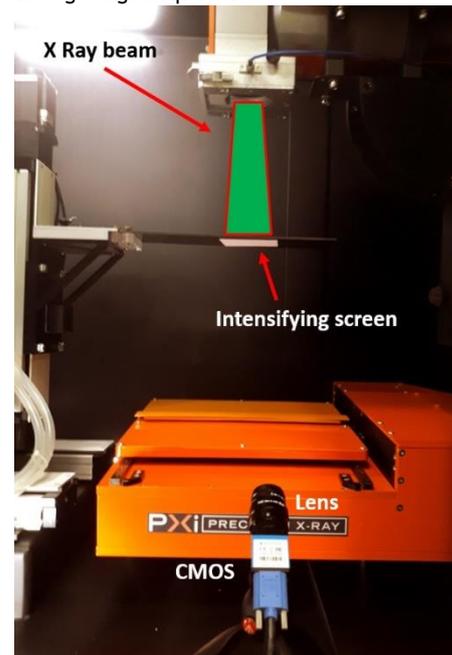

Figure 1 RLI acquisition setup.

The CMOS setting were as follow: gain=22, brightness=50 and exposure time=1/500 sec. A sequence of 60 images were acquired every 1 sec and summed. RLI data were corrected for perspective distortion with an home-made program written in Matlab. The SmART setting were as follow: tube voltage=225kV, current= 1, 3, 6, 9 and 13 mA, the corresponding dose rate at 13 mA was 4.2 Gy/min. Four fields were tested, 2 circular beams with diameter equal to 1 mm and 3 mm and 2 square fields (10x10 mm and 20x20 mm). Measured planar 2D dose distributions and dose profiles were compared against dose calculation performed with Monte Carlo (MC) simulations, including

FWHM estimate. Measurement repeatability was tested on the 20x20 mm beam by repeating by moving and positioning the CMOS for five times. Response linearity and noise variation against current were also measured.

### Results

The agreement of the measured dose profiles and beam sizes is fairly good, with maximum difference being less than 2% for all the four beams tested (see figure 2) with a maximum deviation for FWHM of 0.3mm for the 20x20 mm beam and of 0.1mm for the circular 1mm beam between MC and RLI.

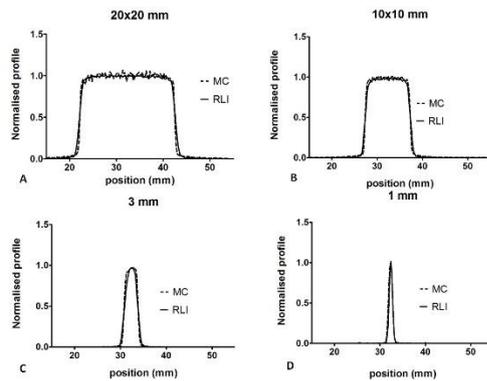

Figure 2 Normalized beams profiles from RLI and MC.

The image correction procedure was confirmed to be able to reduce the perspective distortion at a negligible level and, at the same time, is also robust and reproducible. RLI dose measurements were performed in both lights off/on conditions, the signal can be detected even in the light on condition making the RLI measurements possible even when light can not be removed (e.g. no light-tight irradiators) without relevant impact on dose profiles measurements. Linearity was confirmed ( $R^2=0.9996$ ) and the noise was found to be almost negligible and following Poisson-like behavior against the number of incident photons.

### Conclusion

A novel RLI approach for real time small animal dosimetry was developed. Results show a good agreement with MC dose calculations and linearity with respect to dose. We conclude that RLI can be an alternative approach to gafchromic films

### EP-1698 TRAPS upstream transmission detector for tracking mlc positions in VMAT and IMRT radiotherapy fields

S. Fletcher<sup>1</sup>, J. Haynes<sup>2</sup>, L. Beck<sup>3</sup>, J. Velthuis<sup>4</sup>, D. Crawford<sup>5</sup>

<sup>1</sup>University Hospitals Bristol, Medical Physics Radiotherapy, Bristol, United Kingdom ; <sup>2</sup>University Hospitals Bristol, Medical Physics- radiotherapy, Bristol, United Kingdom ; <sup>3</sup>University of Bristol, Physics, Bristol, United Kingdom ; <sup>4</sup>University of Bristol, Physics, Bristol, United Kingdom ; <sup>5</sup>University Hospitals Bristol, Medical Physics, Bristol, United Kingdom

### Purpose or Objective

Complex dynamic radiotherapy treatment techniques such as VMAT and IMRT present a challenge for beam delivery verification. The TRAPS detector is a prototype device designed for high precision detection of multi-leaf collimator position that could be suitable for real-time upstream monitoring of patients' treatments. We have evaluated its performance within a radiotherapy treatment beam.

### Material and Methods

The TRAPS detector comprises a Monolithic Active Pixel Sensor (MAPS), sensor readout electronics and DAQ, and can be mounted on a holder attached to the linac head. Raw pixel data is pre-processed (bad pixel removal,

background signal subtraction and Gaussian smoothing) and resulting images of the treatment beam is passed through a feature extraction process to locate leaf edges (SOBEL operator).

An Elekta Agility linear accelerator (linac) was used to assess four key characteristics of TRAPS detector performance: attenuation, linearity of signal with dose rate, positional accuracy and dynamic field response. Multi-leaf collimator defined field shapes for 6MV and 10MV photon beams were delivered whilst simultaneously acquiring TRAPS and EPID images (using the Elekta IViewTM amorphous silicon imaging panel).

EPID images were passed through the same feature extraction process and the resultant EPID leaf positions were used as 'standard' and compared with time matched TRAPS leaf positions. Deliberately introduced positional errors (0.5, 1, 2 and 3mm) for individual collimator leaves within thin rectangular fields were used to visually assess error detection capability.

A dynamic treatment plan (VMAT delivery) was devised to test the ability of TRAPS to track the linear leaf movement at varying speeds and under challenging beam scatter conditions.

### Results

The 6MV attenuation factor of the sensor was 1.04% +/- 0.03% for a 5x5cm field size.

Pixel values in TRAPS detector images responded linearly for dose rates up to 450 MU per minute for 6MV and 10MV photons (corresponding to a pulse repetition frequency (PRF) of 380 Hz). For a flattening filter free beam (6FFF) the response was linear to a dose rate of 600 MU per minute (PRF of 150 Hz) but the pixels saturated at higher beam intensities.

Positional accuracy of leaf edges in TRAPS images were within 1mm + 0.26mm of the corresponding EPID images (figure 1).

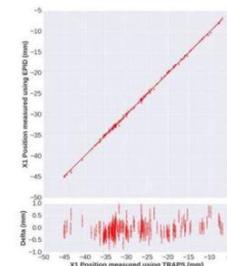

Figure 1 reconstructed leaf positions all segments of an IMRT field for EPID vs TRAPS

Visual examination of TRAPS images (thin rectangular fields with known errors) identified leaf positioning errors as small as 0.5mm, which is within the accuracy of leaf position calibration (1mm).

The dynamic leaf tests demonstrated that TRAPS is capable of tracking leaf movement at velocities up to 3.5cm/s Figure 2.

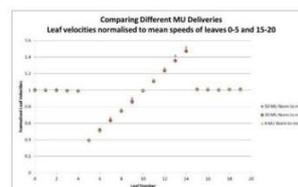

Figure 2 For each leaf, the average leaf velocity is plotted, normalised to the mean values of the outer leaf speeds. Shown for different MU monitor unit or dose deliveries of the same dynamic leaf pattern. The MU value relates to leaf speed, e.g. small MU deliveries require the leaves to travel faster than larger MU deliveries.

### Conclusion

The prototype TRAPS detector has a low attenuation, so is suitable for locating upstream in a treatment beam, and can accurately delineate leaf edges for a range of

clinically relevant scenarios. Modification of the data readout protocol could prevent saturation of sensor elements at the higher dose rates.

### EP-1699 Comparing water equivalent phantom materials using CT scans and conformal prostate treatment plans

M. Kirby<sup>1</sup>, P. Bridge<sup>1</sup>, J. Callender<sup>1</sup>

<sup>1</sup>University of Liverpool, Radiotherapy, Liverpool, United Kingdom

#### Purpose or Objective

Water is the standard reference material specified in national protocols for radiation dosimetry and QA. However solid phantoms are more versatile and easier to use - but materials must have a high water equivalency and/or equivalence to other human tissues to act as a true surrogate with similar attenuation and scattering characteristics. Good equivalence makes them ideal for QA and technique development in radiotherapy and especially for pre-treatment per-patient QA for both IMRT and VMAT.

Typical standard dosimetric characteristics of such materials are often determined by comparing measurements of percentage depth dose curves, build-up and attenuation factors with water. As a precursor to such measurements, we investigated 6 different water equivalent solid phantom materials for their equivalence by comparing analysis made in a treatment planning environment.

#### Material and Methods

Six water equivalent materials were investigated; PTW RW3 (PTW, Freiburg, Germany); Gammex SWHE and SW (Sun Nuclear, Middleton, WI, USA); CIRS PWDT and PW (CIRS, Norfolk, VA, USA) and BARTS SW (Phoenix Dosimetry Ltd., Berkshire, UK). All materials were CT scanned using a clinical pelvis scan protocol (120 kV, 260 mA, 55mAs, 2.5 mm slice thickness, 500mm RFOV) on a GE Lightspeed RT16 scanner. Slices were exported to Eclipse TPS (V13.8) for analysis. Ten-mm diameter ROIs were identified in the central portion of each phantom (9 on the central slice, 2 sup and 2 inf) ensuring that each ROI was in the middle of material slabs. ROI properties were used to measure the average HU in each and then compute (from all 13 ROIs) the min, max, mean and SD of the HU for each of the six types of material. Identical scans and measurements were made for real water.

The mean HU values were used to override existing values for soft-tissue on a real, three field (anterior and two post-oblique fields) conformal 6MV radical (74Gy/37#) prostate plan. Soft-tissue structures were all those within the patient excluding bony tissue. The plan was then recalculated for each of the six mean HU values from the phantom materials and the DVHs (PTV and rectum ORV) compared with the original clinical plan.

#### Results

The Mean (SD) of the measured HUs for each of the water equivalent materials were; PTW RW3 - 14.0 (14.1); Gammex SWHE - 15.1 (11.2); Gammex SW - 26.3 (11.9); CIRS PWDT - -8.5 (10.7); CIRS PW - 66.5 (14.8); BARTS SW - -5.8 (10.6); Water - -1.4 (3.5). The dosimetric impact of applying these mean HUs to the clinical plan is shown in Table 1.

**Table 1:** Dosimetric impact of water equivalent materials for the 6 MV 3-field prostate plan

	Original CT Data	PTW2	Gammex SWHE	Gammex SW	CIRS PWDT	CIRS PW	BARTS SW
D2%	100.3%	100.2%	100.2%	100.3%	100.2%	100.4%	100.2%
D98%	97.4%	97.6%	97.6%	97.5%	97.7%	97.3%	97.7%
V50	37.9%	38.1%	38.1%	38.0%	38.2%	37.9%	38.2%
V60	31.3%	31.5%	31.5%	31.4%	31.6%	31.3%	31.6%
V65	27.4%	27.7%	27.7%	27.6%	27.8%	27.4%	27.8%
V70	21.0%	21.6%	21.6%	21.4%	21.9%	20.9%	21.9%

#### Conclusion

Although the range of mean HUs for the six materials is wide (mean -5.8 to 66.5; range (across all ROIs) -41 to 121), there was little dosimetric impact on the three-field plan. All materials were within 0.3% of the target volume dose objectives (D2% and D98%) achieved in the clinical plan; all were within 1% of the ORV constraints (V50 to V70). All therefore would act as suitable equivalent materials to water/soft-tissue in the treatment planning setting.

### EP-1700 CyberKnife output factors from integral dosimetry

A. Kulmala<sup>1</sup>, J. Heikkilä<sup>2</sup>, A. Väänänen<sup>2</sup>, M. Tenhunen<sup>3</sup>

<sup>1</sup>Clinical Research Institute HUCH, Radiotherapy, Helsinki, Finland ; <sup>2</sup>Cancer Center Kuopio University Hospital, Radiotherapy, Kuopio, Finland ; <sup>3</sup>Helsinki University Hospital- Cancer Center, Radiotherapy, Helsinki, Finland

#### Purpose or Objective

The standard approach of determining output factors of small megavoltage beams has been the construction of smaller detectors to fit in the central area of the smallest fields of interest. As an alternative approach it has been shown that a large ionization chamber (IC) can be used for measuring output factor of a small (diameter 4-20 mm) conical collimator, when a radial response of the chamber and high resolution relative dose distribution (off-axis-ratio, OAR) of the field are known. In the current work we will apply this formalism to determine the output factors of the CyberKnife conical collimators.

#### Material and Methods

The 'radial response' of the PTW34001 (ROOS) parallel plate ionization chamber is deconvoluted from conical collimator OAR sets determined with the IC 'measured signal' and Gafchromic EBT2 film 'true signal' using a non-parametric super-resolution deconvolution method (Kulmala A and Tenhunen M 2012, Phys. Med. Biol. 57 7075-88). The output factors of the Cyberknife cone beams (diameter 5-30 mm) are estimated based on integral dose measurements with the IC, the deconvoluted radial response of the IC and relative dose distributions measured with the film. Finally, the output factors are compared to a reference set. As a reference method we use a direct measurement with the E60012 p-type

unshielded diode detector corrected with the published field-size dependency factors.

#### Results

The reference output factor data for conical collimators has a very close agreement, on average only 0.1 % larger, with output factor data obtained by the integral method. A difference minimum -0.8 % is found with a 25 mm collimator and maximum +0.9 % with a 12.5 mm cone.

#### Conclusion

We have demonstrated that the integral dosimetry can be used to determine the output factors of the CyberKnife conical collimators. The method seems suitable for verification the output factor results of the standard formalism.

#### EP-1701 Inverse square corrections for WAFACs

D. Rogers<sup>1</sup>

<sup>1</sup>Carleton University, Physics Department, Ottawa, Canada

#### Purpose or Objective

To derive systematically the corrections needed when using Wide Angle Free Air Chambers (WAFACs) to convert a value measured or calculated for a finite solid-angle-detector to the corresponding value on axis assuming an isotropic point source and no attenuation. Secondly, to verify these corrections using Monte Carlo simulations.

#### Material and Methods

Using published techniques, corrections for cylindrical, conical and square prisms are derived to give:

$$k_{r^2}^{\text{cyl}} = \frac{\alpha^2}{\left[ \ln(1 + \beta^2) + \frac{2R}{L}(\theta_c - \theta_m) - \frac{d}{L} \ln\left(\frac{1 + \alpha^2}{1 + \beta^2}\right) \right]}$$

$$k_{r^2}^{\text{cone}} = \frac{\alpha^2}{\ln(1 + \alpha^2)} \left( 1 + \frac{L}{d} + \frac{L^2}{3d^2} \right)$$

$$k_{r^2}^{\text{sq-prism}} = \frac{1}{d^2} \left[ \frac{2w^2}{12} + d^2 + dL + \frac{L^2}{3} \right]$$

where L = detector thickness, R = its front radius, d = its distance from point source,  $\alpha = R/d$ ,  $\beta = R/(L+d)$ ,  $\theta_c = \arctan(\alpha)$ ,  $\theta_m = \arctan(\beta)$  and w is the width of a square prism. Monte Carlo simulations are performed for a variety of detector geometries, (e.g., R large and R very small) using the egs\_brachy application based on EGSnrc (PMB 61 (2016) 8214) for a point source in vacuum and low density dry air in the detector volume. The average air kerma in the detector volume is calculated. Values are converted to the on-axis air-kerma values using the above corrections and compared to expected values.

#### Results

The corrections are dominated by the longitudinal  $1/r^2$  effects, e.g., the correction is 1.46 for a conical NIST-like WAFAC geometry. However, in practice NIST and other standards labs eliminate this longitudinal effect by using an effective detector volume rather than the true detector volume (J Res NIST 108 (2003) 337) and only the L = 0 correction is required. That said, for the cylindrical and conical corrections derived above, the Monte Carlo simulations verify their accuracy within the typical statistical uncertainty of 0.04%. However, for the square prism, the correction breaks down by up to 16% for values of L typical of actual detectors (e.g., 10 cm). However, for a detector with L=0.05 cm or less, the square prism corrections are accurate within the statistical uncertainties.

#### Conclusion

By explicit derivations and simulations, the standard correction factors for  $1/r^2$  effects with various WAFAC detectors have been shown to be accurate with the exception of that for thick square prism detectors. However, the corrections for square prism detectors using L=0.05 cm are shown to be accurate at the 0.04% level

which is important since dose-rate constants calculated using the egs\_brachy Monte Carlo application of EGSnrc (Med Phys 35 (2008) 4228) make use of this correction factor and these values have been clinically recommended for a variety of seeds by the AAPM's TG-43 (Med Phys 44 (2016) e297).

#### EP-1702 Examination of the real-time exposure dosimetry system using synthetic ruby on the radiation therapy

A. Maruyama<sup>1</sup>, T. Yamaguchi<sup>1</sup>, D. Ono<sup>1</sup>, T. Kikuchi<sup>1</sup>, Y. Kikuchi<sup>1</sup>, R. Sato<sup>1</sup>, S. Watanabe<sup>2</sup>, Y. Hosokai<sup>1</sup>

<sup>1</sup>International University of Health and Welfare, Department of Radiological Sciences, Otawara-city-Tochigi, Japan ; <sup>2</sup>South Miyagi Medical Center, Radiology, Shibata- Miyagi, Japan

#### Purpose or Objective

It is part of reason in the occurrence of medical accidents on the radiation therapy that the local exposure dose cannot be direct monitoring in real-time. Recently, we developed a real-time exposure dosimetry system using synthetic ruby for interventional radiology (IVR). This time, we discuss some character of the developed real-time radiation dosimetry system for use in radiation therapy condition.

#### Material and Methods

A synthetic ruby scintillator with a diameter of ~2mm was attached to the tip of a 10 m long optical acrylic fiber using quick setting adhesive. The emitted light from the synthetic ruby was measured in real time in terms of the number of photons recorded using a photon counter head. A calibrated ionization chamber with Roos Electron Chamber dosimeter was used as a reference dosimeter. The aims of this study were to measure the following items with synthetic ruby dosimeter.

1. Characteristic features of the percentage depth dose (X-ray)

The measuring devices were irradiated using 10 MV X-ray, at the center of 10×10 cm<sup>2</sup> and 15×15 cm<sup>2</sup> field, and monitor unit (MU) value was fixed 200 MU.

2. Characteristic features of the percentage depth dose (electron beam)

The measuring devices were irradiated using 6, 9 and 12MeV electron beam, at the center of 10×10 cm<sup>2</sup> field, and MU value was fixed 100 MU..

3. Characteristic features of coefficient of variance of MU value

The characteristic features of coefficient of variance (%CV) of MU value in terms of dose and number of photon were measured. The depth of measuring was 10 cm, the measuring number was 10 times.

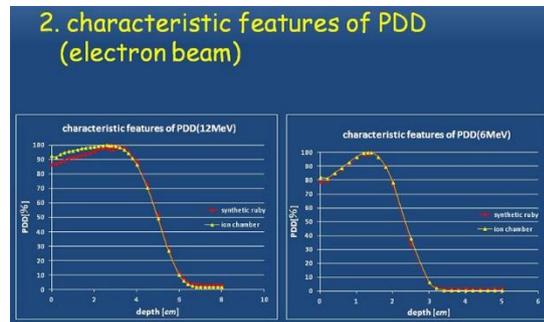

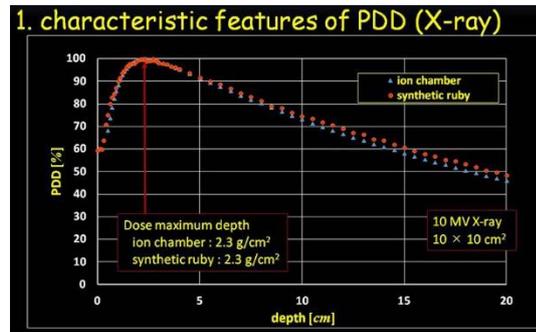

4. Linearity of the number of photons in terms of MU value  
The measuring devices were irradiated 10 MV X-ray, at the center of 10×10 cm<sup>2</sup> field, the depth of measuring was 10 cm. The MU value changed to 10 - 800 MU, the dose rate was fixed 500 MU/min.

#### Results

1, 2. The percentage depth dose (PDD) was same as the reference dosimeter. The dose maximum depth was no clear difference between the reference dosimeter and the ruby dosimeter.

3. The %CV of MU value in terms of dose and number of photon was ±0.67%.

4. There is a significant correlation between the MU value and the number of photons ( $r^2=0.9997$ ).

### Conclusion

The synthetic ruby system which we developed have high temporal resolution, thus, it is possible to measure the total exposure time to read the rise time and the fall time on the graph. The MU value increased linearly with the number of photons which was same as the reference dosimeter, the synthetic ruby system have a potential for the real-time exposure dosimetry system on the radiation therapy. However, we have to discuss the influence of the developed system in the exposure filed, pursuit of the precision, the possibility of multipoint measurement, the size and the covering material of dosimeter.

### EP-1703 Dose Evaluation of Build-up Region of Photon Beam using Thermoluminescence Dosimeter (TLD) Sheet

K. Sasaki<sup>1</sup>, Y. Shiota<sup>2</sup>, M. Miura<sup>2</sup>

<sup>1</sup>Gunma Prefectural College of Health Sciences, Graduate School of Radiological Technology, Maebashi, Japan ; <sup>2</sup>Iwata City Hospital, Medical Physics, Iwata, Japan

### Purpose or Objective

Although there are various devices for measuring high-energy radiation, radiographic films, Radiochromic films and parallel plate ionization chambers are generally used to obtain a dose of surface or build-up region with high accuracy. In this study, a new thermoluminescence dosimeter sheet (TLD) sheet dosimeter with effective atomic number close to water and high measurement flexibility was used to evaluate the dose in the build-up region after passing through the carbon couch. In addition, reduction of surface dose by sandwiching low-density material was also studied.

### Material and Methods

Percent depth dose (PDD) after passing through the carbon couch was measured using 6 MV, 10 MV photon from Novalis-TX (Varian Medical systems). The PDD from the phantom surface to the depth of 5 cm was measured by NACP-02 parallel plate ionization chamber (IBA), Gafchromic film EBT3 (Ashland) and TLD sheet (Toyo Medic). Changes in surface dose by sandwiching the Styrofoam between the phantom and the couch were also measured. The chemical formula of the TLD sheet is  $\text{LiB}_3\text{O}_5$  and its thickness is 150  $\mu\text{m}$ , about half that of Gafchromic film. In order to utilize this thinness as the

resolution of the depth, the measurement was carried out by stacking the TLD sheet.

### Results

The PDD showed consistent data between the ionization chamber and the TLD sheet, but the deviation was large in the TLD sheet. Due to the movement of the build-up region into the couch, the surface dose increased. This increase in surface dose could be evaluated in both the ionization chamber and the TLD sheet. The surface dose increased by approximately 80% by passing through the carbon couch. By sandwiching a 5 cm thick Styrofoam plate between the phantom and the carbon couch, it was possible to reduce the surface dose by 11.9% at 6 MV and 18.1% at 10 MV respectively. In these measurements, the TLD sheet was able to evaluate the dose closest to the surface of the phantom. The TLD sheet was able to evaluate the depth dose with the same variance as the Gafchromic film, and it was an advantage that the depth resolution in the stack measurement was higher. Although it takes time and effort to reduce the measurement interval in the depth direction using the parallel plate ionization chamber, it has been possible to quickly and conveniently measure by stacked method using the TLD sheet.

### Conclusion

We evaluated the dose in the build-up region using the TLD sheet which is a new material, and its usefulness was suggested. The TLD sheet was particularly useful for dose assessment on the surface of the phantom. In the TLD sheet, there is a fluctuation in the intensity of the signal depending on the position in the sheet, and the correction for this is currently under consideration. It was shown that the dose near the surface of the phantom is greatly increased by passing through the carbon couch but the surface dose can be reduced by placing a low density material between the phantom and the couch.

### EP-1704 A 2D reusable OSL-film for class solution specific QA of large modulated fields in the PART trial

R. De Roover<sup>1</sup>, C. Berghen<sup>1</sup>, G. De Meerleer<sup>1</sup>, T. Depuydt<sup>1</sup>, W. Crijs<sup>1</sup>  
<sup>1</sup>Catholic University of Leuven, Department of Oncology, Leuven, Belgium

### Purpose or Objective

The PART trial (NCT03079323) evaluates the effect of prophylactic para-aortic lymph node irradiation in addition to prostate (bed) and pelvic lymph node radiotherapy in histopathologically proven pelvic lymph node metastatic (pN1) prostate cancer. With treatment fields up to 35 cm, the inclusion of the para-aortic lymph nodes challenges the current in phantom patient-specific quality assurance (QA). As state-of-the art reusable dosimeters have a maximum field-of-view (FOV) of 25 cm for single shot measurements. Additionally, these dosimeters consist typically of an array of detectors with a resolution between 0.5 and 1.0 cm. Radiochromic films offer a sub-mm resolution, but these dosimeters are for single use, increasing the cost and excluding a dosimeter specific calibration. A large-sized (43 x 36 cm<sup>2</sup>) reusable optical-stimulated luminescence (OSL)-film may measure such large fields with sub-mm resolution in a single shot measurement. The potential of OSL-film as an absolute infield dosimeter in intensity modulated radiotherapy was previously reported. But the film's out-of-field-low-energy dependent overresponse requires additional modelling. This study investigates the use of such a modelling in a class solution specific calibration for the PART trial.

### Material and Methods

Ten patients currently included in the PART trial were selected for OSL measurements. Prescription was 70 Gy to the prostate bed in 35 fractions or 67.25 Gy to the prostate in 25 fractions and 45 Gy to the pelvic and para-aortic lymph nodes in 25 fractions. Treatment was delivered on

a Varian Clinac 2100CD using 10 MV dual arc VMAT with collimator angles  $350^\circ/10^\circ$ . All treatment plans passed our internal pre-treatment QA protocol.

Agfa HealthCare supplied the OSL-film and flying-spot CR-15-X-engine based reader used for these experiments. The OSL-film was positioned within a 20 cm stack of water-equivalent RW3 at 10 cm depth and the measured signal was scanned and erased 5 min after each irradiation. A class-solution specific OSL-calibration consisted of a uniformity correction and a linear out-of-field dose correction. Dose measurements were compared to the calculations using 3%/3mm gamma evaluation (both global and local normalization) with a low dose exclusion threshold set to 30% of the prescribed dose.

### Results

Plan properties and gamma agreement scores ( $\gamma$ AS) are compiled in Table 1. The median  $\gamma$ AS was 96.7% (range: 91.0% - 99.3%) and 93.0% (range: 87.0% - 96.6%) for global and local normalization respectively. The class solution specific calibration was able to model both the in-field dose and the dose gradients (Figure 1c-d). The zones with a mixture of in-field and out-of-field spectra (arrow in Figure 1b) performed typically worse for all patients.

**Table 1.** Plan properties and gamma agreement score for each patient case.

Patient case	Field size [cm <sup>2</sup> ]		Monitor units [MU] <sup>a</sup>	3%/3mm $\gamma$ AS [%] <sup>b</sup>	
	Arc 1	Arc 2		Global	Local
1	11.0 x 32.0	12.0 x 32.0	805	96.6	94.7
2	12.5 x 28.0	12.5 x 29.0	744	97.7	95.5
3	12.0 x 29.7	12.0 x 29.8	661	96.9	94.1
4	12.0 x 31.0	12.0 x 31.0	738	99.3	96.6
5	12.7 x 28.8	11.9 x 29.9	770	94.3	91.8
6	13.0 x 30.0	13.0 x 30.0	831	97.7	91.8
7	14.5 x 33.0	14.5 x 33.0	794	93.4	88.2
8	10.0 x 30.0	10.0 x 30.0	852	96.9	95.3
9	14.5 x 33.0	14.5 x 33.5	697	95.2	92.0
10	12.5 x 33.0	12.5 x 33.0	773	91.0	87.0

Abbreviations: OSL = optical stimulated luminescence,  $\gamma$ AS = gamma agreement score.  
<sup>a</sup>1 MU corresponds to 0.8 cGy at 10 cm depth delivered by a 10 x 10 cm<sup>2</sup> field at 90 cm source-surface distance.

<sup>b</sup>The  $\gamma$ AS was determined using a low dose exclusion threshold set to 30% of the prescribed dose.

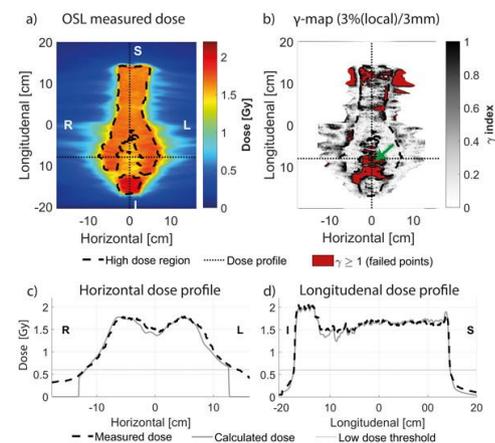

Figure 1. Depicts the OSL measurement and QA results for the worst case (patient 10, Table 1). (a) OSL measured dose map. (b) 3% (local)/3mm  $\gamma$ -map with a low dose exclusion threshold set to 30% of the prescribed dose (white region). (c) Horizontal and (d) longitudinal dose profiles. The location of the dose profiles are depicted as dashed lines on (a) and (b). The arrow in (b) indicates the zone that captures a mixture of in-field and out-of-field spectra, which performs typically worse in the OSL measurements.

### Conclusion

This study reports a class solution specific OSL-calibration for the large modulated fields encountered in the PART trial. This calibration adds a unique combination of reusability, sub-mm resolution and large FOV to the 2D dosimetry in radiotherapy.

### EP-1705 Quality assurance of micro-MLC based IMRT plans using patient-specific phantom

S. Sunel<sup>1</sup>, M. Yeginer<sup>1</sup>, F. Akyol<sup>1</sup>, F. BILTEKIN<sup>1</sup>, G. Ozyigit<sup>1</sup>  
<sup>1</sup>Hacettepe University, Department of Radiation Oncology, Ankara, Turkey

### Purpose or Objective

In this study, it is aimed to propose an alternative method to standard QA procedures by producing tissue-equivalent phantoms in the form of patient surface using 3D printing technology in micro MLC based brain and head&neck treatment techniques.

### Material and Methods

The outlines of the methodology of the study designed with the aims can be summarized as: (i) Transferring the CT images of selected Head&Neck patients to workstation, (ii) Transporting the CT images to 3D Slicer software and then preparing the model with the form of patient surface in computer environment, (iii) Transporting the parts of models to 3D printer and printing the crusts of the phantom, (iv) Filling the crusts with paraffin wax, (v) Taking the CT images of model and calculating the doses in the treatment planning system (TPS), (vi) Delivering the micro-MLC based IMRT treatment plans in Novalis unit by placing the EBT3 films between the phantom slices, (vii) performing the gamma analysis of 2D dose distributions acquired from EBT3 film and TPS. In the gamma analyses of treatment plannings of six head&neck patients, the four sets of criteria were used: 3% dose difference (DD) & 3 mm Distance to Agreement (DTA), 3% DD & 5 mm DTA, 5% DD & 3 mm DTA, and 5% DD & 5 mm DTA.

### Results

In the analysis with 3mm/3% criteria, it was observed that the dose distributions were agreed except for the dose reduction at the edge of the films induced from the deformation. When 5mm/5% criteria were chosen, the agreements between dose distributions of EBT3 film and TPS were found to be 95,7% in average (max. 96,4% and min. 93,4%). The threshold for success was accepted as 90%.

### Conclusion

Consequently, our study showed that the head&neck phantoms produced with 3D printing technology can be used for patient specific QA. By means of new technologies that accelerate the production process, 3D phantom applications including surface contour of patients can be routinely used in radiotherapy facilities.

### EP-1706 Production of samples with specified CT indices by 3D printing

I. Miloichikova<sup>1,2</sup>, Y. Cherepennikov<sup>1</sup>, A. Krasnykh<sup>3</sup>, S. Stuchebrov<sup>3</sup>

<sup>1</sup>Tomsk Polytechnic University, School of Nuclear Science & Engineering, Tomsk, Russian Federation ; <sup>2</sup>Cancer Research Institute of Tomsk National Research Medical Center of the Russian Academy of Sciences, Radiotherapy Department, Tomsk, Russian Federation ; <sup>3</sup>Tomsk Polytechnic University, Research School of High-Energy Physics, Tomsk, Russian Federation

### Purpose or Objective

This work is aimed at developing a method to produce tissue-equivalent phantoms with predetermined density distribution for the purpose of experimental planning and verification of radiotherapy treatments. The phantoms can be customized to mimic individual anatomical features of each patient.

It is advisable to manufacture such phantoms by fused deposition modeling using tomographic data.

The phantoms will make it possible to adjust the radiotherapy treatment plans directly on the radiation therapy machine. This will eliminate systematic errors of calculation algorithms. This becomes especially important with high-density implants installed in the region of interest, which do not allow accurate dose calculation due to artifacts in tomographic images. Customized phantoms will eliminate the inaccuracies of traditional experimental verification of radiotherapy plans based on mass-produced phantoms and thereby reduce the adverse effects of radiation therapy.

The purpose of this research is to develop modified materials for 3D printing with specified CT indices.

#### Material and Methods

Fused deposition modeling was chosen for the production of customized phantoms due to the possibility of simultaneously producing objects from several materials. To estimate the values of CT indices, test samples with a variety of infill values were manufactured on an UP! Plus 2 3D printer from pure polylactide (PLA) filaments and modified filaments. The 2-cm<sup>3</sup> samples were printed with a diamond infill pattern.

The modified filaments were made using a single-screw extruder SJ 45/25 with a diameter of 45 mm and an L/D ratio of 25 from a mixture of PLA and copper powder (particle size 10-20 µm).

The CT indices were measured using a Siemens Somatom Emotion computed tomography scanner. The data obtained were processed by the eFilm software.

#### Results

In the eFilm software, the tomograms were presented in the form of high-contrast black and white images. Each shade of gray was assigned a numeric value that corresponded to a specific value on a Hounsfield unit scale (CT indices). The samples were positioned parallel and perpendicular to the rotation axis for CT scanning.

Based on the processed data, a linear dependence of the CT indices on the sample infill values was obtained. It is shown that CT indices depend on the sample orientation in a CT scanner due to the different number of air gaps lying in the CT scanning plane.

#### Conclusion

The obtained results show that pure PLA can be used to simulate soft tissues with densities ranging from -600 to +200 on the Hounsfield scale. Metal-modified materials allow us to simulate muscle and bone tissue from +100 to -1100 HU.

The obtained dependences can be used to accurately determine the required material infill value for obtaining a specific CT index. That will allow applying the developed materials to produce customized tissue-equivalent phantoms.

#### EP-1707 Polymer gel-based tests for geometric accuracy in a 0.35 T MR-LINAC

S. Dorsch<sup>1,2</sup>, P. Mann<sup>1</sup>, A. Elter<sup>1,2</sup>, A. Runz<sup>1</sup>, S. Klüter<sup>3</sup>, C.P. Karger<sup>1</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>University of Heidelberg, Faculty of Physics and Astronomy, Heidelberg, Germany ; <sup>3</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

As MRgRT is becoming increasingly important in clinical applications, the development of new QA methods is needed. Besides the QA for dose delivery and dosimetry, also the machine-related geometric parameters like the alignment of the irradiation and imaging isocenters as well as the detection and measurement of geometric distortions of the MR are of key importance. Polymer dosimetry gels (PG) may offer a way to perform isocenter alignment tests as PG is visible in MR imaging. Additionally, PG may allow for online 3-dimensional (3D) evaluation. For this purpose we present first measurements of a dedicated phantom to measure both, isocenter alignment with a PG and geometric distortions with a regular 3-dimensional grid.

#### Material and Methods

The in-house developed phantom contains a PG (PAGAT<sup>1</sup>)-filled spherical glass flask embedded in 8 grid sheets building up a 3D grid of 996 control points. To measure the alignment of the irradiation and imaging isocenter, the phantom was irradiated with 5 beams separated by equidistant angles at a clinical MR-Linac (MRIdian, ViewRay) and was scanned immediately and 48 h after

irradiation at the MR-Linac using a double spin-echo sequence. The gel was additionally scanned on a 3 T MR device (Biograph mMR, Siemens) 5 h and 52 h after irradiation using multi spin-echo sequence with 32 equidistant echoes to evaluate the influence of different scanners on the star shot evaluation (Mephisto, PTW). To identify geometric distortions of the clinically used MR sequence (steady-state coherent sequence) of the MR-Linac, the individual control points of the grid were compared to CT-measurements as ground truth. The automatic determination of the control points was performed using the Weka segmentation (Image J, NIH).

#### Results

The evaluation revealed an isocircle radius of 0.5 mm for both imaging devices, image resolutions (0.5 x 0.5 mm<sup>2</sup> and 1.0 x 1.0 mm<sup>2</sup>) and time points after irradiation. The distance of the irradiation to the imaging isocenter was 0.25/0.65 mm (0.5 mm resolution) and 1.3/1.03 mm (1.0 mm resolution) for MR-Linac /3 T MRI respectively. Measurements of the grids of the QA-phantom revealed distortions below 1.2 mm (mean over all control points 0.35 mm) up to a distance along the bore of 102 mm from the isocenter.

#### Conclusion

The evaluation of a star shot measurement in a 0.35 T MR-LINAC is feasible, even immediately after irradiation. No significant differences for isocircle radii and isocentre distances between a diagnostic 3T MR scanner and the MR-Linac machine were found. As the PG can also be evaluated in 3D, future experiments will focus on a 3D isocenter alignment test where several slices along the y-direction will be evaluated. This would allow identifying any misalignment of Linac-components.

#### EP-1708 Organ motion impact on dose delivered with non-coplanar VMAT for lung SBRT

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Unit of Medical Physics, Milan, Italy ; <sup>2</sup>European Institute of Oncology, Radiotherapy, Divisione di Radioterapia pres, Italy ; <sup>3</sup>University of Milan, Physics, Milan, Italy ; <sup>4</sup>IEO- European Institute of Oncology IRCCS, Department of Radiation Oncology, Milan, Italy ; <sup>5</sup>University of Milan, Department of Oncology and Hemato-Oncology, Milan, Italy ; <sup>6</sup>IEO- European Institute of Oncology IRCCS, Radiation Research Unit, Milan, Italy

#### Purpose or Objective

To evaluate the effect of organ motion on dose delivered with non-coplanar VMAT for lung stereotactic treatment.

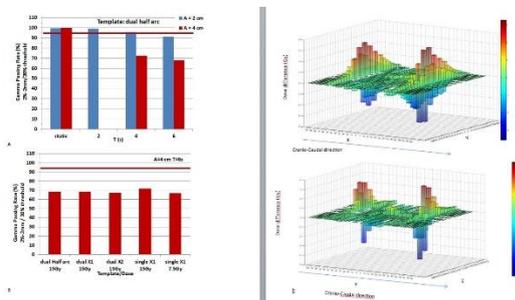

#### Material and Methods

Dynamic Wave Arc (DWA) is a novel non-coplanar VMAT technique implemented on the VERO SBRT system. The fluence modulation is achieved by a synchronized moving of gantry, ring and leaves at a fixed dose rate (400 MU/min). Seven DWA highly modulated VMAT treatments were planned for a single lung patient using Raystation TPS (v7.0, 0.2 mm dose grid) with Collapsed Cone Convolution Algorithm (v3.5) on a 4DCT scan (2.5 mm slice width). Plans were optimized on the mean CT obtained from 10 breathing phases. The goal prescription was D<sub>95%</sub>=95% for ITV+5mm. So far, 3 arc templates, simulating different combinations of gantry/ring speeds, 2 dose levels (15Gyx3 fr and 7.5Gyx8 fr) and 2 extreme organ motion amplitudes (2 and 4 cm) were considered to assess the impact of organ motion on dose delivery. Two ITVs were created from the original GTV to simulate a peak-to-peak tumor motion of 2 and 4 cm in cranio-caudal direction. Plans were delivered on the Delta4 with HexaMotion 6D Motion Platform. Dose distributions obtained with the phantom moving according to different 1D sinusoidal motion patterns (A = 2, 4 cm, T = 2, 4, 6 s, 3 phase shifts with respect to the start of the treatment) were compared with

the corresponding static dose map through a local gamma analysis (2%-2mm, 30% dose threshold) and absolute dose difference evaluation for each diode of both detector matrices.

**Results**

The agreement between static and calculated dose maps showed gamma > 98.5% for all plans. Figa shows that gamma passing rate of dynamic dose distributions is always acceptable (>95%) for the 2 cm peak-to-peak amplitude breathing pattern, for dual half arc template, except for the 6 s period motion for which a value of 91.2% was found. At the extreme peak-to-peak amplitude of 4 cm the gamma passing rate decreased to 70%. As shown in Figb, the gamma passing rates as a function of the different arc templates for the worst breathing pattern scenario (A=4cm, T=6s) are always < 75%. Analyzing the absolute dose deviations between dynamic and static measurements for both detector plates, the blurring effect is clearly predominant at the edge of the fields, but discrepancies up to 4 Gy were observed in the central high dose area, suggesting a possible interplay effect (Fig. c).

Dose level	ITV	Template	Description	Gantry Speed (deg/s)	Ring Speed (deg/s)	Breathing pattern (2Asino1)
15Gyx3fr	GTV+2cm cranio-caudal	dual X1	2 arcs Gantry (°)=184-176 Ring (°)=10-350	Arc1=5.5 Arc2=0.8	Arc1=1.4 Arc2=0.2	A = 4 cm T = 6 s
		dual X2	2 arcs Gantry (°)=184-176 Ring (°)=0-345*	Arc1=0.9 Arc2=1.7	Arc1=0.3 Arc2=0.6	
		dual Half arc	2 arcs Gantry (°)=184-0 Ring (°)=10-350	Arc1=1.2 Arc2=0.5	Arc1=0.6 Arc2=0.3	
		single X1	Single arc Gantry (°)=184-176 Ring (°)=10-350	0.5	0.1	
	GTV+1cm cranio-caudal	dual Half arc	2 arcs Gantry (°)=184-0 Ring (°)=10-350	Arc1=1.2 Arc2=0.5	Arc1=0.6 Arc2=0.3	A = 4 cm T = 4 s A = 4 cm T = 6 s
		dual Half arc	2 arcs Gantry (°)=184-0 Ring (°)=10-350	Arc1=1 Arc2=0.6	Arc1=0.5 Arc2=0.3	A = 2 cm T = 2 s A = 2 cm T = 4 s A = 2 cm T = 6 s
7.5Gyx8fr	GTV+2cm cranio-caudal	single X1	Single arc Gantry (°)=184-176 Ring (°)=10-350	1.1	0.3	A = 4 cm T = 6 s

**Conclusion**

Our preliminary results suggested that the DWA treatment could be safely implemented for lung SBRT without tumor tracking if the tumor motion does not exceed 2 cm. Further investigations are required to evaluate the impact of 3D irregular tumor motion on dose delivery, as well as the impact of the interplay effect inside the target. Nevertheless, we expect a low interplay effect due to the low dose rate, constant gantry and ring speed and high fraction doses.

**EP-1709 Dosimetric response of aSi1000 EPID continuous imaging of FFF beams for in vivo 3D SBRT verification**

A.R. Barbeiro<sup>1</sup>, L. Parent<sup>2</sup>, T. Younes<sup>1</sup>, L. Vieilleveigne<sup>2</sup>, F. Chatrie<sup>1</sup>, F. Younan<sup>3</sup>, X. Franceries<sup>1</sup>

<sup>1</sup>UMR-1037- Inserm- Université Toulouse III Paul Sabatier, Centre de Recherches en Cancérologie de Toulouse, Toulouse, France ; <sup>2</sup>UCT-Oncopole, Dpt. Ingénierie et physique médicale, Toulouse, France ; <sup>3</sup>Groupe Oncorad-Garonne- Clinique Pasteur, Service de Radiothérapie, Toulouse, France

**Purpose or Objective**

Electronic portal imaging device (EPID) dosimetry with flattening filter free (FFF) beams is still challenging, and is not supported by Varian commercial solution for aSi-1000 EPID model. Moreover, in order to develop a model for *in vivo* 3D verification of stereotactic body radiotherapy (SBRT) treatments, the continuous mode should be characterized for small field sizes and high dose-rates, which could saturate EPID response. This study aims at investigating the dosimetric response of an aSi-1000 EPID operating in continuous mode under these challenging conditions, for further *in vivo* SBRT verifications.

**Material and Methods**

An aSi-1000 EPID installed on a Varian TrueBeamSTx was irradiated with 6 and 10 MV FFF photon beams with the maximum available dose rates (1400 and 2400 MU/min, respectively), at variable source-detector distance (SDD) of 150 and 180 cm. Different EPID imaging sets were acquired in continuous mode (C.M.) and were also compared to the commonly used integrated mode (I.M.), in order to study relevant dosimetric characteristics, such as: dose linearity, repeatability and reproducibility of EPID response, ghosting effect and field-size dependence, where EBT3 film measurements were included for fields in the range of SBRT (0.5<sup>2</sup>-10<sup>2</sup> cm<sup>2</sup>). Dynamic arc fields were also measured to study EPID dose response dependence, when subject to potential fluctuations in dose-rate and compared to the static irradiation. In-house Matlab software was implemented to automatically process all data, and handling different image formats.

**Results**

Saturation of EPID response occurred only for continuous mode at higher dose-rate exposures, conversely to integrated mode, due to different reading schemes. Therefore continuous EPID imaging for 10 MV FFF beams and for larger field sizes (>15<sup>2</sup> cm<sup>2</sup>) of 6 MV FFF, should be done at 180 cm SDD. Dose response linearity was found to be similar for both modes, varying within 2.5% (I.M.) and 2.1% to 2.9% (C.M.) for static and dynamic arc fields, respectively, and for small MU values (≤5MU). Response repeatability was slightly better for I.M. and 6 MV FFF, due to lower dose-rate, being in all cases within 0.6%. Reproducibility (over 7 months) was well within 0.5% for both modes and energies. Field size dependence of EPID response in both modes agreed within 1%. However, when compared to EBT3 film, major discrepancies (>3%) were found for fields ≤ 1<sup>2</sup> and 1.5<sup>2</sup> cm<sup>2</sup>, in 6 and 10 MV, respectively. Signal increasing due to ghosting effect was within 1% to 1.2% for the configuration with the highest pre-irradiation dose (300MU), being comparable to the signal variations found between continuous acquisition frames (± 1.1, 1SD).

**Conclusion**

The dosimetric response of aSi-1000 EPID in continuous mode with FFF beams and high dose rates showed comparable results to the commonly used integrated mode, and dosimetric properties similar to those of FF beams. These results are promising to perform 3D verifications of SBRT with dynamic techniques using continuous EPID imaging.

**EP-1710 Update ADAM-pelvis phantom: New possibilities to simulate treatment scenarios in radiotherapy**

### Purpose or Objective

Radiotherapy needs anthropomorphic multimodality phantoms to simulate the treatment of cancer. In this work, we address two requirements and focus on the simulation of prostate cancer treatment: (i) A PSMA-PET/MRI based treatment planning should be simulated and for the following irradiation (ii) the phantom should be able to perform 3D dose measurement by using polymer gels (PG). We present a modified version of the ADAM-pelvis phantom [1] (Anthropomorphic, Deformable And Multimodal), the ADAM with PET extension (ADAM PETer). [1] Niebuhr et al. Med Phys 43(2), pp.908-16, 2016, Technical Note: Radiological properties of tissue surrogates used in a multimodality deformable pelvic phantom for MR-guided radiotherapy.

### Material and Methods

The same basic data as ADAM's is used for the rework of the construction. New possibilities in the 3D-printing made it possible to redesign the shape of the bone in more detail by using the software Geomagic® Freeform®. Now more details of the pelvis bone and all the parts of the joint are visible. For all other modifications, the software Autodesk inventor® was used. Bone tumors and the lymphatic system were integrated. The prostate was modified in such manner that subdivisions or internal spheres (tumor simulation) were created and filling operations from the outside of the segment are now possible.

All parts of the phantom are printed by means of a 3D-printer (Stratasys, Objet 300 Connex 3) from the material VeroClear™ and Agilus30™. Only the bladder, the muscle and adipose tissue are produced like in ADAM.

For PSMA-PET/MRI based treatment planning, gels of different agarose concentrations were mixed with gadolinium and radioactive tracers are added in variant 2 (fig 1b), in the lymphatic system (fig. 1c) and in the bone tumors (fig.1c). In a first irradiation experiment, the prostate variant 1 (fig. 1a) filled with PG was set as target and homogeneously irradiated.

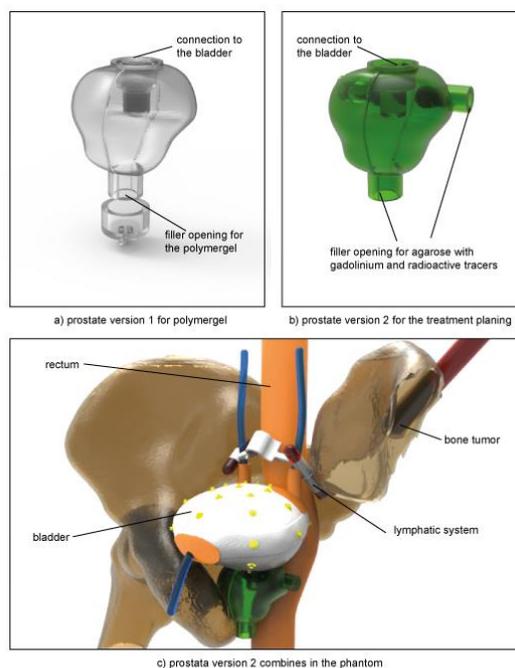

fig. 1: Update ADAM-pelvis phantom

### Results

The new version of ADAM, in which a bone tumor, the lymphatic system and prostates of different types were included, was produced in a 3D-printing process.

It is now possible to insert two bone tumors from outside the phantom. Thus, a simpler handling with radioactivity is facilitated. Further possibilities for tumor simulations with radiotracers are offered by the design of the lymphatic system and the prostate. Both are a closed system in the phantom, such that radiotracers are confined to within these structures.

An anthropomorphic multimodality phantom of the pelvis was created with modular prostate design in which, depending on the configuration, either gel dosimetry can be performed or patient-like PSMA-PET/MR data for treatment planning can be generated.

### Conclusion

With the revised ADAM-pelvis phantom, it was possible to extend the possibilities in simulating end-to-end in radiation therapy. This includes the use of radioactive tracers for treatment planning and the insertion of PG for dose verification in 3D.

### EP-1711 Discover Prostate SBRT or Validation of motion-tracked SBRT treatments with a transmission detector

M. Szegedi<sup>1</sup>, A. Paxton<sup>1</sup>, V. Sarkar<sup>1</sup>, P. Rassiah<sup>1</sup>, H. Zhao<sup>1</sup>, G. Nelson<sup>1</sup>, F. Su<sup>1</sup>, J. Huang<sup>1</sup>, J. Kunz<sup>1</sup>, D. Spitznagel<sup>1</sup>, B. Salter<sup>1</sup>

<sup>1</sup>University of Utah Huntsman Cancer Hospital, Radiation Oncology- Medical Physics, Salt Lake City, USA

### Purpose or Objective

IMRT treatments are typically validated prior to delivery to a patient. There is an assumption that after this initial validation, the patient treatments are delivered correctly. This work reports the patient treatment validation results during ultrasound (US)-image guided and tracked prostate SBRT treatments using a collimator-mounted diode transmission (CM DT) detector.

### Material and Methods

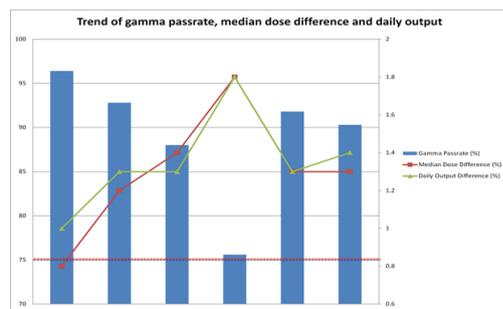

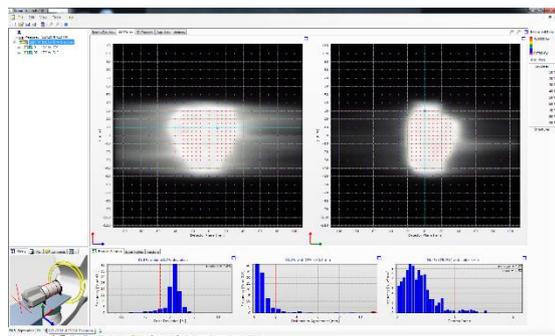

A recently introduced Delta<sup>4</sup> Discover (ScandiDOS) CM DT detector was commissioned for clinical use. Used as

standalone device during patient treatments, the Discover can measure the MLC positions, gantry- and collimator-angle and compare these measurements to the planned values. Combined with the Delta<sup>4</sup> Phantom+ (DP+) for pre-treatment plan validation, the subsequent Discover-only measurements during patient treatment can then be used to calculate the dose distribution for each treatment on the DP+. A gamma analysis can be used to evaluate the delivered treatment fractions the same way the pre-treatment delivery was evaluated.

Patient plans were developed according to our clinical protocol with two VMAT arcs. The attenuation of the Discover was determined for each photon beam energy during its commissioning and was accounted for in the patient plans. Each patient was localized and tracked using the Clarity US IG (Elekta). Tracking margins ensured that the PTV will be within 3 mm (maximum displacement) during beam-on time.

We present five SBRT patients, with five fractions for each patient that were all delivered with the Discover in place. Additionally, the Discover and DP+ were used for all pre-treatment IMRT validations. We accumulated the five dose-fractions into the planning CT data set and compared the Discover measured results that were converted to the total dose outcome with the actual plan. **Results**

To compensate for Discover attenuation, plan monitor units (MU) were increased by 1.3% for 6X flattened beams, 1.5% for 6X flattening filter free (FFF) beams and similarly for 10X for 1.0% and 10X FFF-beams for 1.2%. Figure 1 shows an example of the Discover gamma analysis with a criteria of 2%/2mm for the first fraction for one patient. As an example of our results, we found that the Discover device measured different gamma for each delivered fraction as shown in figure 2. The variation of gamma trended in line with the daily output difference.

**Conclusion**

Using US IG tracking, we assure that our patients have less than 3 mm motion of the prostate during their whole treatment course. Similarly as the US IG tracking assures treatment delivery in the correct position, the Discover device assures the delivery of the radiation plan is as intended. The combination of these techniques gives much greater confidence to the clinician that the dose seen in the treatment plan is the dose that is being delivered to the patient.

**EP-1712 Determination of photon output factors: implementation of the IAEA/AAPM TRS-483 Code of Practice**

P. De La Monja Rey<sup>1</sup>, C. Peraza<sup>1</sup>, M.L. Brosted<sup>2</sup>, A. Chaves<sup>3</sup>  
<sup>1</sup>GenesisCare Madrid - Hospital San Francisco de Asis, Medical Physics Department, Madrid, Spain ;  
<sup>2</sup>GenesisCare Madrid, Medical Physics Department, Madrid, Spain ;  
<sup>3</sup>GenesisCare Spain, Medical Physics Department, Madrid, Spain

**Purpose or Objective**

The aim of this work is to determine the output factors (OFs) measured with six different detectors for an Elekta Versa HD linear accelerator equipped with the Agility head. The measured output factors were subsequently corrected by applying the factors proposed in the Code of Practice International Atomic Energy Agency 483 (IAEA/AAPM TRS-483).

**Material and Methods**

The OFs for field sizes ranging from 1.0 x 1.0 cm<sup>2</sup> to 10 x 10 cm<sup>2</sup> at a depth of 10 cm and at 100 cm source to detector distance were measured for 6 MV and 6 MV Flattening Filter Free (FFF). Several types of detectors, all from PTW-Freiburg, were used for comparison: microDiamond, diode-P shielded, diode-E unshielded, diode SRS - unshielded, PinPoint 3D ionization chamber and 0.125 cm<sup>3</sup> Semiflex ionization chamber. Off-axis dose profiles (in-plane and cross-plane) measurements were performed with the PTW BeamScan water phantom to ensure detector alignment and determine the effective field size. Output correction factors from IAEA/AAPM TRS-483 were applied for all the detectors. In this study, the minimum field size analysed was 1.4 x 1.4 cm<sup>2</sup> for diode-p and 2 x 2 cm<sup>2</sup> for the chamber 0.125 cm<sup>3</sup> Semiflex. A daisy chaining approach was also utilised for the small OFs choosing the 4 x 4 cm<sup>2</sup> measurement as reference.

**Results**

For both energies, 6 MV and 6 MV FFF, the OFs measured for each detector as shown in Figure 1 and Figure 2. For the smaller field size of 1 x 1 cm<sup>2</sup> the maximum OF difference measured was 7.5% for 6 MV and 7.1% for 6 MV FFF, which, once corrected, lead to a maximum deviation respectively of 1.8% for 6 MV and 1.7% for 6 MV FFF. All detector response agree within 0.6 % except for the microDiamond where the OF measured were 1% higher than for other detectors. For field sizes greater than 2 x 2 cm<sup>2</sup>, the deviations of the corrected OFs were within 1% for both beams. The disparity between the direct and daisy-chain approach of OFs corrections was less than 0.3% for 6 MV and less than 0.5% for 6 MV FFF.

Figure 1. Output factors uncorrected and corrected with all detectors for different field sizes (6 MV).

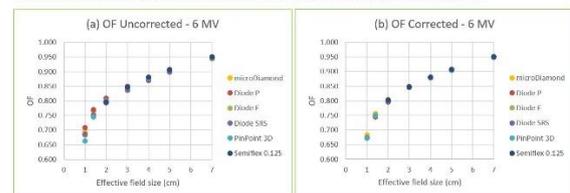

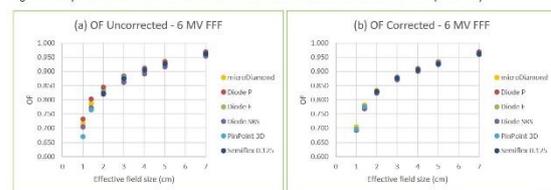

Figure 2. Output factors uncorrected and corrected with all detectors for different field sizes (6 MV FFF).

**Conclusion**

The results indicated that the diode-P overestimated OFs for fields smaller than 4 x 4 cm<sup>2</sup>. The microDiamond overestimated OFs for fields size smaller than 3 x 3 cm<sup>2</sup>,

but to a lesser extent than for the diode-P, while ionization chambers underestimated the OFs. The unshielded diodes for field sizes larger than  $1.5 \times 1.5 \text{ cm}^2$  underestimated OFs and for fields smaller than  $1.5 \times 1.5 \text{ cm}^2$  overestimated the OFs, this overestimation is likely due to density disturbance. The results of this study may assist in the selection of the appropriate method and type of detector to be utilised for small field dosimetry to ascertain the output factor. The variation observed in the output factors, with different detectors in fields size smaller than  $2 \times 2 \text{ cm}^2$ , requires further investigation which will be an ongoing project at our institution.

#### EP-1713 The implementation of 3D chemical dosimetry within a clinical radiotherapy department

J. Poxon<sup>1</sup>, M. Miquel<sup>1</sup>, N. MacDougall<sup>1</sup>

<sup>1</sup>Barts Health NHS Trust, Clinical Physics, London, United Kingdom

##### Purpose or Objective

A high-resolution 3D detector is recommended for the measurement of complex radiotherapy dose distributions, particularly during the commissioning of new techniques. 3D chemical dosimetry has been proposed but has not yet fully realised its potential within clinical radiotherapy departments.

We have developed an in-house method for Fricke gel dosimetry with MR readout and carried out a thorough dosimetric characterisation of this detector. This Fricke detector is energy, dose rate and volume independent and demonstrates adequate precision for a 3-20Gy dose range. When scanned between 10 and 90 minutes, the results are not influenced by chemical instability or diffusion. The aim of this study was to evaluate how the Fricke gel performed when applied to VMAT plans.

##### Material and Methods

Batches of Fricke gel detectors were manufactured in a basic laboratory situated within a clinical radiotherapy department. The T2 quantification of irradiated detectors was carried out using a 3T clinical MR scanner for multiple coronal, sagittal and transverse planes. T2 maps were created and converted to dose maps within OsiriX, an open source image processing application, by irradiating calibration samples to known doses. Measured dose maps were compared with TPS calculated doses in terms of dose profiles and gamma tests using relevant tolerances for dose difference and distance to agreement. The Fricke gel detector was used to measure two high dose VMAT plans delivered with a Varian TrueBeam Linac; for a brain metastasis and spine plan. Results were also compared with measurements carried out using a PinPoint ion chamber and Gafchromic<sup>TM</sup> EBT3 film.

##### Results

There was excellent agreement between measured and TPS dose distributions for coronal and transverse planes of the brain plan (figure 1), demonstrated by high gamma test pass rates (table 1). There was also good agreement in the high dose, steep gradient region of the spine plan. Small deviations between measured and calculated doses were seen in the low dose region for this plan, reflected in the gamma test results for the sagittal and coronal planes (table 1). Results also compared well with doses measured with the PinPoint ion chamber and radiochromic film.

Figure 1: Dose map analysis for the central transverse plane of the brain plan

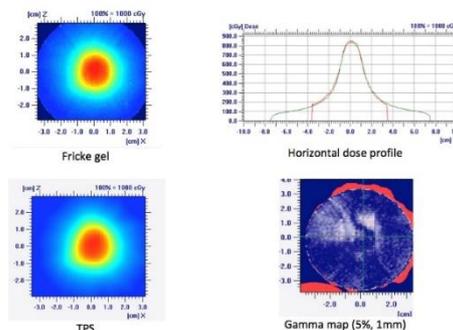

Table 1: Gamma pass rates (%) for the brain and spine VMAT plans

Gamma test settings	Brain Plan		Spine Plan		
	Central transverse plane	Central coronal plane	Central transverse plane	Central coronal plane	Central sagittal plane
3% 2mm	99.8	96.6	98.7	85.5	92.1
5% 1mm	99.8	99.1	98.4	84	92.9

##### Conclusion

The Fricke gel detector was demonstrated to be suitable for the 3D measurement of complex dose distributions. Excellent agreement was seen between measured and TPS calculated dose distributions. This method offers a simple option for 3D dosimetry within a clinical radiotherapy department.

#### EP-1714 Comparison of geometrical distortion of 1.5 T MR sim and 1.5 T MR linac

H. Jensen<sup>1</sup>, U. Bernchou<sup>2</sup>, U. Bernchou<sup>3</sup>, A. Bertelsen<sup>2</sup>, C. Brink<sup>2</sup>, C. Brink<sup>3</sup>, F. Mahmood<sup>2</sup>, F. Mahmood<sup>3</sup>

<sup>1</sup>Odense University Hospital, Afd R, Odense, Denmark ; <sup>2</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark ; <sup>3</sup>University of Southern Denmark, Department of Clinical Research, Odense, Denmark

##### Purpose or Objective

The supreme soft-tissue contrast given by the MR scanner has motivated a strong interest in using MR images for planning and guidance of radiation therapy (RT). With clinical introduction of MR linacs it is possible to adapt the plan to the anatomy at each treatment fraction using MR images.

MR imaging has several significant challenges. Among the most important for MR guided RT is the geometrical distortion that potentially could lead to mistreatments. In this study geometrical distortions are quantified for a standard clinical MR scanner as well as a high-field MR linac.

##### Material and Methods

An MR geometrical distortion phantom (Magphan RT, The Phantom Laboratory) in 35x27x21 cm configuration containing several hundreds of 1-cm spherical fiducials was used. The MR measured fiducial locations was used to generate a 3D distortion map (figure 1). The distortion magnitude was quantified within a radius of 100 mm and 175 mm from the iso-center, respectively. Also, the mean distortion of the 10 % most deviating points within 100 mm and 175 mm radius were evaluated.

A diagnostic 1.5 T MR-sim scanner (Ingenia, Philips Healthcare) was used as reference to evaluate the magnitude of distortion of a 1.5 T MR linac (Unity, Elekta Instrument AB).

Reference Ingenia sequence (MR-sim):

1. T1w 3D FFE (5 min, 34 sec), rBW 228.3 Hz/pix, WFS 0.951 pix, 1.1x1.1x2 mm, 2 averages.

Clinical MR linac sequences for pelvic imaging:

2. T2w 3D TSE (1 min 34 sec), rBW 786.2 Hz/pix, WFS 0.276 pix, 1.5x1.5x2.0 mm.

3. T1w 3D FFE (1 min 31 sec), rBW 433.5 Hz/pix, WFS 0.501 pix, 1.5x1.5x2 mm.
4. T2w 3D TSE (5 min 59 sec), rBW 752.3 Hz/pix, WFS 0.289 pix, 1.2x1.2x1.2 mm, 2 averages.
5. T1w 3D FFE (3 min 47 sec), rBW 431.9 Hz/pix, WFS 0.356 pix, 1.2x1.2x2 mm, 2 averages.

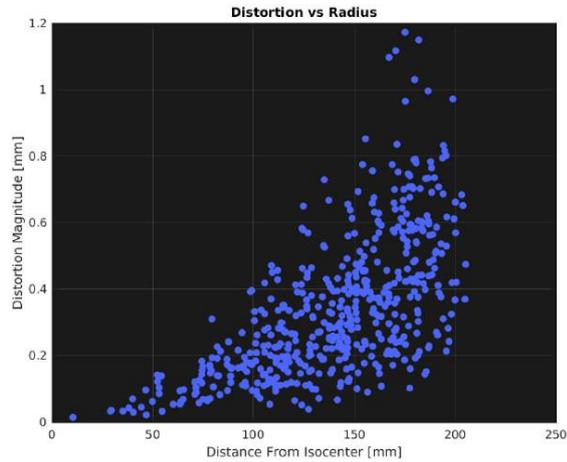

Figure 1 Distortions magnitude plot, Series Description [sequence 3]: T1w 3D FFE, high-field MR-linac Results

For the evaluated sequences the maximum distortions were in the range of 0.39-0.56 mm within a radius of 100 mm from iso-center. The MR linac performed slightly better than the MR-sim for most sequences. Likewise, the MR linac showed a maximum distortion of 0.96-1.28 mm within a radius of 175 mm, which is less than the MR-sim with a maximum distortion of 1.42 mm. Top 10 % most diverting points were analyzed and the mean distortions are listed in table 1, the MR linac shows respectively for 100 mm and 175 mm radius a distortion in the range of 0.28-0.35 mm and 0.68-0.70 mm. In comparison the MR-sim showed slightly more distortion (0.39 mm and 0.99 mm, respectively).

Sequence 3-5	<100 mm distance from isocenter		<175 mm distance from isocenter	
	Max Distortion [mm]	Mean Distortion Top 10% [mm]	Max Distortion [mm]	Mean Distortion Top 10% [mm]
1: 1.5T Ingenia T1w 3D (5m34s)	0.50	0.39	1.42	0.99
2: MR-linac T2w 3D (1m31s)	0.56	0.37	0.96	0.69
3: MR-linac T1w 3D (1m31s)	0.39	0.28	1.17	0.69
4: MR-linac T2w 3D (5m59s)	0.43	0.34	1.02	0.70
5: MR-linac T1w 3D (3m47s)	0.53	0.35	1.28	0.68

Table 1

**Conclusion**

The geometrical distortion on the MR linac was found to be less or similar to the distortions of a diagnostic MR scanner of same field strength. Distortions were of the magnitude of 0.5 mm which is needed to make precise dose delivery with the high-field MR linac. Patient induced susceptibility effects may add additional distortion and should be evaluated separately.

**EP-1715 Development of an antropomorphic brain phantom**

A. Bakhtiar<sup>1,2,3</sup>, A. Runz<sup>1,3</sup>, W. Johnen<sup>1,3</sup>, P. Mann<sup>1,3</sup>, G. Echner<sup>1,3</sup>

<sup>1</sup>DKFZ, Division of Medical Physics in Radiation Oncology E040, Heidelberg, Germany ; <sup>2</sup>Hochschule für Technik und Wirtschaft, Htw Saar, Saarbrücken, Germany ; <sup>3</sup>Heidelberg Institute for Radiation OncologyHIRO, National Center for Radiation Research in OncologyNCRO, Heidelberg, Germany

**Purpose or Objective**

In this work, we present the development of a reproducible anthropomorphic half-brain phantom for MRI, obtained with 3D printing techniques. We modelled the geometry, the shape and the size of the phantom on patient MRI data. The shape of the phantom aimed to reproduce as accurately as possible the shape of the patient brain. We adopted a T1 weighted sequence to obtain a good T1 contrast. We aimed to achieve in the phantom an equivalent contrast. This required the investigation of the concentration of the contrast agents. These are also required to reproduce a T1 relaxation time similar to the one in brain matter. The brain phantom is also foreseen to be used as training data for an automatic segmentation software. The different contrasts in the brain, that lead to the definition of the regions, could be exploited in the automatic segmentation. Moreover, this opens the possibility to compute the volume of the different regions in the brain. These values could be used in hospitals by the doctors to identify brain diseases, e.g. brain mass loss in Alzheimer patients.

**Material and Methods**

In first place, we cut the brain exactly at the center in the sagittal plane of the image. The model included a 1 mm external wall and two independent separated cavities. We produced the phantom with the Ultimaker3 FDM 3D-printer. Once printed, we put the phantom in an alcohol bath in order to make it watertight. In the following step, we filled the brain phantom with solutions made of water and the contrast agent Gadoteridol (0.5mmol/ml). The solutions have been prepared with precise mixing ratios to achieve different contrasts in the T1 weighted MRI. The objective of this experiment was to obtain an artificial contrast as close as possible to the literature values for grey (1124±50) and white (884±50) matter at MRI room temperature. We tested concentrations of 195 vs. 130 µmol/ml and 135 vs. 100 µmol/ml. To obtain the desired concentrations to insert in the phantom, we diluted the original solution of 200 µmol/ml. Finally, we performed MRI scans of the phantom with the support of the software Gel\_Evaluation and we computed the T1 times.

**Results**

The two different substances were recognizable in the MRI images, as shown in Figure 1. We obtained a clear contrast between the white and the grey matter. In agreement with the expectations, the T1-signal that we recorded showed the typical exponential decay.

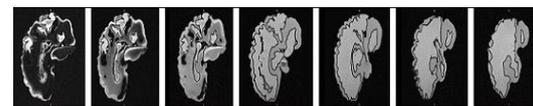

Figure 1.a. MPRAGE Scan for the concentrations 130 vs. 100 µmol/ml

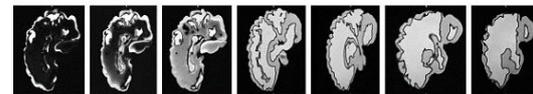

Figure 1.b. MPRAGE Scan for the concentrations 195 vs. 130 µmol/ml

**Conclusion**

Moreover, we compared the different concentration tests. We observed that the best contrast was obtained in the 195 vs. 130 µmol/ml case. In table 1 we restricted the investigation to the concentrations 135 vs. 100 µmol/ml, which have the closest T1 time to the grey and white brain matter. In our experiment, we observed a T1 relaxation time for the grey matter of (1190.1±8.3) ms for 100 µmol/ml, which differs of 5.87% from the literature value. On the other hand, the T1 relaxation time for the white matter was (985.2±84.6) ms, which differs by 11.43% from the literature.

Table 1. Comparison of measured and reference values

Tissue	Literature values [ms]	Measured values [ms]	Contrast agent concentration [ $\mu\text{mol/ml}$ ]	Relative deviation
White matter	884 $\pm$ 50	945.33 $\pm$ 7.5	135	6,93%
Grey matter	1124 $\pm$ 50	1190.12 $\pm$ 8.3	100	5,88%

### EP-1716 The Value of Independent Review in the Implementation of New Techniques at a New Radiotherapy Centre

R. Lally<sup>1</sup>, E. Reilly<sup>1</sup>, D. Stewart<sup>1</sup>, A. Reilly<sup>1</sup>

<sup>1</sup>Western Health and Social Care Trust, Radiotherapy Physics, Derry, United Kingdom

#### Purpose or Objective

Radiotherapy incidents have an adverse effect on treatment outcomes and consequently public perception of the safety of radiotherapy. Factors which contribute to incidents, as set-out in Towards Safer Radiotherapy, include: lack of training, competence or experience, fatigue and stress, poor design and documentation of procedures, over-reliance on automated procedures, poor communication and lack of team working, hierarchical departmental structure, staffing and skill levels, working environment and changes in processes. However, many of these factors are inherent to a new radiotherapy service established in a new centre, staffed by teams where individuals are often in a more senior position than they previously held. To mitigate risk, our centre added an additional safety layer to the commissioning process by requiring all new techniques, and significant changes to an existing technique, to be independently reviewed by a senior MDT. This work shares the benefits to this approach.

#### Material and Methods

Review teams consisted of senior representation from each professional group (i.e. Physics, Radiographers and Oncologists), ensuring no member had been directly involved in the implementation process. Reviews were primarily undertaken as tabletop exercises intended to address the salient points of Towards Safer Radiotherapy. Evidence reviewed included documentation (Process Documents, Records, End to End Test Reports etc.) embedded in the Quality Management System (QMS). To ensure staff were adequately trained, and service provisions adequate, competence matrices were reviewed to ensure sufficient numbers were trained to deliver the service. The teams also focused on legislative requirements. Findings were communicated verbally and tracked via email, alongside clear measurable objectives and milestones. The process was repeated until all outstanding actions had been addressed. A final implementation review report was published and made available in the QMS. Reviews have so far been undertaken for lung and head and neck radiotherapy.

#### Results

Lung radiotherapy was the first site implemented using independent review. The MDT identified n=12 findings, ranging from; the issue of entitlement records; update of competence matrices; documentation of end-to-end testing; through to work instruction changes. Findings were addressed within 13 days. Fewer findings were identified during the Head and Neck review.

#### Conclusion

Considering the many steps associated with radiotherapy, our centre found the implementation review process a valuable tool to identify any errors before they could propagate to an incident. The overall consensus was that the independent reviews provided valuable learning opportunities and reassurance to staff, thus reducing stress and consequently fatigue. Furthermore, through an increased overall awareness of how processes evolve, staff are less fearful of change and are more willing to constructively engage when changes are proposed.

### EP-1717 Challenges of Developing, Managing and Exploiting a National Radiotherapy Dataset - UK Experience

C. Roe<sup>1</sup>, U. Findlay<sup>1</sup>

<sup>1</sup>Public Health England, National Cancer Registration and Analysis Service, London, United Kingdom

#### Purpose or Objective

The Radiotherapy Dataset (RTDS) establishes a national standard for the collection of consistent and comparable data across radiotherapy (RT) providers in order to provide intelligence for service planning, commissioning, clinical practice and research and operational provision.

#### Material and Methods

RT providers are required to collect and submit the dataset and in turn, Public Health England (PHE) receive, validate, quality assure and integrate the data received to provide a timely and definitive analytical resource. This data is linked to data captured from other national cancer datasets (Cancer Outcomes and Services Dataset and Systemic Anti-Cancer Therapy) to support key service metrics to track progress in the provision of radiotherapy and other cancer services. This enables cancer site-specific analyses of outcomes by patient and treatment variables, and provide better understanding and appreciation of the specific role of radiotherapy in improving outcomes compared with other treatment modalities.

#### Results

Public Health England (PHE) took over full responsibility for the RTDS with effect from 1 April 2016. Dataset inclusions: the mechanism for extracting and uploading data; data processing and registration procedural processes internal to PHE; dataset QA; monthly reports to RT providers and additional examples of how the data is used to inform clinical practice and influence outcomes will be presented.

#### Conclusion

RTDS data is been used to inform RT service provision. This can only be achieved through direct partnership with key stakeholders from the RT community. Radiotherapy continues to be a rapidly evolving field. Therefore, there is a real need for a continual cycle of development, ongoing management and exploitation of radiotherapy datasets to ensure benefit to all.

### EP-1718 Determination of ion recombination correction factor by empirical and numerical methods

C. Anson Marcos<sup>1</sup>, P. Castro Tejero<sup>1</sup>, D. Hernández González<sup>1</sup>, M. Roch González<sup>1</sup>, P. García Castañón<sup>1</sup>, A. Viñals Muñoz<sup>1</sup>, R. Fayos-Sola Capilla<sup>1</sup>, S. Martín Juárez<sup>2</sup>, A. Valiente<sup>2</sup>, L. Pérez González<sup>1</sup>

<sup>1</sup>University Hospital La Princesa, Medical Physics, Madrid, Spain ; <sup>2</sup>University Hospital La Princesa, Radiation Therapist, Madrid, Spain

#### Purpose or Objective

Dose measurements using ionization chambers must take into account the effect of incomplete charge collection due to ion recombination as recommended by international protocols. The purpose of this work is to confirm the accuracy of ion recombination correction factor (k<sub>s</sub>) determined by empirical methods by evaluating its deviation to theoretical calculation.

#### Material and Methods

##### Equipment

The cylindrical chambers were studied were PTW: Farmer 30013, Semiflex 31010 and PinPoint 3D 31016 . The collected charge was measured with a PTW MP3 TANDEM electrometer. Varian Clinac 2100CD linear accelerator delivering 6MV flattened photon beam was used.

Measurement setup

Measurements were performed in a water phantom (PTW MP3 Phantom Tank) with vertical beam geometry. The source-to-surface distance was 100 cm and the field size 10 x 10 cm<sup>2</sup>. The chambers were situated at depth 10 cm in the centre of the field and integration time for collecting the charge (Q) was 60 s. Two readings of 100 MU set in 300MU/min rate were collected at each voltage for each measurement of ks. Nine different polarization voltages (V) were used (+50V, +100V, +150V, +200V, +250V, +300V, +350V, +400V). The chambers were at a fixed position and polarization voltage was changing giving enough time elapsed for the chamber to achieve stabilization.

#### Measurement

The ks value was determined; firstly plotting the data 1/Q and 1/V for each ionization chamber in a Jaffé curve (Eq. 1) in order to confirm their linearity and so the reliability of Boag's model for the beam in the range of voltages. A second value of ks was determined by means of two-voltage method (Eq. 2) measuring at polarization voltage +100V and +400V. This method assumes the linear dependence of 1/Q and 1/V. Value of ks was also determined by theoretical calculation taking into account the effects of initial recombination, diffusion and volume recombination (Roos and Derikum, 2000)(Eq.3)

$$\frac{1}{Q} = \frac{1}{Q_{sat}} + \frac{c}{V} \quad k_s = \frac{Q_{sat}}{Q(V)} \quad (\text{Eq.1})$$

$$k_s = \left( \frac{V_1}{V_2} - 1 \right) / \left( \frac{V_1}{V_2} - \frac{Q_1}{Q_2} \right) \quad (\text{Eq.2})$$

$$k_s \cong 1 + \frac{E_i \cdot d}{V} + 2 \frac{k_B \cdot T}{V \cdot e} + \frac{1}{2} \cdot \frac{\mu \cdot d^2 \cdot \rho}{V \cdot W/e} \cdot D_{DPP,a} \quad (\text{Eq. 3})$$

#### Results

Jaffé plots of the three chambers studied are shown in Figure 1. Farmer ionization chamber shows the highest linearity. Table 1 presents ks values determined by different approaches: Jaffé plot, two-voltage method and theoretical calculation, for each chamber. In theoretical calculation, the lowest ks is the one obtained from the PinPoint chamber, since it has smaller electrode distance. However, in the empirical methods ks obtained are larger, as well as deviation. This can be explained by the major instability of the measurements compared to the bigger chambers.

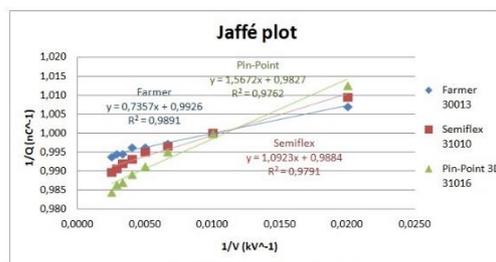

Figure 1. Jaffé plot of three ionization chambers

Farmer 30013			
	Jaffé plot	Two-voltage method	Theoretical
ks	1,0012	1,003	1,0021
Deviation to theoretical	-0,08%	0,09%	
Semiflex 31010			
	Jaffé plot	Two-voltage method	Theoretical
ks	1,0013	1,001	1,0016
Deviation to theoretical	-0,03%	-0,06%	
PinPoint 3D 31016			
	Jaffé plot	Two-voltage method	Theoretical
ks	1,0019	1,005	1,0006
Deviation to theoretical	0,12%	0,44%	

Table 1. ks values obtained from Jaffé plot, Two-voltage method and theoretical calculation

#### Conclusion

Ks value is specific for each ionization chamber and need to be estimated for absolute dosimetry measurements. Two-voltage method should be applied only after verification of the linearity of 1/Q and 1/V in the range of polarization voltage used. Jaffé curve must be measured for obtaining greater accuracy.

#### EP-1719 Automated data processing and BigData in radiation therapy

O. Schmidt<sup>1</sup>, N. Ballmann<sup>1</sup>, C. Bert<sup>1</sup>, R. Fietkau<sup>1</sup>  
<sup>1</sup>University Hospital Erlangen, Radiation Oncology, Erlangen, Germany

#### Purpose or Objective

The wide range of technologies and systems in radiation therapy produces a vast amount of heterogenic data sets. These are neither easy accessible nor processable for automated use in terms of clinical, technical or organizational issues. Therefore an IT-infrastructure has been developed which integrates the different parts of the treatment process in a single setup without a secondary data storage system. This project evaluates the effort, feasibility and validity of a single setup automatization approach with the oncology-information-system (OIS) Mosaiq (Elekta AB, Stockholm).

#### Material and Methods

The Mosaiq database is key to organizational issues and technical treatment delivery data in its role as record & verify system. Therefore a direct read-only access to the database was granted by Elekta. Topics of recurring interest can be displayed in a web application, accessible on every workstation in the institution, whereas non-regular issues are processed in a program within the infrastructure and given templates.

#### Results

The actual usage per treatment series of the different radiation techniques, as recorded in Mosaiq, was of interest for the year 2017. The distribution resulted in 3D-conformal (44%), VMAT (26%), StepNShoot-IMRT (22%) and Arc (8%) as shown in fig.1. Another issue was the identification of patient groups, which could be treated at the Linac VERO (Brainlab GmbH, Munich) without major changes to the treatment plan in order to increase the workload of that specific Linac considering the technical limitations (max. field size (x, y<15 cm), energy level (6 MeV) table rotation (<35°)). The evaluation was performed for the treatment parameters of all delivered series at the department in the given period. The result

showed that already 99% of the suitable prostate carcinoma patients, but only 61% of the lung carcinoma patients are treated at the VERO. This and further diagnoses offered options for a more balanced occupancy of the institution's Linacs. For better scheduling, the relevant tables of the Mosaik database are visualized in a web application within the network of the institution as shown in fig.2. The output can be selected by the timeperiod, ICD-10 diagnose and Linac.

#### Conclusion

As a prove of concept the Mosaik OIS was chosen, several questions have been answered and the result was validated. Currently, the Mosaik queries are integrated with queries to the treatment-planning-system Pinnacle<sup>3</sup> (Philips N.V., Amsterdam), the IMRT-verification systems ArcCHECK (Sun Nuclear GmbH, Neu-Isenburg) and Mobius3D (Mobius Medical Systems LP, Houston) allowing automated analysis of clinical parameters in large cohorts of patients. Including different data sources in a single setup is feasible for issues with the need of linking different data sets or processing vast amounts of data, which cannot be analyzed manually and reproducibly. BigData as well as machine learning applications are both in strong need for extensive and high quality data, therefore this approach is suitable.

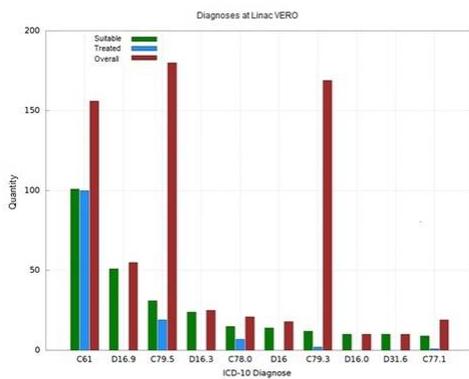

Figure 1: Identification of diagnoses suitable for treatment at the Linac VERO with its technical limitations regarding the plan parameters

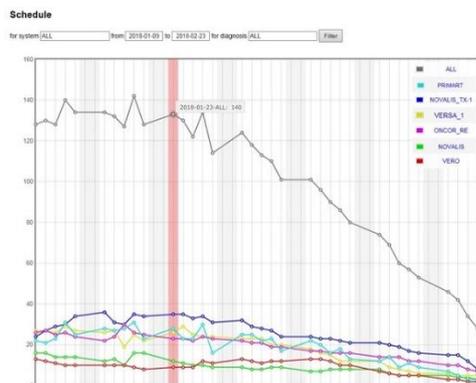

Figure 2: Web application based on Mosaik data for optimized scheduling

### Electronic Poster: Physics track: Dose measurement and dose calculation

#### EP-1720 Evaluation of dose perturbations for metal stent in photon and proton radiotherapy planning

H. Kim<sup>1</sup>, B. Lee<sup>1</sup>, S. Cho<sup>1</sup>, S. Jung<sup>1</sup>, Y. Han<sup>1</sup>, D. Lim<sup>1</sup>, H. Park<sup>1</sup>

<sup>1</sup>Samsung medical center, Radiation oncology, seoul, Korea Republic of

#### Purpose or Objective

This study was conducted to evaluate and apply dose influence of metal stent in photon and proton radiotherapy planning for hepatocellular carcinoma.

#### Material and Methods

Dose perturbations were evaluated by Monte Carlo simulation and Planning system in photon and proton. Computed tomography(CT) data sets of 1.25 mm slice thickness were obtained with containing metal stent in water equivalent solid phantom. The plan with and without metal stent consisting of nickel and titanium base alloys(Nitinol) was performed. We used Truebeam(Varian Medical System) and Pinnacle<sup>3</sup>(Philips Medical System) treatment planning system in photon and proton therapy system of Sumitomo and Raystation(Raysearch) treatment planning system in proton for dose calculation. The photon plan test are designed in an anterior-posterior/posterior-anterior (AP/PA) field technique using 6MV energy and proton plan are designed in AP field of Wobbling beam using 150 MeV energy. The Monte Carlo simulation was programed under same conditions for beam parameters, solid water phantom and metal stent of radiotherapy planning system and we compared the calculated dose distribution effects as with and without metal stent. The Monte Carlo was calculated using Geant4(v10.3) and GATE(v8.0).

#### Results

The thickness of the metal stent is about 0.1 mm. The stent appears blurred in the image because the stent is smaller than the size of the detector used in CT. In RTP, it was confirmed uncertainty for dose calculation that the image blurring of stent in CT can reconstruct the density of 1.08 - 1.3 g/cm<sup>3</sup>, which is much smaller than the actual density of 6.8 g/cm<sup>3</sup>. The treatment planning system cannot calculate dose perturbations due to stents. In the calculation of dose using Monte Carlo, dose enhance effect of photon was 1.6 - 3.0 % depending on the stent size due to multi scatter. The proton calculated dose reduction effect of -1.3 - 0.1% due to dose shadow.

#### Conclusion

Our study was performed to evaluate the uncertainty of dose calculations that could be caused by stents in radiotherapy planning and to apply them in clinical practice. In the Monte Carlo calculation, dose perturbations of 3.0% and -1.3% were observed with the use of metal stents in photons and proton. We confirmed the effect of dose change by metal stent through dose calculation and simulation. In case of RTP used in clinical practice, we can recommend to replace stent density to the average HU value of the surrounding normal tissue considering dose uncertainty by image blurring of stent that metal stent is not reflected in the planning system.

#### EP-1721 Sensitivity study between gamma index passing rate and clinical dose volume histogram

L. Szczurek<sup>1,2</sup>, R. Juszkat<sup>3</sup>, J. Szczurek<sup>4,5</sup>, P. Sosnowski<sup>3,4</sup>

<sup>1</sup>1st Department of Medicine, Poznan University of Medical Sciences, Poznan, Poland ; <sup>2</sup>The International Oncology Center Affidea, Poznan, Poland ; <sup>3</sup>Department of General and Interventional Radiology, Poznan University of Medical Sciences, Poznan, Poland ; <sup>4</sup>Affidea, Diagnostics Department, Poznan, Poland ; <sup>5</sup>Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences

#### Purpose or Objective

The sensitivity was analyzed to correctly identify the pre-treatment volumetric modulated arc therapy (VMAT) plans with high dose errors and to quantify the incidence of false negatives, for various the gamma index method.

#### Material and Methods

Twenty five high-risk prostate cancer patients and fifteen endometrial cancer patients treated with VMAT technique were analyzed. The percentage gamma passing rate (%GP) of two-dimensional (2D) and three-dimensional (3D) pre-

treatment VMAT dosimetric verification and their sensitivity with percentage dosimetric errors (%DE) between the planned dose volume histogram (DVH) and the patient's predicted DVH calculated by Compass and OmniPro system was calculated. Pre-treatment verifications were performed for all plans by acquiring the planar dose distribution with matrix detector. %GP of 2D and 3D with acceptance criteria 3%3mm was obtained by OmniPro and Compass software. %DE were calculated from planned dose volume histogram created in the treatment planning system (TPS) Monaco (Elekta) and the patient's predicted DVH which was calculated with Compass system. Analysis was performed for planning target volume (PTV) and some typical organs at risk (OAR). Parameters  $D_{2\%}$ ,  $D_{98\%}$ ,  $D_{\text{mean}}$  for target and dose in OAR, recommended by QUANTEC group and ICRU, were analyzed.

Sensitivity between %GP and %DE was investigated using receiver operating characteristics (ROCs). The number of false negative (FN) cases and true positive (TP) cases were calculated. FN had DVH errors >3% among those patients with %GP >95%. All the cases TP had DVH errors >3% and %GP <95%. From the FN and TP rates, receiver operating characteristic (ROC) curves were generated to investigate the ability of 2D and 3D methods to identify accurately the plan with dose errors 3%. The average area under curve (AUC) values of ROCs was analyzed.

#### Results

The t-test results between the planned and estimated DVH values for prostate and endometrial cancer group for PTV, bladder, rectum, femoral head, showed that mean values obtained from histograms were comparable ( $p > 0.05$ ). The %DE in PTV between 0.07 and 0.12 for prostate cancer patients, and from -0.14 to 0.21 for endometrial cancer group were observed. For the structures located in the low-dose region (e.g. bowel), a maximum difference of <8% was observed. For criterion 3%3mm the average %GP were acceptable in both groups, with average rates of 99.03% for 2D and 97.70% for 3D, respectively.

The average AUC value of ROCs was  $0.558 \pm 0.11$  and  $0.452 \pm 0.12$  for 3D and 2D, respectively. 3D had a better prediction on the %DE than did 2D, but the accuracy of both gamma index methods were not good enough for clinical acceptable with AUC values lower than 0.6.

#### Conclusion

Low sensitivity of 3%/3 mm 2D and 3D gamma method was confirmed. New approaches to evaluate QA plans need to be urgently implemented into clinical practice.

#### EP-1722 Development and validation of a strategy to use actual leaf positions as a patient QA tool

D. Den Boer<sup>1</sup>, K.M. Van Ingen<sup>1</sup>, Y.R.J. Van Herten<sup>1</sup>, J. Kaas<sup>2</sup>, J. Visser<sup>1</sup>, J. Wiersma<sup>1</sup>, A. Bel<sup>1</sup>

<sup>1</sup>Amsterdam UMC- location AMC, Radiotherapy, Amsterdam, The Netherlands ; <sup>2</sup>Netherlands Cancer Institute- NKI-AvL, Radiotherapie, Amsterdam, The Netherlands

#### Purpose or Objective

At our institute the actual leaf positions during VMAT delivery are stored in our record and verify (R&V) system ('actual values') for all VMAT treatments. This easily accessible information is present for all our patients, all fractions and all our Elekta linacs; an advantage as compared to using machine log files ("TRF") which are only present on newer models. Goal of this study is to develop and validate a strategy to use these actual values as a patient QA tool, which can be used pre-treatment (in a QA fraction), during treatment (for all fractions) and post-treatment (for population-based evaluation).

#### Material and Methods

Three types of data are analysed/compared: the treatment plan (TP), the actual leaf positions and the TRF file. The TRF data (with an entry every 40 ms) are used to validate the actual values (with an entry for every Control

Point, CP, Fig.1). The actual values are compared to the planned positions of the TP. In-house developed code was used to extract the data from these files, analysis was done in Matlab. The actual data per CP (red circles) cannot directly be compared to the TP (blue circles) as we found these are not registered at exactly the same point. We therefore interpolate the leaf positions of the TP between the CPs and compare the actuals to the interpolated plan with the lowest difference between these positions (least mean square). This can be regarded as a "best case scenario".

From the remaining differences we derive a "difference factor" (DF) in 3 steps: 1) Per leaf the difference between the actual value and the planned value (from the "best case scenario" interpolation) is taken. 2) This is normalised to the MU for this CP with respect to the total MU. 3) The top 10 percentile is taken of these MU scaled differences. **Results**

To determine a baseline we analysed the patients of two tumour sites at our institute part of clinically validated templates/class solutions, (prostate, 57 TPs, ~1700 fr and esophagus, 97 TPs ~1500 fr). We found a DF of 0.0031. We compared this to a tumour site where we were so far unable to validate a class solution (cervix, 30 TPs, ~700 fr) and got a significantly higher DF of 0.0040 (Fig.2). As a retrospective case study we examined cases where cervix TPs often led to replanning (due to complexity, n=6). The class solution/template was changed to reduce complexity and consequently we had less problems during Patient QA afterwards. Accordingly, the DFs went from 0.0054 to 0.0039. A higher value seems linked to more challenging patient QA.

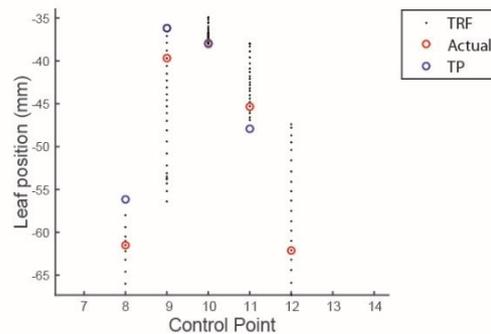

Figure 1 Leaf position for one leaf per CP in data file of actuals (red circle) and machine log file, TRF (black dots). It can be seen that they coincide. The blue dots represent the treatment plan for these CPs.

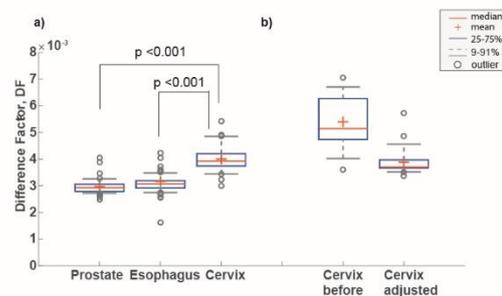

Figure 2 Difference factor (DF) from actuals.

a) For three tumor sites. Cervix is statistically higher than the class solution sites.

b) Case study: DF for cervix before (6 plans) and after (8 plans) an adjustment to decrease complexity that improved the patient QA results.

#### Conclusion

We have developed an approach to compare the actual leaf positions in the R&V software to the treatment plan. The DF difference parameters thus extracted can be used to analyse patient plans during treatment, post treatment and pre-treatment. Ideally such a factor will be monitored

for each fraction as an additional Quality Control. Our next step will be to study the DF with respect to the gamma analysis outcome of our patient QA.

#### EP-1723 Validation of EPID dose prediction and conversion models for flattening filter free beams

A. Ouakad<sup>1</sup>, M. Goubert<sup>1</sup>, L. Vieilleveigne<sup>1</sup>, F. Husson<sup>2</sup>, L. Parent<sup>1</sup>

<sup>1</sup>IUCT Oncopole, Department of Medical Physics, 1 avenue Irène Joliot-Curie-31059 Toulouse Cedex 9, France ; <sup>2</sup>Dosisoft, Department of Medical Physics, 45 Avenue Carnot- 94230 Cachan, France

##### Purpose or Objective

Electronic portal imaging devices (EPID) are interesting for pre-treatment quality assurance (QA) because of their high spatial resolution and ease of use. This study evaluated a new dosimetric portal method based on a superposition/convolution algorithm. It was tested for flattening filter free (FFF) photon beams.

##### Material and Methods

Dosisoft EPIbeam software compares an image prediction generated from the DICOM RT plan and a portal image converted into a dose map at 5 cm depth in water using kernels to account for output factors, field penumbra and arm backscatter. Irradiations were performed with a Varian TrueBeam STx linear accelerator equipped with HD120 MLC and associated with aSi 1000 EPID. Dose prediction from RT plan and EPID image conversion models were assessed in 6 and 10 MV FFF beams by comparing the model to measurements. For output factor measurements, PTW 31010 0.125 cm<sup>3</sup> ion chamber was used for output factors for 2x2 to 20x20 cm<sup>2</sup> field sizes at the isocentre. For clinical plans, prediction and conversion models were assessed with PTW 1000 SRS matrix (pixel resolution between 0.25 and 0.5 cm). Clinical plans were lung (6 MV FFF) and liver (10 MV FFF) stereotactic body radiotherapy plans using dynamic conformal arc technique.

##### Results

Predicted and converted output factors were within 2% of the measured values for field sizes between 2 and 20 cm<sup>2</sup>. For clinical cases, comparison of dose prediction to matrix measurements gave an average gamma passing rate (2%-2.5 mm, global, 10% threshold) of (99.77±0.26)% and (99.98±0.04)% for 6 and 10 MV FFF beams respectively. Comparison of converted EPID image to matrix measurements gave an average gamma passing rate (2%-2.5 mm, global, 10% threshold) of (99.28±0.97)% and (99.98±0.04)% for 6 and 10 MV FFF beams respectively. Both prediction and EPID image conversion model are therefore validated for dynamic conformal arc technique. When the EPID image is used for pre-treatment QA, EPIbeam gave excellent gamma passing rates (2%-2mm, local, 10% threshold): for 6 MV FFF, the average pass rates were (98.79±0.61)% and for 10 MV FFF, the average pass rates were (98.55±0.47)%. Tolerance and action limits were calculated irrespective of the energy and were set to 96% and 87% respectively.

##### Conclusion

For field sizes between 2 and 20 cm<sup>2</sup>, EPIbeam provided a good prediction of the dose in water at 5 cm depth and accurately converted the EPID image into a dose map in water. The software gave consistent results for the studied dynamic conformal arc clinical cases. This work should be extended to study more modulated beams, such as those used in volumetric modulated arc therapy and to study the sensitivity of the method to errors in delivery.

#### EP-1724 Delivery error sensitivity of an EPID based pre-treatment control for FFF dynamic arc therapy

##### Purpose or Objective

EPIbeam is a new algorithm based on a superposition/convolution algorithm and developed for pre-treatment quality control with electronic portal imaging device (EPID). It was tested in this study for dynamic conformal arc therapy with flattening filter free (FFF) photon beams in the context of stereotactic radiotherapy. Its sensitivity to delivery errors was assessed and compared to 3D phantom measurements.

##### Material and Methods

A Varian TrueBeam STx linear accelerator equipped with HD120 MLC was used for the measurements. EPID images were acquired with Varian aSi 1000 detector and analysed with Dosisoft EPIbeam software. 3D phantom measurements were performed with PTW 1000 SRS array inserted in PTW Octavius 4D phantom. Analysis was performed in PTW Verisoft software. Varian Eclipse treatment planning system (version 13.7 AAA algorithm) was used to calculate the reference dose distribution. EPID and phantom pre-treatment controls were first compared for ten 6 MV FFF lung plans (6.0 to 59.0 cm<sup>3</sup> PTV size) and ten 10 MV FFF liver plans (9.8 to 327.5 cm<sup>3</sup> PTV size).
