# ESTRO 38 CONTENT

27 APRIL 2019

## Teaching Lecture

Artificial Intelligence Applications in Radiation Oncology .....	Abs. 1
Using mice to model normal tissue responses to thoracic radiation .....	Abs. 2
State of the art in definitive treatment of locally advanced NSCLC .....	Abs. 3
New ILROG radiotherapy guidelines for haematological malignancies .....	Abs. 4
The role of postoperative radiotherapy in endometrial cancer: what have we learned of the PORTEC trials? .....	Abs. 5
Gating and breath-hold techniques in Radiation Therapy .....	Abs. 6
Technology for precision small animal radiotherapy research: Optimal use and challenges .....	Abs. 7
Ensuring Quality in an Image Guidance Era .....	Abs. 8

## Symposium

Artificial intelligence in Radiation Oncology .....	Abs. 9-12
Mouse models: Animal models the next step for RT .....	Abs. 13-16
Optimal management of patients with unresectable stage 3 NSCLC .....	Abs. 17-20
Combined modality treatment vs chemotherapy alone in lymphoma patients? .....	Abs. 21-24
Image guided adaptive brachytherapy IGABT for primary vaginal cancer in Europe and North America .....	Abs. 25-28

## Joint Symposium

ESTRO-AAPM: QA of on-line adaptive radiotherapy .....	Abs. 29-33
---	------------

## Symposium

Beyond Physical dose .....	Abs. 34-37
Quality in an IGRT .....	Abs. 38-40

## Poster Viewing

Poster viewing 1 : Breast and Skin .....	Abs. 41-49
--	------------

## Symposium

Challenging dose painting: Are we really painting what we aim to or the better outcome is only linked to higher dose spots within the CTV? .....	Abs. 50-53
--	------------

## Proffered Papers

RB 1: Pre-clinical models is the next step for radiotherapy .....	Abs. 54-58
CL 1: Proffered papers : Lung .....	Abs. 59-65
CL 2: Proffered papers Haematology, Sarcoma and oligometastases .....	Abs. 66-72
BT 1: Treatment verification .....	Abs. 73-79
PH 1: Adaptive radiotherapy: tools and technologies .....	Abs. 80-86
PH 2: Applications of dose modelling and calculation .....	Abs. 87-93
RTT 1: Motion management and adaptive strategies .....	Abs. 94-98

## Poster Viewing

Poster viewing 2: Advanced technologies .....	Abs. 99-107
---	-------------

## Award Lecture

Emmanuel van der Schueren Award Lecture .....	Abs. 108
Iridium Award Lecture .....	Abs. 109

## Symposium

MR-guided radiation therapy: hybrid machines and treatment adaptation .....	Abs. 110-113
How to exploit Immunogenic cell death Mechanism in Radiotherapy .....	Abs. 114-117
Oligo-metastatic prostate cancer – shedding light in a quickly emerging field .....	Abs. 118-121
New developments in gynaecological cancers .....	Abs. 122-124
Real time navigation technologies in brachytherapy .....	Abs. 125-127
Automatic / Knowledge based treatment planning:open issues .....	Abs. 128-131

## Joint Symposium

ESTRO-EFOMP: Multi-disciplinary working in Radiotherapy ..... Abs. 132-135

## Symposium

Younger people and radiotherapy ..... Abs. 136-138

## Poster Viewing

Poster viewing 3: Brachytherapy ..... Abs. 139-147

## Multidisciplinary Tumour Board

Soft tissue sarcomas

## Proffered Papers

RB 2: How to exploit immunogenic cell death mechanisms in radiotherapy ..... Abs. 151-157

CL 3: Proffered papers : Prostate and Bladder ..... Abs. 158-164

CL 4: proffered papers : CNS and Paediatrics ..... Abs. 165-171

BT 2: Cervix brachytherapy ..... Abs. 172-178

PH 3: Proffered paper: New developments in automated treatment planning ..... Abs. 179-185

PH 4: Proffered paper: New technologies ..... Abs. 186-192

RTT 2: A patient centered approach to follow up ..... Abs. 193-199

## Poster Viewing

Poster viewing 4: Head-Neck and Lung ..... Abs. 200-208

## Award Lecture

Honorary Members award lectures ..... Abs. 209-211

## 28 APRIL 2019

## Teaching Lecture

Re-irradiation for breast cancer ..... Abs. 212

Extracellular vesicles; are we there yet? ..... Abs. 213

Update on the management of SCLC ..... Abs. 214

How to combine checkpoint inhibitors with radiotherapy? ..... Abs. 215

How does brachytherapy fit in the modern management of penile cancer? ..... Abs. 216

Detector specific output correction factors: How to use them in practice ..... Abs. 217

Uncertainties in Radiomics ..... Abs. 218

New technology and modalities in Radiotherapy - What can the ESTRO School offer? ..... Abs. 219

Precision medicine and systems biology - transforming cancer research in the 21st century ..... Abs. 220

## Symposium

Balancing the risks and benefits of re-irradiation ..... Abs. 221-224

Circulating biomarkers for patient stratification and treatment monitoring ..... Abs. 225-228

## Debate

This house believes that Proton-beam be used routinely in the treatment of lung cancer

## Symposium

Radiation-drug combinations on the 2019 horizon ..... Abs. 229-232

Inverse planning in brachytherapy - A one click solution? ..... Abs. 233-235

Reference and non-reference dosimetry - CoPs and beyond ..... Abs. 236-239

New advances in image reconstruction in CBCT ..... Abs. 240-242

New technology and modalities ..... Abs. 243-245

Combining research and clinical/ professional training/ practice ..... Abs. 246-250

## Poster Viewing

Poster viewing 5: Health Services Research and Health-Related Quality of Life ..... Abs. 251-259

## Networking session

Speed Dating with Quiz

## Joint Symposium

ESTRO-JASTRO: Clinical trials for particle therapy: which ones to run and how? ..... Abs. 260-263

## Proffered Papers

RB 3: Tumour sensitization ..... Abs. 264-268

CL 5: Proffered papers : Randomised Clinical Trials ..... Abs. 269-274

CL 6: Proffered papers Radiation and Targeted Agents ..... Abs. 275-281

BT 3: Prostate HDR brachytherapy ..... Abs. 282-288

PH 5: Proffered paper: Innovations in dosimetry and dose measurements ..... Abs. 289-295

PH 6: Proffered paper: X-ray guided tumour tracking ..... Abs. 296-302

RTT 3: Impact of variations on treatment planning ..... Abs. 303-307

## Poster Viewing

Poster viewing 6 : Radiobiological modelling and quantitative imaging ..... Abs. 308-316

## Proffered Papers

BT 4: Breast and Skin brachytherapy ..... Abs. 317-323

## Presidential Symposium

Presidential symposium ..... Abs. 324

## Award Lecture

Claudius Regaud Award Lecture ..... Abs. 325

## Symposium

How to prevent burnout? ..... Abs. 326-330

The microbiome, inflammation and radiotherapy response ..... Abs. 332-334

Reducing the normal tissue effects of RT ..... Abs. 335-338

Radiotherapy in the era of the Silver Tsunami ..... Abs. 339-342

## Debate

This house believes that margin reduction is the key to improved outcome

Which is the best brachytherapy technique to deliver partial breast irradiation? Pitfalls, results and current recommendations ..... Abs. 343-346

## Symposium

Big data – big problems? ..... Abs. 347-349

From grid therapy to microbeam radiotherapy ..... Abs. 350-353

Focus on the lung ..... Abs. 354-356

Stronger together - news and projects in the young national societies ..... Abs. 357-360

## Poster Viewing

Poster viewing 7: CNS, Paediatrics, Haematology and Gynaecology ..... Abs. 361-369

## Multidisciplinary Tumour Board

Prostate cancer

## Networking session

Quiz and Young networking cocktail

## Joint Symposium

ESTRO-ASTRO: Translating discovery to cure ..... Abs. 370-373

## Proffered Papers

RB 4: Normal tissue effects of radiotherapy ..... Abs. 374-379

CL 7 :Proffered papers: GI ..... Abs. 380-386

CL 8: Proffered papers : Head and Neck ..... Abs. 387-393

BT 5: Optimising dose distribution ..... Abs. 394-400

PH 7: Proffered paper: Outcome modelling .....	Abs. 401-407
PH 8: Proffered paper: Handling intra-fraction motion in MR guided RT .....	Abs. 408-414
RTT 4: Reducing uncertainties in volume definition .....	Abs. 415-421

#### Poster Viewing

Poster viewing 8: TP Developments .....	Abs. 422-430
---	--------------

#### Proffered Papers

BT 6 : Innovative and uncommon indications .....	Abs. 431-437
--	--------------

#### Award Lecture

Jens Overgaard Legacy Award Lecture	
Honorary Physicist Award Lecture .....	Abs. 438

### 29 APRIL 2019

#### Teaching Lecture

Extreme hypofractionation in the treatment of localized prostate cancer .....	Abs. 439
Radio-immunotherapy: challenges and opportunities .....	Abs. 440
Tumor metabolism and radiation response .....	Abs. 441
Radiomic machine-learning to predict radiotherapy outcome .....	Abs. 442
Importance of volumetric staging and biological dose inhomogeneity in IMRT .....	Abs. 443
In-vivo dosimetry : Possibilities and Pitfalls .....	Abs. 444
The vital role of physicists in clinical trials: from design to data analysis .....	Abs. 445
New developments in the treatment of brain metastases: better prognostic tools, improved outcomes .....	Abs. 446

#### Symposium

Radiotherapy in bladder cancer: Standard of care and future perspectives .....	Abs. 447-450
--	--------------

#### Joint Symposium

ESTRO-EACR: Radio-immunotherapy: from concept to clinical practice .....	Abs. 451-454
--	--------------

#### Symposium

Tumor Metabolism and Radiotherapy .....	Abs. 455-458
---	--------------

#### Joint Symposium

ESTRO-ESR: Current status and future challenges in MR-integrated radiotherapy .....	Abs. 459-462
---	--------------

#### Symposium

Improved outcome by smarter use of radiotherapy .....	Abs. 463-465
Quantitative Imaging for Radiation Oncology .....	Abs. 466-468
Advanced methods to account for proton range uncertainties in treatment planning .....	Abs. 469-472
Care, communication and new technology in brain radiotherapy .....	Abs. 473-475

#### Poster Viewing

Poster viewing 9: Applied dosimetry .....	Abs. 476-484
---	--------------

#### Joint Symposium

ESTRO-IAEA: The role of hypofractionation in current radiotherapy and its impact in planning radiotherapy services .....	Abs. 485-488
--	--------------

#### Debate

Which is the best technique for the delivery of APBI? .....	Abs. 489-492
---	--------------

#### Proffered Papers

Biomarkers and bioimaging in radiotherapy .....	Abs. 493-499
CL 9: Proffered papers : Late breaking abstracts .....	Abs. 500-505
CL 10: Proffered papers : Pelvic Tumours .....	Abs. 506-512
PH 9: Proffered paper: Artificial intelligence and novel imaging approaches .....	Abs. 513-519
PH 10: Proffered paper: Treatment planning innovations .....	Abs. 520-526

RTT 5: Improving accuracy in patient positioning ..... Abs. 527-532

### Poster Viewing

Poster viewing 10: Radiobiology ..... Abs. 533-541

### Award Lecture

Klaus Breur Award Lecture ..... Abs. 542

Academic award: Jack Fowler University of Wisconsin Award ..... Abs. 543

Company Award Lectures ..... Abs. 544

### Symposium

Adaptive RT: reactive or proactive? ..... Abs. 545-548

Predictive models of toxicity and big data, big open issues ..... Abs. 549-552

Biological Imaging for Radiotherapy ..... Abs. 553-556

New developments for breast cancer irradiation ..... Abs. 557-560

### Joint Symposium

ESTRO-EORTC: Moving radiation oncology forward to improve patient outcomes ..... Abs. 561-563

### Debate

In 10 years physicists will need different training to include more ...

### Proffered Papers

PH 11: Proffered paper: Proton range and dose verification ..... Abs. 564-570

### Symposium

Education and Advance Practice ..... Abs. 571-573

### Poster Viewing

Poster viewing 11: Novel strategies in IGRT ..... Abs. 574-581

### Multidisciplinary Tumour Board

Bladder cancer

### Debate

Can early-regression-guided adaptive RT eRG-ART improve the pathological response in neo-adjuvant treatments?

### Symposium

Recent insights into adverse cardiac effects from multimodal radiation therapy ..... Abs. 582-585

### Proffered Papers

RB 6: Pre-clinical research in particle therapy ..... Abs. 586-590

CL 11: Proffered papers : Breast ..... Abs. 591-596

CL 12: Proffered papers : Health Economics and Health services research ..... Abs. 597-602

PH 12: Proffered paper: Multi centre analysis of quality ..... Abs. 603-609

PH 13: Proffered paper: Modelling toxicity ..... Abs. 610-616

RTT 6: Education and quality management for optimising patient care ..... Abs. 617-621

### Poster Viewing

Poster viewing 12: GI and Urological Cancers ..... Abs. 622-629

### Award Lecture

Donald Hollywood award lecture ..... Abs. 631

Highlights of proffered papers ..... Abs. 632-635

## 30 APRIL 2019

### Teaching Lecture

The DNA damage response to radiotherapy: mechanisms and therapeutic opportunities ..... Abs. 636

Are adolescents and young adults AYA a specific patients' population? .....	Abs. 637
Hypofractionation; Is there rationale from biology a/b ratio? .....	Abs. 638
Recent insights into radiotherapy tolerance from the REQUITE Consortium .....	Abs. 639
Integration of PET imaging in radiation treatment planning .....	Abs. 640
Implementation and practice of SRS and SBRT: Consensus guidelines and protocols .....	Abs. 641
How to select patients for radiotherapy with protons instead of photons .....	Abs. 642
MR-guided radiotherapy in the pelvic region .....	Abs. 643

### **Symposium**

Radiotherapy biomarkers: a confluence of imaging, genetics and pathology .....	Abs. 644-647
Palliation in RT - How much is enough? .....	Abs. 648-651
Mechanisms of treatment resistance in glioma .....	Abs. 652-655

### **Debate**

This house believes that there is still a role for radiotherapy in pancreatic cancer .....	Abs. 656-659
--	--------------

### **Symposium**

New developments in Head and Neck Cancer treatment .....	Abs. 660-662
New detector developments .....	Abs. 663-666

### **Proffered Papers**

PH 14: Proffered paper: Treatment planning of proton therapy .....	Abs. 667-673
--	--------------

### **Symposium**

Focus on the Pelvic Region .....	Abs. 674-676
----------------------------------	--------------

### **Joint Symposium**

ESTRO-RANZCR: Radiotherapeutical management of oligometastatic disease .....	Abs. 677-680
--	--------------

### **Symposium**

Plan of the day - present status and future aims .....	Abs. 681-684
--	--------------

### **Debate**

This house believes that immunotherapy is really changing radiation oncology .....	Abs. 685-688
This house believes that patients with squamous cell cancer of the esophagus no longer need surgery .....	Abs. 689-692

### **Symposium**

Controversies in the management of brain metastases .....	Abs. 693-696
Improving delineation in RT: not only for the doctor .....	Abs. 697-700
A new era for radiotherapy anthropomorphic phantoms .....	Abs. 701-704

### **Debate**

Workload/clinic logistics, and not technical uncertainties, are the main barrier to widespread implementation of adaptive RT practice .....	Abs. 705-706
---	--------------

### **Closing debate**

Data mining or data farming? .....	Abs. 707-708
------------------------------------	--------------

## **POSTER**

Clinical track: Head and Neck .....	Abs. 709-733
Clinical track: CNS .....	Abs. 734-757
Clinical track: Haematology .....	Abs. 758
Clinical track: Breast .....	Abs. 759-767
Clinical track: Lung .....	Abs. 768-785
Clinical track: Upper GI oesophagus, stomach, pancreas, liver .....	Abs. 786-813
Clinical track: Lower GI colon, rectum, anus .....	Abs. 814-821
Clinical track: Gynaecological endometrium, cervix, vagina, vulva .....	Abs. 822-833
Clinical track: Prostate .....	Abs. 834-862
Clinical track: Urology-non-prostate .....	Abs. 863-864

Clinical track: Skin cancer / malignant melanoma .....	Abs. 865-866
Clinical track: Sarcoma .....	Abs. 867-868
Clinical track: Paediatric tumours .....	Abs. 869-875
Clinical track: Palliation .....	Abs. 876-884
Clinical track: Elderly .....	Abs. 885
Clinical track: Other .....	Abs. 886-890
Physics track: Basic dosimetry and phantom and detector development .....	Abs. 891-898
Physics track: Dose measurement and dose calculation .....	Abs. 899-911
Physics track: Radiation protection, secondary tumour induction and low dose .....	Abs. 912-914
Physics track: Treatment plan optimisation: algorithms .....	Abs. 915-919
Physics track: Treatment planning: applications .....	Abs. 920-946
Physics track: Radiobiological and predictive modelling, and radiomics .....	Abs. 947-969
Physics track: Intra-fraction motion management .....	Abs. 970-979
Physics track: Adaptive radiotherapy and inter-fraction motion management .....	Abs. 980-998
Physics track: Quantitative functional and biological imaging .....	Abs. 999-1000
Physics track: Imaging acquisition and processing .....	Abs. 1001-1012
Physics track: Implementation of new technology, techniques, clinical protocols or trials including QA & audit .....	Abs. 1013-1039
Brachytherapy: Breast .....	Abs. 1040
Brachytherapy: Gynaecology .....	Abs. 1041-1043
Brachytherapy: Head and neck .....	Abs. 1044-1045
Brachytherapy: Physics .....	Abs. 1046-1052
Brachytherapy: Prostate .....	Abs. 1053-1059
Brachytherapy: Miscellaneous .....	Abs. 1060-1064
Radiobiology track: Radiobiology of normal tissues .....	Abs. 1065
Radiobiology track: Radiobiology of stem cells cancer and normal tissue .....	Abs. 1066-1067
Radiobiology track: Radiobiology of particles and heavy ions .....	Abs. 1068-1069
Radiobiology track: Radiation-induced signalling pathways .....	Abs. 1070-1071
Radiobiology track: Immuno-radiobiology .....	Abs. 1072-1074
Radiobiology track: Radiation and tumour metabolism .....	Abs. 1075-1079
Radiobiology track: DNA damage response .....	Abs. 1080-1085
Radiobiology track: Biological therapies e.g. viruses, vaccines .....	Abs. 1086
Radiobiology track: Radiation response biomarkers .....	Abs. 1087-1090
RTT track: Patient preparation, positioning and immobilisation .....	Abs. 1091-1095
RTT track: Imaging acquisition and registration, OAR and target definition .....	Abs. 1096-1105
RTT track: Treatment planning and dose calculation / QC and QA .....	Abs. 1106-1111
RTT track: Image guided radiotherapy and verification protocols .....	Abs. 1112-1116
RTT track: Motion management and adaptive strategies .....	Abs. 1117-1121
RTT track: Patient care, side effects and communication .....	Abs. 1122-1125
RTT track: Education and training/role development .....	Abs. 1126-1130
RTT track: Risk management/quality management .....	Abs. 1131-1132

## **ELECTRONIC POSTER**

Clinical track: Head and Neck .....	Abs. 1133-1205
Clinical track: CNS .....	Abs. 1206-1263
Clinical track: Haematology .....	Abs. 1264-1268
Clinical track: Breast .....	Abs. 1269-1333
Clinical track: Lung .....	Abs. 1334-1391
Clinical track: Upper GI oesophagus, stomach, pancreas, liver .....	Abs. 1392-1445
Clinical track: Lower GI colon, rectum, anus .....	Abs. 1446-1474
Clinical track: Gynaecological endometrium, cervix,vagina,vulva .....	Abs. 1475-1511
Clinical track: Prostate .....	Abs. 1512-1584
Clinical track: Urology-non-prostate .....	Abs. 1585-1592
Clinical track: Skin cancer / malignant melanoma .....	Abs. 1593-1600
Clinical track: Sarcoma .....	Abs. 1601-1608
Clinical track: Paediatric tumours .....	Abs. 1609-1614

Clinical track: Palliation .....	Abs. 1615-1635
Clinical track: Elderly .....	Abs. 1636-1652
Clinical track: Health services research / health economics .....	Abs. 1653-1660
Clinical track: Communication .....	Abs. 1661
Clinical track: Other .....	Abs. 1662-1681
Physics track: Radiation protection, secondary tumour induction and low dose incl. imaging .....	Abs. 1682-1691
Physics track: Basic dosimetry and phantom and detector development .....	Abs. 1692-1719
Physics track: Dose measurement and dose calculation .....	Abs. 1720-1807
Physics track: Treatment plan optimisation: algorithms .....	Abs. 1808-1823
Physics track: Treatment planning: applications .....	Abs. 1824-1891
Physics track: Radiobiological and predictive modelling, and radiomics .....	Abs. 1892-1942
Physics track: Intra-fraction motion management .....	Abs. 1943-1981
Physics track: Adaptive radiotherapy and inter-fraction motion management .....	Abs. 1982-2021
Physics track: Quantitative functional and biological imaging .....	Abs. 2022-2032
Physics track: Imaging acquisition and processing .....	Abs. 2033-2070
Physics track: Implementation of new technology, techniques, clinical protocols or trials including QA & audit .....	Abs. 2071-2117
Brachytherapy: Breast .....	Abs. 2118-2123
Brachytherapy: Gynaecology .....	Abs. 2124-2139
Brachytherapy: Head and neck .....	Abs. 2140
Brachytherapy: Physics .....	Abs. 2141-2147
Brachytherapy: Anorectal .....	Abs. 2148
Brachytherapy: Prostate .....	Abs. 2149-2155
Brachytherapy: Miscellaneous .....	Abs. 2156-2157
Radiobiology track: Radiobiology of particles and heavy ions .....	Abs. 2158-2159
Radiobiology track: Radiation-induced signalling pathways .....	Abs. 2160-2161
Radiobiology track: Tumour microenvironment .....	Abs. 2162
Radiobiology track: Immuno-radiobiology .....	Abs. 2163-2164
Radiobiology track: Radiation and tumour metabolism .....	Abs. 2165
Radiobiology track: DNA damage response .....	Abs. 2166-2168
RTT track: Patient preparation, positioning and immobilisation .....	Abs. 2169-2177
RTT track: Imaging acquisition and registration, OAR and target definition .....	Abs. 2178-2180
RTT track: Treatment planning and dose calculation / QC and QA .....	Abs. 2181-2189
RTT track: Image guided radiotherapy and verification protocols .....	Abs. 2190-2195
RTT track: Motion management and adaptive strategies .....	Abs. 2196-2197
RTT track: Patient care, side effects and communication .....	Abs. 2198-2208
RTT track: Education and training/role development .....	Abs. 2209-2213
RTT track: Risk management/quality management .....	Abs. 2214

# ABSTRACTS

ESTRO 38 Saturday 27 April

**Abstract text**

Artificial intelligence (AI) is a very generic concept defined as “the study of agents that receive percepts from the environment and perform actions” (S. Russell). It is being developed by using information technology, software and hardware, designed to create functions and procedures oriented to learn from, and process, data. First experiences of AI started from the beginning of computer age but thanks to the availability of high performance computing hardware (like GPUs or cloud computing) nowadays AI is booming in many fields of business, technology, e-commerce and, last but not least, health and medicine. What are the main tools available for creating AI based models in medicine? In a simplified slide published on Oracle® website (<https://blogs.oracle.com/bigdata/difference-ai-machine-learning-deep-learning>, Figure 1)

AI world includes applications as Machine Learning (ML), a part of which is constituted by so called Deep Learning (DL). In radiation oncology there are already many potential application of AI, ML and DL, being the number of the last ones increasing, step by step, in last years. For example, fields of application of AI can be the automatic target or organs at risk delineation process, the auto-planning procedures or different modeling processes of patients evaluation and prognosis. In literature there are several examples of AI applications, but a first summary of them needs to understand how AI algorithms can work and be applied to daily workflow, like DL and its use in imaging related applications. The complexity and extraordinary fast evolution of DL based applications seems to prelude the possibility of more and more self automated clinical workflows, starting from treatment prescription aids, going through volumes delineation and finally managing the whole treatment delivery process, both taking into account imaging (IGRT) based and clinical issue for toxicity management. Clinical and concurrent ethical issues will raise as soon as AI based applications will offer in medicine, and radiation oncology, a sufficient grade of automation, likewise the self-driving car are

provoking ethical discussions about how to proceed in case of accidents and damages to the human beings.

**Teaching Lecture: Using mice to model normal tissue responses to thoracic radiation**

---

**SP-0002 Using mice to model normal tissue responses to thoracic radiation**

Andy Ryan<sup>1</sup>

<sup>1</sup>Oxford University, Oncology, Oxford, United Kingdom

**Abstract text**

Thoracic radiotherapy is widely used for the treatment of cancer, with either curative or palliative intent depending on the stage of the disease. Radiation dose is limited by normal tissue effects where common side effects include oesophagitis, pneumonitis and pulmonary fibrosis. As new approaches to improving the effectiveness of radiation enter clinical trials, a key challenge to the field is to understand the potential impact of new agents on the therapeutic ratio in patients. Using PARP, ATR and ATM inhibitors as exemplars, the effects of radiation combination therapy will be described in established models of toxicity (C57BL/6 mice) and efficacy (subcutaneous xenografts grown in BALB/c nude mice). Recently, we have developed a new in vivo approach with the potential to evaluate both toxicity and efficacy in a single mouse model. A/J mice are treated with urethane which leads to the development of lung tumours over a period of 6-9 months. In this model, radiation treatment has significant anti-tumour effects, but also induces pneumonitis and fibrosis. Using this new model, we outline emerging data using PARP, ATR and ATM inhibitors in combination with localised radiation, and suggest this may be a better approach to determining the potential impact of new agents on the therapeutic index of radiation therapy.

**Teaching Lecture State of the art in definitive treatment of locally advanced NSCLC**

---

**SP-0003 State of the art in definitive treatment of locally advanced NSCLC**

C. Faivre-Finn<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Division of Cancer Sciences -Radiation Oncology, Manchester, United Kingdom

**Abstract text**

Approximately one third of patients with non-small cell lung cancer (NSCLC) present with stage III disease and the majority of these patients are inoperable. Treatment of inoperable stage III NSCLC requires both control of the local disease and the distant micrometastases. The international standard of care is concurrent chemoradiotherapy (CIRT) that is associated with a 5 year survival rate of 20-25% (Auperin, Ramnath, Eberhardt). The literature supports the use of concurrent CIRT, in selected patients with good performance status, without major co-morbidities and for whom the RT plan produces acceptable normal tissue doses. Data in the elderly population is limited. The addition of chemotherapy concurrently to RT increases the risk of severe oesophagitis but does not increase the risk of lung toxicity. To date there is no established standard concurrent CIRT regimen in Europe. Neither the addition of induction or consolidation CT to concurrent CIRT have led to improvements in survival in unresectable locally advanced NSCLC. There is no role for dose escalation in stage III NSCLC using conventional dose fractionation

(Bradley).

Major progress has been made in recent years in the field of radiotherapy planning/delivery (i.e. 4DCT, PETCT, IMRT and VMAT) and treatment verification (daily on-line cone beam CT).

For the majority of patients, concurrent CRT is not suitable due to performance status and co-morbidities. The alternative treatment options are chemotherapy followed by RT (sequential CRT), or RT alone. The latter is associated with a 5 year survival rate of less than 10 %, due to both locoregional and distant relapse. There is currently no established role for induction, consolidation chemotherapy or targeted agents in stage III NSCLC. The PACIFIC trial has recently established a new standard of care by showing a progression-free and overall survival advantage for consolidation immune check-point inhibitor (Antonia).

PCI in stage III NSCLC reduces the incidence of brain metastases but has not been demonstrated to reduce survival in the reported studies (Paumier). The role of post-operative RT in completely resected patients with N2 disease is controversial (Le Pécoux).

### Teaching Lecture: New ILROG radiotherapy guidelines for haematological malignancies

---

#### SP-0004 New ILROG radiotherapy guidelines for haematological malignancies

L. Specht<sup>1</sup>

<sup>1</sup>The Finsen Center - Rigshospitalet, Oncology, Copenhagen, Denmark

#### Abstract text

The International Lymphoma Radiation Oncology Group (ILROG) is a worldwide organization of radiation oncologists interested in lymphomas and other haematological malignancies. Our goal is to improve outcome for patients by encouraging the appropriate integration of radiation therapy (RT) in the management of these diseases. One of the most important tasks has been to develop and teach the use of modern, image-guided and highly conformal RT for the many different disease entities and anatomic distributions. A very important task has been the development and publication of guidelines. In 2014-15 we published ILROG

guidelines on the treatment of Hodgkin lymphoma, pediatric Hodgkin lymphoma, nodal non-Hodgkin lymphoma, extranodal lymphomas, and primary cutaneous lymphomas. They proved very popular, being some of the most frequently downloaded publications in radiation oncology. In 2017 we gathered in Boston with the aim of defining other areas where guidelines were needed. We have subsequently published 9 new guidelines covering the following areas:

Relapsed or refractory Hodgkin lymphoma, where RT has long been demonstrated to be a powerful agent in the local control. It may even be effective when used alone in selected cases. Many patients undergo high-dose chemotherapy (HDCT) and stem cell transplant (SCT), but they frequently relapse in sites of prior disease, and this risk is reduced in patients treated with RT. The indications for RT in these patients are: 1) localized relapse, 2) disseminated relapse but with either bulky disease, persistent FDG-avid disease, or involvement of areas considered critical for local control. It is debated whether the RT should be given before or after the SCT. The doses and volumes depend on the response to chemotherapy and the extent of disease.

Relapsed/refractory diffuse large B-cell lymphoma, where RT may also provide effective local control. Young patients without comorbidities and with chemosensitive disease are often offered HDCT and SCT, and RT is used according to the same principles as for Hodgkin lymphoma. For patients who are not eligible for transplant, RT can offer effective palliation and for patients with locoregionally confined disease even cure. Doses vary according to the response to chemotherapy, and may in refractory disease go as high as 45-50 Gy. Volumes depend on disease location and extent.

Solitary plasmacytoma are potentially curable with RT. Doses vary from 35 Gy to small lesions to 40-50 Gy to large lesions. For patients with multiple myeloma RT is an effective palliative treatment at lower doses. Total body irradiation (TBI) continues to be an important part of conditioning regimens for allogeneic SCT. Many different techniques have been used, most often at extended source-to-skin distance (SSD). Increasingly, 3-dimensional planning and intensity modulated therapy are being used. This may allow reductions of the doses to risk organs. With some of these techniques the TBI is no longer delivered simultaneously to the entire body, possibly leading to some circulating leukemia cells receiving reduced doses. The TBI may be delivered at standard SSDs leading to higher dose rates, which has the potential to increase toxicity.

Extramedullary leukemia can pose therapeutic challenges for which RT can have an important role. RT should be considered for isolated choromas with inadequate response to chemotherapy, for isolated recurrences after SCT, and for palliation. Leukemia cutis may be treated with electron therapy, if large areas are involved total skin electron beam therapy may be used. A dose of 24 Gy results in excellent, rapid, and durable local control. Central nervous system leukemia may be an indication for RT, in particular in patients with recurrent or refractory CNS leukemia. Whole brain RT is usually given at doses of 24 Gy, but for selected patients treated with curative intent, cranio-spinal RT may be indicated. Lymphoblastic lymphoma with a large mediastinal mass often relapse in the mediastinum after treatment with intensive chemotherapy. Mediastinal RT can improve local control, but toxicity is a concern.

Proton therapy for mediastinal lymphoma may help to reduce the radiation dose to the normal structures thereby reducing long-term toxicity. There are many uncertainties in proton therapy, and these need to be considered. Imaging with FDG-PET plays a major role in the treatment planning of many lymphoma types. Accurate definition of sites of involvement before any systemic therapy is

important for RT planning. A baseline pre-treatment PET/CT is recommended. Smaller nodes that are not FDG-avid but seen on CT adjacent to FDG-avid nodes should be included. In masses seen on CT with partial FDG-uptake the entire mass should be included. Breathing control techniques are recommended for mediastinal treatment to reduce the doses to the critical structures.

**Teaching Lecture: The role of postoperative radiotherapy in endometrial cancer: what have we learned of the PORTEC trials?**

---

**SP-0005 The role of postoperative radiotherapy in endometrial cancer: what have we learned of the PORTEC trials?**

C. Creutzberg<sup>1</sup>

<sup>1</sup>Leiden University Medical Center LUMC, Department of Radiotherapy, Leiden, The Netherlands

**Abstract text**

In this presentation, the current evidence and recent developments in risk-based adjuvant treatment for endometrial cancer will be discussed, reviewing the data from the PORTEC-1 and PORTEC-2 trials which have been pivotal in determining the role of radiation therapy, especially vaginal brachytherapy, in (high)intermediate risk endometrial cancer.

The PORTEC-3 trial focused on the 15-20% of women with high-risk endometrial cancer (stage IB grade 3 and stage II-II endometrial cancers, and stage I-III non-endometrioid cancers), investigating the efficacy of combined adjuvant chemotherapy and radiation therapy, showing that radiation therapy alone is still standard treatment for stage I-II disease, while combined adjuvant treatment should be considered for women with stage III disease and those with serous cancers. Data on toxicity and quality of life from these trials are essential for shared decision making.

The PORTEC-4a trial builds on the recent knowledge on molecular characteristics of endometrial cancer and investigates the role of an integrated molecular profile to determine adjuvant treatment in high-intermediate risk disease, aiming to reduce overtreatment by sparing the expected 50% with a favourable profile adjuvant brachytherapy, while optimizing outcomes for the 5-10% with an unfavourable profile by using pelvic radiotherapy. Results of the pilot phase have shown the determination of the molecular factors within 2 weeks to be feasible in clinical practice.

The PORTEC-results will be put into perspective of results from other recent randomised trials, and future developments will be discussed.

**SP-0007 Technology for precision small animal radiotherapy research: Optimal use and challenges**

F. Verhaegen<sup>1</sup>, A. Vaniqui<sup>1</sup>, S. Van Hoof<sup>1</sup>, I.P. Almeida<sup>1</sup>, B. Van Der Heyden<sup>1</sup>, P. Granton<sup>2</sup>, J. Theys<sup>3</sup>, M. Vooijs<sup>3</sup>, L. Dubois<sup>3</sup>

<sup>1</sup>Maastricht Radiation Oncology Maastr, Clinical Physics Research, Maastricht, The Netherlands ; <sup>2</sup>Smart Scientific Solutions Bv, Maastricht, The Netherlands ; <sup>3</sup>Maastricht Radiation Oncology Maastr, Maastr Lab, Maastricht, The Netherlands

**Abstract text**

Two major recent developments have boosted radiobiology research in in vivo systems: (1) the development of high-precision image-guided photon irradiation platforms including treatment planning software, and (2) the development of ever more realistic disease models. These platforms have been developed mostly for cancer research, but can also be used for the study of other diseases e.g. in cardiology or neurology.

To guide the users towards optimal use of this new technology, recently ESTRO issued ACROP (Advisory Committee on Radiation Oncology Practice ) guidelines<sup>1</sup>. These guidelines identified several challenges including: (1) what are the key technologies required to downscale clinical treatments into small animal models, (2) how to deal with target motion, (3) which imaging modalities should be integrated into the radiation platforms, (4) what are the optimal irradiation margins, (5) what is the accuracy and precision of small field dosimetry, (6) which methods should be developed to verify the dose distribution, (7) which imaging modalities should be used for treatment planning, given the evolving clinical scenarios, (8) what is the difference between high and low-energy photon irradiation.

These novel platforms combine capabilities for precision irradiation with very small fields (e.g. in an arc), with various modalities of integrated onboard high resolution imaging. The platforms enable for the first time irradiation studies at the mouse/rat level, similar to the clinical standard of image-guided radiotherapy. These platforms include imaging modalities such as micro-cone beam CT, bioluminescent imaging (BLI), advanced targeting capabilities and a dedicated treatment planning system (e.g. SmART-ATP<sup>2</sup>). Further developments at the research stage include orthotopic tumor models, novel BLI targeting, novel CT contrast media, dual-energy CT imaging, spectral CT imaging, phase-contrast imaging, intravital microscopy, microbeam technology, motion-gated therapy, motion-dependent dose calculations, dose painting, margin recipes, autodelineation of anatomical structures, non-coplanar beams, dynamic field collimators, dose verification systems, advanced phantoms, and a preclinical data warehouse. Furthermore, the first studies on precision irradiation of rodent models with proton beams have been published<sup>3</sup>. From the overview to be given in this lecture it is clear the research platforms are reaching a level of maturity which will facilitate translational research. Many more developments are expected in the near future.

### Teaching Lecture: Ensuring Quality in an Image Guidance Era

---

#### SP-0008 Ensuring Quality in an Image Guidance Era E. Miles<sup>1</sup>

<sup>1</sup>Mount Vernon Hospital, Academic Physics, Northwood Middlesex, United Kingdom

#### Abstract text

The radiotherapy process is a series of events during which discrepancies between the planned treatment and actual treatment delivered can occur. This necessitates a comprehensive quality assurance (QA) programme, including regular quality control (QC) checks and audits. As more advanced technology is introduced in the clinical setting, QA activities must continually evolve to provide a safe framework for implementation of technical radiotherapy.

With image guided and adaptive strategies being increasingly employed to ensure accurate delivery of treatment in scenarios such as dose escalation and hypofractionation; techniques must be implemented in a safe and effective manner.

QA in the clinical trial arena has played a leading role in striving for accuracy and consistency of radiotherapy treatment delivery through monitoring protocol compliance in a multi-centre setting. Clinical trials can also evaluate the feasibility and effectiveness of a new technology. A comprehensive trial QA programme not only accredits centres for recruitment to a trial but also benefits the general standard of radiotherapy delivered. This presentation will aim to demonstrate how we can extend the clinical trial QA experience to routine practice to ensure quality of image guidance through discussing examples of clinical trial benchmarking and credentialing processes and their perceived impacts on clinical practice.

### Symposium: Artificial intelligence in Radiation Oncology

---

#### SP-0009 Clinical applications of AI for Radiation Oncology

J. Bibault<sup>1</sup>

<sup>1</sup>Université Paris Descartes - Hôpital Européen Georges Pompidou, Paris, France

#### Abstract text

The application areas of Artificial Intelligence (AI) in radiation oncology include image segmentation and detection, image phenotyping and radiomic signature discovery, clinical outcome prediction, and treatment planning automation.

In this lecture, we will first explain the methods used in AI, such as K-Nearest Neighbor, Decision Trees, Support Vector Machines, and Artificial Neural Networks, with a focus on Deep Learning (DL).

In the second part of the lecture, we will describe studies using DL for image segmentation, outcome prediction (toxicity, treatment response and survival) or treatment planning.

Finally we will explain the limits of these methods and evaluate how they will transform radiation oncology.

#### SP-0010 Acceptance, commissioning, introduction, regulatory aspects and QA of AI

W. Verbakel<sup>1</sup>

<sup>1</sup>VU University Medical Center, Radiation Oncology Department, Amsterdam, The Netherlands

#### Abstract text

Artificial intelligence is increasingly being proposed for radiotherapy. It has the potential to support or even take over several factors in the radiotherapy chain. A few examples are automated delineation, prediction of dose calculation, guiding optimal plan optimization, QA of treatment plans, and verification on the linac. Generally, AI is based on historic information, and a mathematical model, or a deep learning convolutional neural network is built on the basis of a library of data which is used for training. The result is a product that can take over clinical tasks from clinicians, dosimetrists, physicists and technologists. Therefore, such product is considered as a medical device and it should obey the EU rules for medical devices. The data that is used for training is in general patient related data, and the hospital should follow the privacy rules / get patient consent / get permission from the medical ethics committee / use only anonymized data. Furthermore, the clinical data may not be as consistent as we hope. For contouring, it may contain wrongly assigned structure names, or quickly contoured structures that deviate from the standard, and for dose prediction, it may contain sub-optimal treatment plans where insufficient OAR sparing was achieved. This can influence the performance of the AI. The AI result will not necessarily be worse than the contour by the clinician, but it is advisable to always check the output of an AI system. Ideally, a prediction would include an uncertainty with which the prediction is made, which is an important field of work in deep learning. Finally, the output of an AI algorithm also needs to be accepted by the medical staff, which requires convincing testing.

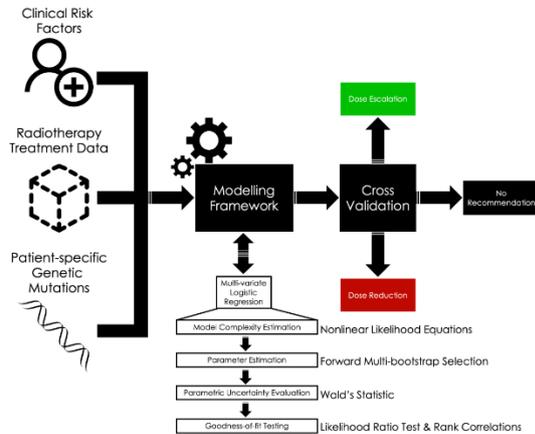

#### SP-0011 Unified Radiogenomic Prediction of Late Radiotherapy Toxicities

J. Coates<sup>1,2</sup>, A. Jeyaseelan<sup>2</sup>, N. Ybarra<sup>2</sup>, J. Tao<sup>2</sup>, M. David<sup>3</sup>, S. Faria<sup>3</sup>, L. Souhami<sup>3</sup>, F. Cury<sup>3</sup>, M. Duclos<sup>3</sup>, I. EL Naqa<sup>4</sup>

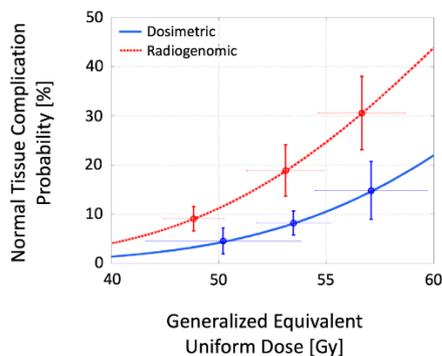

<sup>1</sup>Department of Oncology, University of Oxford, Oxford, United Kingdom ; <sup>2</sup>McGill University, Medical Physics Unit, Montreal, Canada ; <sup>3</sup>McGill University, Radiation Oncology Division, Montreal, CANADA; <sup>4</sup>University of Michigan, Department of Radiation Oncology, Ann Arbor, USA

#### Abstract text

Radiation-induced toxicities are the unavoidable result of damage to healthy tissues that surround solid tumours and directly limit the ability of clinicians to achieve local tumour control. Clinically, they present as acute events, becoming manifest and subsiding within days-to-weeks, or as late effects, in which case disease onset can take years. In this work, we integrate clinical risk factors, radiotherapy treatment plan parameters, and patient specific biological variables together to construct models that more accurately predict such side effects. We make use of a well-established data-driven modelling approach based on logistic regression and optimised specifically for radiotherapy-related data-mining.

We identified a cohort of 100 patients that underwent curative hypofractionated radiotherapy to the prostate (66 Gy in 22 fractions) and retrospectively genotyped for gene dosage (copy numbers) and nucleotide polymorphisms in six different genes reported previously to be involved in response to radiotherapy: XRCC1, XRCC3, ERCC2, SOD2, VEGFA and TGFB1. Predictive models of both late rectal bleeding and erectile dysfunction, two dose limiting side effects of prostate cancer radiotherapy, were identified and cross-validated. The best performing multi-metric models contained dosimetric and biological variables, reflecting the interlinked biophysical nature of late radiation-induced toxicities. Notably, the copy number of DNA repair gene XRCC1, acting via the base excision repair pathway, and TGFB1, a key player in modulating inflammation and matrix remodelling, were found to be valuable predictive markers.

Taken together, we demonstrate that the inclusion of patient-specific mutations in DNA repair genes coupled with dosimetric parameters derived from patient-specific radiotherapy treatment plans provides a significant improvement over non-biological models. We accomplished this using an automated data-mining framework able to deal with clinical, biological, and treatment-related radiotherapy data simultaneously. In

the future, similar frameworks are likely to be used by clinicians to dose-escalate patients at low-risk and reduce the dose for high-risk patient groups.

#### SP-0012 Impact of AI and automation on practice

L. Tagliaferri<sup>1</sup>

<sup>1</sup>Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Radiation Oncology Department - Gemelli ART Advanced Radiation Therapy, Rome, Italy

#### Abstract text

Radiotherapy is involved in 45-55% of newly diagnosed cancer but also in the advanced stage disease thanks to the efficacy in the durable palliation and pain control. However, RT requires training and quality assurance[1] as it is a technologically complex advanced treatment[2]. To meet these needs, there will be an increased request of radiation therapy infrastructures and staffing but also the need to introduce Intelligence Artificial Guided Procedure (IAGP) and Automation in the clinical practice. The impact of this introduction will not be negligible, and it could improve overall health care quality thanks to the support of big data[3], deep learning[4], algorithmic innovation and powerful neural network models[5]. Automation using artificial intelligence is systematically involved in several fields of cancer care and, more specifically, in the radiation treatment workflow[6]. Many software aiming to improve and speed up the “contouring process” through autosegmentation[7] solutions have been released in the last years. Auto-segmentation also allows to perform the adaptive re-planning procedure during treatment[8]. Treatment planning step is also a very time-consuming task and the quality of its output is based on the physicist’s and physician’s knowledge and expertise. There is variability in this field, not only across centers, but even in the same center due to the presence of different planners. Inverse planning optimization and automated knowledge-based treatment planning approaches[9][10] improve the speed of the process and ensure that the quality of the results is optimal and not treatment planner dependent. Many AI applications have also been introduced in the radiation delivery process. Many technologies can indeed check the exact location of the target and the organs at risk improving the quality and speeding up the procedure of patient repositioning[11] and the radiation delivery[12]. Recently, Decision Support Systems (DSS) are spreading more and more: the implementation of large database and radiomics[13] provides physicians a huge amount of data that can improve clinical practice through the use of predictive models[14] and reduce the impact of knowledge gaps between domain-specific experts and non-experts[15] aiming to improve personalized cancer care. Aim of this talk is to present and discuss how the introduction of Intelligence Artificial Guided Procedure (IAGP) and Automation could impact the clinical practice and the radiotherapy workflow, especially in the fields of contouring and treatment planning, quality assurance, radiation delivery and clinical outcomes recording and prediction. It will be also analyzed how, thanks to the minimum human intervention and automatically error detection systems, automation could also provide a reduction in cure costs[16] and an escape from time-consuming repetitious tasks with significant advantages for the physicians and consequent of more time to dedicate to interaction with patients, increasing the level of humanity and patients care perception quality.

**SP-0013 Linking radiation-induced damage to systemic effects: what can we learn from preclinical models of normal tissue complications**

V. Jendrossek<sup>1</sup>

<sup>1</sup>University Hospital Essen, Institute of Cell Biology Cancer Research- Department of Molecular Cell Biology, Essen, Germany

**Abstract text**

Radiotherapy (RT) is part of standard treatment for lung cancer patients but disease progression is common. Herein biological factors such as high intrinsic or microenvironment-mediated radiation resistance of the cancer cells and potentially tumour immune escape limit successful RT or combined radiochemotherapy (RCT). Moreover, adverse late effects in the highly radiosensitive normal lung preclude the use of curative doses leading to decreased quality of life or - as a consequence of treatment with suboptimal radiation doses - to fatal outcomes by local recurrence or metastatic disease. Historically, RT has been introduced as a highly efficient and spatially accurate local therapy. But under certain conditions RT can also elicit systemic effects that impact treatment outcome in normal and tumor tissues locally and occasionally at non-irradiated tumour sites outside the radiation field (abscopal effects). Elegant work in preclinical models in mice has demonstrated that the systemic effects of ionizing radiation are immune mediated. Further experimental work has helped to substantially advance our understanding of the contribution of radiation-induced immune changes in the pathogenesis of radiation-induced adverse late effects e.g. in the lung. The presentation will introduce the molecular and cellular processes that link radiation-induced DNA-damage to activation of cells from the innate and adaptive immune system, highlight the dual face of radiation-induced acute and chronic immune changes in normal and tumour tissues, and discuss the importance of dose and fractionation for RT-induced immune changes. Finally, the presentation will discuss the use of radiation-induced immunoregulatory mechanisms as therapeutic targets that may allow to limit RT-induced adverse late effects and to increase the therapeutic gain of RT. Such compounds may be of future clinical relevance in view of the increasing interest in combining RT with immune checkpoint blockade or other immune modulators to enhance the immune response against the tumour.

**SP-0014 New developments in small animal image guided radiotherapy: Bladder cancer**

A. Kiltie<sup>1</sup>

<sup>1</sup>CRUK/MRC Oxford Institute for Radiation Oncology, Dept. of Oncology, Oxford, United Kingdom

**Abstract text**

Muscle-invasive bladder cancer can be treated clinically by bladder removal (cystectomy) or bladder preservation, where the patient keeps their native bladder. Trimodality therapy, with complete transurethral resection of the tumour followed by concurrent chemoradiation, with or without neoadjuvant chemotherapy is the current standard of care, although many elderly patients receive only radiotherapy alone, due to the toxicity of current radiosensitising agents. There is therefore an urgent need

to find agents less toxic to the normal tissues. Preclinical studies are useful in this regard and use of image-guided radiotherapy in small animals allows the treatment to more closely mimic the radiotherapy delivered in human patients.

We have used our small animal radiation research platform (SARRP) to both treat orthotopic tumours in the bladder and to investigate normal tissue toxicity. As longer term *in vivo* studies of bladder cancer irradiation are hampered by the need to avoid small intestine, we have developed a method of irradiating bladder and large intestine/rectum only by treating the mice head down, which employs gravity to move the small intestine from the radiotherapy field. Image guidance allows us to verify that there is no small intestine in the proposed field.

We also use image guidance to treat mice for longer term toxicity studies, which include histological endpoints in the bladder and intestine evaluated by a veterinary pathologist and also functional assays including stool assessments.

Much of this work has only been made possible with the advent of small animal image-guided radiotherapy.

**SP-0015 RBE of protons: what can we learn from preclinical models?**

C.P. Karger<sup>1</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Department of Medical Physics, Heidelberg, Germany

**Abstract text**

Proton therapy allows highly conformal tumor irradiation and thereby sparing of neighboring healthy tissues. Compared to photon treatments, proton irradiation exhibit a higher biological effectiveness, which is currently considered by a fixed RBE of 1.1. Recent *in-vitro* data, however, indicate that the RBE at the distal edge of the Bragg-peak may increase up to values of 2 [1] and beyond and models have been developed [2-5], which describe this increase as a function of LET, dose and cell-specific parameters. This increase could potentially increase the risk of side effects in normal tissue structure behind the distal edge of the spread-out Bragg-peak. While the clinical relevance and the need to introduce these models in patient treatments is controversially discussed [6, 7], strong supportive data from *in-vivo* experiments and patients are still lacking. This presentation gives an overview on existing data in animal models and discusses their impact and limitations on clinical conclusions. The needs for further research will be outlined.

**SP-0016 Dynamics Changes in Immune Cells During Glioblastoma Response to Treatment: Macrophages at Play**

L. Akkari<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Tumor Biology and Immunology, Amsterdam, The Netherlands

**Abstract text**

New insights into the role of innate immune subsets in cancer requires a thorough investigation of the molecular mechanisms responsible of their evolution in the course of

malignancy and therapy response, in order to effectively harness their anti-cancer potential. This is particularly relevant to late-stage and recurrent disease which are refractory to standard of care treatment, do not respond to targeted or T cell immunotherapy and that are consequently fatal. Glioblastoma (GBM) is such a cancer type, and the most malignant form of primary brain tumor in the central nervous system. Despite aggressive standard of care treatment, the median survival of GBM patients does not exceed 15 months. Tumor-associated macrophages/microglia (TAMs) are the most abundant non-cancerous cell types in human and murine GBM. Using murine models of GBM in which we examined the relative contribution of TAM, we found that radiotherapy alters infiltrating bone marrow-derived macrophages (BMDM) and brain-resident microglia (MG) content and phenotype. These cells undergo profound proteomic and transcriptional changes in the treated GBM tumor immune microenvironment, and support radiotherapy resistance and relapse. We demonstrated that the convergence of MG and BMDM phenotype at recurrence relies on acquisition of neurodegenerating signals within the TIME, with activation of the Notch and TGF $\beta$  pathways at its core. Limiting the acquisition of this recurrent signature in both BMDM and MG led to enhanced radiotherapy response and delayed recurrence in multiple GBM murine models. We propose that dampening the dynamics of macrophage subpopulation phenotype in GBM post treatment may be a fundamental step to take in combinatorial therapy.

**SP-0018 Optimal management of patients with unresectable stage III NSCLC: areas of controversy and ongoing research**

R. Dziadziszko<sup>1</sup>

<sup>1</sup>Medical University of Gdansk, Dept. of Oncology and Radiotherapy, Gdansk, Poland

**Abstract text**

Results of definitive treatment of patients with unresectable stage III NSCLC have changed favourably over the last decade. With more precise imaging, invasive staging, 4D-CT treatment planning, and image-guided treatment delivery, concurrent radiochemotherapy protocols lead to median survival of approximately 24 - 30 months and 5-year survival probability of approximately 30 - 35%. These indices are further improved with integration of consolidation immunotherapy as demonstrated in the PACIFIC trial with PDL1 inhibitor durvalumab. Further progress in this field is likely to result from improvements in both local and systemic therapies. Old dose/volume/fractionation research questions need still to be re-evaluated from the perspective of optimisation of local control versus toxicities. Most effective hypofractionation protocols and perhaps different radiotherapy doses to primary tumour and mediastinal lymph nodes are the key research questions. More research focus on late toxicity, particularly cardiac and pulmonary, is needed as our patients live longer and are more likely to experience this toxicity. Systemic research trials are designed to test the use of different immune checkpoint inhibitors as consolidation treatment with concurrent, sequential or even exclusive radiotherapy in properly selected patient subsets. Further

improvement is likely to occur with integration of novel immunotherapy agents, including multiple checkpoint inhibitors, personalised cancer vaccines, and other immune response modifiers. Tissue and blood-based biomarker data are needed to better understand how to personalise consolidation therapies most effectively.

**SP-0019 Active management of patient's comorbidities (including respiratory and cardiac comorbidities)**

V. Westeel<sup>1</sup>

<sup>1</sup>Hôpital Univ. Jean Minjot, Chest Disease Department, Besançon, France

**Abstract text**

The prevalence of comorbidity is high in lung cancer patients, up to 50 % in non-surgically treated patients. Pathologies, which share the same risk factor, smoking exposure, and diseases at increased risk after 70 years are particularly frequent in patients diagnosed with lung cancer. Chronic inflammation is also considered to contribute to lung cancer carcinogenesis in several comorbidities, such as COPD and cardiovascular diseases (CVDs). Because standard therapy includes chemotherapy, radiotherapy and immunotherapy in PD-L1 $\geq$ 1% NSCLC, many comorbidities can interfere with treatment decision.

**Pulmonary comorbidity**

Several lung diseases are associated with an increased risk of lung cancer. COPD is reported in approximately 50% of patients with NSCLC, including patients treated with chemo-radiotherapy. COPD is a risk factor for lung cancer, independent of smoking history, with COPD smokers five times more likely to develop lung cancer than smokers without COPD. Bronchiectasis has also been reported as an independent risk factor of lung cancer, because of recurrent microbial infections. Diagnosis of obstructive bronchial disease relies on spirometry to measure the FEV1 and the diffusing capacity for carbon monoxide. Therapeutic management can include smoking cessation, pharmacologic treatments, oxygen therapy and noninvasive ventilation, and early treatment and prevention of exacerbations (influenza and pneumococcal vaccination) and pulmonary rehabilitation ([www.goldcopd.org](http://www.goldcopd.org)).

Several studies suggest an association between interstitial lung diseases (ILDs), particularly pulmonary fibrosis, and lung cancer. Treatment-related mortality and the risk of radiation pneumonitis are high in patients with ILD. Therefore, the diagnosis should not be ignored and the benefit of radiotherapy carefully considered, taking into account this high risk of toxicity and patient prognosis.

**Cardiovascular diseases**

Cardiovascular diseases (CVDs) are observed in approximately 25% of patients and represent the first cause of non-cancer death, in locally advanced NSCLC. Heart failure and cardiac arrhythmia are predictive of cardiac complications after chemo-radiotherapy. Heart failure, myocardial infarction and cardiac arrhythmias are associated with decreased survival rates in patients treated with chemoradiation for stage III NSCLC, while hyperlipidaemia might have a protective effect. Beside diagnosis and optimal treatment of CVDs, treatment adaptations may be necessary. Cisplatin, which requires large hydration cannot be used in patients with pre-existing reduced LVEF.

**Other comorbidities**

Chronic renal disease is common in patients with lung cancer and impacts both systemic treatment and survival. The choice of the chemotherapy regimen and dose calculation should be adapted according to the glomerular filtration rate, using carboplatin rather than cisplatin, avoiding pemetrexed...(1)

Infections, especially hepatitis B and HIV infection need to be diagnosed before treatment for stage III NSCLC. Cytotoxic chemotherapy can be responsible for HBV

reactivation, which can be avoided with antiviral prophylaxis. People living with HIV are at high risk of cancer, and especially lung cancer. There are specific guidelines for the management of patients with HIV and cancer (2).

Diabetes mellitus is associated with higher mortality in patients with lung cancer, increasing the risk of cardiovascular and infectious events. Complications of diabetes, such as chronic renal insufficiency and peripheral neuropathy can interfere with the treatment of lung cancer. Frequent need for corticosteroids during chemotherapy requires closed monitoring of glycaemia. Adjuvant durvalumab after chemoradiotherapy has been shown to improve overall survival in stage III NSCLC. Autoimmune diseases or diseases requiring immunosuppressive therapy (including corticosteroids > 10 mg/day) and ILD can preclude their use.

The comorbidity burden of patients with stage III NSCLC is high, with a variety of diseases and a frequent association of several comorbidities. A thorough work-up of patients exploring these comorbidities is needed before treatment decision, which should be best taken after treatment optimization of all comorbidities within a multidisciplinary setting

<sup>1</sup>University of Münster, Department of Radiation Oncology, Münster, Germany

#### Abstract text

Thomas Hodgkin was the first who described the disease in 1832 in his publication entitled "On some morbid appearances of the absorbent gland and spleen". Nowadays Hodgkin's Lymphoma has rendered to one of the best curable malignancies. The treatment of patients in early favorable and early unfavorable consists of chemotherapy followed by Involved-Site Radiotherapy (RT). Patients in advanced stages are treated with intensified chemotherapy and PET-guided radiotherapy. Due to optimized chemotherapy regimen and modern RT Overall Survival (OS) is up to 96,8% for patients in early favorable stages, 94,5% in early unfavorable stages and 95,3% in advanced stages. The development of RT within the past decades is remarkable. Field designs and radiation techniques changed dramatically throughout the years. In early favorable stages RT-dose decreased to 20 Gy Involved-Site RT and in early unfavorable stages the dose is 30 Gy. The recently completed trials conducted by the EORTC and the GHSg tested whether RT can be

omitted in patients with a PET negative result after chemotherapy. The final results from these studies showed, that patients who received chemotherapy only due to a negative PET had a worse PFS. Therefore the combined modality approach remains the standard of care for patients in early stages.

#### SP-0025 Evidence for image guided adaptive brachytherapy in primary vaginal cancer

H. Westerveld<sup>1</sup>

<sup>1</sup>Amsterdam UMC AMC, Radiation Oncology, Amsterdam, The Netherlands

#### Abstract text

Primary vaginal cancer (PVC) is a very rare disease. In most cases, definitive radiotherapy (external beam radiotherapy (EBRT) followed by a brachytherapy (BT) boost) combined with chemotherapy is the treatment of choice. PET (CT), ultrasound and MRI can all play a role in the diagnostic work-up, response assessment and planning of the EBRT and BT in PVC cases. However, due to its superiority of soft tissue contrast and the possibility of functional imaging, MRI is the best image modality in the diagnostic process and for delineation of the target at time of treatment. Due to its rarity, only limited data are available about the use of image guided adaptive brachytherapy (IGABT) in primary vaginal cancer. Most studies include small retrospective series of patients that have been included over a long period of time. The studies can be categorized in two groups with regard to the treatment technique. One group includes older studies where patients have been treated with 2D radiograph-based BT. The other group includes more recent monocenter studies where patients have been treated according to a 3D BT target concept adopted from GEC-ESTRO recommendations for cervical cancer. Although these 3D studies are very small, results are promising showing better local control without additional morbidity. Recently, a retrospective multicenter study was conducted to assess the outcome of patients treated for PVC with IGABT, defined by the use of MRI at time of brachytherapy. At a median follow-up of 29 months (range 3-167), the 3 years local control rate was 82%. Improved local control was found in patients with T2-4 tumor if >80

Gy was delivered to the CTV. In summary, more evidence is coming for the need of image guided adaptive brachytherapy, preferably with MRI, in primary vaginal cancer. A prospective multicenter study is warranted to gain more knowledge about this rare disease.

**Abstract text**

While large prospective experiences with image guided adaptive brachytherapy (IGABT) are accumulating in definitive cervical cancer treatment there is more limited information on the impact of IGABT in the definitive management of vaginal cancers. There is no consensus regarding the ideal dose, definition of the high-risk clinical target volume, or definition of organs at risk (OAR) such as the vagina. The purpose of this talk is to review the literature from North America regarding IGABT for primary vaginal cancers with respect to dose, target/OAR definitions, and clinical outcomes. We will compare the North American experiences with those from Europe and finally review the North American experience with trying to find consensus regarding target definition.

E.M. Vasquez Osorio<sup>1</sup>

<sup>1</sup>The University of Manchester, Division of Molecular & Clinical Cancer Studies- School of Medical Sciences- Faculty of Biology- Medicine and Health, Manchester, United Kingdom

**Abstract text**

Adaptive radiotherapy relies on fast identification of the structures (targets and organs at risk) on the daily image to adapt the treatment plan according to the patient's anatomy on the day of delivery. Two main alternatives for identifying these structures are 1) propagation of contours from the planning image (CT scan/MR scan) into the daily image and 2) generating contours from scratch on the daily image. Contour propagation is the most commonly used and it is implemented in clinical adaptive pathways. No matter how the contours are created, they are manually

edited, which is very time consuming. This delay could compromise the treatment efficacy due to intra-fractional anatomical changes happening while the patient is lying on the couch.

The question to be addressed in this talk is how we could perform quality checks on the daily contours to guarantee safe treatment delivery. To elaborate on that, metrics used to assess contour quality will be discussed, as well as the link between geometry and dosimetry to determine the areas where contours need to be more accurate. For contours propagation, strategies specifically defined for adaptive pathways will be discussed; and general issues with contour generation will be considered.

**SP-0031 QA of deformable image registration**

Marc Kessler<sup>1</sup>

<sup>1</sup>University of Michigan, Radiation Oncology, Ann Arbor, USA

**Abstract text**

Combined hardware and software systems are now available at the treatment unit to support daily dose assessment and enable on-line adaptive radiotherapy using image registration and data fusion to propagate contours and accumulate dose across image data acquired throughout patient treatment. The goal of these systems is to provide up-to-date estimates of anatomical changes and delivered dose. This information aids in the detection of changes that may demonstrate a clinical need to modify the original treatment plan or prescription.

As the output of the image registration process is always used as the input of another process for planning or delivery, it is important to understand and communicate the uncertainty associated with this process, both in general and for a specific registration. Unfortunately, there is no standard mathematical formalism to perform this analysis in actual clinical situations where overall uncertainty conflates image noise and distortion with underlying algorithm bias and complex anatomical variations. Validation of registration performance is also complicated by the lack of documentation available for commercial systems leading to use of these systems in a less-than-desirable 'black-box' fashion.

In view of this situation and the central role that image registration and data fusion play in various clinical workflows, the Therapy Physics Committee of the American Association of Physicists in Medicine commissioned Task Group 132. The resulting report reviews current approaches and solutions for image registration and provides recommendations for quality assurance and quality control of these clinical processes. These recommendations and examples of their use for on-line adaptive radiotherapy will be presented.

**SP-0032 QA of on-line adaptive radiotherapy: Experience of The Royal Marsden Hospital**

S. Nill<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom

**Abstract text**

In room MR image guidance enables the online adaptation of treatment plans based on the current patient anatomy while the patient is on the treatment couch. Therefore conventional methods like pre-treatment plan QA using a phantom to validate the treatment plan are no longer applicable.

In 2016 The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research installed the Elekta Unity system and the first patients were treated in September 2018. The Elekta Unity system consists of a 1.5T MR

scanner and a state of the art linear accelerator. During the commissioning and implementation phase of the MR Linac a series of programs and methods were developed to replace the traditional pre-treatment plan QA approach. This includes the commissioning of a non Monte Carlo dose engine within a second commercial planning system to perform the independent monitor unit check. A high degree of automation and integration is desirable to enable the operator to perform a comprehensive QA of the new treatment plan within the limited time available. While a strong focus of these checks will be on the dosimetric aspects other issues like contours and data transfer error must not be neglected. Within this presentation the methods developed at the RMH/ICR to tackle online plan QA will be presented.

**SP-0033 QA of on-line Adaptive Radiotherapy: Washington University Experience**

S. Mutic<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Department of Radiation Oncology, St. Louis, USA

**Abstract text**

Adaptive radiotherapy (ART) has been a concept for a long time but has become a practicality just in the past few years. This is especially the case for online ART. The online ART has been defined in many different ways and for the purposes of this presentation the online ART consists of 1) Daily volumetric patient imaging, 2) Creation of contours on the images of the day, 3) Creation of a new plan on contours of the day, including full IMRT optimization, 4) Review of the plan, 5) QA with the patient on the table, and 6) patient treatment with the new plan based on the daily anatomy and contours. It is worth noting that the desired time for this entire procedure should not add much time (minutes) to typical radiotherapy treatment appointments. While the main obstacle to practical online ART have been technological limitations, there are also operating paradigms that need to be evolved to enable practical online ART. One of the paradigms that needs to evolve is patient specific QA. While many will equate patient specific QA to IMRT QA, the QA for online ART has many more components. The online ART includes evaluation of daily imaging, contour accuracy, any image registrations or contour propagations, evaluation of clinical and technical integrity of the daily plan, evaluation of deliverability and safety of the daily plan, etc. While most, if not all, of these steps are performed with conventional radiotherapy and offline ART, the unique challenge of online ART is that all of these tests plus the treatment planning process have to be performed in minutes versus hours to days that are used in conventional and offline ART. In addition, during the entire time that planning and QA are performed the patient is on treatment table making any measurement based QA impractical. The needed speed for online ART QA and inability to follow conventional processes mandates reconsideration of conventional patient specific QA paradigms. This presentation is intended to provide systematic analysis of concepts for online ART QA, describe deployment of these concepts in a clinical setting, and description how lessons learned may affect future developments in this area. Learning Objectives: After this presentation, the audience should be able to 1) Describe systems based approach to design of online ART QA2) Describe practical considerations for online ART3) Understand direction in online ART QA as this procedure becomes more prevalent.

**Abstract text**

Clinically, the Relative Biological Effectiveness (RBE) of protons compared to photons is 1.1. However, there is considerable variance between the experimental studies informing this value. It has been shown that RBE is not constant but instead depends on many factors, including dose, Linear Energy Transfer (LET) and cell type. Most studies on proton RBE have concentrated on phenomenological modelling based on linear energy transfer (LET) and parameters derived from the linear quadratic model fitted to cell survival. We have taken a different approach, centred on mechanistic mathematical models. Detailed models of the cell and its DNA are constructed in Geant4-DNA where the DNA volume energy depositions, resulting from radiation track-structure, are recorded. Mechanisms of direct and indirect DNA damage are incorporated by simulation and comparison to experimental data in the literature. Predictions of both the position and complexity in DNA damage are then passed to our model of DNA repair, named DaMaRiS, which incorporates both non-homologous end joining (NHEJ) and homologous recombination (HR). Here, predictions are made on the kinetics and fidelity of repair at various time points. We show preliminary results, which integrate mechanistic mathematical models of DNA damage and repair in the Eclipse™ Treatment Planning System (TPS). We score the dose and LET in each voxel and, using the previously established correlations, convert the scored parameters into biological predictions, specifically the yield of residual and misrepaired DSBs, which can be anatomically mapped. Predictably, residual DSBs across the LET and dose range dominate the biological outcome. The model shows a slight increase in complex damage with LET, i.e. with depth in the patient. We also predict that the increased LET produces more proximal Double Strand Breaks (DSBs), which increased misrepair events between DSBs. These maps can potentially provide valuable information to the clinician by allowing identification of regions of heightened biological effect (and are a step towards biologically augmented radiotherapy).

**SP-0035 Developing metrology support for biologically relevant dosimetry**

H. Rabus<sup>1</sup>

<sup>1</sup>Physikalisch-Technische Bundesanstalt PTB, Radiation Effects, Braunschweig, Germany

**Abstract text**

A number of radiation modalities require weighting factors applied to absorbed dose to account for the biological effectiveness of the particular radiation quality. Examples include proton and ion beams as well as kilovoltage X-rays [1-3]. Micro- and nanodosimetry have been developed to provide radiation quantities that capture the influence of the stochastic nature of radiation interactions and, hence, the properties of different radiation qualities responsible for their different relative biological effectiveness. The European Joint Research Project BioQuaRT (Biologically weighted quantities in radiation therapy) [4-6], funded within the European Metrology Research Programme [7], created a metrological basis for radiation quantities integrating properties of particle track structure and biological radiation effects (Fig. 1).

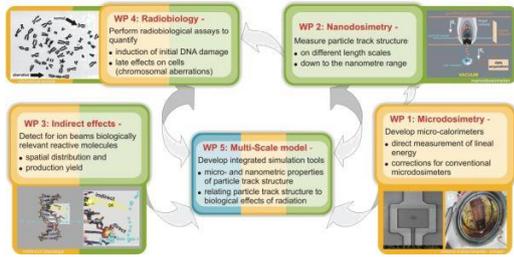

Fig. 1: The BioQuaRT multi-disciplinary approach.

Apart from findings like a simple correspondence between cellular biological endpoints and nanodosimetric parameters of track structure [8], BioQuaRT also came up with novel metrological approaches to radiobiological assays [9-13]. The increasing use of biological assays in radiology [14] and the long-term aim of biology-based treatment planning in radio-oncology require developing a metrological fundament for radiobiology. As the challenges involved require resources and skills beyond those presently available at Metrology Institutes, an initiative has been formed to establish a European Metrology Network (EMN) on Ionizing Radiation Effects within the European Association of National Metrology Institutes (EURAMET).

Such an EMN would link to existing networks in biological dosimetry [15] and would follow a strategic agenda for which four main topics have been identified in stakeholder consultations [16-17]: First, research towards identifying which microdosimetric or nanodosimetric radiation quantities best correlate with radiobiological effectiveness and the development of detectors for their primary realization as well as for practical measurements in clinical practice (Fig. 2). Second, measurements supporting uncertainty assessment and validation of numerical tools, e.g. Monte Carlo track structure codes, used in radio-oncology research. Third, metrology supporting the improvement of radiobiological assays in terms of reliability, reproducibility, solid measurement uncertainty assessment and model-based data interpretation. Fourth, cross-cutting the three aforementioned lines, standardization of procedures and development of tangible as well as written standards.

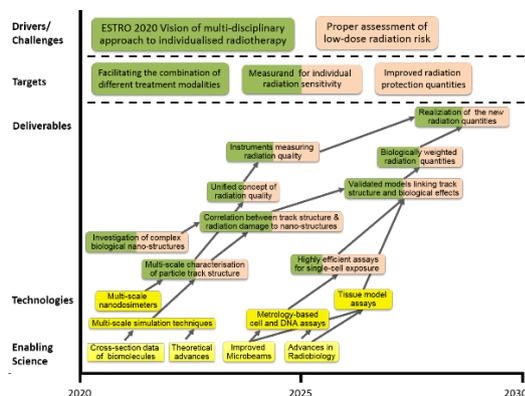

Fig. 2: Draft roadmap of the first EMN topic.

**SP-0036 Understanding biological response**

B.S. Sørensen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Exp. Clin. Oncology, Aarhus C, Denmark

**Abstract text**

There are a number of biological characteristics that have been shown to influence differences in response to radiation for both the tumor and the surrounding normal tissue. These characteristic includes intrinsic radiosensitivity, hypoxia, HPV status, number of cancer stem cells (CSCs), and repopulation between radiotherapy fraction. In the last 20 years, significant progresses in the knowledge of the biological factors influencing radiation response and the causative molecular basis, such as the DNA-damage response and repair mechanisms, signaling pathways and tumor microenvironmental factors, have been made, which both has impact for therapeutic possibilities and has also generated a large number of potential biomarkers.

The issue of biological response becomes more complicated when considering particle radiation. Protons and high LET radiation have a higher relative biological effectiveness (RBE), but RBE is a complex quantity, depending on both biological and physical parameters. RBE is often established as measured by cell death, but emerging evidence also demonstrate an altered response in the surviving cells. This is both evident for high LET radiation and for proton radiation. This differential biological effect is not only relevant in the tumour, but also in the normal tissue. Current research in particle radiobiology is, in addition to the RBE, focusing on the

molecular tissue response, and on the signalling pathways. Studies indicate a differential DNA damage response (DDR) following high LET irradiation, with the double strand breaks DSB preferentially repaired by homologous recombination (HR), leading to an increased level of unrepaired damage, which is reflected in the RBE. This change in DDR may also lead to a differential response in cellular processes downstream of the DNA repair.

**SP-0037 Implementation of nanodosimetric based radiobiological models in treatment planning systems**  
F. Villegas<sup>1</sup>

<sup>1</sup>*Uppsala University, Immunology- Genetics and Pathology, Uppsala, Sweden*

**Abstract text**

Modelling for prediction of relative biological effectiveness (RBE) is a fast-growing research topic within hadron therapy. Carbon ion treatment centers have been at the forefront in the use of RBE models in treatment planning systems (TPS). However, the current exponential expansion of proton therapy seen in the last decades implies questioning of the convention of applying a constant RBE of 1.1 in clinical practice. Several planning studies have shown that proton treatments considering the expected biological outcome per tissue type and particle energy could reduce the side effect risk and increase the probability for tumour control. Unfortunately, the prediction accuracy of the radiobiological models used for optimization has been limited as correlations between simple macroscopic characteristics of the radiation (e.g. physical dose or linear energy transfer) and biological endpoints (e.g. cell survival) are not univocal. A key to strengthen the prediction power is to use nanoscopic properties of the radiation which characterize the textures of the radiation's energy deposition discrete events at the scale of biomolecules (e.g. DNA) directly causing the biological damage. Advancements in experimental and computational nanodosimetry have pushed forward the search for an operational and measurable nanodosimetric quantity capable of RBE prediction. The frequency of cluster size is a promising property upon which published phenomenological models have been based; although the cluster scoring is still a matter of debate whether it be inside a predefined volume [1] or be free from volume [2]. Multiscale energy deposition distributions have also been used for building mechanistic models such as the NanOx model [3] which elegantly incorporates the chemical stages of DNA damage. Regardless of the model, issues concerning benchmarking and uncertainty assessments of Monte Carlo simulations involved need to be addressed first. Validated computational tools can then simulate clinical beams to fully characterize them down to a nanometer level. Such dosimetric charts are the key to bypass the need for LET mapping used by existing TPS optimization engines. In parallel, another set of challenges need to be undertaken to produce a consistent and reproducible biological experimental database to aid the fine-tuning of both mechanistic and/or phenomenological models. Indeed, the fundamental parts towards an RBE optimized treatment planning are already in place thus the biggest challenge is to connect them through standardization processes which will not only make data transferable between facilities but also will help gain the trust of clinical community.

---

**SP-0038 Continuous Quality Improvement Strategies to Support Volumetric IGRT**

W. Li<sup>1</sup>

<sup>1</sup>*Princess Margaret Cancer Center, Department of Radiation Oncology, Toronto, Canada*

**Abstract text**

Technological advances in the field of Radiation Therapy enables online image guidance of patient setup, increasing the precision and accuracy of treatment delivery. Maintaining sustained excellence in an IGRT environment require various continuous quality improvement strategies ranging from education and staff training to development of departmental protocols, procedures, and processes. This presentation will focus on supporting RTT education and training at a large urban cancer centre in Ontario, from initial training strategies and current annual refresher approach (team based and eLearning module approach), to development and implementation of RTT led IGRT rounds, where challenging clinical cases are shared and discussed.

**Abstract text**

Introduction

Image guided radiotherapy (IGRT) is essential in modern radiotherapy. The primary function of image guidance is to confirm tumour positioning to accurately deliver the planned dose to the PTV. Here we present evidence of the further usefulness of these routine images in the calculation of delivered dose to the organs at risk (OARs).

Due to daily organ deformation and anatomical changes, the delivered dose to OARs can be different to planned dose. However, provided that imaging protocol thresholds are met, this is generally not accounted for. Deviations from planned dose induce differences to the normal tissue complication probability (NTCP) since toxicity relates to dose actually delivered to the OAR. The hypothesis of the CRUK VoxTox research programme (UK CRN ID 13716) is that delivered dose can be a better predictor of toxicity than planned dose. Tracking motion-inclusive daily delivered dose allows us to build a more accurate picture of the total accumulated dose received by the OAR. By constructing NTCP models based on delivered dose, the ultimate aim is to identify patients on-treatment who are at increased risk of toxicity, for selectively targeted adaptive radiotherapy.

**Material and Methods**

Daily MVCT scans were acquired for patients undergoing TomoTherapy for prostate cancer (n = 528), head & neck (H&N) cancers (n = 319), and cancers of the CNS (n = 26). Here we focus on the former two cohorts. Automation was vital for large scale processing of over 26,000 MVCT scans, and multidisciplinary expertise spanned engineering,

mathematics, high energy, medical physics and radiation oncology, at the University of Cambridge and Cambridge University Hospitals.

Autosegmentation algorithms were applied for identifying the rectum in prostate radiotherapy (Chan-Vese), and the swallowing OARs (parotids and submandibular glands, pharyngeal constrictors, oral cavity and supraglottic larynx) in H&N radiotherapy (Elastix). CheckTomo, an independent dose calculation system for direct calculation on MVCT images, was integrated into the VoxTox automated processing system. Toxicity data were prospectively collected using electronic case report forms, and all coding to standard scoring systems was externally verified.

For accumulating delivered dose to the rectum, dose surface maps (DSMs) of the rectal wall were generated in order to conserve spatial dose features. Daily delivered DSMs were corrected for positional variations and differences in MVCT field of view, and accumulated. Final accumulated and planned DSMs were parametrised using equivalent uniform dose (EUD) and dose-widths (the lateral extent of an ellipse fitted to a given isodose). Associations with rectal bleeding (RB) at 2 years cumulative incidence were assessed.

For swallowing OARs, the difference between planned and accumulated dose were reported using mean dose. Univariate analyses were performed to assess correlations between baseline clinical factors, mean planned dose, and mean delivered dose, with three toxicity endpoints; xerostomia, salivary duct inflammation, and dysphagia.

#### Results

For a cohort of 109 prostate cancer patients, accumulated EUD to the rectal wall was systematically lower than planned EUD. Accumulated EUD was the strongest discriminator of RB (AUC 0.682). Spatial features of accumulated DSMs were more strongly associated with RB than those from planned DSMs for dose-widths up to 70 Gy. The accumulated DSM 65 Gy dose-width generated the strongest spatial correlation (AUC 0.664). The same trend was observed from a separate cohort of 140 patients in a subsequent analysis (accumulated EUD AUC = 0.651, 65 Gy dose-width AUC = 0.636). A multivariate NTCP model based on parameters of accumulated dose (incorporating baseline RB and previous pelvic or abdominal surgery) was more predictive of 1 year RB than planned dose (AUC 0.809 v 0.782). Model validation is underway.

Mean delivered dose was higher than mean planned dose for all OARs in a cohort of 141 H&N cancer patients. In addition to confirming previously reported relationships between concomitant systemic therapy and pre-treatment symptoms with toxicity 1 year post-treatment, results also suggest stronger associations with delivered dose than planned dose for all endpoints. For H&N patients receiving Proton Beam Therapy (PBT) this may be particularly important.

#### Conclusion

The unique VoxTox dataset exploits routine MVCT IGRT scans, already being acquired for the purposes of patient positioning, to calculate motion-inclusive delivered dose to OARs. Results suggest that associations between accumulated dose and toxicity are stronger than those from planned dose, and this has been verified in a separate cohort in the case of the rectum. Information on spatial dose features may reveal intra-organ radiosensitivities, which could be useful when identifying patients on treatment who would benefit from adaptive radiotherapy, and may also be relevant for patients receiving PBT.

#### PV-0041 Randomized therapeutic trial of combined pentoclo versus placebo in radiation-induced plexopathy

S. Delanian<sup>1</sup>, T. Maisonobe<sup>2</sup>, T. Lenglet<sup>2</sup>, D. Psimaras<sup>3</sup>, M. Resche-Rigon<sup>4</sup>, P. Pradat<sup>5</sup>

<sup>1</sup>Hopital Saint-Louis- APHP, Oncologie-Radiotherapie-Radiopathologie, Paris, France; <sup>2</sup>Hopital Pitié-Salpêtrière- APHP, Neurophysiologie, Paris, France;

<sup>3</sup>Hopital Pitié-Salpêtrière- APHP, Neurologie, Paris, France;

<sup>4</sup>Hopital Saint-Louis- APHP, Statistique, Paris, France; <sup>5</sup>Hopital Pitié-Salpêtrière- APHP, Neurologie, Paris, France

<sup>5</sup>Hopital Pitié-Salpêtrière- APHP, Neurologie, Paris, France

#### Purpose or Objective

Radiation-induced plexopathy (RIP) is a rare and severe peripheral nerve complication after RT for cancer, without any existing treatment that stabilize or slow down neurological progression. Preclinical and clinical studies showed that combined pentoxifylline-vitamin E treatment (PENTO) significantly reduced radiation-induced fibrosis, and that the combination with clodronate (PENTOCLO) allowed healing of progressive mandible osteoradionecrosis and a reduction of some neurological symptoms.

#### Material and Methods

We conducted a randomized, placebo-controlled, double-blind, monocentric trial in RIP patients. Subjects were screened among adults referred to Hôpital Saint-Louis, for limb RIP, after irradiation including axillar-subclavian (breast, lung) or lumbar-iliac lymph area (Hodgkin, seminoma, uterus), excluding recurrence with MRI and PETscan. Included patients were randomized for a daily oral 18 months treatment, in two arms, PENTOCLO (Pentoxifylline 800mg, Tocopherol 1000mg, Clodronate 1600 mg 5d/7) or triple PLACEBO.

Primary outcome measure at M<sub>18</sub> was the SOMA score quoting neurological symptoms divided in 3 domains: pain, paresthesia and motor disability. Secondary endpoints were sensitivity measures (pain - paresthesia VAS), motor function (ODSS, muscle testing), neurological examination, nine hole peg test/ timed 25-foot walk), quality of life (SF36, CGIC/PGIC); and electromyography.

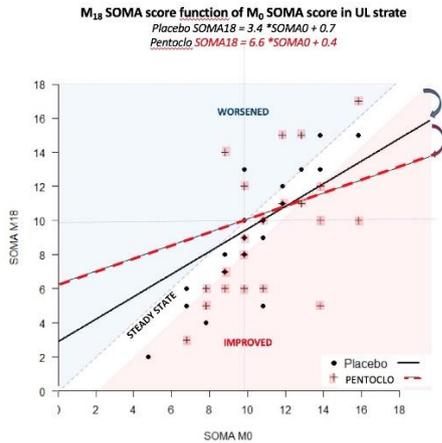

#### Results

Between 2011/03 and 2016/10, 59 patients were included (1 false inclusion developing neoplastic plexopathy): 29 in the placebo (P) group vs 29 in the active (A) group. 46 patients had upper limb RIP (mean 68y) and 12 lower limb RIP (59y), irradiated 26 ± 8y before, with neurological symptoms for 5 ± 5y. SOMA at M<sub>0</sub> was 9 (0-6-3 for each domain) in P vs 9 (1-6-3) in A, with severity bias in A group disfavor.

At M<sub>18</sub>, 51 patients (25 P vs 26 A) were analyzed (7 early discontinuations). No significant difference was observed at M<sub>18</sub> between P and A groups on the primary outcome: global SOMA 8.7 vs 8.8 (p 0.81) with a probable lack of sensitivity of our score. Secondary outcomes showed, in UL strata (figure), a trend for improvement of pain and paresthesia in A group, as assessed by the SOMA score subdomain for pain (1.22 in P vs 0.87 in A) and VAS paresthesia (4.4 in P vs 3.4 in A).

Adverse events were detected in 81% patients, but no difference was observed between the two groups. There was an unexpected excess of RI complications (30%) in both groups, while expected vascular and digestive complications were more frequent in A (+9%).

RIP natural history was lightened by an excess of vascular stenosis in UL stratum (60%), threatening in third, representing an unexpected neurological severity bias.

### Conclusion

This was the first randomized pharmacological drug trial in RIP. No significant therapeutic effect of PENTOCLO was detected. There is a need to develop more sensitive measures to detect the effect of investigational drugs in RIP.

### PV-0042 Radiation related lymphopenia as a predictor of locoregional recurrence in early breast cancer

O. Cho<sup>1</sup>, Y. Oh<sup>1</sup>, M. Chun<sup>1</sup>, O.K. Noh<sup>1</sup>, J. Heo<sup>1</sup>

<sup>1</sup>Ajou University Hospital, Radiation Oncology, Suwon City, Korea Republic of

### Purpose or Objective

Many studies reported that radiation related lymphopenia (RRL) was associated with treatment outcome in various cancers. However association between RRL and treatment outcome in early breast cancer (EBC) was rarely studied. This study aimed to investigate whether RRL could predict clinical outcome in EBC patients.

### Material and Methods

We analyzed 216 EBC patients (stage IA-IIB) treated with adjuvant radiotherapy (RT) after partial mastectomy from 2004 to 2012 in our institution using Kaplan-Meier plots and the Cox proportional hazards model. All patients did not receive chemotherapy. Peripheral absolute lymphocyte counts (ALCs) during two years after RT were collected from each patient. They were divided into pretreatment ALC (ALC0), ALC 3-5 months (ALC1), ALC 9-11 months (ALC2), ALC 15-17 months (ALC3), and ALC 21-23 months (ALC4) after RT.

### Results

ALCs after RT had a tendency of slow increase after rapid decline (median [range] ALC0 1847 cells/ $\mu$ L [623-4085], ALC1 1479 cells/ $\mu$ L [437-3500], ALC2 1626 cells/ $\mu$ L [775-3193], ALC3 1730 cells/ $\mu$ L [854-4408], and ALC4 1855 cells/ $\mu$ L [899-3793]). The 86 patients with ALC1 $\leq$ 1400 cells/ $\mu$ L had significantly lower 8 years locoregional control rate than 118 patients with ALC1>1400 cells/ $\mu$ L (80.5% vs. 98.3%,  $P=0.012$ ) while there was no difference in 8 years disease specific survival rate between two groups (98% vs. 97.1%,  $P=0.758$ ). Young age ( $\leq 40$  years), lymphopenia (ALC1 $\leq$ 1400 cells/ $\mu$ L), and high histologic grade were significant predictors of locoregional recurrence (LRR) in multivariate analysis (hazard ratio [97% confidence interval] 1.39 [1.18-13.7]  $P=0.026$ , 1.74 [1.21-26.8]  $P=0.028$ , and 2.3 [2.6-38.4]  $P<0.001$ ).

### Conclusion

Low ALCs 3-5 months after RT were associated with LRR in EBC patients. Therefore RRL could be a potential predictor for LRR of EBC.

### PV-0043 ESTRO guidelines for volume delineation for RT after immediate implant-based reconstruction

O. Kaidar-Person<sup>1</sup>, P. Poortmans<sup>2</sup>, B.V. Offeren<sup>3</sup>  
<sup>1</sup>Rambam Health Care Campus - Faculty of Medicine, Oncology Institute, Haifa, Israel; <sup>2</sup>Institut Curie, Radiation Oncology, Paris, France; <sup>3</sup>Aarhus University Hospital, Oncology, Aarhus, Denmark

### Purpose or Objective

on behalf of the ESTRO Working Group on Breast reconstruction and radiation therapy: a contouring project.

Immediate breast reconstruction is increasingly used after mastectomy, even if radiation therapy (RT) is indicated. Contouring guidelines in case of postmastectomy RT (PMRT) after implant-based immediate breast reconstruction are missing (IBR-i). We developed delineation guidelines based on a consensus between a global group of breast cancer experts.

### Material and Methods

After designing the project by the core group, an invitation letter was sent to an international multidisciplinary group of experts (including breast surgeons, radiation oncologists, and clinical oncologists) inviting them to participate in the consensus guidelines. The project included: a web-questionnaire, contouring exercise, group discussions, and literature review.

### Results

Based on mailings, the first contouring round, video conferences and a plenary discussion, guidelines are drafted to be validated in the prospective Danish DBCG RT Recon Trial randomising early breast cancer patients between immediate versus delayed breast reconstruction after mastectomy followed by loco-regional RT. Approximately 5-10% glandular tissue is retained after conventional total mastectomy, and more in cases of skin/nipple sparing mastectomy. Therefore, our recommendations include performing a careful evaluation of the patient using visualization/palpation, planning CT, and the extent of the contralateral breast (if intact), to determine the *cranio-caudal borders* of the CTV. The CTV includes the "residual breast tissue and the (subcutaneous) draining lymphatics", thereby excluding the implant. The location of the residual glandular tissue varies; in most cases it is found laterally in the breast, mainly in the "axillary-tail". We recommend consulting with the breast surgeon about the anatomical borders of the breast-skin. Moreover, in cases of a muscle flap/implant procedure, the transplanted flap including its overlaying skin is not part of the target volume, for which the scars should be marked for proper delineation.

The implant and the contralateral breast should be delineated on planning CT as well as all other organs at risk for treatment planning purposes.

Table 1: ESTRO delineation guidelines for the CTV in case of implant-based immediate breast reconstruction  
 Figure 1: Retro-pectoral implant. The CTV is delineated in pink.

### Conclusion

The use of target volume guidelines in the setting of IBR-i, based on recognised zones of tumour recurrence risk, aims to reduce inter- and intra-observer variation. They should be reserved for cases for which the disease staging (mainly T-stage) and surgical procedures used are well-defined. These guidelines are being validated in the DBCG reconstruction trial.

### PV-0044 Mastectomy or breast-conserving therapy for early breast cancer: outcome comparison of 7565 cases

S. Corradini<sup>1</sup>, M. Pazos<sup>1</sup>, D. Reitz<sup>1</sup>, S. Schönecker<sup>1</sup>, M. Niyazi<sup>1</sup>, U. Ganswindt<sup>1,2</sup>, F. Alongi<sup>3,4</sup>, M. Braun<sup>5</sup>, N. Harbeck<sup>6</sup>, C. Belka<sup>1</sup>

<sup>1</sup>LMU Munich, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>Medical University, Department of Radiation Oncology, Innsbruck, Austria ; <sup>3</sup>Hospital Sacro Cuore Don Calabria, Department of Radiation Oncology, Negrar, Italy ; <sup>4</sup>University of Brescia, Radiation Oncology, Brescia, Italy ; <sup>5</sup>Red Cross Hospital, Breast Centre, Munich, Germany ; <sup>6</sup>LMU Munich, Department of Obstetrics and Gynecology- Breast Centre, Munich, Germany

#### Purpose or Objective

Treatment of early stage breast cancer (BC) can be considered as a preference-sensitive care, where decision-making between treatment options can vary according to patient preferences. Typical factors that influence therapy choice in favour of mastectomy include: concerns about cancer recurrence or perceived consequences related to breast conserving surgery (BCT), including potential adverse effects of radiation therapy. Aim of the present study was to compare the oncologic outcome of mastectomy versus breast conserving therapy in patients treated in a modern clinical setting outside of clinical trials.

#### Material and Methods

Data were provided by the population-based Munich Cancer Registry. Between 1998 and 2014, all female patients diagnosed with early invasive BC (pT1pN0, pT2pN0, pT1pN1 and pT2pN1) and treated at two Breast Care Centres were included in this observational study. For comparison of the standard BCT and mastectomy approaches, we excluded patients with more than 3 positive lymph nodes (pN2) as postmastectomy RT (PMRT) would have been routinely recommended in these high-risk patients.

#### Results

The final study cohort consisted of 7565 women with a median follow-up of 95.2 months. After adjusting for age, tumour characteristics and therapies, Cox regression analysis for local recurrence-free survival identified BCS with RT as an independent predictor for improved local control (hazard ratio [HR], 1.476; 95% confidence interval [CI], 1.164-1.872, p<0.001) as compared to mastectomy without RT. Ten-year risk of local recurrences was 8.7% following BCS, compared to 14.8% in patients receiving mastectomy (p<0.001). Similarly, lymph node recurrences (10y LNR 2.4% vs 6.7%, p<0.001) and distant metastasis (10y DM 9.8% vs 15.2%, p<0.001) were more frequent in patients undergoing mastectomy only. This translated into an improved survival outcome among patients treated with BCS plus radiotherapy (10-year OS estimates 86.7% vs 77.6%, p<0.001), which was also significant on multivariate analysis (p=0.011).

#### Conclusion

In conclusion, the present study showed that patients treated with BCS followed by radiotherapy in clinical practice had an improved outcome regarding local control, distant control and overall survival as compared to mastectomy alone in a large cohort reflecting "real-life" clinical practice in this setting.

#### PV-0045 Is proton therapy a "pro" for breast cancer? A comparison of proton vs. non-proton RT using the NCDB

M. Chowdhary<sup>1</sup>, A. Lee<sup>2</sup>, S. Gao<sup>3</sup>, P. Barry<sup>1</sup>, R. Diaz<sup>4</sup>, N. Bagadiya<sup>5</sup>, H. Park<sup>3</sup>, J. Yu<sup>3</sup>, L. Wilson<sup>3</sup>, M. Moran<sup>3</sup>, S. Higgins<sup>3</sup>, C. Knowlton<sup>3</sup>, K. Patel<sup>3</sup>

<sup>1</sup>Rush University Medical Center, Radiation Oncology, Chicago, USA ; <sup>2</sup>SUNY Downstate Medical Center, Radiation Oncology, Brooklyn, USA ; <sup>3</sup>Yale School of Medicine, Therapeutic Radiology, New Haven, USA ; <sup>4</sup>Moffitt Cancer Center, Radiation Oncology, Tampa, USA ; <sup>5</sup>Emory University School of Medicine, Radiology, Atlanta, USA

#### Purpose or Objective

There is limited data demonstrating the clinical benefit of proton radiotherapy (PRT) in breast cancer. Here we investigate the impact of PRT on overall survival (OS) and evaluate predictors associated with PRT use for patients with breast cancer in the National Cancer Database (NCDB).

#### Material and Methods

Women with non-metastatic breast cancer treated with adjuvant radiotherapy from 2004-2014 were identified using the NCDB. Patients were stratified based on receipt of PRT or non-PRT (i.e. photons +/- electrons). A logistic regression model was used to determine predictors for PRT utilization. For OS, Multivariable analysis (MVA) was performed using Cox proportional hazard model. Subset analyses were performed for groups at risk for receiving higher heart dose.

#### Results

A total of 724,492 women were identified: 871 received PRT and 723,621 received non-PRT. 58.3% of the PRT patients were group stage 0-1. Median follow-up time was 62.2 months. On multivariate logistic analysis, the following factors were found to be significant for receipt of PRT (all p<0.05): academic facility (odds ratio [OR]=2.50), South (OR=2.01) and West location (OR=12.43), left-sided (OR=1.21), ER-positive (OR=1.59), and mastectomy (OR=1.47); pT2-T4 disease predicted for decrease PRT use (OR=0.79).

PRT was not associated with OS on MVA for all patients: Hazard Ratio: 0.85, p=0.168. PRT remained not significant on MVA after stratifying for subsets likely associated with higher heart radiation doses, including: left-sided (p=0.140), inner-quadrant (p=0.173), mastectomy (p=0.095), node positivity (p=0.680), N2-N3 disease (p=0.880), and lymph node irradiation (LNI) (p=0.767).

#### Conclusion

In this large national multicenter database, we found receipt of PRT to be associated with left-sided, ER+ tumors, mastectomy, South and West location, and academic facilities, but not higher group stages or LNI. PRT was not associated with OS, including in subsets likely at risk for higher heart doses.

In light of the high cost of proton RT, these data question the utilization of PRT, especially in early-stage patients with expected low heart doses, unless enrolled on a clinical trial.

### Purpose or Objective

Recently, overall survival gain from radiation therapy (RT) of the internal mammary nodes (IMN) was documented. IMN RT inevitably leads to more radiation dose to heart and lungs, thus often target coverage is compromised to meet constraints for doses to organs at risk (OAR). Here, doses to heart and lung are estimated when target coverage is not compromised in consecutive high-risk breast cancer (BC) patients. The aim is to establish dose cut-off points for selection of patients for proton therapy (PT) in the Danish Breast Cancer Group (DBCG) single-arm phase II trial.

### Material and Methods

179 BC patients treated with adjuvant loco-regional RT including the IMN from 18 European departments were included in the study. Each department included 5 patients with left-sided and 5 patients with right-sided BC. The prescription dose ranged from 39.9 Gy to 51.52 Gy in 15 to 28 fractions. Planning techniques included both conformal and several inversely optimized techniques (see Table 1). If the clinically delivered treatment plan did not comply with defined target coverage requirements, the plan was modified retrospectively for this study until sufficient target coverage was reached by allowing OAR constraints to be exceeded. Sufficient target coverage was in this study defined as: V90%  $\geq$  95% of CTV<sub>IMN</sub>, V90%  $\geq$  95% of CTV<sub>n</sub> and V95%  $\geq$  95% of CTV<sub>breast</sub>/chest wall.

Table 1 Treatment characteristics

Abbreviations: 3DCRT, 3D conformal radiotherapy; VMAT, volumetric modulated arc therapy; IMRT, intensity modulated radiotherapy; SCF, supraclavicular field; IMN, internal mammary nodes.  
\*Including patients receiving 51.52 Gy in 28 fractions (n=3). \*\*Including patients receiving 42.3 Gy in 18 fractions (n=2).

### Results

Forty percent of the treatment plans needed modification to fulfil the required dose for target coverage. Median mean heart dose (MHD) was 3.0 Gy (range, 1.1-8.2 Gy) for left-sided BC and 1.4 Gy (range, 0.4-11.5 Gy) for right-sided BC. For left-sided BC patients the median MHD was 2.8 Gy (range, 1.1-7.4 Gy) when breath hold (BH) was used (71%) and 5.2 Gy (range, 2.2-8.2 Gy) when no BH was used (29%). Median mean (ipsilateral) lung dose was 13.4 Gy (range, 5.1-24.9 Gy). Median V17Gy/V20Gy (hypofractionated/normofractionated plans) for lung was 31% (range, 0-57%). To guide selection criteria for referral to PT, we chose to set cut-off points for dose to OAR for departments that aimed for treating all patients with 3DCRT and in BH, which 9 departments did (98% 3DCRT and 93% BH). We chose MHD  $\geq$  4 Gy or lung V17Gy/V20Gy  $\geq$  37% as cut-off points for the PT study based on dose-response relationships for ischemic heart disease and radiation pneumonitis in combination with capacity limitations for PT. In the departments having 3DCRT and BH as standard, 22% of the patients had a MHD  $\geq$  4 Gy or lung V17Gy/V20Gy  $\geq$  37%. The remaining 9 departments mainly used inverse techniques (98%) where BH was used in 31% of the patients. Fifty-two percent of these patients had a MHD  $\geq$  4 Gy or lung V17Gy/V20Gy  $\geq$  37%.

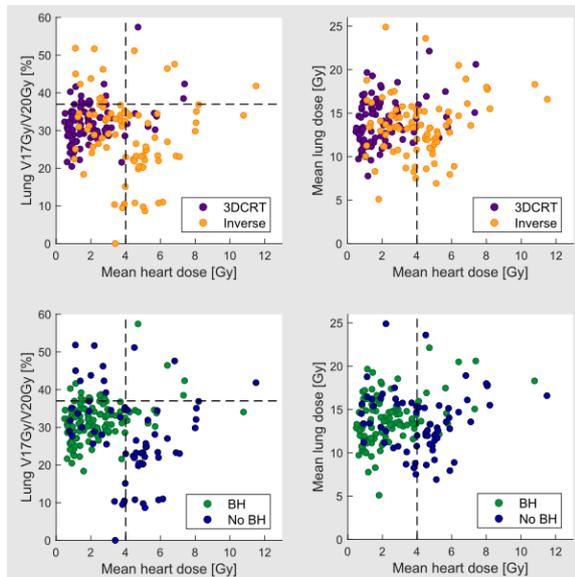

Figure 1: Upper panels show heart and lung dose metrics for 3DCRT (purple circles) and inverse treatment techniques (yellow circles). Lower panels show heart and lung dose metrics for breath hold (BH, green circles) and no breath hold (blue circles). The dashed lines represent the mean heart dose  $\geq 4$  Gy and lung V17Gy/V20Gy  $\geq 37\%$  thresholds.

### Conclusion

Using thresholds of MHD  $\geq 4$  Gy and lung V17Gy/V20Gy  $\geq 37\%$  in departments using 3DCRT and BH, we estimate that 22% of all the patients requiring loco-regional IMN RT will be eligible for the DBCG phase II PT study.

### PV-0047 IMRT versus VMAT for elderly patients with breast cancer: comparison of acute and late toxicities

F. Alongi<sup>1,2</sup>, F. Gregucci<sup>1</sup>, A. Fiorentino<sup>1</sup>, R. Mazzola<sup>1</sup>, V. Figlia<sup>1</sup>, F. Ricchetti<sup>1</sup>, G. Sicignano<sup>1</sup>, N. Gajj-Levra<sup>1</sup>, S. Naccarato<sup>1</sup>, A. Massocco<sup>1</sup>, S. Corradini<sup>3</sup>, R. Ruggieri<sup>1</sup>

<sup>1</sup>Hospital Sacro Cuore Don Calabria- Cancer Care Center, Radiation Oncology, Negrar, Italy; <sup>2</sup>University of Brescia, Radiation Oncology, Brescia, Italy; <sup>3</sup>LMU University Hospital, Radiation Oncology, Munich, Germany

### Purpose or Objective

To evaluate the differences between conventional fractionated intensity modulated radiotherapy (cIMRT) and hypofractionated (HypoRT) volumetric modulated arc therapy (VMAT) in elderly women affected by early stage Breast Cancer (BC) in terms of RT-related acute and late side effect.

### Material and Methods

Between October 2011 and July 2015, 80 consecutive elderly BC patients were treated with cIMRT for 5 weeks (40 patients) or HypoRT-VMAT for 3 weeks (40 patients). Inclusion criteria were: age  $\geq 70$  years, early stage BC (pT1-2 pN0-1), no prior neoadjuvant chemotherapy and non-metastatic disease. For patients receiving cIMRT or HypoRT-VMAT, a total dose of 50 Gy (25 fractions) or 40.5 Gy (15 fractions) were prescribed to the whole ipsilateral breast, respectively. All patients received a simultaneously integrated boost (SIB) up to a total dose of 60 Gy for cIMRT and 48 Gy for HypoRT-VMAT. Acute and late side effects were evaluated using the RTOG/EORTC radiation morbidity scoring system.

### Results

Median follow-up was 45 months. Compliance to treatment was 100% for each RT schedule, without any interruptions. The median age was 75 years (range 70-83). The median PTV breast was 929 cc (range 330-2527). In each group, 90% and 92% of patients received hormone-therapy, respectively. During RT delivery, only low grade acute skin toxicity was observed, with an advantage for

the HypoRT-VMAT group: grade 1 in 25 cases (62.5%) of the cIMRT group and 21 cases (52.5%) of the HypoRT-VMAT group (p=0.2); while grade 2 toxicity was reported in 10 cIMRT patients (25%) and 1 HypoRT-VMAT patient (2.5%) (p=0.001). No skin G3 or other side effects were observed at all. Regarding late adverse events, skin toxicity was overall mild without any grade 2 or higher toxicity, but resulted in significantly better outcome for patients treated with HypoRT-VMAT. Grade 1 side effects were reported in 13 cases (32.5%) of the cIMRT group as compared to 2 cases (5%) of the VMAT group (p=0.001). G1 fibrosis was registered in 4 cIMRT (10%) cases and 2 HypoRT-VMAT patients (5%) (p=0.4). No other late toxicities (e.g. pulmonary or arm edema) were observed. In patients treated with cIMRT, only the breast volume  $>700$  cc was statistically associated with acute G2 skin adverse events (p=0.04). In patients receiving Hypo-RT, factors like age or breast volume did not have any influence on the onset of acute or late skin toxicity. No differences in fatigue were observed for the two groups of treatment groups: 11 cIMRT patients vs 16 HypoRT-VMAT (p=0.1).

### Conclusion

The present study showed that whole breast cIMRT and HypoRT-VMAT are feasible and well tolerated in early stage BC elderly patients and that HypoRT-VMAT is affected by lower risk of acute and late RT-related side effects.

### PV-0048 The Radiosensitivity Index (RSI) predicts for outcomes in triple negative breast cancer

C. Liveringhouse<sup>1</sup>, N.B. Figura<sup>2</sup>, K.A. Ahmed<sup>2</sup>, G.D. Grass<sup>2</sup>, P. Blumencranz<sup>3</sup>, K. Allen<sup>3</sup>, C. Laronga<sup>4</sup>, M.C. Lee<sup>4</sup>, L.B. Harrison<sup>2</sup>, T.J. Robinson<sup>2</sup>, J.F. Torres-Roca<sup>2</sup>, R. Diaz<sup>2</sup>

<sup>1</sup>University of South Florida, Morsani College of Medicine, Tampa, USA; <sup>2</sup>Moffitt Cancer Center, Department of Radiation Oncology, Tampa, USA; <sup>3</sup>Baycare Morton Plant Hospital, Department of Breast Oncology Surgery, Clearwater, USA; <sup>4</sup>Moffitt Cancer Center, Department of Breast Oncology, Tampa, USA

### Purpose or Objective

While genomic biomarkers have been utilized to predict outcomes in ER+ breast cancer, further investigation is needed to develop similar predictors for triple negative breast cancer (TNBC). RSI is a previously validated multi-gene expression index that is thought to be radiotherapy (RT)-specific. Here, we evaluate whether RSI is an RT-specific predictive biomarker in TNBC.

### Material and Methods

Prospectively gathered breast tumor samples were identified from an IRB-approved tissue biorepository representing one academic and two community hospitals. Gene expression of tumor samples was assessed with Affymetrix microarray chips and the RSI 10-gene signature was calculated for each sample using the previously published rank-based algorithm. As in prior studies, radiophenotype was determined by dichotomizing at RSI=0.3745, where RSI $\geq$ 0.3745 is radioresistant (RR) and RSI<0.3745 is radiosensitive (RS). Clinical information was obtained by chart review. Endpoints were locoregional recurrence-free survival (LRF5), distant metastasis-free survival (DMFS), overall survival (OS), and progression-free survival (PFS). Outcomes were estimated with Kaplan Meier (KM) methods and compared with log-rank tests. Associations between characteristics and outcomes were explored with univariable (UVA) and multivariable (MVA) Cox regression.

### Results

97 TNBC tumors with available genomic profiling were identified for analysis. The median age was 55 years (range 25-82). 97.9% of tumors were pT1-T2, and 37.1% had positive lymph nodes. 80% of tumors were high grade. 40.2% were treated with mastectomy alone, 14.4% with

mastectomy + RT, and 42.3% with lumpectomy + RT. The median RT dose was 46.8 Gy. 85.6% received chemotherapy. There were no significant differences in characteristics between RS and RR patients ( $p>0.05$ ). Median follow-up was 7.6 years (range 0.21-17.2). There were 10 locoregional recurrences, 15 distant metastases, and 16 deaths. All results of KM analyses are included in the accompanying table. Among all patients, radiophenotype predicted for all outcomes as RS had superior LRF5, DMFS, OS and PFS. Radiophenotype remained predictive for outcomes among RT-treated patients, as RS patients had superior LRF5, DMFS, OS, and PFS compared to RR patients. In contrast, radiophenotype did not predict for outcomes in patients not treated with RT as there were no significant differences in LRF5, DMFS, OS, or PFS. In RT-treated patients, radiophenotype ( $p=0.034$ ) and surgery type ( $p=0.012$ ) were associated with PFS and both remained significant on MVA (RR vs RS, HR 4.6 95% CI 1.01-20.48,  $p=0.048$ ) (lumpectomy vs mastectomy, HR 0.29 95% CI 0.10-0.83,  $p=0.021$ ). In non-RT patients, no factors predicted for PFS on MVA.

	5-year LRF5	5-year DMFS	5-year OS	5-year PFS
<b>All patients (N=97)</b>				
Radiosensitive	100%	95%	98%	93%
Radioresistant	84%	77%	84%	71%
Log-rank P	0.033	0.020	0.035	0.035
<b>Treated with RT (n=55)</b>				
Radiosensitive	100%	100%	100%	96%
Radioresistant	75%	72%	81%	66%
Log-rank P	0.024	0.007	0.006	0.018
<b>Not treated with RT (n=42)</b>				
Radiosensitive	100%	89%	94%	89%
Radioresistant	96%	83%	88%	79%
Log-rank P	0.409	0.738	0.343	0.699

### Conclusion

In this cohort of consecutively treated patients, we show that RSI radiophenotype predicts for outcomes in TNBC and is specific to RT-treated patients. Patients with radioresistant TNBC have poor outcomes and may benefit from treatment intensification, warranting further prospective validation.

### PV-0049 Merkel cell polyoma viral load predicts overall survival in patients with Merkel cell carcinoma

J. Mueller-von der Gruen<sup>1</sup>, R. Winkelmann<sup>2</sup>, M. Meissner<sup>3</sup>, U. Wieland<sup>4</sup>, S. Silling<sup>4</sup>, D. Martin<sup>1</sup>, E. Fokas<sup>1</sup>, C. Rödel<sup>1</sup>, F. Rödel<sup>1</sup>, P. Balcermpas<sup>5</sup>

<sup>1</sup>University of Frankfurt, Department of Radiation Oncology, Frankfurt, Germany; <sup>2</sup>University of Frankfurt, Dr. Senckenberg Institute of Pathology, Frankfurt, Germany; <sup>3</sup>University of Frankfurt, Department of Dermatology, Frankfurt, Germany; <sup>4</sup>University of Cologne, Institute of Virology- National Reference Center for Papilloma- and Polyomaviruses, Cologne, Germany; <sup>5</sup>University Hospital of Zürich, Department of Radiation Oncology, Zürich, Switzerland

### Purpose or Objective

Merkel cell carcinoma (MCC) is a rare but aggressive neuroendocrine tumor of the skin and its tumorigenesis is linked to the presence of clonally integrated Merkel cell polyomavirus (MCPyV) in up to 80% of the cases. The aim of this study was to determine the prognostic value of quantitative MCPyV viral load and lymphocytic infiltration.

### Material and Methods

CD8+ tumor infiltrating lymphocytes (TILs) and PD-L1 status were assessed using immunohistochemistry in FFPE tissue obtained from 49 patients with MCC treated with

(n=22, 45%) or without postoperative radiotherapy. MCPyV DNA prevalence, DNA integration status and viral load were determined by virus-specific quantitative real-time PCR. Immune marker expression and MCPyV characteristics were correlated with clinicopathological factors and overall survival (OS).

### Results

Median age at diagnosis was 74 (range 42-100) and 51% of the patients were female. 1-, 3- and 5-years OS rates were 65%, 33% and 25%, respectively. Positive MCPyV status was recorded in 79% of the patients and was associated with female gender ( $p=0.033$ ). Further, tumor localization (head and arms vs. trunk) positively correlated with PD-L1 status as well as combined expression of CD8+/PD-L1 ( $p$ -values: 0.011 and 0.038). Stromal TILs correlated significantly with both PD-L1 expression ( $p=0.010$ ) and N-stage ( $p=0.037$ ). Also, N+ stage inversely correlated with TILs ( $p=0.048$ ). A high viral load was significantly associated with worse OS ( $p=0.026$ ) and high intratumoral CD8+ infiltration with improved OS for the entire cohort ( $p=0.045$ ).

### Conclusion

A High MCPy DNA viral load was associated with impaired OS and high intratumoral TILs with improved OS. Furthermore, stromal TILs positively correlated with PD-L1 status, possibly opening new future perspectives for combining treatment approaches such as RT and immune-checkpoint inhibitors.

### Symposium: Challenging dose painting: Are we really painting what we aim to or the better outcome is only linked to higher dose spots within the CTV?

### SP-0050 What is left from dose painting when adding all uncertainties

M. Alber<sup>1</sup>

<sup>1</sup>Heidelberg University Clinic, Radiation Oncology, Heidelberg, Germany

### Abstract text

Multiple levels of dose prescription to the target volume (simultaneous integrated boost, SIB) and highly conformal, yet inhomogeneous dose escalation to small targets (such as in stereotactic body radiotherapy) are becoming rather common in modern radiotherapy. Dose painting (DP) is in essence an image-guided SIB, so it is reasonable to assume that planning- and delivery-related uncertainties play no greater role in DP than in geometry-guided SIB. It is the element of biological guidance that adds the essential layers of uncertainty.

It is instructive to follow a thought experiment that starts with an indiscriminate, geometric SIB to the core target volume (usually the GTV) with the appropriate prescription (to be addressed later). Then, what image information is required to shape the SIB into DP by chipping away dose? The locations where dose can be reduced are tied to the true negative rate (absence of the biological feature) and thus to specificity, while the level of de-escalation is tied to the false negative rate (missing the biological feature) and thus to sensitivity. Thus, low specificity enlarges the boosted volume, low sensitivity forces the dose spread smaller to limit tumour control loss by underdosing. To arrive at the DP prescription, it is sufficient to demand optimum use of the image information content; no sophisticated biological modelling is required.

An imaging modality may appear to be very specific to a particular trait of a tumour, but this does not mean that it is specific to therapy resistance. For example, pre-treatment hypoxia image information may be invalidated by re-oxygenation during therapy, or further unknown tumour characteristics may play a large role in therapy resistance. Thus, any attempt to model tumour response

from imaging data has to cope with incomplete information and temporal changes, effectively degrading both image sensitivity and specificity. The combination of multiple imaging modalities (increase overall sensitivity) and multiple examinations to quantify therapy response (increase overall specificity) can remedy this, and seems to be the most promising route to DP. In practice, it could turn out very difficult to prove the non-inferiority of DP versus a SIB of equal dose. However, at the very least, any imaging modality that is shown to have predictive value stratifies patients into risk groups and can therefore be the basis of patient-specific dose prescriptions, be they applied as SIB or DP. Notwithstanding the difficulties with an evidence base for DP from the tumour control perspective, normal tissue sparing might be the strongest rationale.

**SP-0051 What are the limitations on dose escalation to sub-volumes in head and neck cancer: experience from dose painting**

F. Duprez<sup>1</sup>, J. Daisne<sup>2</sup>, W. de Gersem<sup>1</sup>, I. Goethals<sup>3</sup>, L. Olteanu<sup>1</sup>, T. Vercauteren<sup>1</sup>, W. de Neve<sup>1</sup>

**Abstract text**

Dose escalation of radiotherapy above 70 Gy could potentially lead to higher locoregional control rates but is hampered by severe acute and late toxicities. Molecular imaging based dose-painting is an attractive concept for dose-escalation while keeping toxicity lower to equal. As per-treatment changes of anatomical as well as biological signal intensity often occurs, these techniques are mostly performed in an adaptive radiotherapy program, using re-imaging during the 7-weeks of radiotherapy. Many theoretical as well as planning studies have been performed employing the dose-painting concept, broadly investigating two molecular imaging dose-painting methods:

(1) dose painting by contours (DPBC): using discretely contoured subvolumes within the tumor based on molecular imaging.

(2) dose painting by number (DPBN): using molecular imaging voxel-intensities to directly optimize radiotherapy plans.

In contrast to the relatively high number of planning studies, few clinical trials have been performed. The research program for head and neck radiotherapy at Ghent University Hospital has been focusing on molecular based dose-painting since 2003. Consecutively, following prospective clinical trials have been performed, all of them based on <sup>18</sup>F-FDG-PET:

(1) 2003-2005: phase I, non-adaptive DPBC in fractions 1-10 of 32; n = 41. (2) 2007-2009: phase I, 2-phase adaptive DPBN in fractions 1-20 of 32; n = 21.

(3) 2010-2011: feasibility trial on 3-phase adaptive DPBN in fractions 1-30/30; n = 10.

(4) 2012-2014: feasibility trial on 3-phase adaptive DPBN in fractions 1-30/30 for reirradiation of recurrent head and neck cancer; n = 10.

(5) 2011-2018: phase II randomized trial comparing 3-phase adaptive DPBN in fractions 1-20/30 with standard non-dose painting, non-adaptive IMRT; n = 95.

Trials 2-3-4 demonstrated the feasibility of biological imaging based dose-painting in head and neck cancer. However, during the randomized phase II trial, the DPBN-dose prescription has been adapted twice due to an unanticipated high occurrence of late mucosal ulcers: at the last interim analysis available at time of abstract writing, 9/39 studied patients developed late grade 4 mucosal ulcers, that seemed to be strongly associated not only with the high-dose subvolumes, but also with continuation of smoking or alcohol drinking after DPBN.

Definitive results after closing of recruitment in this phase II randomized trial are awaited.

The presentation will focus on the findings related to the occurrence of acute toxicity and late mucosal ulcers, the latter being the identified dose-limiting factor for further dose-escalation.

**SP-0052 Heterogeneous dose adapted to treatment response during radiotherapy: clinical experience from cervix cancer IGABT**

I. Jürgenliemk-Schulz<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands

**Abstract text**

For many decades, technological developments in cervix cancer brachytherapy have been limited and treatment was based on 2D imaging and standard approaches as developed by the classical brachytherapy schools in the early 20th century. With ICRU38 a system for dose prescription and reporting became available; mainly based on X-ray determined applicator related dose points. In recent years, image guided adaptive brachytherapy (IGABT) has resulted in a major change of practice. The ICRU89/GEC-ESTRO recommendations support the introduction of IGABT. They are based on repetitive tumour assessment through clinical examination and imaging, preferably magnetic resonance imaging (MRI), with adaptation of dose according to the tumour extent at diagnosis, and the response to EBRT at the time of brachytherapy. Adaptive treatment planning takes into account the changes during treatment and prescribes specific doses to the various volumes of interest. For the primary tumour adaptive target volumes can in principle be defined after any treatment phase. The residual GTV reflects macroscopic tumour rest whereas the adaptive CTV takes into account the morphology and topography of the initial GTV and the morphology and/or functional response to treatment. For definitive cervical cancer radiotherapy, these volumes are boosted through brachytherapy to different dose levels according to estimated levels of remaining tumour cell burden and in order to achieve very high doses in defined small volumes. Several mono-institutional studies and the prospective multicentre international RetroEMBRACE and EMBRACE studies have demonstrated that a highly differential dose distribution with significant dose escalation is clinically feasible with IGABT in cervical cancer. This is because with IGABT, the "super-high" doses are only administered to small volumes. The response-adaptation of volume is the key factor to identify volumes which are small enough to tolerate such high doses. The excellent outcome of IGABT has been demonstrated in several mono-institutional reports as well as in the RetroEMBRACE study. The 3-year local and pelvic control rates reached 98-100% and 96%, respectively, for FIGO stage IB1 and IB2 disease, and 93-96% and 89-91%, respectively, for stage IIB disease. For stage III/IVA disease, the local and pelvic control rates between centres were more variable ranging from 73-86%. Comparing with data as published after (chemo)radiation and traditional brachytherapy for cervical cancer the estimated gain of IGABT in its early phase is about 10% for pelvic/local control and not to the cost of additional morbidity. Further fine tuning the therapeutic window of IGABT can be expected as our knowledge on dose levels needed for better control and less morbidity is constantly increasing. Evidence for clinical improvement in terms of local/pelvic control will be the main focus for this presentation but the way to achieve this will also be addressed.

**SP-0053 Exploiting low drug uptake volume for dose painting**

A. Yaromina<sup>1</sup>, L. Dubois<sup>1</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>Maastricht university, Department of Precision Medicine- the m-lab- gUow - school for Oncology and Developmental biology, Maastricht, The Netherlands

#### Abstract text

Several clinical studies have shown the possibilities to give a higher dose to certain hypothetically more radioresistant tumour sub-volumes, typically with high accumulation of FDG or a hypoxia tracer. We have tested the therapeutic efficacy of dose-painting (DP) strategies, i.e. targeted dose escalation and dose redistribution, in a rat syngeneic rhabdomyosarcoma model based on FDG uptake [1]. Our data indicate that, while dose escalation to high FDG uptake sub-volume was not superior to the same dose increase in low FDG uptake areas, dose redistribution was even detrimental, consistent with the hypothesis that tumor response is dependent on the minimum intratumoral dose. Interestingly, in the same tumour model dose escalation to the hypoxic sub-volume, as determined by the highest uptake of HX4 hypoxia tracer, resulted in worse tumour response than the same dose increment to the non-hypoxic sub-volume [2]. This data suggests that dose to the tumour bulk should be sufficient to inactivate non-hypoxic cells.

It might be difficult to achieve clinically sufficient dose escalation to eradicate tumour cells in hypoxic tumor sub-volume. Therefore, we moved beyond the traditional DP approaches combining hypoxia-targeted drugs with inverse dose-painting of hypoxic sub-volume and thus offering, in our view, more efficient utilization of radiation, i.e. radiation boost to non-hypoxic tumour areas with simultaneous inactivation of hypoxic tumour cells by a HAP. Indeed, our results support targeted dose escalation to non-hypoxic sub-volume with no/low activity of HAPs. This strategy applies on average a lower radiation dose and is as effective as uniform dose escalation to the entire tumour.

Routine implementation particularly of hypoxia PET imaging in the clinic is problematic because it is expensive, labor intensive, not attractive for the patient, or even not accessible. Therefore, partial non-targeted tumour irradiation with high dose in combination with immunotherapy might be a new alternative approach to dose-painting, which is currently being tested in our laboratory. It is expected that partial tumour irradiation enables delivery of high doses to tumor sub-volumes reducing normal tissue injury, causes less total damage to intratumoral vasculature permitting immune cells infiltration and provides stronger induction of immunogenic cell death releasing antigens and stimulants to immune system, while immunotherapy boosts anti-tumour immune response with systemic therapeutic potential.

OC-0054 Tumor reoxygenation and image-guided SBRT for the treatment of murine colorectal liver metastases

M. Pruschy<sup>1</sup>

<sup>1</sup>University of Zurich, Applied Radiobiology, Zurich, Switzerland

#### Purpose or Objective

Reactive oxygen species are generated in response to ionizing radiation (IR) and produce amongst others irreversible DNA double-strand breaks. This IR-induced cytotoxic effect is less abundant under hypoxia and thus hypoxic cells are more resistant to IR. Hence, reoxygenation of the hypoxic tumor fraction by a combined treatment modality with a pharmaceutical agent is of high interest to reduce the required dose of IR and thereby to further minimize normal tissue toxicity. Here we investigated the combined treatment modality of the novel anti-hypoxia compound *myo*-inositol trispyrophosphate (ITPP) in combination with IR for the treatment of murine colorectal liver metastases (CLM).

#### Material and Methods

ITPP was developed as an effector of hemoglobin lowering the oxygen/hemoglobin affinity thereby resulting in an enhanced release of oxygen e.g. in hypoxic tumors. Murine colorectal cancer cells (MC38) were injected either subcutaneously or orthotopically in the right lateral liver lobe of female C57BL/6 mice. Mice were treated with a previously identified regimen of ITPP (2x 3g/kg, neoadjuvant) alone and in combination with single fractions of IR ranging from 2.5 to 30 Gy. Tumor detection and irradiation were performed by contrast-enhanced CT and a small-animal radiotherapy (X-Rad225Cx), respectively. Tumor volumes were probed either by caliper measurements (subcutaneous tumors) or by serial MRI. Liver functional parameters in the blood serum were assessed 7 weeks upon irradiation.

#### Results

Treatment with ITPP alone did not reduce the growth rate of subcutaneous tumors as compared to vehicle treatment. However, ITPP in combination with a single high dose fraction of IR (12 Gy) significantly delayed tumor growth in comparison to irradiation alone. Selective intraportal injection of colorectal cancer cells yields a high rate in colorectal liver metastasis formation. An initial IR-dose escalation study for the treatment of the right liver lobe in healthy mice demonstrated that single fractions of 20 Gy and higher resulted in substantial animal body weight loss and impairment of liver functional markers. Preliminary results in this murine CLM model revealed a partial radioprotective effect of ITPP in healthy liver. Targeted irradiation of the right liver lobe with single fractions of 10 and 15 Gy is effective in reducing the growth of metastatic lesions without causing radiation-induced toxicities.

#### Conclusion

Here we demonstrated that the combined treatment modality of ITPP and IR results in a supra-additive tumor growth delay, which is most probably linked to neoadjuvant tumor reoxygenation. Moreover, we demonstrate that the irradiation of murine CLMs is feasible, accurate and effective with a small-animal image-guided radiotherapy platform.

#### OC-0055 Zebrafish model to study the use of nanoparticles as a radiosensitizer in low Z target beams

M. Ha<sup>1</sup>, O. Piccolo<sup>2</sup>, N. Melong<sup>3</sup>, J. Lincoln<sup>4</sup>, D. Parsons<sup>5</sup>, A. Detappe<sup>6</sup>, O. Tillement<sup>7</sup>, R. Berbeco<sup>8</sup>, J. Berman<sup>9</sup>, J. Robar<sup>10</sup>

Matiere, Villeurbanne, France ; <sup>8</sup>Harvard Medical School, Radiation Oncology, Boston, USA; <sup>9</sup>IWK Health Centre/Dalhousie University, Pediatrics/Pathology/Microbiology and Immunology, Halifax, Canada; <sup>10</sup>Dalhousie University/Nova Scotia Health Authority, Radiation Oncology/Physics and Atmospheric Science/Medical Physics, Halifax, Canada

### Purpose or Objective

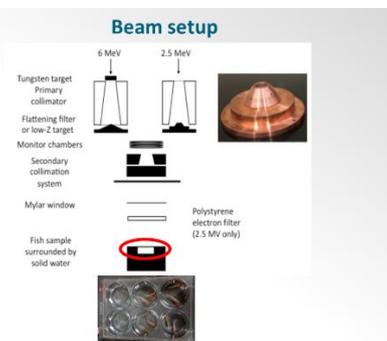

Nanoparticles made of high atomic number (Z) elements have been shown to sensitize cancer cells to radiation beams generated from linacs *in vitro* and *in vivo*. This effect occurs due to the emission of low energy photoelectrons and Auger electrons. Gold (GNP) and gadolinium (GdNP) based nanoparticles are biocompatible, and accumulate passively in tumours due to the enhanced permeability and retention effect, and there is growing evidence that localized radiation-induced tumour vascular damage can be used to clinical advantage. The introduction of low Z (sintered diamond) linac target instead of a standard Cu/W target results in a predicted 7.7 fold enhancement in the immediate proximity of the NP. The efficacy of combining the low Z target beam with NPs remains to be verified *in vivo*. To this end, we employed an established zebrafish xenotransplantation platform to quantify tumour cell proliferation. The zebrafish model offers the advantages of using a transparent fish to allow *in vivo* monitoring of grafts, as well as enabling large sample sizes.

### Material and Methods

**Beam setup:** The samples were irradiated using a standard 6 MV or a custom 2.5 MV/diamond target x-ray beam from a TrueBeam linac. The 2.5 MV/diamond beam was generated by 2.5 MeV electron beam incident upon a sintered diamond target in the carousel. (see figure)

**Cell line screen:** Panc1 (pancreas), FaDu (hypopharynx), A673 (Ewing), MDA-MB-231 (breast), LNCaP (prostate), A549 (lung) were labeled *in vitro* with NPs. They were irradiated with 8 Gy using the low Z or conventional target beam. Proliferation was assayed using Alamar Blue.

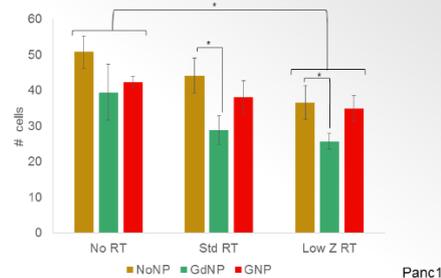

**Xenograft assay:** Cells were co-labeled *in vitro* with NPs and a lipophilic fluorescent dye. Labeled cells were injected into the yolk sac of dechorinated *casper* zebrafish embryos and irradiated 1 dpi (days post injection) with 8 Gy. Tumour viability was measured by a standard *ex vivo* proliferation assay at 3 dpi.

### Results

Cells showed differential responses to being irradiated with standard or low-Z target beam in the presence of GNP or GdNP. Among the cell lines tested, FaDu cells were the most sensitive to NP mediated irradiation. In Panc1 xenografts, there was a statistically significant decrease in the surviving cell numbers in samples treated with low Z target beams.

### Nanoparticle mediated response to low Z beam is seen in xenografted Panc1

### Conclusion

In a proof of principle experiment, we have shown enhanced radiologic cell kill in low-Z target irradiation in xenografted NP labeled cells. We are in the process of testing the model in additional cells with plans to examine tumour response in adult fish model.

### OC-0056 Multiple strategies for resolving radiation-induced neurocognitive dysfunction

C. Limoli<sup>1</sup>, M. Vozenin<sup>2</sup>, M. Acharya<sup>3</sup>

<sup>1</sup>University of California Medical Sciences I, Department of Radiation Oncology, Irvine, USA; <sup>2</sup>Radio-Oncology/CHUV, Department of Radiation Oncology, Lausanne, Switzerland; <sup>3</sup>University of California, Radiation Oncology, Irvine, USA

### Purpose or Objective

The progressive and debilitating side effects manifesting as cognitive dysfunction, mood disorders and a range of persistent pathologies have long hampered the radiotherapeutic management of CNS malignancies. For decades this problem has plagued therapeutic outcomes, and has not been restricted to brain cancer cases, as systemic chemotherapy elicits similar adverse outcomes, problems that remain an unmet medical need. Here we will highlight multiple strategies for resolving these long-standing clinical problems.

### Material and Methods

Work in our laboratories have focused on resolving many of these treatment-associated complications through a variety of stem cell based, genetic, pharmacologic and beam delivery strategies. Cranial transplantation of multiple stem cell types, systemic delivery of stem-cell derived exosomes, retrograde endocannabinoid blockade, microglial depletion, epigenetic modulation and ultra-high dose rate "FLASH" radiotherapy have all been used and characterized to provide significant relief from the normal tissue toxicities transpiring in the irradiated and/or chemotherapy treated brain.

### Results

Cranial grafting of 5 different pluripotent or multipotent human stem cell types, or stem cell-derived exosomes grafted intrahippocampally or systemically have been found to completely resolve radiation and chemotherapy-induced cognitive dysfunction from 1-8 months after treatment. Multiple spontaneous exploration tasks designed to interrogate learning and memory, and other tasks used to quantify anxiety, depression and fear extinction, demonstrate conclusively that our selected interventions improve behavioral performance in multiple preclinical rodent models over extended post-treatment times. This long term relief is associated with a significant preservation of host neuronal morphology, protection of the microvasculature and attenuation of neuroinflammation. Similar results have been obtained with the cannabinoid receptor 1 (CB1) antagonist AM251,

with the colony stimulating factor 1 receptor (CSF1R) antagonist PLX5662 and with inhibitors of adenosine kinase. Interestingly, more recent data implementing FLASH radiotherapy has achieved similar promising results in terms of sparing normal tissue complications in the irradiated brain without compromising tumor cure.

#### Conclusion

Progress in each of these research areas holds significant potential for translation to the clinic with the hope of improving the quality of life of millions of cancer survivors. These will be highlighted in further detail in our presentation.

#### OC-0057 Probing spatiotemporal fractionation on the preclinical level

I. Telarovic<sup>1</sup>, M. Pruschy<sup>1</sup>, I. Grgic<sup>1</sup>, J. Krayenbuehl<sup>1</sup>, M. Guckenberger<sup>1</sup>, J. Unkelbach<sup>1</sup>

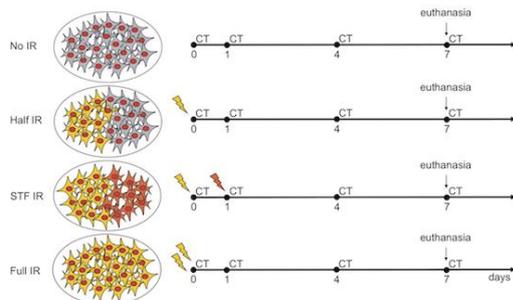

<sup>1</sup>Universitätsspital Zürich, Radiation Oncology, Zürich, Switzerland

#### Purpose or Objective

In contrast to conventional radiotherapy, spatiotemporally fractionated (STF) treatments deliver a distinct dose distribution in each fraction. The aim is to increase the therapeutic window by simultaneously achieving partial hypofractionation in the tumor along with near uniform fractionation in normal tissues. To that end, each fraction delivers high single fraction doses to alternating parts of the tumor while creating a similar dose bath in the surrounding normal tissue. This approach has been studied *in silico* (Unkelbach, 2015) based on the working hypothesis that different parts of the tumor can be treated in different fractions as long as each part receives the prescribed cumulative biological dose in the end. Here, we do an initial step towards verifying this assumption in an experimental animal model.

#### Material and Methods

We compare the tumor growth rate of conventionally treated xenografts derived from mouse colon cancer cells to a reductionistic preclinical model of STF. Upon reaching the tumor volume of  $300 \text{ mm}^3 \pm 10\%$ , animals are randomly assigned to 4 treatment groups (Fig. 1). No irradiation (IR) group is sham irradiated. Half IR group is irradiated with a partial 12 Gy IR covering the cranial half of the tumor. STF IR group receives two partial 12 Gy IRs given on day 0 and day 1, covering the cranial and caudal half of the tumor, respectively. Full IR group receives two partial 12 Gy IRs successively. All animals undergo CT imaging on days 0, 1, 4 and 7 post IR and are euthanized on day 7. To perform such fractionated IR of varying target volumes in small animals, we develop a pipeline that combines a dedicated small animal image-guided research platform (X-RAD 225Cx / SMART-Plan) with the clinical software MIM (MIM Software Inc.). Finally, we compare caliper-based (CALVM) growth rate curves with CT-volumetry (CTVM) in the context of tumor growth rate studies.

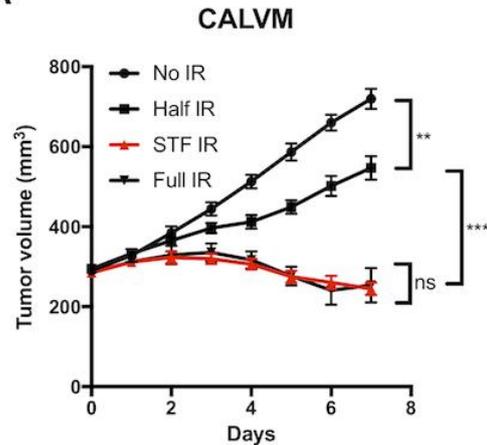

#### Results

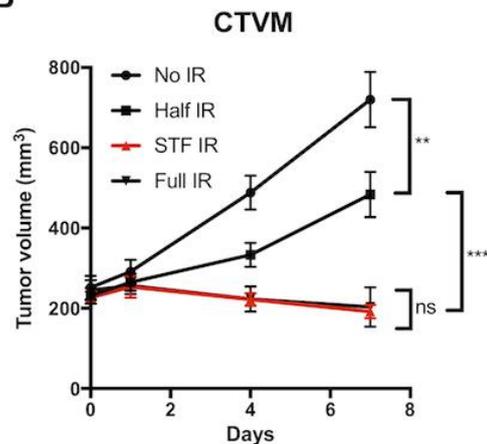

Tumors irradiated to the same dose, either immediately (Full IR) or with a 24 hour delay between two partial IRs (STF IR), exhibited no difference in growth rate (Fig. 2A,

area under tumor growth curve STF IR= $2060 \pm 204$  vs Full IR= $2095 \pm 343$ ,  $P=0.99$ ). Reduction in the irradiated volume resulted in a decreased response (Fig. 2A, Half IR). CTVM (Fig. 2B) measured overall significantly smaller starting volumes with an increased dispersion compared to CALVM ( $V_0$  CTVM= $238 \pm 53 \text{ mm}^3$  vs CALVM= $288 \pm 14 \text{ mm}^3$ ,  $P<0.001$ ), while the relative tumor growth curves (each point normalized to corresponding  $V_0$ ) did not differ between the two methods.

#### A

#### B

#### Conclusion

The assumption of spatiotemporal fractionation that the tumor response can be predicted by locally adding up biological doses from each fraction is confirmed in a reductionistic preclinical model whereby xenografts irradiated either immediately or with a 24 hour delay between two partial irradiations exhibit no difference in growth delay. The study suggests caliper- and CT-volumetry to be interchangeable when considering relative, but not absolute volumes in tumor growth studies.

#### OC-0058 Dose-volume effects in the central nervous system and sparing in microbeam/minibeam radiation

E. Bahn<sup>1,2</sup>, M. Alber<sup>1</sup>

<sup>1</sup>Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany; <sup>2</sup>Clinical Cooperation Unit Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg, Germany

#### Purpose or Objective

Animal experiments with narrow proton beams in the mm-range and bath/shower dose distributions have produced evidence of an abnormally high volume effect in rat spinal cord more than a decade ago. Whether these results have

pertinence for the effects observed in microbeam radiation (whether a microbeam radiation is a kind of bath/shower dose) remains a fundamental question. We present a spinal cord dose response model that predicts relative frequency and localization of late radiation effects after irradiation with arbitrary dose distributions, over scales from few micrometers to the entire organ. The model can predict the posited sparing effect in micro-/minibeam radiation and thereby help to optimize microbeam patterns.

#### Material and Methods

The dynamic repair model (DRM) views a complication as a result of a failed repair/homeostasis process, caused by deletion of critical tissue information via radiation. From general thermodynamic principles, we derive a closed form that relies on only three parameters. In this framework, the volume effect emerges as a result of a finite communication distance in a network-like information storage system.

We tested the DRM on six well-known published datasets of volume effects and bath/shower effects in rat spinal cord, as well as one dataset of synchrotron-based microbeam radiation. Model parameters were obtained from regression to the volume-effect data. Model validation was subsequently performed on the bath/shower and microbeam data.

#### Results

The DRM provides a very good prediction of all small volume and bath/shower datasets. Fig. 1 shows 50 % response doses  $D_{50}$  as a function of irradiated length (or effective length in the case of inhomogeneous irradiation). For the rat spinal cord, we determine a critical information communication distance of  $(4.0 \pm 0.3)$  mm.

The microbeam experiment compares a 1.35 mm wide homogeneous field with an 11 mm wide comb of  $35 \mu\text{m}$  wide microbeams. The homogeneous field response is well predicted by the DRM. The microbeam  $D_{50}$  is underestimated (predicted:  $180 \pm 20$  Gy measured:  $370 \pm 90$  Gy).

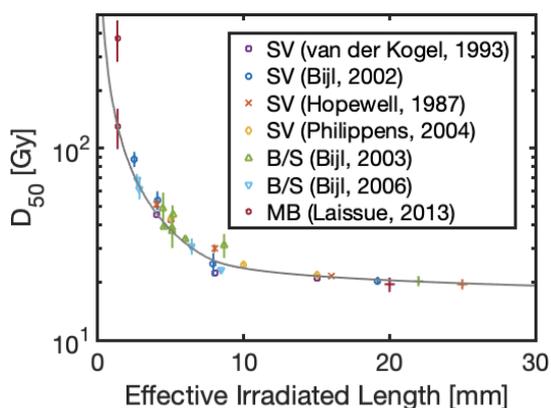

Fig. 1:  $D_{50}$  vs effective irradiated spinal cord length. Error bars denote 95% confidence intervals. SV: small volume; B/S bath/shower; MB: microbeam; Solid line: Model prediction.

#### Conclusion

In micro-/minibeam radiation, dose distributions are highly inhomogeneous on very small scales. The abnormally high volume effect on small scales might provide an explanation, but this requires a model that permits comparison of effects of inhomogeneous doses. The DRM allows a prediction of the dose response for arbitrary dose distributions and it particularly explains the effect of low dose baths adjacent to small high dose regions through a deleterious effect on information critical for repair. Microbeam experiments with peak doses in excess of 200 Gy may lie outside the valid range of the DRM because effects that arise from killing every cell in the high dose region are not modelled. Microbeam

dose response data are scarce and thus definitive conclusions are not justified, but comparison of model prediction with a published dataset indicates an additional dose tolerance beside the volume effect, possibly caused by overkill.

<sup>16</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany

#### Purpose or Objective

Developments of local and systemic therapies have improved the prognosis of metastatic NSCLC. Oligometastatic patients may especially benefit from a more aggressive treatment approach. However, the concept of "oligometastasis" is complex: e.g. limited progression or resistance of disease to systemic treatment. This study aimed to evaluate the outcome of stereotactic radiotherapy (SRT) to oligoprogressive or oligoresistant NSCLC in patients receiving concurrent immuno- or targeted therapy.

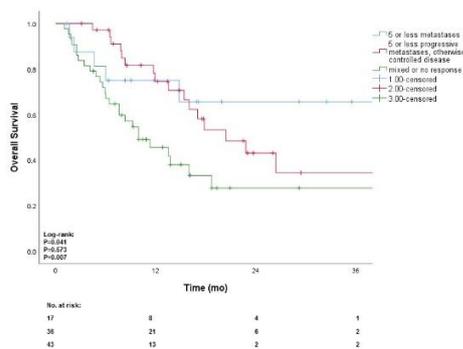

#### Material and Methods

The retrospective international multicenter register study (TOaSTT) collected data on metastatic NSCLC patients receiving SRT concurrent ( $\leq 30$ d) to immuno- or targeted therapy. Patients were grouped in: patients treated for  $\leq 5$  metastases without additional metastases (oligoprogression), treated for  $\leq 5$  progressive metastases with controlled disease of all other metastases (oligopersistent), and patients with mixed response/uncontrolled disease. SRT was performed to  $\leq 5$  extracranial or cranial lesions. Overall survival (OS) was analyzed using Kaplan-Meier survival curves and log rank testing. Secondary outcomes were progression free survival (PFS), local control (LC), time to switch of systemic therapy after SRT and toxicity as defined by the CTCAE v4 criteria.

#### Results

SRT of 192 lesions in 108 patients was performed between 7/2009 and 5/2018 in 16 clinics. Median age was 63y (range 33-80). 75% had synchronous metastatic disease, driver mutations were: EGFR 41%, ALK 14%, other 21%, unknown/no 24%. Median follow-up was 18.7 (range 1-102)

mo. The majority had metastases in 1-3 organs. 90% were ECOG 0-1. Median 1 (range 1-5) metastasis was treated with SRT; 69% cranial and 31% body SRT. Targeted therapies were started a median 5.8mo before SRT in 69%, during SRT in 8%, and a median 14d after SRT in 23% of patients. 60% received an ALK- or EGFR-TKI, 31% nivolumab or pembrolizumab, 8% bevacizumab. Oligoprogressive and oligopersistent patients showed improved OS compared to advanced metastatic disease ( $p=0.008$ ) (Fig.1). PFS was best in oligoprogressive patients; median 20.1 vs 7 and 4.4 mo., respectively ( $p=0.006$ ). LC was median 21.0, 12.0 und 9.0mo; no significant difference between groups. After 1y, 86%, 47% and 39% in the 3 groups continued the same immuno- or targeted therapy as before SRT. Grade 3 and 4 acute toxicity were observed in 6% and 1% ( $n=1$ , headache), late toxicity in 3% and 1% ( $n=1$ , hemiparesis), respectively.

## Conclusion

This study observed excellent survival with limited toxicity when definitive SRT to a limited number of metastases was combined with targeted- or immunotherapy in oligoprogressive and oligopersistent NSCLC patients. High-dose local radiotherapy of metastatic sites allowed continuation of targeted-, or immunotherapy for minimum 1 year in 39% to 86%, with best results observed in oligoprogressive patients. These observations need to be further evaluated within prospective trials.

## OC-0060 I-SABR induces local and abscopal responses in metastatic patients after failure to ICI treatment

R. Chicas Sett<sup>1</sup>, I. Morales-Orue<sup>1</sup>, J.F. Castilla-Martinez<sup>1</sup>, J. Blanco<sup>1</sup>, A. Kannemann<sup>1</sup>, J. Zafra<sup>1</sup>, M. Zajac<sup>1</sup>, M. Lloret<sup>1</sup>, P.C. Lara<sup>2</sup>

<sup>1</sup>Dr. Negrin University Hospital of Gran Canaria, Radiation Oncology, Las Palmas de Gran Canaria, Spain;

<sup>2</sup>San Roque University Hospital/Universiada Fernando Pessoa Canarias, Radiation Oncology, Las Palmas de Gran Canaria, Spain

## Purpose or Objective

The increased probability of abscopal responses that can be triggered by the combination of immune-checkpoint inhibitors (ICI) and stereotactic ablative radiotherapy (SABR) represents a promising therapeutic strategy for eradicating metastatic disease. The aim of the present study is to assess the role of I-SABR in patients with metastatic cancer in progression to ICI.

## Material and Methods

We conducted a prospective study based on metastatic patients (lung, melanoma, H&N, bladder and renal carcinoma) who had experienced disease progression while on ICI (anti-PD1/L1) treatment. SABR was performed by volumetric-modulated arc therapy and each fraction was delivered in a separate interval of 48 hours. Objective overall response (OR) including complete response (CR), partial response (PR) and stable disease (S), acute toxicity

(CTCAE v.4.3), and abscopal response (AR) were measured. One to three metastases were selected on each patient for SABR treatment. All patients had received at least 1 cycle of ICI prior to SABR. In order to evaluate the AR, 2 non-irradiated lesions were selected. AR was defined as 25% reduction in any non-irradiated predefined measurable lesions. These lesions were assessed according to RECIST (v1.1) by CT, MRI or PET at 8-week intervals.

## Results

From September 2017 to October 2018, 60 patients who had received anti-PD-1/L-1 immunotherapy [nivolumab ( $n=31$ ), pembrolizumab ( $n=22$ ) or atezolizumab ( $n=7$ )] were included. Twenty patients were excluded from analysis due to the lack of at least 8-weeks follow-up after SABR. All lesions received SABR doses  $> 6$  Gy/fraction, with a median dose of 35 Gy/5 fractions ( $BED_{10} = 59.5$  Gy). After a 7-month median follow-up (2-14 months), the acute ICI toxicity profile was similar before and after SABR. Median overall survival (OS) was 9 months (SD 0.5, IC95% 8.0-10.4). Local response was reported in 29 patients (73%). AR was observed in 13 patients (33%), 4 of whom had CR, 6 PR and 2 stable. Median time from SABR to AR was 2 months. All patients with AR are alive to date. Overall, 21 patients (53%) presented OR and 5 patients (13%) achieved a sustained systemic CR. OS sub-analysis was significantly higher in the AR group versus the Non-AR group (100% vs 60%,  $p=0.01$ ). OR rate was also higher in the AR group versus the Non-AR group (88% vs. 28%,  $p=0.002$ ). Patients continued to receive the same ICI for a mean of 6 months post-SABR (range: 2-14 months) before subsequent disease progression. Only 9 patients (23%) have required a new systemic treatment. Lastly, an analysis regarding SABR dose was performed. Patients were divided into two groups based on the biologically equivalent dose ( $BED_{10}$ ) received. Patients who received doses  $> 50$  Gy ( $BED_{10}$ ) achieved a superior median OS compared to  $< 50$  Gy ( $BED_{10}$ ) (9 vs 4 months,  $p=0.01$ ).

## Conclusion

Our results show that in patients unresponsive to ICI, I-SABR could rechallenge the immune system resulting in high local and abscopal effect improving survival with maintenance ICI treatment.

### Purpose or Objective

The European Organization for Research and Treatment of Cancer (EORTC) phase II prospective multicentre Lungtech trial 22113-08113 assesses safety and efficacy of stereotactic body radiotherapy (SBRT) in inoperable patients with centrally located non-small cell lung cancer (NSCLC). The trial was closed early due to poor accrual. Here we report on two lethal complications.

### Material and Methods

Patients with centrally located (“tumor within 2 cm or touching the zone of the proximal bronchial tree (PBT) or tumor that is immediately adjacent to the mediastinal or pericardial pleura, with a planning target volume expected to touch or include the pleura”) non-metastatic NSCLC (T1-T3,  $\leq 7$ cm) were included. After prospective imaging review and radiation quality assurance (RTQA) patients were treated with SBRT (8x7.5Gy, ICRU 83). Follow-up is performed 6 weeks after treatment, then 3-monthly for 3 years, 6-monthly in year 4 and 5, including history, clinical examination, toxicity assessment and CT, FDG-PET and biopsy in case of suspected progression. The protocol included recruitment stop in case of potentially SBRT-related death triggering safety review.

### Results

Between 08/15 and 12/17, 39 patients from 13 sites and 6 European countries were included in the trial, 33 passed imaging and RTQA review (58% male, age 57-89 years, tumor size 1.4 - 5.5cm) and were treated per protocol. So far, 2 potentially treatment related deaths were observed.

An 88 year old patient died 3 months after SBRT and death was attributed to radiation pneumonitis. Safety review could not decide on the definite cause of death, also potentially related to pre-existing cardiac disease (CD) or amiodarone lung disease. As a consequence, patients with severe pre-existing CD, interstitial lung disease or concomitant amiodarone intake were excluded from recruitment and a formal policy to treat pneumonitis was added in the protocol. As this patient had a relatively high contralateral mean lung dose (CMLD), the amended recommendation restricted CMLD to  $< 3.6$ Gy.

An 83 year old patient with a tumor broadly abutting the right lower lobe bronchus died 15 months after SBRT, scored as SBRT-related hemoptysis. The PBT received 46.5Gy to 0.54cc, considered as acceptable protocol variation. Safety review revealed that in this patient taking anticoagulants, bronchoscopy, including a biopsy of a necrotic patch at the right lower lobe was performed 4 days before death. The event was categorized as expected toxicity and recommendations for a more careful management of procedures after SBRT were made available to investigators. Although it was not recommended to stop the study for safety reasons, the

repeated safety-related halt in recruitment contributed to the early closure of the trial.

### Conclusion

Safety of SBRT in centrally located lung tumors remains unclear. For the prospective investigation of radiotherapy related toxicities, alternative trial designs to those typically used to investigate medicinal products might be needed.

### OC-0062 Development & validation of prognostic and predictive models in limited-stage small-cell lung cancer

A. Salem<sup>1</sup>, H. Mistry<sup>2</sup>, S. Falk<sup>3</sup>, G. Price<sup>4</sup>, C. Faivre-Finn<sup>1</sup>  
<sup>1</sup>University of Manchester/ Christie NHS Foundation Trust, Division of Cancer Sciences/ Radiotherapy Related Research & Department of Clinical Oncology, Manchester, United Kingdom; <sup>2</sup>University of Manchester/ Christie NHS Foundation Trust, Division of Cancer Sciences & Division of Pharmacy/ Radiotherapy Related Research, Manchester, United Kingdom; <sup>3</sup>Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom; <sup>4</sup>University of Manchester/ Christie NHS Foundation Trust, Division of Cancer Sciences/ Radiotherapy Related Research, Manchester, United Kingdom

### Purpose or Objective

Assessment of prognosis & selection of limited-stage small-cell lung cancer (LS-SCLC) patients who benefit from chemoradiotherapy (CRT) could aid clinical decisions. We used the CONVERT trial & validation cohorts to investigate LS-SCLC prognostic & predictive covariates.

### Material and Methods

CONVERT is a phase III trial that randomised patients between twice-daily (45Gy in 30 fractions) & once-daily (66Gy in 33 fractions) CRT, followed by prophylactic cranial irradiation if indicated. The following covariates were investigated for prognostic & predictive significance (benefit from twice-daily radiotherapy & CRT completion) in CONVERT: clinical (age, performance score (PS), TNM stage, tumour laterality, smoking status, weight loss  $>10\%$  & lung function), laboratory (alkaline phosphatase, sodium & lactate dehydrogenase) & dosimetric (gross tumour volume (GTV), % heart dose & lung V20). Chemotherapy & radiotherapy completion were defined as delivery of all pre-planned cycles (4 or 6) & all radiotherapy fractions, respectively. Multivariate overall survival (OS) & chemotherapy completion regression analyses were conducted after correcting for multiple comparisons with a final model derived via a backward elimination approach using the likelihood ratio-test. The CONVERT OS model was validated in 2 independent LS-SCLC retrospective patient cohorts, treated in the routine setting at The Christie.

### Results

459 CONVERT participants & 2 Christie cohorts treated with CRT (cohort 1; n=108) and radiotherapy  $\pm$  chemotherapy (cohort 2; n=228) were included (table 1). In CONVERT, GTV was the strongest OS prognostic covariate (HR 1.3 (95% CI 1.14-1.48);  $p<0.001$ ). The addition of PS (ECOG 1/2 vs 0) & tumour laterality (bilateral/midline/unknown vs unilateral) modestly improved the models' concordance index (0.59 to 0.61). The HR for OS between high & low risk groups using this model, derived by splitting on the median risk score, was 1.96 (95% CI 1.54-2.49); median OS: 21 m (95% CI 18-25) vs 45 m (95% CI 34-NR), respectively (figure 1A). The models' prognostic significance was validated in the 2 independent Christie cohorts (cohort 1 concordance index=0.62, SE=0.04 & cohort 2 concordance index=0.59, SE=0.02); figure 1B-C. None of the covariates predicted benefit from twice-daily radiotherapy in CONVERT. In CONVERT, increasing patient age (continuous) alone or with hyponatremia & decrease in forced expiratory volume in 1sec (continuous) predicted non-completion of

6 or 4 pre-planned chemotherapy cycles ( $p < 0.05$ ), respectively. Due to high radiotherapy completion in CONVERT ( $\geq 80\%$  in both trial arms), a multivariate analysis to predict radiotherapy completion was not performed. Data on treatment completion were currently unavailable in the routinely treated cohorts.

ECOG PS – Eastern Cooperative Oncology Group Performance Score; GTV – Gross Tumour Volume; RT- Radiotherapy

**Figure 1:** Kaplan-Meier survival curves for CONVERT (A) and Christie cohorts 1 (B) and 2 (C) split into high & low risk groups using the median value derived from final Cox model (GTV, ECOG PS and tumour laterality)

## Conclusion

We report an independently validated LS-SCLC prognostic model from the CONVERT trial, providing information clinicians can relay to patients to aid clinical decisions. The addition of biological covariates could refine this model.

## OC-0063 CREO Project: exploratory radiomics for predicting adaptive radiotherapy in NSCLC

M. Fiore<sup>1</sup>, C. Greco<sup>1</sup>, E. Ippolito<sup>1</sup>, E. Molfese<sup>1</sup>, P. Trecca<sup>1</sup>, M. Miele<sup>1</sup>, E. Cordelli<sup>2</sup>, R. Sicilia<sup>2</sup>, P. Soda<sup>2</sup>, R.M. D'Angelillo<sup>1</sup>, L. Trodella<sup>1</sup>, S. Ramella<sup>1</sup>  
<sup>1</sup>Campus Biomedico University, Department of Radiation Oncology, Roma, Italy; <sup>2</sup>Campus Biomedico University, Research Center in Advanced Biomedicine and Bioengineering, Roma, Italy

## Purpose or Objective

The primary goal of precision medicine is to minimize side effects and optimize efficacy of treatments. Recent advances in medical imaging technology allow the use of more advanced image analysis methods beyond simple measurements of tumor size or radiotracer uptake metrics. The extraction of quantitative features from medical images to characterize tumor pathology or heterogeneity is an interesting process to investigate, in order to provide information that may be useful to guide the therapies and predict survival. The aim of this study was to investigate whether the radiomic features of initial imaging were able to predict tumor reduction during radio- chemotherapy (RCT) in patients with stage III non-small cell lung cancer (NSCLC).

## Material and Methods

We studied 91 patients with stage III NSCLC treated with concurrent RCT: 50 patients were treated at radical dose with adaptive approach (adaptive group), 41 patients underwent radical concurrent RCT in the same period, but who did not achieve target reduction (non-adaptive group). Clinical characteristics of these patients are listed in Table 1. The characteristics investigated were extracted from the initial simulation CT on which the Clinical Target Volume was manually delineated by expert radiation oncologists, providing a 3D ROI. Given each 3D ROI in the images, we computed the radiomic features using our in-house software tool coded in MATLAB (Mathworks Inc, MA, U.S.A.), taking into consideration 12 statistics features and 230 textural features extracted from the CT images. In our study, we used an ensemble learning method to classify patients' data into either the adaptive or non-adaptive group during RCT on the basis of the starting CT simulation. All the experiments were conducted according to a 10-fold cross validation, i.e., a model validation technique which provides a nearly unbiased estimate using only the original data.

	Adaptive group (%) (n=50)	Non-Adaptive group (%) (n=41)	Total (n=91)

Mono	31 (62%)	21 (51%)	52 (57%)

Table 1: Patients' characteristics

## Results

Figure 1 shows the final performance, the area under the receiver operating characteristic curve (AUC). To the best of our knowledge, this is the first trial investigating radiomic strategy to predict tumor shrinkage during RCT and our data suggests that a specific signature can be identified (AUC 0.82).

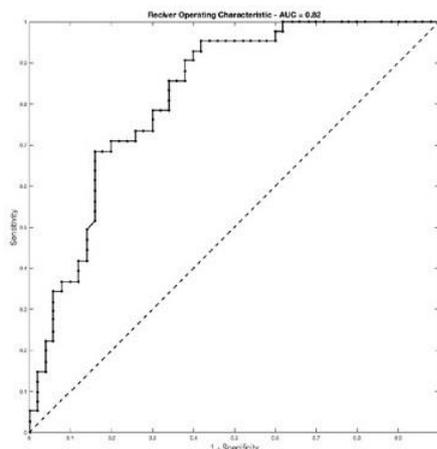

Figure 1: ROC curve of the proposed system

## Conclusion

The initial results of CREO Project obtained are an original and innovative topic that opens up new research in the field of personalized medicine in radiation therapy. The identification of the external validation dataset is actually ongoing.

### OC-0064 Reducing radiotherapy dose to involved lymph nodes in locally advanced NSCLC: efficacy and toxicity.

J. Van Diessen<sup>1</sup>, M. Kwint<sup>1</sup>, J. Sonke<sup>1</sup>, I. Walraven<sup>1</sup>, B. Stam<sup>1</sup>, J. De Langen<sup>2</sup>, J. Belderbos<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands; <sup>2</sup>Netherlands Cancer Institute, Thoracic Oncology, Amsterdam, The Netherlands

## Purpose or Objective

Radiotherapy for locally advanced non-small lung cancer (LA-NSCLC) causes oesophageal and pulmonary toxicity, which might be severe especially when concurrent chemotherapy is applied. A possible solution to decrease severe toxicities, is dose reduction to the involved lymph nodes, thereby reducing the dose to the mediastinal structures. The reported low incidence of regional (lymph node) failures compared to the primary tumour (6% versus 16%) supports this policy [1]. The goal of this study was to assess the safety and efficacy of a dose reduction to the involved lymph nodes in LA-NSCLC patients receiving (chemo)radiotherapy.

## Material and Methods

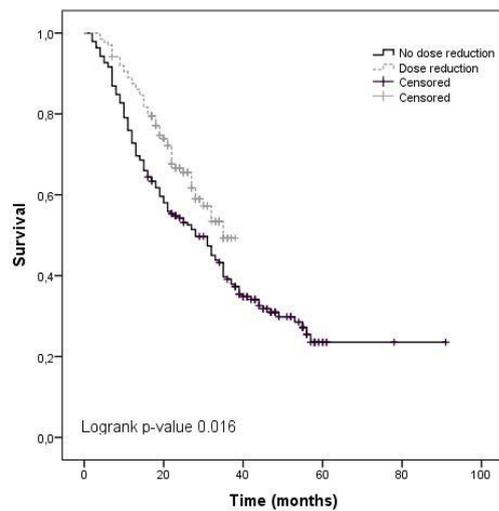

An observational study was performed with a sequential design cohort including 328 patients with LA-NSCLC. Both cohorts received hypofractionated radiotherapy of 24 x 2.75 Gy to the primary tumour. The standard cohort included 191 patients treated between June 2013 and June 2015 with a 24 x 2.75 Gy (EQD<sub>2</sub>=70Gy (α/β=10)) dose scheme to the involved lymph nodes. The dose-reduction cohort (treated from June 2015 until June 2017) consisted of 137 patients who received a reduced dose of 24 x 2.42 Gy (EQD<sub>2</sub>=60Gy (α/β=10)) to the involved lymph nodes. The effect of dose reduction on toxicity and OS was assessed using independent samples t-test, chi-square tests, Logrank and cox regression analyses. Additionally, we assessed whether patient, tumour and treatment characteristics significantly influenced the association between dose reduction and outcomes.

## Results

The median follow-up for the standard cohort and dose reduction cohort was 48 (2-85) and 29 (3-35) months, respectively. Patient and tumor characteristics were comparable between the 2 cohorts. Oes\_V<sub>50</sub> (the volume of the oesophagus receiving ≥50 Gy), mean lung dose (MLD) and mean heart dose were significantly lower in the dose-reduction cohort. The incidence of regional failures was non-significantly lower in the dose-reduction group, 12% versus 7%, respectively (P=0.430). Furthermore, a significantly improved OS was observed in the dose-reduction group, 28 versus 35 months respectively (P=0.016) (Fig 1). Acute toxicity grade ≥2, (dysphagia, pneumonitis, dyspnoea and cough, P=0.001) and late toxicity grade ≥2 (dysphagia, vertebrae fracture and cough, P=0.041) were significantly lower in the dose reduction cohort. MLD significantly influenced the association between dose reduction and OS. Nonetheless, after correction for MLD the independent association remained borderline significant (HR 0.733; 95% CI 0.526-1.021; P= 0.067).

## Figure 1.

Kaplan-Meijer curve for overall survival between the standard and dose reduction cohort.

### Conclusion

In conclusion, a dose reduction from 70 Gy to 60 Gy (EQD<sub>2</sub>) to the involved mediastinal lymph nodes in LA-NSCLC patients receiving (chemo)radiotherapy results in a lower incidence of severe toxicity and an increase OS and is therefore safe and promising. No increase in regional failures was observed.

### OC-0065 Cardiac dose and survival in lung cancer: which cardiac sub-structures matters most?

A. McWilliam<sup>1</sup>, J. Khalifa<sup>2</sup>, E. Vasquez Osorio<sup>1</sup>, A. Abravan<sup>1</sup>, A. Marianne<sup>1</sup>, C. Faivre-Finn<sup>1</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>University of Manchester, Division of Clinical Cancer Sciences, Manchester, United Kingdom; <sup>2</sup>Institut Universitaire du Cancer de Toulouse, Oncopole, Toulouse, France

### Purpose or Objective

There is increasing evidence that dose to the heart for non-small cell lung cancer (NSCLC) patients impacts overall survival. However, despite the growing body of evidence, cardiac sub-structures where excess dose has the greatest impact on overall survival have not been identified. In this work we implement two variable reduction techniques to identify these sub-structures and estimate radiotherapy dose-limits.

### Material and Methods

14 cardiac sub-structures were delineated on 5 template patients including: atria and ventricles, coronary arteries, valves and pulmonary arteries. 1,100 NSCLC patients were non-rigidly registered to the 5 template patients, mapping their planned radiotherapy dose to the template patient's anatomy. Mean and max dose to each cardiac sub-structure were extracted. Across the 5 template patients, a mean of the mean dose was calculated and the max of the max dose extracted for analysis. The cohort was split into training (2/3 patients) and test (1/3 patients) datasets.

Two variable reduction techniques were implemented: an elastic net LASSO model and a random forest survival model. Each model was optimised to extract the variables that contributed the most to overall survival. Models were tested on their ability to predict overall survival at 1 year in the test dataset, ROC analysis and area under the curve (AUC) calculated. The two most important variables, common to the two models, were selected for further analysis. Multivariate cox-proportional hazard models were created for each identified sub-structure. An optimal split on dose was performed for each variable with Kaplan Meier survival curves plotted for the test dataset to show significance.

### Results

978 patients remained in the analysis after visual inspection of the registration. The training and test datasets were well balanced for clinical parameters. The AUC for the elastic net model and the random forest model was 0.74 and 0.68, respectively. Both models identified the max dose to the right atrium (RA) and right coronary artery (RCA) as the most important factors associated with survival.

The individual multivariate models (table 1) showed both RA and RCA were significant with a hazard ratio (HR) of 1.02,  $p=0.02$ . In both model's (log) tumour volume was significant as well as N-stage. Interestingly, mean lung dose was not significant. The optimal cut point for the RA was 29.5Gy and for the RCA 15.5Gy. As these are neighbouring structures, the max dose was strongly correlated. The mean, 22.5Gy max dose, was applied to the test dataset and Kaplan Meier survival curves for the RA and RCA plotted, figure 1. The log rank for both curves was  $p<0.0001$ .

	Univariate		Multivariate		Multivariate	
	HR (95% CI)	p	HR (95% CI)	p	HR (95% CI)	p

2	1.55 (1.17-2.06)	>0.01	1.13 (0.67-1.92)	0.64	1.25 (0.74-2.12)	0.40
3	1.82 (1.21-2.73)	>0.01	1.51 (0.74-3.08)	0.26	1.46 (0.71-2.99)	0.30

Table 1. Uni-variate and multi-variate analysis including the two cardiac sub-structures identified using the variable reduction techniques. Log tumour volume and available clinical covariates are included in the analysis.

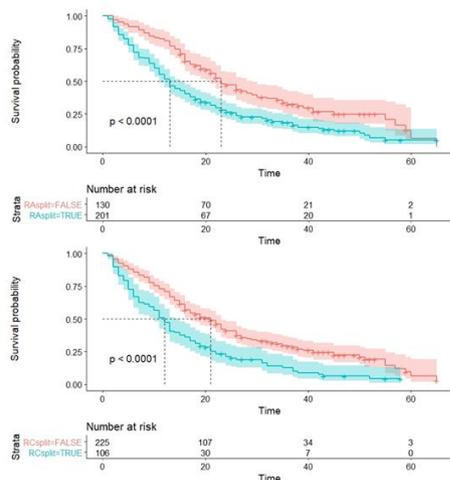

Figure 1. Kaplan Meier survival curves showing the survival difference split as patients receiving greater than or less than 22.5Gy, plotted for the test dataset. Patients receiving greater than 22.5Gy do significantly worse for overall survival.

## Conclusion

We have identified the max dose to the right atrium and right coronary artery as the cardiac sub-structures responsible for the greatest dose-related impact on patient survival. A max dose of 22.5Gy was identified and should be considered for these as avoidance structures in future planning studies.

OC-0066 Effectiveness of radiotherapy for patients not in metabolic remission after chemotherapy for DLBCL

J. Brady<sup>1</sup>, N.G. Mikhaeel<sup>1,2</sup>

<sup>1</sup>Guy's and St. Thomas' NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom; <sup>2</sup>King's College, Division of Cancer Studies, London, United Kingdom

## Purpose or Objective

Persistent metabolic activity on 18-FDG PET-CT at completion of first-line chemotherapy in diffuse large B cell lymphoma (DLBCL) is associated with poor prognosis. Fit patients can be offered salvage high-dose therapy if refractory disease is confirmed, but there is no standard treatment for less fit patients.

Radiotherapy is as an effective treatment for DLBCL and commonly used as part of planned combined modality treatment for localised disease. Its value in patients with localised refractory disease remains to be defined. In this study we aim to evaluate to outcome for patients with incomplete metabolic response (Deauville score 4-5) following first-line chemotherapy who underwent RT to sites of persistent activity.

## Material and Methods

We performed a retrospective review of all patients with DLBCL who received RT at our institution having not achieved a complete metabolic response after first-line chemotherapy. This was defined as a Deauville Score (DS) of 4 or 5 on PET-CT. Eligible patients received RT to a radical dose ( $\geq 30$ Gy in 1.8-2Gy fractions). We collected data on patient, disease and treatment characteristics. Outcomes included relapse rate, site of relapse, time to progression and overall survival (OS). Post radiotherapy PET-CT response was also recorded.

## Results

41 patients who received RT between March 2011 and July 2018 were identified. Patient and disease characteristics are shown in the table below.

Table. Patient and treatment characteristics

Male	21 (51.2%)
Female	20 (48.8%)
Median Age /years (range)	64 (21-89)
Histopathology	
Germinal centre (GC)	17 (41.5%)
Non GC	8 (19.5%)
PMBCL	6 (14.6%)
NOS	10(24.4%)
Stage	
1	4 (9.8%)
2	19 (46.3%)
3	5 (12.2%)
4	13 (31.7%)
IPI	
0-1	16 (39%)
2	9 (22%)
3	8 (19.5%)
4-5	8 (19.5%)
Median no chemotherapy cycles (range)	6 (3-8)
Chemotherapy regimen	
R miniCHOP	8 (19.5%)
RCHOP	29 (70.7%)
RGCVP/RCVP	3 (7.3%)
LMB -B	1 (2.4%)
End of chemotherapy Deauville score	
4	32 (78%)
5	9 (22%)
Radiotherapy dose	
30Gy/30.6Gy	24 (58.5%)
36Gy	13 (31.7%)
40GY	4 (9.8%)

With median 24.3 months of follow up from completion of RT (range 1.7-78.5), 13/41 patients have relapsed/progressed (31.7%). 8 relapses were out of field, 3 both in and out of field and 2 progressed in field only. Median time from completion of RT to progression was 4.0 months (0.8-51).

Of patients with relapsed/progressive disease, 6 received salvage high-dose chemotherapy, and 3 are alive and in

remission. Median OS for all patients was 75 months (1.64-78.5). Median OS for patients with relapsed/progressive disease was 13 months (1.64-74.5).

Deauville score (DS) prior to RT was predictive of relapse risk. 5/9 patients (55.6%) with DS 5 post chemotherapy have relapsed/progressed compared to 8/32 (25%) of those with DS 4.

Response assessment PET-CT scans after RT were performed in 38/41 (92.6%) patients. 18 patients (47.4%) achieved a complete metabolic response (DS 2 or 3), 10 (26.3%) a partial metabolic response (DS 4) and 10 (26.3%) had DS 5. 9/10 (90%) patients with DS 5 post RT have clinically progressed. Only 1/10 (10%) patients with DS4 post RT has progressed.

### Conclusion

Our experience suggests that the majority of patients with an incomplete metabolic response, will not relapse following radiotherapy to the PET positive site. Relapses/progressions were more common in patients with Deauville Score 5 at end of chemotherapy, but a proportion can be successfully salvaged by RT.

### OC-0067 Continuous Positive Airway Pressure (CPAP): an innovative respiratory gating in lymphoma patients

M. Levis<sup>1</sup>, P. Solidoro<sup>2</sup>, S. Bartoncini<sup>1</sup>, E. Gallio<sup>3</sup>, F.R. Giglioli<sup>3</sup>, V. De Luca<sup>4</sup>, L. Focaraccio<sup>2</sup>, C. Cavallin<sup>4</sup>, G.C. Iorio<sup>4</sup>, R. Parise<sup>4</sup>, C. Palladino<sup>4</sup>, V. Di Martino<sup>4</sup>, G. Furfaro<sup>4</sup>, G. Rovere<sup>2</sup>, A. Mattei<sup>2</sup>, R. Ragona<sup>4</sup>, U. Ricardi<sup>4</sup>  
<sup>1</sup>A.O.U. Città della Salute e della Scienza, Radiation Oncology, Torino, Italy ; <sup>2</sup>A.O.U. Città della Salute e della Scienza, Pulmonology, Torino, Italy ; <sup>3</sup>A.O.U. Città della Salute e della Scienza, Medical Physics Unit, Torino, Italy; <sup>4</sup>University of Turin, Department of Oncology, Torino, Italy

### Purpose or Objective

Respiratory gating techniques, as deep inspiration breath holding (DIBH), are strongly encouraged for lymphoma patients with mediastinal involvement in reason of their ability in reducing the dose to normal tissues and to minimize the risk of long term complications. With this background, we aimed to investigate the potential role of Continuous Positive Airway Pressure (CPAP), as an alternative to DIBH, by comparing this innovative respiratory gating with free-breathing (FB) approach in Hodgkin lymphoma (HL) and primary mediastinal lymphoma (PMBCL) patients treated with an optimized volumetric arc therapy (VMAT) solution.

### Material and Methods

After institutional review board approval, 23 patients (9 males and 14 females; mean age 28 years, range 16-38) affected with mediastinal HL (18) or PMBCL (5) were included. All patients underwent computed tomographic simulation twice: with FB and with CPAP. The CPAP pressure used was 18 cm H<sub>2</sub>O for each patient. Median prescription dose to the PTV was 30 Gy in 2-Gy fractions (range 30-40 Gy). Lungs, female breasts, heart and cardiac structures (coronary arteries, valves, atria and ventricles) were all contoured as organs at risk and included in the optimization process of the same VMAT solution in FB or with CPAP for each patient. Maximum and mean dose were compared for all organs and CPAP was used during treatment if judged beneficial. Second breast and lung cancer risks were estimated by calculating the lifetime attributable risk (LAR). Coronary artery disease (CAD) and chronic heart failure (CHF) risks were estimated by calculating the relative risk (RR). CAD risk was derived from the mean dose received by the sum of coronary arteries, while CHF was derived from the mean dose received by the left ventricle, as recently published.

### Results

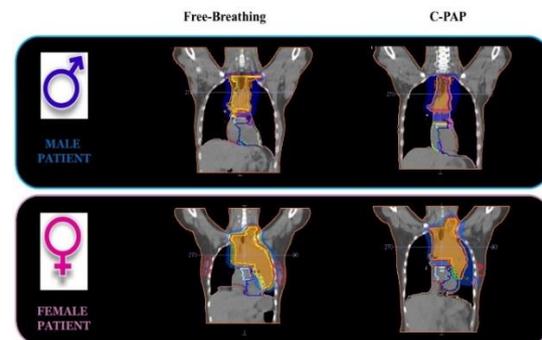

CPAP was well tolerated by all patients. Only one had no benefit from the addition of CPAP and received treatment in FB. CPAP increased mean lungs volume (4.21 vs 2.71 liters, p<0.01) and significantly reduced both lungs

V<sub>20Gy</sub> and V<sub>5Gy</sub> (p<0.01). Moreover, CPAP decreased the intersection between whole heart and PTV volumes (p<0.01) and resulted in lower dose to heart (p<0.01), whole coronary arteries (p<0.01), left ventricle (p<0.01) and aortic valve (p<0.01). Breast V<sub>4</sub> was similar for FB and CPAP (p=0.20). Dose parameters are reassumed in the table. Significant lower RR for CAD (p<0.01) and CHF (p<0.01) were observed for CPAP, with a mean 22% and 8% risk reduction, respectively. LAR for lung cancer was lower with CPAP (p<0.01), while LAR for second breast cancer was similar for CPAP and FB (p=0.81).

Table: Dose parameters comparison between Free-Breathing and C-PAP

Structure	Parameter	Free-Breathing	C-PAP	Wilcoxon test p-value	
PTV COVERAGE	V95	95.3%	95.2%	ns	
	Overall Volume (cc)	2.710	4.210	<0.01	
	V <sub>5Gy</sub>	12.9%	10.4%	<0.01	
LUNGS	V <sub>5Gy</sub>	40.6%	34.5%	<0.01	
	Life attributable risk (LAR)	240.9	207.7	<0.01	
	Intersection Heart/PTV	26.9	12.5	<0.01	
WHOLE HEART	Max dose	32.8 Gy	32.5 Gy	ns	
	Mean dose	5.3 Gy	3.9 Gy	<0.01	
CORONARY ARTERIES	1- Left main trunk	Max dose: 16.5 Gy Mean dose: 12.6 Gy	12.9 Gy 8.9 Gy	<0.01	
	2- Circumflex	Max dose: 15.5 Gy Mean dose: 7.4 Gy	11.2 Gy 4.9 Gy	<0.01	
	3- Left descending	Max dose: 22.4 Gy Mean dose: 10.1 Gy	17.6 Gy 7.2 Gy	<0.01	
	4- Right coronary	Max dose: 19.3 Gy Mean dose: 8.9 Gy	14.1 Gy 6.2 Gy	<0.01	
	5- Coronary SUM (overall)	Max dose: 22.6 Gy Mean dose: 3.2 Gy	19.0 Gy 2.1 Gy	<0.01	
	Relative Risk (for coronary events)	3.7	2.9	<0.01	
	LEFT VENTRICLE	Max dose	22.6 Gy	19.0 Gy	<0.01
		Mean dose	3.2 Gy	2.1 Gy	<0.01
		Relative Risk (for chronic failure)	1.29	1.19	<0.01
	AORTIC VALVE	Max dose	21.1 Gy	16.6 Gy	<0.01
Mean dose		10.5 Gy	6.9 Gy	<0.01	
BREASTS	Max dose	28.5 Gy	24.9 Gy	<0.01	
	Mean dose	4.25 Gy	3.71 Gy	ns	
BREASTS	V <sub>4Gy</sub>	28.9%	23.8%	ns	
	Life attributable risk (LAR)	83.2	82.1	0.81	

Figure: comparison between CPAP and free-breathing in a male and in a female patient

### Conclusion

In this pilot study, we first demonstrated the contribution of CPAP to a reduction in lungs and heart structures dose, with a significant impact on long term complications. CPAP was well tolerated, simple to implement, reproducible and does not require breath-holding. In our opinion, CPAP should be further implemented as a novel strategy for motion management and respiratory gating in lymphoma patients.

### OC-0068 MR-guided adaptive radiotherapy for intra-abdominal lymphoma

F. Spoelstra<sup>1</sup>, P. Cobussen<sup>1</sup>, M. Palacios<sup>1</sup>, A. Bruynzeel<sup>1</sup>, F. Lagerwaard<sup>1</sup>, B. Slotman<sup>1</sup>, S. Senan<sup>1</sup>  
<sup>1</sup>VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

Radiotherapy for intra-abdominal lymphoma may be impaired by geographic misses arising from variations in gastric filling, bowel movement, or respiratory motion. Larger PTV margins are therefore used, resulting in

unnecessary doses to organs at risk. Despite use of larger PTV margins, verification of tumor position is essential. However, visualization of intra-abdominal tumor position is suboptimal using cone-beam CT scans. Daily MR-guidance can enable improved tumor verification, and adaptive radiotherapy may also allow for optimal target coverage. We report on our initial experience of MR-guided adaptive radiotherapy in intra-abdominal lymphoma patients.

#### Material and Methods

Five patients underwent both a planning CT and MRI scan (MRIdian; ViewRay Inc) during shallow inspiration breath hold after at least 3 hours of fasting. The gross tumor volume (GTV) was contoured on the planning MR, and a planning target volume (PTV) generated using a 10 mm margin. The liver, kidneys, spinal cord, and spleen were contoured as avoidance structures for initial treatment planning, but were not contoured daily due to low doses used. Daily breath-hold MR scans were performed before each fraction, and the GTV was manually adjusted when necessary. Re-optimized plans were routinely created and compared to the original plan that was recalculated on the anatomy of the day. Clinicians selected the most optimal of both plans. Treatment was delivered during video-assisted breath-hold based on tracking of the GTV, using the PTV as gating boundary. Inter-fractional changes in GTV were assessed, and the frequency of using re-optimized plans and the rationale for this were analyzed.

#### Results

Five patients, of whom three had a gastric lymphoma and two a mesenteric lymphoma, have been treated with MR-guided adaptive radiotherapy. A total of 67 MR-guided fractions were delivered, with total doses ranging from 24-36 Gy in 12-18 fractions. Daily adjustment of the GTV was performed in 4 patients (49 fractions), with mean GTVs ranging from 244cc to 296cc. Limited inter-fractional changes in GTV were seen in 3 patients, with relative GTV differences between the mean and 10<sup>th</sup>-90<sup>th</sup> percentiles of <11%. The relative difference was 38% in the fourth patient, because fasting instructions were not complied with. Re-optimized plans were superior to recalculated original plans in each fraction studied, with the reason being reduced PTV coverage in 4 patients (mean V95% of 85%, 10<sup>th</sup>-90<sup>th</sup> percentile: 74%-95%). In another patient, the recalculated original plan would have led to a V107% >5% in 12 fractions, whereas inadequate PTV coverage was the reason for using the re-optimized plans in the remaining 8 treatment fractions.

#### Conclusion

MRI guided treatment of intra-abdominal lymphoma allows for improved visualization of the GTV and permits daily plan re-optimization, which led to superior PTV coverage and reduction in plan inhomogeneity.

**OC-0069 5x5 Gy with chemotherapy in borderline resectable soft tissue sarcomas: early results of a trial**  
 M. Spalek<sup>1</sup>, H. Koseta-Paterczyk<sup>1</sup>, A. Borkowska<sup>1</sup>, M. Wągródzki<sup>2</sup>, A. Szumera-Ciećkiewicz<sup>2</sup>, A. Cieszanowski<sup>3</sup>, P. Castaneda-Wysocka<sup>3</sup>, T. Świtaj<sup>1</sup>, M. Dudzisz-Śledź<sup>1</sup>, A. Czarnecka<sup>1</sup>, E. Dąbrowska-Szewczyk<sup>4</sup>, P. Rutkowski<sup>1</sup>  
<sup>1</sup>Maria Skłodowska-Curie Institute - Oncology Center, Department of Soft Tissue/Bone Sarcoma and Melanoma, Warsaw, Poland; <sup>2</sup>Maria Skłodowska-Curie Institute - Oncology Center, Department of Pathology and Laboratory Diagnostics, Warsaw, Poland; <sup>3</sup>Maria Skłodowska-Curie Institute - Oncology Center, Department of Radiology I, Warsaw, Poland; <sup>4</sup>Maria Skłodowska-Curie Institute - Oncology Center, Department of Medical Physics, Warsaw, Poland

#### Purpose or Objective

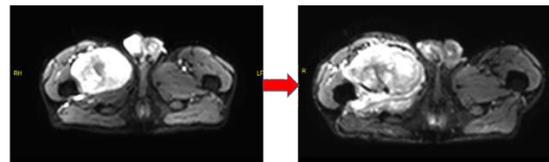

There is a lack of standard treatment of unresectable and marginally resectable sarcomas (STS). Results of commonly used approaches are unsatisfactory. The addition of neoadjuvant/induction chemotherapy before

the irradiation and in the prolonged gap between the end of hypofractionated 5x5 Gy radiotherapy and surgery may allow to obtain the R0 resection rate, high pathological response rate and/or a higher rate of limb-sparing/conservative surgery as well as to increase patients' survival.

#### Material and Methods

A single-arm prospective clinical trial was conducted (NCT03651375). Treatment consisted of one cycle of doxorubicin and ifosfamide (AI), then 5x5 Gy RT, and two cycles of AI in seven-eight weeks gap between the end of RT and surgery. STS response was assessed in DWI-MR imaging (Fig. 1) and pathologically by EORTC STBSG criteria. The primary endpoint is rate of limb-sparing surgeries and R0 resections.

**Figure 1.** UN-RESARC – MRI evaluation of STS response to the treatment

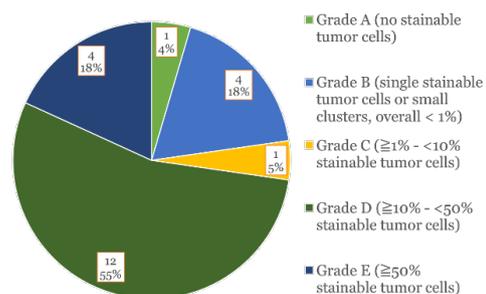

**Description of DWI-MRI after preoperative treatment:** The tumour located in the middle thigh compartment of the right thigh is slightly larger, but it contains slightly larger areas of necrosis and bleeding. Large oedema in the surrounding soft tissues - probably after treatment. The tumour shows smaller areas and less intensive diffusion restriction (the areas of increased signal in ADC) - which suggests a response to the treatment.

#### Results

30 patients(pts) met eligibility criteria, 23 received the whole planned protocol treatment, four are currently receiving the treatment, in three pts the treatment was prematurely stopped. 23 pts underwent limb-sparing or conservative surgery, 3 pts underwent extremity amputation, two after 1st AI cycle due to poor tolerance, one due to extensive tumour invasion without a possibility of vessels reconstruction. Among patients who underwent conservative treatment, in 15 of them resection margin was R0, in 7 pts R1. One toxic death occurred outside our centre related to severe bone marrow suppression with septic shock after the second AI cycle. Early tolerance of chemotherapy was acceptable. Grade 3+ CTCAE4.03 toxicity occurred in 11 pts. Early RT tolerance was good. EORTC grade 1 radiation dermatitis occurred in 14 and grade 2 in three pts. Postoperative wound complications occurred in 7 pts, in two were severe. Very good pathological response (<1% of stainable tumour cells; grade A/B) was found in 5 pts (Fig. 2). Good pathological response (<50% tumour cells; grade C/D) was found in 13 pts (Fig. 2).

**Figure 2.** Evaluation of response after preoperative treatment according to EORTC-STBSG recommendations for pathological examination

#### Conclusion

Preoperative AI combined with hypofractionated radiotherapy is a feasible method of the management of

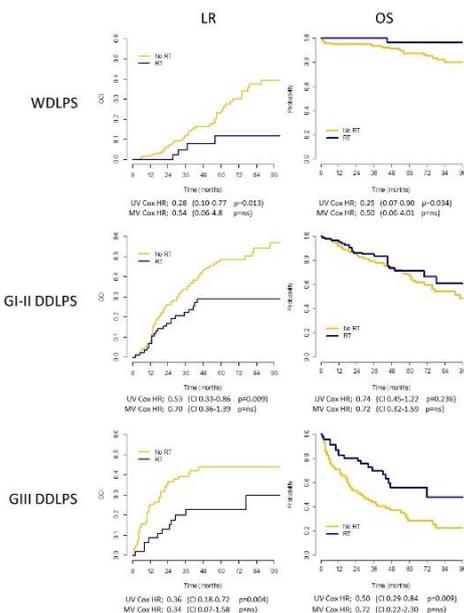

marginally resectable STS. It provides good pathological responses in advanced STS with acceptable treatment toxicity.

#### Purpose or Objective

This study investigates the role of radiotherapy (RT) in patients with primary non-metastatic retroperitoneal liposarcomas.

#### Material and Methods

607 patients with localized retroperitoneal WDLPS and DDLPS were resected with or without RT at 8 high-volume sarcoma centers: 234 WDLPS, 242 GI-II DDLPS and 131 GIII DDLPS. RT was applied in 19.7%, 34.7% and 35.1% of these cohorts respectively. Overall survival (OS) was estimated by Kaplan-Meier method, and the incidences of local recurrence (LR) and distant metastasis (DM) were

estimated in a competing-risk framework. To account for bias consistent with non-random RT-assignment, propensity scores were estimated. Cox univariable analyses of association between RT and oncological endpoints was performed by applying inverse-probability-of-treatment-weight (IPTW) using propensity scores.

#### Results

Age, tumor size, and chemotherapy administration were significantly imbalanced between irradiated and unirradiated patients in all cohorts. IPTW removed all imbalances in key prognostic variables. The 8-year LR incidence in surgery + RT versus surgery only was 11.8% and 39.2% (p=0.011; WDLPS), 29.0% and 56.7% (p=0.008; grade I-II DDLPS), and 29.8% and 43.7% (p=0.025; grade III DDLPS), respectively, however this significant benefit was lost after IPTW-analyses. There were no significant differences in DM and OS between irradiated and unirradiated patients across all three cohorts.

#### Conclusion

Perioperative RT was associated with better LC on univariable unadjusted analyses in all cohorts, but not after accounting for imbalances in prognostic variables. RT did not impact on DM or OS. Appropriate selection of RT in this disease remains challenging. Results of the EORTC-STBSG 62092/22092 study are awaited.

#### OC-0071 Stereotactic radiotherapy for nodal recurrences: an interim analysis from two phase I trials

Gemelli"- Università Cattolica del Sacro Cuore, Department of Radiotherapy, Roma, Italy

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) has been shown to achieve high local control rates in limited metastatic burden of disease. Few papers reported on the efficacy of SBRT in limited nodal metastases. The primary aim was to review institutional outcomes of patients with solitary or oligometastatic lymph nodes treated with SBRT.

#### Material and Methods

Data from DESTROY-1 phase I and SRS-DESTROY-2 phase I clinical trials were reviewed and analyzed. These trials were a 5 fractions SBRT trial and a single fraction radiosurgery study, respectively (Figure 1). End-points were the detection of toxicities, overall response rate (ORR), and local control (LC). Tumor response was assessed according to the RECIST and EORTC PET criteria. Patients with all metastatic sites, primary tumor types and histologies were included between December 2003 and January 2018.

**Dose Escalation STereotactic RadiOtherapy 1**

Level	Lung/extra-pulmonary tumors	Para-thoracic tumors or tumors near chest wall	Extra-thoracic tumors	Re-irradiation		ESRT boost	
				with prior radiotherapy > 60 Gy or re-irradiation of parotid or pelvic cancer	with prior radiotherapy > 60 Gy	after RT dose < 50 Gy	after RT dose > 50 Gy
1	25 Gy	25 Gy	25 Gy	20 Gy	25 Gy	25 Gy	20 Gy
2	37.5 Gy	30 Gy	30 Gy	25 Gy	30 Gy	30 Gy	25 Gy
3	45 Gy	35 Gy	35 Gy	30 Gy	35 Gy	35 Gy	30 Gy
4	50 Gy	40 Gy	40 Gy	35 Gy	40 Gy	40 Gy	35 Gy
5	45 Gy	45 Gy	45 Gy	40 Gy	45 Gy	45 Gy	40 Gy
6	50 Gy	50 Gy	50 Gy	45 Gy	50 Gy	50 Gy	45 Gy

**VMAT based Dose Escalated Stereotactic RadiOtherapy 2 (Radiosurgery)**

Level	Lung	Liver	Bone	Advanced	Vertebrae (after 25 Gy)
1	26 Gy/	26 Gy	12 Gy	16 Gy	8 Gy
2	28 Gy	28 Gy	14 Gy	18 Gy	10 Gy
3	30 Gy	30 Gy	16 Gy	20 Gy	12 Gy
4	32 Gy	32 Gy	18 Gy	22 Gy	
5	34 Gy		20 Gy	24 Gy	
6			22 Gy		
7			24 Gy		

**Results**

180 patients (M/F: 94/86); median age: 67, range 37-88) treated with SBRT for a total of 253 nodal recurrences were analyzed. Patients with different cancer types were included in the analysis, in particular the primary were: gynaecological (N°=49; 27.2%), prostatic (N°=38; 21.1%), gastrointestinal (N°=25; 13.9%), lung (N°=22;12.2%), breast (N°=16; 8.9%), genito-urinary (N°=12; 6.7%), head and neck (N°=11; 6.1%) and skin tumours (N°=7; 3.9%). The most common metastatic sites were the thorax (N°=92; 36.4%) and the pelvis (N°=88; 34.8%), followed by abdominal (N°=61; 24.1%) and neck regions (N°=12; 4.7%). The majority of lesions (79.8%) were treated with VMAT technique, while the former by 3DCRT or IMRT techniques. Dose prescription to the Planning Target Volume varied from 12 Gy/single fraction to 50 Gy/5 fractions. With a median follow-up of 21 months (2-124) no grade 3 acute or late toxicity was recorded. ORR based on CT/MRI/PET was 79.8 % (CI 95%: 73.3-85) with a complete response rate of 57.7% (CI 95%: 50.3-64.5). 24- and 48-months actuarial local control (freedom from progression in the irradiated site) was 81.3% and 69.6%, respectively.

**Conclusion**

These data on a large series of lymph node recurrences in oligometastatic patients demonstrate low risk of morbidity after SBRT and favourable long term local control

**OC-0072 Clinical outcomes of stereotactic MR-guided adaptive radiation therapy for adrenal oligo-metastases**

<sup>1</sup>VU University Medical Center, Radiation Oncology, Amsterdam, The Netherlands; <sup>2</sup>VU University Medical Center, Pulmonology, Amsterdam, The Netherlands

**Purpose or Objective**

Patients presenting with 1-5 distant metastases, so-called oligo-metastases, can have a survival benefit if all lesions are treated using stereotactic ablative radiotherapy (SABR). The delivery of SABR to adrenal metastases can be challenging due to respiration-induced organ motion and proximity of organs at risk (OAR). Consequently, lower radiation doses are often delivered to minimise the risk of toxicity, even though lower doses may be correlated with a worse local control. We implemented stereotactic magnetic resonance-guided adaptive radiation therapy (SMART) for abdominal tumors aiming for a BED 100 Gy<sub>10</sub>, and report on clinical outcomes in adrenal oligo-metastases.

**Material and Methods**

All patients treated for adrenal oligo-metastases on the MRIdian system (ViewRay Inc.) at our institution until June 2018 were included. The OAR and GTV's were contoured on a breath-hold planning MR, and a planning target volume (PTV) was created by adding a 3mm margin to the GTV, but excluding luminal OAR's (see figure). Relevant high dose OARs were stomach, bowel and ipsilateral kidney. A robust baseline plan was generated for daily adaptation. Our institutional protocol mandates accepting underdosage inside the PTV if deemed necessary to meet high dose OAR constraints (see figure). All patients underwent daily on-table MR-imaging before treatment, and to optimise delivery, a new on-table treatment plan was generated based on the anatomy-of-the-day. Gated SMART was delivered during repeated voluntary video-assisted breath-holds, with continuous tracking of the GTV and using the PTV as gating boundary. We analysed toxicity, local control (LC), disease free- and overall survival (DFS, OS).

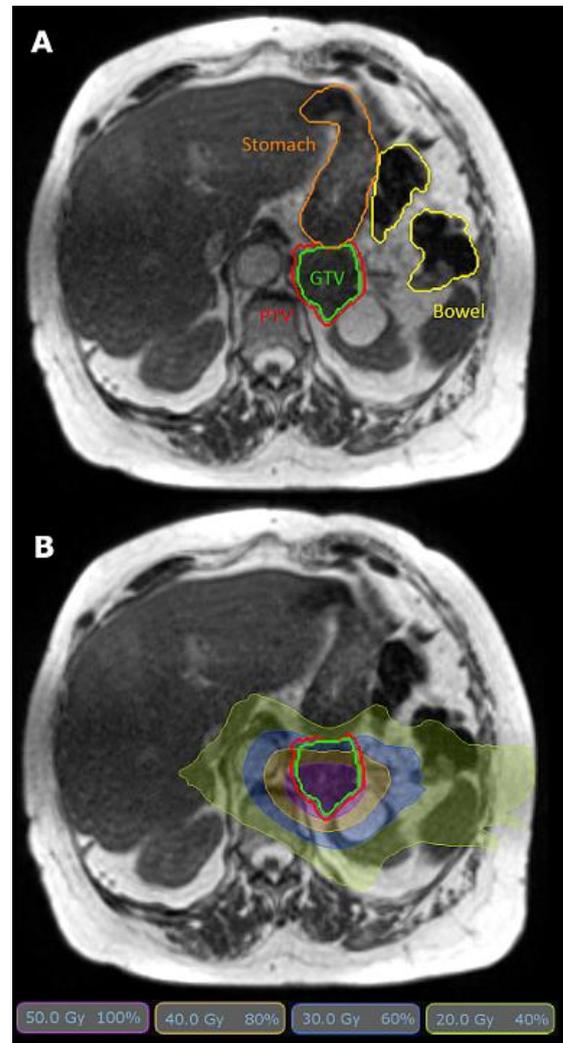

Figure. MR-scan of an adrenal gland metastasis patient showing relevant OARs (A). Dose distribution of a SMART treatment plan showing sparing of the stomach (B).

**Results**

Twenty-five patients underwent SMART for an adrenal oligo-metastasis (68% left-sided). Median patient age was 62 years, and the commonest primary tumor was lung cancer (72% NSCLC, 12% SCLC). The majority (64%) received a dose of 50 Gy in 5 fractions, with total doses

ranging from 24-60 Gy in 3-8 fractions. Thirty-two percent of patients received concurrent immunotherapy or targeted therapies. Median follow-up was 11.6 months. In 48% of patients, acute grade 1-2 toxicities (CTCAE v4) were reported, mostly fatigue and nausea. Acute grade 3 nausea and weight loss were observed in one patient. Another developed a lumbar insufficiency fracture six months post-SMART, a possible late grade 3 adverse event. Only one in-field tumor recurrence was observed eight months post-SMART, resulting in a 1-year LC of 93%. The 1-year DFS and OS rates were 47% and 76%, respectively.

#### Conclusion

Delivery of SMART to adrenal oligo-metastasis is associated with limited acute toxicity, even in a cohort where 32% of patients received concurrent immune and targeted therapies. Local control rates are promising, but long-term follow-up is awaited.

### Proffered Papers: BT 1: Treatment verification

#### OC-0073 BrachyView: A Real-time In-body HDR Source Tracking System with Simultaneous TRUS Image Fusion

S. Alnaghy<sup>1</sup>, D. Cutajar<sup>1</sup>, M. M. Safavi-Naeini<sup>1</sup>, G. Stuart<sup>1</sup>, H. Andrew<sup>2</sup>, A. Bece<sup>2</sup>, J. Jakubek<sup>3</sup>, S. Pospisil<sup>3</sup>, M. Lerch<sup>1</sup>, M. Petasecca<sup>1</sup>, A. Rosenfeld<sup>1</sup>

<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia; <sup>2</sup>St George Hospital, St George Cancer Care Centre, Kogarah, Australia; <sup>3</sup>Czech Technical University of Prague, Institute of Experimental and Applied Physics, Prague, Czech Republic

#### Purpose or Objective

HDR BrachyView is a real-time in-body gamma camera probe for 3D HDR prostate brachytherapy source tracking, providing real-time source position verification. This study constitutes the first experimental demonstration of the HDR BrachyView prototype, performed with a CIRS tissue-equivalent gel prostate phantom. The main objectives of this study are to evaluate the developed real-time acquisition software in terms of the accuracy of spatiotemporal source position estimation, and to evaluate the combination of BrachyView reconstructed positions and dwelling times and the 3D TRUS image data using a custom developed visualisation software.

#### Material and Methods

A prototype in-body gamma camera system with integrated TRUS and associated real-time image acquisition and analysis software was developed for intraoperative source tracking in HDR brachytherapy. The probe utilises a cylindrical 7-pinhole tungsten collimator and a 4x1 array of Timepix high-resolution pixelated silicon detectors. The developed real-time data acquisition and image fusion software is validated against CT measurements of source position during a full clinical treatment plan. The tracking accuracy and temporal resolution of the system was validated experimentally using a deformable tissue-equivalent prostate gel phantom and a full clinical HDR treatment plan. A global coordinate system was defined by CT scanning the phantom with the probe in situ. Fusion of the estimated source dwell positions and timing with the 3D prostate image was performed using an integrated 3D visualisation software.

#### Results

Figure 1 (a) shows the percentage of the reconstructed dwell positions distribution as a function of the discrepancy of the position in respect to the nominal location determined by the TPS and identified in the CT scan of the phantom using implanted CT markers in each catheter. The BrachyView system was able to measure 78% of the 200 source positions with an accuracy within 1 mm. A minimum acquisition time of 0.28 s/frame was required to achieve this accuracy, restricting dwell times to a

minimum of 0.3 s. Due to limitations in the temporal resolution of the system, dwell times of less than 0.3 s could not be resolved for reconstruction, resulting in 175/200 dwell positions being reconstructed. Figure (b) shows the reconstructed prostate volume taken from the TRUS, co-registered with the reconstructed dwell positions from the BrachyView system and CT determined dwell locations. Figure (c), shows the configuration of the experiment.

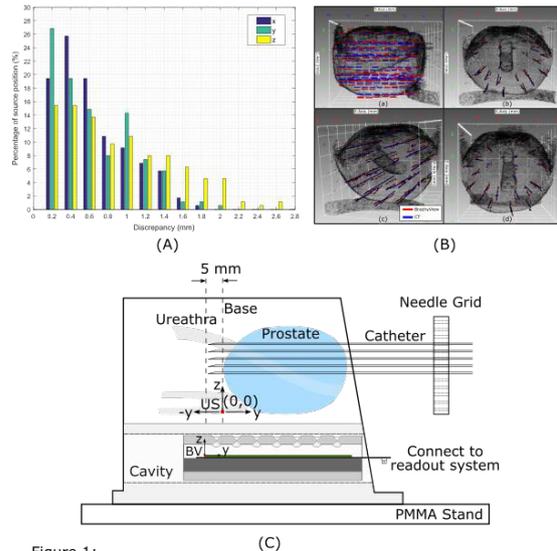

Figure 1:

#### Conclusion

HDR BrachyView is demonstrated to be a valuable tool for intraoperative source tracking in HDR brachytherapy. It can resolve source dwell locations in real-time and potentially in-vivo, with the advantage to visualise the source positions within the prostate anatomy when combined with TRUS. However, a faster readout system combined with a more efficient source localisation algorithm is required to be able to maximise the number of reconstructed dwell positions with short dwell times.

#### OC-0074 Accuracy of an integrated EMT/BT system for dwell-position detection in pelvic BT

L. Van Heerden<sup>1</sup>, J. Schiphof-Godart<sup>1</sup>, M. Christianen<sup>1</sup>, J. Mens<sup>1</sup>, M. Franckena<sup>1</sup>, M. Maenhout<sup>1</sup>, R. Rijnsdorp<sup>1</sup>, L. Luthart<sup>1</sup>, M. Hoogeman<sup>1</sup>, I. Kolkman-Deurloo<sup>1</sup>

<sup>1</sup>Erasmus Medical Center, Radiation Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

Recently, a prototype High-Dose Rate Brachytherapy (HDR-BT) Flexitron afterloader with integrated Electromagnetic Tracking (EMT) has been developed by Elekta AB, enabling pre-treatment in-vivo verification of dwell positions. However, electromagnetic interference originating from surrounding equipment present during HDR-BT procedures could lead to dwell-position detection errors. As of yet, this has not been investigated for the integrated system in various clinical environments for pelvic brachytherapy. The goal of this study is to assess the impact of the interference on the accuracy of EMT-based dwell-position detection in prostate and cervix HDR-BT.

#### Material and Methods

Dedicated prostate and cervix phantoms were constructed holding an implant of 10 catheters and the Utrecht applicator with 6 needles, respectively. CT scans of the phantoms were acquired to reconstruct the implant geometry. Subsequently, BT plans were created with dwell positions at every 5mm. These BT plans were verified by EMT in an interference-free set-up and in

various clinical environments (delivery in the operating room (OR), CT scanner room (CT), and patient bed). To determine the accuracy of EMT-based dwell-position detection, the residual error, i.e. the distance between the EMT-measured and planned dwell positions, was averaged per catheter. In addition, we determined the minimum error that can be detected by EMT by calculating the detection limit, defined as the mean residual error in the x-, y- and z-direction + 2 standard deviations.

### Results

For the prostate phantom the residual error was on average over all catheters 0.6mm, 0.5mm and 0.3mm in the OR, CT room and the patient bed, respectively, compared to 0.3mm in the interference free set-up. For the catheters in the cervix applicator, the mean residual error was <0.4mm in the interference free set-up (Fig. 1). The minimum error that could be detected with EMT was <0.9mm in all cases (Table 1).

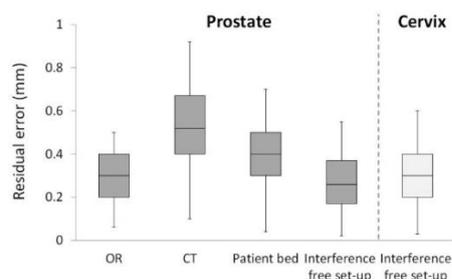

Fig. 1 Boxplot of the residual error between EMT-measured and planned dwell positions averaged over all catheters, in the prostate phantom (left) and the cervix phantom (right).

Minimum detection error (mm)	x-direction	y-direction	z-direction
	<b>Prostate</b>		
OR	0.7	0.4	0.3
CT	0.9	0.6	0.6
Patient bed	0.9	0.5	0.4
Interference free set-up	0.5	0.3	0.3
<b>Cervix</b>			
Interference free set-up	0.9	0.3	0.3

Table 1 The minimum error that can be detected by EMT, for the x- y- and z- direction.

### Conclusion

Using the integrated EMT/BT system, we quantified errors due to EM field interference in the BT clinical setting for pelvic tumours. We found a mean residual error <0.6mm, which is smaller than the dose calculation grid size (1mm). With our current method we are able to detect dwell position shifts >0.9mm. We therefore conclude that the effect of EM field interference due to medical equipment is limited and that EMT is sufficiently accurate for dwell position detection in prostate and cervical cancer.

### OC-0075 Error detection using an electromagnetic tracking system in multicatheter interstitial brachytherapy

S. Masitho<sup>1</sup>, K. Kallis<sup>1</sup>, V. Strnad<sup>1</sup>, R. Fietkau<sup>1</sup>, C. Bert<sup>1</sup>  
<sup>1</sup>Universitätsklinikum Erlangen, Radiation oncology, Erlangen, Germany

### Purpose or Objective

HDR interstitial brachytherapy (iBT) is a common treatment option for breast cancer patients. Despite its clinical success, errors which could occur during treatment planning or treatment delivery can have a dosimetric impact on the planned dose delivery. Currently, there is no extended quality assurance (QA) system available to detect these errors. The hybrid treatment delivery system (HTDS) is one of the possible QA methods for iBT. The system consists of an afterloader prototype system (Flexitron, Elekta, Veenendaal, The Netherlands) with an integrated electromagnetic tracking sensor, combined with an EMT system (Aurora, Northern Digital Inc., Canada). The HTDS allows the automatic measurement of the sensor's position in the implanted catheters. To test the feasibility of the system for error detection for breast cancer patients, possible planning and delivery errors in iBT were simulated using two phantoms.

### Material and Methods

A CT-based treatment plan for each phantom was used as the reference data. Planning errors such as: an incorrect offset value, an incorrect indexer length, tip/connector end swaps, partial swaps, and delivery error such as whole implant displacement were simulated by altering the treatment plan. Other delivery errors such as catheter shifts and catheter connection swaps were simulated using two different phantoms: a rigid phantom with 9 straight catheters and a breast equivalent phantom with 10 bent catheters. To simulate catheter shifts, 1.1 mm thick spacer discs were attached between the phantom's surface and the button at the catheter's tip end. Catheter connection swaps were simulated by connecting the catheters to the incorrect channels. Geometrical deviations between the dwell points of reference data and error-induced data were assessed using an in-house Matlab routine. The median deviation was used to confirm different errors, which were then differentiated visually. For catheter shifts, the median value corresponds to the detected magnitude of the shift.

### Results

The following errors were detected: Incorrect offset values (-10 mm and -15 mm), tip/connector end swaps, partial swaps between two catheters, and whole implant displacement (5 mm in lateral direction) in both phantoms. A total of 37 catheter connection swap measurements were conducted. Catheter connection swaps were detected 100% of the time. Shift measurements of one catheter were conducted 25 times for 1.1 to 5.07 mm shifts in each phantom. ROC analysis for shifts in the rigid phantom showed that 1.1 mm shifts in one catheter can be detected 98.36% of the time, while shifts larger than 2.21 mm can be detected 100% of the time. The measurement to determine the minimum detectable catheter shift in the breast equivalent phantom is still ongoing.

### Conclusion

Simulated treatment planning and delivery errors in iBT were detected. This study showed that it is feasible and beneficial to use the HTDS to detect planning and delivery errors prior irradiation in iBT for breast cancer patients.

### OC-0076 Real time treatment verification in HDR brachytherapy: an in-phantom proof of principle

M. Hanlon<sup>1</sup>, R. Smith<sup>2</sup>, V. Panettieri<sup>2</sup>, J. Millar<sup>2,3</sup>, R. Franich<sup>1,2</sup>  
<sup>1</sup>RMIT University, School of Science, Melbourne, Australia; <sup>2</sup>The Alfred, Alfred Health Radiation Oncology, Melbourne, Australia; <sup>3</sup>Monash University, Central Clinical School, Melbourne, Australia

### Purpose or Objective

HDR brachytherapy treatment verification can be achieved by tracking the source during treatment to confirm correct dwell delivery. Our system utilises a flat

panel detector (FPD) embedded in the treatment couch for source tracking and a ceiling mounted x-ray system for imaging and registration<sup>1</sup>. Here, we present the *real time* capabilities of the system, showing its ability to track the source, measure source position, and compare the measurement to the plan *during treatment*.

#### Material and Methods

An AP radiograph is captured of the phantom with implanted fiducial markers. The treatment plan, consisting of 81 dwell positions across 9 catheters, was registered to FPD coordinate space via the fiducial markers, allowing the tracked source positions to be directly compared to the plan. As the treatment was delivered, the FPD was run in cine mode at 15 fps, continuously capturing autoradiographs of the source radiation.

Each frame was analysed for 2D source position and compared to the planned dwell position. The process is completed in seconds: the analysis of each catheter is performed before the start of the next catheter treatment delivery. Any deviations, if present, are assessed against 'error signatures', shown in previous work<sup>2</sup> to correlate with common errors, enabling rapid identification of errors.

Plans were delivered both with and without deliberately introduced errors to validate the system in a phantom and to verify that treatment errors can be identified.

#### Results

To account for uncertainties and to minimise false positives, an error detection threshold of 5mm was set. When the plan was delivered without introduced errors, 0/81 dwells differed by more than the threshold, thereby, as all dwells were within uncertainty of expected positions, treatment was verified.

For one test of the system, the transfer tubes to two catheters were swapped. During delivery, the system correctly identified the error after the first incorrect catheter, allowing user notification before any additional incorrect catheters were delivered. The analysis was performed quickly: feedback was provided in time for the treatment to be interrupted before the start of the next catheter. Once adapted for clinical use, this will allow treatment to be paused and recover the prescribed plan. The success of the real time treatment verification system for other errors will be discussed.

#### Conclusion

Our *real time* HDR brachytherapy treatment verification system can identify gross errors *during delivery*, and confirm correct delivery with an error detection threshold of 5 mm. The process is performed *during treatment*, allowing for errors to be identified and corrected before completion of treatment. As more experience is gained with the system, it will be used routinely in real time as a treatment verification system with minimal impact on workflow and patient discomfort.

#### OC-0077 Reconstruction of delivered dose based on in vivo dosimetry in prostate brachytherapy

E. Jørgensen<sup>1</sup>, S. Rylander<sup>1</sup>, S. Buus<sup>1</sup>, L. Bentzen<sup>1</sup>, S.B. Hokland<sup>1</sup>, A.K.M. With<sup>2</sup>, G. Kertzschner<sup>1</sup>, K. Tanderup<sup>1</sup>, J.G. Johansen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; <sup>2</sup>Örebro University Hospital, Department of Medical Physics, Örebro, Sweden

#### Purpose or Objective

Novel in vivo dosimetry (IVD) systems for BT, have enabled source tracking (ST) with a sub-millimetre precision. We have used ST to reconstruct the delivered dose and dose volume histogram (DVH) parameters in HDR prostate treatments. Reconstructed DVH parameters are compared to the treatment plans to investigate, if current applicator

reconstruction uncertainties lead to clinically relevant deviations in dose.

#### Material and Methods

IVD was performed during 7 fractions of HDR prostate BT. Patients were treated with two HDR fractions of 8.5Gy delivered after 46Gy EBRT. The needles were implanted under trans-rectal ultrasound guidance. The needle reconstruction and organ delineation were done on MRIs. A dosimeter, based on a small luminescence crystal, was placed inside the prostate in a dedicated needle. Dose rates were recorded during the dose delivery at a read-out frequency of 20Hz and analysed post-treatment. The position of each needle relative to the dosimeter were determined with an optimisation process transforming dose rate patterns into positional shifts of the needles. The tracked needle positions were registered to the patient anatomy (relative to the dosimeter) on the planning MRI and used to reconstruct the delivered DVH parameters. Delivered and planned DVH parameters were compared to investigate the effect of positional uncertainties/changes.

#### Results

The ST analysis of all 117 needles (fig 1) showed longitudinal needle shifts (caudal-cranial direction) with a spread (1SD) of 1.5 mm and radial needle shifts (towards - away from the dosimeter) with a spread (1SD) of 0.5 mm. Any mean longitudinal shift on a fractional level was interpreted as an offset in the dosimeter position and corrected for before calculating the dose. The resulting changes in the dose distributions lead to a mean±1SD fractional change of  $-0.2\pm 0.1$ Gy in prostate  $D_{90}$ ,  $-0.1\pm 0.2$ Gy in urethra  $D_{2cm3}$ ,  $0.4\pm 2.1\%$  point in rectum  $D_{2cm3}$  and  $0.1\pm 4.5$ Gy in bladder  $D_{2cm3}$  (table 1). One needle was shifted 4 mm in the cranial direction into the bladder wall resulting in a bladder  $D_{0.1cm3}$  of 22.8 Gy.

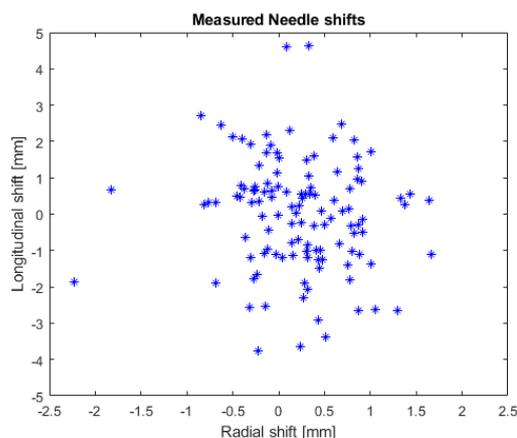

Figure 1: Measured needle shifts across all treatment fractions.

Volume	Planning Aim	Prescribed Dose	Delivered Dose
Prostate	$D_{90} \geq 8.5$ Gy	9.8 Gy (9.6 - 9.9)	9.5 Gy (9.3 - 9.6)
CTV	$D_{90} \geq 8.5$ Gy	9.1 Gy (8.7 - 9.3)	8.8 Gy (8.6 - 9.1)
	$V_{150\%} \leq 45\%$	34 % (32 - 36)	32 % (29 - 35)
	$V_{200\%} \leq 20\%$	12 % (10 - 15)	11 % (10 - 15)
Rectum	$D_{2cm3} \leq 75\%$	78 % (69 - 82)	77 % (71 - 84)
	$V_{100\%} = 0\%$	0 % (0 - 0)	0 % (0 - 0)
Urethra	$D_{0.1cm3} \leq 10$ Gy	9.9 Gy (9.8 - 10.1)	9.9 Gy (9.6 - 10.1)
	$D_{10} \leq 115\%$	114 % (113 - 116)	113 % (110 - 114)
	$D_{30} \leq 110\%$	112 % (110 - 114)	110 % (108 - 112)
Bladder	$D_{0.1cm3}$	11.1 Gy (9.7 - 13.0)	10.3 Gy (10.1 - 22.8)
	$D_{2cm3}$	8 Gy (7.1 - 8.5)	7.9 Gy (6.9 - 10.1)

Table 1: Median (range) of DVH parameters for delivered and planned dose.

## Conclusion

Novel IVD systems can be used to provide feedback on a reconstructed BT dose distribution. The observed needle shifts confirm a precise reconstruction of the needles on MR images and only limited discrepancies in the position of treatment needles ( $1SD < 2mm$ ). The dosimetric impact of the needle movements relative to the dosimeter was small except in one case where the source entered the bladder wall. Overall needle migration has previously been observed during prostate HDR-BT [1] and has a larger dosimetric impact than the needle shifts relative to the dosimeter when the bladder wall case is excluded. Needle migration cannot be observed with the ST method presented here as the dosimeter needle will typically migrate together with the entire needle implant.

[1] Buus S et al. Needle migration and dosimetric impact in high-dose-rate brachytherapy for prostate cancer evaluated by repeated MRI, Brachytherapy 17(2018).

### Purpose or Objective

Real time in vivo dosimetry (IVD) for HDR prostate brachytherapy may provide independent verification of correct dose delivery and is part of our routine clinical workflow since 2014. This study evaluates the use of error detection thresholds in IVD.

### Material and Methods

IVD is implemented using a microMOSFET placed near the centre of the prostate in an additional needle. Error threshold calculation methodology was determined from the first 40 cases. IVD measurements were then performed for a further 72 patients treated with 15Gy or 19Gy single fraction treatments, applying the error thresholds to per-needle and per-plan measurements. Needle insertion and treatment planning use real-time trans-rectal ultrasound (TRUS).

Thresholds are determined individually for each patient using an uncertainty analysis; source-MOSFET distance uncertainty is the dominant component. A measurement is outside the error detection threshold if it is outside the ( $k=2$ ) uncertainty range. Additionally, per-needle measurements are only flagged as outside the threshold if absolute difference between measured and predicted reading is  $>20mV$  ( $-0.2Gy$ ). Plans/needles outside the thresholds were reviewed.

### Results

Table one summarises differences between measured and predicted reading per-plan and per-needle, and the uncertainty based thresholds. Figure 1 shows a measurement for one patient with two needles outside the threshold (highlighted).

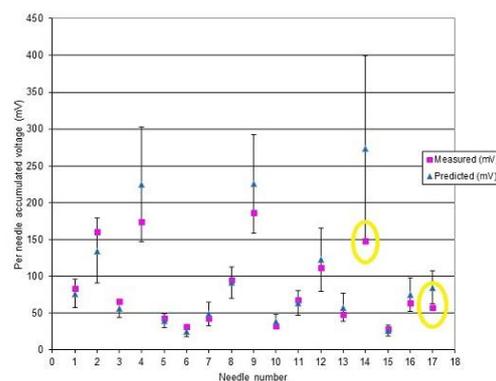

Of 3 plans outside the threshold, 1 was attributed to uncertainty in identifying the MOSFET position. 2 were due to uncertainty calculation limitation in the case where one needle is very heavily weighted so that the overall plan measurement fails even though each per-needle measurement passes. These false errors can be addressed by improvements in measurement technique and developing the method for aggregating per-needle uncertainties at the plan level.

Of 16 needles outside the error threshold, 2 were due to uncertainty in the reconstructed needle position of  $<2mm$ , 4 were due to uncertainty in identifying the MOSFET position. One needle reconstruction error when corrected caused the urethral D10 to increase by 3.5% which would have exceeded the dose constraint. For the remaining 10 needles no obvious error could be determined, however 8 of these were located posteriorly and previous work has

shown that the posterior prostate often drops between treatment planning and treatment.

Results	Number of measurements	Difference (measured - predicted)			K=2 error threshold		
		Median	Min	Max	Median	Min	Max
All plans	72	-5.2%	-15.8%	6.6%	$\pm 12.1\%$	$\pm 9.3\%$	$\pm 21.8\%$
Plans classed as error	3	-15.3%	-15.8%	-13.5%	$\pm 11.9\%$	$\pm 11.5\%$	$\pm 14.2\%$
All needles	1089	-5.4%	-8.6%	2.61%	$\pm 29.0\%$	$\pm 13.6\%$	$\pm 131\%$
Needles with dose difference $\geq 20 mV$	61	-13.4%	-6.9%	4.3%	$\pm 39.7\%$	$\pm 13.6\%$	$\pm 118\%$
Needles classed as error	16	-40.3%	-6.9%	3.9%	$\pm 32.5\%$	$\pm 14.5\%$	$\pm 49\%$

In-vivo Dosimetry - Measured v Predicted MOSFET Readings

## Conclusion

IVD in HDR prostate brachytherapy using a microMOSFET provides a high level of confidence that we are correctly delivering the planned dose to our patients, also allowing detailed analysis of dosimetric effects due to needle movement and reconstruction errors. In common with other IVD methods, it is difficult to completely avoid declaring false errors when defining error detection thresholds for real-time per needle IVD. The results of this analysis can be used to inform decisions on when to interrupt treatment if errors are detected during real-time IVD.

## OC-0079 Expanding Calibration Service for LDR Brachytherapy Seeds by Photon Fluence Determination

T. Schneider<sup>1</sup>  
<sup>1</sup>Physikalisch-Technische Bundesanstalt, Department 6.3 "Radiation Protection Dosimetry, Brunswick, Germany

### Purpose or Objective

The emitted radiation field and the dosimetric properties of LDR brachytherapy photon sources depends on the nuclide and the design of the seeds. BRAPHYQS and GEC-ESTRO encourage promotion of an efficient solution in Europe to monitor and assure seed design constancy, preferably like the CLA2004 - methodology controlled by AAPM.

In Europe, Aspects of the Quality Assurance (QA) in the production of seeds, including the constancy of the sources are not covered by the calibration of the seeds but by the process of CE-certification. Thereby the company's QA system must be outlined, and the effectiveness and permanent improvement must be demonstrated. Low energy photon spectrometry is a very sensitive tool to monitor the constancy of the radiation field of the seeds. However, establishing and maintaining a spectrometry unit requires considerable effort and such services are scarce within the brachytherapy community. The national metrology institute of Germany has decided to expand its calibration service for LDR seeds to include determination of photon fluence spectra at specific polar and azimuthal angles around the source from 2020 on. The inclusion of spectrometry into regular calibration service requires highly automated spectra measurement and data evaluation.

### Material and Methods

A commercially available detector system from Canberra (HPGe) is used controlled by the Genie 2000™ software

program.

To suppress stray radiation, the detector’s crystal is fully surrounded by a cylindrical steel cylinder. Collimators of 10 mm, 5 mm, 3 mm and 0.9 mm diameter are available. The detector’s efficiency was calibrated by means of radioactivity standards. The intensity of the discrete X-ray lines is analysed by a software package that follows the methodology of the “GUPIX” X-ray spectra-analysing software package.

The source holder is mounted to a computer-interfaced rotary stage, thus providing angular control while maintaining the proper orientation of the collimator axis to the source. In this way, spectra for a specific angle, as well as integral spectra, can be determined.

**Results**

In the figure below the step of automated peak detection is exemplify with a spectrum of an I-125 Bebig S17 seed. The upper panel shows the whole spectrum. The lower panel is an enlargement of the region marked red. The black frames represent the values for the detection limits calculated as the sum of three times the peak’s uncertainty plus the uncertainty of the fitted background at the peak’s position. As the peaks are of the Au-L-Lines at 9.7, 11.4 and 13.4 keV are below the frame they are not detected by the algorithm. This result is realistic, as the seed doesn’t feature any golden components. By contrast, the Ti-K-lines at 4.5 and 4.9 keV, arising from the capsule, are clearly detected, as well as the Mo-K-lines at 17.4 and 19.7 keV, arising from the marker.

**Conclusion**

An automated spectrometry set-up for LDR brachytherapy seeds will provide spectrometry as an integral part of the calibration service in the future.

ArcCheck (Sun Nuclear, Melbourne, FL) plus an ionization chamber (IC) and correlated with the independent dose calculation passing rates. An analysis of average changes in monitor units (MU) from one adapted plan to another was also performed.

**Results**

The average difference between the measured and TPS-predicted values for the end-to-end tests was 1.64% (maximum of 2.8%). The average gamma (2%/2mm) passing rate for the independently calculated dose vs the TPS-predicted dose was 98.5%. An example of the in-house software results for an adapted plan is shown in Figure 1. Table 1 shows the average IC, ArcCheck (3%/3mm) and independent QA (2%/2mm) rates for each patient. The average change in monitor units from fraction to fraction was 7.5%, with maximum observed of 20%.

**OC-0080 Comprehensive commissioning of MR-Linac online adaptive radiotherapy QA**

O. Green<sup>1</sup>, A. Price<sup>1</sup>, B. Cai<sup>1</sup>, J. Cammin<sup>1</sup>, V. Rodriguez<sup>1</sup>, J. Park<sup>1</sup>, S. Mutic<sup>1</sup>, D. Yang<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Radiation Oncology- Physics Division, Saint Louis, USA

**Purpose or Objective**

To establish the quality assurance process for online adaptive radiotherapy (ART) performed with a hybrid MR-linac system.

**Material and Methods**

The commissioning process consisted of three parts: independent validation of the vendor-provided Monte Carlo-based secondary dose calculation module; development of an in-house software package for plan integrity and deliverability checks; patient-specific phantom-based QA for each adapted fraction for the first five patients (a total of 42 fractions). The independent validation of the secondary dose calculation was performed via end-to-end tests with an MR-imageable phantom with inserts for ionization chambers (CIRS, Norfolk, VA). Five adaptive scenarios were simulated that included changes in target volume, changes in organ-at-risk positions, and changes in electron density (this was done by adding or subtracting water to the phantom). For each scenario, IC measurements were compared to predicted treatment planning system (TPS) dose values and correlated with independent dose calculation passing rates. The in-house software package was developed in MatLab (MathWorks, Natick, MA) to check contour integrity (gaps, islands, assigned density overrides, volumes, and whether it was used in optimization), flag undeliverable segments, and estimate plan delivery times. Patient-specific QA was performed after each adapted fraction for the first five patients using the MR-

Patient	Fractions adapted	IC % diff from TPS	Ind. Dose Calc.	
			AC 3%/3mm	2%/2mm
1	15	0.90%	96.90%	97.20%
2	15	1.20%	99.00%	91.90%
3	4	1.60%	97.84%	97.68%
4	4	2.30%	97.34%	96.97%
5	4	1.60%	99.08%	98.98%

Table 1 Phantom-based and independent dose calculation results for patient-specific adapted fractions using ionization chamber (IC) and ArcCheck (AC).

**Conclusion**

The complexity of online adaptation necessitates not only thorough commissioning but the establishment of on-going comprehensive quality assurance for each fraction that includes not only a phantom-less QA but also a method to ensure that all other components of the plan are accounted for and checked. In this work we have shown an example of such a comprehensive commissioning method for a hybrid MR-linac.

**OC-0081 Plan-library supported automated replanning for online-adaptive IMPT of cervical cancer**

T. Jagt<sup>1</sup>, S. Breedveld<sup>1</sup>, R. Van Haveren<sup>1</sup>, R. Nout<sup>2</sup>, E. Aresteinidou<sup>2</sup>, M. Staring<sup>3</sup>, B. Heijmen<sup>1</sup>, M. Hoogeman<sup>1</sup>  
<sup>1</sup>Erasmus MC University Medical Center Rotterdam, Department of Radiation Oncology, Rotterdam, The Netherlands; <sup>2</sup>Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands; <sup>3</sup>Leiden University Medical Center, Division of Image Processing- Department of Radiology, Leiden, The Netherlands

**Purpose or Objective**

Intensity-modulated proton therapy (IMPT) is very sensitive to small daily density variations along the pencil beam paths and variations in target and OAR shapes. This makes IMPT for sites with large inter-fraction target

deformations extra challenging, such as in the treatment of cervical cancer. Online replanning is an option to achieve adequate target dose in each fraction. This study evaluates a novel approach employing a pre-treatment established plan-library as prior information in automated online replanning for IMPT of cervical cancer.

#### Material and Methods

CT data of 5 cervical cancer patients was available, comprising of a full and empty-bladder CT and 3-4 repeat CTs. Prescribed dose for the primary tumor and pelvic  $\pm$ para-aortic lymph nodes was 45 Gy. Pre-treatment plan-libraries were created to provide prior spot distributions for replanning on the repeat CTs. One consisted of two treatment plans based on the full and empty-bladder CT +8 mm margin and the other of one treatment plan encompassing all target deformation observed in the full and empty-bladder CT +10 mm margin, i.e. a large ITV. In case of the 2-plan-library the daily bladder volume was used to select the prior plan for replanning.

The reoptimization method starts with a spot-position (Bragg peak) restoration from the selected prior plan by adjusting the energy of each pencil beam to the water equivalent path length in the repeat CT. To further compensate for deformations, new spots are added. The reference point method (RPM) is then used to optimize the spot weights. The RPM has been automatically tuned on benchmark plans of 4 CTs (i.e. optimized from scratch without time constraints) and results in a reoptimized Pareto optimal plan for the new anatomy, with similar trade-offs as in the benchmark plan. Replanning was performed for each repeat CT using tight margins of 5/2 mm (primary tumor/nodes), only meant to account for intra-fraction motion. The prior and reoptimized plans were evaluated on the repeat CTs using the 5/2 mm-PTVs and compared to benchmark plans on the repeat CTs.

#### Results

Evaluating the prior plans on the repeat CTs without replanning resulted in  $V_{95\%} < 95\%$  in most CTs, with values down to 50% (see Fig 1). For both plan-library approaches, reoptimization increased the number of repeat CTs with adequate coverage ( $PTV V_{95\%} \geq 95\%$  and  $V_{107\%} \leq 2\%$ ) from 2/19 to 19/19 CTs. Fig 2 shows the differences between the reoptimized and benchmark plans on the repeat CTs using the ITV or 2-plan-library as prior. Median improvements are seen up to 4.5%-point for bladder  $V_{30Gy}$  when using the 2-plan-library instead of the ITV plan, with outliers up to 13.8%-point. Reoptimization took 3.6 min on average.

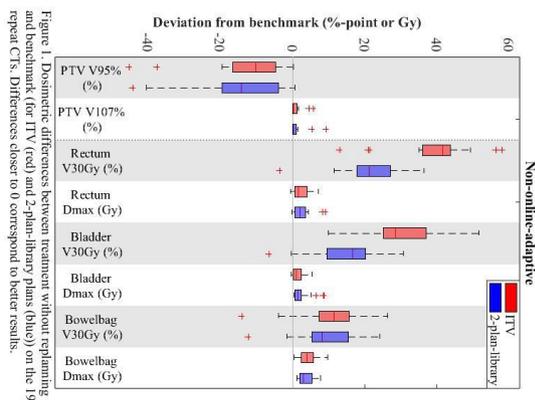

Figure 1. Dosimetric differences between treatment without replanning and benchmark (for ITV and 2-plan-library) on the 19 repeat CTs. Differences closer to 0 correspond to better results.

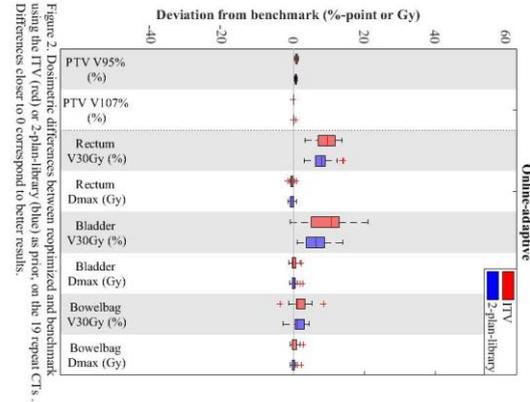

Figure 2. Dosimetric differences between reoptimized and benchmark using the ITV (red) or 2-plan-library (blue) as prior, on the 19 repeat CTs. Differences closer to 0 correspond to better results.

#### Conclusion

With fully automated replanning, adequate target coverage was restored for all CTs, as well as decreased OAR doses. The use of a 2-plan-library yielded lower OAR doses than a single ITV prior plan. With an average time of 3.6 minutes, this method is an important step towards online-adaptive IMPT in cervical cancer.

#### OC-0082 A biomechanical model to generate a library of cervix CTVs

C. Beekman<sup>1</sup>, S. Van Beek<sup>1</sup>, J. Stam<sup>1</sup>, J. Sonke<sup>1</sup>, P. Remeijer<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, radiation oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Patients with cervical cancer treated with radiotherapy experience large daily CTV shape changes. To ensure good coverage while limiting the size of the PTV, a library of plans based on a series of CTVs has been implemented in various clinics. To obtain a series of cervix CTVs, a linear interpolation of a deformation vector field (DVF) between full and empty bladder anatomy is typically performed, leading to volume shrinkage of the intermediate structures. To overcome this shortcoming, we developed a biomechanical model that explicitly models the cervix deformation, which was used to generate a library of CTVs for intermediate bladder volumes.

#### Material and Methods

Twenty cervix cancer patients with empty and a full bladder CT-scans and associated delineations (bladder, cervix, uterus, rectum, bowel area, bones and external) were retrospectively selected. The delineations were converted to 3D surface meshes and imported into HyperWorks[1] for preprocessing and finite element analysis (FEA).

The bowel area was replaced by a constant pressure as they are highly deformable and hard to model explicitly. The empty bladder and rectum meshes were warped onto their corresponding full meshes, while motion of the bone mesh was fully constrained. These enforced displacements drove the deformation of the model. Elastic properties were taken from literature[2], except for the bowel pressure and the elasticity of the cervix CTV, which were subject of a parameter sweep.

A non-linear large-displacement analysis that allowed for continuous sliding between organs was performed. Residual errors between the simulated and target CTV mesh were corrected by an additional thin plate spline (TPS) deformation. Intermediate structural outputs of a linear superposition of the full biomechanical and residual deformation then constituted the library of CTVs for each patient. Optimal model parameters were identified as those that minimized the RMS distance of the residual deformation. Intermediate CTV volumes were compared with those from linearly interpolating the currently used anatomy mapping.

**Results**

Optimal model parameters are found for low bowel pressure and a cervix Young's modulus between 5 and 25 kPa (figure 1). Because the cervix is modeled as nearly incompressible, the FE method is less prone to intermediate volume shrinking effects than linear interpolation of a DVF, especially for large movers (figure 2).

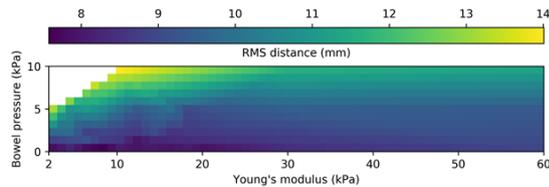

Figure 1. Elasticity of the cervix and bowel pressure against the RMS surface distance.

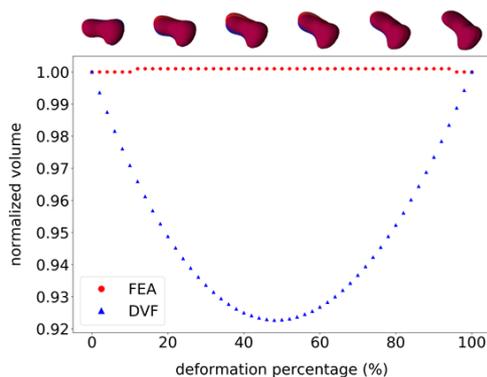

Figure 2. Volumetric comparison between FEA (red) and DVF (blue) CTV deformation. Volumes are normalized by the linear interpolation between the CTV volumes of empty and full bladder anatomy.

**Conclusion**

We developed a novel biomechanical library of plans method for the cervix CTV. By explicitly modeling CTV deformation due to variable bladder filling, volume shrinkage of intermediate library CTVs could be avoided. Moreover, finite element modeling has the potential to accurately describe anatomical deformations in 3D, allowing for improved dose accumulation in the future. However, validation on additional cervix anatomies or internal markers is necessary to further narrow down the optimal model parameter ranges.

**OC-0083 MRI guided set-up corrections for esophageal cancer: what margin do we need?**

M. Boekhoff<sup>1</sup>, S. Mook<sup>1</sup>, A. Borggreve<sup>1</sup>, L. Goense<sup>1</sup>, P. Van Rossum<sup>1</sup>, N. Takahashi<sup>1</sup>, A. Van Lier<sup>1</sup>, A. Kotte<sup>1</sup>, J. Lagendijk<sup>1</sup>, G. Meijer<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

**Purpose or Objective**

MRI linacs allow for online target definition and online replanning for esophageal cancer irradiations, allowing high precision treatments. However, online planning requires online redefinition of target volumes and organs at risk and reoptimization of the plan, both of which can be time consuming. Alternatively, simple online setup corrections using rigid registration of the target volume can be done fast but on the downside do not correct for rotations and shape changes. The aim of this study is to quantify the proportion of treatment fractions at which a simple online setup correction can be safely applied at a given PTV margin in clinical practice.

**Material and Methods**

Thirty esophageal cancer patients underwent six T2-weighted MRI scans (1 prior to treatment and 5 during neo-

adjuvant chemoradiation (23x1.8 Gy) at weekly intervals. GTVs were delineated on each individual MRI. Follow-up scans were registered to the first (reference) scan. Registration consisted of a rigid translation of GTV masks with the Kappa-Statistic metric of the Elastix toolbox (Klein 2010) to ensure that the GTV in follow-up scans overlap with the reference GTV. Subsequently, artificial PTVs with varying margins from 1 to 12 mm around the reference GTV were created. Finally, the amount of voxels of the follow-up GTVs inside the PTV was analyzed for each margin.

**Results**

We found that when a PTV margin of 5 mm was applied the GTV was adequately covered by the PTV using an online correction strategy in 84% of the fractions (Figure 1/ Table 1). Conversely, when using a 5-mm PTV margin, 16% of the fractions would require an online replanning strategy as the shape changes of the target could not be absorbed by a 5-mm margin. At a patient level, replanning was needed for 43% of the patients at 1 or more treatment fractions using a 5-mm PTV margin, mostly for patients with distal tumors due to variable stomach filling (Figure 2). For the majority (57% of the patients) GTVs were properly covered in all instances, using a 5-mm PTV margin.

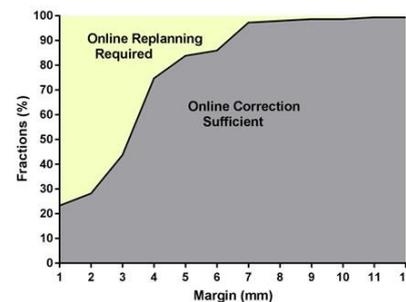

Figure 1) Percentage of fractions which require online replanning vs percentage of fractions where online correction is sufficient, for varying margins.

Margin (mm)	GTV correctly covered by PTV		GTV correctly covered by PTV for all fractions	
	Fractions (#)	Fractions (%)	Patients (#)	Patients (%)
1	33	23%	2	7%
2	40	28%	3	10%
3	62	44%	6	20%
4	106	75%	13	43%
5	119	84%	17	57%
6	122	86%	17	57%
7	138	97%	26	87%
8	139	98%	27	90%
9	140	99%	28	93%
10	140	99%	28	93%
11	141	99%	29	97%
12	141	99%	29	97%

Table 1) Covered fractions and patients for varying margins

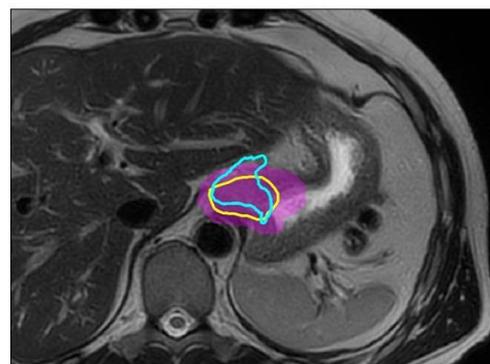

Figure 2) Example of a fraction where the GTV in a follow up scan (blue delineation) is not fully covered by the PTV with a margin of 5 mm (purple mask). This is caused by a change in tumor shape compared to the reference scan (yellow delineation)

## Conclusion

Tumor shape and position of esophageal cancer patients significantly vary on a daily basis. However, for the fast majority of fractions 5-mm PTV margins suffice when online MR guided setup correction are applied, enabling safe and efficient throughput MRI linac treatments for the majority of patients. Target coverage can be increased, but go along with an increased number of fractions that require online replanning. In both scenarios special attention should still be addressed to potential intrafraction tumor drifts.

## OC-0084 Baseline shifts towards the heart after IGRT are linked to overall survival in lung SABR patients

C. Johnson-Hart<sup>1</sup>, G. Price<sup>2</sup>, E. Vasquez Osorio<sup>1</sup>, C. Faivre-Finn<sup>2</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>University of Manchester, Radiotherapy Related Research, Manchester, United Kingdom; <sup>2</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom

### Purpose or Objective

A recent study showed that in a cohort of NSCLC patients treated with standard fractionation, small residual set-up errors that move the high dose region towards the heart following image-guidance have a significant effect on overall survival. As SABR patients are setup daily matching to the tumour itself, baseline shifts of the tumour may influence the unintended irradiation of the heart and mediastinum. This study investigates the association of baseline shifts with survival in a SABR cohort.

### Material and Methods

136 NSCLC SABR patients treated with a daily soft tissue matching, 2mm action threshold, online CBCT IGRT protocol were studied. The mean shift of the high dose region in the direction of the heart due to baseline shifts was determined for each patient by performing a bony-anatomy match starting from the final soft tissue match position recorded during delivery for each fraction (taking bony anatomy as a surrogate for heart location), averaging this value over all fractions, and then projecting the resulting vector in the direction of the heart. This 'heart-baseline shift' was then used to categorise the patients into high and low risk groups based upon the median value. Correlations of this parameter with common clinical variables was tested. Kaplan-Meier survival curves were used to compare patients with baseline shifts towards/away from the heart, and the significance was determined through multivariable Cox regression, correcting for patient age, performance status, GTV volume and existing comorbidities.

### Results

The heart-baseline shifts had a median value of -0.5mm (range -9.0 - 8.6mm) and were independent of all tested clinical variables. Yet this parameter was significantly associated with survival, with patients with baseline shifts towards the heart having significantly worse prognosis as compared to cases with shifts away (Figure 1). Multivariable analysis found a hazard ratio of 1.261 per mm ( $p = 0.002$ ) for the baseline shift, when analysed as a continuous variable (Table 1).

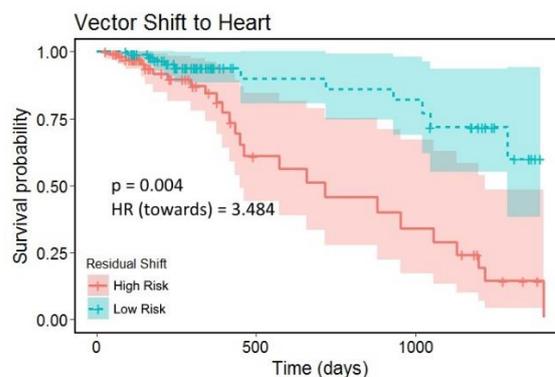

Figure 1: Multivariable Cox regression survival curves, stratified on the median baseline shift towards or away from the heart (-0.5mm) to ensure equal group sizes. High risk patients (those > -0.5mm, meaning that the majority of shifts will move the high dose region towards the heart) have worse overall survival ( $p=0.004$ ). The HR gives the hazard of death for high risk patients as compared to low risk patients.

Variable	p-value	Hazard ratio (95% CI)
Vector shift to the heart (per mm)	0.002	1.261 (1.086 – 1.466)
ECOG-PS	0.322	3.367 (0.305 – 37.207)
Age	0.130	1.035 (0.989 – 1.083)
ln(GTV)	<0.001	2.139 (1.376 – 3.324)
Comorbidity score	0.306	3.261 (0.339 – 31.364)

Table 1: Multivariate Cox regression results with shift to the heart as a continuous variable.

### Conclusion

Baseline shifts of the tumour towards the heart (thereby increasing the heart dose) during SABR significantly correlate with poorer overall survival in this cohort of early stage NSCLC patients. Such increase in dose to the heart appears to have an early effect on survival. These results provide evidence that stricter heart dose constraints are required when planning thoracic SABR. Furthermore, a PRV around the heart may be required to limit the effects of unavoidable baseline shifts.

## OC-0085 Correcting CBCT images for dose calculation using a U-shaped deep convolutional neural network

G. Landry<sup>1</sup>, D. Hansen<sup>2</sup>, F. Kamp<sup>3</sup>, M. Li<sup>3</sup>, B. Hoyle<sup>4</sup>, J. Weller<sup>4</sup>, K. Parodi<sup>1</sup>, C. Belka<sup>3</sup>, C. Kurz<sup>3</sup>

<sup>1</sup>Ludwig-Maximilians-Universität München, Department of Medical Physics, Garching, Germany; <sup>2</sup>Gradient Software, none, Aarhus, Denmark; <sup>3</sup>University Hospital-LMU Munich, Department of Radiation Oncology, Munich, Germany; <sup>4</sup>Ludwig-Maximilians-Universität München, Universitäts-Sternwarte- Fakultät für Physik, Munich, Germany

### Purpose or Objective

Radiotherapy (RT) dose calculations on daily cone beam computed tomography (CBCT) images may eventually allow online-adaptive workflows with current state of the art linac technology. Image correction is crucial when using CBCT for dose calculation; and for online-adaptive RT the corrections should be fast in addition to providing accurate dose calculation. This study evaluated three different deep learning based correction strategies using a U-shaped convolutional neural network architecture (Unet) in terms of their photon and proton dose calculation accuracy.

### Material and Methods

For training, CT to CBCT deformable image registration (DIR) was performed for 42 prostate cancer patients. This

yielded a virtual CT (vCT) which was used as prior for a previously validated projection-based correction method called CBCTcor (requiring >10 minutes of processing time). CBCTcor was used as reference throughout this study. A single Unet architecture was trained on three different datasets: (Unet1) raw and corrected CBCT projections, (Unet2) raw CBCT and vCT image slices and (Unet3) raw and CBCTcor image slices. Patients were distributed in training (27), validation (7) and testing (8) groups. Volumetric modulated arc therapy (VMAT) and proton pencil beam scanning (PBS) single field uniform dose (SFUD) plans with two opposed fields were optimized on the CBCTcor image and recalculated on the obtained Unet-corrected CBCT images. Figure 1 shows the Unet and the data used to train Unet1/2/3.

**Results**

The mean error (ME) and mean absolute error (MAE) over all patients for Unet1/2/3 were -1/2/3 Hounsfield units (HU) and 48/88/56 HU. The 1% dose difference pass rates were better than 98.4% for VMAT for 8 test patients not seen during training, with little difference between Unets. Gamma evaluation results were even better. For protons a gamma evaluation was employed to account for small range shifts, and 2%/2mm pass rates for Unet1/2/3 were better than 85%/89% and 91%. A 3 mm range difference threshold was established. Only for Unet3 the 5th and 95th percentiles of the range difference distributions over all fields, test patients and dose profiles were within this threshold. Example proton dose distributions are presented in Figure 2. The average time to correct an input projection for Unet1 was 12.5 ms, corresponding to 4.4 s for a 350 projections complete scan. For Unet2/3 the time to correct an image slice was 11 ms, with an entire image (264 slices) requiring 2.9 s.

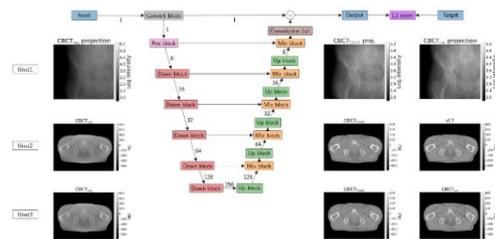

Figure 1. The Unet architecture and the data used for training Unet1, Unet2 and Unet3. The numbers next to the arrows indicate the number of channels.

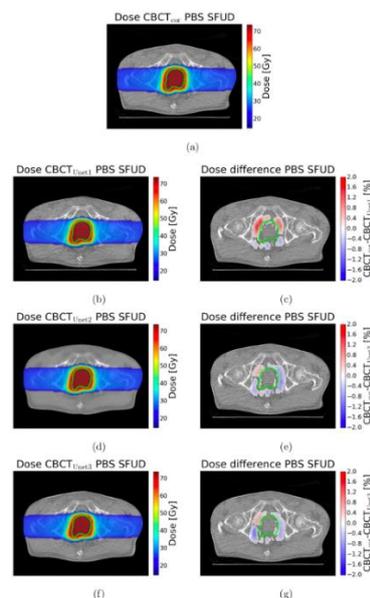

Figure 2. (a) Dose distribution from the PBS SFUD plan optimized on CBCTcor and recalculated on (b) CBCTUnet1, (d) CBCTUnet2 and (f) CBCTUnet3 and (c),(e),(g) the difference to the dose from CBCTcor, respectively

**Conclusion**

A single Unet architecture was successfully trained using both CBCT projections and CBCT image slices. Since the results of the other Unets were poorer than Unet3, we conclude that training directly on corrected CBCT image slices is optimal for PBS SFUD proton dose calculations, while for VMAT all Unets provided sufficient accuracy. Correction times were adequate for online adaptive RT workflows.

<sup>1</sup>UMCG University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

**Purpose or Objective**

Current robustness settings are based on systematic and random setup and range uncertainties. This study, incorporates treatment uncertainties in a probabilistic dose accumulation to investigate plan robustness requirements for clinical head and neck cancer (HNC) treatments.

**Material and Methods**

10 consecutive HNC patients treated with IMPT (IBA) were analyzed. Patients were treated with 70 Gy<sub>RBE</sub> to the primary CTV while immobilized using a 5-point mask (Orfit). Anatomy changes were monitored with daily CBCT and weekly offline verification CTs. For each fraction, 6D corrections were applied based on CBCT using a robotic table (Leoni). Plans were generated using worst-case MiniMax robust optimization with 3% range/ 5 mm setup uncertainties in the treatment planning system (RayStation v6.1). All plans were retrospectively re-optimized using 3%/3mm and 3%/2mm.

Treatment courses were robustly evaluated by sampling one systematic shift and 35 daily random shifts from their normal distributions. Fraction doses were calculated by computing dose on each verification CT 5 times for different shifts. The verification CT was considered representative of the patient anatomy for that week. A treatment course was evaluated 25 times for each plan, for each patient (26.250 fraction doses evaluated).

41 post-fraction CBCTs were acquired during patients' treatment course to assess intrafraction motion. Furthermore, we established the accuracy of the on-board imaging and robotic table from our machine QA results. An extra 0.5 mm was estimated to account for not considered residual systematic errors. From these data the distribution of the systematic and random error was determined. Range errors impact was studied for the patient with worst coverage by adding range uncertainties to the evaluation.

Treatment courses were analyzed in terms of target and organ at risk (OAR) DVH parameters and average tumor control probability (TCP) (Lühr et al.). A Wilcoxon signed rank test was performed ( $\alpha = 0.05$ ).

**Results**

The total random and systematic errors were found to be equal in each direction with  $\sigma = 0.7$  mm each. Treatment courses showed a significantly lower average OAR dose for the 3mm and 2mm plans compared to the 5mm plans for all OARs (Average  $\Delta D = 1.3$  and 2.3 Gy<sub>RBE</sub>). In terms of target coverage all simulations had a D99 > 95%. The average D99 slightly decreased from 69.0 to 68.7 and 68.4 Gy<sub>RBE</sub> for the 5mm, 3mm and 2 mm robust optimized plans, while remaining within the clinically acceptable level. Setup margin reduction resulted in virtually no change in

TCP (50.7% to 50.5% and 50.2%). No relevant change was observed when including range errors in the robust evaluation of the patient with the worst clinically acceptable coverage ( $< 0.1$  GyRBE).

### Conclusion

Reducing the robust optimization setting from 3%/5mm to 3%/2mm reduces OAR dose and can be safely implemented in our clinical practice for HNC IMPT treatment using a 5-point mask, a robotic couch and daily CBCT.

## Proffered Papers: PH 2: Applications of dose modelling and calculation

### OC-0087 A new method for modelling the tongue-and-groove in treatment planning systems

V. Hernandez<sup>1</sup>, J.A. Vera-Sánchez<sup>1</sup>, L. Vieilleveigne<sup>2</sup>, C. Khamphan<sup>3</sup>, J. Saez<sup>4</sup>

<sup>1</sup>Hospital Universitari Sant Joan de Reus, Medical Physics, Reus, Spain; <sup>2</sup>Institut Claudius Regaud - Institut Universitaire du Cancer de Toulouse & Centre de Recherche et de Cancerologie de Toulouse, Medical Physics, Toulouse, France; <sup>3</sup>Institut Sainte Catherine, Medical Physics, Avignon, France; <sup>4</sup>Hospital Clinic de Barcelona, Radiation Oncology, Barcelona, Spain

### Purpose or Objective

Accurate modeling of the MLC by TPSs is known to be a crucial aspect in IMRT dose calculations, the most important characteristics being MLC transmission, the leaf tip end and the tongue-and-groove (TG). However, TPSs typically model the TG by extending the projections of the leaf sides by a certain constant width and it has been found that this model may produce discrepancies of as much as 7-10% in the calculated average doses [1]. The purpose of this study is to introduce and validate a new method for modeling the TG that uses a non constant TG width.

### Material and Methods

We provide the theoretical background with analytical expressions and a detailed methodology to determine the optimal shape of the TG width from measurements of the aSG (asynchronous sweeping gap) tests with a Farmer ion

chamber [1]. For a difference between adjacent leaves equal to  $s$ , the total area of the TG profile to be subtracted from the fluence map,  $A(s)$ , can be obtained from measurements. The TG width  $w(s)$  can then be determined as the first derivative of  $A(s)$  and fitted to a function with two parameters  $a_1$  and  $a_2$ . Parameter  $a_1$  represents the TG width for large  $s$  values and  $a_2$  introduces a reduction in the TG width near the leaf tip end to account for the increased transmission through the tongue due to the rounded leaf design.

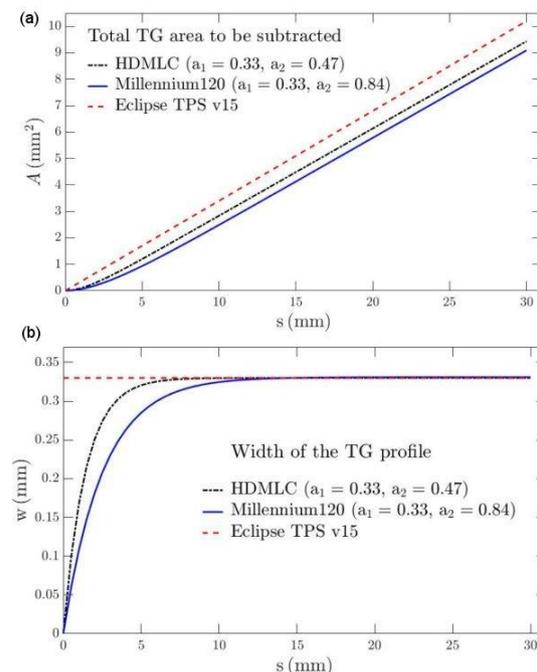

An MLC model similar to the one used by the Eclipse TPS was implemented in MATLAB. Calculated dose maps were obtained by convolution with a dose kernel [2] and were compared to Eclipse v15 calculations and to measurements from six Varian linacs from 4 different institutions: 3 linacs (2100CD, iX, TrueBeam) with the Millennium120 MLC and 3 (Trilogy and 2 TrueBeamSTx) with the HDMLC.

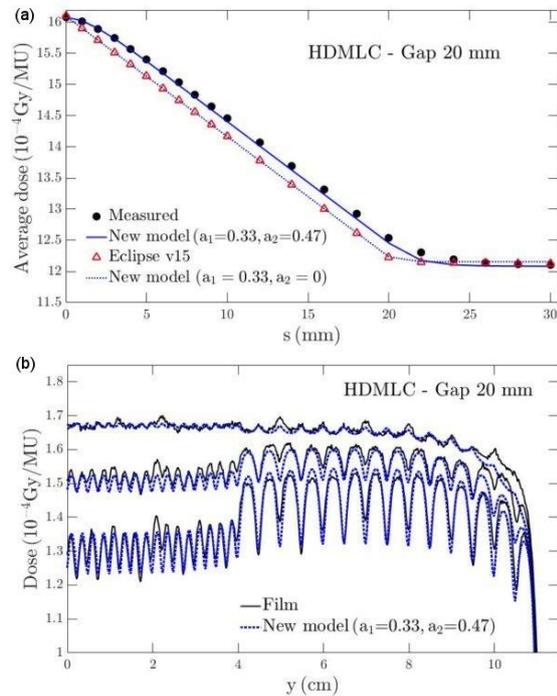

### Results

Parameters  $a_1$  and  $a_2$  were determined from the aSG tests. Parameter  $a_1$  was 0.33 mm for both MLC models, in agreement with the value used by Eclipse. Parameter  $a_2$  was 0.84 mm<sup>2</sup> and 0.47 mm<sup>2</sup> for the Millennium120 and the HDMLC, respectively (Fig 1).

Eclipse produced large discrepancies with respect to measurements, with differences in average doses as high as 4% and 6.5% for the Millennium120 and the HDMLC, respectively, and these calculations were accurately reproduced with the new model for  $a_2=0$ . On the other hand, with the experimentally determined parameters  $a_1$  and  $a_2$ , the new model produced calculations in close agreement with measurements, with all differences in average doses  $< 1\%$  (Fig 2a).

The new model was also in good agreement with radiochromic film results, recreating the fine spatial details associated to TG effects (Fig 2b). We also found that the parameters  $a_1$ ,  $a_2$  depend solely on the MLC design and are independent of the specific MLC device.

### Conclusion

A new method was presented that greatly improves the TG modeling. This method can be easily implemented in commercial TPSs and has the potential to further increase their accuracy, especially for MLCs with rounded leaf ends.

This method is currently in patent pending status.

### OC-0088 A pilot study on the sensitivity of common beam modeling parameters in Eclipse

M. Glenn<sup>1</sup>, D. Followill<sup>1</sup>, R. Howell<sup>1</sup>, J. Pollard-Larkin<sup>1</sup>, S. Zhou<sup>2</sup>, S. Kry<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA ; <sup>2</sup>The University of Texas MD Anderson Cancer Center, Biostatistics, Houston, USA

### Purpose or Objective

Recently, the accuracy of beam modeling parameter configuration has come into question, as IROC Houston has determined that considerable treatment planning system errors exist among institutions that fail its phantom credentialing test. The aim of this study was to determine the calculated dosimetric effects caused by the variations of several common beam modeling parameters in the Eclipse treatment planning system, based on realistic parameter values used by the radiotherapy community at large (as collected across the United States from over 500 institutions).

### Material and Methods

In this pilot study, a clinical 6 MV beam model for a Varian Clinac 2100iX was adapted in Eclipse (AAA 13.5.35) to match reference data collected from the IROC Houston site visit program, thus modeling an “average” performance linear accelerator. 23 output measurements, including PDD values, off-axis factors, and 12 square test fields ranging from 2x2 to 30x30 using both primary collimator- and multileaf collimator (MLC)-defined fields, were assessed in order to characterize the goodness of fit with respect to the reference output data. Once the model was verified, ten clinically acceptable head and neck phantom IMRT plans utilizing both dynamic MLC and VMAT techniques were recalculated following

modification of the dosimetric leaf gap (DLG), MLC transmission factor, and effective target spot size parameters. Parameter values chosen represented the 2.5<sup>th</sup>, 25<sup>th</sup>, 50<sup>th</sup>, 75<sup>th</sup>, and 97.5<sup>th</sup> percentiles of IROC survey responses in order to encompass the realistic extent of modeling variance in the radiotherapy community. Values examined for variations were the minimum dose, maximum dose, and mean dose to TLD structures, primary target volumes, and the organ at risk in the head and neck phantom.

### Results

The “average” performance 6 MV beam model represented the IROC reference data very well, having an average error of only 0.28%. Of the parameters tested herein, the dose calculations using the AAA algorithm were most sensitive to changes in the DLG, which ranged in value from 0.048 cm to 0.235 cm and produced changes from -6% to +3% of the calculated dose to identified structures. MLC transmission and effective target spot size contributed less significant changes, yielding up to  $\pm 1\%$  difference based on the most extreme values tested.

### Conclusion

Based on these initial findings, careful consideration should be made when commissioning clinical beam models, especially with respect to the measurement of the DLG. In this work the use of parameter values that are clinical but are still far from what is agreeable by the radiotherapy community are shown to potentially contribute to clinically significant changes in dose calculations.

### OC-0089 Mitigating inherent noise in Monte-Carlo dose distributions using UNet

U. Javaid<sup>1</sup>, J. Lee<sup>1</sup>, K. Souris<sup>1</sup>, S. Huang<sup>2</sup>, J. Madrigal<sup>1</sup>

<sup>1</sup>UCLouvain, IREC/MIRO, Brussels, Belgium ; <sup>2</sup>Memorial Sloan Kettering Cancer Center, Physics, New York, USA

### Purpose or Objective

Monte-Carlo (MC) algorithms offer accurate modeling of dose calculation by simulating the transport and interactions of many particles through the patient geometry. However, given their random nature, the resulting dose distributions from MC algorithms are affected by statistical uncertainty (*noise*), which renders it difficult to make accurate clinical decisions. This issue can be addressed to some extent using a huge number of simulated particles but it is computationally expensive. Therefore, there is a trade-off between the computation time and the noise level in MC dose distributions. Previous work on denoising the MC dose distributions is based on smoothing the distributions. In this work, we address the mitigation of noise inherent to MC dose distributions using UNet - an encoder-decoder styled fully convolutional neural network, which allows fast and fully automated denoising of whole-volume dose distributions.

### Material and Methods

We propose UNet that has three down-sampling layers for denoising whole-volume MC dose distributions. Mean-squared error (MSE) is used as loss function to train the model. MSE measures the pixel intensity difference between the denoised and reference image by summing all the squared differences. Lower the value of MSE, the similar the two images under observation therefore, we use it to evaluate the optimal weights for our model in its training phase. We train our model on proton therapy MC dose distributions of different tumor sites (*brain, head & neck, liver, lungs, prostate*) acquired from 31 patients. In training phase, we use three different noise realizations per patient to better model the noise inherent to MC dose distributions. We train the network in 3D manner with input MC dose distributions simulated using  $1e^6$  particles while keeping  $1e^9$  particles as reference.

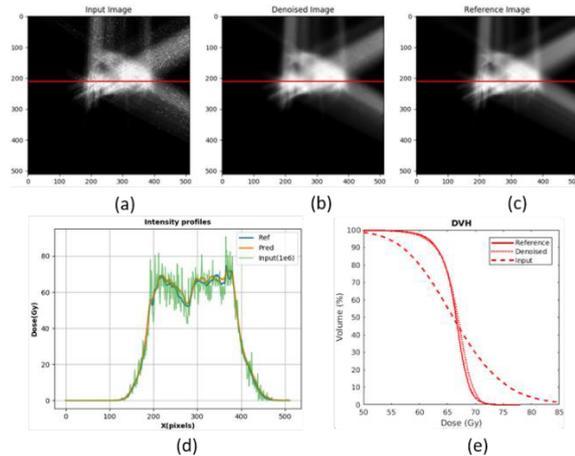

### Results

After training, our model successfully denoises new MC dose distributions. In the example test case (Figure 1), we

show that our model recovers  $D_{95}$  of 61.1 Gy from the noisy MC input of 54.3 Gy whereas the low noise MC (reference) offers 61.5 Gy. We observe higher *Peak signal-to-noise ratio* (PSNR) for reference vs denoised (39.70 dB) than reference vs input (28.12 dB) with an improvement factor of 11.58 dB. Moreover, the inference time of our model is only 7s for a dose distribution of an average dimension of 158x512x512.

### Conclusion

We propose an end-to-end, fast and fully automated UNet based framework for denoising the MC dose distributions. The proposed framework offers good generalization ability as it involves no pre-processing and can be trained on any tumor site. It provides comparable dose-volume histogram (DVH) to the MC simulation using  $1e^9$  particles and thus, identical  $D_{95}$ . We obtain a significant reduction in computational time: 7s vs 100 min (MC simulation using  $1e^9$  particles).

### OC-0090 Use of a realistic breathing lung phantom to verify 4D Monte Carlo dose calculations

S. Gholampourkashi<sup>1</sup>, J. Cygler<sup>1,2,3</sup>, B. Lavigne<sup>2</sup>, E. Heath<sup>1</sup>  
<sup>1</sup>Carleton University, Physics, Ottawa, Canada; <sup>2</sup>The Ottawa Hospital Cancer Center, Medical Physics, Ottawa, Canada; <sup>3</sup>University of Ottawa, Radiology, Ottawa, Canada

#### Purpose or Objective

To validate 4D Monte Carlo (MC) simulations of dose delivery to a programmable deformable lung phantom using realistic respiratory motion traces.

#### Material and Methods

A previously developed tissue-equivalent deformable lung phantom<sup>1</sup>, was modified to enable realistic breathing motion [Fig.1a]. A piston, attached to a programmable motor, provides variable peak-to-peak (P-P) amplitudes in the sup-inf direction.

Measurements were performed on an Elekta Agility linac with the phantom in stationary and breathing states [Fig.1b]. Dose within the tumor, located in the lung, was measured using the calibrated Gafchromic EBT3 film and the RADPOS 4D dosimetry system<sup>2</sup> [Fig.1c]. To measure the dose inside the lung, two RADPOS detectors were mounted on the top and bottom surfaces of the plug [Fig.1d]. RADPOS position tracker recorded the phantom motion with a temporal resolution of a 100 ms.

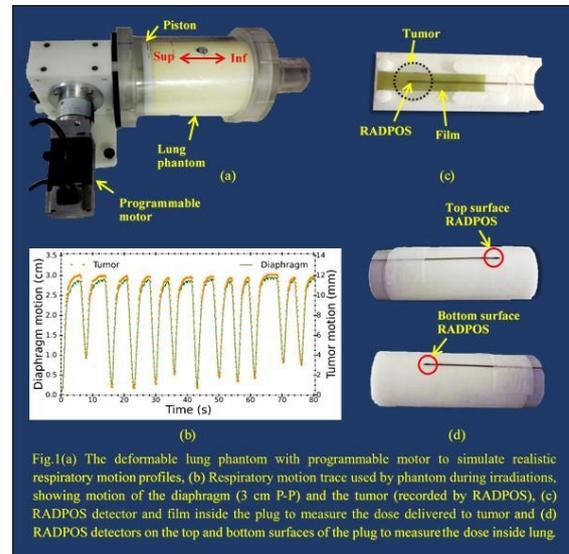

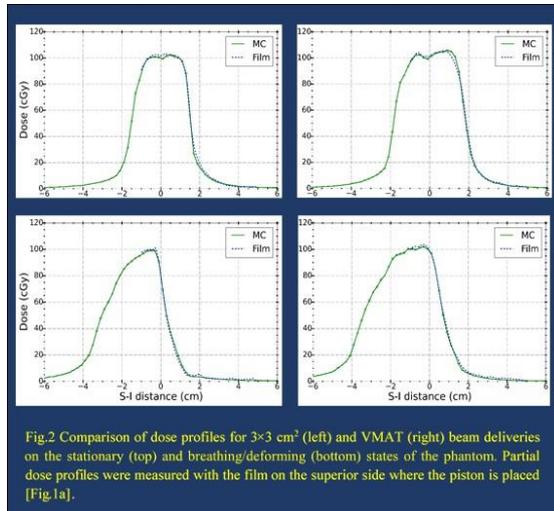

Fig.1(a) The deformable lung phantom with programmable motor to simulate realistic respiratory motion profiles, (b) Respiratory motion trace used by phantom during irradiations, showing motion of the diaphragm (3 cm P-P) and the tumor (recorded by RADPOS), (c) RADPOS detector and film inside the plug to measure the dose delivered to tumor and (d) RADPOS detectors on the top and bottom surfaces of the plug to measure the dose inside lung.

To capture full range of phantom motion, 3D CT scans of the phantom at end-of-inhale (0 cm) and end-of-exhale (3 cm) were acquired using a helical CT scanner. Static 3x3 cm<sup>2</sup> and VMAT plans were created on the end-of-inhale CT scans of the phantom in Monaco TPS V.5.11.01 to deliver 100 cGy to the center of the tumor.

A previously validated BEAMnrc model of our 6 MV Elekta Agility linac was used for all simulations<sup>3</sup>. DOSXYZnrc and 4DdefDOSXYZnrc<sup>3</sup> user codes were used, for stationary and moving anatomy dose simulations, respectively. We used  $8 \cdot 10^7$  histories to achieve a statistical uncertainty of 0.8% on a dose grid resolution of 2.0x2.0x2.0 mm<sup>3</sup>. Data from the linac delivery log files were extracted to generate input files for simulations. For 4D simulations, deformation vectors were obtained by deformably registering 4DCT scans of the end-of-exhale to end-of-inhale states using Velocity AI 3.2.0. Deformation vectors, along with the phantom motion trace measured with RADPOS, were used to model the phantom motion. The exact same motion as during irradiations was used in simulations by synchronizing the start of the phantom motion with the linac beam-on time.

#### Results

Dose values from MC simulations and measurements at the center of the tumor and bottom surface of the plug were found to be within 1s of experimental uncertainties (2.4%). Agreements on the top surface of the plug (high dose gradient region) were found to be better than 4.0%. On the stationary phantom all dose points from simulations passed a 2%/2 mm gamma analysis [Fig.2 top]. On the moving phantom, passing rates were better than 97.0% [Fig.2 bottom].

### Conclusion

Our 4DMC code accurately calculates dose delivered to a realistic breathing/deforming anatomy. This tool can be used for adaptive purposes to calculate the cumulative dose delivered to patients during treatments.

### OC-0091 Patterns of failures among Imaging and Radiation Oncology Core lung and spine phantom irradiations

S. Edward<sup>1</sup>, H.A. Molineu<sup>2</sup>, P.E. Alvarez<sup>2</sup>, D. Followill<sup>1</sup>, S.F. Kry<sup>1</sup>

<sup>1</sup>The University of Texas MD Anderson Cancer Center, Radiation Physics, Houston, USA ; <sup>2</sup>The University of Texas MD Anderson Cancer Center, IROC Houston Quality Assurance Center, Houston, USA

### Purpose or Objective

To investigate and classify the reasons why institutions fail the Imaging and Radiation Oncology Core (IROC) SBRT spine and moving lung phantom (which are used to credential institutions for clinical trial participation).

### Material and Methods

A total of 189 IROC phantom irradiation results (61 spine and 128 lung) irradiated between 2012-present were randomly selected for investigation. Those that failed to meet established IROC criteria for a satisfactory irradiation were categorized as failures. The reports of the failing irradiations, including point dose disagreement, dose profiles, and gamma analyses, were qualitatively analyzed by IROC physicists. Classes of failure patterns were created and used to categorize each instance.

### Results

There were 34 phantom irradiation failures: 16 spine (26% of spine cases) and 18 lung (14% of lung cases). After individual analysis of each report, the phantom failures were classified as follows:

#### Spine

1. **Systematic dose:** uniform overdosing or underdosing of the PTV

2. **Dose fall-off region:** dose error in the steep dose-gradient between the PTV and spinal cord (Fig. 1D)

3. **OAR overdose:** overdose of the spinal cord structure

4. **Localization error:** dose distribution improperly aligned with target

#### Lung

5. **Systematic dose:** a uniform overdosing or underdosing of the PTV (all cases were underdosed)

6. **Local dose failure:** dose error in an isolated area of the plan

7. **ITV error:** dose error at end of motion range associated with using ITV technique (Fig. 1B)

8. **Localization error in the direction of motion (SI):** dose distribution improperly aligned with target in direction of motion

9. **Localization (SI) & ITV error:** a combination of 3 & 4 above

10. **Localization errors in multiple directions:** dose distribution improperly aligned with target in directions other than direction of motion

The number of failures in each category are listed in table 1, and dose profiles showing some of the phantom errors are illustrated in figure 1.

Spine Phantoms		Lung Phantoms	
Category	Number (%)	Category	Number (%)
Systematic:	8 (50)	Systematic dose	2 (11)
➤ Underdose	6 (38)	Local dose failure	2 (11)
➤ Overdose	2 (12)	ITV error	2 (11)
Dose fall-off region	2 (12)	Localization error in direction of motion (SI)	5 (28)
OAR overdose	3 (19)	Localization (SI) & ITV error	5 (28)
Localization error	3 (19)	Localization error in multiple directions	2 (11)

Table 1. Distribution of phantom failure categories

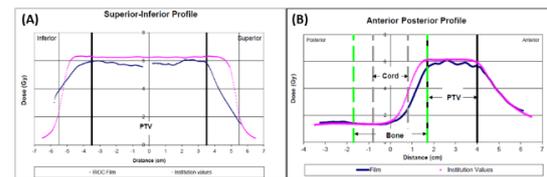

Fig. 1 Screenshots of lung and spine phantom dose profiles; pink represents the planned dose, blue is the measured dose. (A) shows an example of a lung phantom ITV error on the superior and inferior edges (direction of motion). (B) shows a spine phantom with an underdose in the dose fall off region.

### Conclusion

There are two distinct patterns of failure between phantoms. A majority (81%) of the spine phantoms failed due to a systematic dose error. Most (78%) of the moving lung phantom failures were due to localization of the moving target. Both of these errors are clinically relevant and will likely manifest as errors in patient cases. This information can help guide the community in improving the quality of radiation therapy.

### OC-0092 Portal dosimetry of small unflattened beams

A. Torres Valderrama<sup>1</sup>, I. Olaciregui-Ruiz<sup>1</sup>, P. González<sup>1</sup>, A. Mans<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

Unflattened beams allow higher dose per pulse and faster delivery, but dosimetric difficulties arise with shrinking field size: (i) Electron range can exceed the field size yielding loss of equilibrium. (ii) Volume averaging effects smooth the penumbra and reduce the signal on the central axis (CAX). (iii) Accurate positioning of detectors becomes more critical than in large fields. Using traditional dosimetry under such circumstances has led to radiation accidents with over-dosage and harm to patients [1]. IAEA's code of practice TRS-483 [2] addresses these issues, providing output factors for several detector types, beam qualities and machine types. EPIDs have particular dosimetric characteristics requiring several corrections in order to match measurements of dose to water similar to those addressed in TRS-483. In this work we demonstrate that the back-projection algorithm in Ref. [3], after

modifications described below, can accurately convert portal images of small unflattened fields to dose distributions in patients and phantoms, both for static fields and VMAT arcs.

#### Material and Methods

The back-projection model in Ref. [3] was modified to render it applicable for small fields dosimetry as follows: (i) New reference measurements using the PTW microdiamond detector (type 60019) were used as input data for commissioning to reduce the volume effect.

(ii) The blurring EPID scatter kernel ([3] Eq. 5.11A), which mimics the ion chamber's volume effect, was removed for commissioning and dose reconstruction.

(iii) Square fields from  $10 \times 10 \text{ cm}^2$  down to  $1 \times 1 \text{ cm}^2$  were used to extract the primary signal, instead of the  $23 \times 23 \text{ cm}^2$  down to  $3 \times 3 \text{ cm}^2$  data in [3], better capturing the small fields regime.

(iv) Alignment errors between the portal images and the CAX microdiamond data arising from limitations in the accuracy of the EPID positioning system were corrected in the commissioning software.

#### Results

Fig. 1 compares TPS dose and portal dosimetry for small fields using the virtual reconstruction method [4], for a  $1 \times 1 \text{ cm}^2$  square field (a-b) and a VMAT plan (c-d). The standard reconstruction model (SRM) yields underdosage of about 8% compared to the TPS. Fig. (e) shows box plots of the dose difference at the isocenter for 15 VMAT plans expressed as a percentage. The small field model (SFM) reduces the discrepancy for all treatments to less than 3%, the tolerance value for clinical use. The mean dose error (not plotted) reduces from  $-2.9\%$  to  $-0.6\%$ .

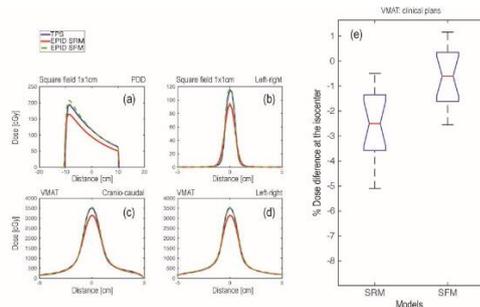

Figure 1: The left panel shows dose profiles obtained by the standard reconstruction model (SRM) and the small fields dosimetry model (SFM) for a  $1 \times 1 \text{ cm}^2$  square field on a polystyrene phantom aligned at the isocenter (a-b), and a VMAT plan reconstructed on the patient planning CT (c-d). (e) Shows box plots of the dose difference for 15 stereotactic VMAT brain plans, on each box the central mark is the median and the box edges are the 25th and 75th percentiles.

#### Conclusion

The EPID back-projection model in Ref. [3] was successfully extended to the small fields regime. With the modifications here described, portal dosimetry (in vivo as well as pre-treatment) can be used for accurate verification of both static fields and VMAT plans of small unflattened beams.

#### OC-0093 Microcavities in the lung affect the dose distribution in microbeam radiation therapy

G. Hombrink<sup>1,2,3</sup>, J.J. Wilkens<sup>1,2</sup>, S.E. Combs<sup>1,3</sup>, S. Bartzsch<sup>1,3</sup>

<sup>1</sup>Klinikum rechts der Isar, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Technical University of Munich, Physics Department, Munich, Germany; <sup>3</sup>Helmholtz Zentrum German Research Center for Environmental Health, Institute of Innovative Radiotherapy, Neuherberg, Germany

#### Purpose or Objective

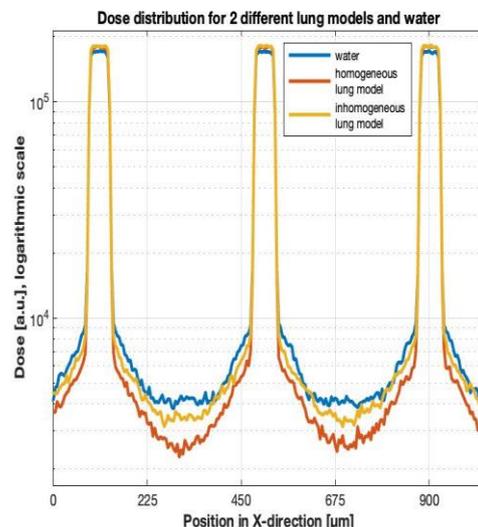

Microbeam radiation therapy (MRT) is a still preclinical technique in radiation oncology, which uses arrays of micro planar beams. High doses are delivered in the areas of the beams (peak dose, several 100 Gy) and a very low dose in between the beams (valley dose). This technique was suggested in the treatment of lung cancer as it promises less healthy tissue damage but equal tumor control when compared to conventional radiation therapy. However, as typical sizes of micro-cavities in the lung (alveoli, bronchioles, etc.) are in the same order of magnitude as microbeam widths and spacings the lung microstructure may have an effect on the dose distribution inside the lung tissue. The aim of this study is to quantify these differences in MRT dose distributions between the inhomogeneous lung tissue and the assumption of a homogeneous water-air mixture in Monte Carlo simulations.

#### Material and Methods

All simulations were performed with the Geant4 tool kit (vers. 10.0 patch 2). Two different lung models were developed, model 1 consisting of homogeneous tissue ( $\rho=0.26 \text{ g/cm}^3$ ) and model 2 of a water filled volume with small spherical air cavities ( $r=100 \text{ nm}$ ) in a cubic face centered packing to reach the same mean density as in model 1. Shape and size of the simulated volumes correspond to the geometry of an ongoing dosimetric validation using radiochromic films. Experimentally a slab of gel foam imitates the porous lung material. For reference the lung tissue and lung model in the phantom were replaced by pure water in a third simulation. A  $20 \times 20 \text{ mm}^2$  radiation field was used for all simulations comprising of 50 microbeams with a beam width of 50  $\mu\text{m}$  and a center to center distance of 400  $\mu\text{m}$ .

#### Results

Simulation results show that in the inhomogeneous lung model the valley dose is up to 41% higher than for the homogeneous model. There is also an up to 2% higher peak dose observed in the inhomogeneous lung model. Subsequently the peak to valley dose ratio (PVDR) is reduced in the inhomogeneous lung tissue (mean PVDR = 48.2) when compared to the homogeneous lung model (mean PVDR = 60.5).

#### Conclusion

The results show that the lung microstructure has a strong impact on the MRT dose distribution and cannot be neglected. At equal mean density the simple assumption of a homogeneous air-water mixture overestimates the PVDR by 25% on average in our simulations. The effect can be explained by secondary electrons that are produced in

the peak regions, traverse air cavities without substantial energy loss and deposit a higher dose distant to the peak in the valley regions. Our results show that the microstructure of the lung cannot be neglected for treatment planning of MRT in lung tissue. Currently, these findings are experimentally validated.

**Proffered Papers: RTT 1: Motion management and adaptive strategies**

**OC-0094 Retrospective evaluation of motion effects in robotic radiosurgery treatments of lung cancer**

S. Trivellato<sup>1,2</sup>, E. Rondi<sup>1</sup>, S. Vigorito<sup>1</sup>, E. Miglietta<sup>3</sup>, F. Castellini<sup>3</sup>, G. Piperno<sup>3</sup>, A. Ferrari<sup>3</sup>, B.A. Jercezek-Fossa<sup>3,4</sup>, F. Cattani<sup>1</sup>

<sup>1</sup>IEO- European Institute of Oncology IRCCS, Unit of Medical Physics, Milan, Italy; <sup>2</sup>University of Milan, Department of Physics, Milan, Italy; <sup>3</sup>IEO- European Institute of Oncology IRCCS, Division of Radiation Oncology, Milan, Italy; <sup>4</sup>University of Milan, Department of Oncology and Hemato-oncology, Milan, Italy

**Purpose or Objective**

Stereotactic body radiation therapy (SBRT) has emerged as a non-invasive standard treatment modality for early-stage lung cancer [1-3]. Respiratory management should be individually assessed to ensure SBRT dose conformity [4]. A treatment planning system for a robotic radiosurgery system is now offering the 4D treatment planning and optimization feature to consider organ motion recorded in a 4D computed tomography (4DCT) [5]. The aim of the study is to exploit this 4D module for a retrospective analysis of motion effects on target coverage and organs at risk (OARs) sparing during robotic radiosurgery in lung cancer treatment.

**Material and Methods**

Ten consecutive lung cancer treatments, 5 in upper and 5 in lower lobes, were retrospectively selected. The robotic system allows treating lesions that cannot be fully tracked. In this so-called 0-view modality, the internal target volume is defined as the envelope of the lesion volume in the full-exhale and full-inhale CT series. A set-up margin of 5 mm is added to get the planning target volume (PTV). The conventional 3D module optimizes and calculates dose distributions on the reference full-inhale phase. The 4D module uses b-splines deformable image registration to accumulate dose distributions calculated on each static 3D-CT image of the 4DCT dataset. For each patient, 3D optimization was performed and followed by both 3D and 4D calculations (3D<sub>opt+calc</sub> Plan and 3D<sub>opt</sub>4D<sub>calc</sub> Plan). A complete 4D optimization and calculation (4D<sub>opt+calc</sub> Plan) were performed when the 3D<sub>opt</sub>4D<sub>calc</sub> Plan resulted clinically suboptimal. All dose distributions were obtained using an 80% isodose prescription, the Ray Tracing algorithm, and 8 respiratory phases.

**Results**

The range of lesion displacement was 0-6 mm and 4-19 mm for upper and lower lobe, respectively. This difference resulted statistically significant at the Wilcoxon Mann Whitney test (*p*-value < 0.02). 3D<sub>opt+calc</sub> Plans showed a median volume covered by the 100% isodose (V<sub>100%</sub>) of 98.2% with a median minimum dose (D<sub>min</sub>) of 93.5%. 3D<sub>opt</sub>4D<sub>calc</sub> Plans resulted in a median V<sub>100%</sub> of 95.6% and a D<sub>min</sub> of 87.6%. Variations in V<sub>100%</sub> metric were in the range (-14.9%, 0%). Seven out of 10 patients were re-optimized with the 4D Module, all lower lesions and 2 upper lesions. 4D<sub>opt+calc</sub> Plans showed a median V<sub>100%</sub> of 97.3% with a median D<sub>min</sub> of 93.8%. Among OARs, most relevant variations were registered in the heart maximum dose. Details are reported in Table 1 and 2.

	SI [mm]	Plan	D <sub>min</sub> [%]	V <sub>100%</sub> [%]
Total (10 patients)	3.8 (0-17.5)	3D <sub>opt+calc</sub>	93.5 (85.1 - 96.7)	98.2 (95.2 - 98.8)
		3D <sub>opt</sub> 4D <sub>calc</sub>	87.6 (75.4 - 96.5)	95.6 (83.3 - 98.3)
		4D <sub>opt+calc</sub>	93.8 (85.6 - 95.5)	97.3 (96.0 - 98.7)
Lower lobe (5 patients)	11.3 (4.0 - 17.5)	3D <sub>opt+calc</sub>	94.2 (91.0 - 95.8)	98.2 (95.2 - 98.6)
		3D <sub>opt</sub> 4D <sub>calc</sub>	86.3 (75.4 - 93.9)	90.1 (83.3 - 96.8)
		4D <sub>opt+calc</sub>	93.8 (92.1 - 95.5)	97.3 (96.0 - 98.7)
Upper lobe (5 patients)	2.5 (0.0 - 3.8)	3D <sub>opt+calc</sub>	92.8 (85.1 - 96.7)	98.4 (97.0 - 98.3)
		3D <sub>opt</sub> 4D <sub>calc</sub>	88.9 (82.8 - 96.5)	97.0 (92.1 - 98.3)
		4D <sub>opt+calc</sub>	89.8 (85.6 - 93.9)	97.1 (96.8 - 97.4)

**Table 1** Dosimetric results for total population, upper and lower lobe lesions: comparison between 3D<sub>opt+calc</sub>, 3D<sub>opt</sub>4D<sub>calc</sub>, and 4D<sub>opt+calc</sub> Plans. Values are presented as median (min-max). 3D<sub>opt+calc</sub>: dose distribution of 3D optimized and calculated plans; 3D<sub>opt</sub>4D<sub>calc</sub>: dose distribution of 3D optimized and 4D calculated plans; 4D<sub>opt+calc</sub>: dose distribution of 4D optimized and calculated plans; D<sub>min</sub>: minimum target dose; V<sub>100%</sub>: percentage volume covered by the 100% isodose.

OARs. D <sub>max</sub>	Δ%
Spinal cord	0.1 (-3.4; 2.0)
Oesophagus	-0.1 (-4.8; 2.7)
Heart	-2.7 (-16.2; 2.5)
Trachea	0.4 (-1.6; 5.7)

**Table 2** Variation between 3D<sub>opt+calc</sub> and 3D<sub>opt</sub>4D<sub>calc</sub> dose distributions for main organs at risk (OARs). Values are presented as median (min-max). Δ%: percentage deviation of 3D<sub>opt</sub>4D<sub>calc</sub> maximum doses with respect to 3D<sub>opt+calc</sub> maximum doses.

**Conclusion**

Due to recorded variations, 70% of plans have been re-optimized. The 4D module is a powerful tool to manage organ motion when lesion tracking is not possible, especially for lesions in lower lobes or close to moving OARs. Further studies will increase the number of patients and a Monte Carlo calculation will permit dose prescription discussion. Results will be validated with film measurements in a 4D anthropomorphic phantom.

**OC-0095 Intrafraction motion management in VMAT breast radiotherapy with AlignRT system: comparison of ROIs**

V. Favre<sup>1</sup>, O. Ruiz Abrard<sup>1</sup>, F. Chabbert<sup>1</sup>, C. Garcia<sup>1</sup>, L. Gonzalez Casabianca<sup>1</sup>, H. Mailleux<sup>1</sup>

<sup>1</sup>Institut Paoli Calmettes, radiotherapy oncology, Marseille, France

**Purpose or Objective**

Intra-fraction motion represents a crucial issue in the era of precise radiotherapy in VMAT breast irradiation. Continuous surface imaging offers the capability to monitor patient movements in three-dimensional space without any additional radiation exposure. During the implementation phase of 3D surface imaging system (AlignRT, Vision RT™, London, UK) in our institution, we noticed that the video camera-based patient localization

system that captures and compares images of a patient's topography to a DICOM-formatted external contour could be broken by the gantry motion during the VMAT session. To increase the accuracy of intra-fraction motion management and to avoid this break, we intend to compare the use of two types of ROIs in VMAT radiotherapy for breast cancer treatment.

#### Material and Methods

From November 2017 to March 2018, sixty breast cancer patients who underwent whole breast radiotherapy (WBRT) with VMAT treatment were selected for this study. CBCT were performed at the 1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup> day of the treatment, and then weekly. Patients were divided into two groups of thirty. Group one (G1) was positioned with the aid of AlignRT using an isocentric region of interest (ROI) containing the treated breast and the upper part of the abdomen (limited ROI). In group two (G2), patients were also positioned with AlignRT with a ROI containing the treated breast and half part of the contralateral breast (extensive ROI). For both groups, extra-treatment sites' ROIs were the same: homolateral arm, neck and head position. All the fractions for each patient were consecutively analyzed.

#### Results

A break in the intra-fraction motion management with AlignRT was noticed in 283/721 (39%) sessions using limited ROIs (G1), versus 52/702 (7%) using extensive ROIs (G2). In G1, 3/30 patients could achieve their treatment without any break versus 18/30 in G2.

#### Conclusion

We demonstrated that intra-fraction motion management with AlignRT in VMAT for breast cancer is reproducible and accurate thanks to a modification of isocentric ROIs, and allows the use of 3D surface imaging system in deep-inspiration-breath hold with VMAT technique in our institution.

#### OC-0096 Implementation of DIBH for gated IMRT of left sided breast cancer using optical surface guidance

N. Gomes<sup>1,2</sup>, A.M. Furtado<sup>1</sup>, M.D.G. Coelho<sup>1,2</sup>, M. Possanzini<sup>3</sup>, J. Morales<sup>1</sup>, C. Greco<sup>1</sup>

<sup>1</sup>Fundação Champalimaud, Radiation Oncology, Lisboa, Portugal ; <sup>2</sup>Mercurius Health, Radiation Oncology, Lisboa, Portugal; <sup>3</sup>Azienda Ospedaliera G. Brotzu, Radiation Oncology, Cagliari, Italy

#### Purpose or Objective

To describe the implementation of a workflow for treating left breast cancer patients with hypofractionated IMRT in DIBH using SGRT (Surface Guided Radiotherapy). This is known to reduce heart dose and therefore cardiotoxicity risk.

#### Material and Methods

24 patients with left sided breast cancer confined to the breast were selected. First, they had a training session on the Linac. The procedure was explained and the breathing amplitude and reproducibility were verified using OSMS (Optical Surface Monitoring System). Patients had to maintain DIBH for a minimum of 25s (mean time for a treatment field delivery). Treatment isocenter was defined to allow spotlight CBCT acquisition in DIBH to confirm lung expansion. Suitable patients then had 2 planning CTs (Free Breathing (FB) and DIBH). As OSMS is not installed in the CT room, spotlight CBCT and DIBH planning CT were merged to confirm reproducibility. Treatment plans using IMRT (2.7Gy to whole breast and 3.2Gy to an integrated boost) in 15 fractions were planned for both CTs to validate DIBH's advantage. Patients selected to be treated with DIBH had their setup confirmed with CBCT in FB before each treatment. OSMS was used to automatically perform shifts to DIBH isocenter. Spotlight CBCT was performed to avoid centring the couch while allowing continuous monitoring, prevent collisions, confirm lung expansion and heart position. If shifts within departmental tolerances (<3mm), treatment

is delivered with a gated beam on threshold of 3mm (fig.1). A spotlight CBCT is acquired at the end of treatment to confirm patient positioning and OSMS accuracy (fig.2). CBCT shifts, DIBH times and overall treatment times were measured.

Fig. 1 – Treatment delivery: a) Patient setup and monitoring, b) Beam held with breathing outsider threshold, c) Beam enabled with DIBH within threshold

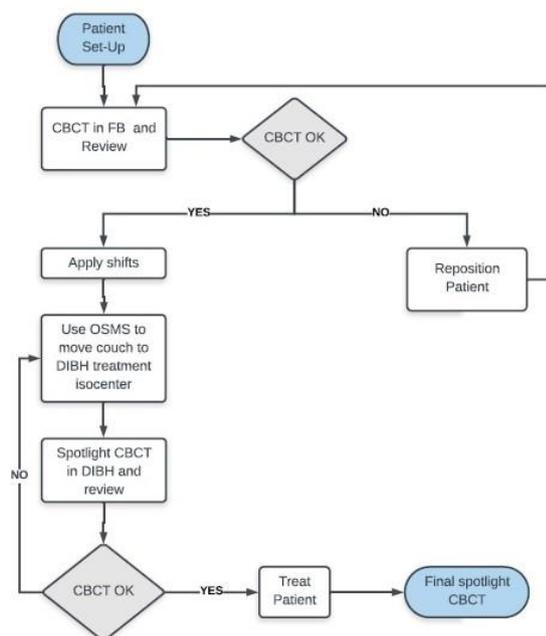

Fig. 2 - Workflow diagram.

## Results

5 patients were not suitable for DIBH. 2 did not meet training sessions criteria and 3 showed no dosimetric advantage when comparing both planning CT's. For the 19 suitable patients the mean DIBH time during training session was 31s, adding 6s to the minimum requisite. The mean overall treatment time was 26min about twice the departmental time slot of a standard FB treatment. For the first patient, adaptations of the planned workflow were made, due to inaccurate positioning of the OSMS cameras. During gantry rotation, cameras are blocked between 20° and 70°, interrupting the treatment repeatedly resulting in longer treatment time. This was solved by increasing the ROI and therefore the detected surface. In the 285 treatment sessions delivered, DIBH CBCT after OSMS positioning was within tolerances for 254 sessions. The remaining 31 sessions required repositioning and image reacquisition. With DIBH, the mean dose to the heart was reduced by 1.4Gy (5Gy in FB vs 3,6Gy in DIBH).

## Conclusion

DIBH using OSMS was successfully implemented in our department and is now a routine procedure. Careful selection of the patients is a key factor for a successful treatment delivery and the increased workflow has to be balanced out with its effective benefit. Our next aim is to implement SGRT in other thoracic treatment sites.

## OC-0097 Detection of GoldAnchor markers implanted in the liver during robotic radiosurgery in the CK system.

K. Szczepanik<sup>1</sup>, M. Stapo-Fudzinska<sup>2</sup>, B. Jochymek<sup>1</sup>, D. Bodusz<sup>1</sup>, L. Kleszyk<sup>1</sup>, E. Telka<sup>1</sup>, M. Kijonka<sup>3</sup>

<sup>1</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Radiotherapy, Gliwice, Poland ; <sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Planning Radiotherapy and Brachytherapy, Gliwice, Poland ; <sup>3</sup>Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Medical Physics, Gliwice, Poland

## Purpose or Objective

The study was to determine the migration values of applied GoldAnchor® intra-markers to the liver and to

assess their visibility in CT, MRI and the verification system.

## Material and Methods

The value of migration and change of the geometry of the system of implanted markers. The group of 66 patients was determined on the basis of a comparison of the distance between central points of all implanted markers during all treatment sessions. Measurement of the distance between the central points was carried out on the basis of images archived in the CyberKnife system.

The usefulness of tags is defined by determining the number of intra-markers used to locate the disc volume by the CyberKnife verification system. The analysis included a group of 66 patients who are treated in the Department of Radiotherapy, Oncology Center, the Branch Gliwice, from January 2010 to June 2017. In each patient, 2 to 5 markers were implanted percutaneously into the liver. In total, 198 gold markers were implanted. On the basis of CT scans, on which the contours of the tumor and critical organs were drawn, a treatment plan was prepared in the MultiPlan system. During each therapeutic session, the patient was positioned using a vacuum mattress, an infrared camera marker system and a Synchrony Vest. After making verification images in the CyberKnife system, the golden markers were located automatically. All detected markers were marked as active in the treatment panel. The number of detected markers by the system in individual treatment fractions was estimated based on a retrospective analysis of 352 archived images.

## Results

The average value of change in distance between markers along with the standard deviation was: 0.53 mm (SD = 0.86). The maximum value of change in distance between markers was 2.5 mm. In 57% of measurements, there was no change in the distance between individual markers during radiotherapy. In 39% of measurements, the measured change in distance was 1-2 mm, and in the case of 15% of measurements, the value was 3 mm. There was no case of tracer migration outside the liver area.

In 50% of patients, despite the implantation of at least 3 markers, the system detected only 2 during the entire treatment, and in the group of 16% of patients, the system detected only one marker. In all patients, where it was impossible to verify at least 3 markers, the implanted markers were developed or occurred in both forms. In the case of patients in whom all markers were folded up, the system correctly detected at least 3 markers.

In all cases, the markers were visible in CT and computed tomography images of nuclear magnetic resonance.

## Conclusion

1. The GoldAnchor® intra-tracer label applied in rolled form does not migrate in the liver parenchyma during the entire healing process,
2. The shape of the implanted tags determines the ability to detect them by the CyberKnife verification system; tags in the expanded form (line) are more often not recognized by the system than those that have a folded form,
3. The GoldAnchor® markers should be implanted in the liver only in rolled form (loops).

## OC-0098 Gated vs coached DIBH treatment in left sided breast cancer radiotherapy: a single centre study

K. Crowther<sup>1</sup>, S. Osman<sup>2</sup>, S. O'Hare<sup>1</sup>, S. Gray<sup>1</sup>, D.

Holland<sup>1</sup>, H. Vennard<sup>1</sup>, G. Hanna<sup>1,2</sup>

<sup>1</sup>Belfast Health and Social Care Trust, Cancer Centre-Radiotherapy, Belfast, United Kingdom ; <sup>2</sup>Queen's University, Centre for Cancer Research and Cell Biology, Belfast, United Kingdom

## Purpose or Objective

Deep inspiration breath hold (DIBH) reduces cardiac and pulmonary dose during tangential-field left breast radiotherapy (RT). We report preliminary results of an ongoing study, comparing voluntary moderate (vm) DIBH

and gated DIBH treatment for left sided breast cancer patients.

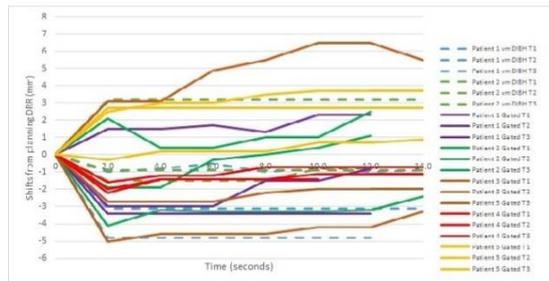

#### Material and Methods

Patients receiving adjuvant radiotherapy for breast cancer who had a maximum heart distance  $\geq 10$ mm from a standard free-breathing tangential field treatment plan underwent a second planning CT scan using a coached DIBH technique. All patients underwent whole-breast or chest wall DIBH RT. For 5 patients, Varian® Real-time Position Management (RPM™) system was used to monitor respiratory movement and to gate treatment delivery. In the other 5 patients, the vmDIBH technique was used to monitor the patient's breath-hold (BH) during treatment delivery by observing the marked isocentre in relation to the laser and treatment interrupted if there was concern that BH depth had changed. Daily cine electronic portal images were acquired, when possible, during delivery of the medial treatment field and treatment delivery times recorded. For every cine image acquired, the central lung distance (CLD), central flash distance, inferior central margin was measured at two-second intervals. Stability and reproducibility of BH was examined.

#### Results

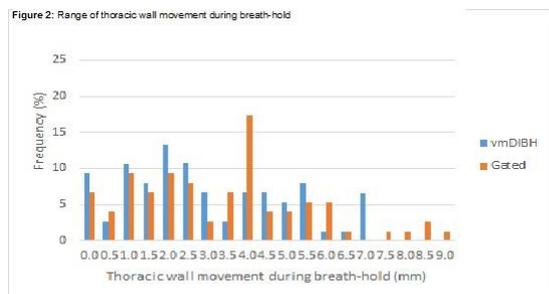

Ten patients were included in this analysis. Age ranged from 32 to 73 years (gated) and 40 to 55 years (vmDIBH). For all patients the treatment course was delivered as planned in DIBH (40Gy/15f) without interruption. Treatment delivery time per field was comparable between the gated (time= 162 seconds (s)) and vmDIBH groups (t=114s). For each patient, the stability of BH was determined from the difference in CLD relative to reference position in CT digitally reconstructive radiograph (DRR). (Figure 1). All images are within local breast imaging tolerance ( $\leq 6$ mm).

Figure 1: Thoracic wall movement during delivery of medial treatment field: first three fractions

The frequency of thoracic movements over a treatment course are presented in Figure 2 with the highest frequency observed thoracic movement for gated DIBH at 1.5mm and vmDIBH 2mm.

Figure 2: Range of thoracic wall movement during breath-hold

Reproducibility of BH was determined from the difference in thoracic movement on first frame of the cine image relative to the DRR. The population mean for vmDIBH was 1.7mm (SD 3.4mm) and the population mean for gated was 0.4mm (SD 3.7mm), indicating high reproducibility.

#### Conclusion

Two DIBH techniques have now been implemented into clinical practice with no significant difference observed between the treatment delivery times. Preliminary results indicate that both techniques ensure good reproducibility and stability of BH. This study will continue with the inclusion of additional patients. Future work will include the roll out of DIBH to enable IMC treatment but this will require a tightening of imaging tolerances and the evaluation of the dosimetric consequences to heart and left anterior descending artery.

#### PV-099 MC simulations and dose measurements of a patient-specific 3D range-modulator for proton therapy

Y. Simeonov<sup>1</sup>, U. Weber<sup>2</sup>, C. Schuy<sup>2</sup>, K. Zink<sup>1</sup>  
<sup>1</sup>Technische Hochschule Mittelhessen - IMPS, Lse, Gießen, Germany; <sup>2</sup>GSI Helmholtzzentrum für Schwerionenforschung GmbH, Biophysics division, Darmstadt, Germany

#### Purpose or Objective

The purpose of this work was to develop and validate a novel 3D range-modulator for very fast treatment of moving targets. In contrast to the pencil beam scanning technique, where the multiple iso-energy layers are associated with relatively long irradiation times, the 3D modulator uses only one single energy to create a homogeneous and highly conformal 3D dose distribution, decreasing extremely the treatment time.

#### Material and Methods

Extending previous extensive research in this field, a 3D modulator was now developed from a real CT patient data, utilizing a ray-tracing algorithm to calculate the necessary information. A lung tumour with a complex 3D contour and irregular distal and proximal edges was deliberately chosen in order to simulate a worst-case scenario and investigate the limitations of the newly proposed technique.

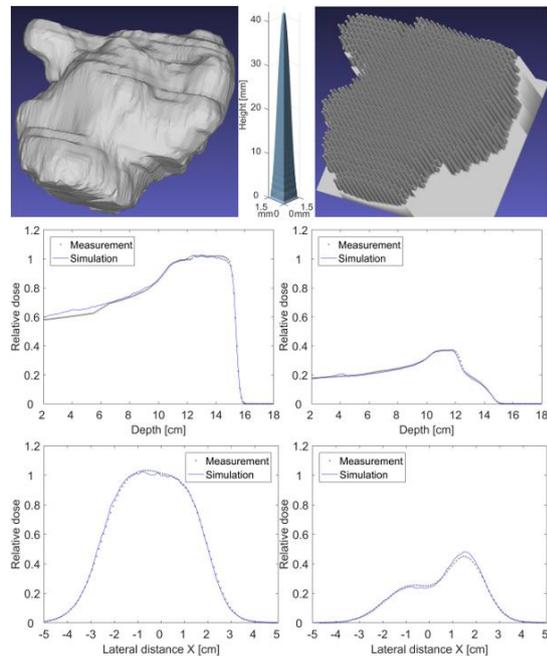

The 3D modulator consists of many fine pyramid-shaped structures (pins) with  $\sim 4$  mm<sup>2</sup> base area (Fig.1). By using this pins an additional degree of freedom is introduced, i.e., the height and shape of each single pins can now be independently varied and optimised in such a way that the final 3D shape of the modulator corresponds to the 3D tumour form. When irradiated, the 3D range-modulator should create a quasi-static irradiation field, tightly shaped around the target.

The modulator was optimised for 151.77 MeV <sup>1</sup>H and was eventually triangulated and manufactured on a 3D-printer in high-quality rapid prototyping technique. The FLUKA Monte Carlo (MC) package was used to investigate the modulating properties of the range-modulator and calculate the resulting dose distribution. A sophisticated in-house user routine was additionally implemented into FLUKA to enable intensity modulated scanning and take into account the complex geometry contour of the modulator.

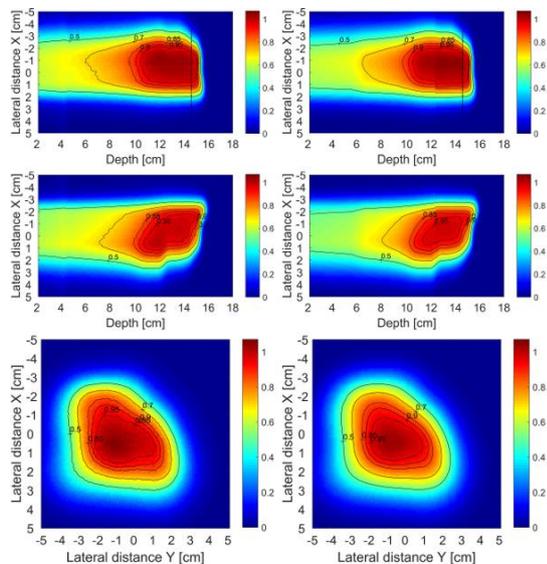

In order to validate the MC simulation results, dose measurements were conducted at the Marburg Ion-Beam Therapy Centre (MIT). The dose was measured with a 2D ionization chamber array (977 ICs) with 2.5 mm lateral resolution. The measurement depth was varied with a binary range shifter consisting of a set of retractable polyethylene plates.

#### Results

There is very good agreement between the measured and simulated dose. Fig 2. shows a homogeneous dose distribution conformed not only to the distal, but also to the proximal edge of the target.

**Fig. 1** 3D tumour contour, a single pin and the corresponding 3D modulator (upper panel); Measured vs simulated dose distributions (middle/lower panel).

**Fig. 2** Measured vs. simulated X-Z (upper/middle panel) and X-Y (lower panel) dose distributions.

**Conclusion**

Utilizing state-of-the-art 3D printing technique to manufacture complex modulators is possible. Combining the advantages of very short treatment time, the 3D range-modulator could be an alternative to treat lung tumours with the same conformity as full raster-scanning treatment. Further measurements must be conducted to investigate the full potential of the 3D range-modulator.

**PV-100 Development of plan quality through EBRT dummy run in the EMBRACE-II study for cervical cancer**

<sup>1</sup>Medical University of Vienna, Department of Radiotherapy, Wien, Austria; <sup>2</sup>Aarhus University

Hospital, Department of Oncology, Aarhus, Denmark ; <sup>3</sup>Leiden University Medical Centre, Department of Clinical Oncology, Leiden, The Netherlands; <sup>4</sup>Cambridge University Addenbrooke’s Hospital, Department of Radiotherapy, Cambridge, United Kingdom; <sup>5</sup>University Medical Center Utrecht, 6 Department of Radiotherapy, Utrecht, The Netherlands

**Purpose or Objective**

The international, multicentre EMBRACE II study combines Image-Guided Adaptive Brachytherapy for cervix cancer with an advanced protocol for external beam radiotherapy (EBRT) with specific target volume selection, contouring and treatment planning procedures. Well-defined EBRT is an integral part of the overall treatment strategy with the primary aim of improving nodal control and reducing morbidity. Before entering EMBRACE II, institutes had to go through accreditation regarding EBRT and brachytherapy. This study describes the development of EBRT plan quality through the accreditation dummy-run.

**Material and Methods**

The EMBRACE II EBRT planning concept is based on improved conformity[1] through eased coverage criteria for planning target volumes (PTV45Gy: V95%≥95% and Nodal PTV D90%≥98%) with the aim to reduce overall irradiated volume and spare OARs. Lymph nodes are irradiated by a simultaneous integrated boost and by coverage probability planning it is ensured that 98% of each nodal CTV is covered by 100% of the prescribed dose. As part of accreditation, a treatment planning dummy-run in combination with educational blocks and submission of an examination case was provided and evaluated by the study coordinators. Replanning and resubmission was required if hard constraints were violated or soft constraints were violated more than once or with a considerable amount. This study describes the plan quality of 113 submitted EBRT dose distributions from 67 centres.

**Results**

Twenty-four centres passed after first submission, and 23 and 10 centers needed one or more revisions, respectively. IMRT, VMAT and tomotherapy were used in 7%, 88% and 5% of the centers, and 6, 10 and 15 MV in 71%, 24% and 5% of centers, respectively. It was possible to produce acceptable plans with all techniques, energies, and treatment planning systems. The most common reasons for revisions were non-compliant conformity index, relatively high OAR doses or insufficient lymph node coverage. Only a few (6) first submissions were rejected because of (minor) hard constraint violations. Individual feedback improved plan quality considerably (Table 1 and Figure 1) with a significant improvement of conformity index from 1.12 to 1.03. A better cooling down of the PTV edges particularly resulted in a median V43Gy reduction of 133cm<sup>3</sup> from first plan submission to approved plan.

Parameter	constraint	Passed	SD (%)	Rejected	SD (%)	Paired analysis Difference after revision (rejected – passed)
Nr of plans		57		54		30
PTV45 (%) V95	95	97.0	1.4 1%	98.7	2.2 2%	-2.0
ITV45 (Gy) mindose	42.75	43.4	0.5 1%	43.5	1.1 3%	0.2
PTV LN1 CoP	90	92	2 2%	97	5 5%	-3
PTV LN2 CoP	90	92	2 2%	96	4 4%	-2
Conformality	115	1.03	0.04 4%	1.12	0.15 13%	-0.12
Bowel (cm3) V30Gy	450	428	58 14%	481	101 21%	-58
Bowel (cm3) V40Gy	222	164	20 13%	192	52 27%	-29
Sigmoid (%) V30Gy		88	8 9%	91	8 9%	-3

Bladder (%) V40Gy	55	42	4 10%	48	11 23%	-7
Rectum (%) V30Gy	90	72	5 7%	75	7 10%	-2
Rectum (%) V40Gy	75	51	6 12%	57	11 19%	-5
PIBS-2cm (Gy)	5	2.7	0.5 19%	2.8	1.1 38%	0
Body (cm3)* V43Gy		1725	71 4%	1869	246 13%	-133
Body (cm3)* V50Gy		38	10 25%	53	28 53%	-11

Table 1. Plan parameters and their median, SD values for all the passed plans, all rejected plans and the difference after revision (paired analysis).

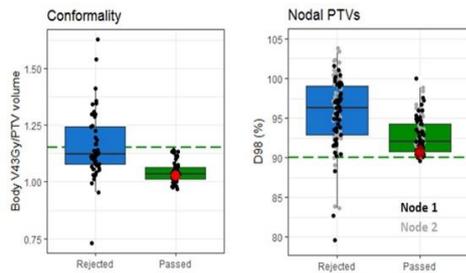

Figure 1. Average and 25%/75% percentile values for all rejected (blue) and passed (green) plans for conformity index and Nodal PTVs. Dotted line: constraint. Red dots: reference plan.

## Conclusion

A dummy-run accreditation as applied in EMBRACE II based on defined dose volume parameters for targets, OARs, conformity indices, V43Gy and including training and examination cases enables to test institutes' treatment planning capabilities and improves plan quality considerably whilst reducing inter-center variations.

[1] Defined as (V43Gy)/(PTV45Gy volume)

## PV-101 Clinical implementation of a dedicated brain treatment planning optimizer for stereotactic treatment

T. Gevaert<sup>1</sup>, A. Girardi<sup>1</sup>, B. Engels<sup>1</sup>, M. Boussaer<sup>1</sup>, C. El Aïsati<sup>1</sup>, M. De Ridder<sup>1</sup>

<sup>1</sup>Universitair Ziekenhuis Brussel, Radiotherapy, Brussels, Belgium

## Purpose or Objective

Clinical implementation of a novel dedicated and automated treatment-planning solution for cranial indications, Elements. Single lesions can be targeted with an inversely optimized VMAT approach using automated arc trajectory optimization (Cranial SRS Element, Brainlab, München, Germany) while up to fifteen metastatic brain tumors can be automatically targeted with a single isocenter and multiple inversely-optimized dynamic conformal arcs (Multiple Brain Mets SRS Element, Brainlab, München, Germany).

## Material and Methods

The very first 25 treated patients were analyzed, each representing a variable number of lesions (1-12). Depending on the number and location of the lesions a dedicated Element was selected and used in order to achieve the specific planning constraints. The plans were evaluated by means of Paddick conformity (CI) and gradient index (GI). Patient specific quality assurance (QA) was performed with gafchromic EBT3 film and portal imager.

## Results

The Elements software tools generated plans with CI of  $0.71 \pm 0.09$  and a gradient index of  $3.9 \pm 1.4$ . All plans achieved the organ at risk constraints. A gamma of 3%/3mm was used for the QA. A 98% and 98,2% passing rate was found for the EBT3 film and portal imager, respectively. This shows also the good concordance between film and EPID, suggesting that patient specific QA can be performed with the portal imager rather than the time-consuming films.

## Conclusion

The automated dose planning Elements revive dynamic conformal arcs as the paradigm for linac-based stereotactic radiosurgery of multiple brain metastases and at the same time implements an improved VMAT approach for single lesions with the use of automated arc trajectory optimization. This study shows the implementation of this technique in the routine clinical environment with an improved planning and treatment efficiency.

## PV-102 A prediction of intrinsic uncertainties in radiotherapy treatment planning systems

K. Kiers<sup>1</sup>, P. Van Horssen<sup>1</sup>, J.T. Trinks<sup>1</sup>, P.R. Pronk<sup>1</sup>, A. Mans<sup>1</sup>, C.J. Schneider<sup>1</sup>, E.M.F. Damen<sup>1</sup>, T.M. Janssen<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

## Purpose or Objective

In radiotherapy treatment planning, differences between the simulated and delivered dose can arise from intrinsic limitations of the treatment planning system (TPS) beam model. Among these limitations, we recognize two types: 1) approximating a continuous VMAT delivery with discrete control points and 2) uncertainties in the beam model. It is expected that increasing plan complexity leads to higher dosimetric uncertainty in both aspects.

The aim of this work is to predict for Pinnacle<sup>3</sup> v9.10 (Philips, Fitchburg, USA) the impact of these two intrinsic TPS problems which could lead independently to dosimetric errors, using complexity metrics (CMs) derived from the plan.

## Material and Methods

Regarding arc discretization, 80 clinical non-SBRT VMAT plans were selected. Each was computed with a control point gantry angle spacing of 4° and 2°. Plans which differed  $\geq 1\%$  in PTV-mean dose were classified as too complex. 9 CMs (Tab. 1) were calculated for all plans. A model to predict  $\Delta D_{\text{mean}} \geq 1\%$  (Prediction 1) was created using leave-one-out cross validated logistic regression and a combination of CMs, and validated on a stratified split train- and test set (80/20).

To test intrinsic beam model uncertainty, the dose distribution was recalculated for 77 non-SBRT VMAT plans comprising of three 'machines' (MLCi, 6 and 10MV; Agility, 10MV (Elekta, Stockholm, Sweden)), using two clinically commissioned beam models based on the same set of measurements. From the commissioning point of view both beam models per machine appear equivalent, only differing marginally in parameters like leaf offset correction, MLC transmission and penumbra blurring. Beam models of different machines were independent. Using CMs (Tab. 1), a linear regression model was trained to predict the  $\Delta D_{\text{mean}}$  between beam models for all MLCi 10MV plans (Prediction 2) and validated against the remaining plans. This model was then applied to 1412 independent plans and compared to their dosimetric outcome using the isocentre gamma value (3%/3mm) derived from in-vivo EPID dosimetry. Results were binned on Prediction 2 and per bin the 90<sup>th</sup> percentile of the isoc-gamma was used as a measure of dosimetric uncertainty.

## Results

Prediction 1: The  $\Delta D_{\text{mean}} \geq 1\%$  could be predicted with a specificity of 0.98 and a sensitivity of 1.0 by linear combination of three CMs (Tab. 1, Fig. 1).

Prediction 2: The predicting value was found using a linear regression of 7 CMs (Tab. 1, Fig. 1B1) with a fit of  $R^2=0.6$  ( $p<0.001$ ) for MLCi-10MV. The model was validated for Agility-10MV and MLCi-6MV with an  $R^2$  of 0.64 ( $p<0.001$ ) and 0.55 ( $p<0.001$ ) respectively. The predicting value has a strong linear correlation with the 90% CI isoc-gamma of the 1412 plans ( $R^2=0.6$ ,  $p<0.001$ , Fig. 1B2). The spread in the data in Figure 1B2 is due to the noisy nature of in vivo data.

Table 1. The complexity metrics. All metrics were calculated per control point and normalized to monitor units per beam and to control point.

	Complexity metrics	Explanation	Used in
Size and location	Field Aperture	Aperture size.	Pred. 2
	Wide Field Score	Sum of all distances from the center of the field aperture to the center of the MLC.	Pred. 2
Shape	Aperture Irregularity	Squared circumference of the aperture / $4\pi \cdot$ segment size.	Pred. 2
	Beam Modulation	$1 - (\text{Aperture size} / \text{union of all aperture sizes})$ .	Pred. 2
Dynamics (VMAT)	Leaf Travel	Average of the total travelled distance per leaf.	Pred. 2
	Modulation	Variation in segment area relative to the maximum aperture multiplied by the differences in position of the leaves relative to the maximum leaf differences.	Pred. 2
	Complexity Score		
	Dynamic Field Aperture	Absolute aperture difference between segments.	Pred. 1
	Traveled area	Traveled area between segments.	Pred. 1
	Segment Union	Union of the aperture area in two consecutive segments.	Pred. 1 and 2

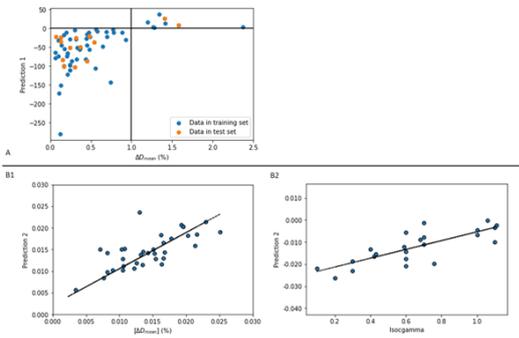

Figure 1 A: Prediction of the difference in dose calculation with a 2 and 4 degree gantry angle spacing ('Prediction 1') to the measured  $AD_{mean}$ . Orange data sets are the test data. B1: Prediction of the difference in dose calculation with different beam models ('Prediction 2') to the measured difference for MLG-10MV plans. B2: 90% CI of 'Prediction 2' of 1412 independent plans, packed in 35 bins, to their isocentre gamma value (3%/3mm).

### Conclusion

We demonstrated that CMs can be used effectively to predict intrinsic uncertainties in the TPS. These results can be used to indicate the probability of dosimetric errors for a given plan.

### PV-103 Linking ACROP guidelines to ICRU91: a multicentre study in lung SBRT on prescription and reporting

E. De Jong<sup>1</sup>, M. Guckenberger<sup>2</sup>, N. Andratschke<sup>2</sup>, K. Dieckmann<sup>3</sup>, M.S. Hoogeman<sup>4</sup>, M. Milder<sup>4</sup>, D. Sloth Moller<sup>5</sup>, T. Bisballe Nyeng<sup>5</sup>, S. Tanadini-Lang<sup>2</sup>, E. Lartigau<sup>6</sup>, T. Lacornerie<sup>6</sup>, A. Mendez Romero<sup>4</sup>, W. Verbakel<sup>7</sup>, D. Verellen<sup>8</sup>, G. De Kerf<sup>8</sup>, C.W. Hurkmans<sup>1</sup>  
<sup>1</sup>Catharina Ziekenhuis, Department of Radiation Oncology, Eindhoven, The Netherlands; <sup>2</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland; <sup>3</sup>Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria; <sup>4</sup>Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands; <sup>5</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark; <sup>6</sup>Centre Oscar Lambret, Department of Radiation Oncology, Lille, France; <sup>7</sup>VU University Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands; <sup>8</sup>GZA St-Augustinus Iridium Cancer Network, Department of Radiation Oncology, Antwerp, Belgium

### Purpose or Objective

In 2017 the ESTRO Advisory Committee on Radiation Oncology Practice (ACROP) consensus guideline on implementation and practice of SBRT for peripherally located early stage NSCLC was published, recommending to prescribe  $3 \times 15$  Gy to the PTV as this results in a  $BED_{10Gy} > 100$  Gy. Later that year the ICRU published report 91 about prescribing, recording and reporting of stereotactic treatments with small photon beams advocating to also report the mean GTV dose. The purpose of this multicentre study is to establish the link between the ACROP and ICRU-91 recommendations.

### Material and Methods

From each of the eight participating centres, 15 consecutive clinical treatment plans of patients with peripherally located early stage NSCLC were selected. Treatment plans were generated following the institutional protocol, centres A and B prescribed  $3 \times 13.5$  Gy, centre C  $4 \times 12$  Gy, centres D and E  $3 \times 15$  Gy, centre F  $3 \times 17$  Gy and centres G and H  $3 \times 18$  Gy. Subsequently, dose parameters of the target volumes were reported as recommended by ICRU91 and also converted to  $BED_{10Gy}$ . The centres employed various techniques for motion management. Four centres used an ITV concept while two centres used the mid-ventilation concept, one centre a mix of the ITV and mid-ventilation concept and one centre

a mix of GTV tracking and the ITV concept. For the ITV planned patients no GTV volume was recorded.

### Results

Figure 1a shows that the minimum dose in the PTV ( $D_{98\%}$ ) is not for all centres higher than a  $BED_{10Gy}$  of 100 Gy (for a  $BED_{10Gy}$  of 100 Gy in 3 fractions, a total dose of 42 Gy is needed while for 4 fractions a total dose of 47.5 Gy is needed). Figure 1b shows that all centres had a GTV/ITV mean dose higher than a  $BED_{10Gy}$  of 100 Gy. The intra-centre variation in dose parameters was much smaller than the inter-centre variation.

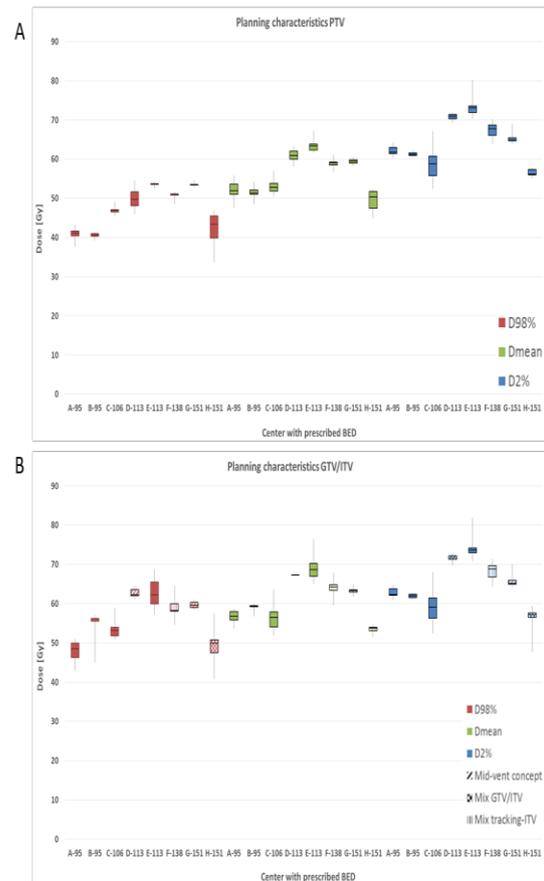

Figure 1: A) Boxplot of the minimum dose ( $D_{98\%}$ ; red),  $D_{mean}$  (green) and the maximum dose ( $D_{2\%}$ ; blue) of the PTV per centre; on the x-axis per centre the prescribed  $BED_{10Gy}$  is given; B) Boxplot of the minimum dose ( $D_{98\%}$ ; red),  $D_{mean}$  (green) and the maximum dose ( $D_{2\%}$ ; blue) of the GTV/ITV per centre; centres using the mid-ventilation concept are shown with a diagonal striped pattern, the centre using a mix of mid-vent and ITV is shown with a checkerboard pattern and the centre using a combination of tracking and ITV is shown with a vertical stripes pattern.

### Conclusion

Three out of 8 ACROP centres did not follow the ACROP guideline in having a  $BED_{10Gy} > 100$  Gy. This, together with the large variation in dose characteristics between centres raises the question whether or not further harmonization is warranted.

### PV-104 Out of field dose for three imaging modalities in case of image guided prostate cancer radiotherapy

C. Le Deroff<sup>1</sup>, R. Lefeuvre<sup>1</sup>, J. Bouvier<sup>1</sup>, R. De Crevoisier<sup>1,2</sup>, C. Lafond<sup>1,2</sup>

<sup>1</sup>Centre Eugène Marquis, Radiotherapy, Rennes, France; <sup>2</sup>Univ Rennes- CLCC Eugène Marquis- Inserm- LTSI-UMR 1099, Radiotherapy, Rennes, France

### Purpose or Objective

In prostate image guided radiotherapy (IGRT), a recent randomized trial reported an occurrence of other malignancies two times higher in case of a daily imaging

control compared to a weekly control (*de Crevoisier, IJROBP 2018*). The purpose of this study was to measure the additional out of field dose delivered by various imaging modalities.

#### Material and Methods

An anthropomorphic phantom was used to mimic a total dose of 78 Gy delivered in the prostate by IMRT/IGRT. We measured the dose related to three imaging techniques (a pair of orthogonal portal images (PI) (6 MV, 2 UM/image), a pair of orthogonal kV images (75 kV, 10 mAs and 105 kV, 80 mAs) and a standard full kV-CBCT (125 kV, 676 mAs)). The doses were measured for 21 points along the central axis of the phantom with thermoluminescent dosimeters (GR-200A). These doses were compared to the measured doses related to the treatment (IMRT, 5 beams, 6 MV, sliding window technique). Finally, the doses for various kV-CBCT parameters were computed: a low dose (260 mAs) and a high dose protocol (1300 mAs).

#### Results

Figure 1 shows the measured out of field dose for the three imaging modalities for one fraction/control. Orthogonal kV imaging (2D-kV) provides the minimum dose inside (1.12 mGy at 0 cm) and outside the field (0.11 mGy at 20 cm, corresponding to 10 cm from the imaging field edge). Standard kV-CBCT imaging provides less dose inside the field (18.6 mGy at 0 cm) than PI (28.8 mGy at 0 cm) but more dose outside the field (1.36 mGy at 20 cm) compared to PI (0.87 mGy at 20 cm). The high dose kV-CBCT protocol provides the maximum out of field dose (2.62 mGy at 20 cm), while using a low dose kV-CBCT protocol provides less dose (0.52 mGy at 20 cm) than PI. The out of field doses related to IMRT are superior to all the imaging control modalities (8.65 mGy at 20 cm).

Considering a weekly control by 2D-kV imaging (8 controls) and a daily control by a standard kV-CBCT imaging (39 controls), the doses at 20 cm were 0.90 mGy and 53.1 mGy, respectively. However, when considering a daily control by 2D-kV imaging and a weekly control by a low dose kV-CBCT imaging the doses are similar with 4.3 mGy at 20 cm.

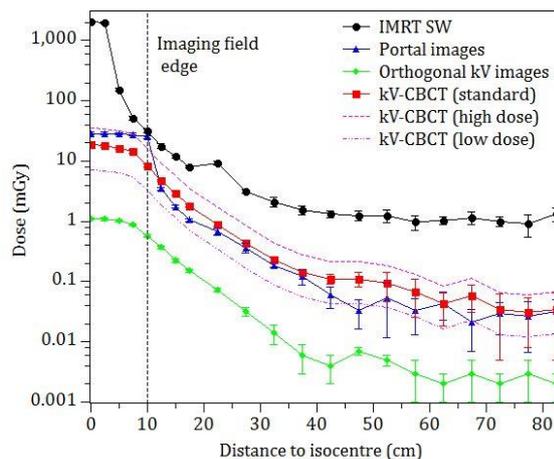

Figure 1: Measured dose profiles for one fraction of IMRT (SW: sliding window technique), one pair of orthogonal portal images (6 MV, 2 MU/image), one pair of orthogonal kV images (75 kV 10 mAs, 105 kV 80 mAs) and one full kV-CBCT (125 kV) with either 260 mAs (low dose), 676 mAs (standard) and 1300 mAs (high dose). The origin represents the treatment and imaging isocenters and is located at the prostate barycenter.

#### Conclusion

Both imaging modality and control frequency as well as treatment fields have an impact on the out of field dose. Regarding one imaging control session, the out of field

dose ranges from 0.1 to 2.6 mGy at 10 cm from the imaging field edge.

#### PV-105 <sup>68</sup>Ga-PSMA PET/CT for quantitative evaluation of radiotherapy-induced cell loss in salivary glands

V. Mohan<sup>1</sup>, N. Bruin<sup>2</sup>, J. Van de Kamer<sup>1</sup>, J. Sonke<sup>1</sup>, A. Al-Mamgani<sup>1</sup>, W. Vogel<sup>2</sup>

<sup>1</sup>The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands ; <sup>2</sup>The Netherlands Cancer Institute, Departments of Radiation Oncology and Nuclear Medicine, Amsterdam, The Netherlands

#### Purpose or Objective

Despite the precision of modern radiotherapy (RT) techniques that are applied to head and neck (H&N) cancer, xerostomia continues to be a complication that affects many patients. Current dose constraints for parotid glands (PGs) and submandibular glands (SMGs) are based on patient and physician-reported xerostomia that is subjective, multifactorial and difficult to quantify. Development of more accurate dose constraints requires quantitative dose-effect relationships. <sup>68</sup>Ga-PSMA is a highly specific and sensitive PET tracer designed for prostate cancer staging, but vital salivary gland cells also abundantly express the PSMA epitope. We aimed to explore the use of PSMA as a quantitative measure of radiation-induced cell loss in salivary glands.

#### Material and Methods

Five H&N cancer patients were included in an ongoing prospective study. They received treatment with 70 Gy in 35 fractions over 7 weeks. <sup>68</sup>Ga-PSMA PET/CT was acquired in treatment position at baseline and at 1-month post-treatment. The PET scans were rigidly registered to the planning CT and the associated dose distribution. The relative change in standard uptake values (SUV) between the two PET scans was compared with the absolute dose received, to establish the response per gland (SUV<sub>peak</sub>) and per voxel (8mm isotropic) within each gland. For the voxel-based evaluation the dose was binned per 5 Gy and the SUV change within each bin was averaged.

#### Results

Figure 1 shows the baseline and post-treatment PSMA PET images, and the RT dose distribution of patient 1. The relative SUV<sub>peak</sub> change for SMGs and PGs (20 glands in total) was highly correlated with the mean dose ( $r = -0.89$ ). At a mean dose of 70 Gy, the average reduction in SUV<sub>peak</sub> was 60% (without background subtraction). Figure 2 shows the relative SUV change in individual voxels, per gland type and averaged for symmetric glands within each patient. The PGs, being larger in volume, received a wider distribution of dose than the SMGs. The average response appears to reach a minimum at about 35 Gy for PGs and at about 45 Gy for SMGs.

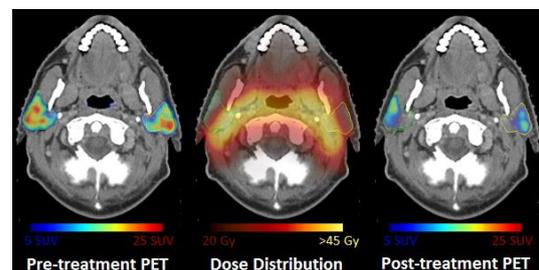

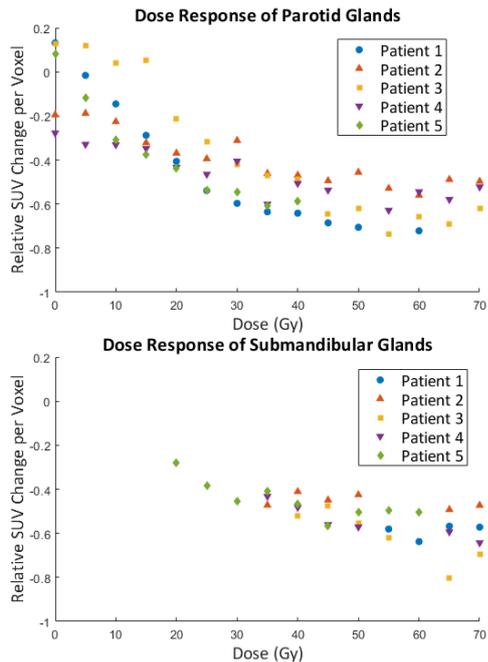

Figure 1. Anatomically registered pre/post-treatment PSMA PET scans and the dose distribution of patient 1, overlaid on the planning CT scan using colour maps. The loss of PET signal in the regions of high dose is evident on the post-treatment PET scan.

**Figure 2.** Dose response per voxel for parotid and submandibular glands of each patient. Dose is binned every 5 Gy and the relative change in SUV is averaged per bin.

### Conclusion

The PSMA PET response in salivary glands after radiotherapy demonstrates a significant dose-effect relationship on the glandular and voxel level, consistent with the hypothesized loss of glandular cells. The accuracy of this method appears to allow detection of differences in radiosensitivity between salivary gland types and between individual patients. If these dose-effect relations can be modelled and related to patient-reported outcomes, this could contribute to new dose constraints and potentially, a lower incidence of xerostomia in H&N RT patients.

### PV-106 An optimized compact microbeam source for preclinical studies

F. Treibel<sup>1,2,3</sup>, J.J. Wilkens<sup>1,2</sup>, S. Bartzsch<sup>2,3</sup>, S.E. Combs<sup>2,3</sup>

<sup>1</sup>Technical University of Munich, Physics Department, Garching, Germany; <sup>2</sup>Technical University of Munich, Department of Radiation Oncology, Munich, Germany; <sup>3</sup>Helmholtz Zentrum München, Institute of Innovative Radiotherapy, Neuherberg, Germany

<sup>1</sup>Technical University of Munich, Physics Department, Garching, Germany; <sup>2</sup>Technical University of Munich, Department of Radiation Oncology, Munich, Germany; <sup>3</sup>Helmholtz Zentrum München, Institute of Innovative Radiotherapy, Neuherberg, Germany

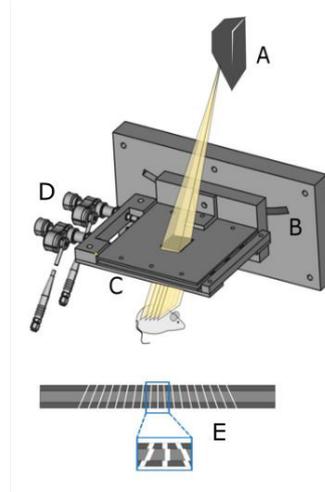

### Purpose or Objective

Microbeam Radiation Therapy (MRT) is based on spatial fractionation of the dose in arrays of highly collimated microbeams. In preclinical investigations MRT showed high normal tissue tolerance while preserving the degree of tumor control. Currently, MRT can only be delivered at large synchrotrons due to beam properties such as high dose rate and low beam divergence. To promote research on MRT, we developed a collimator for an alternative microbeam source using a small animal irradiator (SARRP by Xstrahl). In the design special attention was paid to an optimization of the peak-to-valley dose ratio (PVDR) and the achieved dose rate.

### Material and Methods

Considering the beam divergence of a conventional X-ray source, we developed a collimator with tilted slits. A movable middle plate framed by two fixed plates allows for variable slit widths between 0 and 100  $\mu\text{m}$  (Fig.1). Monte-Carlo simulations in Geant4 were performed to optimize the design of the setup with regard to variations in dose and improvement in PVDR in a water phantom. We

analyzed the impact of the slit widths and the collimator position relative to the X-ray tube. Modifications of the emission angle and respective reduction of the projected focal spot size were evaluated as an innovative approach increasing the PVDR. Apart from the PVDR, we considered a high peak dose rate, as well as small beam penumbra widths as figures of merit. Based on the simulations, the collimator setup was built and is now subject to experimental validation with radiochromic film dosimetry.

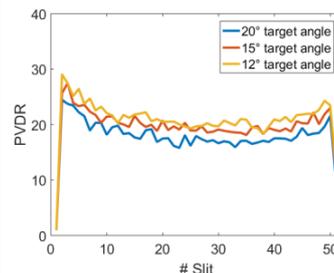

**Figure 1:** Setup of a microbeam source using a conventional X-ray tube (A). The three-layered collimator (C) is rotatorily mounted (B). The middle plate can be shifted by help of two piezo actuators (D). Tilted slits account for beam divergence (E).

### Results

Significant improvements were introduced compared to the previous design of Bartzsch, Cummings, Eismann and Oelfke in 2016 in *Medical Physics*. The source distance of the collimator was increased from 70 mm to 212 mm. We achieved a very high PVDR of up to 25 in 1 cm depth representing an enhancement of 62% versus the PVDR measured at 70 mm by Bartzsch et al. Simultaneously, the divergence of the microbeams is reduced. Larger treatment depths can be obtained, enabling *in vivo* studies in rodents.

Increased flexibility in beam width is achieved by the three-layered collimator design. The observed sensitivity of the dose to variations in slit width demands accuracies below 2  $\mu\text{m}$  which are obtained by use of piezo actuators. The projected focal spot width has a strong effect on the dose profile. At 2 cm depth in water, comparisons of 20° and 12° target angle revealed up to 22% deviation for the peak dose and 3% for the valley. In average, the PVDR was increased by 17% for the smaller projected focal spot size (Fig.2).

**Figure 2:** Impact of the target angle on the PVDR at 2 cm depth in a water phantom.

### Conclusion

Our investigations led to a new microbeam source. Precisely controlled positioning of the collimator and of the slit widths are crucial to provide reproducible dose profiles. Modification of the source distance and the

available. It needs prescription at the right time. It has to be given at the right form. The whole of these elements are covered by the process of 'Quality Assurance' which is the responsibility of all bodies involved". I met Emmanuel vander Schueren early in my career on a European Quality network in RT meeting, he made an impact on me. Since then I have had a special interest on Quality Management in RT and in particular in quality assessment. It is an honor and responsibility to receive this award and I commit myself to be an ambassador of his values.

#### SP-0109 The role of women in the brachytherapy field C. Haie-Meder<sup>1</sup>

<sup>1</sup>Institut Gustave Roussy, Radiation Oncology Department, Villejuif, France

##### Abstract text

Brachytherapy was initiated by a famous woman, Marie Sklodowska-Curie, after her radium discovery in 1898. She was awarded two Nobel prizes in 1903 and 1911, she was the first woman in Europe to get the degree of Doctor of Science, and she became the first female Professor at Sorbonne. She resigned patenting the radium isolation method, claiming that « Radium is a chemical element, a property of all humans ». The Radium Institute was founded in Paris in 1912 due to Marie Curie 's efforts. Thousands of patients were treated with radium for cancers. Her determination, her commitment, her humanity ideal were the basis for new generations of women researchers including medical physicists and radiation oncologists. Among them, at Gustave Roussy, Simone Laborde, head of the radiation department, was one of the first to write a book on brachytherapy technique. She fought against the concept that the heaviest treatments against cancer were the most efficient, after having seen severe complications among her cancer patients. In France, brachytherapy became very popular and women widely contributed to its development : The physicist Andrée Dutreix established the rules of the Paris system, still currently in use. Her pupil, Edith Briot, contributed to the spread of brachytherapy participating to the ESTRO courses and currently Isabelle Dumas who is in charge of brachytherapy physics at Gustave Roussy. Ginette Marinello, was the author of the famous « Practical Manual of Brachytherapy ». Monique Pernot, radiation oncologist in Nancy, accumulated a tremendous clinical experience, especially in head and neck cancer brachytherapy. Her numerous publications served as a basis for dose-rate values in low dose-rate brachytherapy. Outside France, a lot of physicists are dedicated to brachytherapy : Inger Lena Lamm, Taran Paulsen-Hellebust, Astrid de Leeuw, Nicole Nesvacil, Jamema Swamidas, Kari Tanderup, being now the Director of the ESTRO gynaecological course, and many others. Their commitments is the living proof of the continuous interest in brachytherapy. A lot of female doctors have contributed to the development of brachytherapy. Among them Ina Jürgenliemk-Schulz, who is the president elect of GEC-ESTRO, Li Tee Tan, Angela Rovirosa, Alina Sturdza, Henrike Westerveld, Claire Charra-Brunaud, Laurence Thomas, Hana Stankusova and many others. Outside Europe, important ladies, such as Judith Stitt, Beth Erickson , Akila Viswanathan and of course Patricia Eifel are among the most famous brachytherapists in the United States. Female doctors represent currently 60% of the medical community. Their contribution to the development of brachytherapy represents a tremendous step forward. Let's hope that their achievements will be more widely recognized in the future.

##### Abstract text

Compared to computed tomography (CT), magnetic resonance imaging (MRI) provides vastly superior soft-tissue contrast. This makes it much easier to visualize lesion boundaries that will result in a much better delineation of the target volume, helping to better irradiate the lesion and avoid surrounding tissue. Therefore, combining MRI with CT data is increasingly used for radiotherapy planning in the clinic. This combined CT/MRI dataset contains both the information required for targeting and for dose calculations. During this presentation, three studies will be presented where MRI and small animal radiotherapy were combined in the field of neuro-oncology. In a first study, we used a combined CT/MRI dataset to guide the irradiation of brain tumours in a F98 glioblastoma rat model using a micro-irradiator. Contrast-enhanced MRI images were acquired to follow up tumour growth after orthotopic inoculation, to monitor treatment response, and to delineate the target volume during radiotherapy planning. Using multiple non-coplanar arcs the prescribed dose could be delivered to 90% of the target volume, while minimizing the dose to normal brain tissue. A challenging aspects of small animal CT imaging relates to the radiation dose received by the animals. This might become a very important issue when the therapeutic dose has to be delivered in multiple fractions spaced over time, where each individual irradiation requires a CT for accurate animal positioning. Therefore, in a second study we investigated the feasibility of a MRI-only based workflow for radiotherapy planning of the rat brain, that enables both accurate target delineation and accurate dose calculations using only MRI-based volumes. Multiple MRI sequences were used to generate synthetic CT images that could be used for dose calculations, because only one MRI volume was not sufficient to separate all major tissue types (air, soft tissue, bone) in the rat head. The synthetic CT images were sufficiently similar to the segmented CT images that are routinely used for radiotherapy planning on preclinical radiation research platforms. No significant differences were observed between CT and MRI based dose calculations when more complex beam configurations (multiple beams) were used in the dose plan. However, further research is required in the thoracic or abdominal region of small animals, where more tissue classes will be required to allow for accurate dose calculations compared to the rat head. Finally, discrimination between brain tumor recurrence (glioblastoma) and radiation necrosis (RN) remains a

diagnostic challenge because both entities have similar imaging characteristics on conventional MRI. Functional imaging techniques, such as dynamic contrast enhanced (DCE) MRI or positron emission tomography (PET), could overcome this diagnostic dilemma. A third study will be presented to investigate the potential of DCE-MRI and PET in discriminating high-grade glioma from RN in rats. Induction of RN was achieved by irradiating the right frontal region with 60 Gy using multiple arcs. Results suggested that functional imaging can be used to discriminate glioblastoma (recurrence) from RN.

#### SP-0111 On-line MRI-guidance for dose accumulation and plan adaptation

Bas Raaymakers<sup>1</sup>

<sup>1</sup>University Medical Center Utrecht, Radiotherapy, Utrecht, The Netherlands

#### Abstract text

There are two commercial, clinical hybrid MRI radiotherapy systems operational. The promise of these systems is to improve on the targeting accuracy by providing soft-tissue contrast images directly from the treatment table. These MRI data can be acquired both prior to- and during beam delivery. Such on-line visualization enables image guided Radiotherapy (IGRT) as we know it, but then based on soft-tissue contrast images. This presentation will mainly focus on the next steps of using on-line MRI data. The MR images can be used to reconstruct the delivered dose by combining the MRI with the linac output.

This can be done at various time scales. Daily MRI can be used for dose accumulation per day. Intra-fraction MRI, in combination with time-stamped linac output can yield time-resolved dose reconstruction at an intra-fraction level. The goal is to track the dose delivery in real-time, for this MRI, linac readings and dose calculations need to be optimized.

The accumulated dose can be used for treatment response assessment but clearly also as a metric for plan adaptation. Plan adaptation based on daily MRI from the treatment table is a next step for IGRT, the plan is adapted to the patient instead of trying to re-position the patient to the pre-determined plan. Similar to dose accumulation, the frequency of adaptation can be increased by also using intra-fraction MRI. The anatomical changes have to be interpreted live, various options are under investigation to allow real-time digestion of MRI, including faster MRI acquisitions and hybrid patient modelling-MRI techniques. Plan adaptations can be triggered by anatomical changes, but also by accumulated dose metrics. A loop to use the real-time dose accumulation as input for continuous (intra-fraction) plan adaptation will be presented.

In summary, this presentation aims to show that on-line MRI guidance as a next step for soft-tissue based IGRT is only the first step towards continuously adapted radiotherapy so moving targets can be treated as if they are static.

#### SP-0112 First clinical experience and future directions of MR-guided radiation therapy

D. Zips<sup>1</sup>

<sup>1</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany

#### Abstract text

Since September 2018 the 1.5 T MR-Linac system is in clinical use. I will discuss our first clinical experiences and reflect on expectations as well as on our long-term vision for MR-guided adaptive radiation oncology. In addition, I will discuss the potential of MRgRT to facilitate transformation of current radiation oncology into RO4.0.

#### OC-0113 MRI artifact simulation for clinically relevant MR sequences for guidance of HDR brachytherapy

E. Beld<sup>1</sup>, M.A. Moerland<sup>1</sup>, M.A. Viergever<sup>2</sup>, J.J.W. Legendijk<sup>1</sup>, P.R. Seevinck<sup>2</sup>

<sup>1</sup>UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands; <sup>2</sup>UMC Utrecht, Image Sciences Institute, Utrecht, The Netherlands

#### Purpose or Objective

The purpose was to investigate the potential of several clinically relevant MR sequences for application during the HDR brachytherapy intervention to facilitate tracking/localization of brachytherapy devices (HDR source/titanium needle), which could simultaneously be used to visualize the anatomy. Simulations of the MR artifacts were implemented for a spoiled gradient echo sequence, a spin echo sequence, a balanced steady-state free precession (bSSFP) sequence and a bSSFP sequence with SPAIR fat suppression.

#### Material and Methods

##### Simulations

Simulation of the artifact for the spoiled gradient echo sequence was performed as described in [1]. To simulate the other sequences, the implemented MRI signal equation was adapted. For a spin echo sequence, no dephasing effect was included because of the 180° refocusing pulse. For bSSFP, the steady-state signal equation was included. For SPAIR, the spins at a frequency of the SPAIR pulse were set to 0.

##### MRI acquisition

The object, a non-active Ir Flexisource (Elekta)/a titanium needle (Ø1.9mm, Elekta), was positioned in the center of a doped water phantom. MR imaging was performed on a 1.5T MRI system (Ingenia, Philips). 4 types of 2D MR sequences were applied (2 intersecting 2D slices): spoiled gradient echo, spin echo, bSSFP and bSSFP-SPAIR (see Table1). Furthermore, the MR sequences of the clinical prostate HDR brachytherapy scan protocol were applied: a 3D bSSFP-SPAIR sequence, a T2-weighted and a T1-weighted spin echo sequence (both multi-slice 2D), see Table2. Angles of 0° and 20° between source/needle and B0 were applied.

##### Post-processing

The object position was determined by template matching between the MR images and the simulated artifacts, using a subpixel phase correlation algorithm [1]. A 2D phase correlation was performed for the 2D slices, and a 3D phase correlation for the 3D and multi-slice 2D acquired volumes. The average object position (of 7 obtained positions) and the mean deviation from this average were calculated.

**Table 1.** The scan parameters for the spoiled gradient echo sequence, the spin echo sequence, the bSSFP sequence and the bSSFP-SPAIR sequence that were applied (all 2D).

	Spoiled gradient echo	Spin echo	bSSFP	bSSFP-SPAIR
TE/TR (ms)	2.26/4.60	10.0/100.0	2.3/4.5	1.9/3.8
FOV (mm <sup>2</sup> )	256×256	256×256	256×256	256×256
Slice thickness (mm)	10.0	10.0	10.0	10.0
Acquisition matrix	256×256	256×256	256×256	256×256
Flip angle	30°	90°	20°	30°
Readout bandwidth (Hz/pixel)	434	158.8	434	775

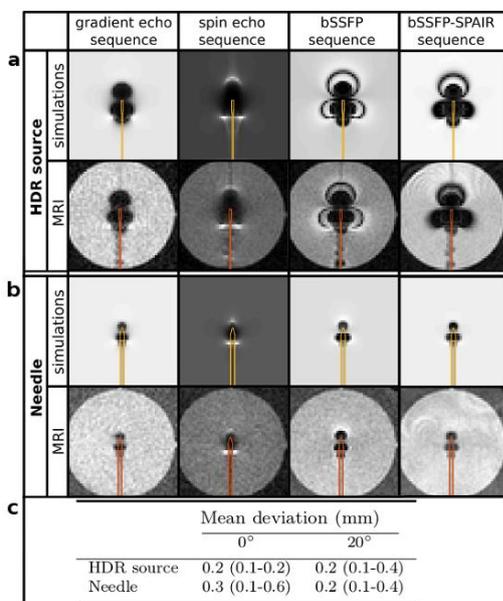

**Table 2.** The scan parameters for the 3D bSSFP-SPAIR sequence, the multi-slice 2D T2-weighted (T2w) spin echo sequence and the multi-slice 2D T1-weighted (T1w) spin echo sequence that were applied (as provided in the current clinical scan protocol).

	bSSFP-SPAIR	T2w spin echo	T1w spin echo
TE/TR (ms)	1.76/3.52	110.0/7126.5	37.4/2000.0
FOV (mm <sup>3</sup> )	256×256×120	200×200×119	224×224×70
Reconstructed resolution (mm <sup>3</sup> )	1.0×1.0×1.0	0.5×0.5×3.0	1.0×1.0×2.0
Flip angle	30°	90°	90°
Readout bandwidth (Hz/pixel)	935.9	194.5	539.1

#### Results

Fig.1 shows the simulated and the MRI images for the 4 applied 2D MR sequences (with the object positions overlaid on the images). These results demonstrate that the simulations highly correspond to the acquired images

as well as that the obtained object positions within the artifacts correspond to the simulated object positions. The mean deviations of the object positions (from average) were 0.2-0.3mm, proving that all sequences were suitable for localization of the objects.

**Figure 1.** The simulated images (top rows) and the acquired MR images (bottom rows) for (a) the HDR brachytherapy source and (b) the titanium needle for an angle of 0°. The images represent the artifacts for the four 2D sequences applied (see the four columns). The contours of the simulated and the acquired object positions are overlaid in yellow and red respectively. (c) The mean deviation (and range) in mm from the average of all object positions obtained from the seven different MR sequences applied.

### Conclusion

This study demonstrated that the MR artifact induced by an HDR source or a titanium needle could be simulated for the 4 investigated types of MR sequences (spoiled gradient echo, spin echo, bSSFP and bSSFP-SPAIR), valuable for object localization in clinical practice. This could be applied for fast 2D acquisitions as well as for volumes acquired using the MR sequences currently provided in the clinical scan protocol, leading to flexibility in the choice of MR sequences for guidance of HDR brachytherapy. 1. Beld E et al 2018 PMB 63 085002

### Symposium: How to exploit Immunogenic cell death Mechanism in Radiotherapy

#### SP-0114 Immunogenic versus Non-Immunogenic Cell Death in Cancer

A. Garg<sup>1</sup>, L. Vandenberk<sup>2</sup>, S. Fang<sup>3</sup>, P. De Witte<sup>4</sup>, P. Salven<sup>3</sup>, P. Agostinis<sup>1</sup>

<sup>1</sup>Ku Leuven, Cell Death Research and Therapy Cdr Unit- Department Of Cellular And Molecular Medicine, Leuven, Belgium; <sup>2</sup>Ku Leuven, Department Of Microbiology And Immunology, Leuven, Belgium; <sup>3</sup>University Of Helsinki, Department Of Pathology, Helsinki, Finland; <sup>4</sup>Ku Leuven, Department Of Pharmaceutical Sciences, Leuven, Belgium

#### Abstract text

Innate immune detection of cells damaged lethally by sterile or pathogenic stimuli is orchestrated through several different immune-modulatory, inflammatory and/or danger signals. In pathogenic contexts, inflammatory chemokines guided (rapid) recruitment of specific innate immune cells from circulation, and their pathogen-associated molecular patterns (PAMPs)-triggered activation is a distinct feature of pathogen-

infected stressed or dying cells. Over the last two decades, it has been widely recognized that in some contexts, sterile dying cells can trigger a potent innate immune response by exposing specific endogenous molecules, analogous to PAMPs, termed damage-associated molecular patterns (DAMPs). This concept has been successfully applied to cancer cells wherein specific therapeutic stimuli have been found to induce immunogenic cell death owing to spatio-temporally defined exodus of immunogenic DAMPs. In some contexts, this immunogenic cancer cell death has been found to have potent anticancer vaccination effect - a feature that has driven its translational popularity. However, there are still a number of basic questions regarding this concept that remain unaddressed. For instance, the PAMPs::DAMPs analogy has frequently raised a challenging question that remains unanswered i.e. can sterile dying cancer cells stimulate innate immunity by moderately mimicking pathogen defense response-like signaling? We have found that sterile immunogenic dying cancer cells indeed trigger (a cell-autonomous) pathogen response-like chemokine (PARC)-signature, which is quite reminiscent of chemokine patterns orchestrated by mammalian cells infected with bacteria or viruses. In fact this PARC signature was specific to immunogenic apoptosis but not to accidental necrosis or non-immunogenic apoptosis. This PARC-signature was found to pave way for neutrophils based phagocytic-targeting of dead/dying cancer cells and subsequent cytotoxic-targeting of residual (live) cancer cells. These observations shed light on the possible evolutionary basis for sterile immunogenic signaling during cancer cell death that needs further systematic investigation in near future.

#### SP-0115 Immunogenic tumor cell death induced by chemoradiotherapy: a clinical point of view

K. Mimura<sup>1</sup>, K. Kono<sup>2</sup>

<sup>1</sup>Fukushima Medical University, Department Of Gastrointestinal Tract Surgery- Department Of Blood Transfusion and Transplantation Immunology- Department of Advanced Cancer Immunotherapy- Department of Progressive Dohad Research, Fukushima, Japan; <sup>2</sup>Fukushima Medical University, Department of Gastrointestinal Tract Surgery, Fukushima, Japan

#### Abstract text

Chemoradiotherapy is generally thought to be immunosuppressive, either by depleting T- and NK-cells or by rendering them functionally inactive, leading to infectious complications and growth of residual tumors. However, radiation oncologists realized a rare phenomenon called the 'abscopal effect' where local irradiation on the tumor causes regression of metastases at sites distant from the irradiated area, although the underlying mechanisms of this effect have not been completely elucidated. In immunogenic tumor cell death (ICD), dendritic cells (DC) were activated by danger signals such as high mobility group box 1 (HMGB1) and calreticulin released by dying cells. The activated DC could then efficiently phagocytize and present cancer antigens, resulting in the induction of tumor specific cytotoxic T lymphocytes. There is a possibility that the abscopal effect is induced by the ICD process. Although we reported that chemoradiotherapy can induce ICD, there was limited information to translate this theory directly in a clinical setting. However, it was recently reported cases of abscopal effect in melanoma patients treated with radiotherapy and immune checkpoint inhibitors (ICI). Further, many clinical trials with this combination approach (radiotherapy and ICI) are ongoing in several types of tumor including melanoma, NSCLC, RCC, Glioblastoma, and HNSCC etc. In this session, I present cellular mechanisms underlying ICD induced by chemoradiotherapy from a clinical point of view.

### SP-0116 Mechanisms of Radiotherapy Induced Inflammatory Signaling

S. Harding<sup>1</sup>

<sup>1</sup>University Health Network, Princess Margaret Cancer Centre, Toronto, Canada

#### Abstract text

Radiotherapy directly leads to clonogenic cell death which is accompanied by inflammatory cytokine signalling. These cytokines have the potential to influence the immune system and may contribute to success of radiotherapy alone and in combination with immune checkpoint blockade. We have recently identified viral response proteins, the pattern recognition receptors (PRRs), as key drivers of this response. In this seminar we will discuss mechanisms by which radiotherapy induces PRRs, drives inflammatory signalling and contributes to the abscopal response in murine models of radiotherapy-immune checkpoint blockade treatment. The goal of these studies is to determine how inflammatory signalling is activated, whether it can be used as a biomarker of treatment response, and if it represents a novel means for improving cancer therapy.

### SP-0118 What are realistic clinical goals in radical radiotherapy for oligometastatic prostate cancer?

T. Hölscher<sup>1</sup>

<sup>1</sup>Universitätsklinikum Carl Gustav Carus, Department Of Radiation Oncology / Oncoray, Dresden, Germany

#### Abstract text

Two decades ago, Hellmann and Weichselbaum postulated that for metastatic solid tumors a broad spectrum of transitional stages (spectrum hypothesis) exists, and that there may be an oligometastatic status potentially to be cured by ablative therapy. Next to the number of metastases (e.g. up to five?), the interval from treatment of the primary tumor and the pace of progression may define such an oligometastatic status.

In prostate cancer (PCa), prostate specific antigen (PSA) is an established tumor marker that is well ahead of clinically significant disease, thus allowing for screening for oligometastatic disease at an early time point. Median time from PSA recurrence to symptomatic disease is 8 years after primary curative treatment, and 2,5 years in patients with castration resistant PCa without detectable clinical metastases, only.

Beyond laboratory and pathology testing (Gleason score), modern anatomical and functional imaging (e.g. PSMA-PET-CT / -MR) has been shown to allow for an improved staging and thus a clinically sound patients selection. There may be different scenarios in prostate cancer, in which local ablative treatment of oligometastatic disease possibly plays a role:

- Identification of metastatic disease in high risk primary PCa
- Treatment failure after primary curative treatment in hormone-sensitive Pca
- Definition of an oligoprogressive status in castration resistant Pca.

Better clinical trials are urgently needed to establish the role of local ablative therapy in these cohorts of patients. These trials need to be competitive, i.e. randomized

against standard of care (comparator: systemic treatment), address proper endpoints (cure, reduction of secondary metastases, prolongation of life, maintenance of quality of life?) and incorporate translational research. In order to be accepted by the community, these trials have to contain optimal imaging and treatment methods and include sufficiently large numbers of patients (multicentre efforts).

During the presentation, I will highlight recent clinical studies in oligometastatic prostate cancer patients at different stages of disease and give a brief outlook on potential future studies the field of radiation oncology should embark on.

### SP-0119 What is the optimal staging for oligometastatic prostate cancer?

L. Miszczyk<sup>1</sup>, A. Napieralska<sup>1</sup>, M. Miszczyk<sup>2</sup>

<sup>1</sup>maria Skłodowska-Curie Memorial Cancer Center and Institute Of Oncology, Radiotherapy, Gliwice, Poland;

<sup>2</sup>Maria Skłodowska-Curie Memorial Cancer Center And Institute Of Oncology, 3rd Radiotherapy Ward, Gliwice, Poland

#### Abstract text

The TNM staging system does not reflect the needs of radiation therapy in terms of prognosis in prostate cancer (PC) patients in terms of oligometastatic disease, both - in the case of lymph nodes as well as bone metastases. It describes only their presence and in the case of lymph nodes metastases - location (in or outside the pelvis). It is known that tumor control probability (TCP) depends on the number of clonogenic cells (which, probably indirectly, is reflected by tumor volume) and delivered dose. TCP could also be dependent on lesion location, which is connected with treatment precision and dose delivery possibility (surrounding critical structures). The last factor influencing TCP is the kind of metastases - lymph nodes vs bones. An additional point which should be considered is imaging - how to find them and which examination ought to be a standard. Because aforementioned issues, we have discussed the usefulness of PC oligometastases volumetric staging relying on our own material. This material comprised 165 PC oligometastases (94 in lymph nodes, 71 in bone - 118 patients) treated locally between 2011 and 2017 with SABR. Up to three metastases were accepted as oligometastatic disease. The total dose (TD) varied from 8 to 60 Gy and was delivered in fraction doses 6-15 Gy. Tumor volume varied from 0.1 to 68.2 ccm (mean 4.8, median 1.6). The median of tumor volume was 1.1 for lymph nodes and 4.0 for bone metastases). Lymph node metastases were mainly located in the pelvis (57). During FU (up to 74.6 months; median 15.7), the tumor volume, local control (LC), biochemical control (BC) and overall survival (OS) were evaluated. For statistical assessment the ROC and Youden index, logrank test and scatterplots were used. On the basis of ROC we specified 2 ccm as a threshold volume. There was a significant difference (p=0.03) in 50 months LC for these two groups (98% vs 75%). We did not find a statistically significant difference for the thresholds 3 and 4 ccm, but there was a clear separation of KM LC curves. We also found significant impact of tumor volume for BC among bone metastases (p=0.006). None of the other analyzed factors had an impact on BC. The obtained results suggest that features of oligometastases have not a significant impact on BC (probably it is linked more to systemic treatment), so when thinking about oligometastatic disease staging we should consider features of these lesions and local result. The basic examination to find such lesions should be probably PSMA PET, which is connected with the issue of volume evaluation (the SUV threshold). Finally, the PC oligometastases staging system ought to take into account the volume of metastases, their number and location (lymph nodes vs bones) when considering the anatomy

(pelvis vs remote for lymph nodes; para-spinal vs rest for bones).

**SP-0120 What is the optimal target volume concept in radiotherapy for oligometastatic pelvic lymph nodes after radical prostatectomy?**

T. Zilli<sup>1</sup>

<sup>1</sup>*Hôpitaux Universitaires de Genève, Radiation Oncology, Geneva, Switzerland*

**Abstract text**

After radical prostatectomy, up to one third of the patients recur mainly with nodal lesions located in the pelvis. Radiation therapy (RT) has been demonstrated to be an effective salvage treatment for oligorecurrent ( $\leq 5$  metastases) prostate cancer, with promising results in terms of disease control and low treatment related toxicity. Both stereotactic body RT (SBRT) and elective nodal RT are been used in this setting and are considered valid, even if still investigational, treatment options. However, the best way to irradiate patients with an exclusive oligorecurrent nodal disease remains debated with many open questions on the performance of imaging techniques in reliably detect the recurrent disease. The aim of this talk is to discuss the rationale supporting the two different approaches (focal versus elective) for oligorecurrent nodal prostate cancer, and to present recent results and ongoing trials that will support the different treatment options.

**SP-0122 Integration of molecular prognostic factors in the management of endometrial cancer**

R. Nout<sup>1</sup>

<sup>1</sup>*Leiden University Medical Center LUMC, Department of Radiotherapy, Leiden, The Netherlands*

**Abstract text**

The majority of endometrial cancer (EC) patients present at an early stage (80% FIGO stage I) and have a good prognosis (overall survival stage I: 85%). Total hysterectomy and salpingo-oophorectomy is the mainstay of treatment. Clinicopathological risk factors (e.g. grade, depth of myometrial invasion, presence of LVSI) are currently used in clinical practice to help identify patients who may benefit from adjuvant (postoperative) therapy. More recently the TCGA group comprehensively assessed molecular alterations in endometrial cancer and found four groups with distinct prognosis: *POLE*-mutant ultramutated, MSI hypermutated, p53-mutant copy-number high (serous like), and a copy number low group without a specific mutation. The *POLE*-mutant group had a very low risk of recurrence despite their ultramutated phenotype and the p53 mutant group had an increased risk of disease progression. Subsequent studies have confirmed the distinct prognostic impact of these four groups, and have identified additional (targetable) prognostic molecular markers. In addition to these molecular features analysis of the impact of grading of LVSI pointed out that substantial LVSI in contrast to no or mild LVSI was a strong independent risk factor for regional and distant recurrence. Furthermore, risk groups based on combined

molecular and clinico-pathologic features were found to have a higher prognostic accuracy than either alone. This concept has been carried forward in the on-going randomised PORTEC-4a trial that investigates molecular profile-based versus standard recommendations for adjuvant therapy, with the overall aim is to further decrease both over- and undertreatment in early stage endometrial cancer.

**SP-0123 Improving outcomes in high-risk locally advanced cervical cancer: extended field RT, adjuvant chemotherapy or immunotherapy?**

C. Chargari<sup>1</sup>, C. Haie-Meder<sup>1</sup>, S. Gouy<sup>1</sup>, E. Deutsch<sup>1</sup>

<sup>1</sup>*Institut Gustave Roussy, Radiation Oncology, Villejuif, France*

**Abstract text**

The implementation of image guided adaptive brachytherapy has allowed achieving very high local control rates in locally advanced cervical cancer patients. However, a threshold seems to have been achieved in terms of survival, which remains alleviated by a high frequency of distant relapses, justifying the development of novel strategies aimed at further improving patients outcome. Conventional approaches are being tested, based on neoadjuvant or adjuvant combinatory chemotherapy. Another strategy relies on the better identification of patients warranting para-aortic irradiation, either through integration of primary para-aortic lymph node dissection or by inclusion of high-tech imaging modalities to better guided treatment fields. An adapted approach has also been proposed to tailor radiotherapy fields for each patient according to conventional risk factors, mainly based on the tumor stage. Finally, the increasing knowledge of tumor biology and the rapidly evolving field of anti-tumor immunity encourage pharmacological approaches in order to exploit the complex interplays between tumor and its microenvironment through radiotherapy.

**SP-0124 Chemo-radiation in Vulvar Cancer: recent developments in (neo)adjuvant and primary therapy**

S. Marnitz-Schulze<sup>1</sup>

<sup>1</sup>*University Clinic Cologne, Radiation Oncology, Cologne, Germany*

**Abstract text**

Chemoradiation in vulvar cancer patients is used postoperatively as adjuvant treatment for patients on high risk for recurrence, in a neoadjuvant setting with the aim to avoid mutilative surgery in patients with locally advanced disease and as a primary treatment to avoid surgery at all. In the recent years there has been a shift to more HPV-positive tumors, younger patients and those with unfavourable tumor localizations. Sentinel node technique has become a standard procedure for inguinal lymph node staging. The use of Sentinel technique lead to a dramatic decrease of morbidity like wound break down and lymph edema compared to full lymphadenectomy and also decreased the treatment related toxicity after radiation. Concerning the optimal diagnostic tool and treatment of pelvic and or para-aortic lymph node metastases, no internationally accepted standard has been established. In contrast to cervical cancer, no data are available with regard to the optimal radiation sensitizer. The talk discusses the data for pre-therapeutic lymph node staging with tailored chemoradiation concepts and the PROs and CONs of (neo-)adjuvant versus primary chemo-radiation, different drugs, dose and target concepts for contemporary treatment of vulvar cancer patients.

### SP-0125 Multi-modal Image Fusion to support Minimally-invasive Therapy

D. Barratt<sup>1</sup>

<sup>1</sup>University College London Ucl, Department Of Medical Physics and Biomedical Engineering / Ucl Centre For Medical Image Computing / Wellcome Trust EPSRC Centre for Interventional and Surgical Science, London, United Kingdom

#### Abstract text

With the increasing availability of new treatment approaches for prostate cancer based on minimally-invasive surgical and radiation therapies, there is a growing need for computer-assisted therapy systems that enable high-accuracy, tumour-targeted therapy delivery within an easy-to-use and efficient clinical workflow. In this presentation, challenges to high-accuracy therapy delivery and clinical usability using computer-assisted planning and guidance systems will be discussed, with a focus on the impact and compensation of soft-tissue motion (including physical deformation). Approaches to automatic generation and application of computer-generated deformable organ models to compensate for organ motion within image fusion software will be described, drawing on the presenter's prior research in this area. Methodological aspects of validation and, in particular, accuracy evaluation, for such systems will then be discussed. Finally, the recent and potential future impact of contemporary machine learning techniques, such as convolutional neural networks, will be explored.

### SP-0126 Steering of needles and applicators

J. Dankelman<sup>1</sup>

<sup>1</sup>Delft University of Technology, Biomechanical Engineering, Delft, The Netherlands

#### Abstract text

It is challenging to steer needles accurately too difficult to reach places. In the first part of the presentation a short overview will be given of different principles to steer needles. Examples from hand held steerable needles and robotically steerable needles presented. Second part of the talk will focus on a novel way to steer needles during brachytherapy treatment of cervical cancer, in cases where the tumour is extending lateral to the pelvic wall or away from the vaginal surface. In these situations the use of an applicator is not sufficient to cover the target area, and free hand steering of needles is difficult and may result in incorrect placement or steering for a long distance through healthy tissue. To overcome this, a method will be presented based on personalised 3D-printed vaginal templates with curved channels. These curved channels are then used to steer needles. The shape of the template will be based on an MRI scans. In this study a template was printed having channels with different curvatures to examine the effect of curvature constraints on placement accuracy. The feasibility of needle steering using curved channels in a template was tested in an experimental set-up using gelatin phantoms.

### SP-0127 3D printed templates for steering of needles

J.C. Lindegaard<sup>1</sup>, P. Petric<sup>1</sup>, A. Traberg Hansen<sup>1</sup>, S. Kynde Nielsen<sup>1</sup>, B. Meisner<sup>1</sup>, K. Tanderup<sup>1</sup>, L.U. Fokdal<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department Of Oncology, Aarhus C, Denmark

#### Abstract text

Standard templates for needles guidance have been used successfully for many years in brachytherapy. Brachytherapy has always been a field of innovative activity towards personalisation as exemplified

by the many customised devices designed and produced for implant optimisation over the years. In this context 3D printing is just a new tool for individualising the implant template in accordance with the distinctive patient anatomy and in close proximity to the clinical workflow, needs and possibilities within the individual departments. Several materials for 3D printing have the advantage of being MRI compatible, biocompatible, autoclavable and sufficiently cheap to allow for single use. However, in relation to safety and legal aspect it should be emphasized that the 3D printed product never should carry the radioactive source directly and only should serve as a platform for optimization of insertion and angulation of approved needles. Whereas commercially available templates can cover many clinical situations well with a standard implant configuration, 3D printed templates for steering of needles are in particular useful when individualised needles tracks are required. However, in such cases the local anatomical conditions should provide a reproducible and robust anchoring of the 3D printed template both with regard to rotation and angulation such that a meaningful pre-plan with virtual angulated needle tracks can be made. Ideally such a pre-plan should be based on MRI with a template in situ performed in a separate session not used for treatment. There is currently very limited data on the clinical use of 3D printed templates for steering of needles. This lecture will seek to review this experience using locally advanced cervical cancer as a practical example of the involved workflow, patient selection and possible outcome.

## Symposium: Automatic / Knowledge based treatment planning:open issues

<sup>1</sup>NHS Greater Glasgow And Clyde, Rt Physics, Glasgow, United Kingdom

#### Abstract text

Knowledge Based Planning (KBP) is now a recognised tool in the creation of high quality and consistent treatment plans. KBP was introduced as the standard planning approach for the majority of radical clinical sites at the Beatson West of Scotland Cancer Centre over three years ago based on the Varian RapidPlan solution. The presentation will describe the process of model implementation including the various barriers and pitfalls that were experienced. Additionally, the challenges faced in the continuing management of KBP models which now underpin over 50% of the daily clinical planning workload, across new software releases and updates, will be considered and how risks can be managed and addressed.

Following the implementation of KBP, a new development in treatment plan optimisation became available through Multi-Criteria Optimisation. This allowed a new strategy to be adopted in the creation of knowledge based planning models by combining Varian's Multi-Criteria Optimization-based Trade-Off Exploration to create base plans of the highest plan quality. These plans were optimised with emphasis in producing plans that offered reduced Organ at Risk (OAR) doses while always maintaining adequate and acceptable coverage of the planned tumour volume. These higher quality plans were then selected for the generation of new and updated knowledge based planning models. Results will be presented on the comparison of KBP plans generated with and without Trade-Offs, describing dose-volume parameters for both organs at risk and the PTVs, and target homogeneity, conformity, and plan complexity and deliverability. Finally, the opportunity afforded by knowledge based planning tools to aid in decision support will be

demonstrated, and specifically, the example of KBP models in the potential for spacing in moderately hypofractionated prostate treatments. KBP models were generated using twenty prostate patients, with and without a hydrogel spacer (SpaceOAR®, Augmenix Inc. Waltham, MA, USA). Four models were developed including plans generated for both pre and post gel implantation, and then a further two models, with these original plans re-optimised in combination with Multi-Criteria Optimisation, with focus in reducing the bladder and rectum doses, whilst ensuring adequate tumour coverage.

**Abstract text**

Trial radiotherapy quality assurance (RTQA) is an important part of the good conduct of a clinical trial. Failure to perform the radiotherapy according to the trial protocol might lead to either a lower tumour control than expected or a higher morbidity. This in turn might lead to false positive or false negative trial results. The most important part of RTQA is a good protocol definition of what radiation treatment should be given in terms of fractionation, dose per fraction and dose to targets and organs at risk. This is assured by several RTQA steps: a facility questionnaire, standard beam output assessments (BOA) under reference conditions, benchmark planning exercises, Individual case reviews (ICRs) and complex dosimetric checks. Recently, it has been shown that BOA results have improved steadily over the last years and approximately only 0.5% of all BOA results are found to be out of the 5% tolerance level (Kerns 2018). This does however not guarantee that complex treatments can be administered with the same accuracy. Complex dosimetry checks have revealed that inaccurate beam modelling in a TPS can be an important reason why phantom dose measurements differ from the calculated dose (Kerns et al. IJROBP 2017). However, in general the current linear accelerators are very stable and individual plan quality assurance measurements show very good results. The most frequent failures to adhere to a trial protocol are found in the ICRs. Unacceptable trial protocol deviation rates between 11 and 48% have been reported and have shown to have a significant impact on the clinical outcome (Weber et al. RO 2012). Mostly, these ICRs were performed retrospectively and thus it seems clear ICRs should be conducted prospectively (Branquinho et al. RO 2018). Prospective feedback also potentially leads to a steeper learning curve on how to adhere to the trial guidelines. In the new EORTC 1735 ADHERE trial investigating the effect of an immune check-point inhibitor after chemoradiation in H&N patients, it will for the first time be prospectively investigated how much impact retrospective vs prospective ICRs will have on the proportion of acceptable patient plans. Until now, the ICR feedback given was usually limited to either per protocol, acceptable variation or unacceptable variation. Once prospective reviews are in place, unacceptable variations can be prevented. However, as protocol plan criteria are set such that most plans will be able to pass the criteria, the enormous potential further improvement in plan quality of

all the plans that pass these criteria is not exploited. With automated planning combined with rapid feedback to the institutions, this potential can be quantified on an individual patient level. The institutions can be presented with an alternative, improved plan which they might be able to use in their department. For example, for the RTOG 0933 whole brain with hippocampus sparing it was shown that automated planning could lead to better treatment plans than plans that were optimised just to adhere to the trial protocol (Krayenbuehl et al. RO 2017). Another example, comparing the plans actually used in the EORTC-1219 Dahanca H&N study plans, showed that the machine learning model was able to generate plans which could frequently improve OAR sparing (Tol et al. RO 2018). For another trial, comparing hypofractionated prostate treatment to conventional treatment, a higher grade 2 toxicity was found in the hypofractionated arm. Looking back at the treatment plans and generating new automated planning plans, it was shown that it was possible to reduce the NTCP of hypofractionated treatment to below the NTCP values of the clinically used standard fractionation schedule. This also indicates that potentially, automated planning could have led to a much lower late toxicity in the experimental arm and thus could have had a mayor influence on the trial outcome (Sharfo et al. RO 2018). In the Trendy trial of primary liver cancer, it was shown in a benchmark exercise that automated planning led to generally better plans with a lower liver NTCP (Habraken et al RO 2017). However, all these studies have been conducted retrospectively. There are still some challenges in order to fully use automated planning in clinical trials prospectively like easy to use software for up- and download of dicom-RT and CRFs including anonymization software which incorporates patient trial numbers and the use of standardized naming conventions for targets and OARs (AAPM TG report 263). Implementation of full prospective ICRs based on automated planning could lead to improved treatment of patients within the trial, a reduction of the number of patients needed in a trial and thus also a reduction of trial costs and more reliable trial outcomes leading to better treatment of future patients.

**SP-0131 Using automated planning for “bias-free” plan comparison**

L. Rossi<sup>1</sup>, A.W. Sharfo<sup>1</sup>, S. Breedveld<sup>1</sup>, B.J.M. Heijmen<sup>1</sup>

*<sup>1</sup>Erasmus Mc - Cancer Institute, Department Of Radiation Oncology, Rotterdam, The Netherlands*

**Abstract text**

Plan quality in current interactive trial-and-error treatment planning (designated ‘manual’ planning) is highly dependent on the planner’s skills and on allotted time. Many treatment planning studies may then suffer from considerable bias e.g. due to differences in planning experience for the investigated techniques, use of different treatment planning systems for the techniques, or a wish that one of the techniques will be superior. Due to the large manual planning workload numbers of plans may be small.

Automated planning can play a key role in substantially reducing bias in these planning studies. Erasmus-iCycle is a system for fully automated multi-criterial planning, based on a wish-list. Resulting plans are always Pareto-optimal and have clinically favourable trade-offs between objectives. Due to the involved prioritized optimization, plan generation is highly consistent among different patients. By using the same wish-list for all evaluated treatment techniques in the study, bias in the comparisons can be substantially reduced. Due to the automation excessive workload may be avoided and studies with large plan/patient numbers may be performed.

<sup>1</sup>IRCCS San Raffaele Hospital, Nuclear Medicine, Milano, Italy; <sup>2</sup>IRCCS San Raffaele Hospital, Medical Physics, Milano, Italy

**Abstract text**

Radiation therapy (RT) is a cornerstone of modern cancer therapy used in approximately 50% of all cancer patients during their clinical course of illness. A common feature of RT treatment with curative intent is to have very sharp dose gradients between the target and adjacent normal tissues. The introduction of more tailored RT planning/delivery techniques using intensity-modulated beams (IMRT), stereotactic radiotherapy (SBRT), tracking with gating or robotic radiosurgery, and precise image-guidance (IGRT) have largely contributed to improve the outcome both in terms of tumor control and in reducing toxicities. In this regard, multimodal imaging and in particular that of the latest generation of hybrid imaging systems (HIS) such as: PET/CT, SPECT/CT and more recently also PET/MRI, can play a crucial role to further exploit the potentialities of modern RT technology. Besides the great clinical value of HIS, technical aspects make these systems also particularly useful for RT applications. In fact, HIS allow the acquisition of anatomical and functional images with the patient being in the same position during the whole study session. This characteristic is further improved in fully integrated PET/MRI systems due to the possibility of truly simultaneous acquisition (spatial and temporal) of the two studies. This “hardware” alignment is very important for an accurate target volume delineation (TV) as errors introduced by image co-registration are minimized. Furthermore, the integration of anatomical, functional and molecular information allows the visualization of various pathophysiological aspects of the tumors which may be important for assessing individual parameters related to cancer cure procedure. In this highly technological scenario the perspective of a nuclear medicine (NM) physicist, who has access to HIS is to work on topics aiming to produce useful and accurate information (images and other type of data) for an optimal and personalized RT. A first of these topics is the set-up of a comprehensive quality control protocol, to guarantee stability/reproducibility of the systems' performance with particular reference to the need of RT applications. Definition and implementation of acquisition, reconstruction and post-processing protocols accounting for different tracers (e.g. 18F-FDG, 18F-FAZA, 11C-Methionine, etc.) and different targets (e.g. brain, lung, liver, etc.) are also important topics of a unique pipeline which aims at the most accurate TV. Delineation of the target volume, and in particular of the biological target volume, is still an open topic that needs to be improved. Several methods based on different image processing techniques (e.g. thresholding, probabilistic, clustering, etc.) have been proposed over the years but none of them have been accepted as standard for clinical use. This has left, to the human operator, the role of gold standard in the TV. However, new techniques based on a machine learning/deep learning, have shown to overtake human performance in computer vision, image recognition, and image interpretation challenges. Furthermore, the same techniques have shown very promising results also when applied to automatic segmentation for TV, in particular when a multimodal and/or a multiparametric imaging approach has been used. An accurate TV also allows a more accurate extraction of information that can be

useful for a more comprehensive characterization of image phenotypes of the tumor. Radiomics analysis has recently emerged as a promising tool for the definition of new imaging biomarkers by high-throughput extraction of quantitative image features. Several studies have shown that texture features extracted from PET, CT or MRI images may have a higher predictive and/or prognostic power than simpler, more “standard” metrics (SUV, tumor shape, tumor volume, etc.). Notwithstanding, such great promises, radiomics analysis presents several challenges that need to be carefully addressed. Standardization (features definition, features computation, features dependences etc ..) is one of the most important aspects which need to be defined to ensure robustness, reproducibility and dissemination of the obtained results among centers. In conclusion, all previously described topics find application when using HIS. HIS have an enormous potential in the generation of complementary information (images and other data type) that, once integrated in a unique model, may allow a more comprehensive understanding of the tumor pathology as well as a more accurate definition of the target for RT treatment. In this scenario the perspective of an NM physicist is to be active in this complex technological and methodological puzzle, working in strong collaboration with all the other people involved in the clinical and research work (physicists, engineers, physicians, technicians, etc.) having as a common objective the best treatment for each patient.

**SP-0133 Working in radiotherapy from the perspective of an MRI physicist**

L.E. Olsson<sup>1</sup>

<sup>1</sup>Lund University, Department of Medical Radiation Physics, Malmö, Sweden

**Abstract text**

There is a substantial increase of imaging in the recent development in radiotherapy. The on-going process of installing dedicated radiotherapy MR-scanners in the oncology/radiotherapy clinics is an obvious proof of this development. MRI is a much more complex modality and applications extend from diagnosis to specific imaging for target identification, treatment planning, treatment follow-up and adaptive regimes. An in-house MR-scanner also brings along many safety issues, both for personnel and patients. Altogether, there is an increasing need for MRI expertise in the radiotherapy department. The demand on accurate geometry and quantification of the data is considerably larger in therapy than diagnostic MRI applications. That means that what can easily be accepted as a well know harmless artefacts in the diagnostic setting can have detrimental negative effects if used for treatment guidance in radiotherapy. Therefore, the MRI-physicist needs specific training in how the image data will be used in the radiotherapy workflow. The MRI-expertise can be an in-house MRI-physicist working with radiotherapy or as a service provided by diagnostic radiology physicists. In any case, it is important that the MRI-physicist will be specifically trained and dedicated to radiotherapy. Not all MRI-physicists from radiology can have the knowledge needed in radiotherapy. Similarly, an MRI-physicist working in radiotherapy cannot be an expert on all MRI techniques. An ideal model is to have a dedicated MRI-physicist in-house in radiotherapy, which will act as a link to the other MRI-physicists in radiology, and thereby facilitate the discussion and knowledge transfer in both directions. The present question will be even more important to discuss when hybrid modalities, such as MR-linacs, will be implemented in the clinics. It is obvious that the MR-scanner is a part of the treatment machine. Therefore, the installation of MR-linacs should be combined with recruitment of in-house MRI-expertise. Traditionally, there have been different physicists

dedicated to radiotherapy, nuclear medicine, MRI and other radiology. The future hybrid modalities in both diagnostics (PET/MR, PET/CT) and therapy (MR/linac) will be the end of the era for "One Modality Physicist". This is a both a challenge as well as a source to opportunities to the physics profession.

#### SP-0134 Working with radiotherapy from the perspective of US physicist

E. Harris<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics, Sutton, United Kingdom

##### Abstract text

Ultrasound can be used to guide radiation therapy of the prostate and prostate bed, breast, gynaecological cancers, and some upper abdominal sites such as liver. The integration of ultrasound with the radiotherapy workflow presents a number of challenges for the ultrasound physicist. One key issue when using ultrasound to guide radiotherapy is the requirement of spatial registration of ultrasound data with the treatment coordinate system which is often not straight forward; ultrasound images are rarely obtained using rectilinear spatial sampling and proprietary information regarding the transducer geometry is not easily obtained. Furthermore, the transformation of ultrasound image data into Cartesian space reduces image quality but is necessary for image display and fusion with CT and CBCT. The pitfalls associated with geometrical registration of ultrasound with the RT treatment isocentre and the importance of working with radiotherapy colleagues to understand geometrical components of the radiotherapy workflow will be discussed.

QA has to be performed at a much greater frequency than is typical for the ultrasound physicist, which is commonly once per year. Traditional ultrasound imaging QA phantoms are typically not suitable to assess the use of ultrasound in radiotherapy (end-to-end testing) and for example, the development of X-ray and ultrasound compatible spatial registration phantoms and anthropomorphic test phantoms, even dynamic phantoms can be challenging. Multidisciplinary working is crucial to generate solutions to these problems. In the design of new systems, the ultrasound physicist has to appreciate there are several practical limitations associated with the radiotherapy setting which can reduce the ultrasound image quality obtainable, including: low (transducer) pressure scanning, high time-pressures, poor selection of imaging parameters, frequent rotation of skilled workforce. The need for greater automation and system redesign will be discussed, including a description of current methods to overcome these problems (used both in an RT setting and elsewhere in diagnostic ultrasound) and potential exciting new multidisciplinary research opportunities.

#### SP-0135 Working with radiotherapy from the perspective of data/computer scientist

#### SP-0136 Considerations for Younger patients receiving RT: psychological, physical, and surveillance

C. Dickie<sup>1</sup>, N. Laperriere<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre- University of Toronto, Radiation Medicine Program, Toronto, Canada

##### Abstract text

Research has demonstrated that adolescents and young adults (AYAs) ages 15 to 39 have unique considerations for cancer care and survivorship. As they transition from pediatric to adult oncology, they also struggle with diverse life changes such as trying to establish independence and identity, a healthy separation from parents/family, employment decisions, higher education and having their own families. Studies show that this transitional period in life is more stressful than other stages with a diagnosis of cancer potentially exacerbating or adding to existing issues. This talk will provide an overview of some of the psychological, physical and surveillance issues that challenge this particular subset of patients with a focus on the supportive role a radiation therapist can play that may positively influence critical outcomes. Psychological distress is well documented in AYA survivors of childhood cancer and for AYAs undergoing therapy. In fact, there have been a series of unmet service needs identified for AYAs including issues involving emotional wellbeing, uncontrolled pain, fear, stress, anxiety, fertility preservation and sex drive / sexual health, fatigue, stressed social and romantic relationships, the inability to meet work demands, school and higher education concerns, and financial issues as they progress through their life during and after cancer therapy. Improvements in the effectiveness of cancer therapy have resulted in increased survival rates often accompanied by chronic toxicities associated with radiotherapy. Anatomical / physical issues include but are not limited to cardiopulmonary toxicity, neurocognitive dysfunction, musculoskeletal issues and secondary malignancy. Survivors also have difficulty with daily activities and physical function due to symptoms from medical interventions. Finally, surveillance considerations are important for the AYA population. A large proportion of adult survivors of childhood or adolescent cancer suffer from toxicities occurring very late and hence late effects screening is critical. In addition, the rate of secondary malignancies is higher than in the general age matched population. AYA patients should be made aware of this risk, have routine follow up, and should be informed to contact their health care team if new symptoms arise. Studies have demonstrated that AYAs frequently do not feel like they have received adequate information at discharge and are non-compliant with regular follow up. Radiation Therapists (RTTs) are in a unique position to improve the evaluation of AYAs unmet needs and management during radiotherapy. Although radiotherapy is often given at the end of the treatment trajectory, RTTs can facilitate access to services and information as the patient's daily point of contact. Research in AYA care shows underutilization of services with associated worse overall health related quality of life and outcomes. Increasing RTT awareness of these needs, how to identify an issue, and how to develop effective strategies to address concerns has the potential to contribute to the reduction of distress in the AYA

population. There may also be a role for an Advanced Practice RT in late effects clinics.

**SP-0137 Radiotherapy in children and adolescents. What do we know until now and what will the future bring?**

**T. Boterberg<sup>1</sup>**

<sup>1</sup>*Ghent University Hospital, Radiation Oncology, Gent, Belgium*

**Abstract text**

Cancer in children and adolescents is rare and at the same time characterized by a wide variety of tumour types, often different from the common adult cancers. Over the past decades, paediatric cancer treatment results have improved significantly: up to 80% of children and adolescents with cancer are currently cured of their disease, although survival figures for the individual cancers vary significantly. This is mainly the result of multi-modality treatment protocols including chemotherapy, surgery, and biological treatment, in addition to selective use of more sophisticated radiotherapy techniques. In addition to that, a better knowledge of molecular characteristics has led to an increasing personalisation of treatment based on risk stratification, which has allowed to further improve cure rates with a reduction in treatment-related morbidity. This is especially important for radiotherapy as treatment modality since almost every organ system is subject to some late effects caused by radiotherapy, in addition to the risk of developing secondary cancers. However, we should take into account that there is a significant variation in frequency of these long-term complications. They are more determined by the affected site, the irradiated volume, the age at time of treatment and the dose given than by the original tumour type treated. Obviously, interaction with chemotherapy may also play a role and should also be taken into consideration. The significant increase in paediatric cancer cure rate over the past years has also increased the number of cancer survivors at risk for developing late effects. While with the passing of time, the risks of cancer relapse recede, monitoring for late effects of treatment becomes more important as they can, as mentioned, affect any body system. The majority of patients will have some form of long-term sequelae, some minor, some major and some that can be ameliorated by timely intervention. Therefore it is strongly recommended that patients should be followed in a multidisciplinary clinic. A detailed treatment summary will help to predict the risk of complications and should guide this long-term follow-up. Finally, increasingly more sophisticated and well-targeted radiotherapy techniques should allow to further minimise the risk of late effects, but that too is still to be investigated and examined long after treatment has finished.

**SP-0138 (VAIRT) Video-Assisted Immobilisation during external beam RadioTherapy for Children**

**N. Ritt<sup>1</sup>**

<sup>1</sup>*Universitätsklinik für Strahlentherapie, Brachytherapie, Wien, Austria (VAIRT) Video-Assisted Immobilisation during external beam RadioTherapy for Children*  
Authors: N. Ritt, S. Hofstätter, A. Osztavics, B. Wisgrill, C. Chao, D. Berger, K. Dieckmann

**Purpose and Objective**

The aim of the pilot study at the Department of Radiotherapy at the Medical University of Vienna (General Hospital of Vienna) was to reduce the number of daily sedations, (which were necessary to keep the patient in treatment position during their radiotherapy fraction) including the presence of anaesthesiologist for children and young patient undergoing EBRT. Therefore, a short cartoon is shown on tablets, to the child lying on the

treatment couch. The impact of this method to reduce stress and anxiety by cognitive distraction, the acceptance by the patients and further the reduction of daily sedations shall be investigated in this work.

**Materials and Method**

In the pilot study between July 2017 and May 2018 the Video-Assisted Immobilisation during external beam RadioTherapy (VAIRT) was offered to all patients below the age of 18 years. The compliance of patients was identified during the preparation process for the radiotherapy treatment. If they were able keep calm during the head-immobilisation mask-preparation and/or CT simulation while watching the short video sequence, the radiation treatment at the LINAC can be performed without daily sedation. Involving the medical staff (Radiology Therapist- RTTs, Radiation Oncologists and Medical Physicists) during the briefing of assistant family member is necessary for the successful implementation of this method of immobilisation in young patients. Results Thirty-eight patients (24 male, 14 female) with a median age of 8 years [from 1 to 18 years] were treated during the pilot study period at the department of radiotherapy. Twenty out of 38 (52%) 7 [3-14] years were successfully cognitively distracted by movies during treatment so that no daily sedation and presence of an anaesthesiologist were needed. Of the remaining patients 13 (34%) at the age of 14 years [8-18] refused to watch any movie while five (13%) at 2 [1-7] year age had to be sedated during treatment. By the introduction of the VAIRT method in the radiotherapy department an increase of 50% of young patients who do not need a daily sedation was observed.

**Conclusion**  
The Video-Assist-Immobilisation method was successfully implemented in the clinical routine for patients below the age of 18 years. For the success of the VAIRT a professional briefing of the patient, relatives and all professional staff involved in the treatment is essential. Reducing sedation during radiation therapy, allows a meaningful handling of resources in saving time (30 min per fraction) and costs (2800€) per patient and treatment. The VAIRT can also be used in adult patients who are stressed and anxious during head-mask preparation and treatment.

**PV-0139 Endorectal HDR brachytherapy boost with MRI guidance for non operative management of rectal cancer**

**R. Engineer<sup>1</sup>, A. Saklani<sup>2</sup>, A. D'Souza<sup>2</sup>, A. Baheti<sup>3</sup>, M. Patil<sup>1</sup>, S. Chopra<sup>1</sup>, P. Patil<sup>4</sup>**

<sup>1</sup>*Tata Memorial Hospital, Radiation Oncology, Mumbai, India;* <sup>2</sup>*Tata Memorial Hospital, Surgical Oncology, Mumbai, India;* <sup>3</sup>*Tata Memorial Hospital, Radlogy, Mumbai, India;* <sup>4</sup>*Tata Memorial Hospital, Gastrointestinal Oncology, Mumbai, India*

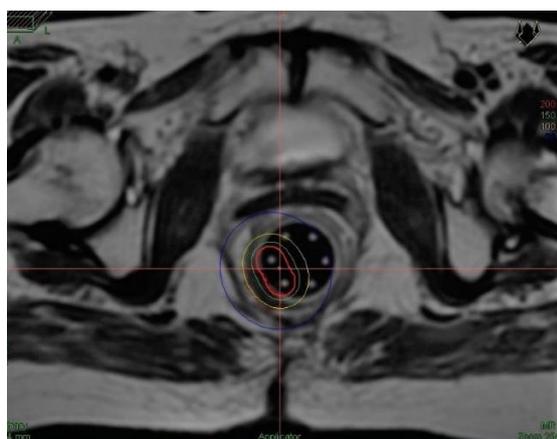

**Purpose or Objective**

In this study we evaluated the role of endorectal brachytherapy as a boost to escalate radiotherapy dose to achieve clinicoradiological complete response leading to organ preservation.

**Material and Methods**

This pilot study consisted of consecutive patients with T2-4 N0-2 M0 distal rectal cancer (within 6 cm from anal verge) treated with radical intent neoadjuvant chemotherapy (NACTRT) between October 2017 and May 2018. External beam radiotherapy consisted of 3D-CRT (4 field) or IMRT to a dose of 50Gy (1.8 to 2 Gy per fractions), to the primary and nodal regions along with daily capecitabine (825mg/msq). Response at conclusion was evaluated by digital per rectal examination (DRE) and those with a residual ulcerative disease and no greater than three-fourth circumferential involvement were

considered for further boost. A planning MRI scan with a multiple channel surface applicator in place was taken within 3 weeks of NACTRT completion. Residual tumour / fibrotic regions were contoured (CTV), dose prescribed at periphery of the residual tumor (7 - 10 mm) depending on depth of invasion and isodose distribution generated for 2-3 channels in closest proximity to the CTV. Plan evaluation consisted of ensuring that the CTV is completely covered by the 85% isodose cloud, while trying to limit the opposing rectal wall from being covered by the 50% isodose line (Fig. 1). High dose rate brachytherapy was delivered with iridium-192 source to a dose of 4 to 6 Gy in 2 fractions one week apart. Patients were assessed for tumor response at 6 weeks from radiation completion with DRE, rectal MRI scan and direct endoscopic visualization a 12 weeks. Patients with incomplete clinical response at 6 to 12 weeks were sent for immediate surgery. Patients with complete (CR) or near complete clinical response (NCR) were observed.

## Results

In all, 66 patients underwent NACTRT in the given period and 21 patients were found to be suitable for brachytherapy boost. 1 patient defaulted immediately after completion of brachytherapy. Four (20%) patients having partial response 3 underwent abdominoperineal resection and 1 had intersphincteric resection. Of these 1 patient had pathological complete response. Of the remaining 20 patients, 15 (75%) had CR to NCR at 12 weeks follow up and were enrolled for the wait and watch approach (Fig. 3). One with nCR underwent local excision.

At a median follow up of 27 weeks (range 16 - 44 weeks) only no patient has had a local regrowth and all 15 (75%) patients continue to be on observation. No rectal toxicity reported.

## Conclusion

Dose escalation with MRI guided endorectal brachytherapy for non operative management of rectal cancer is feasible and can lead to a larger number of patients to achieve complete clinicoradiological response leading to organ preservation.

Longer follow up and a larger sample size would be required to weigh the potential benefits of dose escalation with regard to local response, progression free interval, successful salvage and against risk of long term toxicity.

## PV-0140 Predictive factors and patients' selection for pulsed dose rate brachytherapy boost in anal cancer

T. Brahmi<sup>1</sup>, A.A. Serre<sup>1</sup>, F. Gassa<sup>1</sup>, F. Lafay<sup>1</sup>, M. Sandt<sup>1</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiation Therapy, Lyon, France

## Purpose or Objective

The therapeutic standard of care for localized anal canal cancers is the association of pelvic radiation therapy,

possibly associated with concomitant chemotherapy, followed by a boost either by brachytherapy (BT) or external beam radiotherapy (EBRT). Pulsed Dose-Rate technique (PDR) has become a standard modality, with high local control rates, but questions are remaining regarding patient's selection and predictive factors for local control and toxicities.

## Material and Methods

Between 2005 and 2017, 179 consecutive patients with an anal canal cancer (all histological types), received PDR-BT as a boost after EBRT (+/- concomitant chemotherapy) in our institution. 159 were available for the analysis. Previously reported prognostic factors were analysed in univariate and multivariate analyses with a focus on the local extent of the tumour (T stage; circumference and anal margin and/or rectal mucosa involvement). Local control response was clinically assessed at the time of brachytherapy, then every 3 months for 2 years (MRI every 6 months), then every 6 months.

Late toxicities after BT were classified according to the CTCAE-v5.0.

## Results

The main characteristics of tumours and treatments are detailed in table 1.

With a mean follow-up of 44.5 months, the 5-years loco-regional control and Progression Free Survival (PFS) were respectively 89% (95%CI 86-92) and 82% (95%CI 78-86). Overall Survival (OS) rate was respectively 84% (±4) and 76% (±7) at 5 and 10 years.

Sixteen patients underwent abdominoperineal resection for local recurrence (14) or severe local toxicity (2). 14.5% experienced mucosal grade ≥2 late toxicity. In multivariate analysis, local control response at the time of BT (HR=4.46 for Partial Response rate); EBRT technique (HR = 3.25 for IMRT vs 3D conformal), histology and diabetes were significantly associated with PFS. In that series, gap between EBRT and BT was not significant, but was significantly greater in patients treated with 3D conformal EBRT (30.3 vs 17.6 days, p=0.002). Local extent of the tumour at the initial staging did not significantly influence the PFS in univariate and multivariate analyses. Only tumour recurrence was significantly associated with overall survival (OS).

No significant factors was identified for grade ≥2 late toxicity.

Variables	Number of patients	Percentages
<b>Histological classes</b>		
Squamous cells carcinoma	146	91.8%
Undifferentiated carcinoma	4	2.5%
Other	9	5.7%
<b>Circumference</b>		
<25	13	8.2%
[25 to <33]	37	23.3%
[33 to <50]	33	20.8%
≥50 to 66	76	47.8%
<b>Rectal mucosa involvement</b>		
None	50	31.4%
Present	89	56.0%
Missing data	20	12.6%
<b>Anal margin involvement</b>		
None	104	65.4%
Present	41	25.8%
Missing data	14	8.8%
<b>Staging cT</b>		
1	25	15.7%
2	100	62.9%
3	28	17.6%
4	4	2.5%
<b>Type of treatment</b>		
Exclusive EBRT	51	32.1%
Concurrent Radio-Chemotherapy	107	67.3%
<b>EBRT modalities</b>		
3D conformal	51	32.1%
IMRT	91	57.2%
Missing data	17	10.7%
<b>EBRT treatment time, in days</b>	Mean (SD)	
	38.8 (5.1)	
<b>Gap between EBRT and BT, in days</b>	Mean (SD)	
	23.0 (12.7)	

## Conclusion

PDR-BT is an effective boost modality after EBRT for anal carcinoma patients and may be also indicated in selected patients with a limited involvement of anal margin and rectal mucosa and/or a diameter > 50% (maximal 2/3) of the anal mucosa. The EBRT technique was significantly associated with PFS and IMRT should be applied in these

patients. Results from large multicentre prospective studies are awaited to confirm these observations.

#### PV-0141 Treatment outcomes of HDR brachytherapy for cervical cancer: a comparison of Ir-192 versus Co-60

T. Tantivatana<sup>1</sup>, R. Kanisa<sup>1</sup>

<sup>1</sup>Vajira Hospital, Radiation Oncology, Bangkok, Thailand

##### Purpose or Objective

To determine and compare treatment outcomes between cobalt-60 (Co-60) and iridium-192 (Ir-192) high dose rate (HDR) brachytherapy in stage IB2-IIIB cervical cancer patients at Department of Radiology, Faculty of Medicine Vajira Hospital, Navamindrahiraj University.

##### Material and Methods

A retrospective cohort study of patients diagnosed with cervical cancer and treated with radiotherapy at the Department of Radiation Oncology, Faculty of Medicine Vajira Hospital between 2004 and 2014. Survival rate was analyzed by Kaplan-Meier method and were compared between groups with log-rank test. Multivariate analysis was performed using Cox proportional hazards model.

##### Results

A total of 480 patients with cervical cancer and treated with radiotherapy were included, 274 patients for Ir-192 group and 206 patients for Co-60 group. The 2- and 5-year disease-free survival rate in Ir-192 group were 80.4% and 73.1% and in Co-60 group were 82.5% and 74.7%, respectively (p=0.365). Overall survival rates at 2 and 5 years were 89.4% and 77% of the Ir-192 group, and 91.6% and 81.9% in the Co-60 group, respectively (p=0.238). The complications were primarily grade 1 or 2. Grade 3 and 4 complications were found in 13 of 274 and 7 of 206 in Ir-192 and Co-60 groups, respectively (p=0.23). Grade and clinical stage of cancer significantly affected the survival outcome.

##### Conclusion

Cervical cancer patients who were treated with HDR Co-60 brachytherapy were comparable in survival and toxicity outcomes of those with HDR Ir-192 brachytherapy. Co-60 source has lots of economic advantages over Ir-192 and hence suitable for low resource radiotherapy setting.

#### PV-0142 HDR BRT treatment of non-melanoma skin cancer: outcome and feasibility in a retrospective analysis

D. Delishaj<sup>1</sup>, I.C. Fumagalli<sup>1</sup>, R. D'Amico<sup>1</sup>, G. Sangalli<sup>2</sup>, F. Declich<sup>2</sup>, C. Frigerio<sup>2</sup>, C.P. Soatti<sup>1</sup>

<sup>1</sup>Ospedale Manzoni di Lecco, Department of Radiotherapy, Lecco, Italy ; <sup>2</sup>Ospedale Manzoni di Lecco, Department of Medical Physics, Lecco, Italy

##### Purpose or Objective

Non-melanoma skin cancer (NMSC) is the most common malignancy in the white population, comprising about 2-3 million new diagnosis worldwide every year, with an increasing incidence observed in the last decades. High dose rate brachytherapy (HDR-BRT) is an advantageous treatment option both from dosimetric point of view and for patient convenience due to the small number of fractions.

The purpose of this study was to evaluate tumour control and toxicity in elderly patients treated with HDR-BRT.

##### Material and Methods

A total of 55 patients underwent skin HDR-BRT from October 2007 to July 2018 with Iridium-192 source. 34 lesions in 31 patients affected by NMSC were enrolled; lymphopietic, breast and benign histology (keloids) were excluded from the analysis. The median age at diagnosis was 79,6 years [48,5-102,4]. A surface flap was customized to the size of each target lesion and the catheters were embedded; every treatment was optimized with 3D planning using CT imaging. Different

prescribed doses and fractionation have been chosen: 24-31.5 Gy in 8-12 fractions for palliative treatment (5 cases, 15%), 34-52 Gy in 10-20 fractions for adjuvant treatment (20 cases, 59%) and 36,75-60 Gy in 7-30 fractions for radical treatment (9 cases, 26%); the average biological effective dose (BED) was 35.7, 51 and 60.9, respectively. The treatment was mostly delivered with daily fraction and some schedules were accelerated with 2 fractions a day. Acute and late toxicity has been recorded according to CTCAE 4.0.

##### CHARACTERISTICS

No of Patients 31 No of lesions 34

Age, years Median 79,6 Range 48,5-102,3

Sex Male 24 (70%) Female 10 (29%)

Histology Basal Cell Carcinoma 4 (12%) Squamous Cell Carcinoma 28 (82%) Kaposi Sarcoma 2 (6%)

Size, cm Median 3 Range 1-7

Localization Scalp 16 (47%) Ear 6 (18%) Face 7 (21%) Trunk 2 (6%) Extremity 3 (9%)

##### Results

At a median follow-up of 12 months (range 3-77,2 months), local control was 97%; in particular no patient treated with an adjuvant BRT HDR after radical surgery had local recurrence and 7 of the 9 lesions (78%) who received a radical dose showed a complete response. In only 4 lesions a partial response was observed, mostly in the palliative group, and just 1 case developed a progression. No severe acute toxicity was recorded; just 32% of the cases presented G2 acute toxicity, recovered within 2 months from the end of BRT. Late G1 toxicity was showed in almost a quarter of the lesions; no G2 or greater late toxicity was recorded. 62% lesions showed an excellent cosmetic impact and just 2 cases resulted in a fair cosmetic outcome.

### Conclusion

HDR-BRT represents an effective and safe solution for the treatment of NMSC, even in elderly population, with excellent clinical outcome and very low toxicity. More data with a longer follow-up are necessary.

### PV-0143 High-dose CT-guided interstitial brachytherapy of liver metastases in oligometastatic patients

F. Walter<sup>1</sup>, S. Gerum<sup>1</sup>, M. Rottler<sup>1</sup>, C. Maihöfer<sup>1</sup>, J. Well<sup>1</sup>, L. Nierer<sup>1</sup>, M. Seidensticker<sup>1</sup>, R. Seidensticker<sup>2</sup>, T. Streitparth<sup>2</sup>, F. Streitparth<sup>2</sup>, J. Ricke<sup>2</sup>, C. Belka<sup>1</sup>, S. Corradini<sup>1</sup>

<sup>1</sup>Radiation Oncology, Department of Radiation Oncology LMU, Munich, Germany; <sup>2</sup>Radiology, Department of Radiology LMU, Munich, Germany

### Purpose or Objective

Local treatment for liver oligometastases is a challenging issue. Aim of the present study is to report feasibility and outcome in this setting using high-dose CT-guided interstitial brachytherapy (BT).

### Material and Methods

36 patients (m:f 17:19) with a median age of 68 years (31-88) who received high-dose brachytherapy on liver metastases between 01/18 and 06/18 were retrospectively analysed. Primary tumours were as follows: rectosigmoid carcinoma in 16 patients (pts), breast cancer in 4 pts, NET in 5 pts, gastric cancer in 3 pts and others (sarcoma, GIST, pancreatic cancer, colon cancer, prostate cancer).

### Results

18 out of 36 pts presented with a single hepatic lesion, 12 pts had two lesions and 6 pts had 3 or more lesions. Between 1 to 9 catheters were utilized for the procedure (1=7pts, 2=14pts, 3=5pts, >3=10pts). The median metastases diameter was 2.1cm (range 0.8-13.6cm) with a median volume of 2.4ccm (0.1-550.8ccm). The total liver volume ranged from 891-2761ccm (median 1402ccm). A medium dose of 19.7Gy was achieved in D100 (8.7-26.1Gy), D98: 22.6Gy (9.6-33Gy), D95: 24.5Gy (10.1-39.6Gy), and D90: 26.6Gy (10.6-49.7Gy). Liver dose exposure parameters were V5: 290.3ccm (43.7-1792.2ccm), V10: 101.9ccm, and V15: 57.4ccm (8.4-689.5ccm). Follow-up was available in 32 out of 36 pts and was between 28-144 days (median 86 days). In 29 pts local control was achieved, while in 4pts a local recurrence occurred.

### Conclusion

CT-guided interstitial brachytherapy showed to be a safe and effective treatment approach for oligometastatic liver disease. Longer follow-up is needed to assess the role of this treatment modality in the oligometastatic setting as an alternative to other treatment approaches, including SBRT.

### PV-0144 Custom-made moulds plesiotherapy for non-melanoma skin cancer treatment

M.Á. González Ruiz<sup>1</sup>, J.L. Muñoz García<sup>2</sup>, J. Quirós Rivero<sup>2</sup>

<sup>1</sup>Punta de Europa Hospital, Radiation Oncology, Algeciras, Spain; <sup>2</sup>Badajoz University Hospital, Radiation Oncology, Badajoz, Spain

### Purpose or Objective

To evaluate our results in terms of local disease free survival (LDFS), cosmesis and toxicity in patients (pts) with non-melanoma skin cancer (NMSC) treated with high-dose-

rate brachytherapy (HDR-BT) treatment, plesiotherapy modality, with custom-made moulds.

### Material and Methods

87 pts out of 198 pts (44%) were treated with HDR-BT in our Department (110 NMSC lesions) from May 2015 to May 2017 with custom-made moulds. HDR-BT treatment (6 Gy/fraction; total dose 42 Gy) was used in 88.2% pts with an equivalent 2 Gy dose (EQD2) of 56 Gy. All the lesions were limited 3-4 mm depth. The median age was 79 years old (range 29-97), 60% of pts were males and 40% females. Basal-cell carcinoma (90%) was the most frequent histological type. 80.9% of the lesions were T1 stage (80.9%) and 100% were located on face and forehead. Treatment intention was radical in 83.6% of the pts and adjuvant in the 16.4%.

### Results

The median follow-up was 31 months (range 9-65). LDFS was 95.45%. There were no differences in terms of local control related to tumour stage (p 0.149). Pts had acute skin toxicity grade 1 (62.7%) and grade 2 (29.1%). Conjunctival toxicity appeared in 15.5 % (lesions near to the eyes). Cosmetic results were considered excellent and good in all of the patients.

### Conclusion

In base to our initial results, plesiotherapy with custom-made moulds is a safe, attractive and a good alternative of treatment in NMSC. This modality of treatment provides excellent results in terms of local control and cosmesis.

### PV-0145 The impact of modern imaging on low dose-rate prostate brachytherapy

D. Lamb<sup>1</sup>, L. Greig<sup>2</sup>, G. Russell<sup>3</sup>, J. Nacey<sup>4</sup>, L. Woods<sup>5</sup>

<sup>1</sup>Victoria University of Wellington, School of Biological Sciences, Wellington, New Zealand; <sup>2</sup>Capital and Coast District Health Board, Radiation Physics, Wellington, New Zealand; <sup>3</sup>Southern Cross Hospital, Prostate brachytherapy, Wellington, New Zealand; <sup>4</sup>University of Otago, Surgery, Wellington, New Zealand; <sup>5</sup>Victoria University, Statistics, Wellington, New Zealand

### Purpose or Objective

To determine if modern imaging has improved our understanding of why biochemical failure (BF) and urethral stricture develop in some men after low dose-rate prostate brachytherapy.

### Material and Methods

A prospectively maintained database containing information on 951 men with early stage prostate cancer treated with low dose-rate brachytherapy after transrectal ultrasound planning. In addition, 74 men implanted more recently after MRI planning.

### Results

Median follow up of the 951 men was 7.9 years, with a range 2.0 - 16.3 years. Ten-year prostate specific antigen control was 95% for 551 low-risk patients and 82% for 400 intermediate-risk patients. 73 men developed biochemical failure (BF) and 17 men urethral stricture.

Prostate specific membrane antigen PET-CT scanning performed on 34 men who underwent BF revealed that 27 (80%) had local recurrence, and of these, 25 (93%) had relapsed in the prostate base and/or seminal vesicles.

A low prostate Dose 90 ( $\leq 90\%$ ) did not increase the risk of BF (P=0.127), but a small prostate volume ( $\leq 35$  cc) increased both the risk of BF (P=0.02) and of urethral stricture (P=0.003). Men who developed urethral stricture were found to have twice as many seeds 10 mm below the prostate apex as men who did not, indicating that too low positioning of seed strands was usually responsible for this side effect. The increased risks associated with prostates  $\leq 35$  cc suggest that too low positioning occurs more often when the prostate is small.

Three-Tesla MRI planning of 74 more recently implanted men permitted accurate definition of the prostate capsule and the position of the membranous urethra. Prostates  $\leq 35$  cc were found to be nearly always 35 mm in length

rather than 40 mm as measured previously by trans-rectal ultrasound planning. In response to this finding, the plans of implants on 35 mm long prostates were altered to have less seeds placed in the 40 mm plane and more seeds in the 10 mm plane. Post implant, registered MR-CT images were used to measure the Dose 90 prostate base and Dose 0.1 cc membranous urethra, and these doses made it possible to identify men likely to be at higher risk of BF and urethral stricture.

#### Conclusion

Modern imaging has improved our understanding of factors influencing the risks of BF and urethral stricture after low dose-rate prostate brachytherapy, and has guided modifications to implant technique that could mitigate these risks.

#### PV-0146 RTOG versus CTCAE score: reporting toxicity of HDR brachytherapy Monotherapy for prostate cancer

M. Jolicoeur<sup>1</sup>, E. Hill<sup>1</sup>

<sup>1</sup>CICM Hôpital Charles Le Moyne, Radiation Oncology, Greenfield Park, Canada

#### Purpose or Objective

Compare the Radiation Therapy Oncology Group (RTOG) score and the Common Terminology Criteria for Adverse Events (CTCAE) score for reporting toxicities of HDR brachytherapy as monotherapy for prostate cancer.

#### Material and Methods

Mixed-method methodology was applied. The mixed-method consisted of direct comparison of the scores, a systematic literature review (25 selected articles), and the comparison of the acute toxicity scores classification in a sample of prostatic cancer patients treated by HDR brachytherapy. The patients included in this study were part of the protocol named: HDR Brachytherapy as Monotherapy for Low and Intermediate Risk Prostate Cancer (BRP2)

(<https://clinicaltrials.gov/ct2/show/NCT03424694>). 168 patients were followed up for 3 months after HDR brachytherapy for low and intermediate risk prostate cancer. Patients were evaluated at 1, 3, 6 weeks and 3 months after radiotherapy. Symptoms were classified according to RTOG and CTCAE scores. Descriptive statistics and Fisher Exact test were used to compare RTOG and CTCAE scores. Statistical significance was 0.05.

Toxicity grade	RTOG		CTCAE		
	n	%	n	%	
genitourinary	0	135	80.4	134	79.8
	1	15	8.9	27	16.1
	2	15	8.9	6	3.6
	3	0	0	1	0.6
	4	3	1.8	0	0
<b>Total</b>	<b>168</b>	<b>100</b>	<b>168</b>	<b>100</b>	
Fisher Exact Test p<0.01					
gastrointestinal	0	163	97	164	97.6
	1	3	1.8	4	2.4
	2	0	0	0	0
	3	2	1.2	0	0
	4	0	0	0	0
<b>Total</b>	<b>168</b>	<b>100</b>	<b>168</b>	<b>100</b>	
Fisher Exact Test p<0.01					

#### Results

RTOG score unifies several toxicity symptoms in each of the five grades, while CTCAE score classifies each symptom within five grades, according to their severity. RTOG score lacks reproducibility between acute and late toxicities. CTCAE proposes the same score for describing both late and acute toxicities. 64% of the systematic literature review selected studies were prospective. 76% of them used CTCAE, 20% used RTOG, 4% used neither to evaluate early toxicity. There was no standard for the toxicity reporting methodology. 24% of the articles did not report when the toxicity was evaluated. 48% did not inform how the toxicity was evaluated. Only 19% fully reported which symptoms were evaluated. 48% of the studies did not inform if the toxicity was reported per event or worse toxicity per patient. The early toxicity of

168 patients was compared between RTOG and CTCAE scores (Table 1). RTOG classified patients' genitourinary and gastrointestinal toxicities at higher grade than CTCAE. RTOG and CTCAE scores were associated in all scenarios (p<0.01), even with percentages of  $\geq$  grade 2 toxicities differing.

#### Conclusion

There is no significant statistical difference between the scores, even though RTOG score tends to increase the severity of the described symptoms. While, CTCAE appears to be more complex it is more reliable and reproducible in research, since each symptom is separately described with its corresponding grade. The use of the CTCAE score is preferable for reporting toxicities of HDR brachytherapy as monotherapy for prostate cancer. Detailed methodology and the use of guidelines can improve research quality, guarantee the report quality, and facilitate future research comparisons.

#### PV-0147 MRI-guided salvage HDR brachytherapy for locally recurrent prostate cancer

L. Joseph<sup>1</sup>, A. Sundaramurthy<sup>1</sup>, A. Berlin<sup>1</sup>, J. Helou<sup>1</sup>, C. Menard<sup>2</sup>, P. Warde<sup>1</sup>, C. Catton<sup>1</sup>, B. Lao<sup>1</sup>, A. Bayley<sup>1</sup>, A. Rink<sup>1</sup>, A. Beiki-Ardakani<sup>1</sup>, P. Chung<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada; <sup>2</sup>Centre Hospitalier de L'Université de Montreal, Radiation Oncology, Montreal, Canada

#### Purpose or Objective

Biochemical relapse (BCR) may occur in up to 40% of patients with localized prostate cancer treated with external beam radiotherapy (RT). A proportion of these, the disease recurrence is local alone. Radical salvage treatment options remain limited, and brachytherapy represents an attractive organ-preserving alternative. We report the results of a prospective study of MR-guided salvage brachytherapy.

#### Material and Methods

This was a phase II prospective cohort study. Eligibility were ECOG performance status 0-1, pathologically proven locally recurrent prostate cancer visible on multi-parametric MRI (mpMRI), > 18 months after primary RT, and PSA-doubling time > 6 months. All patients were treated with HDR brachytherapy under MR guidance alone. In cohort 1, patients were treated to a dose of 16Gy to the whole gland with an integrated 6Gy boost to the MR-visible tumor (GTV) in two fractions 7-14 days apart. Cohort 2 patients were treated to a dose of 26Gy to GTV alone in two fractions 1-2 weeks apart. The GTV was defined using mpMRI (T2-weighted, diffusion-weighted, dynamic contrast-enhanced). CTV margin expansion (5 mm in all directions) was restricted to adjacent organs at risk and 2 mm beyond the prostate boundary where applicable. PTV margins of 2 mm cranio-caudally and 1mm elsewhere were then applied. No patients were given neoadjuvant ADT. Patients were followed up with regular PSA, and mpMRI +/- prostate biopsy were performed after a minimum of 2 years. Toxicity was assessed using CTCAE version 4. BCR was determined using Phoenix definition (nadir+2).

#### Results

A total of 43 patients were enrolled, 14 in cohort 1, and 29 in cohort 2. Median age was 70 years (range 62-85). Median PSA pre-salvage was 4.54ng/mL (range 1.68-14). On pre-salvage biopsies, 7%, 72%, 12% and 7% had Gleason Score 6, 7, 8 and 9, respectively and 2% were ungraded. Overall median follow-up was 55 months (range 3-123), 100 in cohort 1, 38.5 in cohort 2. Crude rates of biochemical control at 2 years were 71% in cohort 1 and 82% in cohort 2. 3-year rates were 64% in cohort 1 and 68% in cohort 2. 5-year rates were 50% in cohort 1. Of those eligible and accepting of post-salvage MRI and/or biopsy, 42% (5/12) had localized recurrence confirmed in cohort 1 and 40% (6/15) in cohort 2 (4/15 recurrence within radiation field). Acute GI and GU toxicity was experienced in 13% (<grade 2) all patients, the majority of which

returned to baseline function. Late grade 4 GU toxicity (long-term urinary catheter) was observed in 1 patient.

#### Conclusion

MR-guided salvage brachytherapy appears to have a favourable therapeutic index in the post-RT local recurrence setting with minimal long-term toxicity. Focal brachytherapy alone may have comparable outcomes to whole gland treatment. Further study is needed to improve patient selection, and to determine optimal target volumes and dose schedules.

Germany

#### Abstract text

Functional imaging may be highly beneficial for radiotherapy (RT) planning, response monitoring, and follow-up. In magnetic resonance (MR) imaging, diffusion weighted MR (DW-MR) and dynamic contrast enhanced MR (DCE-MR), are promising functional imaging methods. PET tracers with potential benefit for RT are FDG and dedicated hypoxia tracers such as FMISO. Combined PET/MRI represents a technology allowing for simultaneous, intrinsically registered PET and MR data. In this talk, one focus will be on deriving quantitative parameter maps from functional imaging, discussing models for parameter extraction from DWI, DCE and dynamic FMISO acquisitions. In addition model-free, data-driven approaches such as principal component analysis will be discussed as an alternative approach for parameter map generation.

Another focus will be on approaches to combine single functional parameter maps into multiparametric models for specific tasks, such as the distinction between tumor and non-tumor tissue, the characterization of local tumor biology, and response evaluation. Such models might in the future allow for individually adapted treatment approaches based on multiparametric functional imaging.

#### OC-0151 Radiation and PI3K- $\alpha$ inhibitor enhanced anti-tumor effect of PD-1 blockade in syngeneic tumor model

I.A. Kim<sup>1,2,3</sup>, J.M. Park<sup>3</sup>, J.H. Lee<sup>1</sup>, D. Kim<sup>1</sup>, Y. Lim<sup>1</sup>

<sup>1</sup>Seoul National Univ. Bundang Hospital, Radiation Oncology and Medical Science Research Institute, Seongnam- Gyeonggi-Do, Korea Republic of; <sup>2</sup>Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea Republic of; <sup>3</sup>Seoul National University Graduate School of Medicine, Tumor Biology and Cancer Research Institute, Seoul, Korea Republic of

#### Purpose or Objective

Breast cancer has been showing relatively poor response to immune checkpoint blockades potentially due to low immunogenicity of tumor and immunosuppressive tumor microenvironment. Radiation (RT) has been showing immune stimulatory effect and PI3K $\delta$  has immune suppressive effect via modulation of regulatory T cell (Treg). Therefore, we hypothesize that in situ tumor vaccination via RT and suppression of immune tolerance via PI3K $\delta$  inhibition could enhance the clinical efficacy of immune checkpoint blockade. As PI3KA controls a key oncogenic signaling pathway, we evaluated whether RT or novel PI3K $\alpha$  inhibitor or both could enhance the efficacy of antitumor effect of a PD-1 blockade in immune competent syngenic triple negative breast cancer (TNBC) model.

#### Material and Methods

4T1 murine breast cancer cells were grown subcutaneously in the hind limb of BALB/c mice. The mice were grouped as following seven groups: control, RT, PI3K $\alpha$  inhibitor, PI3K $\alpha$  inhibitor+ RT, PD-1 blockade, PD-1 blockade + RT, and triple combination group. Tumors were irradiated using 24 Gy/3 fractions. PD-1 blockade (10 mg/kg) and PI3K $\alpha$  inhibitor (4 mg/kg) were administered every other day for two weeks, respectively. Tumor size was measured periodically using a Vernier caliper and bioluminescence imaging to evaluate efficacy of each modality and combination therapy. Immune-modulatory function was evaluated using FACS, Elispot assay and immunohistochemical (IHC) staining.

#### Results

Triple combination of RT, PD-1 blockade, and PI3K $\alpha$  inhibitor significantly delayed tumor regrowth whereas PD-1 inhibitor alone showed only modest effect in 4T1 syngenic TNBC model. FACS and IHC study for immune repertoire using tumor samples showed that RT and PD-1 blockade modestly increased the proportion of cytotoxic CD8+ T cells and PI3K $\alpha$  inhibitor led to decrease the proportion of Treg. Triple combination showed remarkable increase of cytotoxic CD8+ T cells suggesting synergistic immune modulatory effect of RT, PD-1 blockade and PI3K $\alpha$  inhibitor. Triple combination led to significant upregulation of c-GAS/STING pathway in tumor and increased IFN-g level in blood compared to each modality alone.

#### Conclusion

Taken together, combination of RT and PI3K $\alpha$  inhibitors maximized immune stimulatory effect in immune competent syngenic TNBC model and enhanced the response of PD-1 inhibitor via non-redundant synergistic immune modulatory effect. This study provides a preclinical rationale for the combination of PI3K $\alpha$  inhibitor and RT with PD-1 blockade to overcome the immune tolerance of breast cancer. #### OC-0152 IDO inhibition strongly enhances effects of combined hRT and PD1/PD-L1 checkpoint blockade

T. Watanabe<sup>1,2</sup>, G. Niedermann<sup>1,3</sup>

<sup>1</sup>University of Freiburg, Department of Radiation Oncology- Faculty of Medicine, Freiburg, Germany;

<sup>2</sup>Kyoto University, Institute for Integrated Radiation and Nuclear Science, Osaka, Japan ; <sup>3</sup>German Cancer Research Center, German Cancer Consortium- Partner site Freiburg, Heidelberg, Germany

### Purpose or Objective

Indoleamine-2,3-dioxygenase (IDO) is an enzyme that degrades the essential amino acid tryptophan to the immunosuppressive metabolite kynurenine. IDO-expressing immune cells play critical roles in peripheral immune tolerance and energy. A recent phase 3 trial evaluating an IDO inhibitor/anti-PD1 antibody (aPD1) combination in metastatic melanoma patients missed its primary endpoint of improving progression-free survival compared to aPD1 monotherapy. However, IDO is induced by IFN-g, and hypofractionated radiotherapy (hRT) alone or in combination with immune checkpoint blockade can induce IFN-g-secreting, tumor-specific T cells. We therefore decided to study, in syngeneic mouse tumor models, whether the triple combination of hRT, aPD1, and an IDO inhibitor (IDOi) is superior to the respective double combinations.

### Material and Methods

We compared the triple treatment of hRT (12 Gy × 2) + aPD1 + IDOi with the double combinations of hRT + aPD1, hRT + IDOi, and aPD1 + IDOi, and with the respective monotherapies in mice bearing relatively large (300–500 mm<sup>3</sup>), aggressively growing B16 melanoma or 4T1 breast adenocarcinoma tumors. Tumor growth and survival of the mice were determined. The dependence of the therapeutic effects on CD8+ T cells and NK cells was studied by additional injection of depleting antibodies. Frequencies and functionality of tumor-specific CD8+ T cells in tumor and secondary lymphoid organs were determined flow cytometrically by using MHC tetramers and various types of antibodies.

### Results

In our models with relatively large tumors, the tumors did not regress following treatment with hRT + aPD1. The aPD1/IDOi double combination was not effective at all. In contrast, the triple treatment induced marked tumor regressions in both tumor models. The survival benefits were highly significant compared to hRT + aPD1 (B16 melanoma model  $p = 0.002$ ; 4T1 model  $p = 0.0001$ ). CD8+ T cell depletion strongly, and NK cell depletion partly, abrogated tumor control and survival benefits. Flow-cytometric analyses showed significant increases in tumor-specific CD8+ T cells for the triple combination group compared to the other groups. In addition, a significant increase in NK cell function was found.

### Conclusion

Our data in two aggressive tumor models show that the triple therapy with hRT, aPD1, and an IDOi can induce much stronger tumor regression than double combinations or monotherapy with the individual components. Our findings may serve as a rationale for the clinical evaluation of this triple combination therapy in patients with high-risk locally advanced tumors.

### OC-0153 Immune infiltrate modulation induced by preoperative radiotherapy in breast cancer patients

A. Matias Perez<sup>1</sup>, A. Bardet<sup>2</sup>, M. Lacroix-Triki<sup>3</sup>, F. Riet<sup>4</sup>, M.C. Mathieu<sup>3</sup>, E. Deutsch<sup>1</sup>, S. Michiels<sup>2</sup>, S. Rivera<sup>1</sup>  
<sup>1</sup>Institut Gustave Roussy, Département de Radiothérapie, Villejuif, France; <sup>2</sup>Institut Gustave Roussy, Service de Biostatistique et d'Epidémiologie, Villejuif, France; <sup>3</sup>Institut Gustave Roussy, Département de Biologie et Pathologie Médicales, Villejuif, France ; <sup>4</sup>Hôpital Pitié-Salpêtrière, Département de Radiothérapie, Paris, France

### Purpose or Objective

There is increasing evidence showing that tumor-infiltrating lymphocytes (TILs) are a marker for adaptive immune response. High level of TILs has been shown to

be associated with higher pathological complete response (pCR) after neoadjuvant anthracycline-based chemotherapy+ anti-HER2 agents, but very little is known regarding TILs and exclusive radiotherapy (RT) treatment in breast cancer (BC). Our series of exclusive preoperative RT is a unique opportunity to address such question. The objective of this study is to evaluate the impact of exclusive preoperative RT on immune infiltrate in BC.

### Material and Methods

TILs were estimated in a retrospective series of 187 BC patients with a median age of 49 years (43-60) with T2-T4 or N2 tumours treated between 1970 and 1984 with exclusive preoperative RT with a median follow-up of 32 years. Patients received a moderately hypofractionated RT (45-55 Gy in 18 fractions of 2.5 Gy over 34 days) to the whole breast and nodes, followed by a modified radical mastectomy plus axillary dissection. The percentage of stromal TILs was centrally evaluated for each patient on her diagnostic biopsy and her mastectomy specimen following the address International TILs working group recommendations.

### Results

Complete pathological response (pCR) was achieved in 18 (9.6%) of the 187 patients: six (8.4%) in Luminal A subtype, one (2.9%) in Luminal B, one (3.4%) in HER2 positive (3.4%) and eight (20%) in triple negative breast cancer (TNBC). The distribution of TILs in biopsies and mastectomy samples within subtypes is shown in figure 1. Overall, median TILs in biopsies was: <10% in 30.7%, between 10 - 40% in 64.5% and ≥50% in 4.8%. In the mastectomies TILs was <10% in 48.1%, between 10 - 40% in 50.3% and ≥50% in 1.6%. The subtypes with higher TILs levels were HER2 positive and TNBC (20% for both in biopsies and 15% and 20% for HER2 and TNBC in surgical samples) compared to Luminal A and B (10% in biopsies and 5% in surgical samples for both). Paired TILs measurements before and after radiotherapy were obtained in 122 (65.2%) patients. There was a slight decrease in TILs level with a mean change value of -3.0 ( $p=0.001$ ) in the whole population. The decrease was stronger in Luminal B subtype and HER2 positive, as shown in table 1.

Figure 1. Distribution of TILs in biopsies and surgical specimens (A= Luminal A; B= Luminal B; HER2 = HER2 positive; TN= Triple Negative; Miss.= missing data)

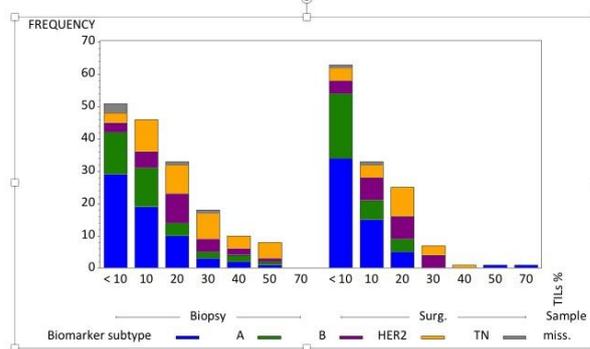

Table 1. TILs decrease within subgroups.

Molecular subtype	Number of analyzable patients	Mean change value (SD)	Median change value	p-value
All subtypes	122	-2.97 (12.01)	0	0.001
Luminal A	50	-1.02 (11.46)	0	0.14
Luminal B	29	-5.24 (12.21)	-4	0.02
HER2 positive	21	-4.29 (9.76)	0	0.05
TNBC	20	-3.00 (15.42)	-5	0.36

### Conclusion

Our preoperative RT series showed higher levels of TILs in HER2 positive and TNBC than in other subtypes before and after RT. In the paired samples, a slight decrease in TILs

was observed after preoperative RT. Specific assessment of lymphocytes in the scar area for patients in pCR and additional analyses of lymphocyte subtypes together with PD1 and FOXP3 Are planned and could be an innovative way to use lymphocytes dynamics after RT to guide the use of RT and immunotherapy combination in the future.

#### OC-0154 Radiation abrogates fibroblast-mediated immunosuppressive effects on dendritic cells

T. Hellevik<sup>1</sup>, R. Berzaghi<sup>2</sup>, M.A. Akhtar<sup>2</sup>, S. Tornaas<sup>2</sup>, I. Martinez-Zubiaurre<sup>2</sup>

<sup>1</sup>Univeristy Hospital of Northern Norway, Department of Radiation Oncology, Tromsø, Norway; <sup>2</sup>University of Tromsø, Clinical Medicine, Tromsø, Norway

#### Purpose or Objective

Recent reviews have highlighted the impact of cancer-associated fibroblasts (CAFs) in tumor development, dissemination and treatment resistance. Reactive CAFs - in contrast to normal fibroblasts - secrete a myriad of immunomodulatory soluble factors at high levels, which directly influence tumor immunity and inflammation, and promote an immunosuppressive tumor microenvironment. However, little is known about the mechanisms by which CAFs modulate immune responses after radiotherapy (RT). Previous studies by our group have uncovered the phenotypical and functional changes provoked by (high-dose) RT on human lung CAFs, characterized by induction of premature cellular senescence, as well as reduced proliferation, migration, and invasion rates. Changes have also been observed on the secretory profile by CAFs. The conditioned medium (CM) from irradiated-CAFs reduces the migratory capacity of endothelial cells, inhibits angiogenesis, and exerts a powerful immunosuppressive effect over activated T-cells. However, neither low-dose nor high-dose RT is affecting baseline CAF-mediated immunosuppressive effects. The present study focuses on effects of ionizing radiation, applied in different regimens, on CAF-mediated immunoregulation of macrophage polarization and dendritic cell phenotype and functions.

#### Material and Methods

CAFs were isolated by the outgrowth method from freshly resected NSCLC tumor specimens and characterized by the presence of lineage-specific markers. Highly pure CAF cultures (at passage 3) were irradiated with high-energy photons delivered as a single-high dose of 18 Gy or three consecutive daily doses of 6 Gy (3x6 Gy). CAF-CM were collected from (sham) irradiated cultures to examine CAF-induced paracrine effects on macrophage phenotype and dendritic cell differentiation, activation and function.

#### Results

We show that CAF-CM from non-irradiated cultures induces A) M2-polarization of monocyte derived-macrophages, promoting elevated surface expression of markers CD206 and CD163; and B) a tolerogenic phenotype of monocyte-derived DCs with decreased expression of differentiation surface markers (CD14, CD1a, CD209), decreased expression of maturation surface markers (CD80, CD86, CD40 and HLA-DR) and decreased functional capacities (migration, antigen-uptake, and T-CD4 cell priming). Interestingly, CM from CAFs irradiated with a single-high dose, or more prominently, with a fractionated medium-high dose (3x6 Gy) *reverts* the CAF-mediated tolerogenic induction on DCs. No significant differences in M2- or M1-macrophage polarization were observed between irradiated and non-irradiated CAFs.

#### Conclusion

Our results unveil advantageous effects elicited by defined radiotherapy regimens by reversing the baseline CAF-mediated immunosuppressive actions on DC phenotypes and functions.

#### OC-0155 Lxr Signaling Regulates Macrophage Survival and Phenotype Polarization Response To Ionizing Radiation

P.C. Lara Jimenez<sup>1</sup>, C. Tabraue<sup>2</sup>, M. Mirecki<sup>3</sup>, J.V. De La Rosa<sup>4</sup>, F. López-Blanco<sup>5</sup>, L. Bosca<sup>6</sup>, L. Fernandez<sup>5</sup>, A. Castrillo<sup>7</sup>

<sup>1</sup>Hospital Universitario San Roque/Universidad Fernando Pessoa Canarias, Oncology, Las Palmas de Gran Canaria-Ca, Spain; <sup>2</sup>Unidad Consejo Superior de Investigaciones Científicas, Grupo de investigación en Medio Ambiente y Salud, Las Palmas, Spain; <sup>3</sup>Universidad de Las Palmas de Gran Canaria, Ciencias Clínicas, Las Palmas de Gran Canaria, Spain; <sup>4</sup>Unidad del Consejo Superior de Investigaciones Científicas, Grupo de Estudio en Salud y Medio Ambiente, Las Palmas de Gran Canaria, Spain; <sup>5</sup>Universidad de Las Palmas de Gran Canaria, Ciencias Clínicas, Las Palmas de Gran Canaria, Spain; <sup>6</sup>Unidad de Consejo Superior de Investigaciones Científicas, Grupo de Investigación en Medio ambiente y salud, Las Palmas de Gran Canaria, Spain; <sup>7</sup>Unidad del Consejo Superior de Investigaciones Científicas, Grupo de Investigación en Medioambiente y Salud, Las Palmas de Gran Canaria, Spain

#### Purpose or Objective

Macrophages are a major cellular component of murine and human tumors, where they are commonly termed tumor-associated macrophages (TAMs). Recent studies indicate that ionizing radiation not only polarizes macrophages towards a M1-like phenotype leading an effective antitumor response, but also decreases macrophage survival through a pyroptosis mechanism.

The purpose of this study was to evaluate the role of LXR in the response of macrophages to irradiation, analyzing both cell viability and functional activity of the macrophage, as a possible strategy focused to deplete TAMs or re-program them towards a M1-like phenotype, in the context of cancer treatment with radiotherapy.

#### Material and Methods

Primary and immortalized murine bone marrow macrophages (BMDMs) from wild type or LXR double knock-out mice were exposed to X-ray irradiation. Subsequently, analysis of LXR signaling on cell proliferation and cytotoxicity induced by ionizing radiation was determined by time-lapse photomicroscopy. Genotoxic cell damage was evaluated by western blot of - H2AX and p53. Pyroptosis was analyzed through cell viability assay, lactate dehydrogenase (LDH) release assay and western-blot of caspase-1 active protein. We analyzed the expression of classic polarization markers, such as inducible nitric oxide synthase (iNOS) and interleukin-6 (IL-6) by real time RT-QPCR of messenger RNA levels of these M1 markers.

#### Results

Genetic and pharmacological inactivation of LXR induced radio sensitivity of macrophages.(figure 2) LXR deficiency decreased cell proliferation and enhanced cytotoxicity induced by ionizing radiation, in both immortalized and primary BMDMs. Protein levels of  $\gamma$ - H2AX and p53, both involved in response to cell damage, were exacerbated in LXR-deficient macrophages exposed to irradiation. Cell membrane damage augmented and cell viability decreased in LXR deficient macrophages compared to LXR-WT macrophages in response to irradiation. In addition, LXR deficiency enhanced both caspase-1 activation and LDH release in BMDM(figure 4) exposed inflammasome activators. Expression of pro-inflammatory markers IL-6 and iNOS was markedly higher in irradiated LXR-deficient macrophages than in LXR-WT macrophages(figure 4). This results show the role of LXR suppression favoring M1-polarization and therefore tumor control.

Fig.2

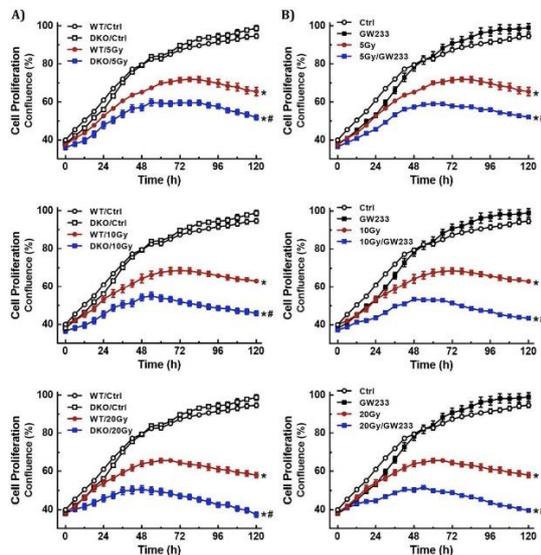

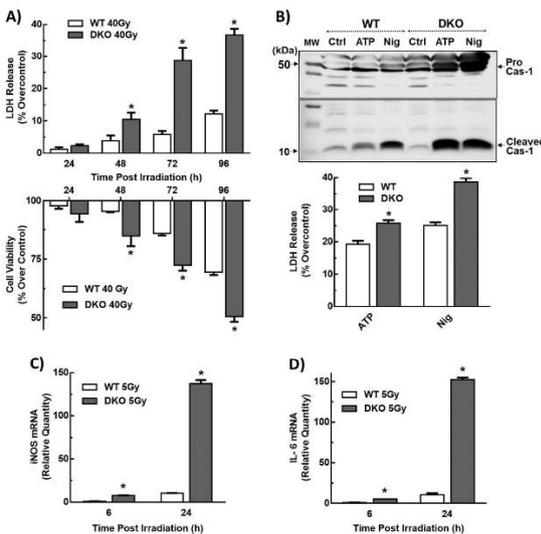

Fig.4

## Conclusion

The present work identifies LXR transcription factors as potential therapeutic targets to enhance the suppressive effects of radiotherapy on tumor growth, through induction of macrophage cell death and polarization towards a pro-inflammatory phenotype

### OC-0156 High-intensity focused ultrasound and radiotherapy: a promising combination?

G. Adema<sup>1</sup>, R. Van den Bijgaart<sup>1</sup>, T. Raaijmakers<sup>2</sup>, M. Den Brok<sup>1</sup>, M. Hoogenboom<sup>3</sup>, J. Fütterer<sup>4</sup>, J. Bussink<sup>1</sup>  
<sup>1</sup>UMC St Radboud Nijmegen, Radiation Oncology, Nijmegen, The Netherlands; <sup>2</sup>UMC St Radboud Nijmegen, Radiation Oncology and Anesthesiology- Pain Management and Palliative Care, Nijmegen, The Netherlands; <sup>3</sup>UMC St Radboud Nijmegen, Radiology and

Nuclear Medicine, Nijmegen, The Netherlands; <sup>4</sup>UMC St Radboud Nijmegen and University of Twente, Radiology and Nuclear Medicine and MIRA Institute for Biomedical Technology and Technical Medicine, Nijmegen, The Netherlands

## Purpose or Objective

In interventional oncology, a large variety of *in situ* tumor destruction techniques like cryo or thermal ablation, radiotherapy (RT) or high-intensity focused ultrasound (HIFU) are successfully applied. Although diverse in technology and the way of inducing cell death, ablative techniques share one key feature: they create *in situ* availability of ablated tumor material. During the efforts of the body to clear this dead material there is a time frame in which the immune system is actively controlling immune responses directed towards antigens from this antigen 'depot'<sup>1</sup>. The ability to stimulate the immune system upon scavenging antigens from dead tumor cells has led to the concept that *in situ* tumor destruction can be used to achieve systemic 'in vivo vaccination' against tumors, ultimately leading to the elusive 'abscopal effect'<sup>2,3</sup>. The aim of this study is to understand which (combination of) techniques results in the most effective release of tumor antigens, creates the most immunostimulatory environment from a molecular perspective, or combines most effectively with optimally timed immune stimulating therapies.

## Material and Methods

We have established multiple different ablation technologies in murine tumor models, including a MR-guided HIFU setup that can be used for thermal and mechanical destruction of murine tumors, including a melanoma (B16F10), a thymoma (EL4) and neuroblastoma (9464D) model<sup>4</sup>. Using these models we have explored the impact of multiple ablation treatments with immunotherapy, including the administration of different immune adjuvants. As read outs we have performed immune activation parameters (DC maturation, cytokine production), analysis of immune responses (T cell activation, proliferation and cytotoxicity) as well as tumor growth experiments.

## Results

Our data demonstrate that a tumor can serve as its own antigenic vaccine after different types of ablation, provided that additional immune activating signals are concomitantly given<sup>5-7</sup>. We have further established a HIFU based protocol to induce mechanical rather than thermal ablation of tumors. This mechanical HIFU based ablation of tissues induces complete subcellular fragmentation rather than tissue coagulative necrosis. RT is the main treatment modality for cancer, and around 50% of all cancer patients receive RT. Currently we are investigating the combination of HIFU and RT ablation with immunotherapy.

## Conclusion

Both HIFU and RT are non-invasive ablation techniques and can have immune modulatory effects<sup>8,9</sup>. Despite the obviously changing immunological parameters, their ablation-induced immunomodulation alone appears insufficient to generate consistent protective antitumor immunity. Combining HIFU with RT and immunotherapy may be more effective than either therapy alone, and is expected to be key to achieve systemic, long-lasting, antitumor immunity.

### OC-0157 Radiation and immunotherapy to fight cancer: a 'pushing the gas and releasing the brakes' approach.

V. Olivo Pimentel<sup>1</sup>, D. Marcus<sup>1</sup>, A. Van der Wiel<sup>1</sup>, R. Biemans<sup>1</sup>, N.G. Liewues<sup>1</sup>, D. Neri<sup>2</sup>, J. Theys<sup>1</sup>, A. Yaromina<sup>1</sup>, L.J. Dubois<sup>1</sup>, P. Lambin<sup>1</sup>

<sup>1</sup>Department of Precision Medicine- The M-Lab- GROW - School for Oncology and Developmental Biology, Maastricht Comprehensive Cancer Centre- Maastricht

University Medical Centre, Maastricht, The Netherlands; <sup>2</sup>Department of Chemistry and Applied Biosciences, Swiss Federal Institute of Technology, Zürich, Switzerland

### Purpose or Objective

Although immunotherapy is currently changing cancer treatment practice, primary resistance is still observed partly due to insufficient immunogenic priming. Radiotherapy (RT) induces the release of tumor antigens and thereby increases tumor immunogenicity. Therefore, combination of these therapies has high potential. Here, we investigated the therapeutic outcome of combining a single dose RT with the immunocytokine L19-IL2 and immune checkpoints inhibitors (ICIs) (aCTLA-4, aPD-L1 and aPD-1), aiming to further activate and prolong the RT-elicited anti-tumor immune response.

### Material and Methods

Balb/c or C57BL/6 mice were injected in the right flank with C51 and CT26 colon carcinoma or Lewis lung carcinoma (LLC) cells, respectively. Upon an average volume of 200mm<sup>3</sup>, animals were randomized in different treatment groups: RT + vehicle/L19-IL2 (1 mg/kg) + IgG or RT + vehicle/L19-IL2 + aPD-L1/aPD1/aCTLA-4 (all 10 mg/kg). Tumors were irradiated with 5Gy (C51 and CT26) or 10Gy (LLC), as the latter is less immunogenic. Vehicle/L19-IL2, aCTLA-4 and IgG were given i.v. on day 1, 3 and 5 after RT; aPD-1, aPD-L1 and IgG were given i.p. 1, 3, 5, 7 and 9 days after RT. Tumor response was quantified as time to reach 4 times starting tumor volume (T4xSV). For mechanistic studies, the same treatment schedule was used and mice were sacrificed at day 6 after RT.

### Results

In the CT26 model, RT + L19-IL2 ( $p < 0.001$ ), RT + aCTLA-4 ( $p < 0.01$ ) and RT + aPD-L1 ( $p < 0.05$ ) resulted in longer T4xSV compared to RT. In the C51 model solely RT + L19-IL2 ( $p < 0.001$ ) was better compared to RT. RT + L19-IL2 efficacy was significantly ( $p < 0.001$ ) better compared to RT + ICIs in the C51 model; a similar trend was observed for the CT26 model, albeit not significant. Adding ICIs to RT + L19-IL2 did not result in improved outcome in C51 and CT26 models. Conversely, in the LLC model the triple therapy of RT + L19-IL2 + aPD-L1 yielded a better outcome compared to RT + L19-IL2 ( $p < 0.05$ ) and RT + aPD-L1 ( $p < 0.001$ ). Mechanistically, in LLC tumors we found an increased infiltration of antigen-experienced (CD44+) CD8+ T cells and NK cells after triple therapy as compared to RT ( $p < 0.001$ ), RT + L19-IL2 ( $p < 0.01$ ) and RT + aPD-L1 ( $p < 0.01$ ). Percentage of regulatory T cells (Tregs) was surprisingly higher in tumors treated with RT + aPD-L1 vs RT + L19-IL2 ( $p < 0.05$ ), knowing that IL2 expands Tregs. Interestingly, other immunosuppressive proteins such as PD-1, Tim-3 and CD39 were upregulated on T cells upon PD-L1 blockade.

### Conclusion

Our results show that in the C51 and CT26 models, the therapeutic effect of RT + L19-IL2 is larger than RT + ICIs, while adding ICIs did not improved efficacy of RT + L19-IL2. In the LLC model, RT + L19-IL2 + aPD-L1 improved outcome compared to RT + L19-IL2 or aPD-L1 and was associated with increased infiltration of NK and CD44+ CD8+ T cells; functional co-culture assays are ongoing to prove their role on the anti-tumor response. PD-L1 blockade upregulated other immune-checkpoint proteins on T cells.

**OC-0158 Effect of EBRT underutilization in prostate cancer on overall survival and local control, NSW, Australia**

G. Gabriel<sup>1</sup>, M. Barton<sup>1</sup>, J. Shafiq<sup>1</sup>, G. Delaney<sup>1</sup>

<sup>1</sup>Ingham Institute for Applied Medical Research, Collaboration of Cancer Outcomes- Research and Evaluation CCORE and University Of New South Wales, Liverpool BC- NSW, Australia

### Purpose or Objective

Evidence-based modelling estimates show that 52% of all Australian prostate cancer patients would benefit from radiotherapy (RT) at diagnosis<sup>1-3</sup>. It was estimated that the 5-year overall survival (OS) shortfall for prostate cancer due to not receiving EBRT was 1.1% and the 5-year irreplaceable local control (LC) benefit for receiving EBRT was 12.4%<sup>4,5</sup>. Previous study indicated that radiotherapy utilization (RTU) rates decreased with increasing travel distance from patient residence to the nearest RT department (RTD)<sup>6</sup>. The objective of the study was to calculate actual RTU rate, to estimate the shortfall in OS and irreplaceable LC and to identify factors affecting RTU.

### Material and Methods

Data from NSW Central Cancer Registry for patients diagnosed with prostate cancer from 2009-2011 were linked to public and private radiotherapy, admitted patient, clinical cancer registry and death datasets. Patients located near the State border where their closest RT center was outside NSW (cross borders) were excluded from the analysis. To assess the irreplaceable benefit of EBRT, all treatment options where surgery or BT monotherapy were options over EBRT were set to 0% use of EBRT<sup>5</sup>. This method described a scenario where benefits of EBRT were counted only for cases where there was no guideline-recommended alternative treatment<sup>5</sup>. Analysis was performed using SAS, SPSS and ArcGIS software.

### Results

There were 19,816 patients diagnosed with prostate cancer during the study period. The median age was 67 years. Our study showed that 65% of prostate cancer patients had localized disease, 4% had distant disease and 30% had unknown or missing stage. Of patients with localized disease, 18% received EBRT, 37% had radical prostatectomy (RP) and 4% had both RP and EBRT. Twenty-eight percent of all prostate cancer patients had RP alone, 3% had RP & EBRT, 20% had EBRT alone and 49% had neither RP nor EBRT. Overall, 23% of all prostate cancer patients received RT within one year of diagnosis. Of the 5636 patients with complete TNM data available, 68% received RT compared to 6% of patients with no detailed TNM. The annual overall survival person-shortfall was estimated to be 41 and irreplaceable local control person-shortfall was 466. Univariate analysis showed that younger age, patients with loco-regional disease, living in more advantaged areas and outside major cities, and living >100 km of RTD were predictors for RT underutilization. On multivariate logistic regression model, all factors remained significant.

### Conclusion

Prostate cancer was the most diagnosed cancer in NSW and contributed to 18% of the total patients diagnosed with cancer during the study period. Actual RTU rate was half of the estimated optimal rate. Underutilization of RT increases the disease burden on health system due to local failure and overall survival shortfall. The study shows that giving EBRT according to evidence-based guidelines will probably prevent 41 immature death and 466 local failure annually.

### Purpose or Objective

This is a report of long-term patient outcome following treatment with external beam radiation therapy (EBRT) and prostate high dose rate (HDR) brachytherapy from a prospective phase II, multi-institutional collaborative trial conducted by RTOG.

### Material and Methods

Patients with clinically localized (T1c-T3b) prostate cancer without prior history of TURP or hip prosthesis were eligible for this study. All patients were treated with a combination of 45 Gy in 25 fractions from EBRT and one HDR implant delivering 19 Gy in 2 fractions. Adverse events (AE) were collected using CTCAE v3. Biochemical failure was assessed using the ASTRO definition and the Phoenix definition. Local failure was determined by clinical exam and distant failure required documentation of regional nodal recurrence or distant disease relapse. Disease-specific deaths included those due to prostate cancer, other causes with active malignancy, and complications of treatment. Cumulative incidence was used to estimate time to severe late GI/GU toxicity, biochemical failure, disease-specific mortality, local failure, and distant failure. Competing risks were death without an event. Overall survival was estimated using the Kaplan Meier method.

### Results

One hundred twenty-nine patients were enrolled from 7/04 to 5/06. One hundred and twenty-five patients were eligible and AE data was available for 115 patients. The pretreatment characteristics (NCCN intermediate to high risk) of the patients were as follows: median age was 68 (range: 48-80), T1c-T2c 91%, T3a-T3b 9%, PSA ≤ 10 70%, PSA >10-≤20 30%, GS 2-6 10%, GS 7 72%, and GS 8-10 18%. Forty-three percent of patients received adjuvant hormonal therapy.

There were 6 (5.2%) patients with grade 3 GI/GU AEs, and no late grade 4-5 GI/GU AEs. The single Grade 3 GI AE was proctitis. The grade 3 GU AEs were: cystitis (n=1), pollakiuria (n=1), renal/genitourinary, other (n=1), urethral stricture (n=1), urinary incontinence (n=1), and urinary retention (n=2). At 5 and 10 years, the rate of late grade 3-5 GI/GU AEs was 17.0% and 19.2%.

Five- and 10-years overall survival rates were 95.0% and 75.7%. The biochemical failure rates using the ASTRO definition: 5-year and 10-year rates of 9.8% and 14.7%; using Phoenix definition: 5- and 10-years rates of 14.0% and 22.6%. The 10-year rate of prostate specific mortality was 6.4%. At 5 and 10 years, the rates of distant failure were 4.2% and 7.7%. The rates of local failure at 5 and 10 years were 1.7% at both time points.

### Conclusion

This prospective trial demonstrates the feasibility to use HDR in a multi-institutional setting with excellent long-term outcomes and very modest toxicity.

This project was supported by grants U10CA180868 (NRG Oncology Operations), U10CA180822 (NRG Oncology SDMC) from the National Cancer Institute (NCI).

### OC-0160 When PI-RADS and ISUP meet each other: identification of candidates for pelvic lymph node dissection

C. Draulans<sup>1,2</sup>, W. Everaerts<sup>3,4</sup>, S. Isebaert<sup>1,2</sup>, T. Gevaert<sup>4</sup>, R. Oyen<sup>5,6</sup>, S. Joniau<sup>3,4</sup>, E. Lerut<sup>6,7</sup>, L. De Wever<sup>5</sup>, A. Laenen<sup>8</sup>, B. Weynand<sup>6,7</sup>, E. Vanhoutte<sup>5</sup>, G. De Meerleer<sup>1,2</sup>, K. Haustermans<sup>1,2</sup>

<sup>1</sup>University Hospitals Leuven, Department of Radiation Oncology, Leuven, Belgium ; <sup>2</sup>KU Leuven, Department of Oncology, Leuven, Belgium ; <sup>3</sup>University Hospitals Leuven, Department of Urology, Leuven, Belgium ; <sup>4</sup>KU Leuven, Department of Development and Regeneration, Leuven, Belgium; <sup>5</sup>University Hospitals Leuven, Department of Radiology, Leuven, Belgium ; <sup>6</sup>KU Leuven, Department of Imaging and Pathology, Leuven, Belgium; <sup>7</sup>University Hospitals Leuven, Department of Histopathology, Leuven, Belgium ; <sup>8</sup>KU Leuven, Leuven Biostatistics and Statistical Bioinformatics Center, Leuven, Belgium

### Purpose or Objective

The aim of this study is to update the current nomograms predicting lymph node invasion (LNI) in prostate cancer (PCa) patients with today's state-of-the-art available tumor information. This tumor information includes magnetic resonance imaging (MRI) based tumor staging and detailed biopsy information according to the International Society of Urological Pathology (ISUP).

### Material and Methods

Between 2008 and 2017, 420 clinical N0 staged PCa patients underwent a radical prostatectomy with pelvic lymph node dissection (PLND). The initial PSA value (iPSA), preoperative tumor stage by MRI (iT-stage), tumor multifocality on MRI, zonal tumor location on MRI, ISUP grade group on biopsy for each positive core, percentage of tumor involvement and exact tumor length in each core and percentage of positive biopsy cores were registered. Using this information, we developed a multivariable model predicting LNI to create a coefficient-based nomogram. A concordance index (C-index) was estimated to quantify the discriminative performance of the model.

### Results

On MRI, 180 (42.9 %) patients had iT1 or iT2 disease, 224 (53.3 %) iT3 and 16 (3.8 %) iT4 PCa based on features described in the literature, similar to the current PI-RADS v2 criteria. A median of 21 (IQR, 16 - 27) lymph nodes was removed per patient. Overall, 71 (16.9 %) patients were finally diagnosed with LNI. A multivariable model detected the iPSA value, MRI based iT-stage, maximum tumor length in one core (mm) and ISUP grade group corresponding to the maximum tumor involvement in one core as independent predictors of LNI (p < 0.05). After 5-fold internal cross validation, the predictive accuracy of our updated MRI and ISUP based nomogram for LNI (table 1) was 79.7 %.

Table 1 – Multivariable logistic regression analyses predicting the presence of LNI in 420 patients

	Odds Ratio (95 % CI)	p value	Parameter estimate
Intercept	-	-	-6.4605
MRI-based imaging T stage	1.467 (1.163; 1.850)	0.0012	0.3833
iPSA	1.023 (1.000; 1.046)	0.0457	0.0228
Maximum tumor length in one core (mm)	1.155 (1.061; 1.258)	0.0009	0.1443
ISUP grade group corresponding to maximum tumor length	1.863 (1.466; 2.367)	< 0.0001	0.6220

CI = confidence interval MRI = magnetic resonance imaging; iPSA = initial prostate specific antigen; ISUP = International Society of Urological Pathology

### Legend

Predicted probability =  $p(\text{LNI}) = \frac{e^{\mu}}{1+e^{\mu}}$

$\mu$ : model linear predictor, estimated by summation of the intercept term and all  $\beta$  values multiplied by that variable.

For example: Intercept +  $\beta$ var1 \* var1 +  $\beta$ var2 \* var2 + ...  $\beta$ varN \* varN

$\beta$  (variable name): parameter estimate associated with a variable

### Conclusion

We report an updated MRI and ISUP based nomogram predicting the presence of LNI in PCa patients. This nomogram will overcome stage migration and will prevent overtreatment, which is a potential risk when MRI

information is used in DRE based nomograms. Furthermore, by incorporating additional core-specific biopsy information instead of the percentage of positive cores as mentioned in the existing nomograms, this nomogram could handle with the paradigm shift from saturation biopsies towards targeted biopsies. This updated nomogram could be a useful tool that helps urologists and radiation oncologists to accurately predict the likelihood of LNI before treatment.

**Purpose or Objective**

REQUIRE is an international, prospective observational cohort study, which recruited patients (pts) in 8 countries (April2014-March2017). It is aimed at multinational validation of clinical/dosimetric/genetic risk factors for prediction of late toxicity following radiotherapy (RT). The purpose here was to present preliminary results on validation of such features for late rectal bleeding (LRB) after conventionally fractionated external beam RT (EBRT) for prostate cancer (PCa).

**Material and Methods**

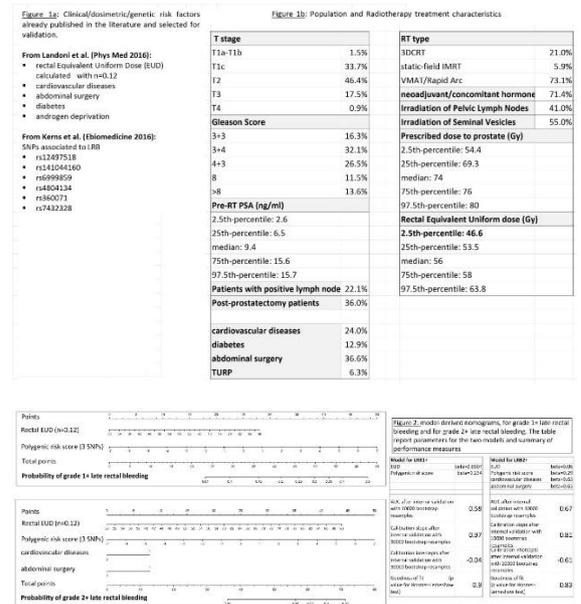

REQUIRE PCa pts treated with 2Gy/fr EBRT and complete 2-year follow-up were included. RT was prescribed according to local regimens, but centres used standardised data collection. Blood samples were collected for DNA extraction/genotyping. Grade≥1 LRB (LRB1+) and grade≥2 LRB (LRB2+) were considered as separate endpoints. Clinical/dosimetric/genetic risk factors already published in the literature were selected from Landoni (Phys Med 2016) and Kerns (Ebiomedicine 2016). Selected features are reported in Figure 1a. Association of selected features with LRB was investigated through logistic regression. A final logistic model including only validated predictors was fitted and a nomogram was developed. Confirmed SNPs were used to calculate a polygenic risk score which was included in modeling as a single genetic parameter.

**Results**

REQUIRE enrolled 1190 PCa pts with 2Gy/fr EBRT, 1178 had complete clinical/dosimetric data, 933/1178 had

complete 2-year follow-up and were included in this analysis. Description of the population is in Figure 1b. 147/933 (15.8%) LRB1+ and 29/933 (3.1%) LRB2+ were scored. Rectal EUD was confirmed as a predictor for both LRB1+ (OR=1.03 for 1Gy increase) and LRB2+ (OR=1.06 for 1Gy increase), with Odds Ratios similar to those reported in literature. Cardiovascular disease (OR=1.97) and abdominal surgery (OR=1.83) were confirmed for LRB2+, with slightly lower ORs with respect to those previously found.

Three SNPs were associated with LRB: rs6999859 (OR=1.37), rs4804134 (OR=0.97) and rs7432328 (OR=1.51) with ORs slightly lower than reported previously. The 3 SNPs were included in a polygenic risk score. Diabetes and androgen deprivation were not confirmed as risk factors, and not included in the final models. Figure 2 reports the two model-derived nomograms, model parameters and summary of performance measures.

**Conclusion**

REQUIRE highlighted the need to collect standardized data and the importance of model validation. The present analysis confirmed the predictive value for LRB of most clinical/dosimetric features previously published, together with validation of some SNPs. Resulting models including validated features well described clinical observation in the multi-center REQUIRE population, but discriminative power remained suboptimal. Use of 3-dimensional dose distributions might overcome the limitations of using dose-volume histogram parameters, which can be explored using the REQUIRE resource.

**OC-0162 PSMA PET/CT for intraprostatic tumor delineation and characterization based on radiomic features**

C. Zamboglou<sup>1</sup>, M. Carles<sup>2</sup>, S. Kiefer<sup>3</sup>, T. Fechter<sup>2</sup>, P. Bronsert<sup>3</sup>, K. Reichel<sup>4</sup>, A. Soerensen<sup>5</sup>, J. Ruf<sup>5</sup>, M. <sup>1</sup>Medical Center - University of Freiburg, Department of Radiation Oncology, Freiburg, Germany; <sup>2</sup>Medical Center - University of Freiburg, Division of Medical Physics - Department of Radiation Oncology, Freiburg, Germany; <sup>3</sup>Medical Center - University of Freiburg, Department of Pathology, Freiburg, Germany; <sup>4</sup>Medical Center - University of Freiburg, Department of Urology, Freiburg,

Germany; <sup>5</sup>Medical Center - University of Freiburg, Department of Nuclear Medicine, Freiburg, Germany

### Purpose or Objective

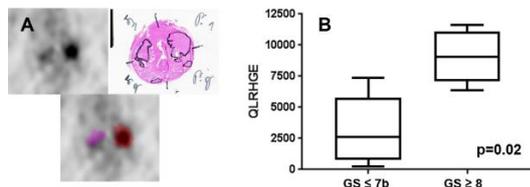

The usage of radionuclide-labelled inhibitors of prostate-specific membrane antigen for positron-emission tomography (PSMA PET) may enable accurate intraprostatic gross tumor volume (GTV) delineation and the characterization of its biological properties. To test these hypotheses we co-registered the PET images with whole-mount prostate sections after surgery in order to perform a correlation study between histology and PSMA PET information, including radiomic features.

### Material and Methods

20 patients with intermediate and high-risk PCa underwent <sup>68</sup>Ga-HBED-CC-PSMA PET/CT followed by radical prostatectomy. Histopathological information from resected prostates was processed and digitalized to obtain a 3D volume of PCa distribution. On each PET scan 5 contours were created: GTV-PET (expert contour of intraprostatic GTV based on PET information), GTV-histo (coregistered histopathology information, see figure 1A), GTV-histo-index (considering only lesions >5 mm in histology) and the subtraction volumes between the prostatic gland and GTV-histo and GTV-PET, respectively. To assess sensitivity and specificity in each CT slice the prostate was separated into 4 equal segments and the distribution of GTV-PET was compared with GTV-histo and GTV-histo-index, respectively. Furthermore, 133 radiomic features (including texture features) from PSMA PET were extracted from the respective volumes. False discovery rate-controlling procedures were implemented to account for multiple testing.

### Results

PSMA PET detected PCa in all patients. Mean sensitivity/specificity for GTV-PET were 81%/86% and 91%/88% considering GTV-histo and GTV-histo-index, respectively. In 83% of image features a strong correlation (Spearman  $\rho > 0.7$ ,  $p < 0.05$ ) between GTV-PET and GTV-histo was observed. Pairwise testing showed that 68% and 81% of image features had significant differences ( $p < 0.05$ ) between PCa and non PCa tissue considering GTV-histo and GTV-PET, respectively. 21% of image features derived from GTV-PET had a strong correlation (Spearman  $\rho > 0.7$ ,  $p < 0.05$ ) with the Gleason score (GS) and 70% of those image features had significant differences ( $p < 0.05$ ) between GS 7 and GS  $\geq 7$  PCa lesions (see exemplary figure 1B for feature: Long-Run High Gray-level Emphasis, QLRHGE).

### Conclusion

Based on histological validation a high sensitivity/specificity for PSMA PET-based GTV delineation was observed. In line with this observation we detected a strong correlation between image features extracted from GTV-PET and GTV-histo. The excellent diagnostic performance of PSMA PET enabled the usage of radiomic features for discrimination between PCa and non PCa tissue and for characterization of its biological aggressiveness.

**OC-0163 Risk classification for PSA relapse after PSMA-PET-guided RT for oligorecurrent prostate cancer**

M. Vogel<sup>1</sup>, S.G.C. Kroeze<sup>2</sup>, C. Henkenberens<sup>3</sup>, N.S. Schmidt-Hegemann<sup>4</sup>, S. Kirste<sup>5</sup>, J. Becker<sup>6</sup>, H. Christiansen<sup>3</sup>, C. <sup>1</sup>Klinikum rechts der Isar- Technical University of Munich TUM, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>University Hospital Zürich, Department of Radiation Oncology, Zürich, Switzerland ; <sup>3</sup>Medical School Hannover, Department of Radiotherapy and Special Oncology, Hannover, Germany; <sup>4</sup>University Hospital Munich LMU, Department of Radiation Oncology, Munich, Germany; <sup>5</sup>University of Freiburg, Department of Radiation Oncology, Freiburg, Germany; <sup>6</sup>University Hospital Tübingen, Department of Radiation Oncology, Tübingen, Germany

### Purpose or Objective

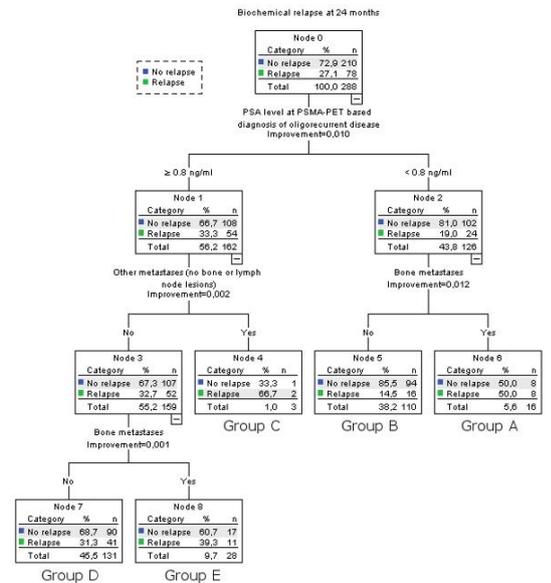

PSMA-PET-Imaging has changed the treatment for patients with few metastases, in particular in form of radical radiotherapy (RT) for oligorecurrent prostate cancer (PC) after prior definitive therapy. However, the majority of patients will develop progressive disease, despite accurate PSMA-PET-Staging and stereotactic RT; how to optimally select patients is unknown. In this analysis, we aimed to develop a risk classification predicting biochemical relapse free survival (BCRFS) after PSMA-PET-guided RT.

### Material and Methods

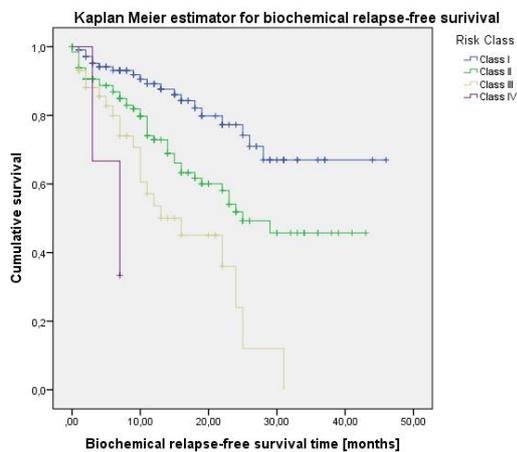

Data of 379 patients were collected at six radiation oncology departments. In this analysis we included 294 Patients with initial radical prostatectomy (RP) and subsequent diagnosis of oligorecurrent PC with positive findings in PSMA-PET-Imaging followed by radical RT. We used univariate and multiple Cox regression to determine significance for known risk factors. Significant factors were analyzed and grouped using recursive partitioning analysis (RPA) with classification and regression (CRT) method. Risk classes I to IV (low to very high risk) were generated using Kaplan-Meier estimator.

### Results

In univariate Cox regression initial nodal status (N0 vs. N1, HR: 0.59, 95%-CI: 0.38-0.90,  $p = 0.02$ ), PSA Persistence  $\geq 0.1$  ng/ml after RP (yes vs. no, HR: 1.61, 95%-CI: 1.05-2.47,  $p = 0.03$ ), PSA levels  $\geq 0.8$  ng/ml at PSMA-PET-based diagnosis of oligorecurrent disease (no vs. yes, HR: 0.51, 95%-CI: 0.33-0.81,  $p = 0.004$ ), presence of bone metastases (no vs. yes, HR: 0.38, 95%-CI: 0.23-0.62,  $p = 0.0001$ ), presence of other metastases than bone or lymph node lesions (no vs. yes, HR: 0.19, 95%-CI, 0.05-0.77,  $p = 0.02$ ), and total number of lesions (HR: 0.65, 95%-CI: 0.42-0.99,  $p = 0.04$ ) were significantly associated with relapse. PSA level at PSMA-PET-Imaging, bone metastases, and other metastases remained significant predictors in multiple regression. Figure 1 shows RPA for BCRFS at 24 months (mos) with a decision-making tree comprising end node groups A to E. 10-fold cross validation showed a risk for miscalculation of 0.295 (Standard error: 0.027), which results in 70.5% accuracy. Kaplan-Meier estimator showed a mean BCRFS of 15.6 mos (95%-CI: 11.2-30.0 mos) in group A, of 36.3 mos (95%-CI: 32.4-40.1 mos) in group B, of 5.7 mos (95%-CI: 2.6-8.7 mos) in group C, of 26.9 mos (95%-CI: 23.4-30.4 mos) in group D, and of 16.6 mos (95%-CI: 11.2-22.0 mos) in Group E. Subsequently, we built risk classes I (Group B), II (Group D), III (Group A and E), and IV (Group C). Kaplan-Meier curve and mean BCRFS stratified for risk classes ( $p < 0.0001$ ) is shown in figure 2 respectively.

Risk class	RPA group	Mean BCRF5 (95%-CI) in months	Predictive factors
Class I (low risk)	Group B	36.2 (32.4-40.1)	PSA level at PSMA-PET based diagnosis of oligorecurrent disease <0.8 ng/ml, no bone metastases
Class II (intermediate risk)	Group D	26.9 (23.4-30.4)	PSA level at PSMA-PET based diagnosis of oligorecurrent disease ≥0.8 ng/ml, bone metastases, no other metastases (no bone or lymph node lesions)
Class III (high risk)	Group A	16.0 (12.3-19.6)	PSA level at PSMA-PET based diagnosis of oligorecurrent disease <0.8 ng/ml, present bone metastases
	Group E		PSA level at PSMA-PET based diagnosis of oligorecurrent disease ≥0.8 ng/ml, no bone metastases, no other metastases (no bone or lymph node lesions)
Class IV (very high risk)	Group C	5.7 (2.6-8.7)	PSA level at PSMA-PET based diagnosis of oligorecurrent disease ≥0.8 ng/ml, present other metastases (no bone or lymph node lesions)

**Conclusion**

We developed a prognostic risk classification for patients with oligorecurrent PC treated with PSMA-PET-guided RT. Internal validation showed good accuracy. Patients with PSA levels at PSMA-PET-Imaging ≥0.8 ng/ml and the presence of other metastases (than bone or lymph node lesions) were at highest risk for biochemical relapse. External validation of the proposed RPA classification is planned as a next step.

**OC-0164 Hypoxia modification in bladder**

**preservation: relating long term outcomes to necrosis and hypoxia**

Y.P. Song<sup>1,2</sup>, H. Mistry<sup>2</sup>, L. Yang<sup>2</sup>, S. Chin<sup>1</sup>, C. West<sup>1,2</sup>, A. Choudhury<sup>1,2</sup>, P. Hoskin<sup>1,2,3</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom ; <sup>2</sup>The University of Manchester, Division of Cancer Science,

Manchester, United Kingdom ; <sup>3</sup>Mount Vernon Cancer Centre, Clinical Oncology, Northwood, United Kingdom

**Purpose or Objective**

The BCON trial showed that the addition of carbogen and nicotinamide (CON) significantly improved recurrence free survival (RFS) and overall survival (OS) rates (Hoskin et al., 2010). Twelve years after the trial closed to recruitment, the long-term clinical outcomes and their relationship to hypoxia markers are reported.

**Material and Methods**

An updated analysis of patients with bladder cancer treated in the BCON trial was undertaken. Cox regression was carried out to relate clinical outcomes to previously published biomarkers: a 24 gene signature hypoxia score (Yang et al., 2017) and necrosis status (Eustace et al, 2013).

**Results**

333 patients were included in the original study. 12 patients were excluded from the analysis. Necrosis and hypoxia score were available for 148 of the remaining patients (73 RT+CON, 75 RT alone). There was a significant improvement in RFS at 5 years (41% vs 33%, p=0.040) which was maintained at 10 years (27% vs 20%). The 5 year OS was 49% vs 40% (p=0.068) with a continued effect seen at 10 years (32% vs 24%). The hypoxia score was prognostic in the RT alone group (p=0.041), but not in the RT+CON group (p=0.634). Necrosis status was a less strong prognostic indicator in the RT alone group (p=0.079) and had no effect in the RT+CON group. The prognostic value of both hypoxia score and necrosis remained following adjustment for other known prognostic factors. Hypoxia scores (p=0.013) (Figure 1) and presence of necrosis (p=0.05) were both independent predictors of benefit from hypoxia modification in the RT+CON group.

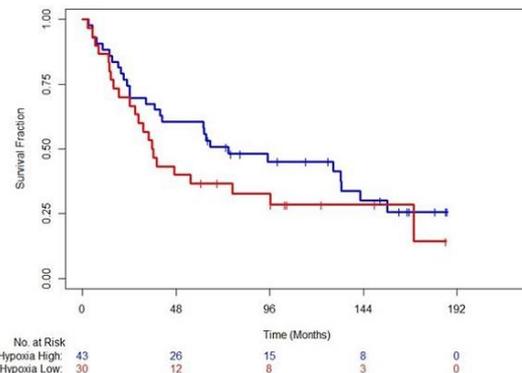

Figure 1. Survival of patients in RT+CON group with high and low hypoxia scores

**Conclusion**

With long-term follow up, there continues to be an advantage in RFS and OS with the addition of CON to radiotherapy, with a statistically significant improvement in 5 year RFS. These findings confirm the significant impact of hypoxia modification on long-term survival for bladder cancer patients undergoing organ preservation treatment. Similarly, the presence of necrosis and hypoxia predicts long-term benefit from hypoxia modification. A prospective biomarker driven clinical trial based on this data is now required to validate the use of hypoxia modification in patients most likely to benefit.

OC-0165 Patterns of treatment and outcomes for 1p19q co-deleted gliomas

D. Yebo<sup>1</sup>, J. Yu<sup>2</sup>, K.E. Liao<sup>3</sup>, J. Huse<sup>4</sup>, M. Penas-Prado<sup>5</sup>, B. Kann<sup>2</sup>, E. Sulman<sup>6</sup>, D. Grosshans<sup>1</sup>, J. Contessa<sup>2</sup>  
<sup>1</sup>MD Anderson Cancer Center, Radiation Oncology, Houston, USA; <sup>2</sup>Yale University School of Medicine, Department of Therapeutic Radiology, New Haven, USA ; <sup>3</sup>MD Anderson Cancer Center, Health Services Department, Houston, USA ; <sup>4</sup>MD Anderson Cancer Center, Department of Pathology, Houston, USA; <sup>5</sup>National Institute of Health, Neuro-Oncology Branch, Bethesda, USA; <sup>6</sup>New York University, Radiation Oncology Department, New York, USA

#### Purpose or Objective

Molecular markers are redefining classification of lower grade gliomas and ushering in a paradigm shift in their management. Our objective was to evaluate the impact of histologic grade on patterns of care and treatment outcomes for 1p19q co-deleted gliomas.

#### Material and Methods

We evaluated 1,618 patients in the National Cancer Database diagnosed with 1p19q co-deleted gliomas from 2010 through 2014 and treated with surgery followed by radiation therapy (RT), chemotherapy (CT), or combined-modality therapy. Kaplan-Meier analysis and log-rank tests were used to assess OS over time. Cox proportional hazards regression modeling was used to assess associations between the World Health Organization (WHO) glioma grade and the outcome of death when adjusting for significant clinical covariates, with a *p* value <0.05 defining significance. Additionally, propensity score matching was done in an attempt to further balance patients by known covariates.

#### Results

Most patients with grade II tumors received surgery alone (51.0%), whereas most patients with grade III tumors (86%) received surgery or biopsy followed by a form of post-operative therapy (*p*<0.001). In a propensity score matched cohort, the Cox multivariable proportional hazards model with frailty testing identified significant covariates were age, comorbidity, histology and grade. Patients ≥60 years had a higher likelihood of death as did those with at least one comorbidity. The hazard for death for grade III 1p19q co-deleted gliomas was about 3.6 times higher ([HR] 3.69, 95% confidence interval [CI] 2.03-6.68, *p*<0.001) than grade II 1p19q gliomas. Oligodendroglioma histology was associated with a lower likelihood of death (HR 0.40, 95% CI 0.23-0.70, *p*<0.001).

#### Conclusion

In conclusion, our study with one of the largest cohorts of specifically grade II versus grade III 1p19q co-deleted gliomas, provides relevant information on real-world outcomes in a national cohort. While we await the results of clinical trials such as CODEL and BN005, our study offers context regarding historical treatment patterns and outcomes in the community for 1p19q co-deleted gliomas.

#### OC-0166 Cumulative metastases volume, not number of brain metastases predicts survival in melanoma patients

#### Purpose or Objective

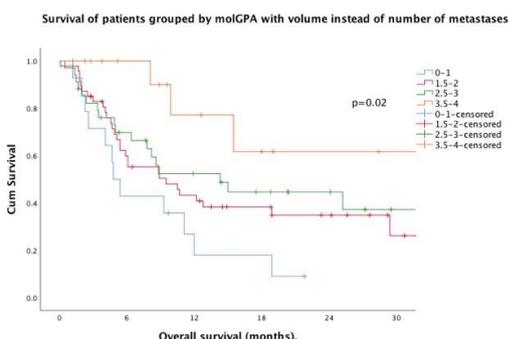

In 2017, Sperduto et al. proposed an updated Graded Prognostic Assessment for melanoma patients with brain metastases (molGPA score), which was validated by Nieder et al. in a cohort of 69 patients. However, both studies included many patients that received whole brain radiation therapy (WBRT). As melanoma patients are increasingly treated with stereotactic radiotherapy or radiosurgery (SRT) alone, we aimed to validate the score in a large cohort of 140 melanoma patients treated exclusively with SRT without WBRT, and concurrent targeted- or immunotherapy.

#### Material and Methods

We retrospectively analyzed data from the international database of efficacy and toxicity of combined SRT and immuno- or targeted therapy (TOaSTT). Patients that received a concurrent WBRT (n=5) with the SRT were excluded, as well as re-irradiations. The updated molGPA score was applied to our cohort to predict survival. The molGPA score included age (≥70 years or < 70 years), performance status, presence of extracranial metastases, BRAF mutational status and number of brain metastases. We used Kaplan-Meier curves to compare overall survival (OS) of groups defined by the score and compared by log rank test.

#### Results

18 centers treated 140 melanoma patients between 05/2011 and 02/2018 with concurrent targeted- or immunotherapy and SRT for 327 brain metastases with a median of 1 (1-6) fractions and a median of 20 Gy (12-30Gy). A median of 2 (1-30) metastases were treated per session with a median cumulative volume of 1.47cc (0.05-24.54cc). The molGPA score could not be validated in our patient cohort (*p* = 0.199). The four groups defined by the score did not show a significant difference in OS, as the number of metastases did not influence survival. However, in univariate analysis, the cumulative volume of irradiated metastases was significantly associated with OS: the group with an irradiated cumulative brain metastases volume smaller than the median volume (1.5cc) survived significantly longer than the group with a larger than or equal to 1.5cc cumulative brain metastases volume (*p* = 0.02). Therefore, the number of brain metastases in the molGPA score was substituted with cumulative brain metastases volume. Using this combination of factors, the four modified molGPA score prognostic groups showed significantly different OS (logrank *p* = 0.02).

**Conclusion**

For melanoma patients with brain metastases treated with concurrent targeted- or immunotherapy and SRT without concurrent WBRT, brain metastases volume impacts OS, but not the number of treated brain metastases. We propose adapting the molGPA score for melanoma patients treated with SRT and concurrent targeted- or immunotherapy.

**OC-0167 Identifying No Fly Zones to prevent long-term thinning of the cerebral cortex in glioma after RT**

S. Nagtegaal<sup>1</sup>, S. David<sup>2</sup>, H. Mesri<sup>2</sup>, M. Philippens<sup>1</sup>, A. Leemans<sup>2</sup>, J. Verhoeff<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands ; <sup>2</sup>UMC Utrecht, Imaging Science Institute, Utrecht, The Netherlands

**Purpose or Objective**

Radiation induced brain injury consists of both anatomical and functional deficits in irradiated healthy brain tissue. Especially cognitive and executional impairments lead to a marked decrease in the patient’s quality of life after radiation therapy (RT), and have been linked to thinning of the healthy cerebral cortex. With the rise of more precise radiation techniques, like image-guided RT and proton RT, knowledge of the long-term effects of radiation on the cortex is important for optimal treatment planning. In this work, we present the results of structural morphometry of the cerebral cortex at different time points in glioma patients treated with RT, and compare the changes to the applied dose.

**Material and Methods**

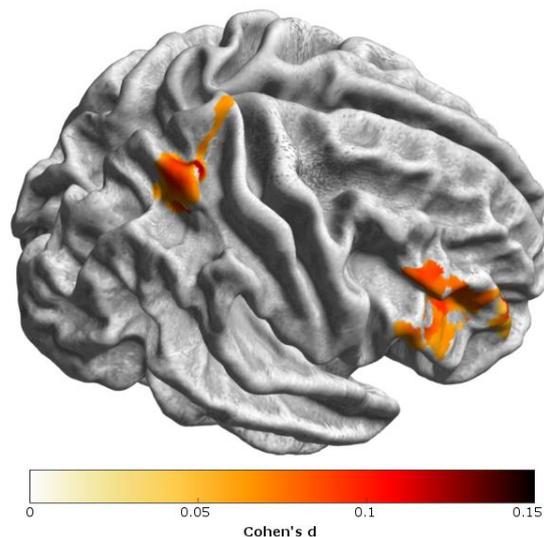

We selected 31 patients with adequate follow-up scans who were treated with RT for glioma (grade II-IV) in our institution. Late follow-up was defined as >9 months after start of RT, and the cortical thickness was compared to baseline.

The CAT12 (Computational Anatomy Toolbox) was used for the automated preprocessing, segmentation and surface estimation of clinical 3T T1 scans. All scans were bias-field inhomogeneity and noise corrected, then segmented into grey matter, white matter and cerebrospinal fluid. Surface calculation was achieved via projection-based thickness estimation and reparametrized to the Freesurfer surface template, consisting of a 152k mesh per hemisphere. RT dose was 3D mapped to the surface. Change in cortical thickness was associated with locally applied dose via non-parametric permutations tests. Age and sex were included as covariates of no-interest, and correction for multiple comparisons with family wise error-rate adjustment was applied. The significance of a test was determined at  $p < 0.05$ . For each test the Cohen’s d was also calculated.

**Results**

Figure 1 shows the regions where a statistically significant dose-dependent decrease in cortical thickness was found. Data on the two regions are shown in Table 1. Figure 2

shows the change in cortical thickness per dose in the vertex with the greatest association between these two variables.

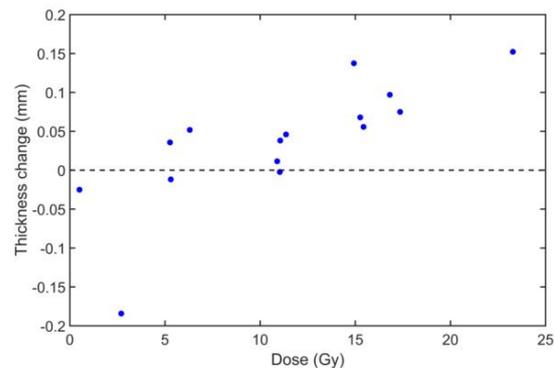

**Figure 1** Cortical areas with statistically significant ( $p < 0.05$ ) dose-dependent thinning between baseline and late follow-up

**Table 1** Data on the cortical areas in the right frontal (1) and parietal (2) lobes

Cluster	Number of vertices	Mean effect size (Cohen’s d)	p	Correspondence to brain atlas region*
1	2452	0.1	0.02	Middle frontal gyrus (45%)
				Inferior frontal sulcus (31%)
				Triangular part of the inferior frontal gyrus (17%)
				Middle frontal sulcus (3%)
				Opercular part of the inferior frontal gyrus (3%)
2	1841	0.1	0.02	Superior parietal lobule (55%)
				Intraparietal sulcus and transverse parietal sulci (28%)
				Postcentral sulcus (11%)
				Paracentral lobule and sulcus (6%)

\* According to Destrieux brain atlas

**Figure 2** Dose-dependant thickness change in a single vertex

**Conclusion**

This study shows that the cerebral cortex is susceptible to long-term radiation-induced cortical changes, and that the rate of change increases with the applied dose. This effect can be considered rapid aging of the healthy brain, which may accompany similar age-related cognitive impairments.

Despite this dose-dependent cortical thinning, changes in the cortex can already be seen at lower doses, suggesting

that sparing of healthy brain tissue should be a crucial aspect in the treatment of brain tumours. Luckily, new techniques are being developed that allow for very precise irradiation of the tumour area, which means cortical sparing is feasible. We here present 2 No Fly zones, to be avoided in cranial radiotherapy. In the future, cognitive symptoms after RT may be diminished further, vastly improving the quality of life of brain tumour patients.

#### OC-0168 Dose-dependent atrophy of the amygdala after radiotherapy

M. Huynh-Le<sup>1</sup>, R. Karunamuni<sup>1</sup>, V. Moiseenko<sup>1</sup>, N. Farid<sup>2</sup>, C. McDonald<sup>3</sup>, J. Hattangadi-Gluth<sup>1</sup>, T.M. Seibert<sup>1</sup>

<sup>1</sup>University of California San Diego, Radiation Medicine and Applied Sciences, San Diego, USA ; <sup>2</sup>University of California San Diego, Radiology, San Diego, USA;

<sup>3</sup>University of California San Diego, Psychiatry, San Diego, USA

#### Purpose or Objective

The amygdalae are deep brain nuclei critical to processing emotions such as fear, anger, and anxiety, as well as to the creation and storage of memory. The effects of brain radiotherapy (RT) on the amygdalae are currently unknown. We sought to quantify radiation dose-dependent change to the amygdalae in a retrospective cohort of patients with primary brain tumors.

#### Material and Methods

52 patients with primary brain tumors who received fractionated partial brain radiotherapy were identified. Study patients underwent high-resolution, volumetric magnetic resonance imaging before RT and 1 year afterward. Images were processed using software approved by the US Food and Drug Administration and Conformité Européenne for automated segmentation of amygdala volume. Results were inspected for accuracy. Tumor and surgical changes were manually censored. Mean dose to the amygdala was tested for correlation with amygdala volume change 1 year after RT via the Pearson correlation coefficient. A linear mixed-effects model was constructed to evaluate potential predictors of amygdala volume change, including patient (random effect), age, tumor hemisphere, sex, seizure history, and bevacizumab treatment during the study period. As 51 of 52 patients (98%) received chemotherapy during the study period, chemotherapy was not included as a predictive variable. A two-tailed *p*-value of <0.05 was considered to be statistically significant.

#### Results

The majority of patients were male (*n*=35, 67%), and the median age at the time of treatment was 54 years (range 19-77). Most patients had grade III-IV glioma (*n*=42, 81%). The most common tumor locations were frontal lobe (*n*=18, 35%) and temporal lobe (*n*=16, 31%). All patients were treated with intensity-modulated RT. Fifty patients (96%) received chemotherapy concurrent with RT; all of these patients received temozolomide. Fifteen patients (29%) had a major seizure during the study period and ten (19%) patients received bevacizumab. After censoring effects of tumor, surgery, or segmentation error, 40 right and 44 left amygdalae (total of 84 amygdalae) were included in the analyses. Mean dose to the amygdala (*r*=0.28, *p*=0.01) was significantly correlated with volume loss. On multivariable analysis, only radiation dose was a significant predictor of amygdala atrophy. The final linear mixed-effects model estimated amygdala volume loss of 0.17% for every 1 Gy increase in mean amygdala RT dose (*p*=0.008).

#### Conclusion

The amygdala demonstrates dose-dependent atrophy at one year after radiotherapy for brain tumors. The potential cognitive effects of radiotherapy to the amygdala warrant further exploration in prospective trials.

#### OC-0169 Spinal change after craniospinal irradiation for pediatric patients

Y. Oshiro<sup>1</sup>, M. Mizumoto<sup>2</sup>, H. Pan<sup>3</sup>, S. Kaste<sup>4</sup>, T.E. Merchant<sup>1</sup>

<sup>1</sup>St. Jude Children's Research Hospital-Memphis, Radiation Oncology, Memphis, USA; <sup>2</sup>University of Tsukuba, Radiation Oncology, Tsukuba, Japan; <sup>3</sup>St. Jude Children's Research Hospital- Memphis, Biostatistics, Memphis, USA; <sup>4</sup>St. Jude Children's Research Hospital-Memphis, Diagnostic Imaging, Memphis, USA

#### Purpose or Objective

To analyze spinal change after craniospinal irradiation (CSI).

#### Material and Methods

896 vertebral bodies in 220 pediatric patients who received CSI were analyzed. All met the following criteria: age at CSI ≤ 13 years, minimal follow up of 2 years with spinal MRI. CSI dose ranged from 15Gy to 43.2Gy. To analyze vertebral growth, vertebral body height were calculated. Signal change of vertebral body on MRI, scoliosis and kyphosis, degenerative change of vertebral bones and disc, and wedging or vertebral height loss were also analyzed on images. Then impact factors on these changes were investigated.

#### Results

Vertebral bone was significantly correlated radiation dose and growth hormone (GH) deficiency. The bone growth rate was 2.6%, 2.0%, 1.6%, 1.8%, 1.0%, and 0.8% for bones receiving < 20Gy, 23.4Gy, 36Gy, 39.6Gy, 40-50Gy, and >50Gy, respectively. Growth rate was significantly worse with the dose more than 38Gy. The growth rates were similar for vertebral bodies treated with growth hormone compared to those in whom growth hormone was not indicated (2.73% per year vs. 2.88% per year) whereas in those who refused or unable to receive growth hormone the rate of growth was significantly lower (1.38% per year) compared to those treated with growth hormone (*p*=0.0022). 83% of the patients showed fatty marrow change and 31% patients had disc degenerative change. Degenerative change of spinal bones and Wedging or spinal height loss was observed in 13% and 17% of the patients. Scoliosis was observed in 27% of the patients.

#### Conclusion

Vertebral bone growth was significantly disturbed with the dose >38Gy, and adequate GH replacement was very important for bone growth. Even with symmetrical irradiation, risk of scoliosis was high after CSI, and moreover, spinal demineralization and degenerative change frequently progressed after CSI, therefore, careful attention should be paid for future spinal symptoms as the patients grow old.

Direction de la Recherche Clinique et de l'Innovation-

**Purpose or Objective**

Hypofractionated Stereotactic Body Radiation Therapy (SBRT) is demonstrated as safe and efficient in many adult situations, including mainly primary/secondary tumors in brain, spine, and lung or in case of re-irradiation (re-RT). In pediatric situations, data are rare and needed to assess feasibility, efficiency and acute/long term toxicities in patients (pts) with radioresistant cancers (sarcomas, brain tumors such as ependymomas) or for re-RT. A multicentric national prospective study considering SBRT in young pts (1.5-20 y.) was opened in 12/2013, with multi-disciplinary staff confirmed indication of SBRT.

**Material and Methods**

The study was built as a prospective cohort study with several arms considering the site of lesion, summarized in Fig. 1. Only pts with ependymomas in relapse after radiotherapy (RT) could be included after complete surgery while the others had no surgery or incomplete macroscopic tumor resection. The main objective was to evaluate the 6-months local control (RECIST 1.1). Secondary objectives were to evaluate the feasibility of SBRT in childhood, 3-months, 1 and 2-years local control rates, acute, and middle-term toxicities (3-24 months) using NCI CTC v 4.0 criteria. Long-term toxicity will be evaluated using the national cohort study PEDIART.

**Results**

48 pts were included in 10 institutions. 4 pts did finally not receive SBRT (, 1 for early progression, 1 pt refusal, 2 pts due to medical decision after inclusion) and were excluded from the analysis. Among the population analysis (n=44), the median age was 12 y. (min 3 - max 20). 15 pts were irradiated in first intention: - 4 pts with brain lesions received a median dose of 32.5 Gy/5fr (isodose 80%).

- 5 pts with lung lesions received a median dose of 50 Gy/5 fr, (isodose 80%)

- 6 pts with spine lesions received a median dose of 50 Gy/5 fr, (isodose 80%)

29 pts were included for re-RT :

- 12 pts were treated by post-operative SBRT for locally relapsed ependymoma (median dose 25/5 fr., isodose 80%)

- 17 pts were treated for re-RT in other situations (brain, spine, lung...) without surgery (median dose 25 Gy/5 fr).

All the pts could receive SBRT. Median follow-up was 23 months (12-24). No pt required general anesthesia. Considering acute toxicity (< 3 months after SBRT), 1 pt reported epilepsy (grade 3). Grade 2 toxicity was observed in 3 pts (asthenia, transitory radiation pneumonitis, headache). Middle term RT toxicity (Grade > 2, 3-24 months after SBRT) was identified for 1 pt (pyloric spasm after spinal SBRT).

**Conclusion**

SBRT is feasible and safe in childhood, considering acute toxicity in brain, lung and spine treatment or in selected cases of re-RT. More follow-up is needed to better

**Purpose or Objective**

To investigate the influence of brachytherapy (BT) technique and applicator type on target dose coverage, isodose surface volumes, and dose to organs at risk (OARs).

**Material and Methods**

949 patients treated with tandem/ovoids (T&O) and tandem/ring (T&R) BT applicators, from 18 centres in the EMBRACE study, were analysed. Patients received external beam radiotherapy with concomitant chemotherapy, followed by MRI guided adaptive brachytherapy with individualised dose prescription. Centres were divided into 4 groups, according to their applicator (T&O vs T&R) and intracavitary (IC) vs intracavitary/interstitial (IC/IS) usage: T&O and T&R IC centres treating mainly with the IC technique; T&O and T&R IC/IS centres treating routinely with the IC/IS technique (>20% of patients). V85Gy EQD2<sub>10</sub>, CTV<sub>HR</sub>D<sub>90%</sub> as well as bladder, rectum and vaginal (lateral point at 5mm with respect to the applicator) doses were evaluated. Data was analysed as independent samples based on Student's t-test or by multiple linear regression models.

**Results**

Patient characteristics, target and OAR doses for each center group are presented in Table 1. T&R IC compared to T&O IC centres had: mean CTV<sub>HR</sub>D<sub>90%</sub> higher by 4.9Gy EQD2<sub>10</sub> for a CTV<sub>HR</sub> volume of 30cm<sup>3</sup> and no statistically significant difference when > 45cm<sup>3</sup> (Fig.1a); mean V85Gy

EQD2<sub>10</sub> smaller by 19.2cm<sup>3</sup> at any given target volume (Fig.1b); mean Bladder ICRU and Rectovaginal Point doses (D2cm<sup>3</sup> is given in parenthesis) smaller by 9.1 (7.5) and 5.6 (3.3) Gy EQD2<sub>3</sub>, respectively; mean vaginal dose higher by 17.1GyEQD2<sub>3</sub>. IC/IS compared to IC centres had: significantly improved target coverage and smaller V85Gy EQD2 for intermediate and large CTV<sub>HR</sub> volumes (Fig. 1c-f); decreased OAR doses, mostly in T&O. T&R IC/IS compared to T&O IC/IS centres had: mean CTV<sub>HR</sub> D<sub>90%</sub> higher by 2.7Gy EQD2<sub>10</sub>; mean V85Gy EQD2<sub>10</sub> smaller by 8.3cm<sup>3</sup> at any given CTV<sub>HR</sub> volume; mean Bladder D2cm<sup>3</sup> and Rectovaginal Point doses smaller by 4.3Gy and 4.8Gy EQD2<sub>3</sub>, respectively; mean vaginal dose larger by 22.5Gy EQD2<sub>3</sub>. All above mentioned differences were statistically significant (p<0.01). For patients treated with IC/IS, needles were used for all fractions in 85% and 55% of cases in T&R IC/IS and T&O IC/IS centres, respectively. Average number of needles/patient was 4.9 (SD:2.5) and 3.5 (SD:1.8) in T&R IC/IS and T&O IC/IS centres, respectively.

Table 1. Patient characteristics, target and OAR doses for each centre group. Mean values and standard deviations (1 SD) are displayed.

	OVOIDS IC CENTRES	RING IC CENTRES	OVOIDS IC/IS CENTRES	RING IC/IS CENTRES

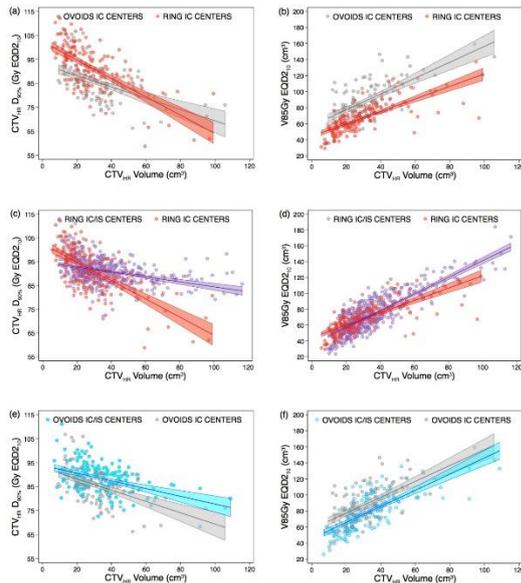

Figure 1. Scatter plots of CTV<sub>HR</sub> D<sub>90%</sub> and V85 Gy EQD2<sub>10</sub> for: (a,b) OVOIDS IC and RING IC centres; (c,d) RING IC and RING IC/IS centres; (e,f) OVOIDS IC and OVOIDS IC/IS centres. Each scatter plot displays the best fitting linear regression line (solid line) and the 95% CI (hatched band) for each center group.

**Conclusion**

The T&R IC applicator plans show better coverage and dose conformity than the T&O IC applicator plans for CTV<sub>HR</sub><45cm<sup>3</sup>. For large target volumes, both T&R and T&O IC plans fail to ensure adequate target coverage. Bladder and rectum are, in general, better spared with T&R IC, while the 5mm lateral vaginal dose is higher. Routine application of IC/IS improves target coverage and dose conformity, and better spares the OARs. With the addition of needles, the differences seen in target/OAR doses and in V85Gy EQD2 between the IC applicators become smaller. These differences are also related to both the number of needles and fractions with needles used.

**OC-0173 Dosimetric comparison of T-O brachytherapy with/without interstitial component in FIGO I-IIb tumors**

M. Federico<sup>1</sup>, A. Perez Fustero<sup>1</sup>, C. Catarina<sup>2</sup>, I. Fernandez<sup>3</sup>, J.L. Perez Molina<sup>3</sup>, I. Morales Orue<sup>1</sup>, M. Lloret<sup>1</sup>

<sup>1</sup>Hospital Universitario de Gran Canaria Dr. Negrin, Radiation Oncology, Las Palmas de Gran Canaria- Ca, Spain ; <sup>2</sup>ULPGC, Centro de Tecnologias de la Imagen CTIM, Las Palmas de Gran Canaria, Spain; <sup>3</sup>Hospital Universitario de Gran Canaria Dr. Negrin, Medical Physics, Las Palmas de Gran Canaria- Ca, Spain

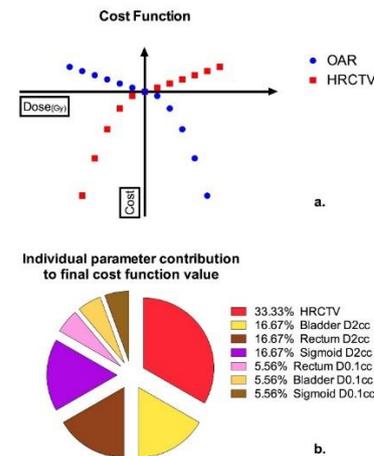

**Purpose or Objective**

Intracavitary/interstitial (IC/IS) brachytherapy (BT) improves HRCTV dose coverage in large locally advanced tumors resulting in improved local control and survival. In small tumors IC/IS brachytherapy may be useful in selected situations due to difficult OAR/tumor topography. A prospective trial was designed in order to evaluate in a series of consecutive patients with small cervical tumors potential gains of IC/IS vs. Intracavitary (IC) brachytherapy

**Material and Methods**

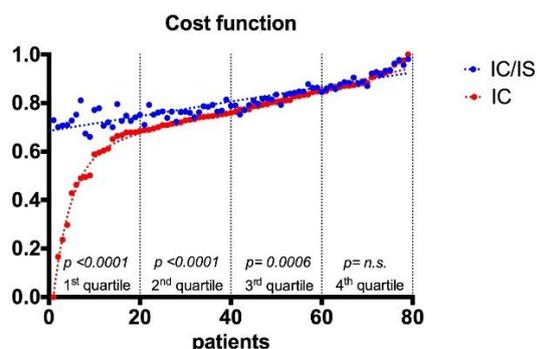

200 consecutive patients with histologically proven cervical cancers treated between 2013-18 with 45 Gy 3D CRT and MR-based IGABT (4 fraction of 7 Gy each in 2 different applications) were analyzed. Out of the original 200 patients the ones receiving TO application were selected (175 pts). To further select only the tumors potentially suited for IC BT application a standard IC 7 Gy point A plan was generated and patients with a HRCTV coverage <86 Gy<sub>EQD2</sub> were discarded (69 pts). Out of the 106 remaining patients 79 had IC/IS application in all 4 BT fractions and were selected for the present study. All pts had a FIGO stage I (20 pts) or II (59 pts).

At the time of their treatment all patients received IC/IS T-O application (Elekta Utrecht applicator) optimized upon the following constraints: HRCTV≥86Gy<sub>EQD2</sub>; Bladder≤90 Gy<sub>EQD2</sub>; Rectum≤70 Gy<sub>EQD2</sub>; Sigmoid ≤70 Gy<sub>EQD2</sub>. For the present study an IC plan was recalculated. To compare IC or IC/IS plans a cost function was generated Fig1a. To assign a specific cost to each individual planification a function was created with a linear and quadratic component. The zero of the function for each ROI was set to its specific constraint (86 Gy EQD2 for HRCTV, 90 Gy EQD2 for bladder, etc) or in case of D0.1 cc values to the median value of the delivered IC/IS planifications. The final cost of each plan was the sum of the individual ROI cost function normalized and weighted as follow (2/6 HRCTV cost, 1/6 for each OAR D2cc value and finally 1/6 for the D0.1cc values of the 3 OARs) (Fig 1b)

## Results

Average cumulative EQD2 doses (Gy) for IC/IS plan were the following: HRCTV D90 88.2±2.6; Bladder D2cc 72.1±7.9, D0.1cc 84.3±10.7; RectumD2cc 58±6.8, D0.1cc 66.7±11.3; Sigmoid D2cc 63±5.3, D0.1cc 73.9±8.6). Average cumulative EQD2 doses (Gy) for IC plan were the following: HRCTV D90 86.6±3.4; Bladder D2cc 74.4±9.9, D0.1cc 91±19.5; RectumD2cc 59.2±7.7, D0.1cc 69.5±13.7; Sigmoid D2cc 64.1±6.3, D0.1cc 76.4±10.4). Difference between IC/IS and IC plan was significant for all ROIs and dose points (wilcoxon test). Average cost function for IC/IS or IC plan was 0.8±0.1 and 0.7±0.2 respectively ( $p < 0.0001$ ). Quartile analysis of the cost function plot (Fig.2) shows that the difference between IC/IS and IC plans is not significant just in the 4th quartile.

## Conclusion

IC/IS plans achieved a significant dosimetric gain in a proportion of patients larger than expected. Given the comparable costs and complication rates between IC and IC/IS, a more extensive use of IS component in small tumors seems justified

## OC-0174 Advancement of brachytherapy for locally advanced cervical cancer in the era of image guidance

J.C. Lindegaard<sup>1</sup>, L.U. Fokdal<sup>1</sup>, P. Petric<sup>1</sup>, S.K. Nielsen<sup>1</sup>, K. Tanderup<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark

## Purpose or Objective

Two decades ago standard treatment for locally advanced cervical cancer (LACC) involved 4-field box external beam radiotherapy (EBRT) and 2D brachytherapy aiming for 80-85 Gy to point-A. In 2005 image guided adaptive brachytherapy (IGABT) was introduced in our department and we joined the newly formed international GEC ESTRO collaboration on IGABT in LACC. The aim of the present study was to evaluate the impact of this collaboration in terms of developments of BT techniques and dose-volume parameters over time.

## Material and Methods

400 consecutive pts treated 2005-2018 using EBRT ±concomitant cisplatin and IGABT were analysed. FIGO stage distribution was I-IIA 9%, IIB 61% and III-IV 30%. EBRT dose was 45-50 Gy delivered in 25-30 fx. A simultaneous integrated boost to 50 Gy (stage IIB) or 60 Gy (stage III-IV) for the primary tumour was used in the early years, but was gradually phased out and the EBRT dose reduced to 45 Gy/25 fx for all pts. IGABT was performed with PDR and was based on MRI with a gradual introduction of planning aims and DVH constraints from our collaborative GEC ESTRO experience as they became available. The Embrace II protocol (www.embracestudy.dk) was formally implemented in 2016.

Combined intracavitary/interstitial technique (IC/IS) was available from 2006, initially beside a tandem-ring

applicator, but from 2007 also with an intravaginal tandem-needle-template (TNT) with no ring. Time trends were visualized by sliding average calculation with 50 pts per frame (Figure 1). The planning aims and DVH hard and soft constraints were evaluated in relation to the Embrace II protocol (Table 1). Equivalent dose in 2 Gy fractions (EQD2) was calculated using  $\alpha/\beta=10$  for tumour and  $\alpha/\beta=3$  for organs at risk. Statistical analysis was done with t-test and Chi square.

## Results

The implant technique for IGABT changed significantly as the use of IC/IS went up from 32% to 68%, with 52% of the implants being performed with the TNT device in the last 50 pts (Table 1). The dose contribution of EBRT to D90 of CTV<sub>HR</sub> was reduced by 7 Gy while the contribution from IGABT enlarged by 11 Gy leading to an overall improvement in the D90 of CTV<sub>HR</sub> from 89 to 93 Gy. This improvement was realised with no increase in TRAK. For D2cm<sup>3</sup> of bladder, rectum and sigmoid the dose was significantly lowered by 3, 8 and 10 Gy, respectively. The dose to the ICRU recto-vaginal point was decreased by 8 Gy. Recording of D2cm<sup>3</sup> for bowel was initiated after the first 75 pts and stayed constant at about 60 Gy over the observation time. EMBRACE hard and soft constraints were fulfilled in 96% and 66% of the last 50 pts.

## Conclusion

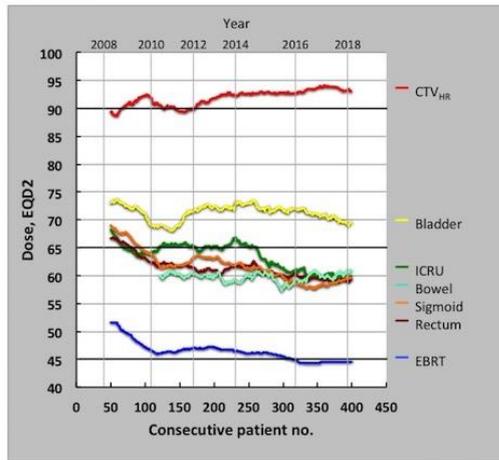

The constraints and planning aims obtained through the GEC ESTRO collaboration on IGABT in LACC has profoundly impacted our treatment practice with significant improvements in the dose-volume parameters. This improvement was primarily obtained by decreasing the dose contribution of EBRT and by use of advanced IC/IS implants for IGABT.

**Table 1**  
 Implant technique, DVH parameters and planning aim fulfillment in 400 consecutive patients treated with external beam radiotherapy +/- chemotherapy and MRI guided brachytherapy. Dose is equivalent dose in 2 Gy fractions, calculated using  $\alpha/\beta=10$  for tumour and  $\alpha/\beta=3$  for organs at risk.

**Figure 1.** Sliding average (50 pts per frame) of dose to tumour (D90 CTV<sub>HR</sub>) and organs at risk (D2cm<sup>3</sup> bladder, bowel, sigmoid, rectum; dose ICRU recto-vaginal point) obtained in 400 consecutive pts treated 2005-2018 with external beam radiotherapy +/- chemotherapy and MRI guided brachytherapy. Dose contribution from external beam radiotherapy (EBRT) to D90 of CTV<sub>HR</sub> is also indicated.

### OC-0175 3D-printed tandem-needle-template for image guided adaptive brachytherapy in cervical cancer

P. Petric<sup>1</sup>, L.U. Fokdal<sup>1</sup>, A. Traberg Hansen<sup>1</sup>, S. Kynde Nielsen<sup>1</sup>, K. Tanderup<sup>1</sup>, J.C. Lindegaard<sup>1</sup>  
<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

#### Purpose or Objective

Intracavitary/interstitial (IC/IS) image guided adaptive brachytherapy (IGABT) is being increasingly employed for locally advanced cervical cancer (LACC). However, narrow vagina and/or extensive local disease may compromise the use of tandem-ring or tandem-ovoid IC/IS applicators. We describe our experience with novel 3D printed vaginal tandem-needle templates (TNT) for insertion of needles in parallel (P) or parallel and oblique (P&O) direction.

#### Material and Methods

Fifty-nine consecutive patients treated with TNT from Jan 2015 - Jan 2018 were included. External beam radiotherapy (EBRT) consisted of 45 Gy/25 fx +/- nodal boost and concomitant cisplatin. Decision to use TNT and pre-planning of its optimal geometry were made after 4-5 weeks of EBRT, based on gynaecological examination and MRI with tandem-ring applicator in situ. Subsequently, TNT was 3D-printed in house, using biocompatible autoclavable material (Figure 1). TNT consisted of a 32- or 36-mm vaginal ring without a ring channel and with P and O holes for guidance of plastic needles. Standard (12 P needles or 8 P plus 7 O needles) or personalized TNT (individualized needle insertion points and angles) was printed. Following EBRT, 2 implants and 2 fractions of PDR IGABT were delivered about 1 week apart. TNT was fitted over commercially available uterine tandem. Plastic needles were placed through the guiding holes to pre-planned depths. The source was not in direct contact with the TNT. Dwell-positions in P needles were used to simulate the ring channel. Planning aims were based on the Embrace II protocol. TNT was discarded after single use.

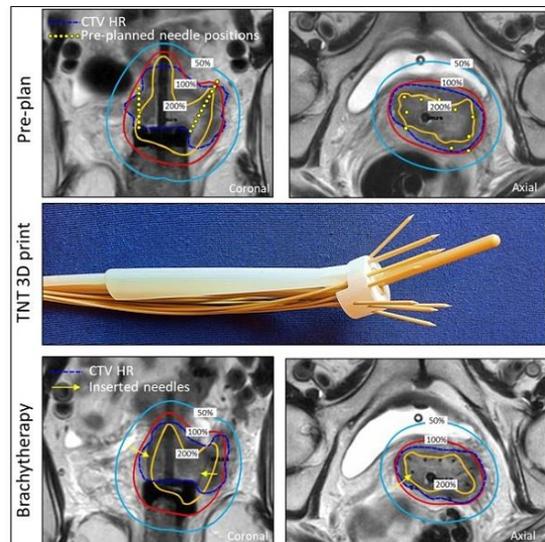

#### Results

Patients selected for TNT were characterised by a median age of 69 years. Performance status (WHO) was > 0 in 49% and 56% of the patients had noteworthy co-morbidity. FIGO stage distribution was: IB 2%, IIB 48% and III-IV 50%. Median tumour width was 60 mm. Patients with P&O implants (n=32) had significantly larger tumours and more extensive parametrial involvement at diagnosis and BT when compared with P group (n=27). Bladder and rectum invasion also predicted for the use of P&O technique,

while vaginal and uterine involvement did not. Median number of implanted/active P and P&O needles at first implant was 8/7 and 12/10, respectively. Individualized 3D printing was used in 13 (57%) patients of the P&O group. Embrace II hard constraints were fulfilled in 95% (Table 1). With a median follow-up time of >18 months, local control was obtained in 56 (95%) and grade  $\geq 3$  radiation related complications observed in 3 pts (5%).

#### Conclusion

The use of 3D printed TNT for IGABT in LACC is promising. It allows for successful management of extensive local disease even in narrow vaginal conditions. 3D printing enables full and affordable control of the production process with the possibility for treatment individualisation and one-time use of the BT template.

of Radiation Oncology, Aarhus, Denmark ; <sup>6</sup>Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

### Purpose or Objective

EMBRACE-II is a prospective interventional multicentre study of IMRT and MRI-based image-guided adaptive brachytherapy (IGABT) in cervix cancer. The EMBRACE-II RTQA process for IGABT is mandatory for centres which did not participate in the first EMBRACE study.

The RTQA process comprised 1) a compliance questionnaire confirming that IGABT was established at the centre, 2) contouring on two benchmark cases by the principal investigator, and 3) submission of dosimetric data from 5 dummy run patients treated according to the study protocol. This abstract reports the results of the contouring assessments for the benchmark cases.

### Material and Methods

Delineation was performed using a bespoke online contouring tool.

Case 1 was a IIIB tumour with 40mm anterior vaginal extension at diagnosis. There was moderate response to chemoradiotherapy (CRT) with a small amount of residual anterior vaginal disease and palpable proximal parametrial disease at BT.

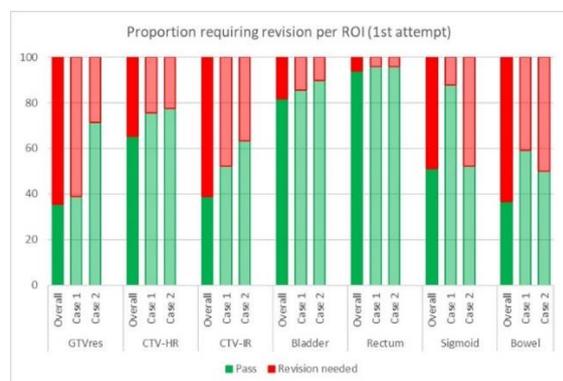

Case 2 was also a IIIB tumour but with no vaginal involvement at diagnosis. There was good response to CRT with no residual palpable or radiological parametrial disease.

The regions of interest (ROIs) assessed were the residual GTV (GTV<sub>res</sub>), high-risk CTV (CTV-HR), intermediate-risk CTV (CTV-IR), bladder, sigmoid, rectum and bowel. Each ROI was scored 0-10 by 2 assessors - a score of  $\geq 6$  was required to pass. Individualised feedback was also provided. A pass on every ROI for both cases was required for accreditation.

### Results

49 clinicians submitted contours for evaluation. 4 (8%) passed at the first attempt and 27 (62%) on resubmission after individualised feedback.

23% of submissions required revision of one ROI, 29% two ROIs, and 30% three or more ROIs. The most common ROIs requiring revision were the GTV<sub>res</sub> (65%), CTV-IR (61%), sigmoid (49%) and bowel (63%) [Figure 1].

A pair-wise comparison of individual performance for each ROI in the 2 cases was performed [Table 1]. The proportion of clinicians failing both cases ranged between 2-24% per ROI; a common conceptual difficulty was often identifiable from the qualitative feedback.

For the GTV<sub>res</sub>, CTV-IR and sigmoid, performance was worse in one case compared to the other which could be attributed to differences in case difficulty. For the CTV-HR, the causes for clinicians passing only one case were not obvious.

ROI	Pass both	Fail both	Fail only Case 1	Fail only Case 2	Common errors (frequency)	Consequence
GTV <sub>res</sub>	17 (35%)	12 (24%)	18 (37%)	2 (4%)	Normal cervix and/or grey zones included (47%) Tumour present on clinical examination missed - case 1 (32%)	Volume too large - unable to meet target dose constraint / objective Insufficient dose to residual tumour
CTV-HR	32 (65%)	6 (12%)	6 (12%)	5 (10%)	Too narrow axially (20%)	Insufficient dose to cervix / residual pathologic tissue
CTV-IR	19 (39%)	11 (22%)	12 (24%)	7 (14%)	Initial extent of disease not covered e.g. vagina - case 1 (33%) or parametrium (31%) Uninvolved tissue at diagnosis inappropriately included e.g. para-uterine tissues (33%)	Insufficient dose to areas of original macroscopic disease Increased dose to organs at risk near the uterine corpus (bowel, sigmoid)
Bladder	40 (82%)	3 (6%)	4 (8%)	2 (4%)	Inner wall contoured (14%)	Falsely low bladder D <sub>2cc</sub>
Rectum	46 (94%)	1 (2%)	1 (2%)	1 (2%)		
Sigmoid	25 (51%)	5 (10%)	1 (2%)	18 (37%)	Sigmoid mislabelled as bowel - case 2 (45%)	Bowel D <sub>2cc</sub> falsely high
Bowel	18 (37%)	12 (24%)	8 (16%)	11 (22%)	Individual bowel loops not contoured - case 1 (36%) Sigmoid mislabelled as bowel - case 2 (45%)	

### Conclusion

This is the first study to correlate the results of summative (pass/fail) assessments for benchmark cases in cervix cancer IGABT with a systematic analysis of qualitative feedback.

The first-time pass rate was low and most submissions required revision of more than one ROI. Qualitative analysis showed that while many errors were due to conceptual difficulties, there were also errors related to variation in case selection.

Individualised feedback improved contouring, but the time taken to manually assess and give relevant feedback was a significant burden.

Improved tools which will allow rapid contouring across a large number of cases with automated assessments are required.

### OC-0177 The value of kV-CBCT in adaptive HDR brachytherapy of cervical cancer patients

C. Constantinescu<sup>1</sup>, N. Jastaniyah<sup>2</sup>, S. Wadi-Ramahi<sup>1</sup>  
<sup>1</sup>King Faisal Specialist Hospital and Research Center, Biomedical Physics, Riyadh, Saudi Arabia; <sup>2</sup>King Faisal Specialist Hospital and Research Center, Radiation Oncology, Riyadh, Saudi Arabia

### Purpose or Objective

To assess the intra-fraction variation of dose delivered to organs-at-risk (OARs) using a kV-CBCT scanner and estimate the potential of this technology for adaptive HDR brachytherapy (BT) of cervical cancer.

### Material and Methods

Data of cervical cancer patients who underwent VMAT pelvic irradiation (45Gy/25fractions) followed by HDR BT (28Gy/4fractions) were retrospectively reviewed. Bladder-filling and rectum/bowel preparation protocols were performed.

A CT scan with 2 mm slice thickness was acquired and images imported to TPS for planning purposes. Contouring of the HR-CTV and the OARs (bladder, rectum and sigmoid) was performed on CT images, guided by MR images previously acquired. Planning objectives were according to (GYN) GEC-ESTRO recommendations. Immediately before treatment, a kV-CBCT scan was acquired with the patient in treatment position, using an in-built pelvis scanning protocol. CBCT images were manually registered with planning CT using the applicators as landmarks and the OARs were re-contoured.

Their D<sub>2cc</sub> and respective EQD2 were recalculated and compared to the planned ones using a Wilcoxon test. The dose variations were evaluated by the relative percentage difference between the doses calculated on planning CT and verification kV-CBCT images. Possible correlation between OARs dose and volume variation was investigated by a linear regression test.

### Results

Data of 19 patients and 57 BT fractions were analyzed. In each BT fraction, variations in OARs (as volume, shape

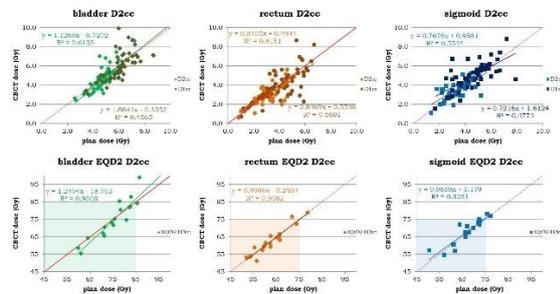

and/or position) always occurred between CT and kV-CBCT acquisition.

The mean relative percentage differences of  $D_{2cc}$  were:  $-2.7\% \pm 15.6\%$  for bladder,  $-1.2\% \pm 21.2\%$  for rectum and  $6.3\% \pm 24.1\%$  for sigmoid.

Table 1. Individual dosimetric variations for the bladder, rectum and sigmoid, expressed as EQD2.

		planning CT dose (Gy)			kV-CBCT dose (Gy)			diff. (%)		p
		mean	SD	range	mean	SD	range	mean	SD	
bladder	EQD2 <sub>2cc</sub>	77.2	9.9	60-102.1	77	12.9	55.3-107	-0.6	5.9	0.0001
	rectum	EQD2 <sub>2cc</sub>	63.3	7.6	53.6-78.7	62.9	7.9	53.7-78.8	-0.6	3.9
sigmoid	EQD2 <sub>2cc</sub>	66.7	6.9	50.5-77.2	67.6	7.3	54.6-78.2	1.4	5.1	0.0001

Figure 1. Correlation between the planning CT and kV-CBCT doses for OARs.

Variations higher than 10% of EQD2 were found in 1/19 (5%) patients for bladder and 2/19 (10%) for rectum and sigmoid, while the (GYN) GEC-ESTRO recommendations for OARs dose limits were met in 15/19 (79%) patients for bladder and 17/19 (89%) for rectum and sigmoid. A weak yet statistically significant correlation was found between volume and  $D_{2cc}$  variations for bladder ( $R^2=0.320$ ,  $p=0.0001$ ), but not for rectum and sigmoid. The time gap between CT and CBCT acquisitions was of  $125 \text{ min} \pm 48 \text{ min}$  (range: 47-204 min). No correlation was found between this time and OARs dose or volume variations.

#### Conclusion

OARs dose intra-fraction variations in HDR BT for cervical cancer are small on average, but large random variations were observed in individual patients. Differences are likely attributed to changes in volume for the bladder and to deformation and movement for the rectum and sigmoid.

A kV-CBCT scan acquired before dose delivery can detect unfavorable anatomical changes, warranting adaptive strategies.

Our data show that without adaptive planning, 21% of the patients will have a chance that at least one OAR will exceed the recommended limits, though a variation in EQD2 higher than 10% will occur in only 10% of them.

#### OC-0178 Indirect Excess Dose Volume Ratio (iRex): A Novel predictor of Late Toxicity in Cervical Cancer IGBT

T. Prasartseree<sup>1</sup>, P. Dankulchai<sup>1</sup>

<sup>1</sup>Faculty of Medicine- Siriraj Hospital- Mahidol University, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand

#### Purpose or Objective

Excess intermediate to high dose out of HR-CTV in IGBT associates with OAR toxicity.  $D_{2cc}$ ,  $D_{1cc}$ , and  $D_{0.1cc}$  demonstrate the dose-toxicity relationship with a limitation of identical locations of the most exposed volumes assumption. From observation, isodose surface volume (ISV) of intermediate dose usually covered the movable space of pelvic organs. To minimize effects of the organ motion in toxicity prediction, Excess Dose Volume (Vex) and its Excess Dose Volume Ratio (Rex), transformed from ISV, were proposed and probably be used as IGBT dose constraints. Indirect Excess Dose Volume Ratio (iRex), the more practical form derived

from Vex and Rex, was studied to demonstrate its correlation with late GI and/or GU toxicities in cervical cancer.

#### Material and Methods

149 cervical cancer patients treated with 44-52 Gy EBRT without central shielding, parametrial or pelvic nodal boost, or re-irradiation with/without chemotherapy with Gynaecologic GEC-ESTRO II directed HDR-IGBT in 2012-2015 were retrospectively reviewed. Late GI and/or GU toxicities were graded using CTCAE version 5.0. The iRex of each IGBT fraction was defined as  $ISV/V_{neg}$ . ISVs were transformed from isodose lines of fractional absorbed doses corresponded to EQD2 ( $\alpha/\beta=3$ ) of 60, 70, 80, 90 and 100 Gy.  $V_{neg}$  was the intercepted volume of ISV (60 Gy EQD2) and delineated toxicity-negligible regions including HR-CTV, uterus, and vagina. No further delineation of any OAR was performed. Numerical mean of iRex was established for each patient. The data of cumulative events of GI and/or GU toxicities was generated to determine the correlations between mean iRex and grade 2-4 late toxicities, using probit analysis.

#### Excess dose volume and its ratio: Vex, Rex, and iRex

**Isodose surface volume (ISV):** Transformed volume from isodose level of 60, 70, 80, 90, and 100 Gy EQD2 ( $\alpha/\beta=3$ )

**Toxicity-negligible volume (Vneg):**

$$V_{neg} = ISV(60 \text{ Gy EQD2}_3) \cap [HR-CTV \cup V_{uterus} \cup V_{vagina}]$$

**Excess dose volume (Vex):**

$$V_{ex} = ISV - V_{neg}$$

**Excess dose volume ratio (Rex):**

$$R_{ex} = V_{ex}/V_{neg} = ISV/V_{neg} - 1$$

**Indirect excess dose volume ratio (iRex):**

$$iR_{ex} = ISV/V_{neg}$$

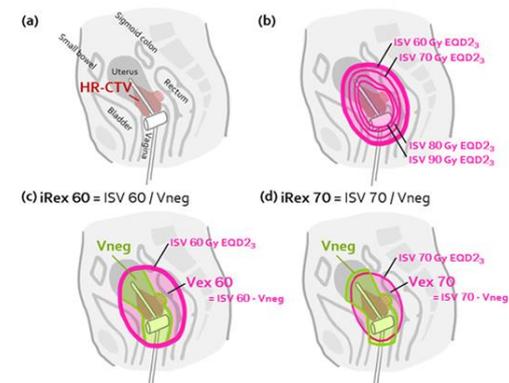

Diagram showing (a) Pelvic organs and HR-CTV, (b) ISV 60, 70, 80, 90 Gy EQD2, (c) ISV 60 Gy EQD2, Vneg, and Vex 60, (d) ISV 70 Gy EQD2, Vneg, and Vex 70

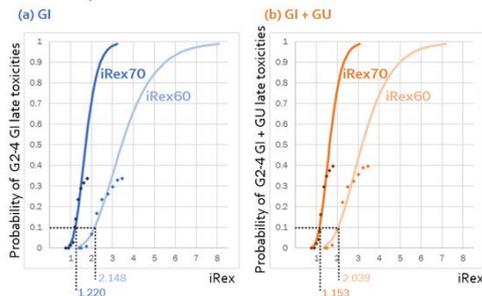

#### Results

50, 15, and 59 patients were affected from grade 2-4 late GI, GU, and combined GI and/or GU toxicities, respectively, with median follow-up time of 36 months. Mean iRex and toxicities correlations established the significant dose-response relationships for iRex60, iRex70 - late GI toxicities and iRex60, iRex70 - combined GI and/or GU toxicities. The effective ratio at 10 percent response values for iRex60 and iRex70 were 2.148 and 1.220 for grade 2-4 GI toxicities. For grade 2-4 combined GI and/or GU toxicities, the effective ratio at 10 percent response values for iRex60 and iRex70 were 2.039 and 1.153.

**Probability of G2-4 late toxicities according to iRex**

iRex	Probability of iRex for G2-4 late toxicities at the incidence rates shown (95% CI)			p value

iRex100	0.485 (0.480-0.489)	0.530 (0.526-0.533)	0.590 (0.587-0.593)	0.631

**Relationship between iRex and G2-4 late toxicities in**

**Conclusion**

iRex significantly established dose-response relationships with grade 2-4 late GI and/or GU toxicities in retrospective data, especially iRex60 and iRex70. Regarding of pelvic organ geometrical uncertainties, with further investigation, the proposed Vex, Rex, and iRex concept could probably be used as the novel IGBT dose constraints in addition to D2cc, D1cc, and D0.1cc.

**Proffered Papers: PH 3: Proffered paper: New developments in automated treatment planning**

**OC-0179 Clinical implementation of plan quality control for automated prostate planning**

M. Kusters<sup>1</sup>, F.J. Dankers<sup>1</sup>, P. Van Kollenburg<sup>1</sup>, R.J. Smeenk<sup>1</sup>, R. Monshouwer<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Academic Department of Radiation Oncology, Nijmegen, The Netherlands

**Purpose or Objective**

Currently most of our radiotherapy plans are automatically generated with a single treatment technique template in the Auto-Planning module in Pinnacle 16.0.2 (Philips Healthcare, Fitchburg, WI, USA). An inhouse-developed plan quality control tool (planQC) was built to check the quality of our automated prostate plans. This tool predicts a personalized dose-volume histogram (DVH) for each organ-at-risk (OAR) based on the anatomy of each individual patient. In this study the planQC tool was clinically implemented.

**Material and Methods**

Historical data of 129 automatically planned clinical prostate patient plans which all fulfill the clinical criteria were used to train and test a prediction model. In all these plans one single VMAT arc was used (95 to 265°), by which 70 Gy is given in 28 fraction of 2.5 Gy. The model was trained on 100 plans and validated on a separate test set of 29 plans based on a random split. The model was made by first calculating principal components (PCs) of the DVH and overlapping volume histogram (OVH), where the latter is a measure to capture individual patient anatomical information. Second, the calculated PCs were used to

train a support vector regression model that predicts DVH PCs from OVH PCs (see Figure 1). In our clinical workflow the planQC tool is initiated when the dicom data of a final clinical plan is exported from the treatment planning system to the planQC DICOM node, where the planQC tool application is executed. The application calculates the predicted and planned DVH curves and generates a personalized scorecard in a PDF report. The report is added to the departmental oncology information system (OIS) and reviewed by the planner. Threshold levels of 3 Gy for dose and 3% for dose and volume metrics at the OARs are set to detect if a plan is eligible for replanning. Plans are replanned by changing the treatment technique template for each of the OAR dose parameters that can be improved and starting the Auto-Planning again.

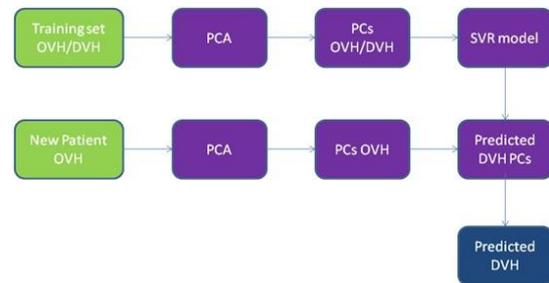

Figure 1

**Results**

The planQC tool was incorporated into the clinical workflow of automated prostate planning on March 1st 2018. Currently, 40 clinical prostate plans have been checked by planQC. For 8 of the 40 patients the plans did not pass the check and further optimization of the plan was done. In Figure 2 an example of a patient plan is shown where the planQC tool detected a suboptimal mean dose for the bladder (upper panel). After replanning the mean dose of the bladder was reduced by 5.3 Gy (lower panel), from 28.2 Gy to 22.9 Gy. In general, the mean improvement for the 8 plans was 3.6 Gy/% for the metrics of the OARs which were improved.

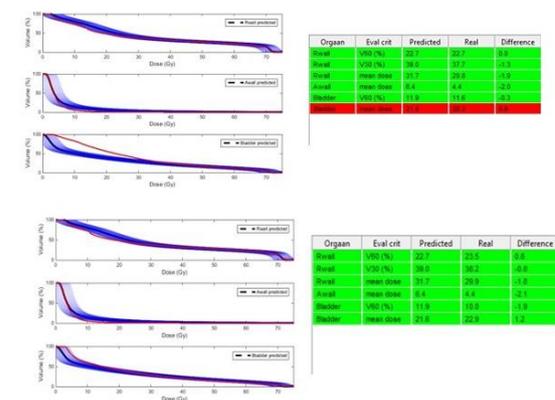

Figure 2: Result before (upper) and after replanning (lower panel)

**Conclusion**

A planQC tool was successfully introduced in the clinical workflow and monitor the quality of automated prostate plans. It can be used to detect plans that deviate from model development cohort and can therefore possibly be improved. For 8 of the 40 patients the plan was labelled suboptimal and could be improved.

### OC-0180 Towards a comprehensive automatic planning with deep neural networks: dose prediction for lung IMRT

A.M. Barragán Montero<sup>1,2</sup>, D. Nguyen<sup>2</sup>, W. Lu<sup>2</sup>, M. Lin<sup>3</sup>, X. Geets<sup>1</sup>, E. Sterpin<sup>1</sup>, S. Jiang<sup>2</sup>

<sup>1</sup>Université Catholique de Louvain- Institute of Experimental & Clinical Research, Molecular Imaging-Radiotherapy and Oncology MIRO, Brussels, Belgium ;

<sup>2</sup>UT Southwestern Medical Center, Medical Artificial Intelligence and Automation MAIA, Dallas, USA ; <sup>3</sup>UT Southwestern Medical Center, Radiation Oncology, Dallas, USA

#### Purpose or Objective

Most automatic planning strategies, such as knowledge-based planning, are based on the prediction of one-dimensional dose volume objectives that are insensitive to the spatial features of the dose distribution, hampering to achieve more individualized treatments. In addition, they rely on consistent beam and dosimetric characteristics among the training database, and often fail in cases where the beam configuration or the anatomy is significantly different. Our model uses neural networks to directly predict 3D dose distributions, combining both dosimetric and anatomical information in order to increase the robustness against heterogeneous patient populations.

#### Material and Methods

The model combines two recent deep learning architectures, UNet and DenseNet, to learn from previous clinical plans. The UNet is a type of convolutional neural network able to include local and global features from the input images. It was modified with the densely connected convolutional architecture used in DenseNet, to achieve a more efficient feature propagation. We used several input channels to include anatomical information from delineated contours (PTV and OARs, 9 channels) and per-beam dosimetric data (1 channel). A set of 129 lung cancer patients treated with IMRT, with heterogeneous beam configuration (4 to 9 beams) and orientation, was used for training/validation (100 patients) and testing (29 patients). Mean squared error was used as objective loss function.

The stability of the model was evaluated by using a 5-fold cross-validation approach, where the model was randomly initialized, trained with 80 patients, and validated with the remaining 20 patients, using a different training/validation combination for each fold. The accuracy of the model was evaluated by comparing the mean dose (Dmean) and other relevant metrics for clinical practice in the predicted and real doses.

#### Results

Figure 1 presents the average absolute error and its standard deviation (SD) on Dmean for the target and OARs for cross-validation (Figure 1.a, average prediction on the validation set for all 5 folds), and testing (Figure 1.b, average prediction on the test set for all 5 folds). The error on Dmean was below 2.5% of the dose prescription for all considered organs, in both cross-validation and testing. Figure 1.c and 1.d show the mostly overlapping DVHs for one of the test patients and the dose at the center of the target, respectively. Table 1 reports some relevant DVH metrics, most of them below 2%, except D2 for esophagus (> 4%) and spinal cord (> 5%). The training time was about 10h and the time employed to predict the 3D dose for a new patient was around 12 s.

Absolute mean error for DVH metrics			
		Cross-validation (mean ± SD)	Testing (mean ± SD)
PTV	D99 (% of D <sub>pre</sub> )	2.69±2.78	2.38±2.32
	D98 (% of D <sub>pre</sub> )	1.98±1.86	1.69±1.56
	D95 (% of D <sub>pre</sub> )	1.20±0.92	1.17±1.02
	D5 (% of D <sub>pre</sub> )	0.79±0.66	0.80±0.69
Esophagus	D2 (% of D <sub>pre</sub> )	4.13±4.59	4.85±5.41
	V40 (% of volume)	0.06±0.09	0.07±0.09
	V50 (% of volume)	0.07±0.09	0.07±0.08
Heart	V35 (% of volume)	0.09±0.14	0.10±0.16
Spinal cord	D2 (% of D <sub>pre</sub> )	6.95±5.57	5.83±4.36
	Dmean (% of D <sub>pre</sub> )	1.14±0.93	0.94±1.00
Lungs	V5 (% of volume)	0.02±0.04	0.02±0.05
	V20 (% of volume)	0.03±0.05	0.04±0.06

Table 1. Absolute error (mean±SD) for relevant metrics on the target and several organs. The values are expressed as percentage of the dose prescription (D<sub>pre</sub> = 60 Gy) for the metrics reporting the dose received by x% of volume (Dx), and as absolute difference for the metrics reporting the volume (in % receiving a dose of y Gy (Vy)).

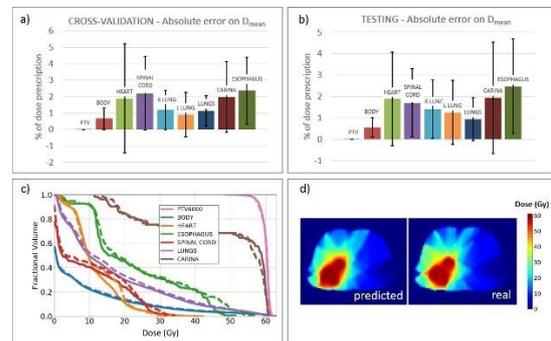

Figure 1. Absolute error on D<sub>mean</sub> for cross-validation (Figure 1.a) and testing (Figure 1.b), expressed as percentage of the dose prescription. The color bars represent the mean value, while the black solid lines represent the standard deviation. Figure 1.c contains the DVHs for one of the testing patients, solid lines correspond to the real dose and the dashed lines to the prediction. Figure 1.d shows the 3D dose (real and predicted) at the center of the target (axial view) for the same test patient.

#### Conclusion

The proposed architecture was able to learn from a very heterogeneous database in dosimetric terms, and generated accurate 3D dose distributions that can be later used as voxel-wise objective to create patient-specific treatment plans. This represents an important step towards an easier and more robust implementation of automatic planning techniques.

### OC-0181 Prostate auto-planning in clinical practice: evaluation of plan acceptance and manual adaptations

R. Van Der Bel<sup>1</sup>, D.A. Eekhout<sup>1</sup>, G.H. Wortel<sup>1</sup>, G. Van Der Veen<sup>1</sup>, R.H. Harmsen<sup>1</sup>, F.J. Pos<sup>1</sup>, T.M. Janssen<sup>1</sup>, E.M.F. Damen<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Radiotherapy Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

Implementation of auto-planning techniques may improve plan quality and consistency in plans and provide a possible time gain. In our clinic we have implemented auto-planning for prostate in 2016. In this retrospective study we aim to evaluate the effectiveness of prostate auto-planning. Therefore, we determined the acceptance rate of auto-plans and investigated the manual alterations made, their effect on the dose distribution and the clinical relevance of these interventions.

#### Material and Methods

Prostate auto-planning is performed using Pinnacle Auto-Planner (Pinnacle 9.10, Philips, Fitchburg, USA) in combination with an in-house post-script for fine tuning. A PTV coverage V<sub>95%</sub> of 99% was strived for. For 177 prostate cancer patients, irradiated at two dose levels with 35x2/2.2Gy between January 2017 and July 2018, DVH data of both the auto-plan (including post-script) as well as the clinically used plan were available for analysis.

DVH parameters and optimization objectives were extracted from archived DVH reports. Data were analysed in SPSS.

### Results

In 10.7% (n=19) of cases the auto-plan was directly accepted for treatment. In 46.9% (n=83) of cases, MUs were scaled before accepting the auto-plan. In 40.1% (n=71), the auto-plan was optimised further. In 2.3% (n=4) of all cases, the auto-plan was rejected entirely and a new plan was made manually. We could identify the following reasons for manual adaptations:

- **Bowel loop:** 14.7% of plans (n=26), a bowel loop was near the PTV. In 4 cases MU were scaled and 22 cases were optimised further.
- **Target coverage:** Upscaling of MUs (n=43) is done to improve target coverage. These auto-plans had a mean  $V_{95\%}$  of  $98.87 \pm 1.12\%$ , upscaling resulted in a mean  $V_{95\%}$  of  $99.41 \pm 0.25\%$  ( $p < 0.001$ ).
- **Hot or cold spots:** Downscaling of MUs (n=40) is mainly done to reduce the high dose volume. Before downscaling, auto-plans had a  $V_{103\%}$  of  $1.11 \pm 1.39\%$ , downscaling resulted in a  $V_{103\%}$  of  $0.48 \pm 0.62\%$  ( $p = 0.002$ ). In 22 cases additional objectives were required to counteract hot or cold spots in the plan.

Figure 1 shows PTV coverage of the auto-plan vs the clinical plan and denotes the reason for manual adaptation. These adaptations had no significant effect OAR mean dose (rectum, anal sphincter) ( $p > 0.141$ ). All manual plans were made due to the presence of a hip prosthesis or bowel loop.

### Conclusion

Although, clinical plans were based on the auto-plan in 97.7% of cases, the direct acceptance rate of auto-plans, including a post-script for fine tuning, was low at 10.2%. Rescaling of MU's was the most performed adaptation, which is easily automated by adding an auto-prescribe step. Overall, the effects of plan adaptations were small and might not have been clinically relevant. These data give rise to further discussion between physicists, physicians and RTTs to provide inside into what manual adaptations would be clinically relevant. Development of automated decisions tools to identify non-optimal treatment plans may be of great value for improvement of auto-planning practice.

### OC-0182 Automated (non-coplanar) beam selection for IMRT in young female lymphoma patients reduces OAR doses

P. Cambraia Lopes<sup>1</sup>, L. Rossi<sup>1</sup>, J. Leitão<sup>1</sup>, C. Janus<sup>1</sup>, M. Van de Pol<sup>1</sup>, J. Penninkhof<sup>1</sup>, B. Heijmen<sup>1</sup>  
<sup>1</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands

#### Purpose or Objective

There are as many variations in tumor location, shape and size in lymphoma patients, as in radiotherapy (RT) techniques clinically applied (Maraldo et al. Int J Radiat Oncol Biol Phys 2015, 92(1):151). This population might therefore benefit from patient-specific, computer selection of beam angles. We investigated the potential dosimetric advantages of automated beam angle selection (BAS), in both coplanar (CP) and non-coplanar (NCP) settings, for young mediastinal lymphoma females, with or without involvement of supraclavicular or axillar nodes, including bulky disease.

#### Material and Methods

A total of 23 patients were included with mediastinal lymphoma disease (PTV sizes: 97cc - 1308cc, median: 495cc; median age: 26 years). Erasmus-iCycle was used to automatically generate treatment plans with/without

BAS. The applied optimization protocol as defined by the 'wish-list' containing the planning hard constraints and prioritized objectives was tailored to RT of young females, where late toxicity to breasts, heart, and lungs are of great concern. The prescription dose was 30 Gy. Coplanar (BAS-CP) and fully non-coplanar (BAS-fNCP) plans were generated (min. beams=5, max.=15), for couch and gantry angles that are possible at the treatment unit. The optimal number of beams and the most common couch positions were investigated. For a subgroup of 16 patients, CP IMRT plans were generated with the clinically used beam angles, typically 5-7 beams manually selected from (and close to) anterior and posterior directions (CLIN-CP).

### Results

BAS-CP plans with the same number of beams as the CLIN-CP plans resulted in similar OAR doses for the same PTV coverage ( $V_{95\%}=98\%$ ), but lower integral patient dose ( $V_{15Gy}$ ,  $V_{20Gy}$ ). The addition of CP beams (10 vs 5) resulted in (1) improvements in heart and lung Dmean for all patients, on average -0.7 Gy (max. -2.4 Gy), and -0.8 Gy (max. -1.6 Gy) improvement respectively; (2) decrease in lung  $V_{5Gy}$  by more than 5% for 6 patients; and (3) a decrease in patients with breast Dmean over 2 Gy (5 vs 8). BAS-fNCP plans showed further reductions in OAR doses relative to BAS-CP: (1) the average lung and heart Dmean were lower by 0.5 Gy and 0.7 Gy, respectively; (2) a decrease in heart Dmean >1 Gy was found for 8 patients (max. 2.4 Gy); (3) a decrease in lung Dmean  $\geq 1$  Gy for 5 patients (max. 1.9 Gy), along with reductions in lung  $V_{5Gy}$  ranging from 6-20%, and (4) less patients with breast Dmean over 2 Gy (3 vs 5). BAS-fNCP with 15 beams resulted in the largest differences with CLIN-CP, with improvements (mean $\pm$ SD) of -1.3 $\pm$ 1.2 Gy (max. -3.6 Gy) and -1.2 $\pm$ 0.7 Gy (max. -3.0 Gy) for the heart and lung Dmean, respectively, and 5% lower lung  $V_{5Gy}$  on average (max. 20%), while the Dmean on both breasts was <2 Gy for 15/16 for BAS-fNCP, compared to 13/16 with CLIN-CP.

#### Purpose or Objective

Automated treatment planning (AP) and multi-criteria optimization via Pareto navigation (MCO) are two important innovations within the field of radiotherapy

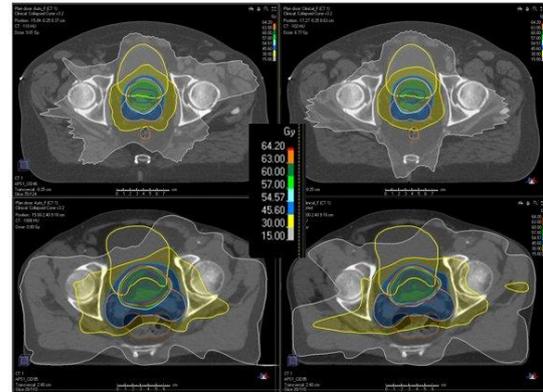

treatment planning, with AP promising step changes in planning efficiency, and MCO enabling a more intuitive exploration of competing trade-offs. Recently a novel fully automated solution (EdgeVcc), which incorporates MCO within the calibration process, has been developed in RayStation (RaySearch Laboratories, Stockholm, Sweden) using scripting and validated in a single institutional setting. This work presents results from a further study across two independent centers for prostate cancer and aims to evaluate the use of MCO in propagating automated solutions across institutions with differing planning techniques or aims.

### Material and Methods

For each institution ( $I_A$  and  $I_B$ ) 30 previously treated prostate cancer patients were randomly allocated into a calibration cohort ( $n=10$ ) and validation cohort ( $n=20$ ). A set of planning goals, comprising of constraints and trade-offs, were defined and the MCO guided calibration process performed on a single calibration patient. MCO enabled differing treatment options to be intuitively explored, with competing trade-offs balanced according to the institutional planning aims. The resultant automated solution was tested across all calibration patients, with planning goals or trade-off balancing (via MCO) refined as required. Following successful calibration, a single automated plan (VMAT<sub>Auto</sub>) was generated fully autonomously for each patient in the validation cohort. VMAT<sub>Auto</sub> plan quality was compared against the previously treated clinical plan (VMAT<sub>Clinical</sub>) quantitatively, using a range of DVH metrics, and qualitatively through blind review by an oncologist and dosimetrist pair based at the local institution.

### Results

A summary of the quantitative and qualitative results is provided in Table 1, with example dose distributions provided in Figure 1. For both institutions automation led to statistically significant improvements across the majority of rectal dose metrics, and D98% for the low and intermediate ( $I_A$  only) dose PTVs. VMAT<sub>Auto</sub> reduced bladder doses for  $I_B$  but for  $I_A$  they were increased. There were also small differences in the conformality indices and D2% between the two techniques, with VMAT<sub>Clinical</sub> performing slightly better, however this did not prevent both institutions from demonstrating a clear preference towards VMAT<sub>Auto</sub>. Across all study patients 92.5% and 95% of VMAT<sub>Auto</sub> plans were considered equivalent or better than VMAT<sub>Clinical</sub> by the reviewing oncologist and dosimetrist respectively.

**Figure 1:** Example dose distributions for institution A (top) and institution B (bottom) with VMAT<sub>Auto</sub> to the left and VMAT<sub>Clinical</sub> to the right

### Conclusion

An MCO guided automated planning solution has been successfully validated against clinical practice in two independent institutions. The novel calibration process enabled intuitive adaptation of automated protocols to an institution's individual planning aims and yielded plans more congruent with the oncologist's clinical preference.

### OC-0184 Predicting patient specific treatment planning Pareto fronts based on anatomy only

E. Van der Bijl<sup>1</sup>, Y. Wang<sup>2</sup>, S.F. Petit<sup>2</sup>, T. Janssen<sup>1</sup>

<sup>1</sup>The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands;

<sup>2</sup>Erasmus MC Cancer Institute, Department of Radiation Oncology, Rotterdam, The Netherlands

### Purpose or Objective

Automated treatment planning is an effective solution to generate fast, consistent treatment plans on the Pareto front (PF). It leads to a single treatment plan that has a specific trade-off between conflicting objectives. Upfront knowledge of the PF will allow to direct automated planning to a plan with a non-standard trade-off tailored to the individual patient and helps with configuring new automated planning solutions. However, even with automatic planning systems a quick upfront estimate of the PF for every patient is clinically infeasible due to the large number of plans that needs to be generated. Since the PF in principle depends only on patient anatomy and delivery system, the purpose of this work is to demonstrate the feasibility of predicting the patient specific PF based only on patient anatomy since only the anatomy varies from patient to patient.

### Material and Methods

The inhouse TPS Erasmus-iCycle was used to generate 42 treatment plans for 115 prostate patients delivering 60Gy in 20 fractions (4830 treatment plans in total). Erasmus-iCycle uses a wish list of prioritized objectives and per definition generates plans on the PF. Here 42 different wish lists were used to create treatment plans on the PF spanned by rectum Dmean, the homogeneity (parameterized by PTV-Dmax) and the conformity, defined as the Dmax at 1cm distance to the PTV. All plans were normalized such that PTV D99% = 95%. First, for all patients the obtained PFs were parameterized using three parameters per patient that were estimated using least squares fitting. Then, patient specific features were selected to predict the parameters of the PF based on patient anatomy, using support vector regression with radial basis function kernels. The features were the proportion of the rectum and average area of the patient outline at the slices of the PTV, the volumes of PTV and rectum and the radii corresponding to 1,10, 50, 90 and 99% overlap of the PTV-rectum overlap volume histograms. The model was trained on 80% of the patients

**Table 1** Dosimetric comparison of VMAT<sub>Auto</sub> and VMAT<sub>Clinical</sub> for Institution A and B (mean  $\pm$  standard deviation). CI: Paddick's Conformity Index for the specified PTV.

using a train-test split approach and validated on the remaining 20%. The performance of the predictions is scored using the rms difference of the actual versus the predicted rectum Dmean for given homogeneity and conformity.

**Results**

Observed rectum-Dmean values ranged 5-28 Gy over all plans and patients. Ranges for the homogeneity and conformity were 97-108%, 69-94% of the prescribed dose, indicating that we sampled a large part of the PF. The PFs could be described well using the 3 parameter parametrization (rms difference of 0.9 Gy in the rectum-Dmean direction), see Figure 1. The model led to an excellent prediction of the patient specific PF, the rms difference between the fit and the prediction was 0.5 Gy. The rms difference to the actual value was 1.1 Gy.

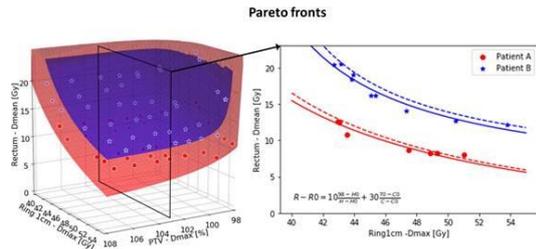

Figure 1: Pareto fronts for two patients in the validation set. The left panel shows the 3D distribution of plans and the surfaces. The right panel is the slice through the fronts at constant homogeneity (H = PTV-Dmax = 103%). The points corresponds to treatment plans with H in range 102%-104%. The Pareto fronts are parameterized by the equation with R0, H0 and C0 the patient-specific fit parameters and R and C the rectum Dmean and conformity respectively in percentage of the prescribed dose. Solid lines represent the fit to the data, the dashed lines is the predicted Pareto front based on the delineations only.

**Conclusion**

We successfully demonstrated that that patient specific PF could be predicted based on patient anatomy only, for a relatively simple site as the prostate.

**OC-0185 A multi-centre knowledge-based treatment planning model for radiotherapy of cervical cancer**

E. Adams<sup>1</sup>, M. Hussein<sup>2</sup>, S. Currie<sup>3</sup>, C. Thomas<sup>4</sup>, C. South<sup>1</sup>, A. Greener<sup>4</sup>, G. Currie<sup>3</sup>, A. Nisbet<sup>1</sup>

<sup>4</sup>Guy's and St Thomas' NHS Foundation Trust, Radiotherapy Physics, London, United Kingdom

**Purpose or Objective**

There can be significant resource requirements in the initial setting up of Knowledge Based Treatment Planning (KBP) models for different treatment sites, particularly as the models depend on a sufficiently sized library of clinically acceptable plans. This can be a barrier for centres with a small number of patients and in rarer clinical sites. Sharing between cancer centres may overcome these issues. The purpose of this work was to address two key questions; whether a KBP model developed in one institution could be successfully used in another; and whether combining the expertise of the different institutions could lead to an improved model. These questions were addressed for the case of cervical cancer VMAT planning in the UK RapidPlan consortium (UKRC) of centres using Varian RapidPlan KBP.

**Material and Methods**

An RP model from one of the UKRC centres, C1, was selected for multi-centre testing. This model had been fully developed and benchmarked for planning cervical cancer cases using VMAT, including both post-hysterectomy and intact uterus cases, with prescribed doses of 45-50.4Gy in 1.8Gy/#. This model (Model<sub>C1</sub>) was shared with two other UKRC centres, C2 and C3, who used the model to generate plans for fourteen patients who had

previously been treated in their respective hospitals. The Model<sub>C1</sub> plans were compared to the clinical plans using the respective local plan acceptance; for C2, the clinical plans had been generated using their own validated in-house RP model; for C3 they were generated using template-based optimisation.

Based on the feedback and learning experience of the model comparisons, further refinements to the Model<sub>C1</sub> parameters were tested. Model<sub>C1</sub> and the refined models were evaluated for ten patients from C1 using a single optimisation without user interaction. The resultant plans were compared using a consensus set of plan acceptance criteria which incorporated the different metrics used in each of the three centres.

**Results**

Initial testing of Model<sub>C1</sub> compared to clinical plans from centres C2 & C3 showed improvements in OAR sparing at higher dose levels, but increased doses at lower dose levels, with higher mean doses for bladder and rectum in Model<sub>C1</sub> compared to clinical plans. Two different approaches (Model<sub>UKRC1</sub> and Model<sub>UKRC2</sub>) to addressing the potential areas for improvement were taken. Both gave statistically significant improvements in OAR sparing, but for Model<sub>UKRC1</sub>, this was at the expense of PTV coverage and homogeneity (see Table 1). However, Model<sub>UKRC2</sub> was able to achieve similar OAR dose reductions with only minimal impact on PTV doses (see Fig 1).

**OC-0186 A system of materials capable of mimicking soft tissues and bone with both CT and MR imaging.**

K. Singhrao<sup>1</sup>, J. Fu<sup>1</sup>, Y. Gao<sup>2</sup>, P. Hu<sup>2</sup>, Y. Yang<sup>1</sup>, J.H. Lewis<sup>1</sup>  
<sup>1</sup>University of California Los Angeles, Radiation Oncology, Los Angeles, USA; <sup>2</sup>University of California Los Angeles, Radiology, Los Angeles, USA

### Purpose or Objective

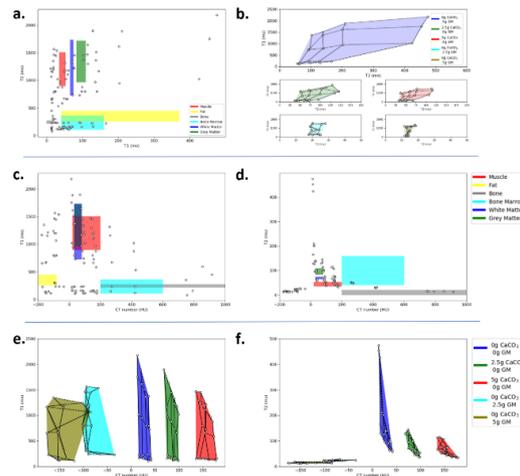

To develop a system of easily made and formed materials with adjustable T1 and T2 relaxation times, and x-ray attenuation properties for mimicking soft tissues and bone in both CT and MR imaging. The growing role of MR in radiotherapy has increased the demand for phantoms capable of cross-modality quality assurance or end-to-end testing. Most commercially available materials and phantoms do not mimic the T1 and T2 relaxation times, and CT numbers for different tissue types simultaneously on both modalities. Producing materials with the capability of producing tissue mimicking contrast on both modalities allows a ground truth to be established for validating a number of medical imaging and therapeutic applications such as MR-CT image registration and each component of MR-only radiotherapy workflows.

### Material and Methods

The effects on T1 and T2 relaxation times, and CT number were measured using a range of concentrations Gd contrast (0 - 250  $\mu\text{mol/g}$ ), agarose (0 - 4 g), glass microspheres (GMs) (0 - 5 g) and  $\text{CaCO}_3$  (0 - 25 g) in a common carrageenan-water gelatinizer. Samples were prepared with the additives, 1.5 g carrageenan and water to weigh a total of 50 g. Samples were imaged in a tissue validation phantom. Each tissue validation phantom contained 20 samples with fixed concentration of  $\text{CaCO}_3$  or GMs. MR images were acquired on a 3T Siemens Skyra and CT images were acquired on a Siemens Somatom. T1 and T2 relaxation time maps were generated using voxel-wise inversion recovery and spin echo signal fitting. A multivariate linear regression-based model (based on fitted coefficients) was generated to predict T1 and T2 relaxation times and CT number based on the concentrations of the 4 additives. Skeletal muscle, adipose tissue, white matter, gray matter, liver, prostate, bone marrow, glandular breast and trabecular bone tissues were mimicked to validate the fit model results and demonstrate the flexible range of values attainable with this system of materials.

### Results

Figure 1(a,c,d) demonstrates that the carrageenan-based system of materials can span a range of T1 values from 82 ms to 2180 ms, T2 values from 12 ms to 475 ms and CT numbers from -117 HU to 914 HU. Figure 1(b,e,f) demonstrates that the addition of 10%  $\text{CaCO}_3$  decreases the maximum T1 range by 36% and maximum T2 range by 83%. Addition of 10% glass microspheres decreases the maximum T1 range by 41% and maximum T2 range by 99%. Using the fit model, we were able to mimic the T1, T2 and CT numbers well compared to literature reported in vivo measurements (Table 1).

Tissue type	a. Tissue mimicking material composition				b. Phantom material measurements				c. Literature reported in vivo measurements		
	Gd (mmol/kg)	Agarose (w/w%)	$\text{CaCO}_3$ (w/w%)	GMs (w/w%)	T1 (ms)	T2 (ms)	CT number (HU)	T1 (ms)	T2 (ms)	CT number (HU)

### Conclusion

We have created a system of carrageenan-based materials capable of simultaneously producing tissue-like contrast for a wide range of human tissues in 3.0T MR and CT imaging. The materials can be cast and formed in the shapes of organs to create anthropomorphic phantoms.

### OC-0187 Comparison of proton range predictions between Single- and Dual-Energy CT using prompt gamma imaging

T. Boon-Keng<sup>2</sup>, Y. Xie<sup>1</sup>, F. O'Grady<sup>2</sup>, A. Lalonde<sup>3</sup>, J. Petzoldt<sup>4</sup>, J. Smeets<sup>4</sup>, G. Janssens<sup>4</sup>

<sup>1</sup>Massachusetts General Hospital, Department of Radiation Oncology, Boston, USA; <sup>2</sup>University of Pennsylvania, Department of Radiation Oncology, Philadelphia, USA; <sup>3</sup>University of Montreal, Department of Physics, Montreal, Canada; <sup>4</sup>Ion Beam Applications, Research, Louvain-la-Neuve, Belgium

### Purpose or Objective

Dual-energy CT (DECT) has been shown to be more accurate for predicting proton stopping power ratios (SPR) than traditional single-energy CT (SECT) calibrations in both surrogate and animal tissue phantoms. Prompt gamma imaging (PGI) is an in vivo imaging modality that has been used to demonstrate the feasibility of proton range verification. In this study, PGI was used to quantify the accuracy of SPR calibration from different CT modalities in a pelvic phantom.

### Material and Methods

Three sets of CT scans were obtained with the Rando phantom using a Siemens Definition Edge CT scanner: 1) 120 kVp SECT; 2) 80/140 kVp sequential DECT scan (SQCT); and 3) 120 kVp Twin-beam scan with Ti/Au dual filter (TBCT). The HU-to-SPR calibration curves were established using the stoichiometric method on SECT and the Eigen tissue decomposition method on DECT scans. Two pencil beam scanning proton plans were created: one with two iso-energy layers and one to cover an artificially drawn target mimicking a prostate treatment. Both plans

were first optimized on SECT then forward calculated on the DECT images. The 1D knife-edge prompt gamma camera system was used to measure the prompt gamma signal profile emitted during the proton beam delivery on a spot by spot basis in pencil beam scanning mode. The shifts in proton range were derived by comparing the recorded PGI profiles with simulations on the different CT images. Aggregation with nearby spots (4 and 8 mm radius) was applied to reduce statistical uncertainty of the retrieved shifts. The calculated range shift detected by the PGI camera was first calibrated on a rectangular water phantom to determine the systematic offset of the PGI system which was then applied to the Rando phantom studies.

**Results**

Figure 1 shows the retrieved proton range shifts with a two iso-energy layer proton plan. The median spot shifts for a 4mm spot aggregation were 6.8 mm/2.7 mm for SECT, 3.3 mm/1.6 mm for SQCT, and -3.3 mm/-4.9 mm for TBCT for 190 MeV (range= 23.8 cm water) and 205 MeV (range= 27.1 cm water) protons respectively.

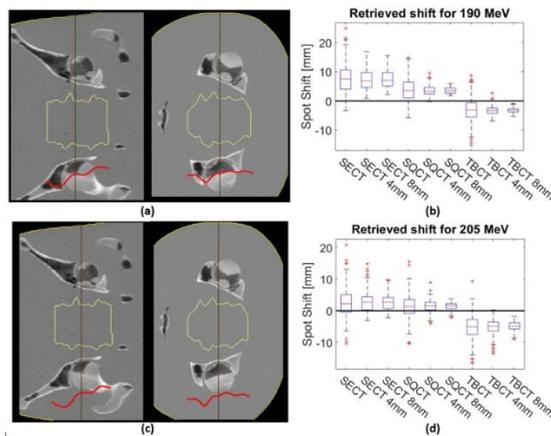

Figure 1: The proton range verification measurements on Rando phantom with two iso-energy layers. Top row figures are for the 190 MeV protons: (a) simulated Bragg peak location (red curve) on SECT (coronal and axial views) and (b) retrieved range shifts for the three CT calibrations (SECT, SQCT, and TBCT). Bottom row (c) and (d) are the corresponding plots for 205 MeV protons. Aggregation with nearby spots (4 and 8 mm radius) was applied to reduce statistical uncertainty of the retrieved shifts.

Figure 2 compared the retrieved shifts for a prostate plan obtained with simulations on three different CT calibrations. For all the layers within the camera’s field of view (FOV), SQCT calibration yielded the best agreement with measurements compared to SECT or TBCT.

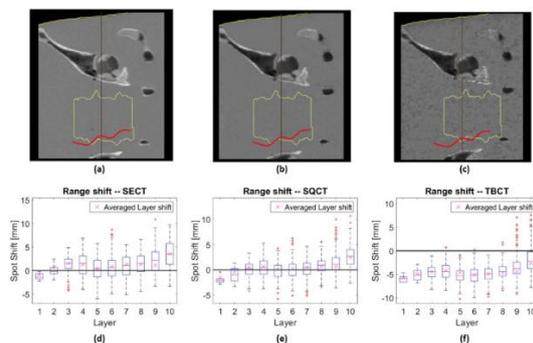

Figure 2: The range verification results comparison among three CT calibrations obtained with Rando phantom. The top row from left to right are the calculated Bragg peak position of one energy layer (red curve) on (a) SECT; (b) sequential DECT scan (SQCT); and (c) simultaneous DECT scan with Twin-beam (TBCT). The bottom row are the retrieved shifts in proton ranges for (d) SECT, (e) SQCT, and (f) TBCT. Only results of energy layers within the camera FOV are plotted.

**Conclusion**

Among the different CT calibrations, the sequential DECT

scan has the highest accuracy in proton range predictions, compared to the Twin-beam DECT method and traditional SECT calibration.

**Purpose or Objective**

Proton therapy is an effective therapeutic option in the treatment of ocular melanomas. Treatment plan is optimized by defining two patients gazing angles (polar and azimuthal) and a brass collimator is used to shape the beam. The patient actively participates in the treatment by fixating a light source, prepositioned according to the treatment plan prescription. At our facility, the fixation light is embedded in an eye tracking (ETS) device which also features optical cameras for eye motion monitoring. The device is mounted on a dedicated robotic arm to guarantee the utmost precision and repeatability in ETS positioning. The system setup is depicted in Figure 1 (a). The close distance between the collimator and the treatment isocenter (7cm) makes for a complicated and sensible treatment setup, particularly considering that the patient wears eyelid retractors and an immobilization mask. Thus, an optimization of the ETS position is required to guarantee a fixation point consistent with the treatment plan while avoiding collisions with collimator and the patient and obstruction of the beam path. In this study we present the development and commissioning of a software application designed to optimize at a patient specific level the ETS position during treatment geometry planning.

**Material and Methods**

The ETS position optimizer is built on a three-dimensional rendering of the treatment setup including all elements: fixed (collimator holder), patient-specific (beam path and patient immobilization mask) and moving (ETS). For each gaze direction, the optimizer evaluates more than 600 ETS positions, consistent with the patient’s gazing angles, and select the one that maximizes distances and avoids collisions between all elements of the setup. To evaluate the capability of properly modelling the treatment scenario (Figure 1(b)), we have used the isocentric stereoscopic X-ray imaging system installed in the treatment room. The ETS and the thermoplastic mask were fitted with radiopaque beads and their 3D position, estimated with the optimizer, was compared to the one measured using radiographies. Errors in the optimizer model was quantified in terms of deviation from the planned gazing angles. The analysis was performed on 11 patients treated between Oct 2017 and Jul 2018, using their specific masks and treatment plans.

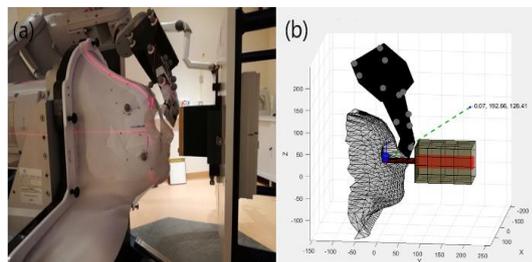

Figure 1: Treatment setup for ocular proton therapy (panel a); Modeling of treatment setup by software application (panel b).

## Results

Results are reported in Table 1. Three-dimensional errors were, on average,  $1.34 \pm 0.19$  mm and  $1.54 \pm 0.35$  mm for the ETS and the mask respectively. These uncertainties propagated into a maximum angular deviations of the fixation direction given to the patient by  $0.6^\circ$ , with an average of  $0.26^\circ$ .

Table 1: Three-dimensional discrepancies between measured and estimated ETS and mask positions. The corresponding deviations from the planned gazing angles are shown.

Patients	3D errors (mm)				Angular deviation ( $^\circ$ )	
	ETS		MASK		Polar	Azimuthal
	mean	std	mean	std		
Patient 1	1.49	0.31	1.63	0.34	0.54	0.19
Patient 2	1.14	0.20	1.34	0.24	0.46	0.60
Patient 3	1.48	0.27	2.17	0.34	0.26	0.03
Patient 4	1.08	0.19	1.02	0.22	0.06	0.10
Patient 5	1.37	0.18	1.34	0.27	0.05	0.26
Patient 6	1.45	0.12	1.74	0.49	0.11	0.14
Patient 7	1.17	0.14	2.14	0.77	0.35	0.50
Patient 8	1.44	0.12	1.45	0.28	0.13	0.43
Patient 9	1.40	0.17	1.03	0.21	0.18	0.36
Average	1.34	0.19	1.54	0.35	0.24	0.29

## Conclusion

The ETS position optimizer is capable of estimating the treatment setup on a geometrical level with errors lower than 1.5 mm. This translates into a deviation to the planned gazing angles below the threshold of clinical significance ( $1^\circ$ ). The proposed method automatically suggests the optimal treatment set-up geometry for a swifter treatment workflow and improved patient safety.

## OC-0189 Brain and Head-and-Neck MRI in immobilization masks: a novel and practical setup for radiotherapy

S. Mandija<sup>1</sup>, F. D'Agata<sup>1</sup>, R. Navest<sup>1</sup>, A. Sbrizzi<sup>1</sup>, C. Raaymakers<sup>1</sup>, R. Tijssen<sup>1</sup>, M. Philippens<sup>1</sup>, E. Seravalli<sup>1</sup>, J. Verhoeff<sup>1</sup>, J. Lagendijk<sup>1</sup>, C. Van den Berg<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

In radiotherapy (RT), it is essential to perform the MRI and CT exams in treatment position. For this purpose and to minimize inter/intra-fraction movement, thermoplastic immobilization masks are used for brain/head and neck (HN) RT. However, standard immobilization masks are incompatible with diagnostic MR head/neck coils. As a compromise, flexible surface coils are adopted despite their technician dependent positioning and inferior signal-to-noise-ratio (SNR) compared to head/neck coils (2-channel vs. the 17-channel for head/neck receive coil). This leads to relatively poor image quality and reproducibility. Here, we explore the feasibility and performance of a new immobilization setup for brain/HN RT, redesigned to fit into the diagnostic head/neck MR coils thereby boosting MR image quality and reproducibility.

### Material and Methods

MR images were acquired on 2 volunteers using a 3T Ingenia MRI (Philips Healthcare, Best, The Netherlands).

The standard and the new RT setups are presented in Fig.1. Several comparative tests were performed.

- **Image quality test:** 3D T1w TFE, 3D T2w TSE FLAIR and 2D T2w TSE scans were acquired for brain, for neck 2D T1w TSE and 2D T2w TSE mDIXON scans were acquired.
- **SNR test:** SNR maps were computed from a T1w scan (2 dynamics, the second being a noise scan) as in (Kellman P., et al. *MRM* (2005)54:1439-47).
- **Motion restriction test:** the maximum motion in the feet-head/left-right directions was estimated from 2D cine-MR T1w bFFE acquisitions (300 dynamics) using Optical Flow (Zachiu C., et al. *Phys Med Biol* (2015)60:9003-29).
- **Inter-fraction repositioning test:** two high resolution 3D T1w sequences were acquired for each setup. Between acquisitions, the immobilization mask was removed and the subject was asked to move to mimic two different MRI sessions. The mean and the standard deviation of the subject movement between each pair of MR acquisitions were computed using Optical Flow as a proxy of the reproducibility of inter-fraction repositioning.

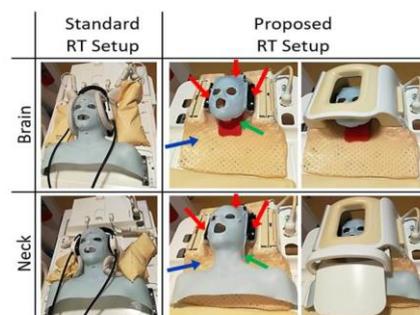

Fig. 1. **The standard RT setup:** individualized five-points head-and-shoulder mask fixated to the MRI flat table top and two MR flexible surface receive coils. **The new RT setup:** individualized three-points mask (for brain) or three-points head-and-shoulder mask (for neck) inside the head/neck coils. A new fixation thermoplastic base (blue arrow) hosting the anchor points (red arrows) for the immobilization masks was created to perfectly fit the head/neck MR coils. A neck support (same of the one used in the standard RT setup) is also integrated (green arrow), which can be made patient-specific. The new setup can be used for both 1.5T and 3T scanners given the same geometry for the base of the head/neck MR coils.

## Results

Brain images acquired with the standard RT coil setup had an inferior diagnostic quality compared to the new setup, especially for the FLAIR contrast (inferior sensitivity in detecting small lesions) (Fig. 2). For neck regions, the image quality was comparable between setups. The proposed setup allowed between 2 and 3 times higher SNR values for both brain/HN MRI (not shown - limited Fig. number).

Comparable motion restriction in the feet-head/left-right directions (maximum motion = 1 mm) and comparable repositioning accuracy (mean inter-fraction movement  $1 \text{ mm} \pm 0.5 \text{ mm}$ ) were observed for the standard and the new setup.

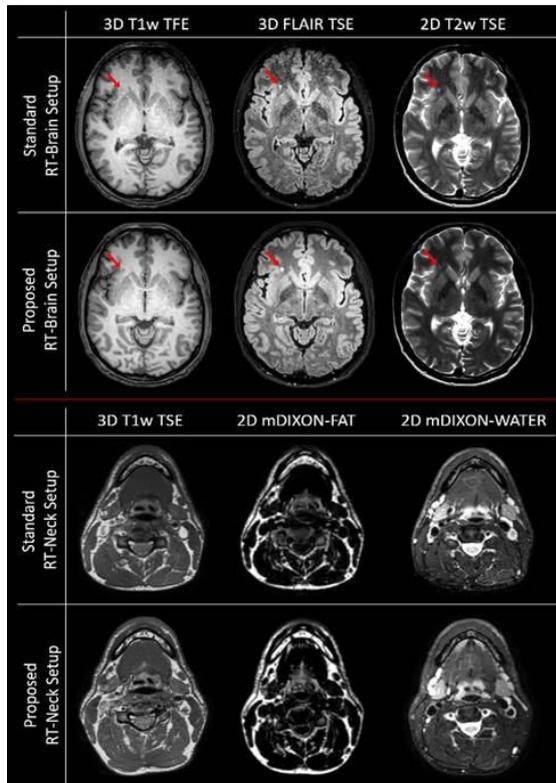

Fig. 2. Image quality comparison for the standard and the proposed RT brain/neck setups. The red arrow points to a white matter lesion.

### Conclusion

We integrated a fixation mask in the diagnostic head/neck MR coils. The proposed setup has several advantages: diagnostic image quality in RT treatment position, high SNR, homogenous signal, restricted motion (1 mm) and accurate inter-fraction repositioning. Translation of the new setup to the treatment table will be investigated.

### OC-0190 Development of Compton-scattered imaging technology for stereotactic radiotherapy of lung cancer

J. Chu<sup>1</sup>, K. Jones<sup>1</sup>, J. Strologas<sup>1</sup>, G. Redler<sup>2</sup>, G. Marwaha<sup>1</sup>, J. Turian<sup>1</sup>

<sup>1</sup>Rush University Medical Center, Department of Radiation Oncology, Chicago IL, USA; <sup>2</sup>University of Chicago, Department of Radiation Oncology, Chicago IL, USA

### Purpose or Objective

Compton scatter is a natural by-product of external beam radiation therapy. The scattered radiation contains information about the patient anatomy and the transient tumor location. Our previous geometrical phantom and computer simulation studies have demonstrated the potential of Compton-scattered imaging for monitoring lung tumor locations during stereotactic ablation radiation therapy (SABR). In preparation for an IRB-approved patient study, we now present experimental results from a new collimator with anthropomorphic and dynamic phantoms.

### Material and Methods

A pinhole collimator was constructed for the study. As seen in Fig 1, the collimator consists of 3 main components, with a wall thickness that can range from 7.6 to 34.7 mm lead equivalent when combinations of different components are used. Spherical tumors (2.1-2.9 cm diameter) embedded in an anthropomorphic LUNGMAN

phantom (Kyoto Kagaku Co.) and another spherical tumor of 3 cm diameter in a QUASAR respiratory motion phantom (Modus Medical Devices Inc.) were irradiated by 6 MV FFF beams from a Varian TrueBeam linear accelerator. The QUASAR phantom was programmed to move sinusoidally at 15 breaths per minute (0.25 Hz) over  $\pm(1.5-2)$  cm to simulate breathing motion. Experimental scatter images were acquired with a 550  $\mu\text{m}$  thick CsI scintillator detector and a pinhole collimator. Tumor centroid locations were measured from various scatter images and compared with the expected values. Contrast-to-noise ratio (CNR) of embedded tumors was calculated for test images to assess their potential for tracking tumor location during treatment.

### Results

The imaging system successfully acquired various phantom images over exposure of 2-1000 MU, or 0.1-50 second time scales. While the lung tumor was discernible for all anthropomorphic phantom images, the image quality improved with increasing collimator thickness. For example, the CNR increased by a factor of 3.6 at 10 MU over the range of collimator thickness studied. The measured tumor centroid locations agreed with the expected values for images from the QUASAR phantom. As shown in Fig 2, the root-mean-squared error (RMSE) for tumor tracking was 0.7-0.9 mm when the phantom was irradiated at 1200 MU/min with an image integration time of 300 ms/frame. As expected, RMSE improved with image integration time, reaching 0.6 mm with 600 ms/frame.

### Conclusion

This study on anthropomorphic and dynamic phantoms confirms the feasibility of using scatter imaging to track lung tumor movement during SABR treatments. The potential benefits may include real-time image guidance in 3D without additional radiation. With the IRB approval of patient studies, we are optimistic that this emerging technology will contribute to improved accuracy and workflow for this highly successful treatment modality.

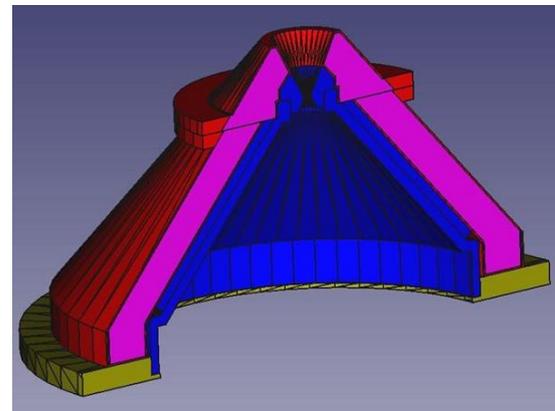

Fig. 1 Cross section of pinhole collimator. Selected shell components can be removed to allow effective wall thickness of 7.6 to 34.7 mm Pb equivalence.

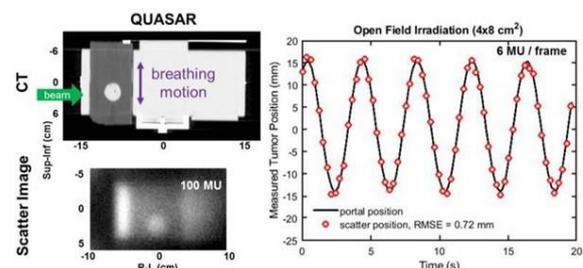

Fig. 2 (left, top): QUASAR phantom CT (coronal slice). (left, bottom) Static scatter image for 100 MU. (right): The scatter image measured position is compared to the true position measured by portal imaging. As shown above, a 3 cm diameter tumor was tracked with a root-mean-squared error (RMSE) of 0.7-0.9 mm for 300 ms (6 MU) frame integration.

**OC-0191 MLC-tracking latencies on Elekta Unity**

M. Glitzner<sup>1</sup>, P. Woodhead<sup>1</sup>, J. Lagendijk<sup>1</sup>, B. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

**Purpose or Objective**

Compared to previous guidance techniques, on-line MRI-guidance promises imaging during radiation and superior soft-tissue contrast. MR-images can be acquired in physiologically relevant frequencies and with clinically acceptable latencies [1]. In this work, we present the current status and latency figures of MRI-guided MLC-tracking on the Elekta Unity (Elekta AB, Sweden), which was previously discussed in [2].

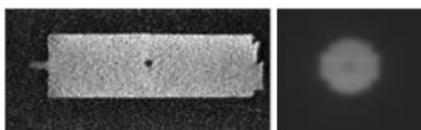

**Material and Methods**

Illustration 1: Phantom in MRI (left) and portal imager (right)

All experiments were performed on a clinical Elekta Unity with modified control software to enable MLC-tracking. The machine integrates a high-field (1.5T) MRI and a 7 MV linac. For the experiments, a circular beam was shaped using the on-board MLC (80 leaf pairs running in IEC1217-y direction). A cylindrical phantom was set in sinusoidal motion using a QUASAR MRI4D motion stage (Modus QA, Canada). The phantom was filled with agar to be detectable by MRI and a  $ZrO_2$  ball bearing for EPID-contrast (Illustration 1). To determine latency between real displacement and the MLC's reaction, EPID images (30Hz frame-rate) captured the position of the moving ball bearing and the projection position of the circular beam tracking the position of the phantom. Both positions were fit to a sinusoidal model which was used to extract the phase shift between the two curves. Real-time position variables for tracking were sourced from 1) the motion stage with real-time position feedback (<1ms latency, 25Hz, STAGE) and 2) MRI images sampled with 4Hz (MRI4Hz) and 8Hz (MRI8Hz), respectively. The MRI images were acquired using T<sub>1</sub>-weighted FFE -sequences (TR/TE=2.6/1.44ms,  $\alpha=6^\circ$ ) and streamed via a proprietary TCP-based interface. The current image position was extracted via detection of the edge of the phantom in the direction of motion.

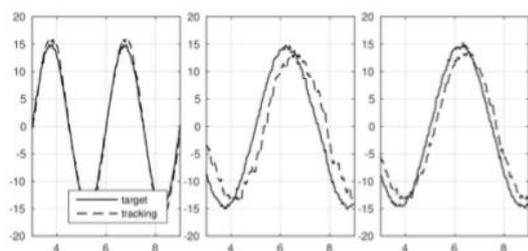

**Results**

Illustration 2: Tracking results for MLCONLY (left), MRI4Hz (center) and MRI8Hz (right)

Illustration 2 shows the tracking results. Naturally, because of the negligible position sensor latency, STAGE matches almost perfectly with the target position. The apparent latency was quantified at 20.67 ms. The tracked position overshoots. This is likely due to the control mode of the control system.

For the MRI-guided tracking, the impact of the longer latency for lower MRI-frequencies become apparent. MRI4Hz yields an apparent latency of 288 ms, while MRI8Hz has a lower latency of only 205 ms. Both MRI-guided

experiments show a loss of amplitude fidelity as the images cannot resolve the peaks of the excursion but can only interpolate between samples.

**Conclusion**

In this work we demonstrate stable tracking responses for the clinical MRI-linac system. Using the independent EPID imager, independent measurements of the tracking performance could be collected. Previously observed oscillatory behavior [2] could be stabilized using an improved version of the control system.

**OC-0192 Prerequisites for using "rapid learning" to optimise technical radiotherapy**

M. Aznar<sup>1</sup>, C. Johnson-Hart<sup>2</sup>, A. McWilliam<sup>2</sup>, M. Van Herk<sup>2</sup>, G. Price<sup>2</sup>

<sup>1</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom; <sup>2</sup>The University of Manchester c/o Christie Hospital- Dept 58- Floor 2A, Division of Cancer Sciences, Manchester, United Kingdom

**Purpose or Objective**

Technical improvements in radiotherapy such as image-guidance are often adopted with enthusiasm without trial or long-term evaluation due to their presumed benefit. "Rapid learning" describes a continuous improvement methodology to monitor the impact of changes and iteratively optimise clinical practice. We previously showed that the direction of residual set-up errors (i.e. shifting the high-dose region *towards* the heart) was *not* correlated with clinical parameters yet strongly correlated with poorer survival in lung cancer patients: this makes shift data vs survival an ideal model system for rapid learning. In this work, we demonstrate that the correlation between residual set-up errors and survival is removed after the application of a stricter IGRT protocol. Since rapid learning must be *rapid*, we also evaluate the minimal number of patients and minimal follow-up to detect this change.

**Material and Methods**

Locally advanced NSCLC patients treated with curative intent in our institution since 2008 were included in the analysis. Patients were treated with IGRT using bony anatomy registration on CBCT (Elekta XVI version 4.2 or 5.0).

Patients were divided into:

1. i) a "before" cohort (pre-November 2016, 780 patients), positioned using an extended non-action level protocol with a 5mm tolerance level,
2. ii) an "after" cohort (post-November 2016, 225 patients), positioned with daily CBCTs and a 2mm tolerance level.

We performed a sensitivity analysis using the "before" cohort to determine the minimal size of the subset of patients required to reliably observe the survival effect. Next, this number of patients was selected from both the "before" and "after" cohorts around the time of implementation of the change i.e. the last and first patients treated with both IGRT protocols, and the analysis repeated.

**Results**

Sensitivity analysis showed that 180 patients (~4 months accrual in our institution), followed up for 1 year, were sufficient to observe the survival effect in the "before" cohort with a power of 0.9 (Fig. 1). The survival discrepancy observed in the "before" cohort was not detected in "after" patients (Fig. 2) - i.e. changing IGRT

protocol significantly reduced the hazard of death to less than that in the “before” cohort.

This shows that a rapid learning approach can provide evidence of the impact of a change to clinical practice in a much shorter timeframe (<1.5 year) than that of a clinical trial.

#### Conclusion

This retrospective analysis demonstrates that continuous monitoring of patient outcomes, or rapid learning, can systematically provide evidence of the impact of even small changes in radiotherapy practice, and highlight where improvements can be made. Furthermore, as it necessarily takes place within a continuously monitored environment, it can make implementing such changes safer as adverse effects will be quickly detected. Rapid learning is complementary to clinical trials, provided that appropriate model system is used.

### Proffered Papers: RTT 2: A patient centered approach to follow up

#### OC-0193 Mobile application for daily patient scheduling during radiotherapy treatment course

J. Kauppinen<sup>1,2</sup>, M. Kokkonen<sup>2,3</sup>, M. Kaunisto<sup>4</sup>, J. Seppälä<sup>1</sup>  
<sup>1</sup>Kuopio University Hospital, Center of Oncology, Kuopio, Finland; <sup>2</sup>Healthcare Mobile Solutions, Medical department, Kuopio, Finland; <sup>3</sup>Kuopio University Hospital, Nuclear Medicine department, Kuopio, Finland ; <sup>4</sup>Kuopio University Hospital, Living Lab, Kuopio, Finland

#### Purpose or Objective

Currently most of the radiotherapy (RT) treatments are delivered with multiple treatment fractions in consecutive days. The RT patients are scheduled for a certain treatment machine and a daily pattern is given as a sequence of treatment days. Currently in most of radiotherapy departments in Finland the detailed timeslots are given to the patient once a week in advance on a paper. The purpose of this work was to determine whether a mobile phone application designed for patient scheduling can replace the previous workflow and simultaneously enhance the scheduling process overall and reduce the workload of the RT personnel.

#### Material and Methods

The testing of a mobile application (HMS, Healthcare Mobile Solutions) for patient scheduling was carried out at Kuopio University Hospital Radiotherapy department. During the three months testing phase (October 2017 - January 2018) 30 radiotherapy patients were involved in the test run. The initial and final patient daily scheduling was organized in Mosaiq (v2.62, Elekta AB, Stockholm, Sweden) patient verification system. The corresponding timeslots were given to the patients by the mobile application and also on the paper “time card”, since we wanted to investigate the patient reported difference between the two methods. In the final phase of the planned treatment (range of the total treatment fractions 5-30), the feedback was collected from the participating patients with five-point scale questionnaire (1 = strongly disagree, 2= disagree, 3 = neither agree or disagree, 4=agree, 5 = strongly agree).

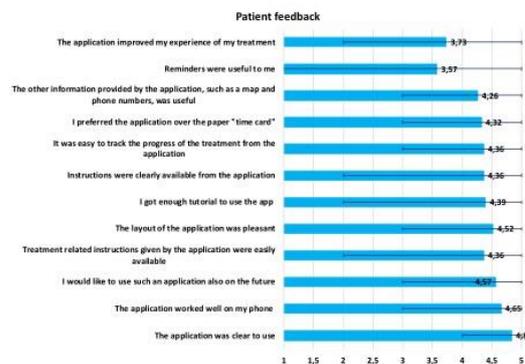

#### Results

The age distribution ranged between the participants in test run from 37-71 years. 75% of the patients were over 50 and 38% over 60 years old or older. 90,5% of the participants were using Android and 9,5% iPhone. The highest scores of the patient reported feedbacks were “the application was clear to use” (av 4.83, range 4-5), “the application worked well on my phone” (av 4.65, range 3-5) and “I would like to use such an application also on the future” (av 4.57, range 3-5). In addition, the overall feedback was that treatment related instructions given by the application were easily available (av 4.36, range 2-5)

and the patients would have chosen the application over the paper “time card” (av 4.32, range 3-5).

#### Conclusion

The mobile application was an effective tool for daily patient scheduling. The patient reported usability of the tested mobile application was high and none of the patients would have preferred the paper version of the time card, even though most of the patients were over 50 years old. In addition to the daily scheduling the application was used to give daily instructions and alerts for example for fasting and included treatment related instructions for the patients. This was the last step to convert our radiotherapy department into paper-less environment.

#### OC-0194 Continuous improvement by crossing patient satisfaction surveys, adverse events and complaints

S. Cucchiario<sup>1</sup>, M. Delgaudine<sup>2</sup>, F. Princen<sup>1</sup>, P. Coucke<sup>1</sup>  
<sup>1</sup>C.H.U. - Sart Tilman, Radiotherapy Department, Liège, Belgium ; <sup>2</sup>C.H.U. - Sart Tilman, STA Quality Department, Liège, Belgium

#### Purpose or Objective

Beyond the technological advances to improve Radiation Therapy (RT), the patient is a key player in security and improvement care processes. The patient's needs and expectations can be assessed through satisfaction surveys, adverse event declarations and records of complaints. However by crossing individual complaints, satisfaction surveys in combination with adverse events received we could get valuable information. The objective is to identify common elements of work between these different sources to improve care and to obtain additional views of caregivers and patients about an event to be more complete and accurate in choosing improvement actions.

#### Material and Methods

A retrospective analysis of patient's complaints, surveys and adverse events was carried out in order to highlight common improvement items between these 3 sources of information. Adverse events bring together caregiver statements and unexpected events completed by patients. Complaints are sent to us by the hospital Mediation. The complaints, adverse events and areas for improvement defined in the satisfaction surveys were examined. This analysis was conducted between June 2017 and June 2018, we have cross-pollated 249 improvement proposals from the surveys, with 7 complaints reporting and 13 patient completed adverse events.

#### Results

We first analyzed the 249 improvement proposals resulting from satisfaction surveys. We highlighted 5 criteria to improve: logistics and infrastructure (parking, waiting room), communication and information (brochure, information about treatment and on side effects), delays to treatment units (information delay, breakdowns), appointments (consultations) and the relationship with RT staff (doctors, nurses). We then compared them with complaints and patient related adverse events. Parking problem, treatment delays due to breakdowns as well as

poor communication about them were also reported through undesirable events. In the registered complaints, we found as concordance, a delay and a lack of communication about treatment and a problem of relationship with the Radiation Therapist staff. These common items have been chosen as events on which the RT department will implement improvement actions in priority (Figure1).

Monitoring decisions: Patient satisfaction surveys, complaints and adverse events				
Action	Decisions	Pilots	Status	Deadline
1	Revised brochures following patient feedback (with more information about treatment and on side effects)	SC FP	Work in progress	01/01/2019
2	Purchase of frames / decorations for waiting rooms	NR	Done	15/09/2018
3	Information given to the patient about the different parking options → Institutional brochure developed by the hospital with different parking possibilities	/	Done	/
4	Work on communication in the event of breakdowns, delays... → Creating a poster for occasional breakdowns or maintenance	FP SC	Work in progress	01/12/2018
5	Review the schedule sheet given to the patient	WS AP	Work in progress	01/10/2018

Figure 1

### Conclusion

By crossing these 3 information channels, we were able to highlight some areas on which we can reinforce improvement in order to increase patients' satisfaction as well as quality and safety of their care. This allows us to actively involve patient in quality processes of RT department so that he becomes a key actor in quality and safety of its own treatment. To continue this process of continuous improvement, a new crossover of these information will be organized at regular intervals.

Our final goal is to strengthen the quality and safety of treatments to create value for the patient and improve the patient experience.

And it's to adjust treatments to the life project of the patient and promote a participative approach focused on the patient's needs and expectations.

### OC-0195 Towards a Patient-Focused Organizational Model for Radiation Therapists

A. Shessel<sup>1</sup>, E. Moyo<sup>1</sup>, A. Koch<sup>1</sup>, J. Ringash<sup>1</sup>, J. Waldron<sup>1</sup>, F.F. Liu<sup>1</sup>, M. Velec<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Center, Radiation Medicine Program - Radiation Therapy, Toronto, Canada

#### Purpose or Objective

Patient experiences over their course of radiotherapy journey are fragmented by the many interactions from different Radiation Therapists (RTs), each focused on specific supportive care / technical activities (e.g. simulation, planning, delivery, etc.). The aim of this project was to determine the feasibility of reorganizing to provide continuity of care by identifying a primary RT partnering with each patient, throughout their entire radiotherapy trajectory.

#### Material and Methods

Two 4-month pilots were conducted in a single department (proof-of-concept phase in 2017, feasibility phase in 2018), with 16 RTs working in the new organizational model. Patients were triaged into the new model based on technique complexity or a perceived need for added psychosocial support (e.g. high anxiety, non-English speaking). Each patient was partnered with a 'primary' RT. This RT performed, all point-of-care activities identified as high priority (critical activities/time-points in the treatment course) for their patients as often as scheduling permitted. The high priority points-of-care were: all education and supportive care activities (including a new pre-treatment session and a new 2-week post treatment follow-up call), CT-simulation, dosimetry review, peer-review rounds and treatment delivery (at least 1st and last fractions). All 'primary' RT activities were documented to assess continuity of care. Patient satisfaction surveys were distributed at the final treatment and stakeholder surveys

were distributed to the multi-disciplinary clinical team following each phase.

#### Results

Over both phases, 312 patients (46% breast, 18% upper gastrointestinal, 36% head and neck) were treated in the new organizational model. On average, 75% of a patient's priority points-of-care were delivered by the primary RT in the new model, compared to 40% in the standard model. Overall, of the 173 patients surveyed, ≥95% of were satisfied with their experience. Compared to the fragmented standard model, 20% more patients in this model were satisfied with the patient education information they received and with staff consistency. Among the patients diagnosed with Breast cancer, 30% fewer reported accessing 'drop-in' nursing support clinics relative to the standard fragmented model. Multi-disciplinary stakeholders (n=83) saw improvements in patient support as a substantial benefit of the new model, with workflow challenges identified as a potential implementation barrier.

#### Conclusion

A patient-focused organizational model was developed to partner individual RTs with patients throughout their radiotherapy course. It was feasible to accrue substantial numbers of patients to this model. These early results suggest improved continuity of care, high quality supportive care and patient experience. Full-scale implementation of this organizational model is currently underway in our large comprehensive cancer centre.

### OC-0196 Predictors for radiation-induced oesophagitis in breast cancer patients

K. West<sup>1</sup>, M. Schneider<sup>2</sup>, C. Wright<sup>2</sup>, R. Beldham-Collins<sup>1,3</sup>, N. Coburn<sup>3</sup>, K. Tiver<sup>3</sup>, V. Gebiski<sup>4</sup>, K. Stuart<sup>1,5,6</sup>

<sup>1</sup>Crown Princess Mary Cancer Centre, Westmead Hospital, Wentworthville, Australia; <sup>2</sup>Monash University, Department of Medical Imaging and Radiation Sciences- Faculty of Medicine- Nursing and Health Sciences, Clayton, Australia; <sup>3</sup>Nepean Cancer Care Centre, Nepean Hospital, Penrith, Australia; <sup>4</sup>NHMRC Clinical Trials Centre, University of Sydney, Sydney, Australia; <sup>5</sup>Breast Cancer Institute, Westmead Hospital, Westmead, Australia; <sup>6</sup>Sydney Medical School, The University of Sydney, Sydney, Australia

#### Purpose or Objective

Radiation therapy (RT) for early breast cancer is increasingly more personalised. Treatment using intensity-modulated RT (IMRT) to the supraclavicular (SCF) nodes has shown potential for development of oesophagitis. This pilot study aims to identify predictors for the onset of radiation-induced oesophagitis.

#### Material and Methods

Patients prescribed RT to the breast or chest wall and SCF nodes (± other nodal groups) to a dose of ≥ 50 Gy in 25 fractions were considered eligible for the study. Patients were recruited consecutively at the time of simulation, and only excluded if they had previous treatment to the ipsilateral breast or chest wall or other contraindications to RT. A hybrid IMRT planning technique with a minimum of 95% of the prescribed dose to cover all PTVs was utilised for all patients. Grading was undertaken twice weekly using the RTOG system to determine the onset of moderate oesophagitis (grade 2). Mean and maximum doses to the oesophagus were recorded, as well as oesophageal length and length of pharynx included in the treatment area. Demographic data including age, treatment areas (SCF, internal mammary chain (IMC), axilla), laterality of disease site, chemotherapy and smoking history were recorded. Data were analysed using Fishers exact test and GraphPad Prism software with a 0.05 significance level.

#### Results

A total of 77 patients were enrolled from September 2012 until July 2015. Twenty-four patients reported a maximum

grade 2 oesophagitis. No patients reported grade 3 or higher oesophagitis. There was a significant difference in the number of patients receiving a mean oesophageal dose of  $\geq 31$  Gy with grade 2 toxicity compared to those receiving  $< 31$  Gy ( $p=0.025$ ). There was a significant difference in grade 2 toxicity in patients who had  $\geq 1$  cm of pharynx included in supraclavicular fields compared with those with  $< 1$  cm ( $p=0.0116$ ). A trend was observed in patients with left-sided SCF treatment, with more experiencing a grade 2 toxicity; this could be explained by the anatomical location of the oesophagus in this region. There was also an increased trend of grade 2 toxicity in patients who did not receive IMC RT; the reason for this may require further investigation. There were no overall significant differences in smoking history, oesophageal length and chemotherapy regimen.

#### Conclusion

This study has identified two potential predictors for moderate oesophageal toxicity in early breast cancer patients receiving RT to the breast or chest wall and supraclavicular nodes. By limiting the mean dose to the irradiated oesophagus to  $< 31$  Gy during the planning process, and if possible ensuring  $< 1$  cm of pharynx is included in the field, oesophageal toxicity could be reduced.

#### OC-0197 A survey of UK practice of radiotherapy skin care for breast patients

H. Nisbet<sup>1</sup>, S. Matthews<sup>1</sup>, R. Cooke<sup>1</sup>

<sup>1</sup>Oxford University Hospitals NHS Foundation Trust, Radiotherapy Department, Oxford, United Kingdom

#### Purpose or Objective

Radiation induced skin toxicity is one of the most common toxicities experienced with radiotherapy treatment and is characterised by erythema, heat, pain, swelling and pruritus. The management of skin toxicities has often been driven by established practices and local conventions rather than on research and evidence, resulting in non-standardised practice with little or no justification<sup>1, 2</sup>. In 2015 The Society and College of Radiographers (SCoR) published guidelines<sup>3</sup> to promote an evidence-based approach. However, a lack of evidence to support or refute the use of any particular product for topical application meant that only general guidance is given. In addition, it is advised that any moisturiser containing sodium lauryl sulphate (SLS) should be avoided as it causes skin irritation. The 2012 SCoR survey of UK practice showed that nearly 70% of radiotherapy departments advised the use of aqueous cream for prophylactic skin care<sup>2</sup>, a product that contains SLS. As a result, the new guidelines provided a review of the evidence base for skin care practice but simultaneously advised against the most common cream in use, creating uncertainty on what products can be recommended to patients. Therefore the objective was to survey current UK skin care practice for patients undergoing treatment to the breast following the implementation of the new guidelines and to evaluate if any one particular topical product had fewer associated skin toxicities.

#### Material and Methods

All UK departments were invited to participate via the SCoR Radiotherapy Information, Support and Review Special Interest Group online forum and provided with a skin assessment tool to record skin toxicity details. Extrinsic factors recorded were treatment technique and beam energy. Intrinsic factors included the co-morbidities of diabetes and cardiovascular disease, smoking, alcohol consumption, weight and patient demographics. The skin care products used during treatment were also documented. Participating departments had implemented the 2015 guidelines and for comparability only external beam radiotherapy to the breast and chest wall, excluding nodal treatment, were included. An assessment of the skin was recorded in week one using the

Radiation Therapy Oncology Group toxicity criteria<sup>7</sup> and for each subsequent week of treatment.

#### Results

594 total responses were received with 542 included in the survey after exclusions. The effect on skin toxicity of the skin care product used, as well as other patient and treatment factors were analysed. No significant differences were found in RTOG grades between any of the skin products used. Weight, cup size, diabetes, cardiovascular disease, mastectomy and beam energy were all found to have statistically significant higher RTOG grades.

#### Conclusion

This survey shows that intrinsic factors are more likely to determine skin toxicity and confirms the SCOR guidelines that any SLS free, topical product can be used for radiotherapy skin care.

#### OC-0198 Using PROs and PROMs in routine head and neck cancer care: what do RTs perceive as barriers?

H. Nguyen<sup>1</sup>, P. Butow<sup>2</sup>, H. Dhillon<sup>2</sup>, L. Morris<sup>1</sup>, A. Brown<sup>1</sup>, K. West<sup>1</sup>, P. Sundaresan<sup>1,3</sup>

<sup>1</sup>Radiation Oncology Network, Western Sydney Local Health District, Sydney, Australia; <sup>2</sup>Centre for Medical Psychology & Evidence-based Decision-making CeMPED, The University of Sydney, Sydney, Australia; <sup>3</sup>Sydney Medical School, The University of Sydney, Sydney, Australia

#### Purpose or Objective

Patient-reported outcomes (PROs) are direct reports from patients about the status of their health condition without amendment or interpretation by others. Patient-reported outcome measures (PROMs) are usually validated questionnaires that patients complete by self-assessing their health status. Domains assessed include the patient's physical, emotional, social and overall quality of life. The use of PROMs to measure PROs has been shown to improve patient overall survival and toxicity outcomes, patient-health professional (HP) communication and service-level quality. Yet, PROMs are not routinely used in many oncology institutions worldwide. The aim of this study was to examine HPs' perception of barriers to the routine use of PROs and PROMs in the care of head and neck cancer (HNC) patients. This report specifically focuses on perceptions of RTs caring for HNC patients.

#### Material and Methods

A custom survey was created to assess HNC HPs' perceptions of barriers to routine PRO use. To create the survey, existing literature was reviewed and potential barriers and enablers to routine PRO use were collated and categorised as patient-level, service-level or HP-level. Participants were asked to rate the degree to which they believe these items are barriers/enablers to PRO use by answering "not at all", "very little", "quite a bit" and "very much". The survey was pilot tested amongst selected HPs before being electronically disseminated to HPs involved in the care of HNC patients in Western Sydney Local Health District, Australia.

#### Results

There were 122 participants; 58% ( $n = 71$ ) of whom were RTs. The response rate amongst RTs was 94.7%. Most RTs (59.2%) had never heard of PROs whilst very few (2.9%) have used PROs to guide patient care. At the patient level, the perceived unavailability of PROMs in patients' preferred languages and patient difficulty understanding PROMs were rated as "quite a bit/very much" by 67.6% and 54.3% of RTs respectively. At the service-level, factors perceived as "quite a bit/very much" a barrier to PRO use included low workplace awareness of PROs (69.6%), low organisational support (69.6%) and insufficient staff resources (69.6%). At the HP-level, factors perceived as "quite a bit/very much" a barrier to PRO use included lack of knowledge regarding how to use PROs (66.7%), concern regarding need for additional time to interpret and action

PROs (56.5%) and lack of knowledge on how to integrate PROs into clinical practice (55.1%). Top enablers highlighted by RTs were staff education on how to use PROs (82.4%), clear definition of roles (80.9%) and designated time for staff to monitor and respond to PROs (80.9%).

#### Conclusion

This study has highlighted important barriers and enablers to the routine use of PROs in HNC care as perceived by RTs. Most barriers appear to lie at the service and HP levels. Findings from this study will guide future interventions to address these barriers such that successful and sustainable implementation of routine PRO collection may be achieved.

#### OC-0199 Patient-reported outcomes after stereotactic body radiotherapy in lung cancer: The Lung PLUS study

L. Van der Weijst<sup>1</sup>, R. Bultijnck<sup>1</sup>, A. Van Damme<sup>1</sup>, M. Van Eijkeren<sup>1</sup>, V. Surmont<sup>2</sup>, Y. Lievens<sup>1</sup>

<sup>1</sup>Ghent University Hospital, Radiation Oncology, Gent, Belgium; <sup>2</sup>Ghent University Hospital, Respiratory Medicine, Gent, Belgium

#### Purpose or Objective

Stereotactic body radiotherapy (SBRT) is the treatment of choice for early stage non-small cell lung cancer (ES-NSCLC) patients unwilling to undergo or ineligible for surgery. SBRT may bring along toxicities, adversely affecting health-related quality of life (HRQoL), with impact on the patients' physical, psychological and social wellbeing. Fatigue is a frequently reported side-effect in patients undergoing SBRT. We here report the initial results of patient-reported toxicity, HRQoL and fatigue in the Lung PLUS study.

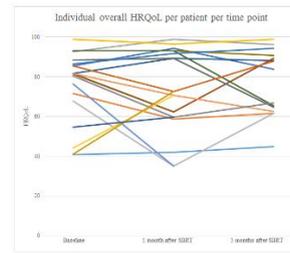

#### Material and Methods

Lung PLUS is a monocentric, prospective, longitudinal study, investigating the predictive value of Patient-Reported Outcomes (PROs), functional exercise capacity (6-minute walk test - 6MWT) and circulating cell-free DNA circulating DNA (cfDNA) on outcome in ES-NSCLC undergoing SBRT. PROs are collected at baseline, and at 1, 3, 6, 9 and 12 months after treatment. Outcome data (overall survival; local and loco-regional control; and metastatic relapse) are recorded during the entire course of follow-up. Socio-economic determinants are collected at baseline.

HRQoL is measured with a validated questionnaire (EORTC QLQ-C30). The patient-reported toxicities, collected with the patient-reported outcome measurement (PROM) version of the Common Terminology Criteria for Adverse Events (CTCAE) (PRO-CTCAE), are as follows: pain, fatigue, cough, anxiety and dyspnea. A meaningful clinically important difference (MCID) of HRQoL was defined as a 10-point difference on the total score of 100 of the EORTC QLQ-C30 between time points. The mixed model approach was applied to analyze the longitudinal data.

#### Results

Between June 2017 and October 2018, 25 patients (median age: 73) out of the 50 patients planned have been recruited. The majority was male (64%) and had stage I disease (96%). Total dose was 60Gy, delivered in 3 (26%), 5 (17%) or 8 fractions (57%). Data is available of 25, 19 and 17 patients at baseline, 1 and 3 months after SBRT respectively. So far, no significant differences in overall toxicity ( $p=0.681$ ), HRQoL ( $p=0.187$ ) and fatigue ( $p=0.221$ ) over time have been found. MCID in HRQoL was found in 50% (40% deterioration; 10% improvement) and 27% (all deteriorated) of patients respectively at 1 and 3 months after SBRT. Graph 1 provides an overview of individual overall HRQoL over time. Toxicity and HRQoL are significantly correlated ( $p<0.001$ ) over time.

Data based on 18 patients due to excessive missing data of one patient.

#### Conclusion

The initial results of the Lung PLUS study indicate that HRQoL, toxicity and fatigue levels remain stable after SBRT in ES-NSCLC. Updated results will be presented.

#### PV-0200 Accelerated- vs chemo-radiation as organ sparing strategies for laryngeal/hypopharyngeal carcinoma

A. M. Elamir<sup>1</sup>, S. Huang<sup>1</sup>, W. Xu<sup>2</sup>, M. Yu<sup>2</sup>, A. Spreafico<sup>3</sup>, A. Bayley<sup>1</sup>, S.V. Bratman<sup>1</sup>, J. Cho<sup>1</sup>, M. Giuliani<sup>1</sup>, A. Hope<sup>1</sup>, J. Kim<sup>1</sup>, B. O'Sullivan<sup>1</sup>, J. Ringash<sup>1</sup>, J.R. De Almeida<sup>4</sup>, D. Chepeha<sup>4</sup>, D. Goldstein<sup>4</sup>, J. Irish<sup>4</sup>, J. Waldron<sup>1</sup>, A. Hosni<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre / University of Toronto, Department of Radiation Oncology, Toronto-Ontario, Canada ; <sup>2</sup>Princess Margaret Cancer Centre / University of Toronto, Department of Biostatistics, Toronto- Ontario, Canada ; <sup>3</sup>Princess Margaret Cancer Centre / University of Toronto, Department of Medical Oncology, Toronto- Ontario, Canada ; <sup>4</sup>Princess Margaret Cancer Centre / University of Toronto, Department of Otolaryngology-Head and Neck Surgery/Surgical Oncology-, Toronto- Ontario, Canada

#### Purpose or Objective

To evaluate the outcomes of locoregionally advanced laryngeal/hypopharyngeal squamous cell carcinoma (SCC) following concurrent chemoradiation (CRT) and accelerated radiation therapy (ART).

#### Material and Methods

Retrospective review was conducted of stage III-IVB (AJCC/UICC-7th edition) laryngeal/hypopharyngeal SCC patients who were treated with curative-intent radiation therapy (RT) from 2000-2016. Patients were preferentially managed with CRT; those unfit or who declined chemotherapy received ART scheduled based on physician and patient preference: moderately accelerated, 70 Gy/35f/6w (A-Mod); hypofractionated, 60 Gy/25f/5w (A-Hypo); or accelerated hyperfractionation, 64 Gy/40f/4w (A-Hyper). Cases were matched 1:1 from our prospective quality assurance system based on: age, smoking and ECOG performance status (PS), T- and N-category, larynx vs hypopharynx, and IMRT vs 3D conformal RT. With propensity score matching, outcomes were compared following: 1) CRT vs the three ART regimens separately, 2) The three different AF-RT schedules. The primary endpoint was 5-yr local control (LC, evaluated by competing risk method) and secondary endpoints were 5-yr regional and distant control, cancer specific survival (analyzed by competing risk method), and overall survival (OS, measured by Kaplan-Meier method).

#### Results

Among 679 patients included, 195 received concurrent cisplatin (only 65 [33%] were able to receive 3 cycles of Q3-week cisplatin, 102 [52%] received 2 cycles, 14 [7%] tolerated only 1 cycle, while 14 patients [7%] received

weekly cisplatin). A total of 484 patients were managed with ART due to: age >70 years (n=216), comorbidity/poor PS (n=102), or declined chemotherapy (n=166). Patients and treatment characteristics are summarized in Table 1. The pattern of failure among the whole cohort is shown in Figure 1a. With a median follow up of 4.3 years, 5-yr LC following CRT, A-Mod (n=128), A-Hypo (n=141), and A-Hyper (n=215) were 81% (95%CI:74-85%), 70% (95%CI:60-78%), 68% (95%CI:59-75%) and 65% (95% CI:58-71%) respectively. Outcomes following propensity score matching are shown in Figure 2; the 5-yr LC following CRT was 80% (95%CI:72%-86%) vs 71% (95%CI:61%-78%) compared to A-mod (p=0.08), 82% (95%CI:72%-88%) vs 71% (95%CI:61%-79%) compared to A-Hypo (p=0.07), and 81% (95%CI:74%-86%) vs 66% (95%CI:58%-72%) compared to A-Hyper (p<0.001). There was no significant difference in 5-yr LC between different ART schedules (p>0.05, Figure 2b). Among patients who had locoregional recurrence (LRR) without synchronous distant metastases (n=202), 113 (56%) had salvage surgery (5-yr OS: 40% [95%CI:32%-51%]), while 89 were not surgical candidates (5-yr OS: 5% [95%CI:2-15%]). Late toxicities are summarized in Figure 1B.

\* BED = D \* (1 + d/(α/β)) = 10.693 \* (1 + d/(2.5)) for tumor local control (BED)10; α/β = 10 Gy; ca = 0.3 Gy; β = 2.5 Gy; d = 2.5 Gy; n = 3.5.  
 - When BED = biologically effective dose (Gy), D = total dose (Gy), d = dose per fraction (Gy), n/F = linear (α) and quadratic (β) components of the linear-quadratic model (Gy<sup>2</sup>); T = overall treatment time (weeks), h = 168 h/F or coast of accelerated repopulation time (days), t = average doubling time during accelerated repopulation (days).  
 - BED for concurrent chemotherapy in the CRT group was considered as 8.8 Gy10

Conclusion

Approximately two thirds of stage III-IVB laryngeal/hypopharyngeal SCC patients who declined or were unfit for concurrent cisplatin achieved LC following ART. There was no significant difference in LC among the different ART regimens.

PV-0201 Development and validation of prediction models for salivary dysfunction in HN cancer patients L. Van den Bosch<sup>1</sup>, A. Van der Schaaf<sup>1</sup>, F.J.P. Hoebers<sup>2</sup>, H.P. Van der Laan<sup>3</sup>, E. Schuit<sup>3</sup>, E. Bakker<sup>1</sup>, O.B. Wijers<sup>4</sup>, A.M. Van der Wel<sup>4</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University of Groningen - University Medical Center Groningen, Radiation oncology, Groningen, The Netherlands ; <sup>2</sup>Maastro Clinics, Radiation Oncology, Maastricht, The Netherlands; <sup>3</sup>Utrecht University - University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, The Netherlands; <sup>4</sup>Radiotherapeutic Institute Friesland, Radiation Oncology, Leeuwarden, The Netherlands

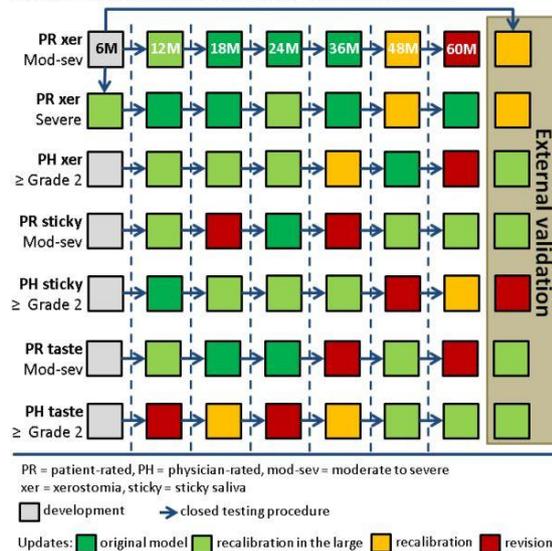

Purpose or Objective

NTCP-models for salivary dysfunction and other toxicities in head and neck cancer (HNC) patients can be used to optimize treatment plans and select the best RT technique. However, currently used NTCP-models have several shortcomings, such as retrospective assessments, being developed on limited data for only a single time point or grade without properly addressing missing data, non-linearity, and multicollinearity, no external validation and a limited number of organs at risk (OARs) investigated. Our aim was to address these shortcomings and to develop and externally validate an NTCP-profile based on a comprehensive set of NTCP-models for patient-rated (PR) and physician-rated (PhR) toxicities. Here we present the results for salivary dysfunction.

**Material and Methods**

This was a prospective cohort study including 750 HNC patients treated with definitive radiotherapy. All endpoints were scored prospectively and the compliance rate was > 80% for all endpoints. OARs were re-delineated according to international consensus guidelines. Multiple imputation was used to deal with missing data to avoid the potential bias of a complete case analysis. During model development we assessed non-linear dose-effect relations and dealt with multicollinearity. Models were developed for moderate-to-severe PR and grade 3 2 PhR (CTCAEv4.0) xerostomia, sticky saliva and changes in taste at 6 months after treatment. A closed testing procedure was used to validate and, if necessary, update the models at subsequent time points (up to 5 years) and higher toxicity grades (fig 1). The models at 6 months were externally validated on 260 HNC patients from 2 other RT-centers using the same closed testing procedure. The proposed model update was performed on the combined data to obtain a more generalized model.

Figure 1: Model development, validation and updating scheme

**Results**

Salivary dysfunction was best predicted by baseline complaints and mean dose to the parotid and submandibular glands and the oral cavity (table 1). For PR changes in taste, age was also a predictor. In most models, a square root or log transformation of the parotid glands or oral cavity dose improved model performance. All models performed well with an ROC-AUC ranging from 0.65 for PhR changes in taste to 0.77 for PhR xerostomia. When validated over time, none or minor model adjustments were necessary. The external validation showed good performance of the models and only minor updates sufficed to allow proper model performance,

thereby indicating good generalizability of the models.

Table 1: Model predictors and performance at 6 months

	PR xer	PH xer	PR sticky	PH sticky	PR taste	PH taste
Both parotid glands	sqrt	sqrt	sqrt		log	sqrt
Both submandibular glands						
Oral cavity					sqrt	
Baseline complaints						
Age						
AUC development	0.73	0.77	0.67	0.69	0.68	0.65
AUC external validation	0.65	0.74	0.73	0.64	0.71	0.67
Proposed update	Recal	RITL	RITL	Revis	RITL	RITL
AUC after update on combined data	0.72	0.78	0.69	0.64	0.69	0.65

variable in the model  
 sqrt = square root, log = natural logarithm  
 AUC = Area Under the Receiver Operation Characteristic (ROC) Curve  
 Recal = recalibration, RITL = recalibration in the large, Revis = revision

**Conclusion**

We developed and externally validated a comprehensive NTCP-profile for both PR and PhR salivary gland toxicities at different time points after head and neck radiotherapy, based on the newest OARs contouring guidelines. Such a profile can be used for treatment planning optimization and selection of patients for different RT techniques.

**PV-0202 3-D reconstruction of radiotherapy dose associated with advanced osteoradionecrosis after IMRT**

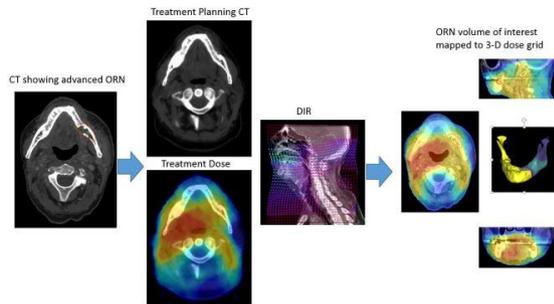

A.S.R. Mohamed<sup>1</sup>, K. Al Feghali<sup>1</sup>, S.P. Ng<sup>1</sup>, H. Elhalawani<sup>1</sup>, K. Hutcheson<sup>1</sup>, M. Chambers<sup>1</sup>, J. Phan<sup>1</sup>, J. Kraeima<sup>2</sup>, H. Glas<sup>2</sup>, M. Witjes<sup>2</sup>, G.B. Gunn<sup>1</sup>, A. Garden<sup>1</sup>, D. Rosenthal<sup>1</sup>, S. Frank<sup>1</sup>, W. Morrison<sup>1</sup>, C. Fuller<sup>1</sup>, S. Lai<sup>1</sup>  
<sup>1</sup>The University of Texas- MD Anderson Cancer Center, Radiation Oncology, Houston, USA; <sup>2</sup>University of Groningen- The Netherlands, Oral Surgery, Groningen, The Netherlands

**Purpose or Objective**

IMRT carries the ability to limit dose to organs-at-risk. However, recent findings by our group and others, reported no reduction in osteoradionecrosis (ORN) rates in oropharyngeal cancer (OPC) patients after IMRT in comparison to conventional radiotherapy techniques. We recently demonstrated that a wide range of two-dimensional dose-volume parameters in the intermediate and high dose beam-path are associated with the development of advanced ORN in patients with OPC treated with IMRT. To this end, we aim to further characterize the dosimetric correlated of advanced ORN by determining the three-dimensional (3-D) spatial dose distribution of the mandibular area of ORN.

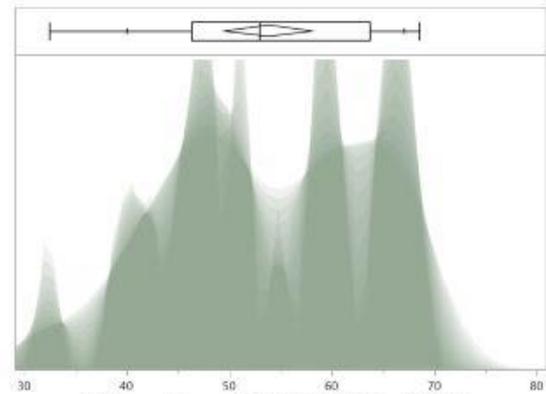

**Material and Methods**

After institutional review board (IRB) approval, we identified patients with grade IV ORN requiring major surgery among patients with OPC treated with IMRT between 2002 and 2013. The initial CT scans documenting the diagnosis of ORN were identified. The mandibular areas affected with ORN were manually segmented for all patients to create 3-D ORN volume of interest (ORN-VOI). Planning CTs and dose grids were subsequently retrieved. ORN-depicting CT scans were then co-registered to planning CT scans using a validated commercial image registration software (Velocity AI 3.0.1, Atlanta, GA). Finally, ORN-VOIs were mapped to planning CT scans, and dose grid then dosimetric parameters were extracted for each VOI (Figure 1).

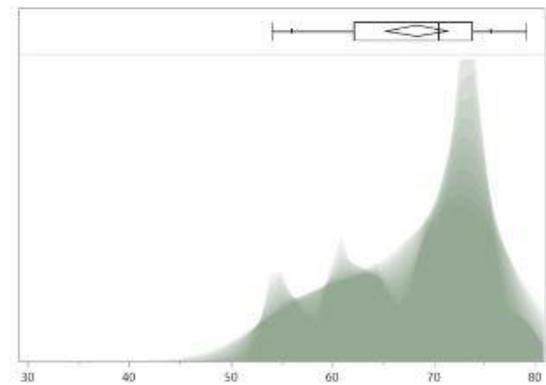

### Results

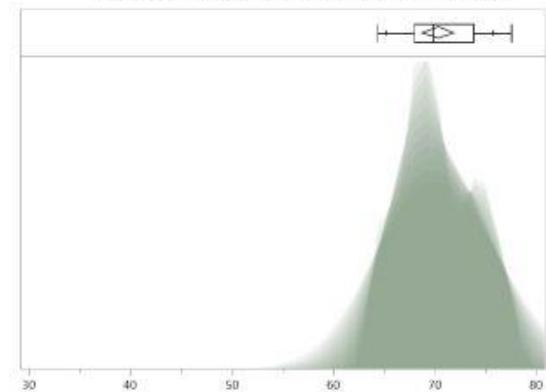

Twenty-five patients with grade IV ORN were identified. Median follow-up was 76 months (range 24-183) and median time to development of ORN was 22 months (range 5-132). Median age at diagnosis was 61 years (range 47-72), and 84% were men. The site of tumor origin was base of tongue, tonsil, and posterior pharyngeal wall in 12, 12, and 1 patient(s), respectively. Median radiation prescription dose was 70 Gy in 33 fractions. Only two patients developed ORN contralateral to the tumor site. The average of minimum dose to ORN-VOIs (i.e. the isodose line that covers 100% of the ORN volume) was 54.3 Gy. The first, second, third, and fourth quartile minimum dose distribution for ORN-VOI ranged from 32.4-46.7, 46.7-54.6, 54.6-64.6, and 64.6-68.5 Gy, respectively (Figure 2). The averages of mean and maximum doses to ORN VOIs were 66.3 Gy (range 54-75) and 72.5 Gy (range 64-78), respectively.

**Min. dose ORN VOIs (Gy)**

**Mean dose ORN VOIs (Gy)**

**Max dose ORN VOI (Gy)**

### Conclusion

The mandibular areas of origin of advanced ORN in OPC patients treated with IMRT received at least 55 Gy in approximately half of the examined cohort. However, lower doses, in the intermediate dose range (32-55 Gy), were also associated with mandibular ORN. Our findings suggest that the intermediate dose beam-path results in long-term bone toxicity for OPC survivors. Dose-volume constraints in both intermediate and high dose range of the mandibular organ at risk should be adopted in future IMRT plans.

### PV-0203 Adaptive proton therapy for patients with Head and Neck tumors involving skull base

S. Karaman<sup>1</sup>, R. Malyapa<sup>2</sup>, U. Langner<sup>2</sup>, T. Houser<sup>2</sup>, Z. Fellows<sup>2</sup>, J. Moreau<sup>2</sup>, Z. Vujaskovic<sup>2</sup>

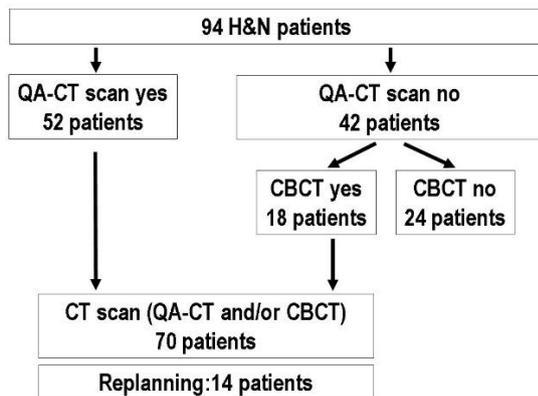

<sup>1</sup>Istanbul University Oncology Institute, Radiation Oncology, Istanbul, Turkey ; <sup>2</sup>Maryland Proton Treatment Center, Radiation Oncology, Baltimore, USA

### Purpose or Objective

To determine the impact of anatomical changes in target volume, sinus filling and weight on dose distribution in patients undergoing pencil beam scanning proton therapy (PBS-PT) for head and neck cancers (HNC) involving the skull base. This information was used in order to assess the need for adaptive replanning.

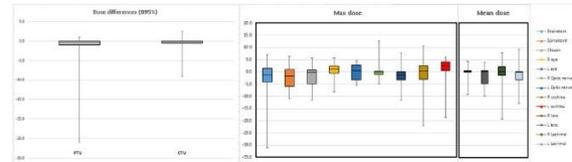

### Material and Methods

We analyzed 94 HNC patients treated with PBS-PT between 2016 and 2018 (Fig 1). The structures defined on initial planning CT were used as a reference to merge images on QA-CT scans to evaluate changes in anatomy and dose distribution during the course of treatment. For image registration we used a three-dimensional rigid registration algorithm. Patients' weekly QA-CT scans and/or daily cone beam CT (CBCT) was overlaid with the initial planning CT to evaluate target coverage and organs at risk (OAR) dose to assess the need for replanning as a result of anatomic changes. To evaluate target coverage, we looked at the dose difference for 95% of the volume (V95) for CTV and PTV, and for critical dose limiting OAR we looked at the absolute increase in maximum dose between initial planning CT and QA-CT scans.

### Results

Weekly QA-CT scans ± daily CBCT were performed for 70 patients. 24 patients did not have any CBCT since it became available only in late 2016. Daily CBCT alone was used to evaluate changes for 18 patients who had no gross disease or where disease site was not extending into sinus cavity and when the beams were not passing through sinus air cavity. Replanning was deemed necessary in 14 patients (20%) due to weight loss (40%), sinus filling (33%) and changes in tumor or in the post operative bed (27%). Replanning was necessary for the following tumor sites: Sinonasal undifferentiated carcinoma, skull base chordoma extending to cervical region, nasopharynx and maxillary sinus. Replanning was performed once in 13 patients and twice in one patient during the treatment course. Median differences for prescription dose coverage for 95% of the target volume between the initial planning CT and QA-CT scans were found to be -1 (range -26,+1) for CTV, and zero (range -9, +2.5) for PTV. Although we found median of maximum dose differences for all OARs to be <5%, we found our plans were robust to tolerate these changes. Only in two patients should we have continued to treat without replanning, the cumulative doses would have exceeded the tolerance dose (Fig 2).

### Conclusion

Despite the robustness of the initial treatment plan, replanning was necessary in 20% of patients due to anatomical changes during the treatment. While factors influencing plan robustness is important in HNC treatment, the importance of vigilance to anatomical changes and continuous monitoring during treatment is necessary for a safe and effective outcome.

### PV-0204 Mortality after radiotherapy or surgery in early stage NSCLC: a population based study

C. Ostheimer<sup>1</sup>, F. Palm<sup>1</sup>, E. Christoph<sup>1</sup>, M. Katharina<sup>1</sup>, M. Rafael<sup>2</sup>, D. Vordermark<sup>1</sup>, D. Medenwald<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology, Halle/Saale,

Germany ; <sup>2</sup>Martin-Luther University Halle-Wittenberg,

Institute of Medical Epidemiology- Biostatistics and

Informatics, Halle Saale, Germany

### Purpose or Objective

Stereotactic body radiotherapy (SBRT) can achieve high tumour control with limited toxicity for inoperable early stage non-small-cell lung cancer (NSCLC) patients. The objective of this study is to evaluate the impact of the introduction of SBRT on survival of stage I lung cancer patients in the general population.

### Material and Methods

The German Epidemiologic Cancer Registries from the Robert Koch Institute were assessed in three time periods according to availability of SBRT: (1) 2000-2003 (pre-SBRT), (2) 2004-2007 (interim) and (3) 2007-2014 (broad availability of SBRT). To assess the association of cancer related parameters with mortality, hazard ratios (HR) from Cox proportional hazards models were computed. To evaluate the change of treatment related mortality, we performed interaction analyses and the relative excess risk due to interaction (RERI, additive scale) was computed. For the tumor-specific survival, subdistributional hazard ratios from Fine-Gray models were estimated.

### Results

A total of 16.292 patients with UICC stage I NSCLC diagnosed between 2000 and 2014 were analysed. Radiotherapy utilization increased from 5% in pre-SBRT era to 8.8% after 2007. Tumor-specific mortality was more favourable in all treatment groups in the years after 2007 compared to 2000-2003 (strongest for the radiotherapy group: HR=0.63, 95% CI: 0.5- 0.79). Comparing surgery and radiotherapy the interaction analysis revealed a stronger improvement for radiotherapy (multiplicative scale for 2000-2003 vs. >2007: 0.78, 95% CI: 0.62-0.98). On an additive scale, treatment\*period interaction revealed a RERI for 2000-2003 vs. >2007 of -1.18 (95% CI: -1.84, -0.52).

### Conclusion

Using population-based data, we observed a survival advantage in stage I lung cancer. With an increasing utilization of radiotherapy, a stronger improvement occurred in patients treated with radiotherapy when compared to surgery.

### PV-0205 Quantification of Changes in Lung Cancer during Radiotherapy: a comparison between CT and MRI

E. Huang<sup>1</sup>, S. Kumar<sup>1</sup>, D. Moses<sup>2</sup>, L. Holloway<sup>3</sup>, S. Vinod<sup>1</sup>

<sup>1</sup>Liverpool Hospital, Cancer Therapy Centre, Liverpool, Australia; <sup>2</sup>Prince of Wales Hospital, Department of Radiology, Randwick, Australia; <sup>3</sup>Liverpool Hospital, Ingham Institute of Applied Medical Research, Liverpool, Australia

### Purpose or Objective

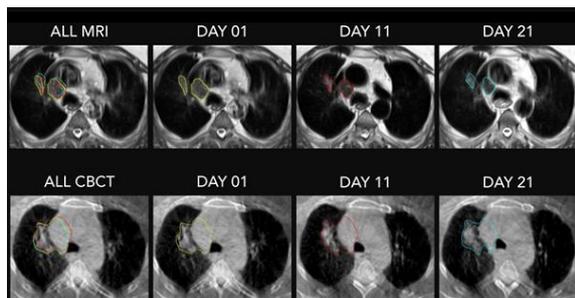

There has been growing interest in use of MRI in lung cancer radiotherapy. This study aims to evaluate the changes seen in lung cancer volume and position on MRI during a course of radiotherapy, and compare this with the current standard of practice, serial cone-beam CT (CBCT).

### Material and Methods

Patients with histologically or cytologically confirmed lung cancer receiving more than 12 fractions of radiotherapy, either alone or with concurrent chemotherapy, were enrolled in a prospective study of serial CBCT and MRI in during-treatment (Day 1, Day 11, & Day 21) scans. Time-matched CBCT and MRI primary gross tumour volumes (GTVp) were manually delineated by a single observer on MIM software. Derived parameters (volume, & centre of mass (COM)) were analysed descriptively and using Bland-Altman plots and linear regression.

### Results

20 patients with 23 GTVp were eligible for inclusion. 60 CBCT/MRI scan pairs were analysed. Mean ( $\pm$  standard deviation) CBCT vs MRI volume change compared to baseline (Day 1) were 81% ( $\pm$ 17) vs 80% ( $\pm$ 29), and 70% ( $\pm$ 31) vs 72% ( $\pm$ 46) for Day 11 and Day 21 respectively. CBCT contours were on average 23% larger than paired MRI contours. MRI vs CBCT demonstrated a systematic bias of -0.92 mL, with absolute volume of CBCT being greater than MRI. Bland-Altman analysis demonstrated CBCT and MRI were not equivalent imaging modalities. No significant regression was found in during-treatment CBCT or MRI ( $p=0.65$ ). No significant difference in slope of tumour regression was found between CBCT and MRI. A significant ( $> 0.5$  cm) COM shift was observed from Day 1 to Day 21, at 0.54 ( $\pm$ 0.42) vs 0.66 ( $\pm$ 0.41) cm for CBCT vs MRI respectively.

### Conclusion

Changes in lung cancer volume and position during radiotherapy are different on CBCT and MRI. Further investigation is warranted if MRI is to be used for adaptive radiotherapy in the future.

### PV-0206 Gross endobronchial disease: predictor of clinical outcomes for early stage NSCLC treated with SBRT

N. Aghdam<sup>1</sup>, S. Kataria<sup>1</sup>, M. Pernia<sup>2</sup>, C. Hall<sup>3</sup>, T. O'Connor<sup>3</sup>, L. Campbell<sup>1</sup>, S. Suy<sup>1</sup>, S.P. Collins<sup>1</sup>, R. Krochmal<sup>4</sup>, E. Anderson<sup>4</sup>, J. Lischalk<sup>1</sup>, B.T. Collins<sup>1</sup>  
<sup>1</sup>Georgetown University Hospital, Department of Radiation Medicine, Washington DC, USA ; <sup>2</sup>Metropolitan Hospital Center, Department of Internal Medicine, New York, USA ; <sup>3</sup>Cornell University, The college of arts and sciences, Ithaca, USA ; <sup>4</sup>Georgetown University Hospital, Division of Pulmonary and Critical Care Medicine, Washington DC, USA

### Purpose or Objective

SBRT with fiducial tracking is a safe and effective treatment for medically inoperable early stage non-small cell lung cancer (ES-NSCLC). Bronchoscopy affords an all-in-one evaluation of mediastinal lymph nodes, visualization of the central airway, biopsy of the primary tumor, and placement of fiducials for tracking. Tumor proximity to the central airway is a known risk factor for toxicity. In this report, we examine the clinical outcomes of a diverse cohort of patients with both central and peripheral tumors treated with 5 fraction SBRT using fiducial tracking. We identify endobronchial involvement as a predictor of poor clinical outcome and treatment-related death.

### Material and Methods

Medically inoperable patients were treated with frameless robotic SBRT per institutional protocol. Majority (41) underwent bronchoscopy with placement of 3 to 5 fiducials with the remainder placed under CT guidance. Clinical examination and PET/CT imaging were completed for staging and at 6 month follow up intervals. Follow-up was performed using a combination of clinical evaluation and PET/CT scans. Patients were stratified based on clinical stage, tumor location (central versus peripheral) and endobronchial involvement.

### Results

From December 2010 to December 2015, 50 patients with biopsy proven ES-NSCLC (stage I - 31; stage II - 19) deemed medically inoperable with median age of 75 were treated with fiducial-based SBRT to 50 Gy in 5 fractions. Twelve central and 38 peripheral tumors were treated with a median tumor diameter of 3.4 cm (range, 1.1 to 7.3 cm) and staged as T1 (n=18), T2 (n=22), and T3 (n=10) per the AJCC 7<sup>th</sup> edition. At median follow up of 36 months, overall survival (OS) was 52%. Survival did not differ between peripheral and central tumors (53% vs 50%;  $p=0.47$ ) nor between stage I and stage II disease (51% vs 52%;  $p=0.674$ ). Local control (LC), regional control (RC), distant metastasis free survival (DMFS), and disease free survival (DFS) were 88%, 89%, 83% and 73%, respectively. Of 41 patients who underwent bronchoscopy for fiducial placement, five tumors, all of which were centrally located, were found to have gross endobronchial involvement. LC and OS for this cohort was 66% and 20%. Cox regression analysis identified endobronchial involvement as a predictor of OS while controlling for age, location, and stage (OR: 4.096,  $p$ -value=0.046). Endobronchial involvement was also an independent predictor for grade 5 pulmonary toxicity (n=4,  $p=0.007$ ). Specifically, 3 patients with gross endobronchial disease went on to experience grade 5 bronchial stricture.

### Conclusion

Central location of ES-NSCLC is known to predict for SBRT-related toxicity. Here we report endobronchial involvement observed during staging bronchoscopy as a significant predictor of poor overall survival and Grade 5 pulmonary toxicity. The poor prognosis and high rates of treatment-related toxicity in patients with central ES-NSCLC may be due in part to gross tumor endobronchial involvement.

### PV-0207 Is V37Gy a Better Dose Predictor for Radiation Pneumonitis for Lung Proton Therapy?

W. Harris<sup>1</sup>, S. O'Reilly<sup>1</sup>, V. Jain<sup>1</sup>, B.K. Teo<sup>1</sup>, L. Dong<sup>1</sup>, S. Feigenberg<sup>1</sup>, A. Berman<sup>1</sup>, W. Zou<sup>1</sup>  
<sup>1</sup>University of Pennsylvania, Radiation Oncology, Philadelphia, USA

### Purpose or Objective

Radiation pneumonitis (RP) is one of the most common forms of toxicity that affect lung cancer patients. About 15-20% of locally-advanced non-small cell lung cancer (LA-NSCLC) patients treated with chemoradiotherapy (CRT) develop RP. The dosimetric parameters used clinically to reduce the likelihood of RP have traditionally been V20Gy

$\leq 30\%$  and mean lung dose  $\leq 20\text{-}23\text{Gy}$ ; however, these parameters are based on photon therapy. The purpose of this study is to evaluate if such dosimetric predictors for RP still hold for LA-NSCLC patients treated with proton therapy.

#### Material and Methods

A total of 129 (46 photon, 83 proton) LA-NSCLC patients treated with concurrent CRT between 2011-2016 were used in the study. In this selected cohort, with a higher rate than clinically observed, 46 (20 photon, 26 proton) were patients that exhibited RP (all grades using CTCAE v4.0) after photon or proton therapy. Dose volume histograms for the uninvolved lung were generated for each patient. The percent lung volume receiving above various dose levels (e.g. V35Gy) were obtained in addition to the traditional V20Gy and mean lung dose. These dosimetric parameters for RP and non-RP patients in photon and proton groups were evaluated with a two-tailed student's test and compared with the V20Gy and mean lung dose. Receiver Operating Characteristic (ROC) curves were generated for various dose levels. The volumetric constraint for the optimal dosimetric parameter was obtained through analyzing RP and non-RP sensitivity/specificity values.

#### Results

For proton patients, a greater separation between the RP and non-RP cohort was observed between V35Gy and V45Gy, when compared with the current clinical standard of V20Gy; however, the greatest difference between RP and non-RP photon patients remains around V20Gy. For proton patients, the maximum difference occurs at V37Gy, with  $24.65 \pm 4.62\%$  and  $18.96 \pm 6.38\%$  for RP and non-RP patients, respectively, while V20Gy was  $31.63 \pm 4.99\%$  and  $26.26 \pm 7.74\%$  for RP and non-RP patients, respectively. Mean lung dose values were consistent between proton and photon patients. A greater separation between RP and non-RP patients is observed when using V37Gy ( $p=0.0001$ ) as compared to V20Gy ( $p=0.002$ ) for proton patients. V20Gy ( $p=0.024$ ) is significant for photon patients, but V37Gy ( $p=0.053$ ) is not. V37Gy ROC curve had the highest Area Under the Curve (AUC) value compared with other dose levels for proton patients. Based on sensitivity/specificity, the optimal volume constraint of V37Gy is  $\leq 23\%$  for proton therapy and the constraint of V20Gy  $\leq 30\%$  is confirmed for photon patients.

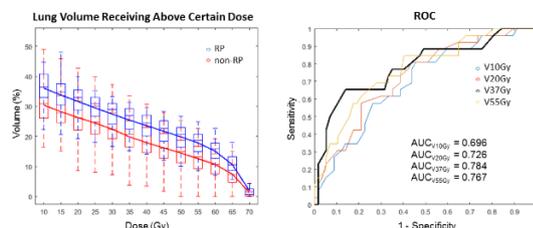

Figure 1: (Left) Box of lung volume receiving above a certain dose for proton therapy patients with radiation pneumonitis (RP - blue) and patients without RP (non-RP - red). (Right) ROC curves for V10Gy, V20Gy, V37Gy and V55Gy for proton patients. V37Gy resulted in the highest AUC value of 0.784 compared with the other dose levels.

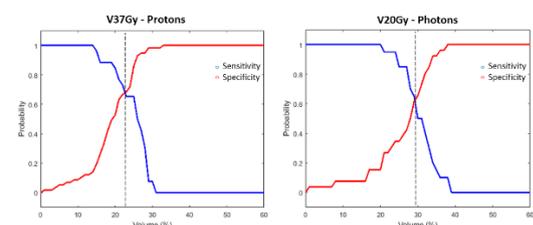

Figure 2: Sensitivity and specificity for V37Gy for proton patients (left) and V20Gy for photon patients (right). Blue line represents sensitivity and the red line represents specificity. The black vertical dotted line shows the point of intersect, which indicates at what volume level most likely predicts RP for V37Gy for protons and V20Gy for photons.

#### Conclusion

While V20Gy is a strong predictor for RP in photon therapy, the volume receiving a higher dose, such as V37Gy, may

be a better indicator for RP for LA-NSCLC patients treated with proton therapy. Further statistical analysis with this data needs to be performed. However, this new dosimetric criteria could potentially help with the RP control in LA-NSCLC treated with proton therapy.

#### PV-0208 Immune-related pneumonitis in NSCLC patients treated with ICI: impact of previous thoracic RT

A. Botticella<sup>1</sup>, T. Ibrahim<sup>2</sup>, L. Mezquita<sup>2</sup>, L. Hendriks<sup>2</sup>, J. Le Pavec<sup>3</sup>, R. Ferrara<sup>2</sup>, C. Caramella<sup>4</sup>, S. Champiat<sup>5</sup>, J. Michot<sup>5</sup>, P. Lavaud<sup>2</sup>, P. Gustin<sup>1</sup>, D. Planchard<sup>2</sup>, A. Gazzah<sup>2</sup>, A. Marabelle<sup>5</sup>, E. Deutsch<sup>1</sup>, B. Besse<sup>2</sup>, C. Le Pechoux<sup>1</sup>

<sup>1</sup>Institut Gustave Roussy, Radiation Oncology Department, Villejuif, France ; <sup>2</sup>Institut Gustave Roussy, Oncology Department, Villejuif, France ; <sup>3</sup>Centre Chirurgial Marie Lannelongue, Laboratoire de Chirurgie Expérimentale-UPRES EA-2705, Plessis Robinson, France ; <sup>4</sup>Institut Gustave Roussy, Radiology Department, Villejuif, France; <sup>5</sup>Institut Gustave Roussy, Département D'Innovation Thérapeutique et des Essais Précoces DITEP, Villejuif, France

#### Purpose or Objective

Pneumonitis is a potentially lethal side effect of immune checkpoint inhibitors (ICI), occurring in 1-5% of patients enrolled in clinical trials. Little is known about the interactions between ICI and previous thoracic radiotherapy (RT). This is the aim of the present study.

#### Material and Methods

Between December 2012 and November 2017, 318 consecutive non-small cell lung cancer (NSCLC) patients received ICI in our Institution and their charts were retrospectively analyzed. Primary endpoint was to determine whether previous radiotherapy had an effect on pulmonary toxicity. Pulmonary toxicity was retrospectively assessed by Common Terminology Criteria for Adverse Events version 4.0.

#### Results

Median follow-up was 32.8 months [95%CI: 5-190]. Median age at the start of ICI was 63 years. 205 patients (64,5%) were males, 103 (32,4%) smokers and 250 (78,6%) with PS  $\leq 1$ ; 206 (64,8%) had adenocarcinoma and 76 (23,9%) squamous; 79 (24,8%) were KRAS mutated, 18 (5,5%) EGFR mutated and 5 (1,6%) ALK positive. PDL1 was  $\geq 1\%$  by immunohistochemistry in 86 (27%), negative in 37 (11,6%) and unknown in 196 (61,3%) patients. ICI treatment was median 3<sup>rd</sup>line (range: 1-12), 89,4% monotherapy PD-(L)1 inhibition.

72 patients (22,6%) received a thoracic RT: 62 out of the 72 RT patients (87,5%) were irradiated with a curative intent. 53 patients (73,6% of the RT patients) received thoracic 3D-conformal RT or intensity modulated RT (normo- or mildly hypofractionated), whereas 9 received SBRT.

16,7% of the RT patients (12/72) showed a G1-4 immune-related pneumonitis (with a G $\geq 3$  of 11,1%), whereas for never-irradiated patients the G1-3 rate of immune-related pneumonitis was 2,4% (6/246), with only 1 G3 toxicity observed and no G $>4$  (t-test, p 0,001).

Median interval between the onset of the immune-related pneumonitis and the end of the RT was 22,4 months.

#### Conclusion

NSCLC patients treated with ICI may be at higher risk of developing immune-related pneumonitis if previously treated with curative-intent thoracic RT.

**SP-0211 Putting down the scalpel. The evolution of rectal cancer treatment**

A. Habr-Gama<sup>1</sup>

<sup>1</sup>Angelita and Joaquim Gama Institute, Colorectal Surgery, São Paulo, Brazil

**Abstract text**

The benefits of neoadjuvant chemoradiation were not restricted to long-term local disease control as confirmed by an update of the German Trial after 11 years of follow-up. Neoadjuvant treatment may lead to variable degrees of tumor regression, reflected by primary tumor reduction in size (downsizing), in depth of penetration and possible perirectal node sterilization (downstaging). In up to 42% of the cases, complete pathological tumor regression has been reported. Such findings challenged the role of standardized radical resection in all patients with rectal cancer irrespective of tumor response to neoadjuvant therapy. One could ask about the oncological benefit in a patient following radical rectal resection where not a single cancer cell is removed. But the solution is not straightforward, as it seems. Assuring complete tumor regression is not an easy task, unless radical resection is performed. However, exposing patients to considerable morbid procedure leading to urinary, sexual and fecal dysfunctions, the requirement for temporary or permanent stomas and the expected procedure-related mortality may not be considered the best alternative. In addition, the degree of tumor regression may be influenced by several different factors that should be taken into account. Studies have not definitively explained the reasons why after similar doses some tumors respond completely while others seem to be absolutely resistant to such therapy. Another factor that seems to influence tumor regression is the time elapsed between completion of treatment and response assessment. This was first suggested by data of patients with anal cancer. Similarly, in rectal cancer, retrospective studies also indicated that longer interval periods were associated with increased rates of complete tumor regression, suggesting that the more you wait, the more you get in terms of tumor regression. In this setting, patients with apparent complete clinical tumor regression would be ideal candidates for alternative treatment strategies including no immediate surgery and rigorous close observation. The main obstacle to this approach is the risk of leaving microscopic residual disease. Indeed, distinguishing transmural fibrosis from microscopic residual disease maybe quite difficult. Clinical assessment alone has been shown quite disappointing sensitivity and specificity rates in previous retrospective studies. However, some of these studies included tumor response assessment performed at 6 weeks from CRT completion, possibly too early and reflecting the detection of residual disease in the setting of ongoing necrosis. Also, studies have detected residual microscopic nodal disease in ypT0 patients. Again, these studies included patients managed by radical surgery after 6 weeks from CRT completion. This is suggested by the observation of absence of residual nodal disease in patients with ypT0 after periods of longer intervals than 6 weeks after CRT completion. It has been our strategy to assess tumor response at least after 8

weeks from CRT completion including clinical assessment with digital rectal examination, rigid proctoscopy and CEA levels in combination with radiological assessment, mainly performed to rule out residual extra-luminal disease. Only patients fulfilling these stringent criteria have been considered for this non-operative approach (Watch & Wait). Patients managed by this approach, did no worse than patients managed by radical surgery and pathological complete response in terms of survival. Late local relapses were all amenable to salvage resection, occurring in approximately 10% of these patients not immediately operated on and in a considerably longer interval when compared to systemic relapses. In a retrospective review, there was no survival compromise in patients with initial suspicion for complete clinical response who undergone delayed surgery for early tumor regrowth. Recently, other Institutions have observed similar results further supporting this treatment strategy in highly selected patients. Assessment of tumor response remains a challenging issue associated with a learning curve that has probably improved over time during our 25-year experience period. Even so, a subset of patients who were initially considered as complete responders presented with residual disease or early tumor regrowth/recurrence within 12 months of follow-up. It is worth mentioning that we have arbitrarily considered this period of 12 months as the minimum to consider a sustained complete clinical response in these patients. The share of patients with complete tumor regression may actually increase with modern CRT drugs and regimens and earlier baseline disease.<sup>20</sup> In fact the addition of chemotherapy cycles during the RT and the “resting” period between RT and surgery with a modest increase in RT dose (50.4Gy to 54Gy) has led to a significant increase in complete clinical response rates to over 50% of patients.

### Teaching Lecture: Re-irradiation for breast cancer

---

#### SP-0212 Re-irradiation for breast cancer

P. Poortmans<sup>1</sup>, O. Kaidar-Person<sup>2</sup>, S. Oldenburg<sup>3</sup>

<sup>1</sup>Institut Curie Ensemble Hospitalier, Department Of Radiation Oncology, Paris Cedex 05, France ; <sup>2</sup>Rambam Health Care Campus, Department Of Oncology- Radiation Oncology Unit, Haifa, Israel ; <sup>3</sup>Academic Medical Center, Departement of Radiation Oncology, Amsterdam, the Netherlands

#### Abstract text

Half of locoregional recurrences (LRR) after primary breast cancer treatment are isolated events. Re-staging should be done to rule out metastatic disease in order to select patients for potential curative salvage treatment. The treatment approach depends on the characteristics of the primary and recurrent cancer, previous locoregional and systemic treatments, site of recurrence, comorbidities and the patient's wishes. A multidisciplinary discussion should be associated to the shared decision-making process. As treatment has the potential to provide long-term disease-free survival, for radiation therapy (RT) meticulous target volume delineation and selection of the most appropriate techniques should be used to decrease the risk of toxicity, especially in patients who were previously treated with chemotherapy and/or RT. For patients who did not receive prior RT, resection followed by RT is the standard approach, including a boost to site of recurrent disease and with a higher radiation dose in case of residual macroscopic disease. Re-irradiation after previous RT should be considered also for all patients with isolated locoregional disease, preferably after surgical debulking. It can also be performed as primary treatment for gross disease, if surgery is not feasible or not accepted by the patient. The effective re-irradiation dose is generally limited to reduce adverse effects from the accumulated radiation dose. Combining lower re-irradiation doses combined with hyperthermia results in improved tumour control without additive toxicity. In selected patients, salvage breast-conserving surgery can be considered even in the case of earlier RT. Careful patient selection is needed and most experience is available with interstitial brachytherapy. Patients with LRR should also be considered for "adjuvant" systemic therapy as part of their treatment management, depending on the receptor status of the recurrent disease.

### Teaching Lecture: Extracellular vesicles; are we there yet?

---

#### SP-0213 Extracellular vesicles and potential implications for radiation therapy

A. Dal Pra<sup>1,2</sup>

<sup>1</sup>University of Miami, Department of Radiation Oncology, Miami, USA; <sup>2</sup>University of Bern, Radiation Oncology, Bern, Switzerland

#### Abstract text

Extracellular vesicles are a heterogeneous group of cell-derived membranous structures comprising exosomes and microvesicles that reflect the genetic and non-genetic materials of parent cancer cells. They are present in biological fluids and are involved in multiple physiological and pathological processes. Extracellular vesicles are

currently deemed as an important mechanism to cell-cell communication, allowing cells to exchange proteins, lipids and genetic material. These vesicles carry molecules such as oncoproteins and oncopeptides, RNA species (e.g., microRNAs, mRNAs, and long non-coding RNAs), lipids, and DNA fragments from donor to recipient cells. These compounds are potential sources of prognostic and/or predictive biomarkers as well as markers of treatment response. We will review the current role of extracellular vesicles in radiation therapy, with a particular focus on the development of clinical assays for treatment personalization.

#### Teaching Lecture: Update on the management of SCLC

---

##### SP-0214 Update on the management of SCLC

C. Le Pechoux<sup>1</sup>, A. Botticella<sup>1</sup>, A. Levy<sup>1</sup>

<sup>1</sup>*Gustave Roussy Cancer Campus, Radiation Oncology, Villejuif Cedex, France*

##### Abstract text

Small cell lung cancer (SCLC) accounts for about 13% of lung cancers. With a decreasing incidence in the last twenty years, SCLC remains a cancer with a dismal prognosis due in particular to a short doubling time which explains the metastatic presentation in nearly two thirds of the cases at diagnosis. This disease has a particular propensity to recur locally and disseminate in the brain. Hence, there have been several randomized trials assessing the role of thoracic and brain radiotherapy. Two individual data-based meta-analyses showed that thoracic radiotherapy and prophylactic cranial irradiation (PCI) should be part of the therapeutic strategy. Although platinum based chemotherapy combined to etoposide remains the cornerstone of SCLC treatment, since the 1980s radiotherapy has taken a growing place in multidisciplinary care. The treatment of stages I to III, is based on concomitant chemoradiation in fit patients and prophylactic cranial irradiation at the dose of 25 Gy in 10 fractions. Recent studies have confirmed that concomitant hyperfractionated accelerated radiotherapy at the dose of 45 Gy in 30 twice daily fractions, in 3 weeks gives the best results. However for patients who cannot receive HFART, once daily radiotherapy at the dose of 66 Gy in 33 fractions, may be an alternative. Five-year survival in the latest randomized studies is around 30-35% in SCLC patients having received concomitant CRT and prophylactic cranial irradiation. Radiotherapy has also a place in metastatic SCLC. The pivotal treatment is of course systemic treatment with platinum based chemotherapy and Etoposide. There is however randomized evidence that consolidation thoracic radiotherapy at the dose of 30 Gy in 10 fractions, administered to responders may improve the outcome of patients with extensive disease. A randomized phase II trial has also tried to evaluate the role of consolidation radiotherapy, not only to intra-thoracic disease, but also to extracranial metastases in ED SCLC. The results were encouraging. Prophylactic cerebral irradiation (PCI) remains a standard of care in non metastatic disease in good responders but its place is more controversial in the metastatic setting. Most advances in SCLC management are based on a better integration of radiotherapy and chemotherapy, even in extensive disease.

#### Teaching Lecture: How to combine checkpoint inhibitors with radiotherapy?

---

##### SP-0215 How to combine checkpoint inhibitors with radiotherapy?

K. Harrington<sup>1</sup>

<sup>1</sup>*The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Division of Radiotherapy and Imaging, Sutton, United Kingdom*

##### Abstract text

There is enormous excitement about the potential for combining radiotherapy with immune checkpoint inhibitors as a means of enhancing outcomes for patients with a variety of cancers. In recent years, we have begun to understand in great detail the biological effects of radiation on tumour (and normal) cells and this knowledge has informed our thinking on how we might best exploit radiation-induced immunogenic cell death for patient benefit. In particular, we have a much clearer perspective on the importance of molecular responses to DNA damage and their interactions with immune sensing mechanisms in the cell. In this presentation, the interplay between DNA damage and nucleic acid sensors will be reviewed, with specific focus on the cGAS/STING axis. However, other innate immune effectors such as toll-like receptors, RIG-I and mda5 will also be discussed. In addition, opportunities for combination therapies will be discussed in the context of neoadjuvant, concomitant and adjuvant use of immune checkpoint inhibitors, encompassing the PD-1/PD-L1 axis but also considering other more novel agents. The importance of the fractional and total dose of radiation will also be discussed with a view to interpreting existing clinical trial data and informing future trial design. Finally, the current and potential future roles for both predictive and prognostic biomarkers will be evaluated.

---

#### Teaching Lecture: How does brachytherapy fit in the modern management of penile cancer?

---

##### SP-0216 How does brachytherapy fit in the modern management of penile cancer?

J. Crook<sup>1</sup>

<sup>1</sup>*BC Cancer Agency - Southern Interior, Radiation Oncology, Kelowna, Canada*

##### Abstract text

Penile cancer is uncommon in western society, accounting for fewer than 1% of malignancies in men. When detected early, it is curable and penile conserving modalities should be considered first and foremost. If neglected and associated with spread to regional nodes, 5-year survival is reduced to 20-50% for inguinal node involvement and 10% when pelvic nodes are involved. The majority of penile cancers are of squamous cell (SCC) origin, and as such are both radiosensitive and radiocurable. About 50% are associated with HPV and as is the case for HPV-induced squamous cancer at other sites, may be more responsive to chemo-radiotherapy.

For SCC localized to the glans, brachytherapy is a convenient and effective means of delivering radiotherapy. There is abundant experience over several decades using low dose rate brachytherapy (LDR) employing temporary implantation of iridium-192 wire, or more recently using Pulse Dose Rate afterloading with a high intensity Ir-192 stepping source and hourly fractions that mimic LDR radiobiology. Penile preservation rates are about 85% at 5 years and 70% at 10 years. Ideal tumors are confined to the glans and < 4 cm in diameter. Higher grade is not a contraindication to brachytherapy but does determine nodal management. Surgical nodal staging is

recommended for all stage T2 or higher, grade 3, or T1b with LVI. The implant procedure is performed under either local (penile block) or general anesthesia and takes about 30-45 minutes. A minimum of a 2 plane implant is recommended, but up to 3 planes may be required. The median number of needles is 6 (4-12) and ideal spacing between adjacent needles and planes for LDR is 15 mm (range 12-18). Dosimetry can be calculated according to active length and spacing as per the rules of the Paris system for Iridium-192 wire manually after-loaded implants (dose prescribed at 85% of the dose rate minima in the central plane), or calculated from a planning CT scan performed with 1mm slice thickness through the region of interest. The patient is usually hospitalized during the treatment which takes about 5 days at an hourly dose rate of 50-60 cGy per hour. Needles can be removed at the bedside with suitable parenteral analgesia; bleeding is minimal.

With increasing availability and popularity of high dose rate brachytherapy, (HDR) and a growing general reluctance regarding manual after loading, HDR is taking a more prominent role in penile brachytherapy, with 4 recent series reporting on over 100 patients. Although the procedures are very similar, in contrast to an LDR implant, needle spacing should be closer in HDR, between 9 and 12 mm. Treatment is fractionated, twice daily with a minimum of 6 hours between. Fraction size is 3-3.5 Gy with a total prescribed dose of 42-51 Gy. Homogeneity parameters are important to minimize complications and it is recommended that the V125% be < 45% and the V150 < 20%. Penile preservation is reported at 93-100% at 2 years and 70% at 10 years.

Another HDR option involves an individualized or custom mold technique. This is suitable for Tis or minimally invasive T1a tumours. The prescribed dose is 40 Gy in 10 fraction given bid over 5 days. The dose can be prescribed at the required depth (3-5mm). Maximal skin dose should be limited to 120%, with central urethral sparing to receive < 90% of prescription. Two recent small series show promising results.

For both methods of brachytherapy, treatment is well tolerated with the acute reaction healing in 2-3 months. As the tumor resolves it will leave a crater which then must re-epithelialize. Cleanliness is maintained with saline soaks, and topical antibiotics, with the addition of Vitamin E as healing progresses. The most common long term complications are soft tissue ulceration in 5-25% (depending on implant volume, dose and tumour stage) which can usually be managed conservatively although hyperbaric oxygen will speed healing in more serious cases, and meatal stenosis requiring either urologic or self-dilatation in 9-45% (depending on proximity of the sources to the meatus).

With all the brachytherapy techniques for penile cancer, prolonged follow up is necessary. Although 80% of local failures are within the first 2 years, approximately 20% can occur late, after 5 years. Local recurrences can be managed surgically with no impact on cause specific survival but must be recognized and managed promptly. Patients must be aware of this limitation

#### Teaching Lecture: Uncertainties in Radiomics

---

#### SP-0218 Uncertainties in Radiomics

M. Hatt<sup>1</sup>

<sup>1</sup>Inserm, Laboratory of Medical Information Processing Latim- Umr 1101, Brest, France

#### Abstract text

This lecture will highlight the major uncertainties and methodological pitfalls of radiomics studies. Building on previous experience as well as on a critical review of important published papers, the lecture will detail most important issues associated with image acquisition and pre-processing, object of interest (semi)automatic delineation, features definition, nomenclature and standardization, as well as statistical analysis and machine learning for models training and validation. For each pitfall and issue, the lecture will provide the most up-to-date and currently available methodological solutions, with a focus on options facilitating the transfer of radiomics to the clinical practice.

#### Teaching Lecture: New technology and modalities in Radiotherapy - What can the ESTRO School offer?

---

#### SP-0219 New technology and modalities in Radiotherapy - What can the ESTRO School offer?

J.G. Eriksen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. of Experimental Clinical Oncology, Aarhus, Denmark

#### Abstract text

Radiation Oncology is probably one of the most technology-driven medical specialties at all. This is very much reflected by the multidisciplinary nature needed for delivering the optimal treatment at the right time and in the right place. MD's, medical physicists and RTT's are some of the well-known key persons but also engineers, technicians and IT-professionals play an important role. The development of new technologies in radiotherapy are moving fast forward and it is both a privilege and an obligation of the ESTRO School to keep updated on the educational offers that reflect the technological development. The educational offer should be updated, being able to look into the future and be critical, objective and well balanced. The lecture will discuss why this obligation is so important, the current strategy of the School and give a glimpse of what we can expect in the near future.

---

#### Teaching Lecture: Precision medicine and systems biology - transforming cancer research in the 21st century

---

#### SP-0220 Precision medicine and systems biology - transforming cancer research in the 21st century

W. Kolch<sup>1</sup>

<sup>1</sup>University College Dublin- Ireland, Systems Biology Ireland and Conway Institute, Dublin, Ireland

#### Abstract text

Advances in technologies, especially genome sequencing and other omics methods, are enabling the precise molecular phenotyping of individual cancer patients. Major challenges are now unlocking the information contained in these data and integrating them with each other, but also with clinical data and imaging data. The aim is to obtain a clinically relevant and actionable view of an individual patient's cancer that allows finer diagnostic stratification, predictions of the course of

disease and response to therapies, ultimately enabling highly precise interventions with high efficacy and less side effects. Mathematical and computational modelling techniques developed by systems biology to analyse dynamic living systems play a key role in achieving these goals. I will discuss the role of such models for precise diagnostic stratification, the identification of efficacious drug combinations, and the personalisation of treatment.

**Symposium: Balancing the risks and benefits of re-irradiation**

---

**SP-0221 Indications for re-irradiation - changes in the era of effective systemic treatment options?**

M. Hoyer<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Danish Center For Particle Therapy, Aarhus, Denmark

**Abstract text**

The recent years have brought a number of drugs directed towards novel targets of the cancer cells. Many of these have given led to some improvement of the survival. This survival gain is moderate in most cancers, but it may a reason for reconsideration of strategies in treatment of radio-recurrent cancer? Reirradiation is always related to an increased risk of complication and selection of patients for reirradiation represents a delicate balance between disease control and survival gains on one hand and risk of severe complication on the other.

The presentation will give examples of considerations in selection of radio-recurrent patients for reirradiation. However, it will conclude that systemic therapies cannot replace radiation therapy in the attempt to achieve long lasting tumor control.

**SP-0222 Radiobiology of normal tissue repair - what are the implications for reirradiation?**

R. Coppes<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Radiation Oncology and Cell Biology, Groningen, The Netherlands

**Abstract text**

The response of normal tissues to irradiation is mainly determined by the survival and regenerative potential of the tissue stem cells, and modulated by inflammatory processes, vasculature damage and altered neuronal innervation and fibrosis. Interestingly, transplantation of tissue specific stem cells has been shown to restores tissue homeostasis and sparing stem cells may preserve tissue function and prevent late radiation effects. It is for long recognized that the number of surviving clonogens determines the time to recovery after irradiation and with that also the retreatment tolerance of many tissues. Since these clonogens are often stem cells or derived progenitor it seems eminent to spare these as much of possible to reduce normal tissue side effects and potentially allow reirradiation when needed. Recently much improvement has been made to described and characterized the tissues stem cells. This now allows localisation and studying of radiation responses in vitro and in vivo. In combination with accurate localised tissue proton irradiation this has yielded novel insight in the regenerative processes of several tissues. Dose volume effects, inhomogeneous irradiation field and uneven distribution of stem cells greatly influences the regenerative potential and with that the retreatment tolerance of normal tissue. Moreover, studies of post irradiation form in tissue isolated stem cells show regenerative potential in vitro being much higher than in situ, indicating that not only the radiation damaged stem cells themselves determine regenerative potential but also the affected environment. In this presentation the radiobiology of reirradiation will be discussed and examples of several tissue will be

provided to show insight in factors that influences stem cells functioning and how this may be used to enhance post-irradiation tissue regeneration and consequential retreatment tolerance.

**SP-0223 Protons, stereotactic radiotherapy and adaptive radiotherapy - what is their value for reirradiation?**

A. Richter<sup>1</sup>

<sup>1</sup>Universitätsklinikum Würzburg, Department of Radiation Oncology, Würzburg, Germany

**Abstract text**

For re-irradiation highly conformal treatment techniques are needed. Some technological developments such as proton therapy, stereotactic and adaptive radiation therapy have improved targeting accuracy and offer the possibility of highly conformal dose distributions. For proton therapy, the low exit dose is advantageous to achieve a high degree of dose conformity. The availability of proton therapy is limited to proton centers. The wider availability of in-room imaging and advanced treatment delivery systems means that more institutions are now offering stereotactic radiation therapy. The stereotactic approach uses an inhomogeneous dose distribution with a sharp fall-off dose and tight margins to achieve a high biological effective dose in the target and a dramatic sparing of normal tissue. For both techniques (proton and stereotactic radiotherapy), motion management strategies should be implemented to considered interfraction and intrafraction motion. Adaptive radiation therapy accounts for changes in patient's anatomy and/or physiology during the treatment course. The adaptive radiation therapy is based on repeated anatomical and/or functional imaging and the use of deformable image registration. Further elements of the adaptive workflow are the automatic recontouring, plan evaluation and reoptimization, dose calculation, and quality assurance. Adaptive radiation therapy can be performed in real-time, online or offline. The clinical realization of online adaptive radiotherapy is extremely challenging, mainly due to the inability for real-time treatment re-planning. The implementation of adaptive radiotherapy presents some challenges such as accuracy of deformable image registration and the higher workload for the staff. Despite some challenges, proton and stereotactic radiation therapy offer the possibility of highly conformal dose distributions. Adaptive radiation therapy holds significant promise in maximally compensating for intra and interfraction anatomical uncertainties.

**SP-0224 Brachytherapy in the reirradiation situation - what are benefits and limitations compared to modern EBRT?**

C. Gutiérrez Miguélez<sup>1</sup>

<sup>1</sup>Institut Català d'Oncologia, Brachytherapy Unit, L'Hospitalet de Llobregat, Spain

**Abstract text**

In this talk, I will do a revision of indications of Brachytherapy for reirradiation, a revision of the results in published in the literature and our results in different localizations. In the last years, due to the advances in imaging and dosimetry optimization, the interest and use of Brachytherapy (BT) for treating relapses is growing. The benefits of reirradiation with Brachytherapy versus External Radiotherapy (ERT) are: Smaller treated volume; Accuracy: no motion; Rapid dose fall-off; Accelerated treatment (therapeutic gain); Preferably intraoperative approach; If intra/peroperative implant, only 1 procedure. The limitations or disadvantages would be: Very small treated volumen; Operator dependent; Need of skills to insert applicator; Need of Operating Theatre; Help of other especialists (surgeons); Inhomogeneous dose distribution (Hot spots);

High complication rate. Currently there are some groups that are using BT for: Breast (second conservative approach). The GEC-ESTRO Breast group experience (JM Hannoun-Levy) published their experience with the same local control as the primary treatment and with good cosmetic results; Prostate (Salvage HDR or LDR BT): the rate of biochemical control, survival and complications by different groups are described. For Head&Neck, I will explain in detail Navarra's experience (R Martinez-Monge) and Erlangen's (V Strnad). I will also describe other indications, as Gynecology, Rectum, Chordoma, and other second primary cancers occurring in previously treated in-field. And finally I will describe our results in Breast (40 cases), Prostate: (96 analysed), Head&Neck: 13, Rectum: 14 and a miscellaneous.

---

**Symposium: Circulating biomarkers for patient stratification and treatment monitoring**

---

**SP-0225 Blood biomarkers to predict radiotherapy response**

G. Hanna<sup>1</sup>

<sup>1</sup>*Peter MacCallum Cancer Centre, Department of Radiation Oncology, Melbourne, Australia*

**Abstract text**

The use of predictive biomarkers in radiation oncology is a field still very much in its infancy. Very few validated biomarkers exist which are used to select or modify the treatment of a patient scheduled to receive radiotherapy and which are in routine use in clinical practice. Moving towards a precision medicine based approach in radiation oncology, it is hoped that predictive biomarkers may be used in a range of scenarios to inform clinical decision making. It is hypothesised that biomarkers could select patients for treatment versus no treatment, for selection of a specific radiation technique or dose and/or fractionation schedule and perhaps they may be used to select patients for a specific systemic therapy agent in combination with radiotherapy. It is hoped that circulating biomarkers could be used in combination with or in place of tissue samples. This presentation will review these considerations and will suggest potential blood based biomarkers which may be of potential clinical benefit in the future.

**SP-0226 ctDNA as a non-invasive liquid biopsy for patient stratification and treatment monitoring**

D. Gale<sup>1</sup>

<sup>1</sup>*University of Cambridge, Cancer Research UK Cambridge Institute- Li Ka Shing Centre, Cambridge, United Kingdom*

**Abstract text**

This talk will focus on the use of circulating tumour DNA (ctDNA) as a non-invasive liquid biopsy for treatment monitoring and patient stratification.

Different technologies will be discussed, including amplicon-based sequencing, exome sequencing, the use of patient-specific panels and digital PCR to monitor disease in advanced and early stage cancer in high-grade serous ovarian cancer, melanoma, breast and non-small cell lung cancer (NSCLC).

**SP-0227 Cancer detection using methylated cell-free DNA**

S. Bratman<sup>1</sup>

<sup>1</sup>*Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada*

**Abstract text**

Circulating biomarkers play an important role in personalized cancer medicine and adaptive therapy. In

particular, liquid biopsies using circulating tumour DNA (ctDNA) are rapidly gaining acceptance in clinical settings. Current methods for the detection of ctDNA involve sequencing somatic mutations using cell-free DNA, but the sensitivity of these methods may be low among patients with localized cancer given the limited number of recurrent mutations. By contrast, large-scale epigenetic alterations—which are tissue- and cancer-type specific—are not similarly constrained and therefore potentially have greater ability to detect and monitor cancers in patients with localized disease. A prime example is DNA methylation, which differs between cancerous and normal tissues and between distinct cancer types. In this talk, I will describe current approaches to measuring methylated cell-free DNA. We have developed a new immunoprecipitation-based technique that addresses several limitations of previous assays. Our technique avoids chemical conversion of cell-free DNA (i.e., bisulfite treatment), therefore enabling genome-wide methylome analysis of small quantities of circulating cell-free DNA. We show that large-scale DNA methylation changes that are tumour-specific are enriched within cell-free DNA. Robust performance is seen in cancer detection and classification across an extensive collection of plasma samples from several tumour types. In a cohort of patients with head and neck squamous cell carcinoma, we demonstrate how methylated cell-free DNA analysis could be used for longitudinal monitoring and evaluating treatment response.

**SP-0228 Circulating biomarkers tumor immune response**

D. De Ruyscher<sup>1</sup>

<sup>1</sup>*Maastrro Clinic, Radiation Oncology, Maastricht, The Netherlands*

**Abstract text**

Immunotherapy (IO) is increasingly used to treat a variety of cancers, both in the curative and palliative setting. In contrast to TKIs, where biomarkers are in use for over a decade, leading to increased success and insights in resistance mechanisms and new targets, the landscape in IO is more sober. Although many IO targets are being identified in pre-clinical models and in human material, robust and highly predictive biomarkers are still lacking. The reasons may partly due to the complexity and dynamic nature of the immune system. Ideally, all parts of the immune system as well as the inflammatory status of the tumor at a certain moment in time should be known from a blood sample. The cancer immunogram was developed to describe the cancer-immune system interaction including a framework of seven parameters that are known to affect the anticancer immune response and that can be interrogated in individual cancer patients. These parameters are: tumor mutational burden; the general immune status of the patient; presence of T cell immune infiltrates; tumor PD-L1 expression; sensitivity of tumor cells to T-cell killing (including MHC expression, functional IFN-gamma receptor pathway); a myeloid cell-mediated inflammation (high C-reactive protein (CRP) and IL-6 levels); and high serum lactate dehydrogenase (LDH) (reflecting both tumor burden and anaerobic glycolysis). PD-L1 expression, with all its shortcomings, is the most commonly used biomarker for IO, but is not usable as a circulating biomarker.

In contrast, tumor mutational burden (MB), which is associated with response to IO, is experimentally detectable in the blood. The hypothesis is that the higher the number of mutations, the higher the probability of neo-antigen expression and thus the higher the likelihood that the tumor is being recognized as “foreign” by the immune system.

Patients with either germline or somatic mutations in mismatch repair genes have a very high number of non-synonymous mutations. This is reflected by unstable

microsatellite regions in the genome. Patients with mismatch repair deficient tumours (dMMR) have a high overall response rate to PD-1/PD-L1 blockade. TMB measurement is highly dependent on the method and a clear cut-off has not yet been defined. However, the likelihood that TMB will become a standard test is high. The diversity of the T-cell repertoire can be measured by DNA sequencing of the TCR V $\beta$  genes. The presence of a restricted or uneven TCR repertoire measured in the peripheral blood had a negative impact on survival in patients with melanoma or bladder cancer treated with IO. At present, this is still a highly experimental technique.

As the inflammatory status of the tumor micro-environment is also determining the response to IO, markers like lactate dehydrogenase (LDH), CRP, vascular endothelial growth factor (VEGF) and soluble CD25 are associated with response to anti-CTLA-4 and PD-1/PD-L1 blockade in advanced melanoma. However, more work is needed to validate these findings and to establish cut-off values that would make these clinically relevant. Baseline neutrophil-to-lymphocyte ratios and relative eosinophil count are associated with response to IO, but none of these have an accuracy which is high enough to be useful in the clinic.

Finally, circulating tumor DNA seems to be a very sensitive marker that allows to detect both tumor growth as well as response far before imaging does.

It is likely that the coming years circulating biomarkers will become available and more specific in order to change the landscape of IO to make it more efficient for more patients.

#### Symposium: Radiation-drug combinations on the 2019 horizon

---

##### SP-0229 Barriers and solutions to increase the number of clinical trials of new drug-radiotherapy combinations

R. Sharma<sup>1</sup>

<sup>1</sup>*UCL Cancer Institute, University College London, London, United Kingdom*

##### Abstract text

Radiotherapy is a fundamental component of treatment for the majority of patients with cancer. In recent decades, technological advances have enabled patients to receive more targeted doses of radiation to the tumour, with sparing of adjacent normal tissues. There is great potential for new drug-radiotherapy treatment strategies to improve clinical outcomes for patients. Novel combinations from the most relevant preclinical models of cancer biology and immune-oncology should be prioritised for rapid advancement to the clinic. Early and frequent communication between multiple stakeholders including industry, academia, regulatory agencies and patient advocates is essential to generate sufficient numbers of clinical trials and to increase the rate of progress. Intelligent trial designs are required to increase the number of studies which efficiently meet their primary outcomes. Endpoints including local control, organ preservation and patient-reported outcomes may demonstrate clinical benefit and are of specific relevance to clinical trials of new drug-radiotherapy combinations. In this talk, I will discuss barriers that have been identified to the development of new drug-radiotherapy combinations, and solutions to increase the number of clinical trials. Interested readers are recommended to read the review article published by the NCRI CTRad Academia-Pharma Joint Working Group: Sharma, R.A., et al., NCRI CTRad Academia-Pharma Joint Working Group. (2016). Clinical Development of New Drug-Radiotherapy

Combinations. *Nature Rev Clin Oncol*, 2016. doi: 10.1038/nrclinonc.2016.79.

Abstract not received

##### SP-0231 Radiotherapy in combination with DNA damage response inhibitors in 2019: are we any closer to clinical benefit?

A. Chalmers<sup>1</sup>

<sup>1</sup>*Inst. of Cancer Sciences-Univ. Glasgow, Department of Clinical Oncology, Glasgow, United Kingdom*

##### Abstract text

Clinical evaluation of radiotherapy in combination with inhibitors of the DNA damage response has been underway for several years now and, while knowledge about effects on normal tissue toxicity is accruing, evidence of improved tumour control is still awaited. PARP inhibitors are the most advanced class of agents to be tested in the clinic, and this presentation will summarise the key observations made in the early phase trials that have been conducted to date. I will also consider how progress might have been accelerated if more efficient clinical trial designs had been adopted.

Inhibitors of additional DNA damage response proteins are also entering the clinic, both as single agents and in combination with radiotherapy, and pre-clinical data indicates that some of these may be more potent radiosensitizers than PARP inhibitors. After summarising the pre-clinical findings, I will review the key clinical trials and consider how we might select patients for particular radiation-DDRi combinations. Finally I will present some novel clinical trial designs that might enable us to make more rapid progress in this area.

##### SP-0232 Cost-estimate models for radiation-drug combinations

A.H. Ree<sup>1</sup>

<sup>1</sup>*Akershus University Hospital, Department of Oncology, Lørenskog, Norway*

##### Abstract text

Programs within precision cancer medicine are being conducted at an increasing number of cancer centers internationally, in line with recommendations from multiple governmental and independent initiatives. A common objective for such activities is the integration of existing resources and new investments in technologies and therapies that reside in the industrial, regulatory, academic, and clinical practice sectors. The presentation will discuss modeling of costs of the required infrastructure to conduct precision medicine studies with rational radiation-drug combinations in the public health services.

The model compares cost-per-patient figures for:

- Radiation alone (the benchmark)
- Radiation combined with biomarker-agnostic use of a given drug (combination A)
- Radiation combined with molecularly matched medication (combination B)

The estimations include costs for:

- The medication
- Outpatient clinic visits
- Admission from adverse events
- The biomarker-based diagnostic procedures

The input parameters comprise:

- A set of given diagnosis-related-group indicators
- Wholesale drug prices, including costs for required oncology nursing to administer intravenous drugs

- Personnel costs and factual investments within the biomarker-based procedures.
- The main cost drivers for radiation-drug combinations will probably be:
- The medication and management of adverse events for combination A
  - The diagnostic procedures for combination B

Abstract not received

**SP-0234 Inverse treatment planning in clinical practice, one click and done?**

D. Todor<sup>1</sup>

<sup>1</sup>Virginia Commonwealth University, Radiation Oncology, Richmond- VA, USA

**Abstract text**

Treatment Plan Optimization is one of those subjects which strongly polarizes brachytherapy practitioners. Part of the problem is that we got where we are today by slowly building on decades of successful clinical experience, relying on clinical knowledge sublimated in collections of rules called 'systems': Stockholm, Paris, Manchester. These systems described, sometimes in great details, *how* things should be done; they represent practice not theory. This approach had a lot to do with reproducibility of treatments that seem clinically successful and little to do with understanding how things work, *why* a certain placement of radioisotopes actually works and explaining the mechanism behind.

Fast forward to the current era in which we learned how to compute radiation transport through the body very accurately and to describe our plans by employing dose volume histograms (DVH). Having now a set of DVH parameters that describes a dose distribution, one is in the position of optimizing that distribution by simultaneously maximizing those parameters to some structures (anatomical or disease related) while minimizing other parameters to structures related to normal anatomy, which typically one tries to spare.

Optimization is an interesting applied mathematical domain and attracts computer scientists, AI researchers, physicists and mathematicians.

The less than optimal reality (pun intended) is that optimization is seldom used in the clinic (at least in the brachytherapy practice) and when it is used, a physician or a physicist will typically 'adjust' a solution obtained straight out of the optimizer with the intent of further improving it.

My plan is to discuss the origins and the [i]rationale of this state of affairs as well as to describe possible avenues for increased utilization of true optimization. I will present three cases (cervical, prostate and breast cancer) as how-to examples of what optimization can deliver. I will devote a second part of my talk describing the obvious fact that plan optimization really is dose optimization and more precisely DVH-based optimization. I will do my best to question central concepts like prescription dose, targets, dose coverage, Ds and Vs, (all ingredients in the Optimization) and try to setup alternative constructs. An example based on cervical cancer data and/or prostate cancer will follow.

**SP-0235 Intuitive and Insightful Evolutionary Intelligent Treatment Planning**

P. Bosman<sup>1</sup>

<sup>1</sup>Centrum Wiskunde and Informatica CWI, Life Sciences and Health, Amsterdam, The Netherlands

**Abstract text**

Artificial Intelligence (AI) increasingly pervades the daily news, with self-driving cars, robots, and face recognition even on smart phones. The reason for this revolution is threefold: 1) several AI techniques have matured algorithmically, 2) there have been spectacular advances in computing hardware (e.g., GPUs), and 3) digitizing and storing large amounts of data has become common practice.

AI will increasingly be a key driver of automation, including in radiation oncology. In this talk, placed within the broader context of existing automation approaches to brachytherapy treatment planning in general, I will present the AI efforts undertaken so far by my research group to automate. These are mainly focused around a particular subfield of AI: that of Evolutionary Algorithms (EAs).

EAs are loosely based on the natural evolution principles and have the advantage of being relatively straightforward to apply to optimization and machine learning tasks. A disadvantage is that most textbook EAs are 'blind', as they randomly combine solutions. I will introduce the state-of-the-art Gene-pool Optimal Mixing Evolutionary Algorithm (GOMEA) family that automatically determines how to best combine solutions. I will illustrate the advantageous properties of GOMEAs over classical 'blind' EAs, showing how GOMEAs are capable of obtaining (near-)optimal results for problems with millions of variables in less than an hour on a normal desktop computer, where classic EAs can only do this for tens or a few hundred variables.

I will show how with GOMEA we are able to solve bi-objective problem formulations based directly on dose-volume indices for automated HDR brachytherapy treatment planning for the prostate, thereby finding not just one treatment plan, but trade-off curves consisting of many interesting potential treatment plans that trade-off target coverage with sparing organs at risk for large numbers of dose calculations points in mere minutes on a single modern GPU. Visualizing such a trade-off curve gives an insightful overview of what types of dose-volume indices are achievable for a particular patient.

Beyond this, I will briefly touch upon near-future avenues for further AI-based automation.

#### Abstract text

The data in IAEA TRS-398 for MV beams was prepared in the mid-1990s, and since that date a number of new developments have taken place, such as the publication of ICRU 90 on key data for measurement standards in the dosimetry of ionizing radiation, free flattening filter beams, new detectors and dosimetry for small fields. IAEA decided to update its protocol and by the end of 2015 asked for volunteers to measure (based on primary standard dosimeters) and calculate (with Monte Carlo codes) updated  $k_{Q,Q_0}$  values for reference-class ionization chambers (IC).

Primary standard dosimeters for absorbed dose to water are water and graphite calorimeters. IAEA requested primary and secondary standard dosimetry laboratories to measure  $k_{Q,Q_0}$  values for at least 5 ICs of the same type, ideally from different manufactured batches and to include one chamber with well-known  $k_{Q,Q_0}$  values such as NE 2571. For calculations, the Monte Carlo codes have to pass the Fano test like EGSnrc and PENELOPE. One IC with well-known  $k_{Q,Q_0}$  values has to be simulated first to demonstrate appropriate skill for these calculations. The complete results are to be delivered by December 2018 and the data analysis is to begin in 2019. Following IAEA demand, EURAMET decided to launch the EMPIR project 16NRM03 RTNORM in mid-2017 to provide  $k_{Q,Q_0}$  factors to the IAEA. In the MV photon beams workgroup, DTU (Denmark), LNE-LNHB (France), NPL (United Kingdoms) and VSL (the Netherlands) were to measure  $k_{Q,Q_0}$  factors for 6 IC types and ENEA (Italy), IST-ID (Portugal), STUK (Finland) and THM (Germany) were to calculate  $k_{Q,Q_0}$  factors for 10 IC types. This presentation will give a description of the RTNORM measurements and calculations. The results will serve as examples to show which kind of data the IAEA received and how to evaluate them in order to select the ones that will be used for the TRS-398 update.

#### SP-0237 Clinical application of kQ factors for reference dosimetry in flattening filter free (FFF) photon beams

L. De Prez<sup>1</sup>, C. Andersen<sup>2</sup>, J. De Pooter<sup>1</sup>, H. Palmans<sup>3</sup>  
<sup>1</sup>VSL, *Ionizing Radiation Standards, Delft, The Netherlands*; <sup>2</sup>Center For Nuclear Technologies DTU Nutech, *Dosimetry, Roskilde, Denmark* ; <sup>3</sup>National Physical Laboratory, *Radiation Dosimetry, Teddington, United Kingdom*

#### Abstract text

Flattening filter free (FFF) photon beams were introduced several years ago and are now widespread for application in radiotherapy. There are several clinical advantages of FFF beams over conventional beams with flattening filter (WFF), however differences in beam spectra at the point of interest in a phantom potentially affect the ion chamber response. FFF beams are also non-uniform over the length of a typical reference ion chamber and recombination is usually larger because of the higher dose delivered per pulse. Several studies have described FFF beam characteristics and their effect on beam calibration using conventional reference dosimetry, including the use of  $k_Q$  factors. Some studies predicted significant discrepancies in  $k_Q$  factors (0.4% up to 1.0%) if TPR<sub>20,10</sub> based codes of practice (CoPs) were to be used. Recently the IAEA published a new code of practice for dosimetry of small and non-reference static fields, including a description on the application of reference dosimetry for FFF compared to conventional WFF beams. This presentation addresses the application of the new code of practice and how to perform reference dosimetry in FFF beams by applying  $k_Q$  factors in relation to  $k_Q$  values available literature and performed by the authors within

the EMPIR 16NRM03 RTNOM project. Examples of  $k_Q$  studies will be given and special attention will be paid on how to deal with, e.g., ion recombination and beam non-uniformity.

#### SP-0238 TRS 483: past, present and future

H. Palmans<sup>1,2</sup>

<sup>1</sup>EBG Medaustrom GmbH, *Medical Physics, Wiener Neustadt, Austria* ; <sup>2</sup>National Physical Laboratory, *Medical Radiation Science, Teddington, United Kingdom*

#### Abstract text

IAEA TRS-483 [1] is the first Code of Practice for the dosimetry of small high-energy photon fields published at either national or international level. The subsequent publication of a Summary paper in Medical Physics [2] marks the conclusion of a joint effort by the IAEA and the AAPM in publishing, for the first time, a Code of Practice for dosimetry together. In this presentation, the developments in the past decades that have shaped the small field recommendations in IAEA TRS-483 are presented, followed by an overview of the key steps in its application to the determination of small field output factors. A discussion will then be given on experience with the application of the Code of Practice and new developments and findings that have emerged from those. The aspects related to reference dosimetry for radiotherapy machines that cannot generate the conventional 10 cm × 10 cm reference field, and in particular those pertaining to the reference dosimetry of flattening-filter-free beams, are addressed in the previous presentation in this symposium.

The first part of this presentation discusses past developments that have been determining IAEA TRS-483 include the following. There has been the realization that for small fields the collimator setting and field size at FWHM are not congruent and an unambiguous definition of field size is needed. The definition of lateral charged particle equilibrium range has enabled a quantitative criterion to distinguish between fields for which small field conditions exist and broad beams. A paper by Alfonso et al [3] formally defined a small field output factor as a ratio of detector readings multiplied with a small field output correction factor which enabled the consistent determination of such factors using experiment or Monte Carlo simulations and the subsequent compilation of literature data for the Code of Practice. The work of Cranmer-Sargison et al [4] showed that for the representation of small field output factors and correction factors, the equivalent square field size of irregular small fields is better represented by a field with equal area than by a field with equal scatter conditions, as is the case for broad beams.

The second part of the presentation outlines the key steps in applying IAEA TRS-483 to the determination of field output factors. The first step is the selection of suitable measurement equipment. The second step consists of the characterisation of the small field profiles and the derivation of the equivalent square field size from those profiles. Then the alignment procedures for real-time and off-line detectors are considered followed by the selection and interpolation of output correction factors and the determination of their uncertainty. The last part of the presentation discusses the experience with applying the code of practice, new information that has become available in the literature and new detectors that have become commercially available.

### SP-0239 Following TRS 483: reference and relative dosimetry in Tomotherapy

M.D.C. Lopes<sup>1</sup>, T. Santos<sup>1,2</sup>, T. Ventura<sup>1</sup>, M. Capela<sup>1</sup>  
<sup>1</sup>*Ipcfg- Epe, Medical Physics, Coimbra, Portugal* ; <sup>2</sup>*fc- University Of Coimbra, Physics, Coimbra, Portugal*

#### Abstract text

**Introduction and purpose:** The joint IAEA and AAPM international code of practice (CoP) for small static fields dosimetry - TRS 483- was issued on December 2017, after almost a decade from the publication, in 2008, of a formalism that outlined the extension of the dosimetry based on absorbed dose to water to small and composite fields and to non-reference conditions [1]. Both publications rely on universally adopted codes of practice like IAEA TRS 398 and AAPM TG 51, building on the established reference dosimetry for conventional reference 10 cm × 10 cm field and extending the dosimetry down to small and non-reference fields by introducing the concept of machine specific reference (*msr*) field. This concept applies to those treatment units where the conventional reference field is not permitted. Helical Tomotherapy (HT) is one of such machines. Exradin A1SL ionization chamber, from Standard Imaging, is the chamber included in the standard dosimetry package for HT but it is not included in the list of reference dosimeters in TRS 483. The motivation for the present work was to obtain the global correction factor for A1SL chamber that would account both for quality and geometry following the recommendations of TRS 483, in the context of performing reference dosimetry in Tomotherapy and exploring the different ways and concepts embodied in the document. Also relative dosimetry with A1SL has been explored through the determination of output factors using free-correction film results and other detectors suitable for small field dosimetry.

**Methods and materials:** According to TRS 483 the absorbed dose to water for the *msr* field ( $f_{msr}$ ), in the beam of quality  $Q_{msr}$ , at the reference depth in water is given by:

$$D_{w,Q_{msr}}^{f_{msr}} = M_{Q_{msr}}^{f_{msr}} N_{D,w,Q_0}^{f_{ref}} k_{Q_{msr},Q_0}^{f_{msr},f_{ref}}$$

where the chamber reading corrected for all charge collection influences ( $M$ ), multiplied by the chamber calibration factor from certificate ( $N$ ) has to be corrected both for beam quality and geometry by a correction factor

denoted by  $k_{Q_{msr},Q_0}^{f_{msr},f_{ref}}$ . This global correction factor for A1SL was obtained through different approaches following TRS 483 recommendations - cross calibration with reference chamber, radiochromic film independent dosimetry and using the hypothetical reference field concept. The results were compared with published values following other approaches like Monte Carlo calculations [1,2] or alanine dosimetry [3,4]. To underpinning small field relative dosimetry in HT, a set of small fields was configured through its pneumatically controlled binary multileaf collimator (MLC) for the three field slits - 1, 2, 5

and 5 cm. An intercomparison of output factors was done using different detectors like microdiamond, unshielded diode, micro chamber and also film dosimetry to set against A1SL chamber response. Once more the information conveyed in TRS 483 has been abundantly explored to reach a sustained way of performing relative dosimetry in HT.

#### Results

In agreement with values from literature, an average value of  $0.9962 \pm 0.0040$  has been obtained for the global correction factor of Exradin A1SL chamber to be applied in absolute dose determination for helical Tomotherapy. Concerning relative response, output factors obtained with different detectors were within agreement, given the level of uncertainty. Considering film output factors as free of corrections, the average value for A1SL output factors corrections was  $1.000 \pm 0.007$ .

#### Conclusions

The results of the present work justify Accuray practice of not correcting the A1SL chamber reading for quality and geometry in absolute dose determination in Tomotherapy as the derived factor is compatible with unity, within the associated uncertainty. Also in relative measurements, the ratio of A1SL chamber readings do not need further correction to be taken as output factors for the considered small clinical field sizes when normalized to the machine specific reference field in HT.

### Symposium: New advances in image reconstruction in CBCT

---

#### SP-0240 Breathing motion in cone-beam CT

S. Rit<sup>1</sup>

<sup>1</sup>CREATIS CLB, Radiotherapy, Lyon, France

#### Abstract text

Breathing motion during cone-beam CT (CBCT) acquisition blurs moving structures and causes streaks along x-rays adjacent to these structures. Correcting for these artifacts is required to improve image-guided radiotherapy and for adapting the radiotherapy of lung and upper abdominal cancers. Current clinical solutions use respiration-correlated reconstruction: a large number of projection images is sorted in respiratory phases based on a breathing signal and a 3D CBCT image of the respiratory phase is reconstructed separately from each subset of projections to yield a 4D CBCT image. More advanced breathing motion correction techniques, which make use of less projection images, can be categorized in motion-compensated and iterative 4D CBCT. The former is essentially a 3D imaging technique in which the motion is first estimated and then compensated for during CBCT reconstruction. The latter compensates the lack of

projection images per respiratory phase with spatial and/or temporal regularization(s). This presentation will review these techniques, discuss the pros and cons of each and report on a recent attempt to evaluate them from the same dataset.

#### SP-0241 Deep image formation algorithms for CT and CBCT

M. Kachelriess<sup>1</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Department of Medical Physics, Heidelberg, Germany

##### Abstract text

##### Purpose

To give an overview of the potential of deep learning in the field of x-ray CT and CBCT image formation.

##### Methods

With the introduction of deep learning in general, and with deep convolutional neural networks (CNNs) in particular, machine learning has spread into many medical areas with great success. In particular medical imaging may benefit from the new technology. Important applications such as image analysis, image segmentation and object recognition are well-known and start to become widely available.

The applications of machine learning to the field of image formation, which describes the process of data acquisition, preprocessing, image reconstruction and post processing, however, are less known, not as mature and not always available, yet. In CT and CBCT, which are the focus of this lecture, the use of machine learning can be mainly categorized into the categories 1) replacement of time-consuming computations (image reconstruction, scatter prediction, material decomposition, ...), 2) replacement of missing data (sparse view acquisition, limited angle tomography, ...), and 3) incorporation of a priori knowledge (non-contrast CT from contrast-enhanced CT, pseudo CT from MR, ...). This lecture discusses the underlying technology and application examples.

##### Results

Methods that promise to fill in missing data need to be taken with care because they are just another way of inter- or extrapolating data: Claims that a reduction of x-ray dose or of the number of x-ray projections, when combined with CNNs, yields the same image quality as high dose imaging are not proven and, if at all, demonstrated using simple phantoms or smooth CT images. In contrast, applications to replace time-consuming computations by real-time CNNs have the potential to provide accurate results even for a great input data variation because their output is typically a smooth but non-local function of the data input. Successful examples are networks that replace Monte Carlo calculations and compute deep scatter estimations (DSE) and deep dose estimations (DDE) in real time. Even more important are deep learning-based image reconstruction algorithms which also vendors have started to implement into their products. Such deep recons (DR) have the potential to outperform the conventional analytical reconstruction (AR) and iterative reconstruction (IR) algorithms, by far.

##### Conclusions

Deep learning has the potential to significantly improve CT and CBCT image formation. However, not all proposed methods may keep their promises. Care has to be taken in all cases because due to the large number of open parameters the behavior of neural networks is difficult to analyze or predict and it cannot be foreseen how they react to data that are not adequately represented by the training set.

#### SP-0242 Hounsfield corrected CBCT images - dose calculation and potential for bio-markers

C. Brink<sup>1</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark

##### Abstract text

CBCT scans are part of the daily clinic in many institutions. Quite often the 3D/4D CBCT information are reduced to three numbers indicating the patient translation needed in order to place the iso-center in the correct position. However, the CBCT images do contain much more information than just the positional uncertainty. An obvious use of the CBCT images is to validate that the overall patient anatomy is unchanged during a fractionated treatment schedule. Typically the RTT's will, as part of their online assessment of the images, notice whether anatomical changes are present. If there are anatomical changes the next question is whether these differences impact the planned dose distribution. Since grey levels in standard CBCT images are not representing the Hounsfield Units, the patient is often referred for a validation CT that can be used for dose calculation. If the CBCT images could be made to match Hounsfield Units it would be possible to use the CBCT images for dose validation directly. This would make it much faster to obtain information of the potential dose impact and also spare the patient for an additional visit to the CT scanner. Such a procedure is introduced as clinical practice for some of our local lung trial patients. During the talk different methods to obtain Hounsfield units from standard clinical CBCT images will be discussed. The potential of CBCT images are however even larger than just the ability to be used for dose calculation. CBCT and other medical images do have the potential to be used as early bio-markers that during RT could indicate the potential outcome of the patient. This could be used as a way to performed patient specific correction to the treatment plan based on the radiation sensitivity of the individual patient. However, the image noise is still a partly hindrance for obtaining valuable bio-markers. Some of the methods to reduce image noise will be discussed and some of the results related to bio-markers and CBCT images will be discussed during the talk.

#### Symposium: New technology and modalities

---

#### SP-0243 How to secure the right competencies when new modalities are implemented - a clinical aspect in proton therapy

H. Pennington<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Proton Therapy, Manchester, United Kingdom

##### Abstract text

In late autumn 2018 The Christie Foundation Trust in Manchester, United Kingdom, opened the first high energy proton therapy centre in England for National Health Service (NHS) patients.

In the opening of a new proton therapy service a new modality of radiation therapy was implemented with the intent of treating a wide range of complex and challenging cases. Key safeguards needed to, and have been, built into the service to ensure safe treatment of patients. One of these key safeguards was the training and education of the workforce. Such considerations started early in the project with a number of senior team members visiting operational proton therapy departments to gather as much information as possible to guide service development. We employed staff early and implemented extensive training packages. Clinical Oncologists, senior physicists and therapists have all undergone an extensive programme of training which included overseas education programmes and practical placements in established proton centres. This was complimented by bringing expertise to our site to discuss site specific treatment planning solutions, exercises in comparative planning, as well as discussion of the issues and challenges that are particular to proton therapy.

Overseas experience was backed up by on site applications training and a significant amount of time was incorporated into the commissioning schedule for end to end testing/patient treatment dry runs. During this time a comprehensive competency based in house training was developed and incorporated into an accredited quality system.

#### SP-0244 Personalized treatment planning and automation in modern radiotherapy

T. Piotrowski<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Medical Physics, Poznan, Poland

##### Abstract text

Treatment planning for dynamic radiotherapy techniques (e.g. IMRT, VMAT, Tomotherapy), needs high knowledge of the planner to ensure high plan quality. Different level of knowledge and practical skills of planners can lead to variability in the quality of treatment plans and the time efficiency of productions of the plans.

The control of the realization is the additional aspect of the treatment plans and their potential modification during radiotherapy.

To standardize the planning process, the planning approaches with automation support were intensively developed in last years. There are also a lot of new technical solutions to control the accuracy of the dose delivery according to the prepared treatment plans.

This study critically reviews the body of publications up to the end of 2018.

The review is described for (i) automated planning - different types of automation algorithms and for (ii) the dose delivery - inaccuracies for the displayed doses caused from the actually implemented tools.

#### SP-0245 Advanced practice role in breast cancer radiation therapy

G. Lee<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Center, Radiation Medicine Program, Toronto, Canada

##### Abstract text

Implemented in 2007, the Clinical Specialist Radiation Therapist (CSRT) project is a model-of-care to develop advanced practice radiation therapy in Ontario, Canada. The breast-site CSRT is one of the first advanced practice roles piloted at the Princess Margaret Cancer Centre. The goal of this role is to enhance radiation therapy practice and patient-focused outcomes for patients requiring breast radiotherapy. The breast-site CSRT is an integral part of an inter-professional team and practices within the radiotherapy new patient clinic, follow-up clinic, and "on-treatment reviews" to provide clinical care and performs cavity target delineation for radiotherapy planning. As part of a multi-disciplinary team, the CSRT leads a rapid process for same-day breast radiotherapy. This session explores the breast-site CSRT role and evaluates the accumulated 10-year evidence in advanced practice role development.

#### Symposium: Combining research and (clinical/professional) training/ practice

---

#### SP-0246 Taking time off for full-time research - is it worth it?

A. Levy<sup>1</sup>

<sup>1</sup>Gustave Roussy, Radiation Oncology Department, Villejuif, France

##### Abstract text

For health practitioners, taking a break from clinics to undertake full-time research could be seen as an opportunity and/or a disadvantage. In this session, pros and cons of taking time off for full-time research will be discussed.

#### SP-0247 Why do we need to be trained in statistics? Need and pitfalls

A. Escande<sup>1</sup>, L. Lebellec<sup>2</sup>

<sup>1</sup>Oscar Lambret Comprehensive Cancer Center, Academic Department Of Radiation Oncology, Lille, France ; <sup>2</sup>Oscar Lambret Comprehensive Cancer Center, Biostatistics, Lille, France

##### Abstract text

Evidence based medicine is necessary for routine clinical practice. Understanding and taking into account large amount of data should permit to predict accurate outcome and tailoring the best individual treatment. However, clinicians need to understand statistical and data analysis in order to take the best decision and better criticize published studies. This need is also reinforce by the

increasing of treatment cost and the aim of treatment toxicity control. Some studies described misuse of statistical tests in medical studies but also difficulties to understand biostatistics for most of medical doctor. Thus, medical school should develop statistical tests and data analysis lessons. Moreover, we are now into artificial intelligence era partially based on advanced statistical analysis and medical doctor should be aware of multiple existing biases to not be victim of non-accurate conclusion but also better interact with biostatistical team. Here, we briefly explain how to use and pitfalls of most used tests such as Parametrical and non-parametrical tests, Kaplan Meier, Log Rank, Cox regression, Fine and Gray, Restricted Mean Survival and Classifier.

#### SP-0248 Research and training in medical physics

S. Petit<sup>1</sup>

<sup>1</sup>Erasmus Mc Cancer Institute, Department Of Radiation Oncology, Rotterdam, The Netherlands

##### Abstract text

In this session I will discuss how to acquire (and keep on having) a staff medical physicist position with dedicated and protected time for research. The first part of the talk is about the training to become a medical physicist. The training period is a period to decide in which direction you would like to develop yourself, gain relevant experience in different institutions, and making yourself seen among the medical physics community. The key for enhancing your visibility and increasing your attractiveness for institutes with combined medical physics and research positions, is research. I will present tips on how to achieve as much as possible with the limited time for research you may have during training. In the second part of the talk I will present the challenges and possible solutions of being a medical physicist with research time that sees his/her research time evaporate in the demanding and hectic environment called clinical practice.

#### SP-0249 Clinical vs lab research for clinicians Combining research and (clinical/professional) training practice

D. Milanovic<sup>1</sup>

<sup>1</sup>University Hospitals of Leicester NHS Trust, Department of Oncology, Leicester, United Kingdom

##### Abstract text

Radiation Oncologists are regularly confronted with a treatment of non-curative diseases. To improve their outcome the development of new treatment strategies will be necessary. Ideally more Radiation Oncologists should actively participate in relevant pre-clinical studies designing further clinical trials based on their findings. Realistically, this approach is challenging and difficult achievable due lack of ideas, facilities and financial support. In this presentation, possibilities to perform clinical and lab research during the training and afterwards in two large European Health Systems (German and British) will be elucidated. We can conclude that to retain motivated colleagues who want to actively participate in lab and clinical research projects, the appropriate length of time close to their routine clinical activities should be ensured.

#### SP-0250 Lessons learnt from a young head of department

R. Baumann<sup>1</sup>

<sup>1</sup>St. Marien Hospital Of Siegen, Radiation Oncology, Siegen, Germany

##### Abstract text

A head of department must be a true all-rounder in radiation oncology. In addition to the professional experience, the chief physician must show the economic competence, leadership, training and organizational skills

that are necessary for the development of his department and its integration into a scientific network. In Germany, a large part of the radiation therapy is performed at outpatient centers. Thus, university hospitals and maximum care hospitals have a particular responsibility to contribute to education and research. In addition to continuously securing high standards of care on a daily basis, it is also necessary to establish sufficient staff resources to be able to carry out high quality scientific projects.

Within the next two years, the Marien Hospital Siegen hospital together with three other regional hospitals will become a university hospital associated with a newly established medical school. Opportunities in the so called "Rethink Medicine" project include the economic cooperation of four hospitals within one city and the development of translational research projects in collaboration with international partners such as the Erasmus Medical Center Rotterdam (EMC) and the University of Oxford. One of the key challenges will be to establish basic and translational research programmes to complement the clinical research already taking place today.

In this lecture, the mentioned points are reflected from the perspective of a young head of a department (35 years old) for radiation oncology in Germany.

##### Purpose or Objective

The Inuit are one of three indigenous groups in Canada. Despite living in a high-income country (HIC), their unique sociodemographic characteristics mirrors those of low-and-middle income countries (LMIC) in terms of cancer care and outcomes. Geography is an important barrier. Inuit cancer patients from the northern Arctic territory of Nunavut must fly significant distances to access radiotherapy (RT) in southern Canada. RT utilization (RTU), the proportion of patients receiving RT, is an essential step to create policies for designing affordable and equitable RT service, which is a critical, and complex component of better cancer outcomes. However, RTU has never been specifically studied among the Inuit.

##### Material and Methods

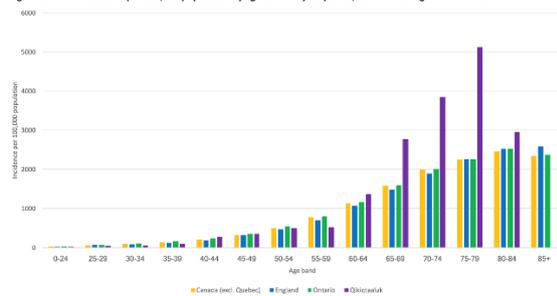

We conducted descriptive analyses comparing the cancer incidence among Nunavut's largest health region

(Qikiqtaaluk), to other regions in Canada and England. We calculated this region's RTU from 2011-2016, and compared it to the modelled optimal RTU (ORTU) using the evidence-based MALTHUS model, which contains 2,000 clinical decisions relating to RT. RTU for the Qikiqtaaluk region was obtained using incidence data from the Nunavut cancer registry and treatment data from the region's oncology referral centre, The Ottawa Hospital Cancer Centre (TOHCC).

### Results

The all-cancer incidence rate in the Qikiqtaaluk region was 265 per 100,000 over a 5-year period, compared to 524 in Canada, 546 in Ontario, and 536 in England. Figure 1 displays the incidence rate split by age range. This, in contrast to the lower overall cancer incidence rate, reveals a markedly higher incidence among older age ranges in the Qikiqtaaluk region compared to others. Of the cancer registry patients, 68% were seen at TOHCC. However, at least 20 cancer patients seen at TOHCC did not have a record in the cancer registry, suggesting under-reporting of Nunavut's cancer incidence. The majority of patients were diagnosed at stage IV (33%). The most common cancer type was lung (38%). The ORTU, based on the UK Malthus evidence-base, is 43% (excluding retreatments). Actual RTU for the Qikiqtaaluk region was 54%.

Figure 1. Cancer incidence per 100,000 population by age over a 5-year period, for the four regions of interest.

### Conclusion

This is the first study to describe RTU among any Inuit population worldwide. The Qikiqtaaluk region displays a lower overall cancer incidence, which may in part be due to under-reporting. Despite this, the 3-fold increased incidence among the region's older population is alarming. The higher calculated RTU among the Qikiqtaaluk region is also likely attributed to under-reporting of the cancer incidence. Solutions to increase RT uptake should include the development of robust systems for cancer reporting within the territory, in partnership with their oncology referral centres. Concurrently, novel models of RT delivery must not only address geographical barriers, but also the unique sociodemographic and cultural needs of this under-served population. Further in-depth analyses comparing incidence, stage and RTU for regions within HICs exhibiting LMIC traits is in progress.

### PV-0252 From theory to practice: assessing the use of radiotherapy in population based cancer registries

J.M. Borrás<sup>1</sup>, J. Corral<sup>1</sup>, J. Galceran<sup>2</sup>, R. Marcos-Gragera<sup>3</sup>, L. Vilardell<sup>3</sup>, J. Solà<sup>1</sup>, A. Ameijide<sup>2</sup>, M. Carulla<sup>2</sup>, X. Cardó<sup>2</sup>, À. Izquierdo<sup>3</sup>, J.A. Espinàs<sup>1</sup>

<sup>1</sup>IDIBELL, Catalan Cancer Plan, Hospitalet del Llobregat, Spain; <sup>2</sup>FUNCA, Registre de Càncer de Tarragona, Reus, Spain; <sup>3</sup>IDIBGI, Unitat d'Epidemiologia i Registre del Càncer de Girona, Girona, Spain

### Purpose or Objective

Planning for radiotherapy services requires evidence based information on the optimum and the actual use of this therapy in a population in order to assess the potential gaps in the utilization of external beam radiotherapy.

The objective of this study was to assess the actual utilization of external beam radiotherapy in two population based cancer registries in Girona and Tarragona, Catalonia, Spain. In addition, problems of access due to distance between patients residence to radiotherapy departments were analysed.

### Material and Methods

There are two cancer registries in Catalonia, Girona (750,000 inhabitants) and Tarragona (800,000 inhabitants), in both cases only one Radiation oncology department is available in each health region. All incident cancer patients (with the exception of non-melanoma skin cancers) of both regions diagnosed during the years 2009-2011 were linked to the reimbursement database of the Catalan Health Care Service. We calculated the proportion of patients receiving an external radiotherapy treatment during the first year after the diagnosis of the cancer, by type of tumour. Only the first radiotherapy treatment was included in this analysis, even if they subsequently received a retreatment.

### Results

The proportion of incident cases receiving radiotherapy treatment during the first year after diagnosis was 24.3%. The proportion of treatments decreased significantly at older ages (from 21.3% younger than 40 years old and 32% for 40-64 to 14.3% in patients older than 75 years). There were no differences in uptake of radiotherapy by distance from the residence of the patient to the Radiation oncology department.

The tumour sites (all stages at diagnosis) with highest proportion of radiotherapy use in the first year after diagnosis were breast (58%), head and neck (42%), Rectum (41%), Prostate (33%) and lung (30%).

### Conclusion

There is a significant gap between optimal use and actual use (although this study is focused on first year after diagnosis) and this is especially relevant in some tumour sites like bladder and haematological cancers. Population based data on actual use is an essential element for planning resources needed and it makes feasible to assess potential factors to explain the optimum-actual utilization gap and to reduce it when required to increase evidence based indications of radiation oncology.

### PV-0253 A critical quality appraisal of studies estimating the cost of radiotherapy

N. Defourny<sup>1</sup>, Y. Lievens<sup>2</sup>, C. Montens<sup>2</sup>, J. Monnet<sup>3</sup>, P.B. Dunscombe<sup>4</sup>, C. Grau<sup>5</sup>, L. Perrier<sup>6</sup>

<sup>1</sup>ESTRO A.I.S.B.L., HERO, Brussels, Belgium; <sup>2</sup>Ghent University Hospital, Department of Radiation Oncology, Ghent, Belgium; <sup>3</sup>Leon Berard Cancer Centre, Univ Lyon, Lyon, France; <sup>4</sup>University of Calgary, Department of Medical Physics, Calgary, Canada; <sup>5</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; <sup>6</sup>Leon Berard Cancer Centre, Clinical research platform, Lyon, France

### Purpose or Objective

The rapid innovation in technique and technology of the radiotherapy increases the necessity of health economic evaluation (HEE). Indeed, given their increasing impact of HEE studies on policy, it is essential to appreciate their quality. We aim to assess the quality of selected HEE studies of radiotherapy against quality instruments, such as checklists. In addition, we want to evaluate differences between quality instruments and how well they perform in practice, with a dedicated focus on the costing side.

### Material and Methods

Building upon a previous systematic literature review of EBRT costing studies (Defourny et al., 2016) published from 2004-2015 in MEDLINE, Embase and the NHS EED databases, an assessment of the quality of the selected articles was performed by four independent reviewers. Based on 3 existing instruments - CHEC, CHEERS, and QHES - the selected articles were critically rated focusing on the

transparency of their reporting. Robustness of this analysis and instrument comparison were examined using the Kendall coefficient of concordance and Inter-Class-Correlation coefficients.

### Results

The systematic review lead to the selection of 15 records matching the search strategy: these were most frequently conducted in Canada (n=4) and France (n=3). Instruments' mean score were evaluated respectively at 59.4%, 69.7% and 73.6% for CHEC, CHEERS and QHES. The overall quality score was fairly good, even an in-depth analysis per criteria reveals that essential costing items - discount rate, time horizon, sensitivity analysis - were only partially completed.

Over time, instruments scores rise specifically for QHES. The statistical analysis confirms that raters have scored in a similar manner. In addition, as inter-rater reliability coefficients show that that the reviewers score converged more with CHEC (ICC=0.86\*\*\*) than for QHES (ICC=0.73\*\*\*) and CHEERS (ICC=0.64\*\*\*)).

Figure 1. Mean quality score of EBRT costing studies for each quality instrument.

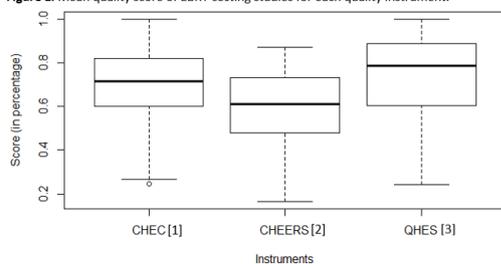

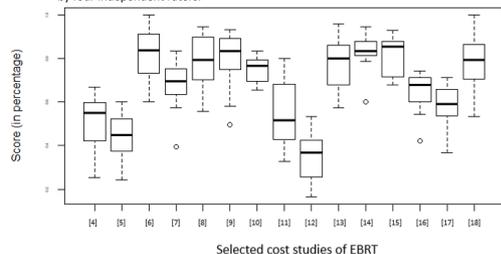

Figure 2. Mean quality score of each EBRT costing studies, reviewed against three instruments by four independent raters.

### Conclusion

The two-fold objectives of the present quality appraisal demonstrate a fairly good quality of reporting overall amongst EBRT costing studies published in the last decade. While we found no major difference in the instrument score, the CHEERS checklist has the most extensive consideration of cost components across all three instruments.

Yet essential improvement in reporting both acknowledged costing methodology and sufficient input information need to be put forward in order to continue improving the quality of future HEE study, supporting indirectly appropriate decision-making about the allocation of scarce healthcare resources.

### PV-0254 Mortality and Morbidity Review of serial radiotherapy accidents in Epinal, 1987-2006

J. Simon<sup>1</sup>, P. Maingon<sup>1</sup>, E. Francois<sup>2</sup>, E.H. Labib<sup>3</sup>, M. Vincent<sup>3</sup>, N. Alain<sup>3</sup>, L. Mihai<sup>3</sup>, M. Christian<sup>3</sup>, P. Didier<sup>3</sup>  
<sup>1</sup>Hôpital Pitié-Salpêtrière, Radiotherapy, Paris, France ;  
<sup>2</sup>Centre Antoine Bécélère, Centre Universitaire des Saints-Pères, Paris, France ;  
<sup>3</sup>Institut de cancérologie de Lorraine, Radiotherapy, Vandoeuvre-les-Nancy, France

### Purpose or Objective

Between 1987 and 2006, five serial accidents occurred in the radiotherapy department of the Jean Monnet Hospital in Epinal, France, resulting in over-irradiation of more

than 5,500 patients (pts) to varying degrees, from 3% to more than 50% of the prescribed dose. Five cohorts of pts were defined according to their specific cause of over-irradiation. We report the Mortality and Morbidity Review of those radiotherapy accidents.

### Material and Methods

Cohort 1: Between 2004 and 2005, 24 prostate cancer pts were over-irradiated more than 20%, because of the improper use of a treatment planning system. For prescribed doses between 69 Gy and 78 Gy, pts received doses between 81 Gy and 120 Gy.

Cohort 2: Between 2000 and 2006, 409 prostate cancer pts received 9-10% radiation overdose because of failure to consider doses delivered by daily portal imaging. For prescribed doses between 70 Gy and 78 Gy, pts received doses between 76.7 Gy and 85.5 Gy.

Cohort 3: Between 1987 and 2000, at least 5,000 pts were irradiated with 3% (1,100 pts), 5.5% (3,600 pts), or 7.1% (306 pts) more radiation than planned, depending on the photon energy used for their radiotherapy. The cause was an error in the homemade informatic program written to carry out calculations of monitor units (MU).

Cohort 4: in 1993, 8 breast cancer pts received a dose 20-68% higher than the prescribed dose because of an inappropriate correction factor used for the calculation of MU when filters for tangential beams were used.

Cohort 5: in 1999, 36 breast cancer pts had radiation overdose to the heart because of exclusive use of direct 6 MV photon beam to deliver 50 Gy to the internal mammary chain.

Moreover, one patient developed a radiation-induced myelitis after overlap of irradiation fields for breast cancer in 1998 and vertebral bone metastasis in 2003.

Adverse effects of radiotherapy were graded according to CTCAE v3.0 grading system. Accident severity was graded according to ASN/SFRO scale (classification of radiation protection events affecting patients).

### Results

Cohort 1: 10 pts died from radiation-induced injury of the gastrointestinal and/or genitourinary tract. This accident was rated level 7 (up to 7) on the ASN/SFRO scale.

Cohort 2: among 405 evaluable pts for toxicity, 372 (82.5%) developed late gastrointestinal toxicity (LGIT)  $\geq$  Grade 1, 155 pts (38%) had LGIT Grade  $\geq 2$ , 66 pts (16%) had LGIT Grade 3, and 2 pts died of radiation-induced rectovesical fistula (level 6 on the ASN/SFRO scale).

Cohort 3: 2 pts died of radiation-induced rectovesical fistula (level 6 on the ASN/SFRO scale).

Cohort 4: 1 patient developed a radiation-induced grade 3 skin complication (level 3 on the ASN/SFRO scale).

Cohort 5: 9 pts (24%) developed radiation-induced grade 4 cardiac adverse events (level 4 on the ASN/SFRO scale).

### Conclusion

Overall, 14 radiation-induced deaths occurred after these accidents. Since 2007, each French radiotherapy center is now inspected once a year by ASN. National measures have been taken to prevent recurrence of such accidents.

### PV-0255 Advocating for radiation oncology through the development of a massive open online course

M. Leech<sup>3</sup>, C. Poole<sup>1</sup>, S. Gallagher<sup>2</sup>, W. Fox<sup>2</sup>  
<sup>1</sup>Trinity College, Discipline of Radiation Therapy, Dublin, Ireland ;  
<sup>2</sup>Trinity College, Trinity Online Services, Dublin, Ireland ;  
<sup>3</sup>TCD Discipline of Radiation Therapy, Trinity College, Dublin, Ireland

### Purpose or Objective

Radiotherapy is an effective and cost effective treatment for most cancers however there is sub-optimal access worldwide and it is underutilised. Lack of information and awareness of radiation therapy is reported within the literature as a patient-related barrier to accessing radiation therapy. The aim of this project was to develop a massive open online course to inform cancer patients,

their families and health professionals about radiation oncology as a treatment for cancer.

#### Material and Methods

Online learning platform was designed with a focus on ensuring a rich learning environment by situating the course through the story of patients and allowing opportunity for reflection, questions and discussion. The platform consisted of 39 steps-15 videos, 15 articles, 2 discussion for a, 6 multiple choice quizzes and 1 final exercise. The Massive Open Online Course was launched in September 2018 and the steps were delivered over a 2 week period.

#### Results

1,489 people signed up to the MOOC from 111 countries. The majority were from the UK (24%), Ireland (20%), Australia (5%), India (4%), US (4%), Egypt (3%), Canada (2%), Spain (2%) and Mexico (2%). 50% of attendees were >56 years of age. A total of 958 comments were posted within the MOOC platform by 225 learners. In the post course evaluation survey, 97% stated that the course met or exceeded their expectations. 96% said the course provided them with new knowledge or skills. 65% have shared the knowledge they learned with other people and 51% have already applied what they learned.

#### Conclusion

Using online technology to explain radiation oncology is an engaging and effective methodology that has been very positively reviewed. This MOOC is available to an international audience and is one method that appears constructive in bridging the gap in knowledge of radiation oncology worldwide.

#### PV-0256 European survey on electronic patient-reported outcomes by the EORTC young Radiation Oncology Group

<sup>1</sup>Charité-Universitätsmedizin Berlin, Department of Radiation Oncology, Berlin, Germany; <sup>2</sup>University Hospital of Bern, Department of Radiation Oncology, Bern, Switzerland; <sup>3</sup>Tenon University Hospital - Sorbonne University, Department of Radiation Oncology, Paris, France; <sup>4</sup>Centro Hospitalar Lisboa Norte- E.P.E. - Hospital Santa Maria, Department of Radiation Oncology, Lisbon, Portugal; <sup>5</sup>University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany; <sup>6</sup>Azienda Ospedaliero Universitaria Careggi - University of Florence, Radiation Oncology Unit-Oncology Department, Florence, Italy; <sup>7</sup>Campus Bio-medico, Radiation Oncology, Rome, Italy; <sup>8</sup>Institute of Cancer Research - The Royal Marsden NHS Foundation Trust, Radiotherapy and Imaging, London, United Kingdom; <sup>9</sup>Radboud University Medical Center, Department of Radiation Oncology, Nijmegen, The Netherlands; <sup>10</sup>Rambam Medical Center, Oncology Institute- Radiation Oncology and Neuroncology Unit, Haifa, Israel; <sup>11</sup>University Hospitals Leuven, Lab of Experimental Radiation Oncology, Leuven, Belgium; <sup>12</sup>University of Antwerp, Molecular Imaging- Pathology- Radiotherapy & Oncology MIPRO, Antwerp, Belgium; <sup>13</sup>Iridium Cancer Network, Department of Radiation Oncology, Wilrijk- Antwerp, Belgium; <sup>14</sup>University Hospital CHRU Morvan, Radiation Oncology Department, Brest, France; <sup>15</sup>Rigshospitalet- Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark; <sup>16</sup>GROW - School for Oncology - Maastricht University Medical Centre, Dept. Radiation Oncology Maastricht, Maastricht, The Netherlands; <sup>17</sup>Universität Halle, Department of Radiation Oncology, Halle, Germany

#### Purpose or Objective

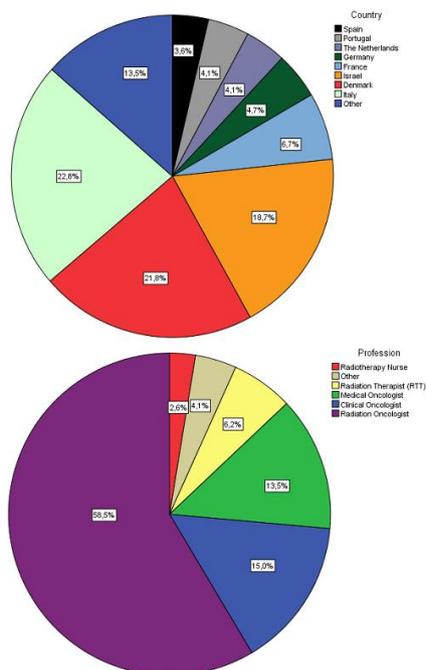

Complete and accurate examiner-independent documentation of meaningful patient orientated clinical outcomes is essential for both clinical trials and daily practice. Currently, adverse events (AEs) following radiotherapy (RT) are mostly investigator-reported, neglecting the essential perspective of the patient. Patient-reported outcomes (PROs) can be prognostic for clinical outcome and are becoming increasingly important. The young Radiation Oncology Group (yROG) of the European Organisation for Research and Treatment of Cancer (EORTC) is conducting a pan-European survey to capture utilization rates, importance and perceived benefits of PROs and to rank ideal features of an electronic tool for PRO assessment (ePRO) in regards to RT. The findings will be used to create an app for RT specific PRO assessment usable on handheld devices and PCs which will be freely available as a science tool for the radiation oncology community.

#### Material and Methods

The survey was addressed to physicians, radiation therapy technicians (RTTs) and nurses who regularly treat and manage patients undergoing radio(chemo)therapy. A publicly accessible online survey consisting of 40 questions and rating each ePRO-feature on a 5-point scale was created and promoted via newsletters. Members of the EORTC network and national radiation oncology societies from Belgium, Denmark, France, Germany, Israel, Italy, the Netherlands, Portugal, Spain, Switzerland and the United Kingdom participated in the survey. The survey is ongoing and will be closed as of 31st October 2018.

#### Results

The survey collected 199 replies up until 22nd October 2018. The distribution by profession and country is reflected in Figure 1. PROs were considered to be important for RT treatment, although assessments were implemented by less than half of the interviewees only (41.2%). Reasons for non-use of PROs were additional time consumption and absence or inaccessibility of ePRO. The majority of survey respondents confirmed the convenience of and demand for PROs. Almost unanimously (97.9%), respondents affirmed they would use ePRO in clinical routine if it were available at their institution. One of the features ranked most highly for ePRO was patient usability (on average 4.69 of 5 points). A first usable prototype of the app could be created and its further development will consider the rating of features (Figure 2).

Question 1 of 12

**In the last 7 days, what was the SEVERITY of your DRY MOUTH at its WORST?**

None  
 Mild  
 Moderate  
 Severe  
 Very severe

Next

© 2018 <http://www.toxicity.pro>

### Conclusion

A high demand for ePRO could be concluded from the survey. An app to assess PROs for RT-related AEs was successfully created and its design will be adapted to results of the survey.

### PV-0257 Radiotherapy impact on quality of life in localised prostate cancer: validation of EPIC-16 in Spain

Radiation Oncology, A Coruña, Spain ; <sup>4</sup>Hospital Universitari Son Espases, Department of Radiation Oncology, Palma de Mallorca, Spain ; <sup>5</sup>Hospital Universitario de Salamanca, Department of Radiation Oncology, Salamanca, Spain ; <sup>6</sup>Hospital Ramon y Cajal, Department of Radiation Oncology, Madrid, Spain ; <sup>7</sup>El Hospital Infanta Cristina de Badajoz, Department of Radiation Oncology, Badajoz, Spain ; <sup>8</sup>Hospital Universitario Reina Sofía, Department of Radiation Oncology, Córdoba, Spain ; <sup>9</sup>Astellas Pharma Inc., Head of Medical Affairs Hospitals - Oncology, Madrid, Spain ; <sup>10</sup>Astellas Pharma Inc., Oncology, Madrid, Spain; <sup>11</sup>ERESA-Hospital General Universitario de València, Department of Radiation Oncology, València, Spain

### Purpose or Objective

Prostate cancer (PCa) is the third most prevalent type of cancer in Spain, with various treatment options, including radiotherapy (RT), depending on disease stage. Health-related quality of life (HRQoL) is greatly affected by functional alterations specific to PCa and its treatment. The Expanded Prostate Cancer Index Composite (EPIC-16), a shorter version of EPIC-50, was designed to be administered in routine clinical practice in patients (pts) with clinically localised prostate cancer, evaluating aspects of therapy that are most bothersome to pts. The objectives of this study were to measure the impact of RT on quality of life and to validate the Spanish version of EPIC-16 in routine clinical practice in Spain.

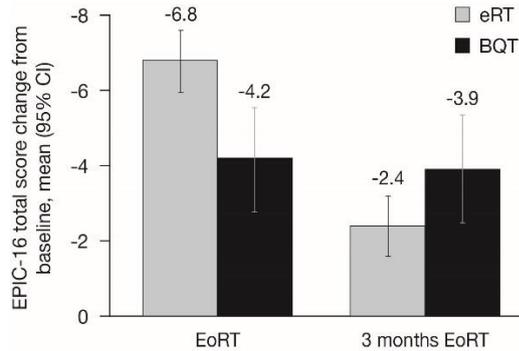

### Material and Methods

An observational, non-interventional, multicentre study was conducted in Spain with pts >40 years (yrs) of age with localised PCa, initiating treatment with external RT (eRT) or brachytherapy (BQT). Changes from baseline in EPIC-16 and UCLA Prostate Cancer Index (PCI) and patient-perceived state of health were measured at two follow-up visits. Psychometric evaluations of the Spanish version of EPIC-16 were conducted to assess its validity.

### Results

Of the 516 pts enrolled this study, 495 were included in the analysis (eRT, n=361; BQT, n=134). Mean (standard deviation [SD]) age was 71.7 (6.4) yrs [eRT] and 66.7 (7.5) yrs [BQT]. At baseline, 264 (73.1%) eRT and 21 (15.7%) BQT pts had a Gleason score  $\geq 7$ ; mean (SD) EPIC-16 global score (range 0-60, 60 being the worst) was 11.9 (7.5) in eRT pts and 10.3 (7.7) in BQT pts. For eRT pts, the total EPIC-16 score increased from baseline by a mean (SD) of 6.8 (7.6) for visit (V) 2 and 2.4 (7.4) at V3 (Figure). For BQT pts, total scores increased from baseline by a mean (SD) of 4.2 (7.6) and 3.9 (8.2) at end of treatment and 3 months after RT, respectively (Figure). Changes from baseline in individual domains (range 0-12, 12 being worse HRQoL) are shown in the table. Changes in the Spanish EPIC-16 domains correlated well with those of the UCLA-PCI for urinary, bowel and sexual domains. Patients perceived no change in their HRQoL status compared to baseline. EPIC-16 showed good internal consistency (Cronbach's  $\alpha=0.84$ ) and reliability, with a moderate intraclass correlation coefficient in all domains, with the exception of the bowel domain. Construct validity was shown with a 5-factor analysis indicating that EPIC-16 domains are conceptually distinct and merit an independent measure. Longitudinal validity was not evident in all HRQoL domains.

**Figure.** EPIC-16 total score mean (95% CI) change from baseline for eRT- and BQT-treated patients

BQT=brachytherapy; CI=confidence interval; EoRT=end of radiotherapy; EPIC-16=Expanded Prostate Cancer Index Composite; eRT=external radiotherapy

**Table.**

Change from baseline in EPIC-16 domains	Analysed patients (n=495)	
	eRT (n=361)	BQT (n=134)
Incontinence, V2/V3	n=322/n=320 -0.6 (1.7)/0 (1.7)	n=124/n=132 -0.3 (1.4)/-0.3 (1.8)
Irritation/obstruction, V2/V3	n=321/n=319 -2.2 (2.8)/-0.1 (2.6)	n=121/n=130 -2.5 (2.8)/-1.7 (3.2)
Bowel, V2/V3	n=322/n=320 -2.1 (3.1)/-0.7 (2.5)	n=123/n=130 -0.8 (2.8)/-0.6 (2.6)
Sexual, V2/V3	n=319/n=316 -1.5 (2.9)/-1.4 (3.1)	n=120/n=132 -1.0 (2.6)/-1.4 (3.1)
Vitality/hormonal, V2/V3	n=319/n=317 -0.5 (2.5)/-0.2 (2.5)	n=120/n=130 0.2 (2.3)/0.1 (2.8)

All data is mean (SD). BQT=brachytherapy; EPIC-16=Expanded Prostate Cancer Index Composite; eRT=external radiotherapy; RT=radiotherapy; SD=standard deviation; V2=visit 2, end of RT; V3=visit 3, 90 days after end of RT.

**Conclusion**

Overall, scores worsened after RT in different HRQoL domains, but pts did not perceive a global change in their HRQoL status. The Spanish version of the EPIC-16 questionnaire demonstrated sensitivity to detect PCa treatment-related effects and sensitivity for clinical improvement after RT. It also showed strong discriminative properties and reliability, demonstrating its validity for use in clinical practice and clinical trials to evaluate the effect of interventions.

**PV-0258 Patient reported outcome and survival analysis after stereotactic body RT (SBRT) of lung metastases**

R. Grosse<sup>1</sup>, K.A. Kessel<sup>1,2</sup>, D. Marciana-Nona<sup>2,3</sup>, M. Oechsner<sup>1</sup>, S.E. Combs<sup>1,2</sup>  
<sup>1</sup>Klinikum rechts der Isar- Technical University of Munich, Radiation Oncology, Munich, Germany; <sup>2</sup>Institute of Innovative Radiotherapy, Institute of Innovative Radiotherapy, Munich, Germany; <sup>3</sup>Klinikum rechts der Isar - Technical University of Munich, Radiation Oncology, Munich, Germany

**Purpose or Objective**

Stereotactic body radiation therapy (SBRT) is a high-precision method to irradiate extracranial targets. In this evaluation, we analyzed patients that underwent SBRT of pulmonary metastases. We focused on toxicity and the efficiency of SBRT in order to gain a long-term patient reported outcome (PRO).

**Material and Methods**

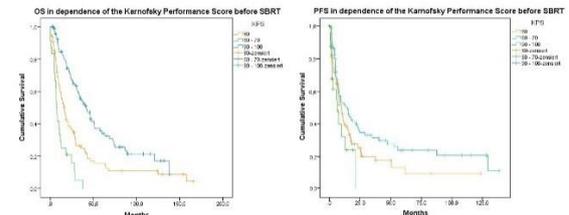

307 lung metastases in 209 patients were treated with SBRT between 2002 and 2017. All patients were enclosed into our retrospective study and documented in the research database of the department of radiation oncology.

We documented side effects according to the CTCAE criteria (v.4.03). Patients, that were still alive and had no follow-up visit for more than six months in our department, received an invitation to our patient survey via mail. The questionnaire contained 13 questions of PRO-CTCAE™ (developed by the NCI) and two self-created questions regarding their state of health and wellbeing. Patients were able to participate using our web-based survey system or if preferred paper-based.

**Results**

**Patients**

Median overall survival (OS) was 19 months (interquartile range (IQR) 7.8 to 41.3 months), median progression-free survival (PFS) was 6.4 months (IQR 2.2 to 16.9 months). The median local control (LC) was 11.6 months (IQR 4.6 to 27.6 months). The pulmonary lesions were treated with a median dose of 35 Gy to the 60% isodose. The Karnofsky Performance Score approved as a statistically significant impact on OS (p<0.001) and PFS (p=0.018).

**Toxicity**

The documented side-effects were mainly graded 1 or 2 (Table 1). Doctors only recorded severe side-effects (grade 3 or 4) in six participant's cases.

CTCAE grade	baseline RT n=209				6-12 months n=153				12-24 months n=114				patient reported n=47			
	1	2	3	4	1	2	3	4	1	2	3	4	1	2	3	4
fatigue	1.9%	3.4%			1.3%	3.3%			1.3%	3.5%			1.1%	3.2%		
nausea																
dermatitis																
hyperpigmentation																
edema																
neuropathy																
asthenia																
motor																
weightloss																
diarrhea																
anorexia																
alopecia																
hypocalcaemia																
cough																
hemoptysis																
apnoea																
stridor																

**PRO assessment**

Out of living 40 patients, 36 (90%) participated in our survey; four patients told us only the status of their actual disease which was stable. The median time between radiation therapy (RT) and PRO was 46.8 months (IQR 16.9 to 93.1).

Patients noted radiodermatitis grade 3 (n=1), sensory disorders grade 4 (n=1) and 3 (n=2), motor disorders grade 3 (n=2), dysphagia grade 3 (n=1), dyspnea grade 3 (n=2) and 4 (n=2) and cough grade 3 (n=1). All patients with severe dyspnea were diagnosed a COPD before SBRT. During PRO assessment, one patient noted four and another patient three grade 3 adverse effects. It appears that subjective personal sensitivity has a relevant influence on how patients filled out the questionnaire.

**Conclusion**

Our results showed low levels of acute, late, long and PRO toxicities. Hence, SBRT is a suitable treatment method for patients with lung metastases, who are unwilling to undergo surgery, or patients, who are functionally

inoperable or whose metastases are unresectable due to their location.

**PV-0259 Cosmetic outcome in irradiated breast cancer patients and association with patient reported outcomes**

M. Batenburg<sup>1</sup>, M. Gregorowitsch<sup>1</sup>, D. Van den Bongard<sup>1</sup>, W. Maarse<sup>2</sup>, H. Verkooijen<sup>3</sup>

<sup>1</sup>UMC Utrecht, Radiation Oncology, Utrecht, The Netherlands; <sup>2</sup>UMC Utrecht, Plastic Surgery, Utrecht, The Netherlands; <sup>3</sup>UMC Utrecht, Imaging Division, Utrecht, The Netherlands

**Purpose or Objective**

Locoregional treatment of breast cancer consists of surgery and, in the majority of cases, irradiation of the breast. These modalities affect cosmetic appearance of the breast. In this study, we evaluated the level of satisfaction with cosmetic outcome one to three years after the start of breast irradiation, determinants of low satisfaction, and its association with quality of life (QoL).

**Material and Methods**

This study was conducted within the UMBRELLA cohort, a prospective observational cohort including breast cancer patients referred for radiation treatment to the department of Radiation Oncology at the University Medical Centre Utrecht. In UMBRELLA, patients consent to collection of clinical and patient reported outcomes (PROs) for research purposes. All 821 patients treated with either lumpectomy or mastectomy followed by breast reconstruction between October 2013 and June 2018, with at least one year follow up were selected. Cosmetic satisfaction, QoL and depression were measured via self-reported questionnaires (resp. Sneeuw, EORTC QLQ-BR23 and C30, and HADS-NL). Patient reported cosmetic outcome was assessed in a 5 point scale: very satisfied, satisfied, neutral, dissatisfied and very dissatisfied with cosmetic outcome. For analysis, satisfied and very satisfied were considered "satisfied with cosmetic outcome" and dissatisfied and very dissatisfied were considered "dissatisfied with cosmetic outcome". Multivariate logistic regression analysis was used to assess the association between patient and tumor characteristics and poor cosmetic satisfaction.

**Results**

After respectively one, two and three years there were 64/821 (8%), 29/422 (7%), and 13/181 (7%) dissatisfied patients. BMI >25 and mastectomy followed by breast reconstruction were significantly associated with cosmetic dissatisfaction, (resp. adjusted OR 2.7 (95%CI 1.1-6.8) and 5.7 (95%CI 1.1-30.0)). High scores on the HADS depression subscale (>8) were significantly more common in dissatisfied patients than in satisfied/neutral patients after one and two years (Table 1). Patients who were dissatisfied with cosmetic outcome reported significantly lower scores for emotional functioning and body image than patients who were satisfied/neutral with their cosmetic outcome after one, two and three years (Figure 1).

**Conclusion**

Dissatisfaction with cosmetic outcome was present in 7-8% of the breast cancer patients one to three years after irradiation. BMI >25 and mastectomy followed by immediate reconstruction were associated with dissatisfaction with cosmetic outcome. Dissatisfied patients reported lower quality of life scores and higher depression scores. Late radiation complications like fibrosis, can occur years after radiation therapy. Therefore, to assess the impact of fibrosis on cosmetic outcome, long-term research has to be performed.

**Joint Symposium: ESTRO-JASTRO: Clinical trials for particle therapy: which ones to run and how?**

**SP-0260 International collaborations in proton therapy: networks, trials and data collection**  
C. Grau<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus N, Denmark

**Abstract text**

The key clinical research agenda for particle therapy (PT) is to establish the full range of indications for proton therapy. This will in most cases involve studies of PT applied to prevent radiation-induced side effects and/or induction of secondary tumours. In order to promote clinical research and integration of PT into radiation oncology, the European Particle Therapy Network (EPTN) will encourage and foster collaboration on trials and uniform prospective data registration. The vision and scope for clinical trials in the EPTN has been outlined in the special issue of *Radiother Oncol* July 2018:

- Emphasis should be on performing high quality clinical trials with properly selected patients and using relevant, validated clinical endpoints.
- A small number of pivotal RCTs are urgently needed. However, we need to develop, test and validate alternative evidence-based methodologies (e.g. "cohort multiple RCTs").
- Model-based selection (as predictive biomarker) is a useful concept for normal tissue complication probability (NTCP)-based clinical trials, and this concept should later be extended to incorporate Tumor Control Probability (TCP) as well.
- Trials involving state-of-the-art photon RT are welcome, as particle therapy should be an integral component of radiation oncology.
- European trials should be open to accredited centres with expertise and relative high numbers who wish to collaborate.
- Prospective collection of high-quality data for patients treated with proton therapy outside of clinical trials (using common ontology and data collection forms).
- Uniform guidelines for target and organ at risk delineation, as well as guidelines on dose constraints.
- There is a need to develop an IT-infrastructure and European QA platform, not only for particle therapy trials, but also for prospective data registries. The platform for data collection and clinical trials QA have been secured through the collaboration of ESTRO-EPTN with EORTC. With a network of many recently opened and upcoming PT centres in Europe, all with a high academic interest and a capacity to perform clinical trials, the prospects for new clinical trials in PT are encouraging.

**SP-0261 Trial quality assurance and audits for proton therapy**

C. Clark<sup>1</sup>

<sup>1</sup>National Physical Laboratory, Medical Radiation Physics, Teddington, United Kingdom

**Abstract text**

One of the roles of quality assurance (QA) in clinical trials is to enable high quality practice-changing techniques to be tested rigorously for the benefit of patients. This is undertaken by monitoring adherence to trial protocol and thus minimising variations between recruiting centres. Currently extensive proton trial investigations are relatively new in Europe (and world-wide) and hence the QA programmes are in early development across most groups. Particle therapy (PT) raises some different requirements for QA, however there is also much we can learn from the established photon therapy approaches. In an environment where individual countries have few

proton therapy centres there is a need for international cooperation and consensus in developing appropriate QA procedures. The Global Quality Assurance of Radiation Therapy Clinical Trials Harmonisation Group (GHG) is a multi-professional group with Clinicians, Physicists and RTTs collaborating to address this issue by learning from what has already been done for early trials and working together to find solutions to the unaddressed challenges. However, the centres also need confidence in their delivery from day one and other groups such as the European Particle Therapy Network (EPTN) are developing surveys and audits which can help to set the standards required for the implementation of practice-changing trials. Simultaneously, there is a need for calibration procedures which are specific to PT. Primary standards laboratories are working with clinical centres to develop calibration protocols and procedures which are straightforward to use whilst creating minimal uncertainty in the complete dosimetry chain. The aim will be to bring these endeavours together to determine which QA is important for PT clinical trials and how it impacts on clinical outcomes. Longer term this will create confidence that the trial outcomes reflect differences in randomisation schedules rather than variations in accuracy of treatment delivery across different centres. An additional benefit of comprehensive trials QA is the impact on the general standard of treatment delivered.

**SP-0262 Limitations of current RBE models and their implication for clinical trial design**

N. Matsufuji<sup>1</sup>

<sup>1</sup>National Institute of Radiological Sciences NIRS, Department for Accelerator and Medical Physics, Chiba, Japan

**Abstract text**

Unlike conventional X-ray, changing radiation quality within irradiation field and resultant enhancing relative biological effectiveness (RBE) toward its range end makes ion-beam therapy advantageous in realizing intense clinical effect on the deep-seated target while sparing surrounding normal tissues. On another front, this changing RBE of the ion beam makes it indispensable to use an appropriate RBE model that bridges between the radiation quality as input and biological effectiveness as output for safe and efficient ion-beam therapy. In Japan, the first RBE model dedicated for carbon-ion radiotherapy (CIRT) was established in a pragmatic manner, *i.e.*, dose distribution was at first designed from *in-vitro* cell survival response of a reference human salivary gland (HSG) cell as a verifiable biological endpoint, then it was scaled to meet clinical response for therapeutic purpose. Recently the model was updated by integrating the microdosimetric kinetic model (MKM) that realizes to estimate the biological effectiveness of any radiation accurately from its microdosimetric therefore measurable quantity while the indication of the RBE-weighted therapeutic dose has been inherited. At National Institute of Radiological Sciences (NIRS), clinical trials of CIRT have been conducted with the RBE model since 1994 for various solid tumors. More than 11,000 patients have been treated in the past 24 years, and the retrospective analysis of the derived clinical outcomes have revealed the appropriateness of the RBE model. At the same time, there is still certain room for future improvement in the ongoing RBE model especially for coming biologically adaptive therapy. Among possible biological factors, current model explicitly considers only the radiosensitivity of one HSG cells. The tumor-specific difference in response is treated just as the difference in optimum dose found in the dose-escalation clinical trials. In addition, heterogeneity of the tumor such as variation in O<sub>2</sub> pressure or the existence of radioresistant stem cells are not considered yet. The response of surrounding normal

tissues has been analyzed recently, however, further study is necessary to take them into consideration in the treatment planning. In the world, different approach has been adopted in European facilities. Local Effect Model (LEM), another biological model developed at GSI Helmholtzzentrum für Schwerionenforschung (GSI) in Germany, shows almost comparable performance with MKM as model itself, however, different biological endpoint and reference condition selected for therapeutic application results in different indication of the therapeutic RBE-weighted dose even though the same physical dose is delivered. The difference in RBE between the models needs careful translation of the therapeutic RBE-weighted dose from one to the other. For instance, in the international clinical trial for pancreatic cancer treatment CHIPHER (Trial of Carbon Ion Versus Photon Radiotherapy for Locally Advanced, Unresectable Pancreatic Cancer), 57.6 Gy (RBE) will be prescribed in total for those to be treated in Japanese CIRT facilities while 59.4 Gy (RBE) will be given for those placed to European facilities to deliver the identical absorbed dose. Translation of the tolerance dose of organs-at-risk (OARs) between the models is further complex therefore not yet achieved, however, add further weight in international clinical trials ahead.

**SP-0263 Clinical trials on carbon ion radiotherapy for locally advanced pancreatic cancer.**

T. Ohno<sup>1</sup>

<sup>1</sup>Gunma University, Gunma University Heavy Ion Medical Center, Maebashi, Japan

**Abstract text**

Carbon ion radiotherapy (C-ion RT) offers excellent dose distribution, enabling a concentrated administration of a sufficient dose within a target volume while minimizing the dose in the surrounding normal tissues. Additionally, C-ion RT provides biological advantages not seen in proton or photon therapy, owing to high linear energy transfer (LET); C-ion RT induces increased double-stranded DNA structures, causing irreversible cell damage independently of cell cycle phase or oxygenation, more so than lower LET irradiation such as proton and photon therapy. C-ion RT has been in use for more than 20 years in Japan and the efficacy and safety of this therapy, especially for photon-resistant tumors such as bone and soft tissue sarcoma, non-squamous cell carcinomas of the head and neck, pancreatic cancer, and rectal cancer is well accepted. For locally advanced unresectable pancreatic cancer, a phase I/II clinical study was conducted and recommended schedule of the combination of carbon ion radiotherapy (55.2 Gy (RBE) in 12 fractions for 3 weeks) and gemcitabine (1000 mg/m<sup>2</sup>/weekly) was determined. Subsequently operated C-ion RT centers have used the schedule. Recent multicenter retrospective clinical study demonstrated that the reproducible clinical efficacy was observed. The 2-year overall survival was 60% for patients treated with 55.2 Gy (RBE) in 12 fractions concurrent with chemotherapy. Based on these backgrounds, multicenter randomized clinical study on locally advanced pancreatic cancer comparing carbon ion radiotherapy with IMRT was conducted. In my talk, rationale, accumulated clinical outcomes, and future perspectives of C-ion RT for pancreatic cancer will be presented.

**OC-0264 CDK4/CDK6 inhibition radiosensitises HPV-neg HNSCC through inhibition of homologous recombination**  
E. Gottgens<sup>1</sup>, K. Leszczynska<sup>2</sup>, J. Bussink<sup>1</sup>, E. Hammond<sup>2</sup>, P. Span<sup>1</sup>

<sup>1</sup>UMC St Radboud Nijmegen, Department of Radiation Oncology, Nijmegen, The Netherlands; <sup>2</sup>CRUK-MRC

*Oxford Institute for Radiation Oncology, Department of Oncology, Oxford, United Kingdom*

#### **Purpose or Objective**

Radiotherapy is an important modality in the treatment of head and neck squamous cell carcinomas (HNSCC). Patients with human papillomavirus (HPV) negative carcinomas have a poorer treatment response and prognosis than patients with HPV+ HNSCC. Therefore, it is important to develop new treatment strategies to improve treatment for HPV- HNSCC patients. p16, a tumour suppressor and cyclin dependent kinase (CDK) 4/CDK6 inhibitor, is commonly overexpressed in HPV+ HNSCC and has been linked to the high radiosensitivity of HPV+ cells. We hypothesised that blocking CDK4/CDK6 using palbociclib in HPV- HNSCC would result in radiosensitisation.

#### **Material and Methods**

In this study, three HPV+ and ten HPV- HNSCC cell lines were exposed to clinically relevant levels of palbociclib, combined with ionising radiation (0-8 Gy). Cell survival was measured by colony forming assays. Levels of DNA damage and recruitment of DNA damage repair factors were assessed by 53BP1/RAD51/BRCA1 foci measurement and genome instability by metaphase spreading. Cell cycle analysis was performed by propidium iodide staining and flow cytometry. Mitotic catastrophe was measured by immunofluorescent staining for  $\alpha$ -tubulin and DAPI. Homologous recombination was measured using a GFP reporter-based system.

#### **Results**

A strong radiosensitising effect of palbociclib was observed in ten HPV- cell lines, whereas this did not occur in three HPV+ cell lines. This effect could also be observed in low oxygen tensions (1% O<sub>2</sub>) that are commonly known to cause radioresistance. Concurrent radiation with palbociclib resulted in elevated levels of residual 53BP1 foci in HPV- UT-SCC-24A cells (figure) and high levels of chromosomal aberrations. We discovered that palbociclib reduced the expression of RAD51 and BRCA1, leading to decreased protein expression, reduced localisation to DNA damage sites, and dysfunctional homologous recombination. In addition, we showed that this repression was cell cycle independent. As a consequence of this, we observed high amounts of mitotic aberrancies which suggests that combining radiation with palbociclib leads to cytotoxicity via mitotic catastrophe.

#### **Conclusion**

Palbociclib caused a strong radiosensitising effect in HPV-, but not HPV+ HNSCC cell lines. Taken together, we highlight a therapeutic strategy to improve the radiosensitivity of HPV-ve HNSCC, a patient group that has an unmet and urgent need for improved radiotherapy efficacy.

#### **OC-0265 MiR-205 enhances radiation sensitivity of prostate cancer cells through PKC $\epsilon$ and ZEB1 inhibition**

R. El Bezawy<sup>1</sup>, S. Tinelli<sup>1</sup>, A. Cicchetti<sup>2</sup>, R. Valdagni<sup>3</sup>, P. Gandellini<sup>1</sup>, N. Zaffaroni<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Department of Applied Research and Technological Development, Milan, Italy ; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Department of Medical Physics, Milan, Italy ;

<sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Department of Radiation Oncology 1, Milan, Italy

#### **Purpose or Objective**

Radiotherapy is one of the main treatment options for non-metastatic prostate cancer (PCa). Although treatment technical optimization has greatly improved local tumor control, a considerable fraction of patients still experience relapse due to development of resistance. Radioresistance is a complex and still poorly understood phenomenon involving the deregulation of a variety of

signaling pathways as a consequence of several genetic and epigenetic abnormalities. In this context, cumulative evidence supports a functional role of microRNAs, endogenous small non-coding RNA molecules that negatively regulate gene expression, in affecting radioresistance, suggesting the modulation of their expression as a novel radiosensitizing approach. In this study, we investigated for the first time the ability of miR-205 to enhance the radiation response of prostate cancer cells.

#### **Material and Methods**

miR-205 reconstitution by a miRNA mimic in PCa cell lines (DU145 and PC-3) was used to elucidate miR-205 biological role. Radiation response in miRNA-reconstituted and control cells was assessed by clonogenic assay, immunofluorescence-based detection of nuclear  $\gamma$ -H2AX foci and comet assay. Target-protection experiments were performed by using a custom oligonucleotide designed to physically disrupt the pairing between the miRNA and its target PKC $\epsilon$ . For in vivo experiments, xenografts generated by implanting DU145 cells stably expressing miR-205 in SCID mice, were exposed to 5 Gy single dose irradiation using an image-guided animal micro-irradiator (225Cx, Precision X-ray).

#### **Results**

Experimental data showed that reconstitution of miR-205 is able to significantly enhance the radiation response of prostate cancer cell lines and xenografts. Specifically, miR-205 exerts its radiosensitizing effect through the impairment of radiation-induced DNA damage repair, as a consequence of PKC $\epsilon$  and ZEB1 inhibition. Indeed, phenocopy experiments based on knock-down of either PKC $\epsilon$  and ZEB1 were able to reproduce miR-205 radiosensitizing effect, hence confirming a functional role of both targets in the process. At the molecular level, miR-205-induced suppression of PKC $\epsilon$  counteracted radioresistance through the impairment of EGFR nuclear translocation and consequent DNA-PK activation. Consistently, disruption of miR-205-PKC $\epsilon$  3'UTR pairing almost completely abrogated the radiosensitizing effect, therefore further substantiating the role of PKC $\epsilon$  as a key effector of miRNA induced enhancement of radiation response.

#### **Conclusion**

Overall, our results uncovered the molecular and cellular mechanisms underlying the radiosensitizing effect of miR-205, suggesting this miRNA as a potential positive modulator of radiation response. These findings support the clinical interest in developing a novel therapeutic approach based on miR-205 reconstitution to increase Pca sensitivity to radiotherapy.

#### **OC-0266 Pancreatic ductal adenocarcinoma sensitization to radiotherapy by bioactive food components**

V. Vendrely<sup>1</sup>, S. Amintas<sup>2</sup>, C. Noël<sup>2</sup>, I. Moranvillier<sup>3</sup>, I. Lamrissi<sup>3</sup>, B. Rousseau<sup>2</sup>, S. Coulibaly<sup>4</sup>, A. Bedel<sup>2</sup>, F. Moreau-Gaudry<sup>2</sup>, E. Buscaïl<sup>5</sup>, L. Chiche<sup>5</sup>, G. Belleannée<sup>6</sup>, C. Dupin<sup>1</sup>, S. Dabernat<sup>2</sup>

<sup>1</sup>CHU de Bordeaux, Radiotherapy, Pessac, France ;

<sup>2</sup>Bordeaux University, Biotherapy, Bordeaux, France ;

<sup>3</sup>Inserm 1035, Biotherapy, Bordeaux, France ; <sup>4</sup>CHU

Bordeaux, radiotherapy, Bordeaux, France ; <sup>5</sup>CHU de

Bordeaux, Surgery, Pessac, France ; <sup>6</sup>CHU de Bordeaux,

Histopathology, Pessac, France

#### **Purpose or Objective**

Pancreatic ductal adenocarcinoma (PDAC) is of poor prognosis in part because of resistance to conventional treatments such as chemotherapy or radiotherapy. Some naturally occurring bioactive food components (BFCs), with pro-oxidant properties are able to potentiate the cytotoxic action of conventional drugs in the PDAC. In addition, these BFCs could increase the DNA breaks induced by ionizing radiation. Our objectives were to

evaluate the combined action of several BFCs in combination with chemotherapy and radiotherapy in PDAC models and to identify mechanisms involved in chemo / radiosensitization at the cellular and molecular levels

#### Material and Methods

Cell survival was evaluated *in vitro* in the presence of BFCs in combination on 4 pancreatic tumor cell lines. The production of reactive oxygen species (ROS) was measured by flow cytometry and fluorescence microscopy. Molecular mechanisms have been decrypted by western blot (signaling pathways) and flow cytometry (cell cycle and apoptosis). Finally, we evaluated the association of BFCs in gavage with intraperitoneal gemcitabine chemotherapy and with radiotherapy (2 Gy/fraction) *in vivo*, on subcutaneous CAPAN-2 cell xenografts.

#### Results

*In vitro*, resveratrol (R), capsaicin (C) and sulforaphane (S) were cytotoxic with significantly higher inhibitory effect in combination (R + C), (C + S) or (R + C + S), without effect on fibroblasts. In addition, the combinations potentiated the otherwise limited action of gemcitabine on cells tested *in vitro*. *In vivo*, the addition of R + C to treatment with gemcitabine at reduced dose allowed tumor inhibition equivalent to that obtained with gemcitabine at full dose. Furthermore, *in vitro*, the addition of BFCs alone and in combination with radiotherapy significantly increases cellular toxicity on the CAPAN-2 epithelial line, compared to radiotherapy alone and BFCs alone or combined. *In vivo*, the combination R + C associated with radiotherapy allowed a significant decrease in tumor volumes compared to radiotherapy alone. The study of signaling pathways showed an increase of pro-apoptotic proteins with the association R + C and radiotherapy, in relation with an increased induction of ROS, but also, surprisingly, an inhibition of the repair of the DNA by inhibition of ATM phosphorylation. These two combined effects precipitated the death of the tumor cells.

#### Conclusion

Combinations of R + C have a chemosensitizing and radiosensitizing effect in a preclinical model of PDAC, with identified molecular mechanisms relevant in the context of the therapies tested. By combining BFCs with radiochemotherapy with gemcitabine, we can hope for a double potentiation of radiotherapy and chemotherapy, by increasing the effectiveness of RT, and by reducing the dose of gemcitabine associated for similar efficiency and better tolerance treatment.

#### OC-0267 Imaging the effect of Atovaquone on the hypoxia-related marker CAIX in head and neck cancer models

F. Huizing<sup>1</sup>, B.A. Hoeben<sup>1</sup>, O.C. Boerman<sup>2</sup>, S. Heskamp<sup>2</sup>, J. Bussink<sup>1</sup>

<sup>1</sup>UMC St Radboud Nijmegen, Radiation oncology, Nijmegen, The Netherlands ; <sup>2</sup>UMC St Radboud Nijmegen, Nuclear Medicine, Nijmegen, The Netherlands

#### Purpose or Objective

Tumor hypoxia is an important cause of radio resistance and is associated with poor patient outcome. Therefore, methods to reduce hypoxia before or during radiotherapy are of great value. The drug Atovaquone shows great potential in this prospect. By reducing the oxygen consumption rate of cells it has been shown to reduce hypoxia both *in vitro* and *in vivo*.

Recently, the radioactive tracer <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> was developed for imaging of the hypoxia related marker Carbonic Anhydrase IX (CAIX). Successful imaging of the hypoxia reducing effect of Atovaquone could help predict the effectiveness of radiotherapy. Aim of this study is to assess the effect of Atovaquone on tumor hypoxia with the use of the SPECT tracer <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub>.

#### Material and Methods

Athymic mice with subcutaneous FaDu or SCCNij202 head and neck carcinoma xenografts were treated with Atovaquone (50mg/kg) during 8 days or were held for 48 hours in a hypoxic chamber (8% O<sub>2</sub>). After treatment mice were injected with <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> and 24 hours after injection the mice were imaged using a microSPECT/CT. Tracer uptake was also measured by analyzing *ex vivo* radioactivity counting and autoradiography of the tumor sections. Immunohistochemical staining was used to determine CAIX expression and hypoxia.

#### Results

Atovaquone treatment decreased both CAIX expression and hypoxia staining by 54 ± 33% and 50 ± 21% in the FaDu tumor model, while in the SCCNij202 no difference was observed. Treatment with hypoxic breathing did not increase CAIX expression or hypoxia staining in both tumor models. <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> tumor uptake was generally in line with CAIX expression, however mice treated with hypoxic breathing showed an increased amount of necrosis and a decreased amount of tumor tracer uptake.

#### Conclusion

Atovaquone decreases tumor hypoxia in the FaDu tumor model, but not in the SCCNij202 model. <sup>111</sup>In-girentuximab-F(ab')<sub>2</sub> specifically targets to CAIX-expressing areas in head and neck cancer xenografts. The radiotracer has potential for therapy monitoring, but differences in tumor perfusion and necrosis can hamper accurate quantification.

#### OC-0268 Intrinsic radiosensitivity, genomic-adjusted radiation dose and patterns of failure of penile cancer

P. Johnstone<sup>1</sup>, G.D. Grass<sup>1</sup>, M. Azizi<sup>2</sup>, K. Ahmed<sup>1</sup>, G.S.J. Yoder<sup>3</sup>, E. Welsh<sup>4</sup>, W. Fulp<sup>4</sup>, J. Dhillon<sup>5</sup>, J. Torres-Roca<sup>1</sup>, A. Giuliano<sup>6</sup>, Z. Yuan<sup>1</sup>, P. Spiess<sup>2</sup>

<sup>1</sup>Moffitt Cancer Center, Radiation Oncology, Tampa, United States Minor Outlying Island ; <sup>2</sup>Moffitt Cancer Center, Urology, Tampa, United States Minor Outlying Island ; <sup>3</sup>Moffitt Cancer Center, Genomics Core, Tampa, United States Minor Outlying Island ; <sup>4</sup>Moffitt Cancer Center, Biostatistics and Bioinformatics, Tampa, United States Minor Outlying Island ; <sup>5</sup>Moffitt Cancer Center, Anatomic Pathology, Tampa, United States Minor Outlying Island ; <sup>6</sup>Moffitt Cancer Center, Cancer Epidemiology, Tampa, United States Minor Outlying Island

#### Purpose or Objective

Our group previously developed algorithms to characterize a genome-based radiosensitivity index (RSI) and a clinically actionable model to calculate genomic-adjusted radiation dose (GARD), which have been validated in various clinical cohorts. Herein, we characterized the RSI and GARD profiles in a cohort of patients with penile squamous cell carcinoma (PeSCC). We further assessed the potential correlation of GARD with the clinical outcomes in PeSCC patients treated with postoperative radiation therapy (PORT).

#### Material and Methods

A total of 25 PeSCC samples were identified from our institution's tissue bank to analyze RSI. Fresh frozen PeSCC tissue samples were analyzed using Affymetrix U133 2.0 microarray chips. RSI score (range 0-1.0) was derived for each sample using the previously published algorithm for a specific 10 genes signature. The comparison of RSI among PeSCC and various selected epithelial cancers were assessed. GARD values were calculated as described in our prior studies using a postoperative RT dose of 50 Gy. A cohort of 18 patients treated with PORT was reviewed for clinical correlation.

#### Results

The median RSI for the tissue cohort was 0.475 (range 0.215-0.682). The majority of the lesions (n=21; 84%) are radioresistant using a previously reported RSI cut-point of

0.375 (RSI >0.375 =radioresistant). In comparison to cohorts of other histologies including bladder transitional cell carcinoma, glioma, cervical SCC, esophageal adenocarcinoma, melanoma, non-melanoma skin cancer, non-opharynx and oropharynx head and neck SCC, PeSCC is one of the most intrinsically radioresistant cancers. Genomically, PeSCC is significantly more radioresistant while comparing with oropharynx head and neck SCC ( $p=0.01$ ) and cervical SCC ( $p=0.002$ ). The PeSCC GARD values ranged from 9.56 to 38.39 (median 18.25), suggesting various radiation therapeutic effects if treated with a uniform PORT dose of 50 Gy. GARD-modeled dose of 50 Gy controls only 52% of PeSCC lesions. Median follow-up from the completion of RT for the clinical cohort was 12.1 months. The majority of patients presented with pathological N2 or N3 disease ( $n=15$ ; 83%) and treated with adjuvant concurrent platinum-based chemoradiotherapy (CRT,  $n=16$ ; 89%). Nine out of the 18 patients had locoregional recurrence (LRR). Of whom, 6 patients presented with LRR within six months since completion of PORT.

### Conclusion

The majority of PeSCC are intrinsically radioresistant with low GARD-based radiation therapeutic effect. This finding is consistent with the observed high rate of LRR (50%) in the clinical cohort treated with PORT doses of 45-59.4 Gy. A GARD-based strategy may help personalize radiation therapy dose prescription to individual tumor biology and improve outcomes.

#### OC-0269 A randomized phase III trial for alleviating radiation-induced xerostomia with chewing gum

J.K. Kaae<sup>1,2</sup>, L. Stenfeldt<sup>1</sup>, B. Hyrup<sup>3</sup>, C. Brink<sup>2,4</sup>, J.G. Eriksen<sup>5</sup>

<sup>1</sup>Odense University Hospital, Oncology, Odense, Denmark; <sup>2</sup>University of Southern Denmark, Clinical Research, Odense, Denmark; <sup>3</sup>Fertin Pharma A/S, Fertin Pharma, Vejle, Denmark; <sup>4</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark; <sup>5</sup>Aarhus University Hospital, Experimental Clinical Oncology, Aarhus, Denmark

### Purpose or Objective

Radiation-induced xerostomia is a serious problem affecting quality of life (QOL) after radiotherapy (RT) for head and neck cancer. The aim of this study was to assess the effect of tasteless chewing gum to improve salivary flow after radiation-induced xerostomia for Head and Neck Cancer Survivors (HNCS).

### Material and Methods

HNCS treated with curative intended primary RT and without loco-regional failure were recruited from the follow-up clinic. Inclusion criteria were subjective feeling of xerostomia as rated by the DAHANCA score, sufficient dental health, and minimum six months follow-up after end of RT. HNCS were randomized 2:1 to one month of daily chewing gum or best supportive care. Intervention was a customized experimental sugar-free chewing gum without flavors. Unstimulated and stimulated sialometry were performed to measure saliva flow. Saliva viscosity was tested with the Inclined Plane Test (IPT) by recording the saliva transit time on a 20 cm vertical plate with cutoff at 5 cm. The validated Groningen Radiotherapy-Induced Xerostomia (GRIX) questionnaire was completed to evaluate the subjective QOL in relation to xerostomia. The primary endpoint was the difference in salivary flow rate between unstimulated and stimulated sialometry after using chewing gum for one month.

### Results

From Aug 2016 to Aug 2018, 109 HNCS were enrolled. Ninety-one were eligible for analysis and randomized to intervention ( $n=55$ ) or control ( $n=36$ ) (Table 1). Median age was 61 years (range 34-80). Oropharynx was the predominant tumor location (95%). Prescribed treatment dose was 66-68 Gy. Sialometry showed an increase in mean salivary flow from unstimulated 0.15 ml/min to stimulated 0.57 ml/min ( $\Delta$ Saliva 0.42 ml/min) for the intervention group ( $p < 0.0001$ ) (Fig. 1). Viscosity on the IPT showed that the transit time of saliva at 5 cm was significantly faster for the stimulated saliva output (3 sec) compared to the unstimulated output (21 sec) for the intervention group ( $p = 0.02$ ) (Fig. 1). For the control group, mean salivary flow also increased with chewing gum stimulation ( $\Delta$ Saliva 0.56 ml/min,  $p < 0.001$ ) and saliva transit time for viscosity improved from 15 to 4 sec ( $p = 0.06$ ). No significant difference was seen between the unstimulated and stimulated mean salivary flow when comparing the two groups. The GRIX questionnaire showed improved QOL for the intervention group for items concerning xerostomia during the day (Q2,  $p = 0.001$ ), xerostomia when being outdoor (Q3,  $p = 0.001$ ) and while eating (Q4,  $p = 0.004$ ).

Table 1 Patient characteristics

	Randomized patients	Eligible patients Arm A	Eligible patients Arm B	P-value (2-sided)
Included patients	109	55	36	
Dropout	18	13	5	
Age (median)	61 [34-80]	61 [34-80]	60.5 [40-79]	0.5
Under 70 yr	95 (87%)	45 (82%)	33 (92%)	0.2
Above 70 yr	14 (13%)	10 (18%)	3 (8%)	
Gender (male)	72 (66%)	33 (60%)	27 (75%)	0.1
Weight, kg	76.9 [45-121]	76.9 [45-115]	78.4 [18-37]	0.4
BMI	25.4 [18-38]	25.5 [18-38]	25.6 [18-37]	0.6
Tumor site				
Oropharynx	103 (94%)	51 (93%)	35 (97%)	0.4
Oral Cavity	6 (6%)	4 (7%)	1 (3%)	
Concomitant chemotherapy	77 (71%)	39 (71%)	24 (67%)	0.7
Performance status				
PS 0	90 (73%)	46 (84%)	30 (83%)	1.0
PS 1	19 (17%)	9 (16%)	6 (17%)	
Time post RT				
Under 2 yrs (6-24 mths)	82 (75%)	39 (71%)	29 (81%)	0.3
Above 2 yrs (36-60 mths)	27 (25%)	16 (29%)	7 (19%)	
Smoking status				
Never smoker	39 (36%)	21 (38%)	15 (42%)	0.9
Former smoker	62 (57%)	30 (55%)	19 (53%)	
Active smoker	8 (7%)	4 (7%)	2 (5%)	
Comorbidity	72 (66%)	38 (69%)	21 (58%)	0.3
Daily aid with water	95 (87%)	48 (87%)	32 (89%)	0.8

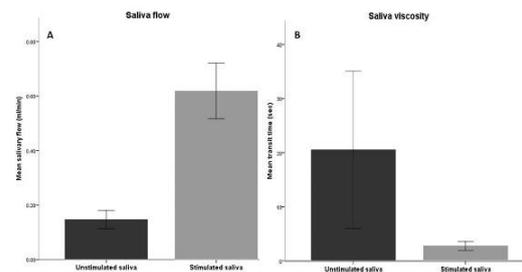

Fig 1 Saliva outputs before and after use of chewing gum at follow-up for the intervention group. (A) Mean salivary flow (ml/min) for unstimulated and stimulated saliva. (B) Mean transit time (sec.) for saliva viscosity at 5 cm on the inclined Plane Test (IPT) for unstimulated and stimulated saliva.

### Conclusion

Customized experimental chewing gum was able to increase salivary flow and decrease viscosity for Head and Neck Cancer Survivors experiencing radiation-induced xerostomia for both the intervention and control group. Xerostomia-related QOL only improved for the intervention group.

**Purpose or Objective**

Preoperative radiotherapy (RT) is an option for a subset of patients with locally advanced primary or relapsed tumors. Yet, its impact on efficacy in terms of pathological response is limited, highlighting the need for novel multimodal therapies aimed at local control with low toxicity.

NBTR3 is made of hafnium oxide nanoparticles which, injected intratumorally (IT) and activated by ionizing radiation, yield a tumor-localized high energy deposit and increase cell death compared to the same dose of RT alone.

We report here the results of a phase II/III randomized clinical trial of NBTR3 given as preoperative treatment to patients with locally advanced soft tissue sarcoma (STS) of the extremity and trunk wall [NCT02379845].

**Material and Methods**

Act.In.Sarc is an international, multicenter, open-label, active-controlled phase II/III trial in which patients (pts) with locally advanced STS of the extremity or trunk wall were randomized 1:1 to receive a single IT NBTR3 injection and RT (Arm A) or RT alone (Arm B), followed by surgical resection. RT consisted of Intensity Modulated RT or 3D-RT of 2Gy\*25 fractions (total 50 Gy) over 5 weeks.

The primary endpoint was pathological Complete Response Rate (pCRR), defined as the proportion of pts presenting <5% of residual viable cancer cells evaluated by a Central Review Board on anonymized tumor specimen. Key secondary endpoints included negative surgical margin (R0) and general safety.

#### Results

Among the 180 randomized pts, 176 were included in the intent-to-treat full analysis set (ITT-FAS). In the ITT-FAS population, pCRR was 16.1% in Arm A vs 7.9% in Arm B (p=0.0448). R0 margin was achieved in 77.0% of pts in Arm A vs 64.0% in Arm B (p=0.0424). The limb amputation rate, another secondary outcome, was decreased by 50% in Arm A as compared to Arm B. NBTXR3 showed very good local tolerance without any modification of RT alone safety profile. In all the treated pts in Arm A, who received any amount of NBTXR3 or at least one RT dose, the IT administration of NBTXR3 caused injection-site pain in 12 (13.5%) pts. NBTXR3 was also associated with grade 3-4 acute immune reactions in 7 (7.9%) pts, but these adverse events were of short duration, manageable, and, in some cases, resolved spontaneously. Long-term efficacy and safety results will be presented.

#### Conclusion

In this study both the primary and secondary endpoints (pCRR and R0 rate, respectively) were met with a safety profile of NBTXR3 activated by RT comparable to that of RT alone. As pCR is associated with improved progression-free and overall survival, NBTXR3 activated by RT represents a new preoperative treatment option for locally advanced STS. These data support ongoing studies investigating NBTXR3 in recurrent/metastatic HNSCC or metastatic non-small cell lung cancer [NCT03589339]; HNSCC [NCT01946867; NCT02901483]; prostate cancer [NCT02805894], liver cancer [NCT02721056] and rectal cancer [NCT02465593].

#### OC-0272 Hypofractionated vs conventional radiotherapy for prostate cancer: 7 yr results from the HYPROtrial

L. Incrocci<sup>1</sup>, K. De Vries<sup>1</sup>, R. Wortel<sup>1</sup>, E. Oomen<sup>1</sup>, W. Heemsbergen<sup>1</sup>, F. Pos<sup>2</sup>

<sup>1</sup>Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Department of Radiation Oncology, Rotterdam, The Netherlands ; <sup>2</sup>Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

In the phase 3, Hypofractionated irradiation for PROstate cancer (HYPRO) trial, hypofractionated radiotherapy was compared with conventionally fractionated radiotherapy. In previous reports, we could not demonstrate the postulated superiority of hypofractionation in terms of relapse-free survival (RFS) at 5-year follow-up. The use of long-term androgen deprivation therapy in more than 60% of the patients might have obscured potential benefits of hypofractionation at 5-year follow-up. In this analysis, we provide the 7-year outcomes on biochemical failure, clinical failure, local failure and overall survival (OS).

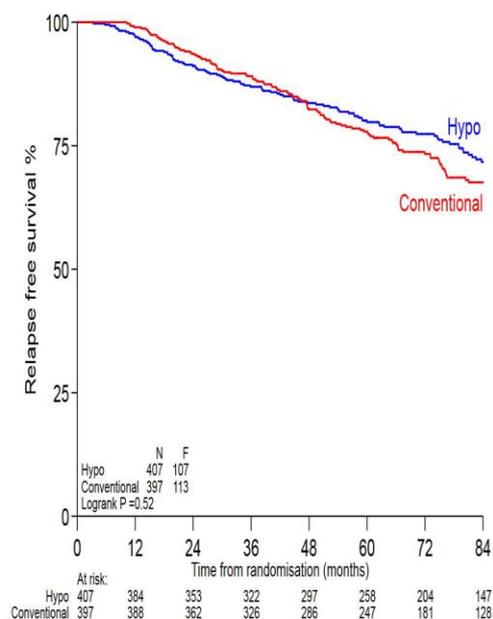

#### Material and Methods

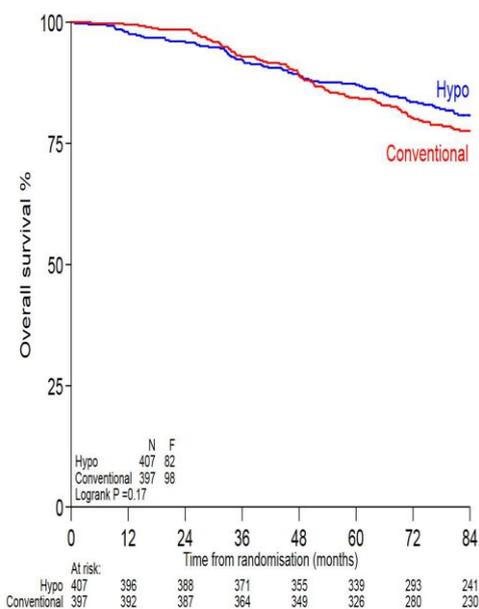

Patients with intermediate to high-risk localized prostate cancer (cT1-cT4NXOMX0), a PSA concentration  $\leq 60$   $\mu\text{g/L}$  and a WHO performance status of 0-2, were included in 7 Dutch radiotherapy centers. Patient were randomly assigned (1:1) to hypofractionated radiotherapy of 64.6 Gy (19 fractions of 3.4 Gy, three fractions per week) or conventionally fractionated radiotherapy of 78.0 Gy (39 fractions of 2.0 Gy, five fractions per week). Based on an estimated  $\alpha/\beta$  ratio for prostate cancer of 1.5 Gy, the equivalent total dose in fractions of 2.0 Gy (EQD2) was 90.4 Gy for hypofractionation versus 78.0 Gy for conventional fractionation. Primary outcomes have been previously published. This analysis will report on RFS en

OS survival at 7 year follow-up, and the effect of hypofractionation on local failure.

#### Results

Between 2007 and 2010, 820 patients were enrolled. A total of 804 were assessable for the current evaluation. Of these, 407 were assigned hypofractionated radiotherapy (HF) and 397 conventionally fractionated radiotherapy (CF). 537 (67%) of 804 patients received concomitant androgen deprivation therapy for a median duration of 32 months (IQR 10-44). Median follow-up was 89 months. Treatment failure at 7 years was reported in 183 (89 HF vs 94 CF) of 804 patients. 7-year relapse-free survival was 71.7 % (95% CI 66.4-76.4) for patients assigned hypofractionation and 67.6% (95% CI 62.0-72.5) for conventional fractionation (p=0.52). Overall survival was 80.8 % (95% CI 76.5-84.4) in the hypofractionated group versus 77.6 % (95 % CI 73.0-81.5) in the conventional fractionated group (p=0.17). Local failure as first site of recurrence was reported in 15 in the hypofractionated arm and 25 in the conventional arm (p=0.09). For Gleason  $\geq 8$ , a statistically significant difference in local failure free survival was found in favor of hypofractionation (p=0.003).

### Conclusion

The outcomes on 7-year relapse free survival and overall survival demonstrated no difference between hypofractionation versus conventional fractionation. A trend toward better local control was found after hypofractionation, whereas local control was statistically significant superior in patients with Gleason  $\geq 8$  tumors. These data on local control suggest that hypofractionation might be beneficial provided that high risk patients with subclinical metastasis at start of treatment are identified.

### OC-0273 Organ preservation after chemoradiotherapy for rectal cancer: 5-year results of the GRECCAR2 trial

V. Vendrely<sup>1</sup>, P. Rouanet<sup>2</sup>, J. Tuech<sup>3</sup>, A. Valverde<sup>4</sup>, B. Lelong<sup>5</sup>, M. Rivoire<sup>6</sup>, J. Faucheron<sup>7</sup>, J. Mehrdad<sup>8</sup>, G. Portier<sup>9</sup>, J. Asselineau<sup>10</sup>, E. Frison<sup>10</sup>, Q. Denost<sup>11</sup>, E. Rullier<sup>11</sup>

<sup>1</sup>CHU de Bordeaux, Radiotherapy, Pessac, France ; <sup>2</sup>ICM, Surgery, Montpellier, France; <sup>3</sup>CHU Rouen, Surgery, Rouen, France; <sup>4</sup>Hospital Diaconesses Croix saint Simon, Surgery, Paris, France ; <sup>5</sup>Institut Paoli Calmettes, Surgery, Marseille, France ; <sup>6</sup>Centre Léon Bérard, Surgery, Lyon, France; <sup>7</sup>CHU Grenoble, surgery, Grenoble, France; <sup>8</sup>Centre Oscar Lambret, Surgery, Lille, France; <sup>9</sup>CHU Toulouse, surgery, Toulouse, France ; <sup>10</sup>ISPED, Statistics, Bordeaux, France; <sup>11</sup>CHU Bordeaux, Surgery, Bordeaux, France

### Purpose or Objective

To evaluate the long term results at 5 years of the multicenter randomized trial comparing local excision (LE) vs. total mesorectal excision (TME) in good responders after chemoradiotherapy (CRT) for T2T3 low rectal cancer.

### Material and Methods

From March 2007 to September 2012, 148 patients clinically good responders after CRT for T2T3 rectal cancer, size  $\leq 4$  cm, were randomized in 74 LE vs. 74 TME, 3 were excluded and 145 analyzed. In the LE group, 26 had a completion TME for ypT2-3, which was part of the protocol. Kaplan-Meier and Cox regressions were used to estimate and compare local and metastatic recurrence and survival at 5 years.

### Results

Local recurrence (7% vs. 7%; hazard ratio (HR)=1.41, p=0.599), metastatic recurrence (18% vs. 19%; HR=0.86,

p=0.734), overall (84% vs. 82%; HR=0.92, p=0.845) and disease-free (70% vs. 72%; HR=0.87, p=0.682) survivals were not different between the LE and the TME groups at 5 years. No predictive factor of local recurrence was found, whereas ypT2-3 stage was independent factor of metastatic recurrence (HR=2.88, p=0.02).

### Conclusion

The 5-year results of this multicenter randomized trial suggest the oncologic safety of the strategy in selected patients with small T2T3 low rectal cancer.

### OC-0274 5x5 Gy and consolidation chemotherapy vs. chemoradiation for rectal cancer: a phase III study

K. Bujko<sup>1</sup>, X. On Behalf Of The Polish Colorectal Study Group<sup>2</sup>

<sup>1</sup>The Maria Skłodowska-Curie Memorial Cancer Center, Department Of Radiotherapy, Warsaw, Poland

### Purpose or Objective

This study evaluated whether preoperative short-course radiotherapy combined with consolidation chemotherapy (CCT) is superior to chemoradiation in terms of R0 resection rate. Previously we reported no differences in R0 resection, complete pathological response, postoperative complications, late complications, disease-free survival, incidence of local failure and distant metastases after 3 years of median follow-up (Ann Oncol 2016, 27:834-42). However, in the short-course/CCT group, we observed lower acute radiochemotherapy-induced toxicity (75% vs. 83%, p=0.006) and 8% benefit (p=0.046) in overall survival at 3 years. The main aim of the current analysis is to find out whether benefit in overall survival is sustained with longer observations.

### Material and Methods

Patients with fixed cT3 or cT4 rectal cancer were randomised either to 5x5 Gy and three cycles of FOLFOX4 given in tight sequence or to chemoradiation (50.4 Gy in 28 fractions combined with two 5-day cycles of bolus 5-Fu 325 mg/m<sup>2</sup>/day and leucovorin 20 mg/m<sup>2</sup>/day during the first and fifth week of irradiation along with five infusions of oxaliplatin 50 mg/m<sup>2</sup> once weekly). The protocol was amended during accrual to allow oxaliplatin to be omitted in both groups.

### Results

In total, 515 patients were eligible for analysis: 261 in the short-course/CCT group and 254 in the chemoradiation group. The median follow-up was 7.0 years (interquartile range 5.7-8.3 years). The benefit in overall survival at 3 years after short-course/CCT previously reported was also observed (71.6%, 95% confidence interval [CI] 66.1%-77.1% vs. 63.0%, 95% CI 57.1%-68.9%). However, this benefit disappeared later; at 8 years, overall survival was 48.8% in the short-course/CCT group vs. 48.6% in the chemoradiation group: hazard ratio (HR) 0.89 (95% CI 0.70-1.14), p=0.35. The corresponding values for disease-free survival were 42.6% vs. 41.0%, HR 0.94 (95% CI 0.75-1.19), p=0.64. The cumulative incidences of local failure and distant metastases did not differ between the short-course/CCT group and the chemoradiation group, and after 8 years were 35.0% vs. 31.9%, (relative risk [RR]=1.08, 95% CI 0.70 - 1.23), p=0.59 and 35.5% vs. 33.3%, (RR=1.11, 95% CI 0.67 - 1.21), p=0.49, respectively. The rate of late complications in the short-course/CCT group was 21.5% vs. 21.2% in the chemoradiation group, p=0.58.

### Conclusion

There was no difference in long-term overall survival between the short-course/CCT group and the chemoradiation group. Nevertheless, we suggest that benefits in short-term survival and acute toxicity favour short-course/CCT.

### OC-0275 Safety and efficacy of concurrent SRT and targeted- or immunotherapy for melanoma brain metastases

#### Purpose or Objective

During their course of the disease, many melanoma patients develop brain metastases and receive stereotactic radiotherapy (SRT) concurrent to targeted- or immunotherapy. In this study, we investigated the safety and efficacy of this treatment combination and analyzed factors associated with toxicity and survival.

#### Material and Methods

This study is based on the international retrospective database on concurrent ( $\leq 30$  days) SRT and immunotherapy (TOASTT). Primary outcome of this study on malignant melanoma patients was overall survival (OS), secondary outcomes were progression free survival (PFS), local control (LC) and toxicity using CTCAE v4. Statistical analysis consisted of Kaplan Meier survival curves and log rank testing.

#### Results

Data of 145 melanoma patients from 18 international centers was analyzed. Patients were treated between 05/2011 and 02/2018. SRT was performed for 473 brain metastases in 180 sessions. At time of SRT, median patient age was 60 (25-92) years, patients were characterized by BRAF-mutation in 46.4%. Median number of treated brain metastases per patient was 2 (1-30), with a median of 1 fraction (1-6) and a total median dose of 20 (16-30) Gy, most commonly prescribed to the 80% isodose line. At 63.5% of treatments, immunotherapy was administered with SRT, in 28.7% SRT was combined with tyrosine kinase inhibitors (TKI; over 90% containing BRAF inhibitors) and 6.7% used a combination.

Median follow up was 10 (0-65) months from first concurrent treatment. Median PFS and OS was 4.1 (0.2-64.6) months and 9.5 (0-70) months, respectively. Median cumulative volume of brain metastases treated at one course of SRT was 1.5cc (0.04-24.54cc). For 42.7% of individual metastases imaging-based local metastases control was available: 176 metastases (85.8%) were controlled at last time of follow-up. Median time to local progression was 4.5 months. Infield toxicity of SRT was low: Acute grade 3 and 4 toxicities occurred in 5.5%, and 2.2%, respectively. One patient died of cerebral edema.

Late grade 3 toxicity occurred in only in 4.4%, no late grade 4 or 5 toxicities were reported. For the combination with systemic treatment, grade 3 and 4 toxicities were reported in 13.8% and 4.9%, respectively. 2 patients developed grade 5 toxicity and died of heart failure and a thromboembolic event, respectively. A longer OS was associated with controlled/non-existent other metastases vs. mixed response/uncontrolled other metastases ( $p=0.001$ ), and immunotherapy vs. TKI ( $p=0.01$ ). Need for steroids negatively impacted survival ( $p=0.01$ ), as did presence of body metastases ( $p=0.04$ ). BRAF status was not significant.

#### Conclusion

Concurrent targeted- or immunotherapy with SRT for melanoma brain metastases appears safe in this multicenter analysis. Longest OS was observed when SRT was combined with immune checkpoint inhibition; need for steroids was associated with worse OS.

### OC-0276 Stereotactic radiosurgery plus immunotherapy or targeted therapy for brain metastases from NSCLC

E. Olmetto<sup>1</sup>, C. Delli Paoli<sup>1</sup>, L.P. Ciccone<sup>1</sup>, M. Perna<sup>1</sup>, R. Grassi<sup>1</sup>, S. Erika<sup>1</sup>, S. Scoccianti<sup>1</sup>, D. Greto<sup>1</sup>, I. Desideri<sup>1</sup>, G. Simontacchi<sup>1</sup>, L. Marrazzo<sup>2</sup>, C. Arilli<sup>2</sup>, M. Casati<sup>2</sup>, A. Compagnucci<sup>2</sup>, G. Pecchioli<sup>3</sup>, S. Pallotta<sup>2</sup>, L. Livi<sup>1</sup>

<sup>1</sup>University of Florence, Azienda Ospedaliero Universitaria Careggi- Radiation Oncology Unit - Oncology Department, Florence, Italy; <sup>2</sup>University of Florence, Medical Physics Unit, Florence, Italy; <sup>3</sup>University of Florence, Azienda Ospedaliero Universitaria Careggi- Neurosurgery Unit, Florence, Italy

#### Purpose or Objective

Immunotherapy (IT) and Targeted Therapy (TT) have strongly changed the therapeutic management of Non-Small Cell Lung Cancer (NSCLC) patients. Radiosurgery (RS) is very effective in achieving local control of brain metastases (BM); moreover, it may have a symptomatic effect by reducing or preventing neurological deficits, in order to maintain a good quality of life longer. So far, data regarding the interactions between these novel drugs and RS in terms of efficacy and toxicity are not available. Aim of the present study is to evaluate outcome and safety of RS delivered in association to IT or TT for BM from NSCLC.

#### Material and Methods

We retrospectively analysed data from NSCLC patients with BM treated with RS plus IT or TT. We selected patients who received IT or TT within 4 weeks before or after RS. RS were performed with Gamma-Knife and Cyber Knife. Clinical toxicity was evaluated according to CTCAE v.4. During follow-up, all the patients underwent contrast-enhanced brain MRI every 3 months for the first year after RS, every 4 months thereafter. Local progression-free survival (L-PFS) was defined as the time from RS to radiological progression at the site of the treated lesion, while intracranial progression at a different site, defined as distant-PFS (D-PFS), was the time interval from RS to the appearance of new BM.

#### Results

We selected 30 patients treated at our centre from 2011 to 2018. There were 16 women (53%) and 14 men (47%) with a median age of 63 years (range 51-82). All patients were affected by adenocarcinoma; 13 (43%) were EGFR-mutated, 4 (13%) were ALK-rearranged and 4 (13%) were PD-L1 over-expressed. Twelve patients (40%) had metastatic disease when the lung tumor was newly diagnosed; among these, 10 patients (33%) had BM. At the time of RS, the majority of patients had a KPS of 90-100%, the median GPA-score was 2.6, while the median RPA-class was 2. The median number of treated lesions was 3 (range 1-11). Most of the patients ( $n=21$ , 70%) received a single-fraction of 24 Gy, whereas the others were treated with a dose of 18 or 21 Gy. IT and TT consisted of Pembrolizumab (4), Nivolumab (2), Erlotinib (11),

Gefitinib (4), Crizotinib (3), Ceritinib (1), Alectinib (1), Afatinib (1), Lorlatinib (1), Nintedanib (1), Rociletinib (1). IT or TT was started after the completion of RS in 18 patients; in the remaining cases (n=12), IT or TT was begun before RS (IT or TT was interrupted for a median period of seven days from RS in the majority of patients). Median follow-up was 12 months. One patient developed G1 radionecrosis after 18 months from RS. No G3 toxicity was observed. Median L-PFS and D-PFS were 10.6 and 7 months, respectively.

#### Conclusion

RS for BM may be safely associated with IT or TT in patients with NSCLC. Prospective studies are needed to confirm our results.

#### OC-0277 Interim safety analysis of RAPPOR trial - SABR with pembrolizumab in oligometastatic RCC

S. Siva<sup>1</sup>, M. Bressel<sup>2</sup>, S. Sandhu<sup>3</sup>, B. Tran<sup>3</sup>, J. Mooi<sup>3</sup>, J. Lewin<sup>3</sup>, S. Loi<sup>3</sup>, G. Toner<sup>3</sup>, D. Moon<sup>4</sup>, J. Goad<sup>4</sup>, M. Shaw<sup>1</sup>, S. Chander<sup>1</sup>, T. Eade<sup>5</sup>, A. Guminski<sup>5</sup>, D. Jayamanne<sup>5</sup>, D. Pryor<sup>6</sup>, K. Cuff<sup>6</sup>, S. Wood<sup>6</sup>, N. Lawrentschuk<sup>4</sup>, D. Murphy<sup>4</sup>  
<sup>1</sup>Peter MacCallum Cancer Centre, Department of Radiation Oncology, Melbourne, Australia; <sup>2</sup>Peter MacCallum Cancer Centre, Biostatistics and Clinical Trials, Melbourne, Australia; <sup>3</sup>Peter MacCallum Cancer Centre, Department of Medical Oncology, Melbourne, Australia; <sup>4</sup>Peter MacCallum Cancer Centre, Department of Surgical Oncology, Melbourne, Australia; <sup>5</sup>Northern Sydney Cancer Centre, Oncology, Sydney, Australia; <sup>6</sup>Princess Alexandra Hospital, Oncology, Brisbane, Australia

#### Purpose or Objective

SABR is a locally effective modality for metastatic renal cell carcinoma (RCC) (1, 2). Preclinical data in RCC has demonstrated improved disease control in both irradiated and unirradiated sites with single fraction SABR and anti-PD1 checkpoint blockade (3), although prospective clinical trials with this combination have not yet been reported.

#### Material and Methods

RAPPOR is a multi-institutional, single arm, phase 1b/II clinical trial (NCT02855203). Patients with 1-5 oligometastases from clear cell RCC were eligible. They received a single fraction SABR of 18-20Gy to all metastases (or 30Gy in 10 fractions of conventional radiotherapy if SABR was not feasible) followed by 8 x 3 weekly cycles of 200mg intravenous pembrolizumab. This is a preplanned interim safety analysis of the first 12 patients who completed SABR and 12 weeks of pembrolizumab. Adverse events were graded using CTCAE v4.0.

#### Results

At the date of reporting 25 patients with 76 metastases have been enrolled. The mean age is 62 years, with 18 males and 7 females enrolled. The commonest site of metastasis is lung (n=38, 50%). Most patients have ECOG performance status 0 (64%), with a minority ECOG 1 (36%). For the pre-specified interim safety analysis, 12 patients with a total 37 metastases were irradiated, with 32 (86%) receiving SABR and 5 (14%) receiving conventional radiotherapy. The number of lesions per patient was 1 in 3 patients (25%), 3 in 4 patients (33%), 4 in 3 patients (25%) and 5 in 2 patients (17%). The predominant site of metastases was the lung (n=24, 65%). No treatment courses were abandoned due to toxicity (radiotherapy + 8 cycles of pembrolizumab), although one patient ceased treatment early due to progressive disease. Grade 1 and graded 2 treatment related adverse events were recorded in 6 patients (50%, mixed events) and 1 patient (hypothyroidism, 8%), respectively. No grade 3 or greater treatment related adverse events were recorded.

#### Conclusion

The combination of SABR + pembrolizumab in a small cohort of patients to date is well tolerated. Based on this interim safety analysis the independent safety monitoring

committee have recommended continuation of planned recruitment (n=30).

#### OC-0278 Radiation-induced lymphopenia: Fractionation effect and association with infections and mortality.

C. Terrones Campos<sup>1</sup>, B. Ledergerber<sup>1</sup>, I. Vogelius<sup>2</sup>, M. Helleberg<sup>1</sup>, L. Specht<sup>2</sup>, J. Lundgren<sup>1</sup>  
<sup>1</sup>Rigshospitalet, Department of Infectious Diseases-Centre of Excellence for Health- Immunity and Infections CHIP, Copenhagen, Denmark; <sup>2</sup>Rigshospitalet, Department of Oncology- Radiation Oncology Section, Copenhagen, Denmark

#### Purpose or Objective

Radiotherapy may cause lymphocyte depletion in cancer patients. We designed this study to identify whether the radiation dose and duration of radiation exposure, among other factors, are associated with the end of radiotherapy (EoRT) lymphocyte count; and to determine the association of radiotherapy-induced lymphopenia with the risk of acquiring subsequent infections and mortality.

#### Material and Methods

Consecutive patients with a non-hematological cancer diagnosis were included in the study if they had received their first course of external beam radiotherapy (EBRT) with curative intent at Rigshospitalet, University of Copenhagen, from 01 January 2005 to 31 December 2016; and had a pre-treatment lymphocyte count collected within one year of radiotherapy start and an EoRT lymphocyte count collected within six months after radiotherapy ended. The EQD2 for every radiation scheme was calculated assuming an  $\alpha/\beta$  of 10. Factors associated with square-root transformed EoRT lymphocyte counts were identified using linear regression analysis, adjusting for cancer diagnosis and pre-treatment lymphocyte count, modelled as restricted cubic splines (tri-variable); and additionally, adjusting for age, gender and Charlson score (multivariable). Using negative binomial regression, the risk of acquiring a subsequent infection and mortality, according to the EoRT lymphocyte count, was determined after adjustment for age, gender, cancer diagnosis, and Charlson score.

#### Results

A total of 4,343 patients were studied. Compared to patients who received radiation schemes with EQD2 = 50-63 Gy delivered in 25-45 days, patients receiving a regimen with an EQD2 >63 Gy in <25 days (mostly NSCLC receiving stereotactic radiotherapy [77%]) had the highest predicted EoRT lymphocyte count (1,351 cells/ $\mu$ L 95% CI [1,210-1,492] vs. 804 cells/ $\mu$ L [774-834]; p<0.001), Figure 1. Radiation to multiple sites vs. single site (721 cells/ $\mu$ L [680-764] vs. 835 cells/ $\mu$ L [817-852]; p<0.001) and concomitant chemotherapy, particularly the use of platinum compounds vs. none (594 cells/ $\mu$ L [548-640] vs. 929 cells/ $\mu$ L [903-954]; p<0.001), also affected the EoRT lymphocyte count. An EoRT lymphocyte count <500 cells/ $\mu$ L was associated with both a higher risk for a new infection in the first year after EBRT (IRR=3.48 [2.54-4.77]; p<0.001) and death (IRR=1.31 [1.14-1.52]; p<0.001), compared to patients with an EoRT lymphocyte count >1,000 cells/ $\mu$ L, Figure 2.

#### Conclusion

Short duration (<25 days) treatment schedules with a higher radiation dose were associated with higher EoRT lymphocyte counts, an observation consistent with published models indicating less radiation dose of circulating blood by an approach of radiotherapy using fewer fractions. Radiation to multiple sites and concomitant chemotherapy conversely independently lowered EoRT lymphocyte count. Radiation-induced lymphopenia was associated with increased risk of acquiring a subsequent infection and mortality.

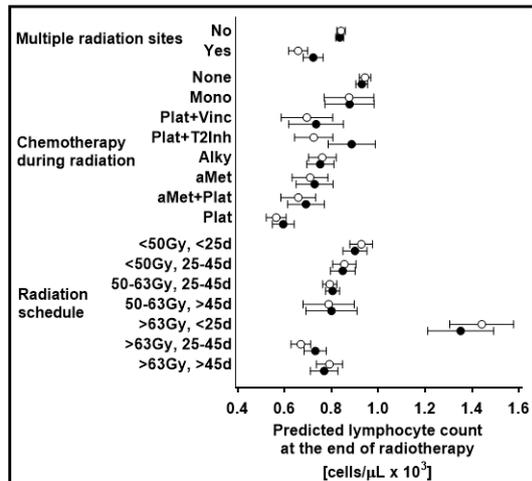

Figure 1. Factors associated with the lymphocyte count at the end of radiotherapy. Empty circles represent tri-variable and full circles multivariable analyses. Mono, monoclonal antibodies; Plat, platinum compounds; Vinc, vinca alkaloids; T2Inh, type II topoisomerase; Alky, alkylating agents; aMet, antimetabolite drugs.

**OC-0279** Concurrent and adjuvant effect of bevacizumab on hypofractionated tailor-made IMRT for glioblastomas

T. Iuchi<sup>1</sup>, R. Hara<sup>2</sup>, K. Hatano<sup>3</sup>, T. Sugiyama<sup>4</sup>, G. Togasaki<sup>2</sup>, T. Setoguchi<sup>1</sup>, Y. Hasegawa<sup>1</sup>, M. Itami<sup>4</sup>, T. Sakaida<sup>1</sup>

<sup>1</sup>Chiba Cancer Center, Neurological Surgery, Chiba, Japan; <sup>2</sup>Chiba Cancer Center, Radiation Oncology, Chiba,

Japan; <sup>3</sup>Tokyo Bay Advanced Imaging and Radiation Oncology Clinic Makuhari, Radiation Oncology, Chiba, Japan; <sup>4</sup>Chiba Cancer Center, Surgical Pathology, Chiba, Japan

**Purpose or Objective**

Hypofractionated high-dose IMRT had improved the local control of glioblastomas (GBMs), but still had higher risk of radiation injury even with tailor-made setting of radiation doses owing to the methylation status of *MGMT* gene promoter. We investigated the effect of bevacizumab (BEV) on control of the tumor and prevention of radiation injury after hypofractionated tailor-made IMRT.

**Material and Methods**

Newly diagnosed GBMs were enrolled. Residual enhanced lesions plus surgical cavity were defined as GTV, and 3-layered CTVs were contoured surrounding the GTV: CTV1=GTV+3mm, CTV2=GTV+18mm, and CTV3 was high-intensity volume on FLAIR images. PTV1, PTV2 and PTV3 were defined by expanding CTVs with 2mm margin. Prescribed doses for PTV2 and PTV3 were unified as 40Gy and 32Gy, but the dose for PTV1 was settled as 48Gy for *MGMT* methylated (Met) but 68Gy for unmethylated (UnMet) cases. IMRT was initiated 5 weeks after craniotomy, and the above doses were delivered with IMRT technique by 8 fractions. BEV was administered 3 weeks after craniotomy (2 weeks prior to IMRT), and continued bi-weekly for 6 cycles. Temozolomide (TMZ) was also initiated 3 weeks after craniotomy and administered for 42 days. Adjuvant BEV/TMZ was administered every 4 weeks for 12 cycles or until tumor progression. The primary endpoint was overall survival (OS), and secondary endpoints were progression-free survival (PFS), radiation necrosis-free survival (RNfS), and qualitative survival (QS) which was defined as the time to KPS<70%. The outcome of patients was compared with historical control of 76 patients with GBM treated by tailor-made IMRT without BEV.

**Results**

25 GBMs, 10 Met and 15 UnMet cases, were enrolled. The PFS of patients treated with BEV (median: 19.2m, 95%CI: 13.3m- not reached) was longer than that without BEV (9.7m, 7.8-16.3m), although this difference was not significant ( $P=0.140$ ). BEV improved the 6-months and 12-months RNfS rates from 83.0% to 98.8% and 58.5% to 72.6%. However, this difference disappeared after completion of the protocol treatment, and 18-months RNfS rates in BEV group (35.8m) was similar to that in historical group (40.9%). BEV significantly prolonged the median QS (13.8m vs. 19.0m,  $P=0.037$ ), but did not improve the OS of patients (not reached vs. 21.2m,  $P=0.657$ ).

**Conclusion**

BEV showed effect on prevention of radiation injury after hypofractionated IMRT, but this effect discontinued after withdrawal of this agent. Concurrent use of BEV had contributed to keep patients' performance status, but showed only limited efficacy on tumor control.

**OC-0280** ReRT with bevacizumab is related to lower rate of radionecrosis as reRT alone for recurrent glioma

D. Fleischmann<sup>1</sup>, J. Jenn<sup>1</sup>, S. Corradini<sup>1</sup>, V. Ruf<sup>2</sup>, R. Forbrig<sup>3</sup>, M. Unterrainer<sup>4</sup>, N. Thon<sup>5</sup>, F.W. Kreth<sup>5</sup>, C. Belka<sup>1</sup>, M. Niyazi<sup>1</sup>

<sup>1</sup>University Hospital- LMU Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Faculty of Medicine- LMU Munich, Institute of Neuropathology, Munich, Germany; <sup>3</sup>University Hospital- LMU Munich, Institute of Neuroradiology, Munich, Germany; <sup>4</sup>University Hospital- LMU Munich, Department of Nuclear Medicine, Munich, Germany; <sup>5</sup>University Hospital- LMU Munich, Department of Neurosurgery, Munich, Germany

### Purpose or Objective

Reirradiation (reRT) was applied with concomitant bevacizumab (BEV) for glioma patients with tumour recurrence as in-house standard until 2016 in our department. After disapproval of BEV of the European Medical Agency for glioma treatment, BEV was no longer applied as concomitant therapy in the reRT setting. As treatment related side effects seemed to increase without concomitant BEV, we investigated the rate of radiation necrosis (RN) and RN related symptomatic edema in patients treated with reRT with and without concomitant BEV.

### Material and Methods

Glioma patients with tumour recurrence treated with reRT between April 2007 and December 2017 in our department were included into the cohort study. Study endpoints were the occurrence of RN and a compound endpoint of RN and/or symptomatic edema (RNSE). RN was diagnosed in contrast-enhanced MRI and verified in FET PET or histopathological examination after stereotactical biopsy, if available. Univariate and multivariate logistic regression analysis were performed to assess factors significantly related to the risk of RN and RNSE.

### Results

161 patients were included into the cohort study, of which 124 were treated with BEV and 37 without BEV concomitant to reRT. RN was detected in 6/124 patients treated with reRT with (4.8%) and in 5/37 patients treated with reRT without concomitant BEV (13.5%;  $p = 0.078$ ,  $p = 0.02$  on univariate and multivariate logistic regression analysis respectively). RN-free survival was significantly related to concomitant BEV treatment to reRT ( $p = 0.025$  on log-rank test;  $p = 0.036$ ,  $p = 0.013$  on univariate and multivariate cox-regression analysis respectively) and prescribed dose ( $p = 0.002$ ;  $p = 0.001$ ,  $p = 0.001$ ).

### Conclusion

reRT with concomitant BEV was significantly related to a lower rate of neurologic toxicity in our large monocentric cohort. Therefore, we strongly advise the use of concomitant BEV to reRT for glioma patients at tumour recurrence.

### OC-0281 Phase I/II trial of hafnium oxide nanoparticles activated by SBRT in the treatment of liver cancers

Croisé-Laurent<sup>4</sup>, E. Rio<sup>7</sup>, Y. Rolland<sup>1</sup>, S. Le Sourd<sup>1</sup>, P. Gustin<sup>3</sup>, C. Perret<sup>7</sup>, F. Mornex<sup>8</sup>, D. Peiffert<sup>9</sup>, P. Merle<sup>8</sup>, E. Deutsch<sup>3</sup>  
<sup>1</sup>Centre Eugène Marquis, Radiotherapy, Rennes CEDEX, France; <sup>2</sup>Centre Eugène Marquis, Medical oncology, Rennes CEDEX, France; <sup>3</sup>Gustave Roussy, General surgery, Villejuif, France; <sup>4</sup>Hôpital de Brabois Adultes, Hepato-gastro-enterology, Nancy, France; <sup>5</sup>Groupe Hospitalier Sud - Hôpital Haut-Lévêque, Radiotherapy, Bordeaux, France; <sup>6</sup>Hôpital de Brabois Adultes, Radiotherapy, Nancy, France; <sup>7</sup>ICO - Site René Gauducheau, Radiotherapy, Saint Herblain Cedex, France; <sup>8</sup>Centre Hospitalier de la Croix Rousse, Hepato-gastro-enterology, Lyon, France; <sup>9</sup>Institut de Cancérologie de Lorraine, Radiotherapy, Nancy, France

### Purpose or Objective

Patients with hepatocellular carcinoma (HCC) and liver metastasis (mets) present with a wide range of underlying liver dysfunctions and concomitant malignancies. Stereotactic body radiation therapy (SBRT) is well-tolerated and a valuable alternative for patients who are not eligible for invasive procedures. Yet, like all radiation therapy (RT) techniques, the energy dose deposit to tumor cells is limited by the surrounding healthy tissues. NBTXR3, composed of hafnium oxide nanoparticles, was designed to effectively absorb ionizing radiation and augment the dose deposit within the tumor cells only

when activated by RT, thereby increasing tumor-specific physical killing through DNA damage/cell destruction and enhancing the immunogenic tumor cell death.

### Material and Methods

Patients suffering from primary HCC (with/without portal vein tumor thrombosis) or liver mets were included and treated with a single intralesional injection (IL) of NBTXR3 followed by SBRT (45 Gy/3 fractions/5 to 7 days).

The phase I part of the study was designed as a 3 + 3 escalation dose with tested dose levels at 10%, 15%, 22% and 33% of baseline tumor volume. Primary endpoints include the determination of the recommended dose and incidence of early dose limiting toxicities (DLTs). Secondary endpoints include assessment of global safety profile, characterization of the body kinetic profile, liver function evaluated by Child-Pugh score (CPS), AST to Platelet Ratio Index (APRI), and response rate (mRECIST/RECIST v1.1).

### Results

The enrollment is complete in the first 3 dose levels: 10% (6 pts), 15% (4 pts) and 22% (4 pts) and is ongoing at the last IL dose level at 33% with no early DLTs, no AE related to NBTXR3, and no serious AE related to RT or the injection. So far, four AEs related to the IL were observed (Malaise, grade 2; two Abdominal pain, grade 3 and Bilateral pleural effusion, grade 1) at dose level 10%, 15% and 22% respectively. NBTXR3 remained localized within the tumor, validating the relevance of the single IL. No relevant change in CPS or APRI was observed over time which is consistent with the low toxicity observed.

In 7 HCC pts evaluable for response, the mRECIST assessment by MRI on target lesions resulted in the following best observed response: 3 complete responses, 3 partial responses and 1 stable disease. In 5 evaluable liver mets pts, the RECIST v1.1 assessment by MRI on target lesions resulted in the following best observed response: 1 partial response, 3 stable disease and 1 local progressive disease.

### Conclusion

NBTXR3 was well tolerated and showed a promising safety profile. Recruitment at the highest dose level of 33% is ongoing for the IL part and, once completed, will be followed by the expansion phase.

NBTXR3 is also being evaluated in 6 other clinical trials, including a phase II/III trial in soft tissue sarcoma [NCT02379845] and phase I/II trials in prostate [NCT02805894], head and neck [NCT01946867] and rectum cancers [NCT02465593].

### Proffered Papers: BT 3: Prostate HDR brachytherapy

---

### OC-0282 HDR brachytherapy Monotherapy for prostate cancer: a one-day schedule phase II trial acute toxicity

M. Jolicoeur<sup>1</sup>, T.V. Nguyen<sup>1</sup>, T. Derashodian<sup>1</sup>, E. Hill<sup>1</sup>, M. Mondat<sup>1</sup>, M. Nachabe<sup>1</sup>, E. Antebi<sup>1</sup>, G. Wakil<sup>1</sup>, R. Héliou<sup>1</sup>  
<sup>1</sup>CICM Hôpital Charles Le Moyne, Radiation Oncology, Greenfield Park, Canada

### Purpose or Objective

To determine the early acute toxicity of a randomized phase II clinical trial of one 19.5 Gy fraction or two 14.5 Gy fractions of high-dose-rate (HDR) brachytherapy monotherapy delivered on a one day schedule.

### Material and Methods

205 patients with low or intermediate-risk prostate cancer were randomized between one fraction of 19.5Gy (Arm 1) or two fractions of 14.5Gy (Arm 2) on an HDR brachytherapy as monotherapy protocol (BRP2, NCT03424694), this the report of acute toxicities for the first 170 patients.

Treatments were delivered with a single implant on a one-day schedule. All patients had a post implant MRI based dosimetry with dominant intra prostatic lesion (DIL) boost

allowed. Patients on the 2 fractions arm had 2 dosimetries and fractions were delivered 6 hours apart. Toxicity was evaluated at 1, 3, 6 weeks and 3 months after treatment using Common Terminology Criteria for Adverse Events (CTCAE) score, IPSS and International Index of Erectile Function (IIEF-5), and compared to baseline. Descriptive statistics, t test, paired t test, Pearson Chi-Square and Fisher Exact test were used to describe and compare the groups. Statistical significance was 0.05

#### Results

Median Follow-up is 16 (3- 33) months. Pre-treatment median prostate-specific antigen for arm1 and arm 2 were 6.6±3and 6.7±2.7 respectively. T stages for arm 1 and arm2 were T1c = 55% and 57%, T2a = 31% and 31%, T2b = 9% and 12%, T2c 5% and 2 % respectively. Gleason score were mostly 7(3+4) 52% and 57%, 7(4+3) 28% and 30% respectively.

Evaluation of sexual function showed the following values: with a mean base line of 13±6.8 and 15.2±6.5 compared to 12.9±6.8 and 12.2±6.4 at 12 weeks for arm1 and arm 2 respectively.

IPSS categories at baseline were mild 6.3±4.4 and 6.7±4.4 for arm 1 and arm 2, respectively. At 1 week there was a small increase of the IPSS score 11.5±7.9 for arm 1 and 12.6±8.1 for arm 2. Patients start to recuperate at 3 weeks with IPSS being 8.4±5.7 vs 10±6.4 and returned to baseline at 3 months with 6.5±5.5 and 7.6±5.4 respectively. The most frequently symptoms at 3 weeks were urinary frequency and burning sensation. Most patients had Grade 0-1 acute urinary toxicity: 89.7 % or arm 1 and 90.4 % for arm 2. Urinary retention occurred in 6.7% of patients in arm 1 and 2.1% arm 2.

There was a small increase in Grade 2 acute gastrointestinal toxicity 1% for arm 1 and 4.8% for arm 2. However, acute toxicity did not differ between arms (GU p=0.62, GI p= 0.47).

#### Conclusion

Both arms of the protocol either a single fraction of 19.5Gy or 2 fractions of 14.5Gy delivered in a one-day schedule are well tolerated. Acute GI and GU toxicities are the same in both arms during the first 12 weeks, erectile dysfunction seems to follow the same pattern. Further report with longer follow-up on toxicity will follow.

#### OC-0283 Pattern of relapse and dosimetric analysis of a single dose 19Gy HDR-brachytherapy phase II trial

A. Gomez-Iturriaga<sup>1</sup>, D. Buchser<sup>2</sup>, P. Minguez<sup>3</sup>, J.M. Espinosa<sup>3</sup>, F. Perez<sup>3</sup>, J. Cacicedo<sup>2</sup>, F. Suarez<sup>2</sup>, A. Gonzalez<sup>2</sup>, P. Bilbao<sup>2</sup>, F. Casquero<sup>2</sup>

<sup>1</sup>Hospital Universitario Cruces- Biocruces Health Research Institute, Radiation Oncology, Barakaldo, Spain ; <sup>2</sup>Hospital Universitario Cruces- Biocruces Health Research Institute, Radiation Oncology, Barakaldo-Bizkaia, Spain ; <sup>3</sup>Hospital Universitario Cruces- Biocruces Health Research Institute, Radiation Physics, Barakaldo-Bizkaia, Spain

#### Purpose or Objective

To report the pattern of relapse within the prostate with reference to the initial site of disease in patients treated with single fraction 19-Gy and to determine the dose delivered to these areas of recurrence to inform potential strategies of focused dose escalation.

#### Material and Methods

A total of 44 patients with low and intermediate-risk prostate cancer were treated according to an institutional review board-approved prospective study of single-fraction HDR brachytherapy. Treatment was delivered using <sup>192</sup>Ir to a dose of 19 Gy prescribed to the prostate, no margins were applied.

Patients who experienced a biochemical failure underwent a re-staging multiparametric MRI(mpMRI) and MRI-TRUS fusion biopsy to rule-out local recurrence.

Forty-two patients (95%) had a pre-treatment mpMRI. In patients with visible Dominant intraprostatic lesions (DIL)

on pre-treatment mpMRI, the DIL was contoured with the use of 2 sequences (T2W and DWI). Contours were generated by consensus of two physicians. The site of local relapse was compared with the initial site of disease. The dose received by the site of recurrence was investigated.

#### Results

Forty-four percent of patients were low-risk and 56% intermediate-risk. The median prostate volume was 34cc (17-60). Median CTV and OAR doses were: V100: 96.5% (95-99.4), V150 20.5% (13.7-35.1), V200 5.3% (3.1-10.1), Urethral Dmax 106% (103-111) and rectum 2cc 53 % (45-48).

The median follow-up period was 37 months (range 23-50). The PSA nadir was reached at 24 months follow-up, with a median value of 1.07 ng/mL. To date, 14 patients (32%) have experienced biochemical failure (4 patients low-risk and 10 intermediate-risk; p=0.013). Re-staging mpMRI showed local relapse in 12 patients (27.2%) and 11/12 patients underwent MRI-TRUS fusion biopsy confirming local relapse in 10 patients.

The analysis of DVH of all 44 patients revealed that patients with biochemical failure had received significantly lower doses in terms of V100, V125 and D90 (p=0.032, p=0.018 and p=0.018 respectively).

Of the 25 patients with DILs on diagnostic mpMRI, the mean D90 and D98 on DIL were lower for patients with biochemical failure (21.8 Gy and 20.1 Gy vs 22.2 Gy and 20.8 Gy, respectively; p=n.s). And in patients with confirmed local failure, the doses received by the index lesion were median D90=21.8 Gy (range 19.9 Gy-24.7 Gy) and median D98=20 Gy (19.9 Gy-22.5 Gy)

#### Conclusion

This dosimetric analysis demonstrates a dose-response relationship in patients treated with single fraction 19Gy. Patients with intermediate-risk disease, with visible DIL on mpMRI and patients treated with cooler implants have higher incidence of biochemical and local failure. The recurrence pattern is predominantly local in patients with initial gross disease on mpMRI. Patients in this study failed after receiving doses as high as D90=24.7Gy providing some rationale for further dose escalation to dominant intraprostatic nodules.

#### OC-0284 Radiomic and dosimetric analysis of urethral strictures following prostate HDR monotherapy

Y.M. Tsang<sup>1</sup>, D. Vignarajah<sup>2</sup>, A. Mcwilliam<sup>3</sup>, H. Tharmalingam<sup>4</sup>, A. Choudhury<sup>3</sup>, P. Hoskin<sup>4,3</sup>

<sup>1</sup>Mount Vernon Cancer Centre, Radiotherapy, Northwood Middlesex, United Kingdom ; <sup>2</sup>Sunshine Coast University Hospital, Clinical Oncology, Queensland, Australia ; <sup>3</sup>University of Manchester, Division of Cancer Sciences-School of Medical Sciences- Faculty of Biology Medicine and Health- Manchester Academic Health Sciences Centre, Manchester, United Kingdom ; <sup>4</sup>Mount Vernon Cancer Centre, Clinical Oncology, Northwood Middlesex, United Kingdom

#### Purpose or Objective

High dose-rate (HDR) brachytherapy as monotherapy is accepted as a safe and effective local treatment for organ-confined prostate cancer. However, urethral stricture has been reported as one specific late effect with HDR monotherapy with conflicting results in and rethral dose. Radiomics is an emerging field in the era of precision medicine and there is great potential with mining MRI radiomics to capture the intra-tumour heterogeneity of prostate cancer. Against this background, we have analysed a cohort of HDR monotherapy patients to establish the frequency of non-malignant urethral stricture and explore the relation between stricture formation and (i) dose distribution along the length of the urethra and (ii) MRI radiomic features of the prostate gland.

**Material and Methods**

From Nov 2010 to July 2017, there were 178 patients treated with HDR monotherapy of 19Gy in a single fraction using the urethra dose constraints of D10% <22Gy, D30% <20.8Gy and maximum dose <28.5Gy. There were a total of five ≥grade2 strictures as defined by CTCAE v4.0 as being symptomatic, requiring dilatation or catheterization strictures (confirmed on cystoscopy). A matched pair analysis used one control for each stricture case matched for pre-treatment IPSS score, number of needles used and clinical target volume (CTV) size

For all data sets, pre-treatment T2-weighted MRI images were used to define regions-of-interests as urethra and the whole prostate gland. The urethra was divided into membranous urethra and inferior, mid and superior thirds of the prostatic urethra for the dosimetric analysis. MRI textural radiomic features associated with prostate cancer response in the literature of energy, contrast and homogeneity were selected. Pyradiomics was used to extract textural features on the whole prostate gland volumes.

Wilcoxon signed-rank test was performed to investigate significant differences in dosimetric parameters and MRI radiomic feature values between cases and controls.

**Results**

There were no statistically differences in pre-treatment IPSS score, number of needles used CTV and urethra volume size between the two groups of patients with and without strictures. As suggested in table 1, the urethral dosimetric parameters investigated were not statistically different between cases and controls (p>0,05). With regards to MRI radiomics feature analysis, significant differences were found in contrast and homogeneity between cases and controls (p<0.05). However, this did not apply to the energy feature.

		Patients with	Patient without	p value
		≥grade 2 stricture	≥grade 2 stricture	
		Median Value	Median Value	
Baseline Demographics	Pre-treatment IPSS	8.00	8.00	0.94
	Number of needles used	21.00	20.00	0.37
	CTV volume (cc)	40.90	41.10	0.39
	Whole urethra volume (cc)	2.20	2.10	0.31
Urethra D10% (Gy)	Whole	20.50	21.10	0.22
	Membranous	18.50	18.30	0.25
	Prostatic	20.60	21.20	0.22
	Inferior third prostatic	20.30	20.80	0.58
	Mid third prostatic	20.30	20.80	0.32
	Superior third prostatic	20.80	21.00	0.26

	Contrast	30.10	50.30	0.04
	Homogeneity	13.70	22.10	0.04

**Conclusion**

In this matched pair analysis, no association between post-treatment stricture and urethral dosimetry was identified. The MRI radiomic features of homogeneity and contrast of the prostate gland identified patients who develop strictures after HDR monotherapy. Although sample size is small, this warrants further investigation.

**OC-0285 Clinical outcomes of focal salvage high-dose-rate brachytherapy for radiorecurrent prostate cancer.**

M. Peters<sup>1</sup>, M.J. Van Son<sup>1</sup>, M.A. Moerland<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, J.R.N. Van der Voort van Zyp<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiation Oncology Department, Utrecht, The Netherlands

**Purpose or Objective**

Radiorecurrent prostate cancer is conventionally treated with palliative androgen deprivation therapy (ADT) or curative whole-gland salvage, both with a high risk of significant side-effects and a detrimental impact on quality of life (QoL). MRI-guidance has made focal salvage high-dose-rate (HDR) brachytherapy (BT) possible. Focal treatment could postpone or prevent ADT and substantially reduce side effects. Tumor control, toxicity and QoL of MRI-guided focal salvage HDR-BT are described here.

**Material and Methods**

From July 2013 to July 2018, 96 patients with locally recurrent, non-metastatic prostate cancer after primary radiotherapy were treated with MRI-guided focal salvage HDR-BT. Multiparametric-MRI and PSMA or Choline-PET/CT were used for intraprostatic disease assessment and exclusion of metastases. A single dose of 19Gy was prescribed. MRI compatible catheters allowed MRI-guided treatment planning after insertion. Biochemical failure was defined by the Phoenix-definition (nadir+2ng/ml). Prospective data collection included genitourinary (GU) toxicity, gastro-intestinal (GI) toxicity and erectile dysfunction (ED) with the Common Terminology Criteria for Adverse Events (CTCAE) 4.0. Urinary symptoms and erectile function were further assessed with IPSS and IIEF questionnaires. RAND-36, EORTC QLQ-C30 and EORTC QLQ-PR25 were used for QoL assessment.

**Results**

Median age pre-focal salvage was 72 years (interquartile range [IQR] 67-74). Median PSA was 5 (3-7), median PSADT 17 months (12-25). Tumor (rT)-stages were T2 (64%), T3 (34%), T4 (2%). Primary treatment was mostly EBRT (55%) and I-125 BT (42%). D95 was median 19Gy (18-20), urethral D10 16Gy (11-18), D1cc bladder 8Gy (5-11) and D1cc rectum 10Gy (8-12). Median follow-up was 11 months (5-23). Two patients had grade 3 urethral stricture, at 6 and 24 months (Figure 1). There was no grade 3 GI toxicity. IPSS scores increased until 12 months (8.3 to 11.1, p=0.001), after which they normalized (10.6 and 9.2 at 24 and 36 months [p=0.07, and p=0.26], respectively). IIEF decreased from 10.9 at baseline to 8.1 at 12 months (p<0.001) and 7.6 at 24 months (p=0.004). Corrected for multiple testing, QoL only deteriorated in the first month due to urinary complaints. At 2 years, biochemical disease-free survival was 77% (95% CI 65-91%), metastases-free survival 84% (95% CI 73-92%) (Figure 2) and overall survival 98% (95% CI 93-100%).

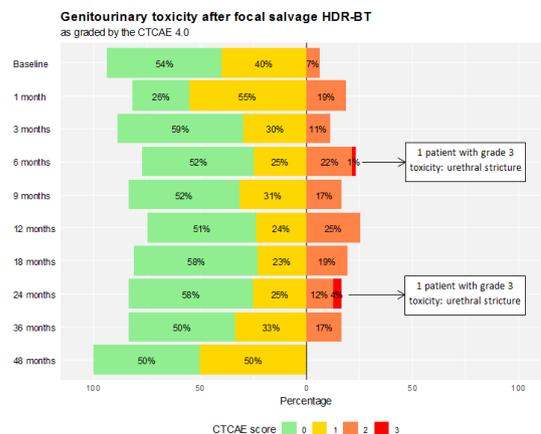

Figure 1: genitourinary toxicity as graded by the CTCAE 4.0.

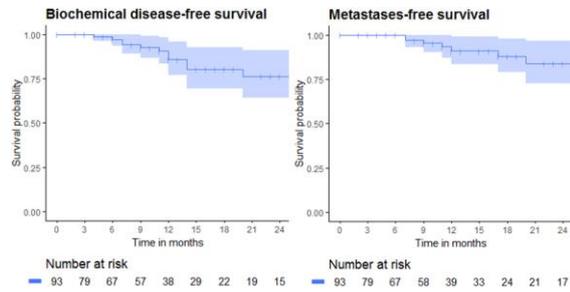

Figure 2: biochemical disease-free survival and metastases-free survival in the cohort with  $\geq 1$  month follow-up. 3/96 patients had not reached 1 month follow-up as of yet and are excluded from the calculations. 95% confidence intervals are presented here in blue.

## Conclusion

Focal salvage MRI-guided HDR-BT leads to high tumor control with low severe toxicity rates and short, self-limiting increases in urinary complaints.

**OC-0286 Focal high-dose-rate brachytherapy for localized prostate cancer: long-term clinical follow-up.**  
 M. Van Son<sup>1</sup>, M. Peters<sup>1</sup>, M.A. Moerland<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, J.R.N. Van der Voort van Zyp<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

## Purpose or Objective

Focal treatment of localized prostate cancer is an emerging paradigm in the search of optimal patient-tailored therapies with minimal toxicity. Though whole-gland treatments such as radiotherapy or prostatectomy reach excellent tumor control rates, they are associated with toxicity and quality of life (QoL) deterioration. Focal high-dose-rate brachytherapy (HDR-BT) may reduce toxicity and thereby preserve QoL in a selected patient group. Here we present long-term follow-up data.

## Material and Methods

Thirty patients with localized prostate cancer were treated with focal HDR-BT between May 2013-April 2016. Local disease status was evaluated by systematic biopsies and 3T MRI, using multiparametric MRI for the last 5 patients. After the brachytherapy implant procedure, 1.5T MRI's were made for organ contour adjustments and a final check of catheter positions. In a single dose, 19 Gy was delivered to the tumor area with a margin of 5 mm. Before treatment and during follow-up, genitourinary (GU) toxicity, gastro-intestinal (GI) toxicity and erectile dysfunction (ED) were graded according to the Common Toxicity Criteria for Adverse Events (CTCAE) 4.0. In addition, International Prostate Symptoms Score (IPSS) and International Index of Erectile Function score (IIEF-5) were obtained. QoL was measured with validated questionnaires (RAND-36, EORTC QLQ-C30 and EORTC QLQ-PR25). PSA was monitored, with biochemical recurrence defined as nadir+2 (Phoenix definition).

## Results

At baseline, median PSA was 7 ng/ml (range 1-10), median PSA doubling time was 4.5 years (range 0.5-38) and highest Gleason grade was 4+3=7 (2 patients). All tumors were stage T2. One patient received 1x45 mg Eligard 3 months before treatment. Median follow-up was 48 months (range 19-60). Improper removal of a brachytherapy catheter caused acute hemorrhage of the prostate in one patient. No grade >2 GU (Figure 1) or GI toxicity occurred and ED was relatively stable throughout follow-up. Mean IIEF-5 score decreased from 14 at baseline to 9.5 after 6 months, remaining stable around 10 afterwards (moderate ED,  $p < 0.01$ ). Mean IPSS increased in the first month from 6 to 9 (moderate symptoms,  $p = 0.02$ ), returning to baseline-level afterwards. There were no significant differences in QoL. Biochemical recurrence occurred in 10 patients, of which 9 had local recurrence on imaging (two in-field recurrences). Five patients were re-treated with curative salvage treatments. Two patients started ADT. After 4

years, biochemical disease-free survival was 70% (95% CI 52-93%) and metastases-free survival was 93% (95% CI 85-100%) (Figure 2).

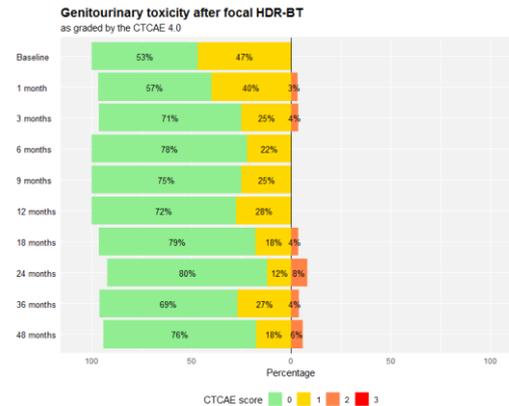

Figure 1: genitourinary toxicity as graded by the CTCAE 4.0.

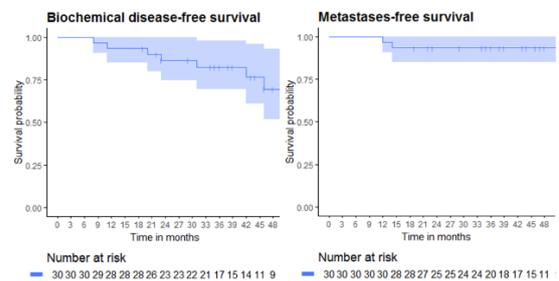

Figure 2: biochemical disease-free survival and metastases-free survival. 95% confidence intervals are presented here in blue.

## Conclusion

In terms of toxicity, focal HDR-BT is a safe treatment. Apart from one perioperative complication (3%), no grade >2 GU or GI toxicity occurred. Patient-reported QoL did not decrease over time. However, long-term biochemical control is inferior to whole-gland treatments. This might in part be attributed to inadequate patient selection.

## OC-0287 Dose to the dominant intraprostatic lesion using HDR vs. LDR monotherapy: Phase II Randomized trial

J. Crook<sup>1</sup>, D. Batchelar<sup>2</sup>, M. Hilts<sup>2</sup>, D. Anderson<sup>2</sup>, F. Bachand<sup>1</sup>, S. Tissaverasinghe<sup>1</sup>, B. Farnquist<sup>3</sup>, T. Bainbridge<sup>4</sup>, C. Araujo<sup>2</sup>  
<sup>1</sup>BC Cancer Agency - Southern Interior, Radiation Oncology, Kelowna, Canada; <sup>2</sup>BC Cancer Agency - Southern Interior, Radiation Physics, Kelowna, Canada; <sup>3</sup>Kelowna General Hospital, Radiology, Kelowna, Canada; <sup>4</sup>Kelowna General Hospital, Pathology, Kelowna, Canada

## Purpose or Objective

To present the dosimetric results of a Phase II randomized trial comparing dose escalation to the magnetic resonance imaging (MRI)-defined dominant intraprostatic lesion (DIL) using either low dose rate (LDR) or high dose rate (HDR) prostate brachytherapy.

## Material and Methods

Patients receiving prostate brachytherapy as monotherapy were randomized to LDR or HDR brachytherapy. Prostate and DILs were contoured on pre-operative multiparametric MRI. These images were registered with transrectal ultrasound (TRUS) for treatment planning. LDR brachytherapy was preplanned using I-125 seeds. Postplan dosimetry was performed at day 30 using MR-CT (computed tomography) fusion. HDR brachytherapy used intra-operative TRUS-based planning to deliver 27 Gy/2

fractions in separate implants. DIL location was classified as peripheral, central or anterior. Directed biopsies of DILs were performed at the time of brachytherapy for pathologic confirmation of mpMRI results. A student t-test compared DIL D90 between modalities and DIL locations.

#### Results

Of 60 patients, 31 underwent LDR and 29 HDR brachytherapy. Up to 3 DILs were identified per patient (100 total) with 74 peripheral, 6 central, and 20 anterior DILs. Mean DIL volume was 1.9cc (SD: 1.7cc) for LDR and 1.6 cc (SD 1.3cc) for HDR ( $p=0.279$ ). Mean DIL D90 was 151% (SD 30%) for LDR (217 Gy) and 132% (SD 13%) for HDR (17.8 Gy/fraction  $\times$  2). 88% of patients had biopsy confirmation of at least one DIL.

DIL D90 for peripheral lesions was higher than anterior and central ( $p<0.001$ ). The mean DIL D90 per location for LDR was 159% for peripheral lesions, but only 122% and 124% for central and anterior lesions, reflecting the planning algorithm which delivers 150% to the peripheral zone but limits the urethra to  $< 130\%$ . The mean D90 per location for HDR was 137% for peripheral lesions, and 123% and 118% for central and anterior DILs. DIL D90 coverage was further evaluated as a percentage of the desired peripheral zone dose coverage, which was 150% for LDR and 125% for HDR. For both central and anterior lesions, HDR DIL D90 values were significantly closer to the peripheral zone benchmark dose than for LDR ( $p=0.007$  and  $0.002$  respectively).

#### Conclusion

DIL location affects dose escalation, particularly because of urethral proximity, such as for anterior and central DILs. HDR brachytherapy may dose escalate better when target DIL is close to critical organs.

#### OC-0288 Long-term results of 15Gy HDRBT boost in intermediate risk-prostate cancer: Analysis of 500+ patients

L. Mendez<sup>1</sup>, K. Martell<sup>1</sup>, H. Chung<sup>1</sup>, C. Tseng<sup>1</sup>, Y. Alayed<sup>1</sup>, P. Cheung<sup>1</sup>, S. Liu<sup>1</sup>, D. Vesprini<sup>1</sup>, W. Chu<sup>1</sup>, E. Szumacher<sup>1</sup>, A. Ravi<sup>2</sup>, A. Loblaw<sup>1</sup>, G. Morton<sup>1</sup>

<sup>1</sup>Sunnybrook Odette Cancer Centre, Radiation oncology, Toronto, Canada; <sup>2</sup>Sunnybrook Odette Cancer Centre, Medical Physics, Toronto, Canada

#### Purpose or Objective

To report long-term biochemical control associated with single-fraction 15Gy high-dose-rate (HDR) brachytherapy boost followed by external beam radiation (EBRT) in intermediate-risk prostate cancer patients.

#### Material and Methods

All patients with intermediate-risk prostate adenocarcinoma that received treatment with 15Gy HDR brachytherapy (BT) boost followed by EBRT between 2009 and 2016 were retrospectively reviewed. Descriptive statistics were used to characterize the cohort. Biochemical failure was defined based on the Phoenix criteria. Kaplan-Meier method estimated biochemical relapse free survival (bRFS) at 5 and 7 years. Cumulative incidence of ADT use at 7 years was also calculated. R statistical software package v3.2.2 (www.r-project.org) was used for this analysis.

#### Results

545 patients met the inclusion criteria for this study. Median age at HDR BT was 67 years (IQR 61-72). Median baseline PSA was 7.4 ng/mL (IQR 5.4-9.9). 302 (55%) and 243 (45%) patients had cT1 and cT2 stage disease. 9 (2%), 346 (67%) and 164 (32%) had ISUP Gleason Grade Group 1, 2 and 3, respectively. A median of 5 (IQR 3-7) out of 12 (IQR 10-12) biopsied cores were positive. A total of 90 (18%) patients received neoadjuvant ADT for a median time of 6 months (IQR 3-6). The most frequent EBRT regimen was 37.5Gy in 15 fractions with 508 patients (93%) receiving this fractionation. All patients received 15Gy in a single HDR brachytherapy fraction. Median HDR prostate

V100, V150 and V200 were 97% (IQR 96-97), 36% (IQR 33-39) and 12% (IQR 10-14), respectively. After a median PSA follow-up time of 4.3 years (IQR 2.4-6.0), 44 (8%) patients experienced biochemical failure. After a median overall follow-up time of 4.9 years (IQR 2.6-6.4), 20 patients (4%) went on to receive ADT. Kaplan-Meier estimated bRFS rates were 91% (CI 88-94) and 82% (CI 77-87) at 5 and 7 years, respectively (Figure 1). The cumulative incidence of ADT use was 7% (CI 3-10) at 7 years (Figure 2). Figure 1- Kaplan-Meier estimate of biochemical relapse-free survival post 15Gy HDR-BT and EBRT

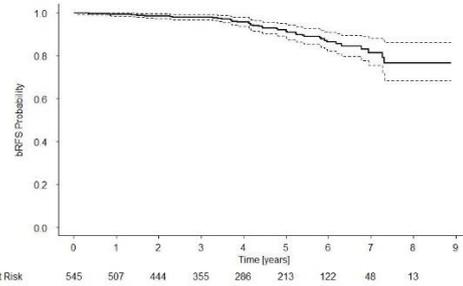

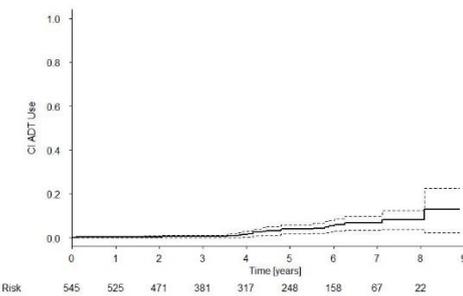

Figure 2- Cumulative incidence of ADT use post 15Gy HDR-BT and EBRT

#### Conclusion

In this large cohort of intermediate-risk prostate cancer patients, 15 Gy HDR BT boost plus EBRT results in durable long-term biochemical control and low rates of ADT salvage.

#### OC-0289 A water calorimeter as a primary standard for absorbed dose in magnetic fields

L. De Prez<sup>1</sup>, J. De Pooter<sup>1</sup>, B. Jansen<sup>1</sup>, S. Woodings<sup>2</sup>, J. Wolthaus<sup>2</sup>, B. Van Asselen<sup>2</sup>, T. Van Soest<sup>2</sup>, J. Kok<sup>2</sup>, B. Raaymakers<sup>2</sup>

<sup>1</sup>VSL, Ionizing Radiation Standards, Delft, The Netherlands; <sup>2</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands

#### Purpose or Objective

MRI guided radiotherapy devices are currently in clinical use. Detector responses can be significantly affected by the magnetic field. Therefore, there is a need to characterize detectors in terms of absorbed dose to water,  $D_w$ , against primary standards that are operated under the magnetic field condition. The aim of this study was to commission a water calorimeter, accepted as the Dutch national standard for  $D_w$  and validate its claimed

standard uncertainty of 0.37 % in the 7 MV photon beam of an MRI linac in a 1.5 T magnetic field.

#### Material and Methods

Measurements were done with a magnetic field of 1.5 T and, after ramp-down, without magnetic field. Methods were developed for measurement of detector depth, distance and beam output. A thermodynamic description was used to demonstrate potential temperature effects due to the magneto-caloric effect (MCE). To evaluate the primary standard on a fundamental basis, realisation of  $D_w$  at 1.5 T was evaluated parameter by parameter.

#### Results

It was shown that the measurement of  $DT_w$ , are either independent of, or can be determined in, a magnetic field. The chemical heat defect,  $h$ , was considered zero within its stated uncertainty, as for 0 T. Evaluation of the MCE and measurements done during magnet ramp-down, indicated no changes in the specific heat capacity of water. However, variation of the applied transmission monitor in the bore was the limiting factor for output normalization.

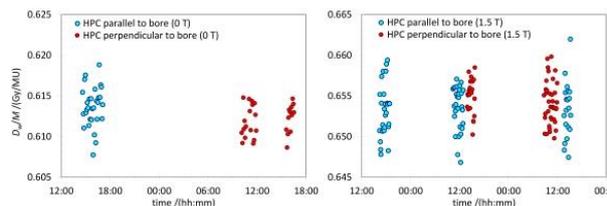

The table shows the calculated correction factors for heat conduction,  $k_c$  measured correction factors for perturbation of the calorimeter HPC both with and without magnetic field,  $k_{HPC}$  and the correction for beam non-uniformity  $k_{nu}$ . Hardly any significant effect of the magnetic field on the correction factors is observed.

The figure shows the corrected calorimetric  $D_w$  measurements in a 0 T magnetic field of an Elekta MRI-linac (left) and in the same machine with 1.5 T magnetic field (right). Both graphs show  $D_w$  measurements normalized to the monitor in the bore with the HPC perpendicular and in parallel direction to the bore. Note that values on the vertical axes cannot be compared due to the magnetic field dependence of the applied monitor.

#### Conclusion

This study confirmed that the uncertainty for measurement of  $D_w$  with a water calorimeter in a 1.5 T magnetic field is estimated to be the same as under conventional reference conditions at 0 T. The VSL water calorimeter can therefore be applied as a primary standard for  $D_w$  in magnetic fields and is currently the only primary standard operable in a magnetic field that provides direct access to the international traceability framework.

correction	$B = 0$ T	$B = 1.5$ T
$k_{c,\perp}$	0.9976 (18)	0.9979 (18)
$k_{c,\parallel}$	0.9970 (18)	0.9969 (18)
$k_{nu,\perp}$	1.0013 (5)	1.0015 (5)
$k_{nu,\parallel}$	1.0014 (5)	1.0016 (5)
$k_{HPC}$ (#06)	1.0033 (5)	1.0025 (5)
$k_{HPC}$ (#07)	1.0031 (5)	1.0028 (5)

#### OC-0290 Consistency of PTW30013 and FC65-G ion chamber magnetic field correction factors

S. Woodings<sup>1</sup>, B. Van Asselen<sup>1</sup>, T. Van Soest<sup>1</sup>, L. De Prez<sup>2</sup>, J. Lagendijk<sup>1</sup>, B. Raaymakers<sup>1</sup>, J. Wolthaus<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands ;

<sup>2</sup>VSL, Dutch Metrology Institute, Delft, The Netherlands

#### Purpose or Objective

Reference dosimetry in a strong magnetic field is made more complex due to (i) the change in dose deposition and (ii) the change in sensitivity of the detector. Potentially it is also influenced by thin air layers, interfaces between media, orientations of field, chamber and radiation, and minor variations in ion chamber stem or electrode construction.

The PTW30013 and IBA FC65-G detectors are waterproof Farmer-type ion chambers that are suitable for reference dosimetry. The magnetic field correction factors have previously been determined for these chamber types.

The aim of this study was to assess the chamber-to-chamber variation and determine whether generic chamber type-specific magnetic field correction factors ( $k_{B,M,Q}$ ) can be applied for each of the PTW30013 and FC65-G -type ion chambers when they are oriented parallel (//) to, and perpendicular (|-) to, the magnetic field.

#### Material and Methods

The experiment was conducted with 12 PTW30013 and 13 FC65-G chambers. The  $k_{B,M,Q}$  were measured using the practical method of van Asselen et al. (2018, PMB, 63 p125008) that can be performed in the clinic. In this study each chamber was cross-calibrated against the local standard chamber twice; with and without magnetic field. Measurements with 1.5 T magnetic field were performed with the 7 MV FFF beam of the MRI-linac. Measurements without magnetic field (0 T) were performed with the 6 MV conventional beam of an Elekta Agility linac.

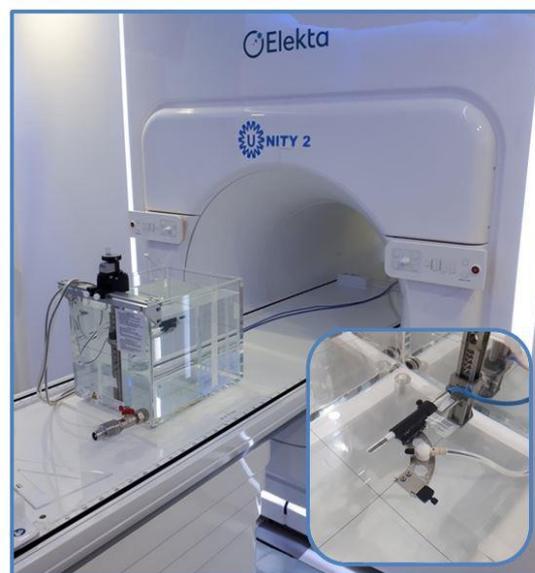

Figure 1: PTW prototype MR-compatible MP1 waterphantom at the MRI-linac with (picture insert) PTW prototype holder, with PTW30013 chamber and CC13 monitor chamber.

A prototype MR-compatible PTW MP1 phantom was used along with a prototype holder that facilitated measurements with the chamber aligned 90 degrees counter-clockwise (|-) and 180 degrees (//) to the direction of the magnetic field. A monitor chamber was also mounted on the holder and all measurements were normalized so that variations in the output of each linac were removed.

Measurements with the local standard chamber were repeated during the experiment to quantify the experimental uncertainty.

Recombination was measured in the 6 MV beam. Generic beam quality correction factors were applied. The differences in these factors between beams is constant within each chamber type (dependent on beam quality and dose-per-pulse).

By comparing the results for the two cross calibrations the  $k_{B,M,Q}$  can be determined for each chamber, and the variation within the chamber-type determined.

### Results

Table 1: Average results for each chamber type. The standard deviations of the results are shown in brackets.

Chamber-type	$N_{D,w,00}$ (cGy/nC)	$k_{B,M,Q}$ (parallel)	$k_{B,M,Q}$ (perpendicular)
PTW30013	5.384 (0.017)	0.995 (0.002)	0.966 (0.001)
FC65-G	4.817 (0.015)	1.005 (0.002)	0.961 (0.002)

The factors within both PTW30013 and FC65-G chamber-types were found to be very consistent, with observed standard deviations of  $k_{B,M,Q}$  for the PTW30013 of 0.19% (|-) and 0.13% (//), and for the FC65-G of 0.15% (|-) and 0.17% (//). These variations are comparable with the observed measurement uncertainties ( $1\sigma$ ) of 0.14% - 0.20%.

### Conclusion

The consistency of the results for the PTW30013 and FC65-G chambers implies that for these two chamber types it is not essential to measure the  $k_{B,M,Q}$  specifically for each individual chamber. Values for each chamber-type, magnetic field strength and relative chamber orientation can therefore be applied from the literature.

### OC-0291 Development of a deformable phantom for validation of adaptive irradiation methods in MRgRT

A. Elter<sup>1,2,3</sup>, S. Dorsch<sup>1,2,3</sup>, P. Mann<sup>1,2</sup>, A. Runz<sup>1,2</sup>, W.

Johnen<sup>1,2</sup>, S. Klüter<sup>2,4</sup>, C.P. Karger<sup>1,2</sup>

<sup>1</sup>German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany ;

<sup>2</sup>Heidelberg Institute for Radiation Oncology HIRO, National Center for Radiation Research in Oncology NCRO, Heidelberg, Germany; <sup>3</sup>University of Heidelberg, Faculty of Physics and Astronomy, Heidelberg, Germany;

<sup>4</sup>University Hospital Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

One of the key features of MRgRT is the online adaption of treatment plans to account for daily anatomy changes. Due to the complex adaption process, specific end-to-end tests need to be performed that require the development of new phantoms. Such phantoms should include:

- flexible and reproducible geometric insert positioning
- various anthropomorphic MR and CT image contrasts
- dose measurement methods (1D-3D)

While (i) and (ii) are necessary to test the performance of the deformable imaging registration (DIR) method, (iii) allows verification of beam delivery. For this, a promising method is the use of 3D polymer gels (PG). However, due to the high reactivity with oxygen, its application is yet limited to few container materials and shapes.

The aim of this work was to evaluate different 3D printing materials for the use with PG and to develop a phantom that meets (i)-(iii), using arbitrarily-shaped structures filled with PG.

### Material and Methods

Using various 3D printing materials and techniques, PG containers were produced and filled with PAGAT [1] dosimetry gel. The containers were irradiated at a linear accelerator (Linac, Artiste, Siemens) with photons using either a homogenous large field or a small field (1x1cm<sup>2</sup>) to test the compatibility with the PG. The PG was evaluated by MRI and the results were compared with those obtained in already established BAREX<sup>TM</sup> containers [2]. Having found that the VeroClear printing material was compatible with the PG, the phantom was designed with variable components meeting requirements (i)-(iii). The phantom was used in a first experiment at a clinical MR-linac (MRidian, ViewRay) to test parts of the adaptive

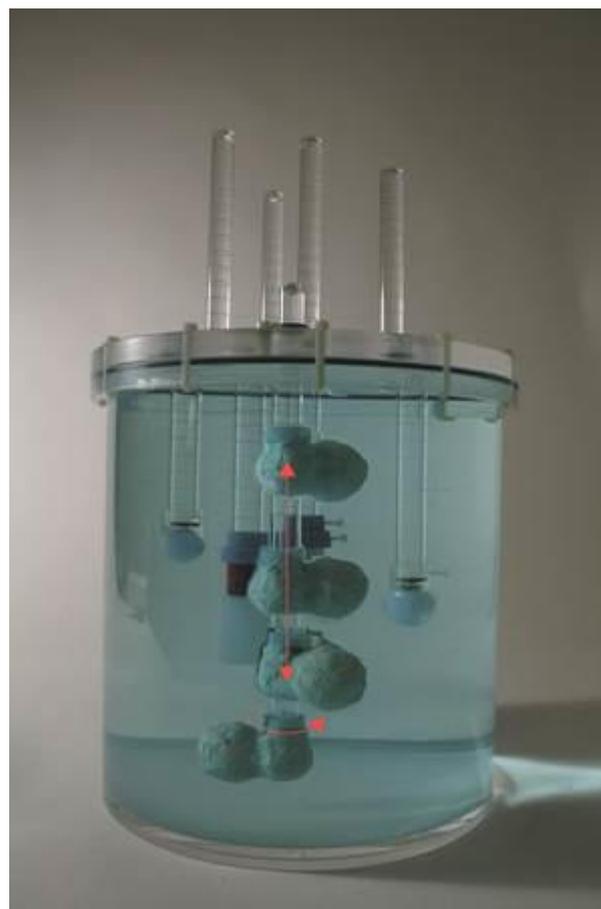

planning procedure in the presence of a target deformation.

[1]Baldock et al., doi:10.1088/0031-9155/55/5/R01

[2]Mann et al., doi:10.1088/1361-6560/aa51b1

### Results

The VeroClear material used in the Objet30 Pro printer (Stratasys) showed no significant interaction with the gel and provided a homogeneous dose response with differences of <3 % in the homogeneous irradiation. In addition, a high geometric accuracy when measuring the small field size was found (FWHM: 8.82 mm in VeroClear vs 8.96 mm in BAREX<sup>TM</sup>). Varying MR and CT imaging contrast can be realized by combining Agarose, Ni-DTPA and potassium chloride in various concentrations. First measurements showed a good performance of the DIR algorithms in case of linear component shifting but were not fully capable to detect rotations or changes in electron density like bone and air.

### Conclusion

We found a 3D printing material compatible with PG allowing to create arbitrary shaped and PG-filled inserts that can be used for 3D dose measurements. In a first experiment, the developed phantom could be used to test the performance of a DIR algorithm and to trigger a re-optimization process. Future experiments will focus on 3D-dosimetric validation of the adapted treatment plans and the development of a suitable end-to-end test for the validation of complete adaptive irradiation procedures in MRgRT.

### OC-0292 When we have to apply volume corrections in dosimetry?

K. Zink<sup>1</sup>, C. Andersen<sup>2</sup>, L. De Prez<sup>3</sup>, F. Delaunay<sup>4</sup>, S. Duane<sup>5</sup>, C. Gomà<sup>6</sup>, M. Pimpinella<sup>7</sup>, P. Teles<sup>8</sup>, J. Tikkanen<sup>9</sup>, M. Pinto<sup>7</sup>

<sup>1</sup>Universitätsklinikum Marburg- Klinik für

Strahlentherapie Partikeltherapie, Clinic for Radiotherapy and Radiation Oncology, Marburg, Germany; <sup>2</sup>DTU, Center for Nuclear Technologies, Kongens- Lyngby, Denmark; <sup>3</sup>VSL, Dutch Metrology Institute, Delft, The Netherlands; <sup>4</sup>CEA-Saclay, Laboratoire National Henry Bequerel- PtC 104, Gif-sur-Yvette-Cedex, France; <sup>5</sup>National Physical Laboratory, Chemical- Medical & Environmental Science Department, Teddington, United Kingdom; <sup>6</sup>KU Leuven, Department of Oncology, Leuven, Belgium; <sup>7</sup>ENEA, National Institute of Ionizing Radiation Metrology INMRI, Rome, Italy; <sup>8</sup>IST University of Lisbon, Centre of Nuclear Sciences and Technology, Lisbon, Portugal; <sup>9</sup>STUK, Stuk, Helsinki, Finland

### Purpose or Objective

In reference dosimetry we are interested in the absorbed dose,  $D_w$ , at a reference point in water. In small or non-reference fields it is common to apply a volume averaging correction,  $k_{vol}$ . The IAEA-AAPM report TRS-483 introduces  $k_{vol}$  for the non-uniformity of the lateral dose profiles in flattening-filter free beams (FFF). This approach is new compared to the treatment of conventional flattening-filter beams (cFF). In current codes of practice (e.g. IAEA TRS-398) volume averaging was not corrected for. In TRS-483, however,  $k_{vol}$  is applied as a contribution to the beam quality correction factor  $k_Q$ . Accordingly, TRS-483 gives independent tables of  $k_Q$  for cFF and FFF beams. When to apply or when not to apply  $k_{vol}$  might lead to confusion. Currently, the IAEA TRS-398 CoP is revised and new experimental and Monte Carlo based  $k_Q$  data are becoming available. Within the EMPIR 16NRM03 RTNORM project  $k_Q$  data were measured and calculated. As there are no clear recommendations on how to report or include the volume averaging, its impact for different ion chambers in cFF and FFF beams was determined.

### Material and Methods

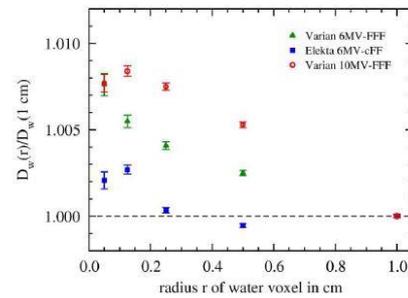

$k_Q$  for beam quality  $Q$  is defined as a ratio of calibration coefficients  $N_{D,w,Q}/N_{D,w,Q_0}$  with  $N_{D,w,Q} = (D_w/M)_Q$  and reference beam quality  $Q_0$  (<sup>60</sup>Co).  $M$  is the corrected ion chamber reading. With Monte Carlo  $k_Q$  is calculated as  $(D_w/D_{det})_{Q,Q_0}$  with  $D_{det}$  the scored dose to the detector volume. However due to volume averaging, depending on the beam profile, measured and calculated  $k_Q$  values may differ:  $k_{vol}$  would be applied to the ion chamber corrections applied to  $M$  or removed in the MC calculated dose.

Calorimetric measurements were performed with a selection of ion chambers by different national standard labs in cFF and FFF beams. For all beams the dose profiles at the reference depth were measured with a small volume detector and the volume correction factor  $k_{vol}$  was determined. The  $k_Q$  factor for the different chambers was also calculated applying the Monte Carlo code EGSnrc. As in the experiments the dose profiles were determined for different source types (point source, phase space files, linac head) and  $k_{vol}$  was determined for the ion chambers and also for the water voxel used to determine  $D_w$ .

### Results

Table 1 shows measured  $k_{vol}$  data for three ion chambers in cFF and FFF beams of different accelerators. As can be seen, also in cFF beams  $k_{vol}$  may be in the range of several parts per mille. Similar results were obtained in the Monte Carlo simulations. Regarding the calculated dose to water  $D_w$  in Monte Carlo simulations, Fig. 1 shows, that the voxel size used to calculate  $D_w$  also has an impact of several parts per mille on the resulting  $k_Q$ .

**Figure 1:** Impact of the voxel radius  $r$  to determine the dose to water  $D_w$  in Monte Carlo simulations in beams of different accelerators. The voxel height is always 0.1 cm.

**Table 1:** Experimentally determined volume averaging corrections  $k_{vol}$  for three different ion chambers in cFF and FFF beams of a GE Saturne 43, an Elekta Versa HD, a Varian Truebeam accelerator and a cobalt-60 unit.

	<sup>60</sup> Co	GE Saturne 43			
		6 MV cFF	6 MV FFF	12 MV cFF	20 MV cFF
PTW 30013	1.0009	1.0009	0.9986	1.0039

PTW 30013	0.9999	1.0033	0.9998	1.0054	
NE2571	0.9999	1.0036	0.9998	1.0059	
Varian TrueBeam					
	6 MV cFF	10 MV cFF	15 MV cFF	20 MV cFF	
PTW 30013	0.9991	0.9997	1.0004	1.0002	
NE 2571	0.9991	0.9997	1.0004	1.0003	
Exradin A1SL	0.9996	0.9999	0.9999	0.9996	

### Conclusion

The results show, that  $k_{vol}$  even for cFF beams may be not negligible and its contribution to  $k_Q$  should be indicated. Regarding Monte Carlo simulations especially the dose value  $D_w$  to calculate  $k_Q$  should be corrected for volume averaging to achieve a coherent  $k_Q$  data set in the revised TRS-398 protocol.

### OC-0293 Cerenkov emission-based dosimetry is a promising perturbation-free technique

Y. Zlateva<sup>1</sup>, B. Muir<sup>2</sup>, I. El Naqa<sup>3</sup>, J. Seuntjens<sup>1</sup>  
<sup>1</sup>McGill University, Medical Physics Unit, Montreal, Canada; <sup>2</sup>National Research Council of Canada, Measurement Science and Standards, Ottawa, Canada; <sup>3</sup>University of Michigan, Department of Radiation Oncology, Ann Arbor, USA

### Purpose or Objective

Cherenkov emission (CE)-based dosimetry is promising as a micrometer-resolution 3D perturbation-free in-water technique. Considering a potential formalism for broad-beam on-axis CE-based external radiotherapy dosimetry, we experimentally validate Monte Carlo (MC) calculation of the CE-to-dose conversion in a relative sense with a simple detector. We optimize detection configurations for electron beams and estimate achievable dosimetric uncertainties.

### Material and Methods

The EGSnrc code SPRRZnrc is modified to calculate the CE-to-dose conversion, kC, on beam axis in water. The code is validated through a relative experimental study with 6-20 MeV electron beams using a plano-convex lens pair/apertures and long optical fiber leading to a spectrometer outside (Fig. 1). The circular field-of-view is aligned at the water surface. Motivated by the experimental validation, kC is then calculated for 20 electron beam qualities (4 BEAMnrc models, 4-22 MeV). Detection geometry is considered, beam quality specification is addressed, and a preliminary dosimetric uncertainty is estimated.

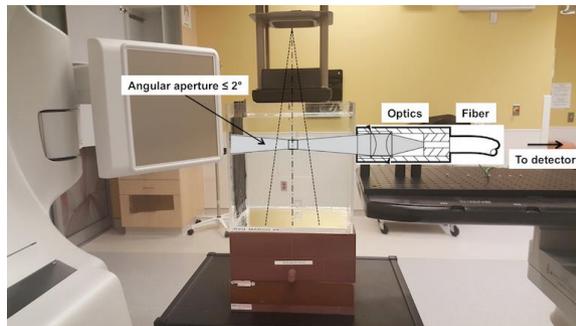

Fig. 1: Cherenkov detection setup. Not to scale.

## Results

MC and measured relative  $k_C$  factors agree to within 1% for percent-depth CE (PDC) > 50% (Fig. 2). At other depths, deviations are in accordance with approximations. Simulated electron beam quality specifier R50 is estimated from the depth of 50% CE C50 to within 0.1 mm and 0.4 mm (maximum) with large and small apertures respectively. The fit performance on measured R50 supports this finding. The  $k_C$  value is uniquely specified by R50 at a given depth with preliminary dosimetric uncertainty estimate of the order of 1% (Table 1). A PDC downstream shift by the R50-C50 difference is derived from theory and found to reduce the  $k_C$  depth dependence tenfold to 2.5%.

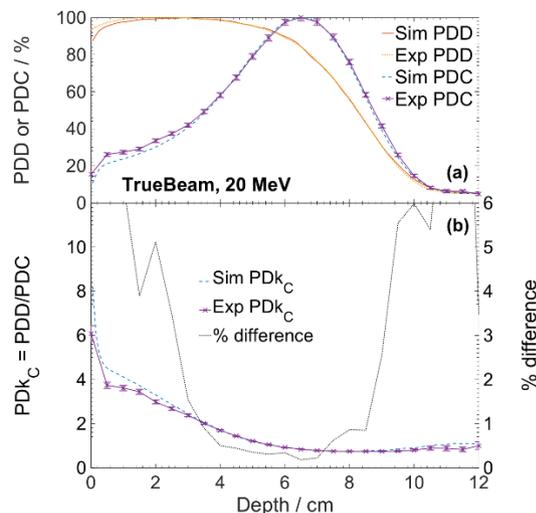

Fig. 2: (a) Simulated (Sim) and experimental (Exp) percent-depth dose, PDD, percent-depth Cherenkov emission (CE), PDC, at 90 degrees to beam, and (b) PDD/PDC (i.e., normalized CE-to-dose conversion,  $k_C$ ) in water from 20 MeV TrueBeam electrons. The error bars define an interval estimated to have 95% level of confidence.

Table 1: Preliminary best-case uncertainty budget of Cherenkov emission-based measurement of absorbed dose to water in electron beams at optimal depth  $d_{ref} = 0.6R50 - 0.1$  [cm] under reference conditions.

	4 $\pi$ detection	90°±5° detection
<b>Measurement</b>		
$M_{raw}$	0.3%	0.3%
SSD	0.10%	0.10%
Position	0.33%	0.33%
Field size	0.10%	0.10%
Temperature	0.06%	0.06%

## Calibration

Calibration factor	0.7%	0.7%
Calibration stability	0.1%	0.1%

## Conversion

$k_C$	0.50%	0.53%
$k_C$ assignment	0.40%	0.84%

## Influence quantities

Linac stability	0.05%	0.05%
<b>COMBINED (k=1)</b>	<b>1.1%</b>	<b>1.3%</b>

## Conclusion

The excellent agreement between MC and experiment motivate CE-based dosimeter design efforts. Based on these results, we recommend a large-aperture detector and downstream PDC shift for beam-axis CE-based electron beam dosimetry in water. This is an attractive alternative to current methods as it avoids perturbations, can be extended to 3D via tomography or optical sectioning, and is especially promising for small fields due to the high resolution achievable with optical methods.

## OC-0294 Separating initial and general recombination in reference dosimetry of proton pencil beam scanning

J.B. Christensen<sup>1</sup>, E. Almhagen<sup>2,3</sup>, L. Stolarczyk<sup>2,4</sup>, M. Liszka<sup>4</sup>, A. Vestergaard<sup>5</sup>

<sup>1</sup>Technical University of Denmark, Center for Nuclear Technologies, Roskilde, Denmark ; <sup>2</sup>The Skandion Clinic, The Skandion Clinic, Uppsala, Sweden ; <sup>3</sup>Uppsala University, Medical Radiation Sciences- Department of Immunology- Genetics and Pathology, Uppsala, Sweden ; <sup>4</sup>Institute of Nuclear Physics- Polish Academy of Sciences in Krakow, The Bronowice Cyclotron Centre, Krakow, Poland; <sup>5</sup>Aarhus University Hospital, Danish Centre for Particle Therapy, Aarhus, Denmark

## Purpose or Objective

Gas-filled ionization chambers are the detectors of choice for calibrating ion beams at proton therapy facilities. The charge liberated in the ionization chamber is collected via an applied voltage and related to the absorbed dose. However, ion pairs of opposite charge may recombine and lead to an underestimation of the dose. The recombination events cannot be corrected with Monte Carlo methods as the recombination cross sections contain too large uncertainties. As a result, recombination losses are traditionally corrected with methods dating anywhere from decades to a century back. The main objective is to obtain a more precise determination of the recombination correction by separation of initial and general recombination for use in reference dosimetry.

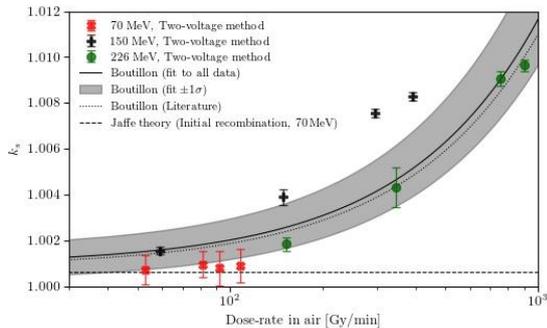

## Material and Methods

A Roos type parallel-plate ionization chamber was irradiated with a continuous scanned proton beam at 70, 150, and 226 MeV and 4 dose rates at in a water phantom. The liberated charge was for each configuration collected at 5 polarization voltages between 50 and 200 V. A detailed Monte Carlo model of the beam line enables an accurate calculation of both the particle spectrum and a conversion from delivered MU/minute to dose rate as the beam scans over the ionization chamber. The charge collection at several dose rates in turn permits a calculation of the recombination as a function of dose rate using the Boutillon theory [1]. The results are compared to the Jaffé theory [2] for initial recombination, the two-voltage-method (TVM) suggested in TRS-398 [3], and recombination corrections using extrapolation methods.

## Results

The experimentally determined recombination correction factors calculated with the TVM and extrapolation methods agree within 1.5%. The TVM data are in the figure plotted as a function of the calculated dose rate for a collecting voltage of 200 V. The dotted line represents the Boutillon theory for initial and general recombination

calculated with literature values from [1], whereas the Boutillon theory is fitted to all data points and shown with a solid line. The general recombination parameter  $m$  obtained from the fit is in 5% agreement with values in [1], and the initial recombination parameter  $A$  in the Boutillon theory is 11 % larger than that predicted by the Jaffe theory.

### Conclusion

The recombination for dose rates of proton pencil beams below 1 kGy/min in the Roos type ionization chamber is found to be below 1.1 %. The recombination for high energies and dose rates is completely dominated by general recombination where the recombination increases linearly with the dose rate. The recombination for low energies and dose rates below 0.1 kGy/min, on the other hand, is relatively constant. Such a behavior suggests a need to consider initial recombination for low dose-rates which also is indicated by the agreement with the Jaffe theory.

### OC-0295 Comparison of PENH, FLUKA and Geant4/TOPAS for radiation transport calculations in proton beams

K. Baumann<sup>1</sup>, F. Horst<sup>2</sup>, K. Zink<sup>2</sup>, C. Gomà<sup>3</sup>

<sup>1</sup>University Medical Center Giessen-Marburg, Department of Radiotherapy and Radiooncology, Marburg, Germany ;

<sup>2</sup>University of Applied Sciences Giessen, Institute of Medical Physics and Radiation Protection, Giessen, Germany; <sup>3</sup>KU Leuven, Department of Oncology-Laboratory of Experimental Radiotherapy, Leuven, Belgium

### Purpose or Objective

At the time, the IAEA TRS-398 Code of Practice is being updated. Within this framework the RTNORM project is supporting the IAEA working group with experimental as well as Monte Carlo calculated beam quality correction factors for different ionization chambers and beam qualities such as photons and protons. Whereas the use of Monte Carlo codes like EGSnrc and PENELOPE for calculations in high energy photon beams is well established, data for protons are sparse. This work compares the performance of the Monte Carlo codes PENH, FLUKA and Geant4/TOPAS in the calculation of beam quality correction factors in therapeutic proton beams.

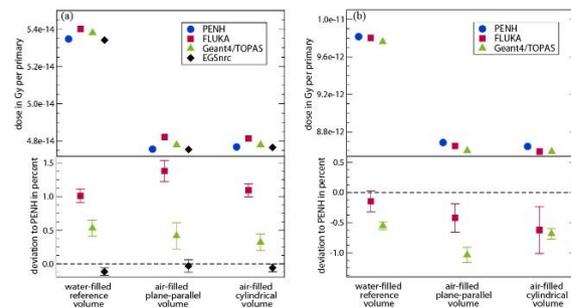

### Material and Methods

The absorbed dose to water ( $D_w$ ) in a reference volume in a water phantom was calculated with each of the Monte Carlo codes PENH, FLUKA and Geant4/TOPAS for the beam qualities  $Q_0$  (1.25 MeV mono-energetic photons) and  $Q$  (150 MeV protons). Additionally, the absorbed dose ( $D_{air}$ ) in two air cavities representing cylindrical and plane-parallel ionization chambers was calculated. EGS was also used to calculate  $D_w$  and  $D_{air}$  in the photon beams. From these absorbed dose values the ratios  $f_Q = (D_w/D_{air})$  (for

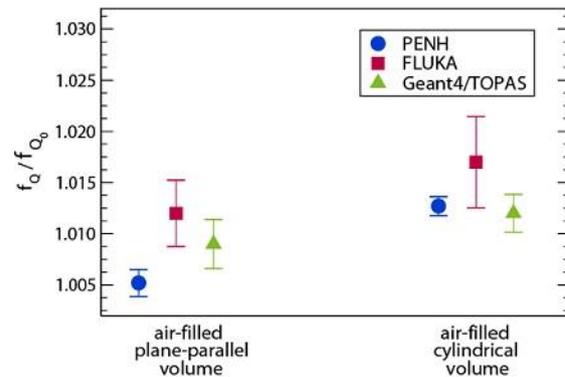

beam qualities  $Q$  and  $Q_0$ ) and the ratios  $f_Q/f_{Q_0}$  were calculated for both beam qualities and air cavities. This ratio  $f_Q/f_{Q_0}$  is the basis of beam quality correction factors. The particle transport settings and physics lists in each Monte Carlo code were adapted to simulate the radiation transport as accurately as possible.

### Results

In Figure 1 the dose values in the water reference volume and the air cavities for both beam qualities (panel (a) for photons, panel (b) for protons) are shown for the different Monte Carlo codes. In the bottom panel the deviations relative to PENH are shown. For the photon irradiation the results from EGSnrc and PENH agree within two standard deviations or better (largest deviation 0.1%). The dose values obtained with FLUKA and Geant4/TOPAS are up to 1.4% larger compared to PENH. For the proton irradiation the deviations of the three codes capable of transporting protons (PENH, FLUKA and Geant4/TOPAS) are 1% at maximum.

In Figure 2 the ratios  $f_Q/f_{Q_0}$  for the two air cavities and each Monte Carlo code are shown. The results agree within two standard deviations or better. The maximum deviation is 0.6%.

### Conclusion

It was shown that by using appropriate transport settings the results of the  $f_Q/f_{Q_0}$  - ratios agreed within 0.6%, although the dose values show deviations of up to 1.4%. However, these dose discrepancies tend to cancel out in the  $f_Q/f_{Q_0}$  -ratios. In other words, PENH, FLUKA and Geant4/TOPAS are suitable to calculate  $f_Q/f_{Q_0}$  - ratios in proton beams.

### OC-0296 Validation of motion-including dose reconstruction on a ground-truth time-resolved moving anatomy

J. Bertholet<sup>1</sup>, B. Eiben<sup>2</sup>, M.J. Menten<sup>1</sup>, E.H. Tran<sup>2</sup>, D.J. Hawkes<sup>2</sup>, S. Nill<sup>1</sup>, J.R. McClelland<sup>2</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and the Royal Marsden NHS Foundation Trust, Joint Department of Physics,

London, United Kingdom; <sup>2</sup>University College London, Centre for Medical Image Computing- Department of Medical Physics and Biomedical Engineering, London, United Kingdom

**Purpose or Objective**

Motion-including dose reconstruction (MIDR) aims at reconstructing the actually delivered dose to the moving anatomy during radiotherapy. However, the time-resolved patient anatomy during treatment is generally unknown and commonly estimated using 3D or 4D pre-treatment images. In this study, we reconstructed the delivered dose on a ground-truth, fully time-resolved anatomy (GT-MIDR) and used this to evaluate the accuracy of MIDR based on 3D and 4D CT images.

**Material and Methods**

The digital XCAT phantom was used to generate three regularly breathing thorax phantoms, each with a lung tumour moving according to its location (Fig 1). A 4DCT was generated and treatment plans were created for either a mid-ventilation approach (midVent) or treatment delivery with dynamic MLC tracking (tracking) (9-beam step-and-shoot IMRT, RTOG 1021). Treatment delivery under regular motion or regular motion and continuous drift was simulated in our in-house software.

For MIDR, the treatment fluence is discretized into sub-beams; each sub-beam is associated with the anatomy instance that it was delivered to and shifted to account for residual tumour position difference between the estimated anatomy and the actual target position if any. I.e. motion is modelled by a sub-beam isocenters shift, to emulate the actual relative target/beam position. The dose for each instance is then calculated in a research treatment planning system (TPS) and accumulated on the reference anatomy via deformable registration.

For GT-MIDR, ground-truth anatomy instances were generated from the XCAT. For 3D-MIDR, only one anatomy instance, the midVent 4DCT phase, was used and motion was accounted for by sub-beam isocenter shifts only. For 4D-MIDR, anatomy instances were chosen as the 4DCT phase where the tumour is closest to the actual tumour position and sub-beam isocenter shifts accounted for residual position differences.

**Results**

Differences between GT-MIDR and planning (Fig 2) show the effect of motion (midVent) or motion and mitigation (tracking) on dose delivery. Target underdosage was highest for tumour A. Tracking resulted in higher dose to the spinal cord and heart (tumour A, B) or aorta (tumour C).

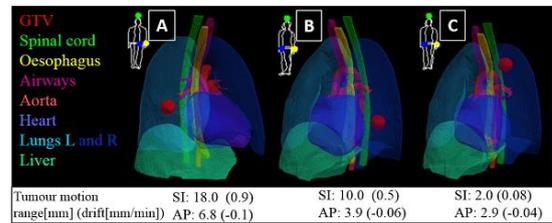

Fig 1. Anatomy, motion range and drift (if applicable) for tumours A, B and C. Tumour motion was determined by their location in the lungs.

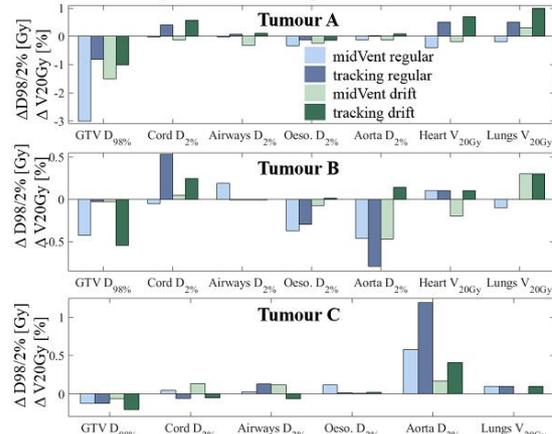

Fig 2. Ground truth reconstructed dose (GT-MIDR) minus plan dose to the target and the OAR for the tumour A (top), B (middle) and C (bottom).

Differences between 3D or 4D and GT-MIDR (Fig 3) show the accuracy of the respective methods. Reconstructed target dose errors above 1Gy were observed for 3D-MIDR. For tumour A, reconstructed dose to the organs-at-risks (OAR) were underestimated by 3D-MIDR. For tumour B, dose to the oesophagus and aorta was overestimated by 3D-MIDR. For tumour C, dose to the spinal cord and the oesophagus were overestimated by 4D-MIDR and dose to the aorta was underestimated by 3D and 4D-MIDR.

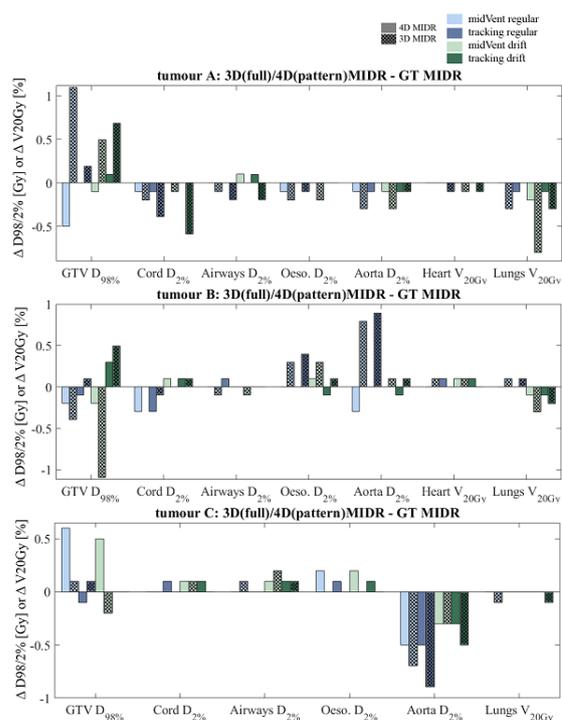

Fig 3. 3D(full) or 4D(pattern) MIDR minus Ground truth reconstructed dose (GT-MIDR) to the target and the OAR for the tumour A (top), B (middle) and C (bottom).

**Conclusion**

In the first demonstration of GT-MIDR, we calculated the delivered dose to target and OAR for a range of lung

tumour locations. We showed that MIDR based on planning data does not accurately resolve the delivered dose even in the case of regular motion. Our method may be used to validate MIDR for other motion models and treatment sites.

**OC-0297 Detailed PTV margin assessment for liver SBRT with CBCT-guidance or realtime monitoring and gating**

E. Worm<sup>1</sup>, R. Hansen<sup>1</sup>, M. Høyer<sup>2</sup>, J. Bertholet<sup>3</sup>, B. Weber<sup>2</sup>, A. Dolcet<sup>4</sup>, P.R. Poulsen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Oncology, Aarhus C, Denmark; <sup>2</sup>Aarhus University Hospital, Danish Centre for Particle Therapy, Aarhus C, Denmark; <sup>3</sup>Institute of Cancer Research, Division of Radiotherapy and Imaging, London, United Kingdom; <sup>4</sup>University Hospital Virgen de las Nieves, Radiophysics, Granada, Spain

**Purpose or Objective**

Implanted markers are often used to guide liver SBRT treatments, but position errors remain due to marker localization uncertainties, liver deformations, and intrafraction motion. Knowledge of the full error budget is lacking thus hindering realistic margin estimations. Here, we analyze in detail all error contributions to determine appropriate PTV margins in marker-based liver SBRT in two treatment scenarios: (A) CBCT guided free breathing or (B) respiratory gating with realtime motion monitoring.

**Material and Methods**

The van Herk formalism of systematic ( $\Sigma$ ) and random ( $\sigma$ ) errors was used to quantify the geometric errors from (1) CBCT match uncertainties (only Scenario A), (2) intrafraction motion, (3) interfraction deformations and marker migration, and (4) intrafraction deformations. Here, (1) was obtained by re-analyzing data of 29 liver SBRT patients where online manual CBCT marker match (Fig.1C) was compared with the marker positions accurately obtained from marker segmentation in individual CBCT projections [Bertholet, Acta Oncol,56(2017)]. (2) was reported in a recent study [Worm, IJROBP,101(2018)] of 15 patients receiving 3-fraction Calypso-guided liver SBRT (3 implanted electromagnetic markers, continuous monitoring, Fig.1A). Treatment delivery was respiratory gated around the end-exhale phase. Non-gated treatment was also simulated. (3+4) were based on individual marker motion in the Calypso-data (Fig.1A) using one marker as surrogate-tumor (Fig.1B). (3) was derived from the mean difference between the marker-tumor vectors in the planning CT and the mean marker-tumor vectors during the first treatment field. Patients (n=1) with interfraction deformations >8mm were excluded since these receive re-planning in our daily clinical practice (based on marker-marker mismatch in CBCT). (4) was derived from the difference between the mean marker-tumor vectors during the first treatment field and the marker-tumor vectors during the rest of each treatment (Fig.1A+B).

**Results**

Table 1 shows the errors for scenarios A (CBCT guidance) and B (gating). For scenario A, errors were dominated by intrafraction motion and interfraction liver deformations. PTV margins of 4.6mm (LR), 9.6mm (CC), and 3.5mm (AP) were required for a 67% PTV dose prescription level (Nordic standard). Real-time monitoring and gating (scenario B) eliminated the need for the uncertain CBCT marker-match, reduced intrafraction motion, and slightly reduced the error of interfraction liver deformation. PTV margins of 2.9mm (LR), 3.9mm (CC) and 2.8mm (AP) were needed in (B).

**Conclusion**

Error analysis based on unprecedented detailed motion monitoring showed that intrafraction motion and interfraction deformations dominate the geometrical errors in liver SBRT. Gating based on realtime monitoring

largely reduces required PTV margins not only by decreasing motion, but also by reducing deformations and avoiding error-prone marker localization in CBCT's. Target delineation errors were not considered in this study.

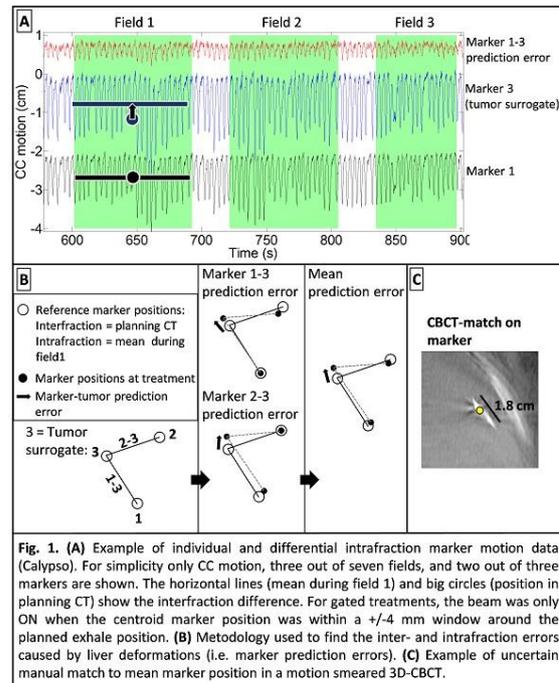

Fig. 1. (A) Example of individual and differential intrafraction marker motion data (Calypso). For simplicity only CC motion, three out of seven fields, and two out of three markers are shown. The horizontal lines (mean during field 1) and big circles (position in planning CT) show the interfraction difference. For gated treatments, the beam was only ON when the centroid marker position was within a +/-4 mm window around the planned exhale position. (B) Methodology used to find the inter- and intrafraction errors caused by liver deformations (i.e. marker prediction errors). (C) Example of uncertain manual match to mean marker position in a motion smeared 3D-CBCT.

**Table 1.** Required PTV margins calculated from the observed systematic ( $\Sigma$ ) and random errors ( $\sigma$ ) in non-gated and respiratory gated liver SBRT

**OC-0298 MLC tracking for lung cancer SABR is clinically feasible: results of first-in-human clinical trial**

J. Booth<sup>1</sup>, V. Caillet<sup>1</sup>, A. Briggs<sup>1</sup>, N. Hardcastle<sup>2</sup>, D. Jayamanne<sup>1</sup>, K. Szymura<sup>1</sup>, O. Ricky<sup>3</sup>, T. Eade<sup>1</sup>, P. Keall<sup>3</sup>  
<sup>1</sup>Royal North Shore Hospital, Northern Sydney Cancer Centre, St Leonards, Australia ; <sup>2</sup>PeterMacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia ; <sup>3</sup>ACRF Image X Institute, University of Sydney, Sydney, Australia

**Purpose or Objective**

MLC tracking is an emerging technology to improve tumor targeting and reduce normal tissue irradiation during radiotherapy. The purpose of this work was to determine if MLC tracking for lung cancer SABR is clinically feasible, measure the target and normal tissue doses with comparison of these to SABR treatment.

**Material and Methods**

Seventeen patients with stage 1 lung cancer or lung metastases were recruited into the ethics-approved MLC

tracking clinical trial (NCT02514512). Each patient had three electromagnetic beacons (Calypso) inserted into the lung surrounding the tumor. An MLC tracking SABR plan was generated with the planning target volume (PTV) expanded 5mm from the end-exhale gross tumor volume (GTV). For comparison a conventional motion-encompassing SABR plan was generated with PTV expanded 5mm from a 4DCT-derived internal target volume (ITV). Treatment was delivered using a standard linear accelerator using in-house developed software to continuously adapt the MLC motion based on the Calypso beacons' movement. The rate of successful treatment fractions with MLC tracking, tumor motion, treated volume and reconstructed delivered dose were compared between MLC tracking and conventional ITV treatment planning.

#### Results

All seventeen patients were treated successfully with MLC tracking (70 successful fractions), completing the primary endpoint of this study. Tumor motion range varied during treatment, between fractions and from the planning 4DCT; significantly, larger motion was observed during treatment that exceeded standard PTV boundaries. The MLC tracking PTVs for all patients was smaller than with ITV based planning (mean 29%, range 2%-47% reduction, or 2-18 cm<sup>3</sup> with MLC tracking). Subsequent reductions in normal lung dose were observed. Reconstruction of delivered treatments confirmed accurate delivery of MLC tracking, with 100% of the prescribed dose delivered to the GTV for all 70 fractions.

#### Conclusion

Real-time adaptation via MLC tracking on a standard linac has been successfully performed in seventeen lung cancer patients. Reductions in treated volumes up to 47% were observed, which translated to reductions in lung dose.

#### OC-0299 Fully automatic detection of heart irradiation in cine MV images during breast cancer radiotherapy

P.R. Poulsen<sup>1</sup>, M.S. Thomsen<sup>2</sup>, R. Hansen<sup>2</sup>, E. Worm<sup>2</sup>, E. Yates<sup>2</sup>, H. Spejlborg<sup>2</sup>, B. Offersen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; <sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark

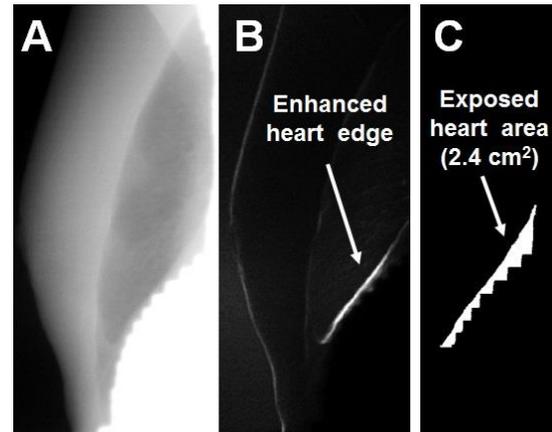

#### Purpose or Objective

Heart irradiation during radiotherapy of breast cancer can lead to late cardiac morbidity and increased mortality for long-time survivors. Left-sided breast cancer patients are therefore often treated in deep-inspiration breath-hold (DIBH) to better separate the breast and the heart. However, daily variations in the heart position can give heart exposures that are much larger than planned. For tangential treatments, continuous portal images (cine MV images) may be used to monitor the heart exposure at each treatment fraction with no additional dose to the patient. Challenges include low image contrast and the location of the heart edge in or near the field penumbra. In this study, we develop and test automated heart detection in cine MV images.

#### Material and Methods

Cine MV portal images (Figure 1A) of 302 tangential field deliveries were recorded at 7.7 Hz for ten left-sided breast cancer patients who received DIBH radiotherapy in 15-18 fractions. An algorithm for fully automatic detection of the heart edge in cine MV images was developed and tested for all available images. The algorithm exploits that the intensity of pixels at the edge of the heart will change cyclically with frequencies of 1-3 Hz due to heartbeat and that the intensity changes of all pixels at the heart edge will be highly correlated with each other because they have the same physical origin (heartbeat). The algorithm first identifies a candidate pixel on the heart edge as the pixel in the image with highest value of (1) intensity variations in the 1-3 Hz frequency range multiplied by (2)

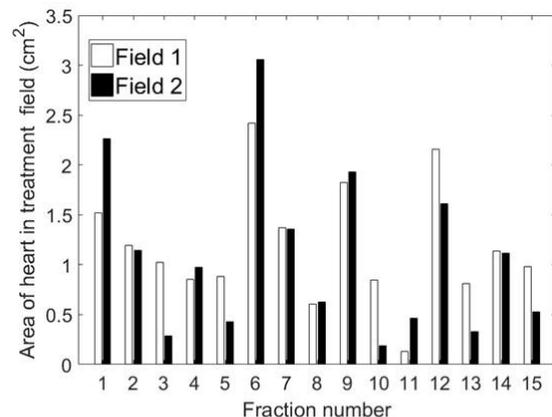

intensity variation correlation with a set of neighboring pixels. Next, an enhanced heart edge image is generated by multiplying the 1-3 Hz intensity variation of each pixel with the correlation of intensity variations between the pixel and the heart edge candidate pixel (Figure 1B). Finally, the heart edge is segmented in the enhanced heart edge image and the exposed heart area is calculated as the area between the heart edge and the medial field edge (Figure 1C).

**Figure 1.** Cine MV image of a tangential breast treatment field (A) before processing and (B) after enhancement of the heart edge by the proposed algorithm. (C) Automatically extracted heart exposure area.

#### Results

Part of the heart was exposed at 169 out of 302 field deliveries. Using all cine MV images, the heart edge was correctly identified in all cine MV series except for 11 cases with heart drift motion during field delivery. For these cases, analysis of a shorter time series with less drift motion (30-50% of the MV images) correctly identified the heart edge. Figure 2 shows an example of the exposed heart area for a patient. While large interfraction variations occurred the intrafraction variations were smaller with high correlation between the heart exposure at field 1 and field 2 at a fraction ( $r = 0.85$ ,  $p < 0.001$ ).

**Figure 2.** Example of exposed heart area at all fractions for a patient as extracted automatically in cine MV images as illustrated in Figure 1.

#### Conclusion

An algorithm for automatic identification of pixels at the heart edge in cine MV images was proposed, developed and shown to be highly efficient for heart exposure detection in tangential breast fields. The algorithm can be

used in a surveillance program with automated heart exposure monitoring of all breast cancer treatments in a clinic.

### OC-0300 Experimental validation of an MLC tracking treatment simulator with dose reconstruction

A. Hagner<sup>1</sup>, T. Ravkilde<sup>2</sup>, S. Skouboe<sup>3</sup>, C.G. Muurholm<sup>3</sup>, R. Hansen<sup>2</sup>, E.S. Worm<sup>2</sup>, P.R. Poulsen<sup>4</sup>

<sup>1</sup>Aarhus University, Department of Physics and Astronomy, Aarhus, Denmark; <sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark; <sup>3</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; <sup>4</sup>Aarhus University, Department of Clinical Medicine, Aarhus University, Denmark

#### Purpose or Objective

Tumour motion may cause substantial deterioration of planned dose distributions. However, the dosimetric impact of tumour motion can be mitigated by MLC tracking. Current QA for MLC tracking involves pre-treatment delivery of the treatment plan to a moving dosimeter to determine its suitability for MLC tracking. This is a time-consuming process that may be replaced by dose delivery simulations for easier assessment of the suitability of MLC tracking for a given plan. In this study, we simulate delivered doses to a moving dosimeter with and without MLC tracking and validate the simulations by comparison with measurements.

#### Material and Methods

MLC tracking experiments were performed on a TrueBeam linear accelerator using iTools Tracking (Varian, CA) guided by an optical marker block. Delivered doses were measured at 72 Hz using a Delta4 dosimeter mounted in a HexaMotion motion stage (Scandidos, Sweden). The motion stage reproduced motion from four liver SBRT patients previously treated using VMAT plans with tumor motion monitoring by kilovoltage intrafraction monitoring. Three VMAT fields per patient were delivered to the dosimeter both with and without MLC tracking. The time-resolved motion-induced 3%/3mm gamma failure rate was determined for each VMAT field delivery faced with motion by comparing measured cumulative dose distributions with a measured static reference. In order to simulate the experiments, two in-house developed programs for 1) treatment delivery simulation and 2) dose reconstruction (DoseTracker) were combined. The treatment simulator took as input the DICOM treatment plans and motion stage trajectories used at the experiments and generated a log file with synchronized target positions and simulated linac parameters (gantry, MLC positions, MU, etc.) with 21Hz resolution. The log file was used by DoseTracker to reconstruct time-resolved delivered doses to all 1069 diodes in the dosimeter and calculate gamma failure rates comparing simulated and planned cumulative doses.

Finally, the time-resolved gamma failure rates of simulations and experiments were compared and the root-mean-square deviation (RMSD) calculated.

#### Results

The simulated gamma failure rates agreed well with the measurements throughout beam delivery for both MLC tracking and standard non-tracking treatments (Fig 1-2) with a root-mean-square deviation of 2.0 %-points.

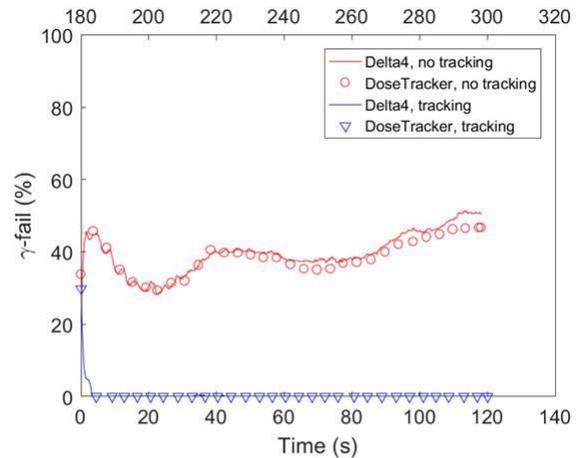

Figure 1: Example of measured (lines) and simulated (circles/triangles) motion-induced 3%/3mm gamma failure rates during delivery of the third field for patient 4 with MLC tracking and without.

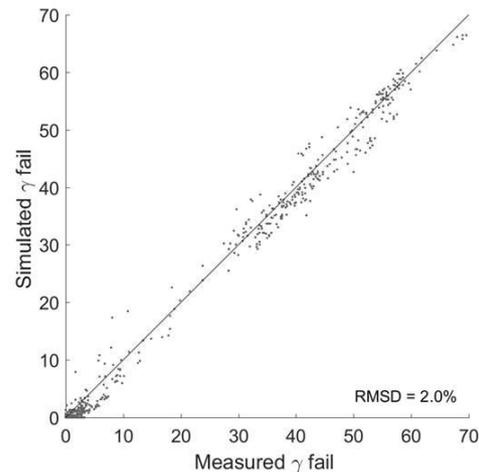

Figure 2: Scatter plot of all simulated vs. measured motion-induced 3%/3mm gamma failure rates. The unity line represents perfect simulation of motion-induced gamma failure rates.

#### Conclusion

End-to-end simulations of advanced radiotherapy delivery, from treatment plan to delivered dose distributions, were demonstrated and experimentally validated. The simulator accurately predicted motion-induced dose errors for VMAT liver SBRT to a moving target throughout both MLC tracking and standard non-tracking deliveries.

An accurate tracking simulator can eliminate the need for time-consuming experiments and QA measurements for MLC tracking. It allows easy evaluation of the motion robustness of treatment plans and their suitability to MLC tracking for a wider range of motion than practically possible with experiments.

### OC-0301 Real-time kV image guidance in the treatment of pancreatic SBRT: quantifying the purpose and impact

B. Jones<sup>1</sup>, Y. Vinogradskiy<sup>1</sup>, W. Campbell<sup>1</sup>, Y. Ding<sup>1</sup>, T. Schefter<sup>1</sup>, K. Goodman<sup>1</sup>, M. Miften<sup>1</sup>

<sup>1</sup>University of Colorado School of Medicine, Radiation Oncology, Aurora, USA

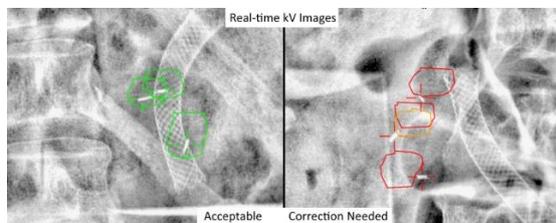

#### Purpose or Objective

Ablative radiotherapy of the pancreas requires extremely precise delivery in order to achieve local control while minimizing toxicity to the duodenum and

stomach. However, the pancreas undergoes erratic and unstable respiratory-induced motion, which makes it challenging to deliver dose accurately. Recent studies have demonstrated that traditional motion-mitigation techniques are often insufficient in guiding SBRT to the pancreas. The purpose of this study was to evaluate real-time imaging and tracking as a tool for pancreatic SBRT and quantify the ability of real-time imaging to correct for unpredictable tumor motion.

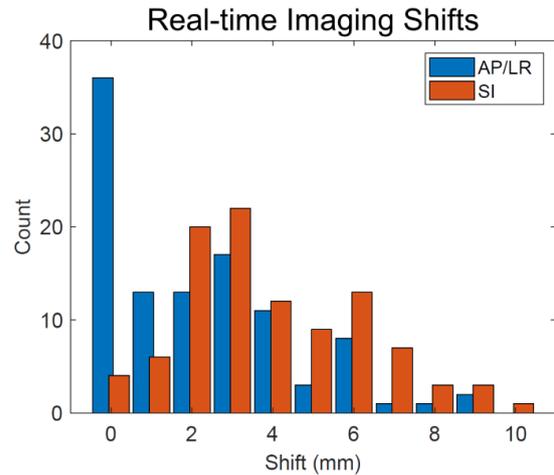

#### Material and Methods

To understand the effects of tumor motion on treatment, we apply a computational technique that uses the location of implanted fiducial markers in CBCT projection data to reconstruct the motion of these tumors. These data were used to determine the accuracy of 4DCT, and to analyze the impact of respiratory gating, abdominal compression, and real-time imaging on treatment accuracy. Following this, 68 patients were treated with pancreatic SBRT under real-time kV image guidance. Corrections were made to the position if the markers were observed >3 mm from the expected reference position. To understand impact of this imaging on treatment accuracy and clinical workflow, we retrospectively analyzed all treatment interruptions and corrections made based on this imaging. Throughout, we analyzed the effects of tumor motion by developing an artificial neural network-based dosimetric framework to model the dose distribution in the area immediately adjacent to the tumor.

#### Results

On average, 4DCT underestimated the 3D range of pancreatic tumor motion by 5.1 mm. These differences were driven by erratic components of respiratory and digestive motion. In retrospective analysis, respiratory gating outperformed abdominal compression, with an average superior-inferior range of motion of 5.5 mm vs 8.5 mm. In the dosimetric model, mean dose errors were less than 5% at all distances from the PTV, and mean absolute dose errors were 5-10%. Real-time imaging resulted in 0.81 pauses per fraction of treatment, with 40% of these resulting in re-localization of the target. The median 3D shift for patient re-alignment was 5.2 mm. 45% of shifts resulted in dosimetric differences to the tumor; of these, the median point dose difference was  $23\% \pm 22\%$  of prescription dose.

#### Conclusion

The pancreas undergoes unpredictable motion, which decreases the accuracy of 4DCT. Traditional methods of motion mitigation (compression and gating) were unable to decrease the average range of motion below 5 mm. We successfully treated 68 patients using a real-time imaging protocol that corrected positional variations >3 mm, resulting in significant dosimetric benefit to target coverage. In this way, real-time kV imaging allows for the correction of erratic and unpredictable pancreatic motion, and may allow for the safe delivery of future dose-escalated therapies.

#### OC-0302 Dose-guided motion management during liver SBRT delivery using real-time reconstructed tumor DVHs

C.G. Muurholm<sup>1</sup>, T. Ravkilde<sup>2</sup>, S. Skouboe<sup>1</sup>, E. Worm<sup>2</sup>, R. Hansen<sup>2</sup>, M. Høyer<sup>3</sup>, P.J. Keall<sup>4</sup>, P.R. Poulsen<sup>1</sup>

<sup>3</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus, Denmark; <sup>4</sup>Sydney Medical School -

The University Of Sydney, Radiation Physics Laboratory, Sydney, Australia

#### Purpose or Objective

Abdominal SBRT is susceptible to tumor motion due to high fraction doses and steep dose gradients. As a QA tool, we have developed a computer program, DoseTracker, that uses streamed tumor positions and linac parameters to reconstruct the dose to a moving tumor in real time during treatment delivery. While the tumor DVH provides intuitive and clinically relevant information on the fully delivered fraction dose it is often not meaningful for a partially delivered fraction. Here, we propose a time-resolved DVH that is useful for partial treatments and demonstrate its use for dose evaluation and dose-guided treatment adaptation in simulated liver SBRT treatments with real-time dose reconstruction.

#### Material and Methods

The proposed time-resolved DVH(t) describes the current deviations between the actual delivery with motion and the planned static delivery. Before treatment start DoseTracker calculates the planned static DVH (plan-DVH) of the full treatment. During treatment DoseTracker continuously calculates the cumulative actual dose with motion and planned static dose in all calculation points. The DVH(t) is then obtained by multiplying each calculation point used in the plan-DVH with the ratio of actual and planned dose. Hereby, the full treatment DVH is adjusted based on the current dosimetric state, which results in a real-time calculated DVH that meaningfully describes the current cumulative dose delivery and

converges towards the final motion-including DVH. The accuracy of DoseTracker's real-time calculated DVHs was first investigated by simulating 39 fractions from 13 liver SBRT patients with Calypso-measured motion. The motion-induced reduction in the CTV D95% ( $\Delta D95\%$ ) after each fraction was compared between DoseTracker and our treatment planning system (TPS; Eclipse). Next, the real-time DVH concept was used in two simulated dose-guided treatment scenarios where inter-field couch corrections were performed to correct mean position errors if  $\Delta D95\%$  exceeded either 5% or 10%.

### Results

Fig 1A compares the motion-including DVH(t) with the planned static DVH at different time points during a treatment. DoseTracker's final real-time estimated  $\Delta D95\%$  was in general in good agreement with the TPS with a root-mean-square error of 2.3 %-points and with the largest errors for small tumors (Fig 1B).

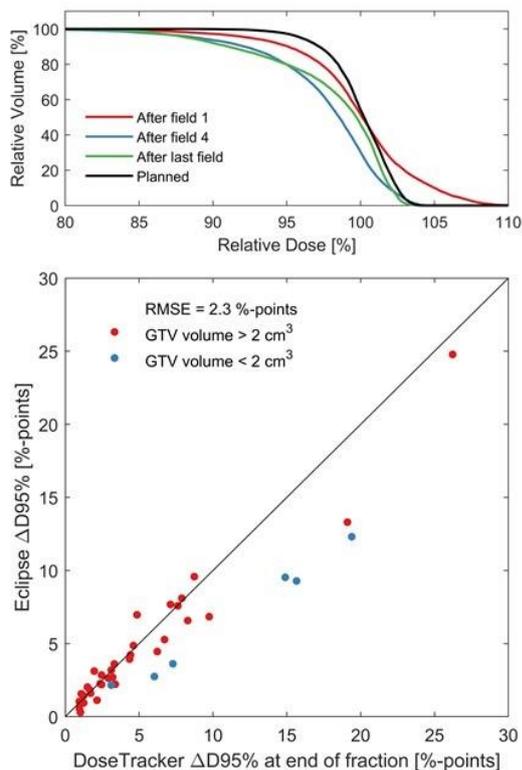

Figure 1. A: Examples of liver tumor DVHs without motion (black) and with motion calculated at different time points during a treatment. B: Motion-induced reduction in D95% after each fraction calculated with DoseTracker versus the treatment planning system (Eclipse).

Fig 2 shows the evaluation of  $\Delta D95\%$  during simulated treatments with and without dose-guided couch corrections. The mean (range) of the final  $\Delta D95\%$  was 5.9 %-point (1.0-26.2 %-point) without inter-field couch corrections and 3.8 %-point (1.0-10.0 %-point), and 3.1 %-point (0.6-9.5 %-point) with dose-guided couch corrections using 10% and 5%  $\Delta D95\%$  thresholds, respectively. The mean number of dose-guided couch shifts per fraction was 0.4 (10% threshold) and 1.1 (5%).

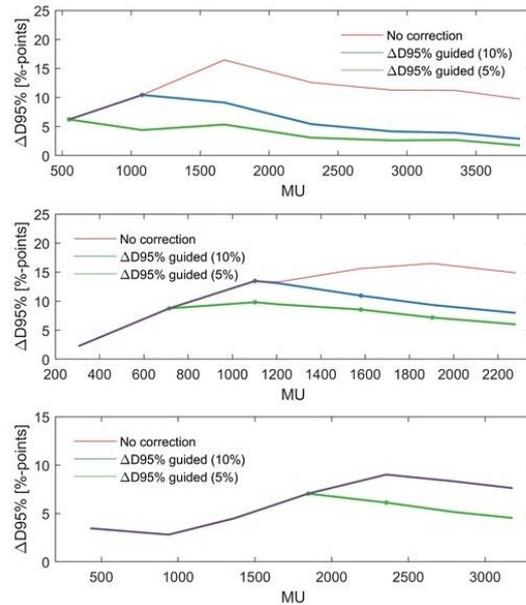

Figure 2.  $\Delta D95\%$  using the time-resolved DVH method as a function of MU delivered for 3 of the 39 simulated fractions.

### Conclusion

A new method for real-time motion-including dose evaluation that relates to a traditional DVH was presented and used for simulated dose-guided couch corrections based on reconstructed tumor dose deficits.

### Proffered Papers: RTT 3: Impact of variations on treatment planning

#### OC-0303 Dosimetric benefit of a clinically applied adaptive plan selection strategy for rectal cancer

R. De Jong<sup>1</sup>, J. Visser<sup>1</sup>, N. Van Wieringen<sup>1</sup>, K. Crama<sup>1</sup>, J. Wiersma<sup>1</sup>, D. Geijsen<sup>1</sup>, A. Bel<sup>1</sup>  
<sup>1</sup>Amsterdam UMC, Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

For rectal cancer radiotherapy, an adaptive strategy by means of plan selection was clinically implemented in May 2016. We evaluated target coverage and dose to the organs at risk for the clinically used adaptive plan selection strategy compared to a non-adaptive approach for both short (5x5Gy) and long (25x2Gy) treatment schedules for rectal cancer patients.

#### Material and Methods

For this study the first 20 consecutive patients treated between May and September 2016 were included, if the length of the upper part of the mesorectum, as measured from the base of the bladder, was over 4.5 cm. For each patient 3 plans were created with different ventral PTV margins to the upper mesorectum (fig 1), i.e. the most mobile part of the target volume. The chosen margins depended on status of rectal filling on the CT scan: 25/15/0 mm for empty rectum versus 15/0/-15 mm for full rectum. All patients were planned with VMAT. Based on daily Conebeam CT (CBCT) scans RTTs selected the plan with the smallest PTV that encompassed the complete target volume for treatment. These plans were compared to a non-adaptive strategy with a single plan and a ventral PTV margin of 20 mm. For each fraction bowel cavity, bladder and target volume (mesorectum) were delineated on the CBCT scan by a single observer. The dose

distribution of each selected plan and the non-adaptive plan were used to calculate daily DVHs. To evaluate the dose levels as suggested in the QUANTEC papers (V15Gy, V30Gy, V40Gy, V45Gy), the corresponding dose levels per fraction were tested for significance: V0.6Gy, V1.2Gy, V1.6Gy, V1.8Gy and V95% for long, and V3.0Gy, V95% for short treatment schedules, respectively. Significance was tested using Wilcoxon signed ranks test for related samples. Coverage of the total CTV, as expressed by V95%, was also tested.

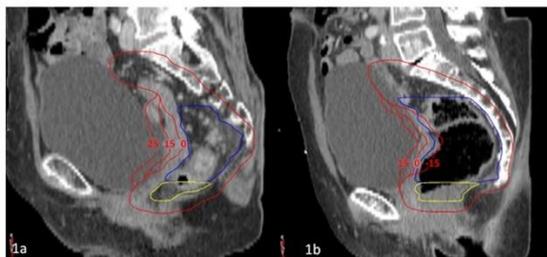

Fig. 1. Margin sets based on anatomy as captured on planning CT. (1a) shows empty rectum with a set of 25 mm, 15 mm, and 0 mm anterior margins (red) for upper mesorectum (blue). (1b) shows full rectum with a set of 15 mm, 0 mm, and -15 mm anterior margins (red) for upper mesorectum (blue)

## Results

In total, 10 short and 10 long treatment schedules were included, resulting in 300 plan selections. The margin set of 25/15/0 mm margins was used for 13 patients, the margin set of 15/0/-15 for 7 patients. Overall the -15mm, 0 mm, 15, and 25 mm plans were selected in 2%, 41%, 40%, 17% of fractions, respectively. For bowel cavity, limited but significant reductions were found in favor of the adaptive strategy for the long treatment schedule for V0.6Gy, V1.6Gy, V1.8Gy, and V95% ( $p < 0.05$ ). For the short treatment schedule the tested dose parameters (V3.0Gy and V95%) were not significantly different. For bladder limited but significant reductions were found in all dose parameters and both schedules (Table 1). Target volume V95% increased from 98% to 99%, but this increase was not significant.

Table 1. Dose to the organs at risk for all patients all fractions.

	Dose level per fraction	Median values (range)		p-value
		ART	non ART	
long schedule (25x2 Gy)				
Bladder	V0.6Gy (%)	99.8 (87.6-100.0)	100.0 (85.6-100.0)	.000
	V1.2Gy (%)	43.0 (12.6-99.3)	49.6 (19.1-96.8)	.000
	V1.6Gy (%)	22.8 (1.8-91.1)	29.0 (4.2-85.3)	.000
	V1.8Gy (%)	15.0 (0.2-87.0)	21.8 (0.4-77.6)	.000
	V95% (%)	10.8 (0.0-82.2)	17.8 (0.0-72.4)	.000
	Dmean (Gy)	1.23 (0.89-1.95)	1.30 (0.98-1.88)	.000
Bowel cavity	V0.6Gy (cm3)	847 (332-1447)	853 (294-1363)	.001
	V1.2Gy (cm3)	309 (119-554)	309 (120-557)	.542
	V1.6Gy (cm3)	205 (99-431)	214 (99-434)	.000
	V1.8Gy (cm3)	179 (93-381)	187 (90-390)	.000
	V95% (cm3)	160 (83-358)	170 (82-366)	.000
short schedule (5x5 Gy)				
Bladder	V3.0Gy (%)	29.7 (5.7-58.6)	33.8 (9.9-60.5)	.001
	V95% (%)	4.4 (0.0-16.4)	7.1 (0.0-27.7)	.013
	Dmean (Gy)	2.7 (2.1-3.5)	2.8 (2.3-3.6)	.001
Bowel cavity	V3.0Gy (cm3)	329 (139-456)	317 (137-477)	.237
	V95% (cm3)	176 (87-274)	191 (93-275)	.135

Dose levels per fraction V0.6Gy, V1.2Gy, V1.6Gy, V1.8Gy for long schedule corresponding to total dose V15Gy, V30Gy, V40Gy, V45Gy respectively and V3.0Gy for short treatment schedule corresponding to V15Gy total dose.

## Conclusion

The adaptive strategy with plan selection improved target coverage and lowered the dose to the organs at risk. Over all patients the clinical benefit seems limited.

### OC-0304 Dosimetric impacts of VMAT FFF large-field on standard dose fractionation

D. Julian<sup>1</sup>, S. Muraro<sup>1</sup>, O. Lauche<sup>1</sup>, A. Moustamia<sup>1</sup>, K. Serre<sup>1</sup>

<sup>1</sup>Clinique Clementville, CCGM Unité de Physique, Montpellier, France

## Purpose or Objective

Volumetric modulated arc therapy (VMAT) combined with flattening filter free beams (FFF) is generally used for stereotactic body radiation therapy (SBRT). Compared to flattened beams (FF), FFF provides advantages clearly identified in the literature to treat small lesions. In this study, an analysis of the dosimetric impacts of large X6<sub>FFF</sub> beams used in VMAT plans is developed for three major cancer locations.

## Material and Methods

A retrospective cohort of 90 patients treated between 2016 and 2017 includes 30 lung, 30 brain and 30 head & neck (H&N) cancers. The prescribed doses are respectively ranging from 50 to 66 Gy, 30 to 50 Gy and 60 to 70 Gy, 2 Gy per fraction. Planned target volumes (PTV) range from 35.0 to 482.0 cm<sup>3</sup>. Patients treated with VMAT X6<sub>FFF</sub> plans with 2 opposed coplanar arcs at 600 UM.min<sup>-1</sup> maximum dose rate on Varian Clinac® system. Plans are optimized on Varian Eclipse® TPS (AAA, PRO, V13.6). For each case, a new VMAT objective function and dose distribution are determined using X6<sub>FFF</sub> beams at 1400 UM.min<sup>-1</sup>. Both results are normalized so as 95% of the dose covers 98% of the PTV. VMAT X6<sub>FFF</sub> and X6<sub>FF</sub> plan comparisons included doses at the PTV and at 2 cm, specific organ-at-risk (OAR), 50% isodose prescription volumes (V50%), number of monitor units (MU) and treatment time. 3D  $\gamma$ -indexes (3%, 3mm, local dose) on Varian Portal Dosimetry® software is used to validate the plans.

## Results

PTV coverage do not differ significantly between the X6<sub>FF</sub> and X6<sub>FFF</sub> energies (<0.2%,  $p=0.5$ ) for any given location. At 2 cm around PTV, an average dose reduction of  $-4.0\% \pm 0.1\%$  ( $p < 0.001$ ) stands out for lung location,  $-2.75\% \pm 2.4\%$  ( $p < 0.001$ ) for brain and  $-0.8\% \pm 1.7\%$ ; ( $p=0.004$ ) for H&N targets. The V50% average dose decreases by  $3.9\% \pm 2.1\%$  ( $p=0.001$ ) for lung but no significant difference for brain and H&N is found. For all lung plans, doses at OAR decrease between  $-2.9\%$  and  $-6.5\%$  for normal lung, heart, spinal cord and esophagus; the overall decrease is due to the lower energy spectrum and scattered radiation. However, lower doses to the OAR are found for only 24 plans in brain and 20 plans in H&N with X6<sub>FFF</sub> beams. VMAT X6<sub>FFF</sub> plans requires a global greater MUs, with  $+10.7\% \pm 4.9\%$  than in X6<sub>FF</sub> for the lung,  $+8.7\% \pm 10.9\%$  for the brain,  $+28.3 \pm 16.1\%$  in H&N. X6<sub>FF</sub> and X6<sub>FFF</sub>  $\gamma$ -indexes do not show significant differences except for H&N: pass rate is less than 95% score for 70% of plans. Treatment time reductions using X6<sub>FFF</sub> high dose rate is limited by the gantry rotation speed. To ensure dosimetric objectives, X6<sub>FFF</sub> large field fluence is compensated by the segmentation algorithm. Except for lung location, X6<sub>FFF</sub> does not improve outcomes systematically.

## Conclusion

For lung localizations, the use of large X6<sub>FFF</sub> VMAT plans improves dose conformity to the target volume and generate high dose gradients which spare surrounding normal tissues and organs at risk. However, large X6<sub>FFF</sub> fields do not seem suitable for systematic brain and H&N plan management.

### OC-0305 Organ sparing potential and inter-fraction robustness of IMPT for cervical cancer

E.M. Gort<sup>1</sup>, J.C. Beukema<sup>1</sup>, M.J. Spijkerman-Bergsma<sup>1</sup>, S. Both<sup>1</sup>, J.A. Langendijk<sup>1</sup>, W.P. Matysiak<sup>1</sup>, C.L. Brouwer<sup>1</sup>  
<sup>1</sup>University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

## Purpose or Objective

Current chemoradiation (CHRT) for cervical cancer results in severe chronic bowel toxicity in one out of eight patients. Moreover, severe hematologic toxicity is a frequent cause of discontinuation of CHRT which may have an impact on treatment outcome. Our pencil beam scanning proton facility allows highly conformal intensity modulated proton therapy (IMPT), however inter-fraction

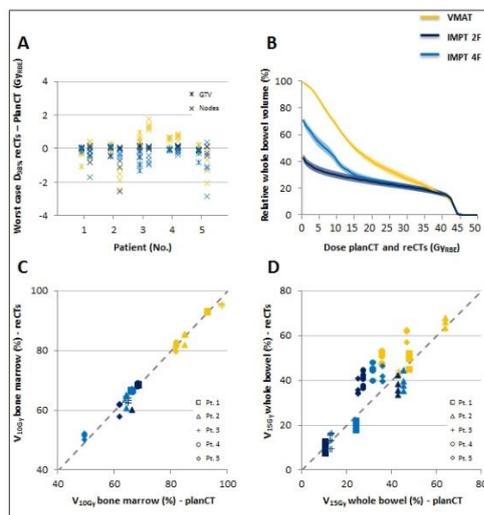

motion and increased sensitivity to range uncertainties may affect target dose coverage and dose to OAR. This in silico planning study was performed to evaluate robustness and the potential of IMPT to reduce dose to OAR in locally advanced cervical cancer, compared to the current photon treatment (VMAT).

#### Material and Methods

Five weekly repeated CT scans from 5 cervical cancer patients treated with CHRT were available for this study. The target volumes, with the para-aortic region included, were delineated according to the EMBRACE II intermediate IGRT protocol and three different primary treatment plans were created for 25 fractions of 1.8 Gy<sub>RBE</sub> using RayStation 6.99: a two-field IMPT (2F), a four-field IMPT (4F) and a two-arc VMAT plan. Robustness evaluation using a 5-mm setup and 3% range uncertainty margin was performed. Each repeated CT scan was contoured and registered to the plan CT scan and subsequently the primary treatment plan was recomputed on each repeated CT scan. The voxelwise minimum dose (worst case dose) delivered to 98% of the GTV (D<sub>98%</sub>GTV) and lymph nodes (D<sub>98%</sub> nodes) as well as the nominal OAR doses were evaluated on each of the CT scans. The selected clinical relevant OAR dose parameters were bone marrow V<sub>10Gy</sub> and V<sub>20Gy</sub> [1], femoral head D<sub>mean</sub> [2], sacrum D<sub>mean</sub> [2] and D<sub>50%</sub> [3] and whole bowel V<sub>15Gy</sub> [4]. In addition, entire DVHs for the whole bowel were compared.

#### Results

IMPT (2F and 4F) and VMAT showed similar plan robustness with regard to target coverage (GTV and nodes), with a mean dose deviation from the planCT of  $-0.11 \pm 0.43$  Gy<sub>RBE</sub> (IMPT 2F),  $-0.40 \pm 0.58$  Gy<sub>RBE</sub> (IMPT 4F) and  $0.04 \pm 0.90$  Gy<sub>RBE</sub> (VMAT) (Figure 1A). The DVHs of the whole bowel showed a lower mean dose in the range of 0 - 40 Gy<sub>RBE</sub> for the IMPT plans compared to VMAT (Figure 1B). Bone marrow V<sub>10Gy</sub> and whole bowel V<sub>15Gy</sub> were significantly lower for IMPT 2F and 4F compared to VMAT (Figure 1C and 1D). For both dose parameters the dose on the planCT was predictive for the resulting dose on the repeated CT. Mean bone marrow V<sub>10Gy</sub> and V<sub>20Gy</sub>, femoral heads D<sub>mean</sub>, sacrum D<sub>mean</sub> and D<sub>50%</sub> and whole bowel V<sub>15Gy</sub> were markedly lower in both types of IMPT plans compared to VMAT treatment plans (Table 1). IMPT 4F resulted in significantly lower bone marrow V<sub>20Gy</sub> in comparison to IMPT 2F.

**Figure 1.** Comparison of IMPT two-field (2F), four-field (4F) and VMAT plans for five patients with ITV prescription dose 45 Gy<sub>RBE</sub>. A: Worst case D<sub>98%</sub>GTV and D<sub>98%</sub> nodes (Gy<sub>RBE</sub>) difference between each repeated CT and its corresponding planCT for each patient. B: relative volume (%) vs received dose (Gy<sub>RBE</sub>) for the whole bowel for the plan CT and repeated CTs, the error bands display the standard error. C: V<sub>10Gy</sub> bone marrow (%) repeated CTs vs corresponding planCT. D: V<sub>15Gy</sub> whole bowel (%) repeated CTs vs corresponding planCT. The symbols in Figure 1.C and 1.D represent the different patients.

**Table 1.** Average  $\pm$  SD OAR dose for VMAT, IMPT two-field (2F) and IMPT four-field (4F) evaluations on all 5 planCTs and 25 repeated CTs. For each OAR dose parameter, the results for all 5 patients are combined.

OAR parameter	OAR doses for 5 patients		
	VMAT	IMPT 2F	IMPT 4F
V <sub>10Gy</sub> bone marrow (%)	87.6 $\pm$ 6.0	65.6 $\pm$ 3.2	62.7 $\pm$ 5.7
V <sub>20Gy</sub> bone marrow (%)	66.4 $\pm$ 3.8	54.7 $\pm$ 2.5	40.9 $\pm$ 3.6
D <sub>mean</sub> femoral heads (Gy <sub>RBE</sub> )	20.4 $\pm$ 3.4	6.2 $\pm$ 1.9	8.1 $\pm$ 2.5
D <sub>mean</sub> sacrum (Gy <sub>RBE</sub> )	36.4 $\pm$ 1.7	35.6 $\pm$ 1.0	33.5 $\pm$ 2.1
D <sub>50%</sub> sacrum (Gy <sub>RBE</sub> )	35.9 $\pm$ 1.9	35.8 $\pm$ 1.1	34.1 $\pm$ 3.1
V <sub>15Gy</sub> whole bowel (%)	52.6 $\pm$ 9.7	27.4 $\pm$ 13.7	31.7 $\pm$ 13.3

3. A. Ramlov et al., "Risk Factors for Pelvic Insufficiency Fractures in Locally Advanced Cervical Cancer Following Intensity Modulated Radiation Therapy," *Int. J. Radiat. Oncol.*, vol. 97, no. 5, pp. 1032–1039, Apr. 2017.
4. S. Chopra et al., "Predictors of Grade 3 or Higher Late Bowel Toxicity in Patients Undergoing Pelvic Radiation for Cervical Cancer: Results From a Prospective Study," *Int. J. Radiat. Oncol.*, vol. 88, no. 3, pp. 630–635, Mar. 2014.

#### Conclusion

Robustly optimized IMPT treatment plans for cervical cancer patients show equivalent target coverage robustness when compared to VMAT treatment plans, but offer significantly better OAR sparing. Potentially, this could reduce bowel and hematologic toxicity for this young patient population.

#### OC-0306 Using CBCT and VelocityTM Software for delivered dose verification during head and neck radiotherapy

L. Hay<sup>1</sup>, A. Duffton<sup>1</sup>, P. McLoone<sup>2</sup>, E. Miguel<sup>1</sup>, S. Currie<sup>1</sup>, C. Paterson<sup>1</sup>

<sup>1</sup>NHS Greater Glasgow and Clyde, The Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; <sup>2</sup>The Institute of Health & Wellbeing, University of Glasgow, Glasgow, United Kingdom

#### Purpose or Objective

Anatomical changes during head and neck radiotherapy (RT) can increase dose to OAR and under dose target volumes. On-treatment dose verification with Image Guided RT can aid the reduction of set-up uncertainties, ensuring planned dose is delivered to the correct structures. Currently a mid-treatment (#16) CT2 scan is compared with the initial planning CT (pCT1) to verify dose distribution. IGRT using cbCT and deformable image registration (IR) may allow the development of a process to reduce the number of patients receiving #16CT2 scans during RT. The study aimed to determine the suitability of Velocity<sup>TM</sup> Software in creating synthetic CT (sCT) images for mid-treatment dose verification, in patients receiving RT for locally advanced SCC of the oropharynx.

#### Material and Methods

20 patients treated with VMAT, 65Gy in 30#s, underwent weekly cbCT scans #s 1, 6, 11, 16, 21 and 26, post-treatment. Image registration between the pCT1 and cbCTs was undertaken and the structure set duplicated to the cbCTs. Within Velocity<sup>TM</sup> the pCT1 was deformed with the weekly cbCT volumes, and re-sampled to create a new primary sCT volume, which had the unit values of the pCT1 volume. IR between the cbCT and sCT1 was performed and the structures applied to the sCT volumes. VMAT #16sCT1 plans were re-calculated in Eclipse<sup>TM</sup> applying the pre-set values of the original plan optimisation. #16sCT2 verification plans were generated by the #16cbCT being deformed with the mid-point #16CT2, to compare plan

differences at the same point in the treatment course. The #16sCT1 plans were also compared with #16CT2 plans. pCT and sCT plans were compared for equivalent dose and fractions.

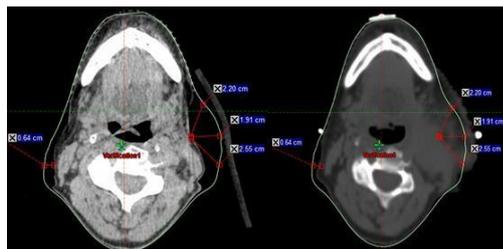

**Results**

D95% to PTV1 was visually comparable between CT and sCT plans. There were no statistically significant differences in the mean cumulative dose difference between sCT and pCT plans for any of the OAR, at the weekly intervals (p<0.05). The #16sCT2 verification plans were comparable with the CT2 verification plans, with no statistically or clinically significant differences in the mean doses between the planning structures (Table 1). There were no statistically or clinically significant differences in the maximum dose to brainstem (p=0.19) or spinal cord (p=0.51) detected between the #16sCT1 and CT2 plans. Mean dose difference between the #16sCT1 and #16CT2 plans for brainstem was 4cGy (SD5.0) and spinal cord 0cGy (SD3.6). Where large contour changes arose through weight loss and mass reduction, visible air gaps between the body structure and skin surface were illustrated on cbCT and Velocity™ overestimated the soft tissue distortion (Figure 1). This occurred where gaps >1-1.5cm were visible.

Table 1: Mean dose (cGy) differences between #16sCT2 and CT2 at fraction 16

PRV Brainstem:	Mean (cGy)	95% Conf. Interval	
Dose sCT	133.0	120.8	149.3
Dose pCT	135.3	120.8	149.8
Difference	-0.2	-4.1	3.7
			p=0.990
PRV Spinal Cord:	Mean	95% Conf. Interval	
Dose sCT	186.4	184.5	188.3
Dose pCT	185.1	184.0	186.2
Difference	1.3	-0.2	2.8
			p=0.409
Contralateral PG:	Mean	95% Conf. Interval	
Dose sCT	88.4	74.9	101.9
Dose pCT	88.9	75.0	102.9
Difference	-0.5	-3.2	2.2
			p=0.70
Ipsi-lateral PG:	Mean	95% Conf. Interval	
Dose sCT	49.3	40.0	58.9
Dose pCT	47.8	39.3	56.3
Difference	1.6	-0.6	3.9
			p=0.1441
PTV1	Mean	95% Conf. Interval	
Dose sCT	217.9	216.7	219.1
Dose pCT	217.9	216.2	219.6
Difference	-0.0	-1.1	1.0
			p=0.9830

Figure 1: Overestimation of tissue by Velocity™

**Conclusion**

It appears feasible for sCTs to be used for dose calculation within Eclipse™ for select patients. Where weekly cbCT indicates large contour changes, a mid-point #16CT2 scan would be recommended. The process may reduce the number of repeat #16CT2 scans required during RT.

**OC-0307 Feasibility of cardiac sparing in isotoxic dose escalated radiotherapy for NSCLC**

L. Turtle<sup>1</sup>, A. Willett<sup>2</sup>, J. Leadbetter<sup>1</sup>, M. Brada<sup>3</sup>, J. Fenwick<sup>3</sup>

<sup>1</sup>Clatterbridge Cancer Centre NHS Foundation Trust, Radiotherapy, Wirral, United Kingdom; <sup>2</sup>Clatterbridge Cancer Centre NHS Foundation Trust, Physics, Wirral, United Kingdom; <sup>3</sup>University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom

**Purpose or Objective**

Heart dose-volume constraints used in the planning of NSCLC radiotherapy have not changed greatly in the past two decades, despite increasing evidence that there may

be an association between heart irradiation and decreased survival following treatment. Consequently heart constraints have easily been met in recent trials of dose escalated concurrent CRT for NSCLC, such as the phase I/II isotoxic IDEAL-CRT study in which prescribed doses were the highest possible between 63 and 73Gy while meeting several normal tissue dose constraints. We have therefore carried out a planning study to determine the extent to which heart doses can be reduced without diminishing plan quality, in particular target coverage. Specifically, we investigated the feasibility of reducing mean heart doses, and the volume of left atrial wall receiving doses in excess of 63Gy, both of which have been associated with survival.

**Material and Methods**

20 NSCLC patients planned using 4D-CT were selected for this study (IIIA (n=12) and IIIB (n=8), with an even number of left and right sided tumours), and re-planned following the IDEAL-CRT protocol using a VMAT technique. We identified new target levels for mean heart dose (MHD) and the volume of left atrial wall (LAW) receiving ≥ 63Gy (V<sub>LAW63</sub>). These levels are listed in Table 1 as ambitious, moderate and basic, and were identified from the 20<sup>th</sup>, 50<sup>th</sup> and 80<sup>th</sup> percentiles of treated values reported in related trials. Patients were then re-planned, more highly prioritising heart and LAW dose constraints, and determining the extent to which heart and LAW irradiation could be reduced while still meeting the IDEAL-CRT protocol target dose coverage levels (PTV V98 > 90%; CTV V99 > 95%) and dose constraints on other normal tissues.

**Results**

Table 1 shows numbers of patients (n) achieving the ambitious, moderate and basic levels of the (a) V<sub>LAW63</sub> and (b) MHD constraints, following baseline IDEAL-CRT planning and again after tightening of the V<sub>LAW63</sub> and MHD constraints while continuing to meet all other IDEAL-CRT dose-constraints. After routine IDEAL-CRT planning, 8 patients met the ambitious level for V<sub>LAW63</sub>; however after prioritising constraints on LA Wall irradiation the ambitious level could be achieved for 19/20 patients. Similarly after routine IDEAL-CRT planning the ambitious level for MHD was met for only 3 patients, and 5 failed to meet the basic level; but after prioritising reductions in MHD, the ambitious level was achieved in 8 patients and none failed to meet the basic level.

Table 1a

	V <sub>LAW63</sub> Constraint				
	Constraint Level	Ambitious	Moderate	Basic	Failed
		0%	≤2.2%	≤20%	>20%
	Prescribed Dose (Gy)				
	Median [range]				
IDEAL Baseline	68.8 [63, 73]	n=8	n=8	n=4	n=0
Tighter V <sub>LAW63</sub> planning	68.8 [63, 73]	n=19	n=1	n=0	n=0

Table 1b

	Mean Heart Dose Constraint				
	Constraint Level	Ambitious	Moderate	Basic	Failed
		≤5Gy	≤11Gy	≤20Gy	>20Gy
	Prescribed Dose (Gy)				
	Median [range]				
IDEAL Baseline	68.8 [63, 73]	n=3	n=9	n=3	n=5
Tighter MHD planning	68.8 [63, 73]	n=8	n=8	n=4	n=0

**Conclusion**

By setting more demanding and more highly prioritised heart dose constraints, MHD and LAW doses can be substantially reduced while continuing to meet the target coverage and normal tissue constraints of the IDEAL-CRT protocol, potentially improving survival.

**PV-0308 MRI based radiomics improves prognostic assessment in soft tissue sarcoma patients**

J. Peeken<sup>1</sup>, A. Ott<sup>2</sup>, M.B. Spraker<sup>3</sup>, D. Münzel<sup>4</sup>, M. Devecka<sup>1</sup>, A. Thamer<sup>1</sup>, M.A. Shouman<sup>1</sup>, F. Nüsslin<sup>1</sup>, N.A. Mayr<sup>3</sup>, M.J. Nyflot<sup>3</sup>, S.E. Combs<sup>1</sup>

<sup>1</sup>Klinikum rechts der Isar- Technical University of Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Technical University of Munich, Institut für Medizinische Statistik und Epidemiologie, Munich, Germany; <sup>3</sup>University of Washington, Department of Radiation Oncology, Seattle, USA; <sup>4</sup>Klinikum rechts der Isar- Technical University of Munich, Department of Radiology, Munich, Germany

**Purpose or Objective**

Multimodal therapy involving surgical resection and radiotherapy (RT) is regularly performed in patients with high-grade soft tissue sarcomas (STS) of the extremities and other anatomic sites. While local progression-free survival (LPFS) is high, distant progression-free survival (DPFS) and overall survival (OS) remain comparably low. In this work, we sought to determine whether radiomic analysis of multiparametric MRI carries a prognostic benefit for pre-therapeutic individual risk assessment.

**Material and Methods**

Fat-saturated T2-weighted sequences (T2FS) and contrast-enhanced T1-weighted fat-saturated (T1wFSGd) sequences were collected from two independent retrospective patients cohorts from the Technical University of Munich (TUM: 73 patients) and the University of Washington (UW: 136 patients). Patient records were assessed for demographics, staging and therapy information. After preprocessing, 2052 radiomic features were extracted. Features with a low correlation between a set of independent segmentations were excluded. For feature reduction and model building to predict OS, DPFS and LPFS the least absolute shrinkage and selection operator (LASSO) method was applied to the TUM cohort. External validation was performed on the UW cohort.

**Results**

The LASSO algorithm selected 10, 2, and, 5 features to predict OS, DPFS and LPFS using T1wFSGd-derived radiomic features. Prediction of OS and LPFS achieved better performances (OS: C-index: 0.80 (95% confidence interval: 0.68-0.92), LPFS: C-index: 0.81 (0.66-0.95)) than of DPFS (C-index: 0.65 (0.55-0.75)). All three models showed lower but significant performance in the validation set (OS: C-index: 0.66 (0.56-0.75), LPFS: C-index: 0.65 (0.54-0.77), DPFS: C-index 0.58 (0.50-0.67)). A clinical model performed better for OS (C-index: 0.74 (0.65-0.83)) and DPFS (C-index: 0.70 (0.62-0.79)) but similar for LPFS (C-index: 0.65 (0.53-0.77)) in the validation set. In multivariate cox-regression models accounting for age, grading and TNM staging, the radiomic scores of OS (HR=2.3, p=0.003) and LPFS (HR=3.7, p=0.007) were significantly associated and improved total model performance up to C-indices of 0.78 (0.68-0.87) and 0.69 (0.57-0.80), respectively. A model combining age and AJCC TNM staging groups with the radiomics scores showed a similar performance. T2FS-based radiomic phenotypes showed overall lower prognostic capabilities (validation set: OS: C-index: 0.61 (0.50-0.72), LPFS: C-index: 0.58 (0.45-0.72), DPFS: C-index: 0.57 (0.44-0.66)). Combining both MRI sequences did not effect an incremental benefit.

**Conclusion**

We first show that a T1-based radiomic phenotype is able to improve prognostic assessment above clinical staging and independent of the T2-based radiomic phenotype for OS and LPFS. As consequence, the radiomics analysis can be simplified by focusing on the T1wFSGd sequence. Such a radiomic phenotype may help to personalize sarcoma therapy above the current clinical staging system.

**PV-0309 Pretreatment ADC does not predict local recurrences in head and neck squamous cell carcinoma**

B. Peltenburg<sup>1</sup>, J. Driessen<sup>2</sup>, J. Vasmel<sup>1</sup>, R. De Bree<sup>3</sup>, C. Terhaard<sup>1</sup>, M. Philippens<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands; <sup>2</sup>UMC Utrecht, Otorhinolaryngology, Utrecht, The Netherlands; <sup>3</sup>UMC Utrecht, Head and Neck Surgical Oncology, Utrecht, The Netherlands

**Purpose or Objective**

In head and neck squamous cell carcinoma, pretreatment identification of radio-insensitive tumors would affect treatment planning. ADC has been reported to be a predictor of local recurrence. However, correction for known clinical parameters such as tumor volume has rarely been performed. The aim of this study is to find the added value of ADC to tumor volume in predicting local recurrence.

**Material and Methods**

This retrospective cohort study included 217 patients with T2-T4 oral cavity, oropharyngeal, laryngeal or hypopharyngeal squamous cell carcinoma. All patients were treated with (chemo)radiotherapy, prior to treatment an MRI examination was performed. The tumor delineation procedure was semi-automatic. First, a seed point was placed in the tumor on the axial DW-MRI with the highest available b value (800 or b1000 s/mm<sup>2</sup>) and with a maximum intensity threshold of 50% the tumor was segmented. The delineation was transferred to the ADC map and high intensity areas at the edges of the segmentation were manually removed. The variables obtained from this segmentation were median ADC and total volume. The predictive effect of the variables on local recurrence was analyzed in univariable and multivariable regression.

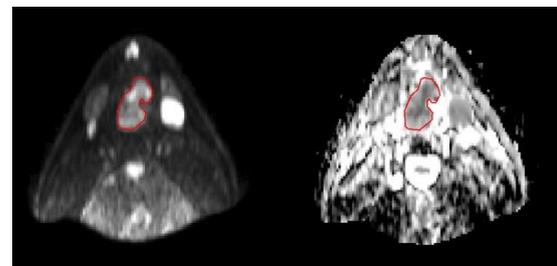

**Results**

Univariable analysis showed no significant correlation between tumor ADC and local control within three years after (chemo)radiotherapy. However, tumor volume was predictive for local recurrence. Multivariable cox regression including ADC and volume showed that tumor volume was an independent predictor of local recurrence with a hazard ratio of 1.032 (CI95% 1.020 - 1.044). ADC was not an independent predictor of local recurrence.

**Conclusion**

ADC has no added value in predicting local control in patients with HNSCC. Tumor volume, however, is predictive of recurrence.

<sup>3</sup>Università Cattolica del Sacro Cuore, Istituto di Radiologia, Roma, Italy ;  
<sup>4</sup>Fondazione Policlinico Universitario A.Gemelli IRCCS, U.O.C. Radioterapia Oncologica- Dipartimento di Diagnostica per immagini- Radioterapia Oncologica ed Ematologia, Roma, Italy

### Purpose or Objective

Magnetic Resonance Imaging (MRI) is a complex and extreme versatile imaging technique. This may potentially jeopardize the generalizability of radiomics of images acquired with different field strengths and scan protocols. Aim of this study was to develop a generalized radiomics model for predicting pathological complete response (pCR) after neoadjuvant chemo-radiotherapy (CRT) in locally advanced rectal cancer (LARC) patients (pts) using pre-CRT T2-weighted (T2-w) images acquired at a 1.5 T and a 3 T scanner.

### Material and Methods

In two institutions 195 patients were scanned with a T2-weighted imaging protocol. In institution A 142 patients were scanned on a 1.5 T MR scanner (GE Signa Exite, Little Chalfont, United Kingdom) whereas in institution B 59 pts were scanned on a 3-T MR-scanner (Philips Medical System, Eindhoven, The Netherlands).

The heterogeneity between the two cohorts of pts was evaluated in terms of Wilcoxon Mann Whitney (WMW) and Pearson's  $\chi^2$  test.

Gross Tumor Volumes (GTV) were delineated on the MR images and all the images were resampled to a fixed spatial planar resolution of 0.7x0.7 mm<sup>2</sup> before to perform features extraction.

A total of 225 radiomic features belonging to four families (fractal, statistical, textural and morphological features) were extracted, applying two image filters (Laplacian of Gaussian (LOG) and Intensity Based (IB)). Features were standardized with Z-score normalization and an initial feature selection was carried out using WMW test: the most significant features at 1.5 T and 3 T were selected as main features.

Several logistic regression models combining the main features with a third one selected by those resulting significant in both datasets were elaborated and evaluated in terms of Area Under Curve (AUC) of the Receiver Operative Curve (ROC).

Features that combined together maximised the AUC value and minimised the Aikake Information Criteria (AIC) were selected. A 10-fold cross validation was repeated 300 times to evaluate the model robustness.

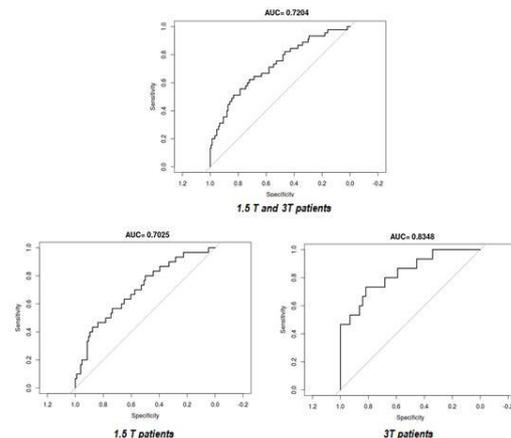

### Results

Table 1 reports the clinical characteristics: no statistical difference was observed between the two cohorts of patients demonstrating matched populations.

Table 1. Patients (pts) characteristics and descriptive statistics of variables in the cohort of 1.5 T and 3T patients. For statistical test were used the Pearson's  $\chi^2$  test ( $\chi^2$  test) for categorical variables and the Mann-Whitney Test (MW test) for continuous ones.

Patient Characteristics		1.5 T pts		3 T pts		p-values of differences		
		Mean	Range	Mean	Range	$\chi^2$ test	MW test	
Age	M	64	28-84	63	40-79	-	0.57	
	F	61.9	43-80	64	49-76	-	0.69	
Age (overall)		63.0	28-84	63	40-79	-	0.87	
Clinical Characteristics		N	%	N	%	$\chi^2$ test	MW test	
Response	pCR	30	22	15	25	0.74	-	
	not pCR	106	78	44	75			
Stage	cT	3	89	65	49	83	0.13	-
		4	47	35	10	17		
	cN	0	6	4	2	3	0.44	-
		1	43	32	5	8		
	2	87	64	52	88			

Three features were selected based on their performance: maximum fractal dimension with IB=0-50, energy and grey level non uniformity calculated on the run length matrix with IB=0-50. Figure 1 reports the ROC curves of the model: the AUC of the model tested on the whole dataset after cross-validation was 0.72, while 0.70 and 0.83 were obtained when only 1.5T and 3T patients were respectively considered.

### Conclusion

A MR radiomics prediction model for pCR after neoadjuvant therapy in locally advanced rectal cancer was developed. The model showed good performance, even when data from patients scanned on 1.5T and 3.0T were merged. This shows that magnetic field intensity variability can be overcome by means of selecting appropriate images features.

Unit, Pavia, Italy; <sup>6</sup>National Centre of Oncological Hadrontherapy CNAO, Diagnostic Imaging Unit, Pavia, Italy

### Purpose or Objective

To estimate a tumour control probability (TCP) model from a group of patients affected by skull-base chordoma and treated with C-ions radiotherapy (CIRT), integrating information from diffusion-weighted (DW-) MRI.

### Material and Methods

From 2013 to 2016, 59 patients were enrolled for CIRT (70.4 GyE total prescribed dose) and 20 of them underwent a pre-treatment harmonized imaging protocol, including DW-MRI scan (b-value=50,400,1000 s/mm<sup>2</sup>). Local control (LC) was clinically assessed at a median follow-up time of 45.8 months as a binary variable, which was found to relate to D<sub>98</sub> (the maximum dose received by at least 98% of the volume) in the target. Survival fraction was defined by the linear-quadratic (LQ) formalism and the probability of killing was assumed to be Poissonian, thus following a classical analytical formulation of the TCP. The linear LQ parameter,  $\alpha$ , was obtained by setting the population TCP to 79%, which corresponds to the LC for all the chordoma patients treated at the facility, and by fitting an average TCP based on D<sub>98</sub>;  $\beta$  was set to 0 to account for the in-vitro experiments. Apparent diffusion coefficient (ADC) maps were computed from DW-MRI and converted into cellular density (cells/cm<sup>3</sup>) by using a relationship found in a histology-based study [1]. Therefore, two types of TCP, one based on ADC (TCP<sub>ADC</sub>) and one based on parameters from the literature (TCP<sub>LIT</sub>), were computed for each patient and their diagnostic performance with respect to LC was evaluated through a ROC curve analysis.

### Results

TCP<sub>ADC</sub> and TCP<sub>LIT</sub> were found to agree with the relation between LC and D<sub>98</sub>, showing a good fitting performance (R<sup>2</sup>=0.981 and R<sup>2</sup>=0.976), and the first being more conservative in estimating patients' TCP values (Fig.1). ROC curves (Fig.2) identified the same sensitivity (0.867) and specificity (0.600) and the same optimal threshold, at which the pointwise confidence bounds at 95% confidence were CI<sub>95%</sub>=[0.539 1] and CI<sub>95%</sub>=[0.625 1] for TCP<sub>ADC</sub> and TCP<sub>LIT</sub>, respectively. This allows to state the significant difference from the random performance but not between the two models.

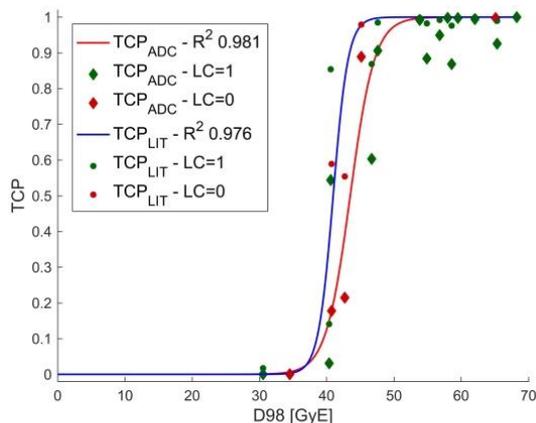

Figure 1 – TCP<sub>ADC</sub> (red) and TCP<sub>LIT</sub> (blue) curves with the respective datapoints (diamonds and dots), for patients with positive (green) and negative (red) LC, with respect to D<sub>98</sub> expressed in [GyE].

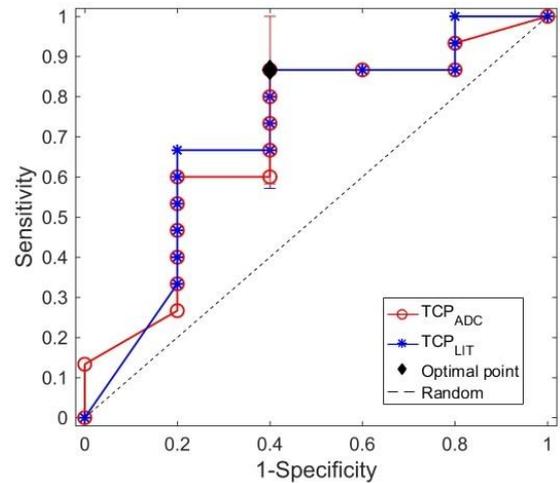

Figure 2 – ROC curves for TCP<sub>ADC</sub> (red) and TCP<sub>LIT</sub> (blue) models, with pointwise confidence intervals reported at the point (black diamond) with the best trade-off between specificity and sensitivity. The line describing random performance is shown as well.

### Conclusion

Two TCP models were obtained for a homogeneous group of patients, as for dose prescription, and they were both found to agree with clinically assessed LC. In particular, DW-MRI has confirmed to be a promising tool to predict the outcome in particle therapy, when coupled to dose information. Nevertheless, a more robust relationship between ADC and tissue microstructure is needed before DW-MRI usefulness can be established.

Oncology, Amsterdam, The Netherlands ; <sup>12</sup>University Medical Center Utrecht, Department of Radiotherapy, Utrecht, The Netherlands ; <sup>13</sup>The Netherlands Cancer Institute, Department of Head and Neck Oncology and Surgery, Amsterdam, The Netherlands

### Purpose or Objective

Radiomics has been shown a promising prognostic biomarker for different tumor types. However, one of the major challenges in radiomics is collection of data from large, preferably multicenter cohorts, which is important for reliable model training. Sharing data between the hospitals is restricted by legal and ethical regulations. Distributed learning is a technique to train models on multicenter data without data leaving the hospitals. In this study we tested the feasibility of distributed learning with radiomics data in the context of overall survival prediction in head and neck cancer patients.

### Material and Methods

Pretreatment, contrast-enhanced CT images were collected from 1005 head and neck cancer patients in 5 different centers Tab. 1. All patients underwent definitive radiochemotherapy. 981 radiomic features were extracted from the tumor region using Z-Rad software implementation. Two years overall survival was chosen as endpoint. For comparison, both feature selection and final classification was performed in a centralized and distributed manner. Five different models were trained, four datasets were always used for training while one of the datasets was left out for validation. The maximum relevance minimum redundancy (MRMR) method was used in the feature selection step. The MRMR was performed over 100 bootstrap samples, but in the distributed setting the selection rate was averaged over the different datasets. The final models for 2y-OS was trained with logistic regression. For the distributed solution the grid binary logistic regression was implemented. In the validation dataset, the receiver operating characteristics were compared between the models trained in the centralized and distributed manner using DeLong test ( $p < 0.05$ ). Additionally, patients were split into two risk groups based on median prediction from the training cohort and the misclassification error rate between the centralized and distributed models was calculated.

	center	A	B	C	D	E
	number of patients	176	441	100	147	141
HPV	positive	58	274	23	8	0
	negative	82	116	77	28	141
	unknown	36	51	0	111	0
subtype	oropharynx	113	441	100	81	63
	hypopharynx	37	0	0	10	47
	larynx	16	0	0	12	31
	oral cavity	10	0	0	44	0

Table 1. Patient characteristic

### Results

In the centralized training, 16-18 features were selected in the MRMR step. 7-11 features were selected in distributed setting, but 78-100% of those features overlapped with features selected centrally. Fig. 1 shows the area under the curve (AUC) for models trained in the centralized and distributed manner. No difference was observed between AUC for models with features selected with two methods, indicating no loss of prognostic power with smaller feature set. Also, final logistic regression coefficients resulted in similar predictions for both methods. No significant difference in AUC was observed. The misclassification rate was 5-12% and considered only patients close to splitting threshold. For the center E model validated poorly, however these was a subgroup of solely HPV negative patients.

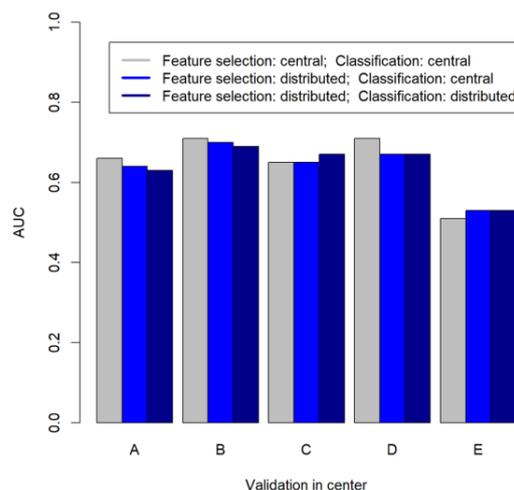

Fig 1. Area under receiver operating characteristic (AUC) for a logistic regression models in the validation cohort. No significant difference was observed between models trained in central and distributed manner.

### Conclusion

We have shown that both feature selection and classification are feasible in distributed manner for radiomics data. This opens new possibility for training more reliable radiomics models by gaining access to larger multi-institutional data.

**PV-0313 Ventilation functional lung volumes obtained from SPECT and 4D-CT do not identify the same voxels.**  
T. Nyeng<sup>1</sup>, L. Hoffmann<sup>1</sup>, K.P. Farr<sup>2</sup>, A.A. Khalil<sup>2</sup>, C. Grau<sup>2</sup>, D.S. Møller<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Medical Physics Department of Oncology, Aarhus C, Denmark; <sup>2</sup>Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark

### Purpose or Objective

Several imaging modalities are available to obtain functional lung (FL) information. The overall lung toxicity may be decreased by reducing dose to the highly functional lung tissue during radiotherapy (RT), at the expense of added dose to the less functional lung regions. Recently, methods using 4D-CT and deformable registration have been shown to produce a map of ventilated lung regions. We have compared 4D-CT derived ventilation volumes with SPECT derived ventilation volumes, generally considered the gold standard for lung ventilation imaging.

### Material and Methods

Seventeen non-small cell lung cancer patients had a 4D-CT scan (10 bins phase sorted), and a ventilation SPECT-CT (V-SPECT) scan prior to RT treatment. For each patient, the total lung volume ( $V_{LUNG}$ ) was delineated on the exhale phase of the 4D-CT (4D-ex) and on the CT-part of the V-SPECT. The inhale and exhale phases of the 4D-CT were deformably registered using a free form intensity based deformable registration algorithm (DRA) (MIMv6.7) and the Jacobian determinant of the deformation matrix was used to segment expanding regions within the  $V_{LUNG}$ . The best ventilated third of the lungs ( $V_{FL-4D}$ ) was segmented and transferred to the 4D-ex. The best ventilated third of the lungs as defined using the V-SPECT ( $V_{FL-SPECT}$ ) was also segmented. The V-SPECT was then deformably registered to the 4D-ex, using the same DRA.  $V_{FL-SPECT}$  was propagated to the 4D-ex and the two FL volumes were compared in terms of overlap fraction (OF) with respect to  $V_{FL-SPECT}$ ,  $(V_{FL-SPECT} \cap V_{FL-4D}) / V_{FL-SPECT}$ . The fraction of the total lung volume indicated as inferiorly functional by both methods,  $V_{non-FL-SPECT}$  and  $V_{non-FL-4D}$ , was calculated as  $(V_{non-FL-SPECT} \cap V_{non-FL-4D}) / V_{LUNG}$ .

**Results**

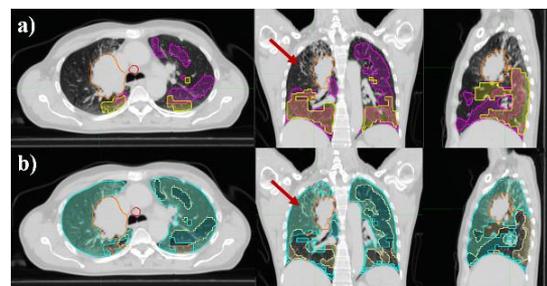

The employed 4D-CT phases were of an acceptable quality. A few patients had breathing motion artefacts close to the diaphragm. The DRA performed well in regions of reasonable image contrast. Some patients with very low contrast lung regions showed several deformation artefacts influencing the FL segmentation especially near the diaphragm. The V-SPECT segmentations also often indicated regions near the diaphragm. The  $V_{LUNG}$  varied widely, with a median volume [range] on the 4D-ex of  $3159\text{cm}^3$ [2093-5446] (see Table1). The two segmented FL volumes for each patient were comparable in size, with a median difference between the two volumes ( $V_{FL-SPECT}-V_{FL-4D}$ ) of  $33\text{cm}^3$ [-80-142] (see Figure 1a). The median OF of the two volumes was 38%[27%-69%]. The volume of lung indicated as inferiorly functional by both methods, corresponded to a median 47%[42-58] of  $V_{LUNG}$  (see Figure1b).

**Conclusion**

The ventilation FL segmentations obtained using 4D-CT and V-SPECT did not identify the same lung voxels. However, though the overlap of the two FL volumes was low, the two methods indicated the same general areas as inferiorly functional. It is possible that the 4D-CT ventilation FL segmentations may highly depend on the quality of the 4D-CT scans and the quality of the deformation in low contrast areas.

**Table 1:** Functional lung (FL) volume statistics for all 17 patients. All volumes are measured on the 4D-CT exhale phase. The FL volume difference is calculated relative to the V-SPECT FL volume. The overlap and union of the FL volumes are denoted FL overlap and FL union respectively. The inferiorly functional lung volume (nonFL) is the total lung volume minus FL union, relative to the total lung volume. The overlap fraction is  $(V_{FL-SPECT} \cap V_{FL-4D}) / V_{FL-SPECT}$ .

**Figure 1.** Orange = GTV tumour; Red = GTV lymph node; a) Yellow = FL as defined by ventilation SPECT-CT; Magenta = FL as defined by 4D-CT. The two methods do not define the same voxels and the OF is 0.43 for this patient. b) Cyan = Lung volume minus SPECT-CT FL; Sand = Lung volume minus 4D-CT FL. The large contiguous area in the top right lung (red arrow) is indicated by both methods as inferiorly-functional. The total volume indicated as non-functional by both methods, corresponds to 49% of the total lung volume for this patient.

**PV-0314 Machine learning helps identifying relations and confounding factors in radiomics-based models**  
 A. Traverso<sup>1,2</sup>, M. Kazmierski<sup>1</sup>, L. Wee<sup>1</sup>, A. Dekker<sup>1</sup>, M. Welch<sup>2</sup>, A. Hosni<sup>3</sup>, D. Jaffray<sup>2</sup>, A. Hope<sup>3</sup>

<sup>1</sup>Maastricht Radiation Oncology Maastricht Clinic, Radiotherapy, Maastricht, The Netherlands; <sup>2</sup>Princess Margaret Cancer Centre, Radiation Physics, Toronto, Canada ; <sup>3</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada

**Purpose or Objective**

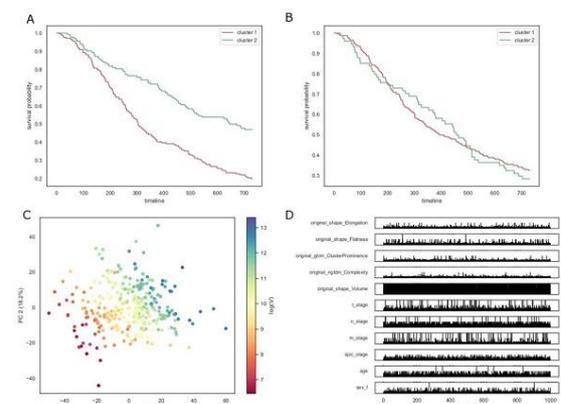

Imaging biomarkers derived from computed tomography (CT) scans (“radiomics”) have been used to generate predictive models for clinical outcomes such as overall survival (OS) following radiation therapy. Models based on imaging features have been shown to achieve similar performance to traditional models based on semantic features (e.g. tumor volume and staging). However, several challenges remain including: generalizability and reproducibility of radiomics-based models, risk of overfitting due to high number of model covariates, and strong correlations between features and clinical variables. These issues limit usage of radiomics-based prediction models in decision support systems. In our study, we applied unsupervised and supervised learning techniques to investigate the relationships between radiomics features, clinical features, and clinical outcomes with a special focus on the relationship between radiomics features and tumor volume.

**Material and Methods**

We used two publicly available datasets: 420 Non Small Cell Lung Cancer patients and 130 Squamous Cell Carcinoma oropharynx patients. CT scans, manually delineated GTV (Gross Tumor Volumes), clinical variables were available. Radiomics features were extracted from GTVs using the open source Pyradiomics library. Hierarchical clustering was used to discover groups of patients with similar radiomic signatures. Dependencies between radiomics features and tumor volume were evaluated with the Spearman concordance correlation coefficient ( $\rho$ ). Overall survival was compared between clusters using Kaplan-Meier analysis. Tumor volume distributions were also compared. Bootstrap-based methods were used to evaluate the stability and importance of radiomic features in predicting 2-year OS.

**Results**

As shown in Figure1A, it is possible to identify two groups of patients with different OS by using all radiomics features. However, when only using volume-independent features ( $\rho < 0.2$ ) the groups cannot be distinguished (1B). PCA (1C) revealed that tumour volume is highly correlated with the first and second dimensional PCA, which explains the higher variability in the data. Semantic features and volume explained most of OS variability in both datasets (1D).

**Figure 1.** 2-year OS in patients clustered by A) full set of radiomic features B) volume-independent features ( $\rho < 0.2$ ). C) shows the patient radiomic signatures projected on first 2 principal components and colored by volume. D) shows the relative importance of covariates in a logistic regression model of 2-year OS across bootstrap resamples (higher bar indicates greater importance in a particular resample).

**Conclusion**

We demonstrated a significant dependence of radiomic features on tumor volume in lung and head & neck CT images. Volume could be reconstructed as a linear combination of even moderately correlated features. Volume-independent features did not show substantial discriminating power. We highlight the importance of accounting for the volume effect when evaluating the predictive performance of imaging biomarkers. Unsupervised and supervised machine learning techniques provide powerful tools to investigate the robustness of radiomics models and relations / redundancies with clinical features.

**PV-0315 A risk assessment method including credible intervals for lymphatic metastatic spread for HNSCC**

B. Pouymayou<sup>1</sup>, O. Riesterer<sup>1</sup>, M. Guckenberger<sup>1</sup>, J. Unkelbach<sup>1</sup>  
<sup>1</sup>Universitätsspital Zürich, Radiation Oncology, Zürich, Switzerland

**Purpose or Objective**

When treating head and neck squamous cell carcinoma (HNSCC) with radiotherapy, a large portion of the CTV aims at a prophylactic irradiation of the lymph node levels (LNL) at risk of harboring microscopic tumor despite the absence of visible metastases on imaging. We present a statistical model to estimate a probability range of ipsilateral microscopic involvement of LNL based on the patient's observed state of tumor progression, i.e. the location of metastases detected in imaging.

**Material and Methods**

We apply Bayesian Networks (BN) to model tumor progression. Each LNL is associated with 2 binary random variables (nodes on Fig. 1), the first corresponding to the hidden microscopic state of involvement and the second to the observable macroscopic state, i.e. whether metastases are detected on imaging for a LNL. The relationship between these two states is given by the sensitivity and specificity of the imaging modality.

The model assumes that tumor cells can spread directly from the primary tumor (PT) to a LNL or from one LNL to the next. The possible spreading paths are given by the graph of the BN and are depicted by arrows on Fig. 1. In this work, we investigate ipsilateral lymphatic spread (levels Ib to IV) for oropharyngeal (T1-T2) tumors. For learning the BN network parameters, we reconstructed a training data set of 103 cases from a published neck dissection series [1]. To assess parameter accuracy, we apply multinomial parameter learning (MPL) [2] to estimate the posterior distribution of parameters. An inference algorithm retrieves the probabilities of microscopic involvement of LNL, given the observed macroscopic involvement.

**Results**

Fig. 1 shows the BN model together with the posterior distribution over the parameters describing lymphatic spread. For example, p02 is the probability of the primary tumor to spread to LNL II, and p23 is the probability to spread from II to III. As a result, we can define credible intervals (CI) similar to confidence intervals. We construct 3 models describing the microscopic spread: one where all the parameters are set to the CI lower bounds, one where they are set to the expectation of the distribution and one where they are set to the upper CI bound. Fig. 2 summarizes the ranges of microscopic risk of involvement for each LNL and different scenarios. For example, even for the most pessimistic model, the probability of microscopic involvement of level IV despite negative finding on imaging does not exceed 10% as long as level III is not harboring macroscopic metastases.

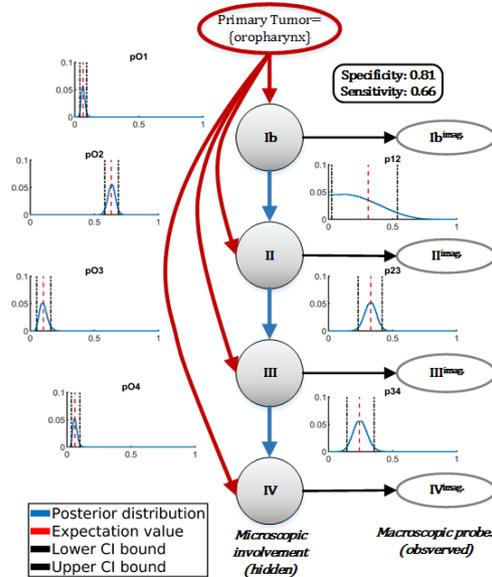

**Conclusion**

Bayesian networks provide a framework for combining patient characteristics with population based patterns of lymphatic progression and thereby guide an individualized

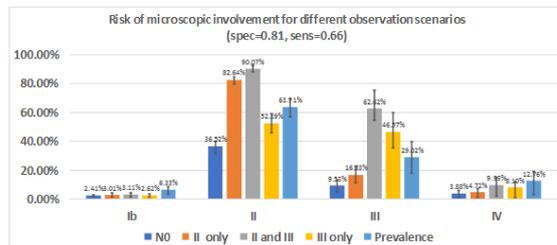

CTV definition. We present a model that addresses the limitations of small size datasets by providing a range of risks of microscopic involvement.

**Figure 1:** Bayesian Network modeling the microscopic ipsilateral spread (level Ib to IV) of an oropharyngeal primary tumor. The posterior distribution of the microscopic spread parameters are reported in blue, the expectation value in red and the boundaries of the credible interval (CI) containing 95% of the probability density in black. The sensitivity and the specificity of the macroscopic (e.g. imaging) are fixed.

**Figure 2:** Probability of microscopic involvement at level II, III and IV given different combinations of macroscopically involved LN levels, assuming a primary tumor in the oropharyngeal region. Percentages are reported for the model built with the parameter expectation values. The lower and upper error bars report the predictions of the models built with the parameter lower and upper CI bounds, respectively. Prevalence refers to the probability of microscopic involvement without any macroscopic observation except for the primary tumor.

**PV-0316 Deep Learning Based Automatic Grading of Colon Cancer in Digitized Histopathology Images**

S. Chen<sup>1</sup>, J. Wang<sup>1</sup>, W. Hu<sup>1</sup>, Z. Zhang<sup>1</sup>, M. Zhang<sup>2</sup>, M. Xu<sup>2</sup>, D. Huang<sup>2</sup>, W. Sheng<sup>2</sup>  
<sup>1</sup>Fudan University Shanghai Cancer center, Radiation Oncology, Shanghai, China ; <sup>2</sup>Fudan University Shanghai Cancer center, Pathology, Shanghai, China

**Purpose or Objective**

The status of tumor differentiation is a crucial reference for cancer diagnosis and prognostication. However, the tumor differentiation grading can be difficult and time-consuming for pathologists. In this study we manage to use deep learning algorithm to automatic grading colon cancer.

**Material and Methods**

The workflow was presented in figure 1. 169 whole slide images (WSI) were enrolled into this study. These data were come from The Cancer Genome Atlas (TCGA). Two-

thousand-three-hundred-ninety rectangle regions were selected and annotated by pathologist with four categories including normal tissue, low, middle and high differentiation tumor. A convolutional neural networks (CNN) model which is similar to Xception model structure was used to training. Briefly, 256 \* 256 pixels' small patches with 40x magnification were extracted from WSI and assigned to their category. In model training, 152(90%) WSI images were used for training and 17 (10%) WSI images were used for validation. The initial learning rate is 1e-4 and the optimization algorithm is Adam. Each epoch has 1000 batches; each batch have 32 patches. The learning rate will decrease 10 times after every 150 epochs. An additional test WSI, which was not enrolled in model training and validation, was selected for demonstration our model's results.

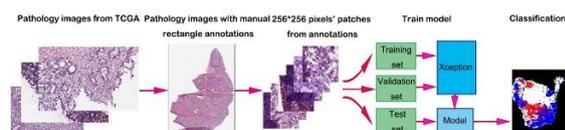

Fig1. Workflow of our current works.

## Results

The results were presented in table 1. The category accuracy of predicting small patch was 81.6% for training set and 79.6% for validation set. The model has consumed 8 days to research this accuracy. Figure 2 demonstrated a results of test WSI.

Table.1 Performance (accuracy) of model for series classes.

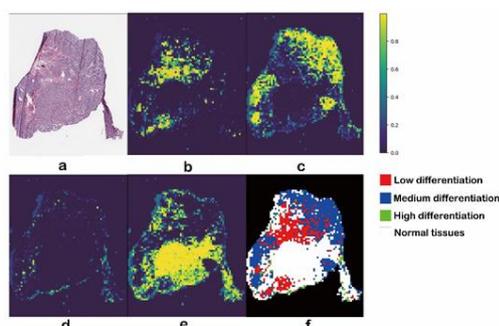

Figure 2. The pathology images and category heatmaps. a. Origin pathology image; b. Low differentiation; c. Medium differentiation; d. High differentiation; e. Normal tissue. f. Result of classification

## Conclusion

Our model can precisely distinguish tumor and normal tissue on small patches. The accuracy for single WSI may further improve by combining these patches results. And deep-learning model can assist pathologists in the detection cancer differentiation. Meanwhile it can be used for prognosis prediction and assist decision making in the future study.

## Purpose or Objective

In case of second ipsilateral breast tumor event (2<sup>nd</sup>IBTE) occurring after primary breast conserving surgery, salvage mastectomy or 2<sup>nd</sup>conservative treatment (2<sup>nd</sup>CT) including breast conserving salvage-surgery and salvage accelerated partial breast re-irradiation (APBrI) with brachytherapy can be performed. We report update results of 2<sup>nd</sup>CT from the database of the GEC-ESTRO Breast Cancer Working Group.

## Material and Methods

Between 2000 and 2014, 331 patients (pts) underwent a 2<sup>nd</sup>CT in 12 hospital/cancer centers from 7 European countries. After salvage-lumpectomy, APBrI was performed using either low (30 - 55 Gy reference isodose) or high dose-rate brachytherapy (28 - 34 Gy). Oncological outcome including 3<sup>rd</sup>IBTE, regional (RFS) or metastasis-free survival (MFS), specific (SS) and overall survival (OS) was analyzed. The belonging to a specific group of the GEC-ESTRO APBI classification (GAC) was also investigated. Simultaneously late side effects and prognostic factors for 3<sup>rd</sup>IBTE were analyzed.

## Results

With a median follow-up of 72 months (range: 67 - 80 months), 143 pts (43%), 140 pts (42 %) and 48 pts (15%) were classified as low (LR), intermediate (IR) and high-risk (HR) respectively. For the whole cohort, 6-year 3<sup>rd</sup>IBTE free survival, RFS, MFS, SS and OS rates were 92.9%, 96.4%, 87.4%, 90.1% and 85.8% respectively. 6-year 3<sup>rd</sup>IBTE free-survival rates for LR, IR and HI were 99.3%, 90.4% and 92% respectively (p = 0,009). 6-year RFS, MFS, SS and OS rates according to GAC are reported in Table 1. In UVA, SBR (1,2 vs 3 - p = 0.008), age (< 50 y vs. <sup>35</sup>50 y - p = 0.002) and GAC (p = 0.009) were considered as significant prognostic factors for 3<sup>rd</sup>IBTE, while, in MVA, SBR (p = 0.046) and GAC (p = 0.01) were the two remaining prognostic factors. In terms of late toxicity, 194 pts (87%) presented G1,2 complications while G<sup>3</sup>3 complication rate was 13%.

6 years	3 <sup>rd</sup> IBTE-FS	RFS	MFS	SS	OS
Whole cohort	92.9	96.4	87.4	90.1	85.8
APBI LR	99.3	94.4	87.2	92.0	87.8
APBI IR	90.4	92.7	89.6	91.8	86.7
APBI HR	92.0	88.9	81.0	80.4	77.8

Table 1: Oncological outcomes for the whole cohort and according to the GEC-ESTRO APBI classification

## Conclusion

In case of 2<sup>nd</sup>IBTE, 2<sup>nd</sup>CT combining re-lumpectomy + APBrI represent a valid therapeutic option in terms of oncological outcome as well as toxicity profile. Patient and tumor characteristics have to be carefully evaluated

while patient information remains crucial for the discussion of treatment choice.

#### OC-0318 10-year clinical and cosmetic outcomes of high-dose-rate brachytherapy for early breast cancer

F. Arcidiacono<sup>1</sup>, F. Trippa<sup>1</sup>, P. Anselmo<sup>1</sup>, M. Italiani<sup>1</sup>, M. Casale<sup>1</sup>, L. Draghini<sup>1</sup>, S. Fabiani<sup>1</sup>, A. Di Marzo<sup>1</sup>, S. Terenzi<sup>1</sup>, E. Maranzano<sup>1</sup>

<sup>1</sup>Radiotherapy Oncology Centre, "S.Maria" Hospital, Terni, Italy

##### Purpose or Objective

In GEC-ESTRO randomised trial accelerated partial breast irradiation (PBI) with high-dose-rate brachytherapy (HDR-BRT) was not inferior to adjuvant whole breast irradiation at 5-year follow-up. The long-term results are lacking in literature. We report 10-year clinical and cosmetic outcomes of PBI with <sup>192</sup>Ir HDR-BRT in early breast cancer patients (pts).

##### Material and Methods

From May 2005 to July 2013, 129 early breast cancer pts were recruited in a phase II trial of exclusive <sup>192</sup>Ir HDR-BRT. Inclusion criteria were: age >40, PS 0-2, unifocal invasive ductal cancer, intraductal cancer component <25%, negative axillary nodes and tumor size ≤2.5 cm. Treatment schedule was 4 Gy twice a day for 4-5 days, up to a total dose of 32 Gy in 8 fractions with a minimum interval between daily fractions of at least 6 hours. Late toxicity was graded according to RTOG/EORTC scoring criteria and cosmetic outcomes according to Harvard criteria (i.e., excellent, good, fair and poor).

##### Results

Median age was 67 years (range, 42-85). There were 11 (8.5%) pT1a, 44 (34%) pT1b, 68 (53%) pT1c and 6 (4.5%) pT2. Estrogenic and/or progestinic receptors were positive in 118 (91.5%) pts. 116 (90%) and 20 (15.5%) patients received adjuvant hormonal therapy and chemotherapy, respectively. Median follow-up was 108 months (range, 8-162). 3(2%) isolated in-field breast relapse occurred 92, 123 and 129 months after HDR-BRT; 1(0.7%) isolated out-field breast relapse occurred 107 months after HDR-BRT. 4(3%) patients developed contralateral breast cancer, another one (0.7%) isolated regional relapse in axillary node and 4(3%) distant progression of disease. 16(12.5%) patients reported a second primary cancer. 5- and 10-year overall survival and cancer specific survival were 95% and 86%, 100% and 100%, respectively. At last follow-up, 105(81%) patients were alive without disease and 4(3%) with systemic disease. 20 (16%) patients died: 10 (8%) for other cancers and 10 (8%) for other causes. Cosmetic outcomes were excellent in 106 (82.5%), good in 12 (9.5%), fair in 8 (6%) and unknown in 3 (2%) pts. Late skin toxicity was registered in 29 (23.4%) pts, grade 1-2 in 28 (22.5%), grade 3 in 1 (0.8%). Late toxicity was significantly related to the skin administered doses (≤ 55% vs. > 55%, P < 0.05).

##### Conclusion

PBI delivered with <sup>192</sup>Ir HDR-BRT in selected breast cancer patients was associated to high local control and survival with excellent cosmetic outcomes overall when skin dose was ≤ 55%.

#### OC-0319 Twelve-year clinical outcomes with APBI with interstitial multicatheter brachytherapy after BCS

<sup>1</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Brachytherapy Department, Gliwice, Poland; <sup>2</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Radiotherapy Planning Department, Gliwice, Poland; <sup>3</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute

of Oncology, Tumor Pathology Department, Gliwice, Poland; <sup>4</sup>Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, III Department of Radiotherapy and Chemotherapy, Gliwice, Poland

##### Purpose or Objective

To report the long-term results, toxicity, and pattern of failure of 481 patients treated with APBI using interstitial multicatheter high-dose-rate brachytherapy (HDR-BT) after breast-conserving surgery in a single institution.

##### Material and Methods

Between July 2006 and September 2018, a total of 481 women with low-risk invasive and in-situ carcinoma after breast-conserving surgery (BCS) were treated with APBI using interstitial multicatheter HDR-BT at our department. The inclusion criteria were: ZUBROD 0 or 1, age ≥50 years, T1-2aN0M0, T≤3 cm, unifocally, invasive carcinoma without neuroinvasion, angioinvasion, a minimal surgical margin of 2 mm or DCIS with a minimal margin of 5 mm, without extensive intraductal component (EIC), positive estrogen receptors.

The total dose was 32 Gy in 8 fractions delivered twice daily with a minimum 6-hour break. The primary endpoint was local recurrence.

##### Results

The median age was 61 years (range 47-86 years). The median follow-up was 55 months (range 1-146 months). In the analyzed group, 262 patients were followed up for 5 years or longer. The mean volume of the PTV was 71.5 cm<sup>3</sup>, with the mean value of its coverage with the prescribed dose (PTV ref) amounting to 94.6%. The PTV mean value was 67.6%, and D90 was 105%. The mean values of key indices were acceptable, with a mean conformity index (COIN) of 0.69 and a mean dose homogeneity index (DHI) of 0.68.

The mean value of the maximum skin dose was 41% of the prescribed dose. The mean value of the ipsilateral lung dose to 2 cm<sup>3</sup> volume was 40.3% of the prescribed dose, and the mean value to 10 cm<sup>3</sup> volume was 30.1%; the maximum dose for ipsilateral lung was 50% on average. The mean maximum dose for the closest rib was 77.8% of prescribed dose.

There was no acute severe toxicity. The treatment was well tolerated. In 19.7% a hematoma following catheter insertion was noted. In 2.1% local inflammation requiring oral antibiotic therapy was noted, but in 22.2% of cases prophylactic antibiotic therapy was given. There was no late severe toxicity, and cosmetic outcome was good. In the whole group of patients, 11 failures (2.3%) were noted: seven local recurrences (1.5%) treated with amputations and four cases (0.8%) of distant metastases. All patients with local recurrence are alive without any symptoms of disease; two patients with distant metastases have died; two are still undergoing therapy.

The 5- and 10-year OS was 94.4% and 83.5% respectively. The 5- and 10-year DFS was 92.3% and 78.6% respectively.

##### Conclusion

APBI with Interstitial Multicatheter High-Dose-Rate Brachytherapy is an effective treatment modality, associated with very low toxicity and a low relapse rate. In our opinion, patient selection criteria should be revised and could likely be extended. Further studies are needed to validate this approach.

<sup>2</sup>Fundación Instituto Valenciano de Oncología, Department of Radiation Physics, Valencia, Spain ;

<sup>3</sup>National Cancer Institute., Department of Radiation Oncology, Budapest, Hungary ; <sup>4</sup>Catalan Institute of Oncology, Department of Radiation Oncology, Barcelona, Spain

**Purpose or Objective**

Accelerated partial breast irradiation (APBI) is a standard treatment for early breast carcinoma after conserving surgery. High dose rate (HDR) with multi-catheter interstitial brachytherapy (MIBT) is used twice a day (3.4Gy x 10, 4Gy x 8 or 4.3Gy x 7 fractions), to a total irradiation time of 4-5 days. We present the preliminary results of the first part of a Phase I-II trial endorsed by the GEC-ESTRO Breast Working Group, using a very accelerated scheme (VAPBI) with HDR-MIBT in 4 fractions, to decrease the total time of treatment to 2-3 days.

**Material and Methods**

The criteria to include patients were the same as the APBI GEC-ESTRO Phase III trial, only invasive carcinomas were included. Between August 2017 and July 2018, 31 patients from three centers, with low risk early invasive breast carcinoma have been treated with 4 fractions of 6.25Gy. The total dose was 25Gy prescribed to the CTV. Ten patients have been implanted perioperatively (32%), during the surgical procedure, and 22 postoperatively using CT or US-guided implantation of plastic tubes. 22 cases (71%) have been treated in two days. Mean age was 64 (51-87). Pathology showed invasive ductal carcinoma in 27 cases, invasive lobular carcinoma 2, tubular carcinoma 1 and colloid carcinoma in 1 case. All were with negative sentinel node, free margins 2mm or greater. Luminal A: 23

cases, Luminal B: 8. Grade 1: 20, G 2:10, G3: 1 case. Mean time between surgery and MIBT was 67 days (39-104) in postoperative cases. Median number of plastic tubes was 13 (range 7-24) implanted in a median of 3 planes (2-5). Regarding the dosimetry, mean V100 was 86cc (19.5-171cc) mean V150 was 24.2cc (6-41cc); mean D90: 105.4% (96-112.4%); mean DNR: 0.29 (0.23-0.41).

**Results**

The technique is the same as used for the GEC-ESTRO Phase III trial, and no differences have been recorded during the implantation and removal. Temporary hematoma developed in 7 cases (5 after perioperative implantations). Pain was referred in one third of cases, well managed with painkillers, and the tolerance was good. No case of infection. With a median follow-up of 7 months, and minimum of three months, slight pigmentation changes (G1) in the entrance of tubes were described in 26%, but with progressive attenuation with longer follow-up. Slight induration or fibrosis (G1) in 16%.

**Conclusion**

VAPBI with MIBT using four fractions of 6.25Gy in two or three days is feasible. No differences have been observed after a median follow-up of six months (minimum three months), compared with the previous experience of the APBI Phase III trial. Acute effects are similar. A longer follow up is needed to evaluate chronic effects. The shorter total time is beneficial for the patients and reduces the workload of the Brachytherapy unit.

**OC-0322 HDR Skin applicator fabrication for clinical cases: handmade vs digitally designed and 3D printed**

S. Nic A Bhaïrd<sup>1</sup>, R. Caines<sup>1</sup>, C. Lee<sup>1</sup>

<sup>1</sup>Clatterbridge Cancer Centre, Department of Physics, Liverpool, United Kingdom

**Purpose or Objective**

Several studies have demonstrated feasibility of digitally designed 3D-printed HDR skin applicators [1-2], but none have systematically compared this process against traditional hand-formed methods. This study compared five clinical hand-formed applicators previously used for treatment to digitally designed 3D-printed applicators retrospectively created for the same cases. Geometric and dosimetric measurements were performed.

**Material and Methods**

The traditional applicators comprised of a thermoplastic shell, hand-formed wax stand-off and catheters for source transfer. These applicators were constructed to meet specifications for skin-catheter distances and catheter-catheter distances. A process was developed to design these applicators digitally in the contouring module of an EBRT treatment planning system (TPS) (Eclipse v13.6, Varian Medical Systems, CA). The thermoplastic shell of the original applicators was used as a base for the 3D printed applicators. Applicator designs were exported and printed locally with the Axium 20 3D printer (Airwolf3D, CA).

All applicators were CT scanned at high resolution and over 3,800 geometric measurements made in the TPS. Skin-catheter and catheter-catheter distances were inspected and for each applicator type the proportion of measurements within a 1 mm tolerance determined.

Treatment planning and delivery was performed for both applicator types according to local protocol. Dosimetry at the centre of each treatment area was verified by TLD.

**Results**

**Skin-catheter distances:** The proportion of geometrical measurements within 1 mm of specification was 0.56 [95% CI: 0.53-0.59] for the hand-formed applicators compared with 0.69 [95% CI: 0.67-0.72] for the 3D-prints (p<0.01, Fig. 1)

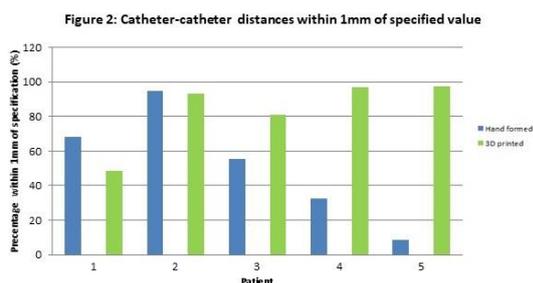

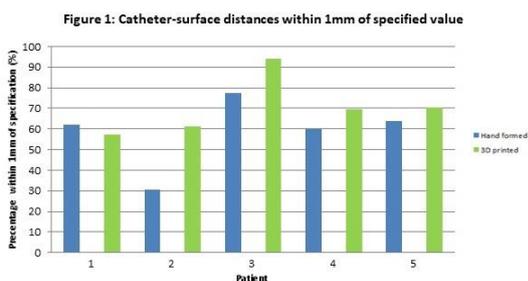

**Catheter-catheter distances:** The proportion of geometrical measurements within 1 mm of specification was 0.58 [95% CI: 0.55-0.61] for the hand-formed

applicators and 0.82 [95% CI: 0.80-0.85] for the 3D-prints ( $p < 0.01$ , Fig. 2)

Dosimetry: TLD measurements for both types of applicators agreed with the expected doses predicted by the TPS within a local tolerance of  $\pm 5\%$ .

#### Conclusion

The applicators made using the digitally designed 3D printing process were more geometrically accurate compared with the applicators made using the current traditional fabrication process. Both types of applicators gave satisfactory dosimetric performance. The 3D-printing process is faster and less labour intensive. The resulting applicators are durable, lightweight, low cost and visually appealing. They can be easily reprinted for teaching or further studies. As a result of this study digitally designed 3D-printed HDR skin applicators will be incorporated into our routine clinical practice.

#### OC-0323 Perioperative interstitial high dose rate brachytherapy for keloids scars

V. Vera Barragam<sup>1</sup>, M. De Juan Marín<sup>2</sup>, S. Blanco Parajón<sup>1</sup>, J. Fernández García<sup>3</sup>, G. Juan Rijo<sup>1</sup>, A.I. Alonso García<sup>1</sup>

<sup>1</sup>Hospital Universitario Central de Asturias, Radiotherapy oncology, Oviedo, Spain ; <sup>2</sup>Hospital Universitario Central de Asturias, Plastic Surgery, Oviedo, Spain; <sup>3</sup>Hospital Universitario Central de Asturias, Physics, Oviedo, Spain

#### Purpose or Objective

The treatment of keloid scars is still a clinical challenge due to their high recurrence rate, which can happen in up to 30% of the cases. The use of radiation therapy combined with surgical excision is considered as one of the most effective treatments. However, there is little consensus among the medical community about the most optimal treatment in terms of dose, fractionation, and type of treatment: external or internal, i.e. brachytherapy. This study evaluates the treatment outcome in terms of local control, as well as from a cosmetic point of view, of keloid

scars treated with perioperative interstitial high dose rate (HDR) brachytherapy.

#### Material and Methods

The patient cohort under study comprised 61 keloids in 51 patients. All keloid lesions were treated with 12Gy in 4 fractions, during 48h, i.e., one fraction every 12h. The treating physician inserted a catheter along the scar during the surgical procedure, which served for the delivery of the subsequent brachytherapy fractions. The lapse of time between surgery and brachytherapy was less than 90 minutes.

Local failure was defined as recurrence of the apparent keloid as well as symptoms at the same location. The median age of the patients was 46 years (20-89 years). Keloids had an average size of 6.3cm and were located on the chest (41%), ear lobe (21%), back (1.6%), and extremities (11.5%). The IBM SPSS v.24 software was used for statistical analysis of quantitative variables (Analysis of Variance, ANOVA test) and qualitative variables (Chi-square test), such as the scar size or patient's race. P-value  $\leq 0.05$  was taken as significant.

#### Results

The recurrence rate, with a median follow-up of 48 months (range 1-96 months), was only of 4.9%, all of them located on the chest. In addition, most patients with successful treatment presented an excellent cosmetic result at the scar location, except some patients (below 20%) for which a small part of the scar remained but no pain, stinging or tissue thickening was reported.

The ANOVA and Chi-square tests showed no significant statistical relationship between the recurrence rate and the race ( $p=0.312$ ), or the size of the scar ( $p=0.525$ ).

Figure 1 illustrates the cosmetic outcome in one of the patients with a keloid scar located in the ear lobe, before (Figure 1.a) and after treatment (Figure 1.b).

#### Conclusion

Perioperative interstitial HDR brachytherapy appears to be a high effective treatment against keloid scars, with a decreased recurrence rate below 5%. All failed treatments happened in the chest, which suggests the investigation of higher dose for this site. The treatment was well tolerated by all patients and did not present significant side effects. The cosmetic results were also excellent and the patients reported great satisfaction after treatment.

#### Award Lecture: Claudius Regaud Award Lecture

#### SP-0325 Is fractionation history?

D. De Ruyscher<sup>1</sup>

*<sup>1</sup>Maastricht Clinic, Radiation Oncology, Maastricht, The Netherlands*

#### Abstract text

Claudius Regaud will mostly be remembered as the father of fractionation and therefore the possibility to spare better normal tissues than tumors. Already in 1906, he hypothesized that X-rays could be used against rapidly growing cells other than gametes, such as cancer. Historical experiments in rams indeed established the concept of fractionation. Regaud was a pathologist who tried to understand the biology of radiation in a real multidisciplinary way.

While even in the earlier days of radiotherapy attempts were made to test hypotheses in pre-clinical models and to understand the underlying biology, increasingly hypotheses were directly applied in patients. Large numbers of patients were exposed to potentially toxic treatments and as there was nor is a comprehensive database, nobody could evaluate the outcome. The standard fractionation scheme for stage III NSCLC, 60 Gy in 2 Gy QD fractions was established in the 1980's, but was already in use for many decades and has largely remained the same, while there have been countless patients who received other doses, fractions sizes and overall treatment times (OTT). Nobody knows what the results are. Accelerated radiotherapy was used since the 1920s, but before an influence on survival was demonstrated, we had to wait for the CHART trials in the 1990s and for level I evidence until 2012. At that time, concurrent chemoradiotherapy had become standard and we and others, without understanding the biology, used the same strategy of acceleration for the latter patients, unfortunately without benefit. Fortunately, improved techniques and integration of molecular imaging lead to less side effects than ever.

Stereotactic radiotherapy (SBRT) truly revolutionized our field, but at some moment, it was used at anatomical sites where it was predicted to be very toxic. Implementation without proper understanding of the underlying biology and prospective studies led to a high incidence of side effects and here again, the absence of a prospective database and the lack of formal testing precludes us to get more insights in the relation between toxicity and treatment and patients parameters.

The technological evolution has overwhelmed the complex biology and its benefit is not assessed properly. Assumptions about gains are in general not supported by reproducible data with dose-escalation and adaptive radiotherapy as a good examples.

Immune treatment is now changing oncology profoundly and we should embrace this evolution. It gives us the platform to investigate the biology thoroughly, not only of photons, but also of protons and to revise fractionation and volumes. This will only work when we work with many other disciplines, perform pre-clinical and clinical trials and establish usable prospective databases. AI will be needed to learn from these networks with countless nodes and to implement the results. AI will also enable to take into account the (forgotten) knowledge of the past, to avoid making the same mistakes.

Fractionation will however remain relevant.

#### Symposium: How to prevent burnout?

---

#### SP-0326 Perspectives on burnout in the medical professions

P. Franco<sup>1</sup>

*<sup>1</sup>University of Turin, Department of Oncology- Radiation Oncology, Turin, Italy*

#### Abstract text

Human beings are able to survive within a given environment as far as they are able to maintain an individual balance (homeostasis), which is constantly challenged by intrinsic and extrinsic causes, also known as stress factors (1). Stress can be seen as a physiological response in the shape of a 'general adaptation syndrome' and can be subdivided into 3 different phases: a) alarm, b) resistance c) exhaust (1). Individual can implement coping strategies in response to stress. They have 2 main goals: changing the situation causing stress and controlling the emotional response to the stressful agent. Certain coping strategies (emotional response) may lead to exhaustion, a final step in which the individual cannot accomplish to re-establish the inner balance. This may lead to the so-called 'Burn-out Syndrome' (BOS), which has been described by Maslach et al in the '90s (2). The terms forwards to a significance implying to burn something to exhaustion, until it is consumed (3). It is considered one of the mostly impacting factor for physical and mental well-being within the working environment. It particularly affects healthcare professionals (4). The three classic presentation clusters are loss of enthusiasm for work (emotional exhaustion), reduced empathy and increased cynism (depersonalisation) and a decreased perception of the meaningfulness of someone's work, finally leading to inefficacy (personal accomplishment) (2,4). Symptoms can be classified into physical (insomnia, lack of energy, back pain, loss of appetite, ulcer, migraine, nausea) and psychological (cynism, irritability, denial of failures, loss of sense of humor, indifference, insecurity, disinterest, indecision, reduction of self-esteem and loss of memory) cluster. BOS is a stress-related syndrome and it is particularly frequent within Oncology professionals and staff (5). The incidence has been shown to be as high as 50-70% (5-7). In team environments, such as in radiation oncology, situations of increased job stress and burn-out can lead to impaired cognitive functioning, increasing the potential for patient harm. BOS for hospital staff include illness, absenteeism, staff conflict, distrust of management, poor coping and substance abuse. Clinical consequences may include medical errors and adverse events, poor prescribing habits, low patients satisfaction and low adherence to physician recommendations (4). Different inherent factors may be related to BOS development. One of the most important is each individual's coping style. Poor coping may lead to impairment in job performance and ineffective coping strategies may lead to a higher likelihood to develop BOS. In general, emotion-oriented coping styles are associated to higher levels of BOS (9). Personality traits may also predispose individuals to develop BOS. Alexithymia and empathy are personality traits. Alexithymia is a psychological construct broadly describing individuals with deficits in emotion processing and awareness (10). Those who score high on measure of alexithymia show difficulty distinguishing emotions from bodily sensations, discriminating between cognition and emotions and describing and communicating emotions to others (11). Empathy is the ability to share and understand another's 'state of mind' or emotion. It is often characterized as the capacity to 'put oneself into another's shoes'. In the healthcare environment, effective emphatic communication enhances the therapeutic effectiveness of the clinician-patient relationship. The Young ESTRO Committee developed the PRO BONO study (PROject on Burn-Out in Radiation Oncology) to explore BOS in the field of radiation oncology and to investigate whether alexithymia and empathy may potentially affect the likelihood for BOS development. The project is also endorsed by the Young Radiation Oncology Group (yROG) of EORTC. The survey was aimed at all radiation oncology professionals and was completely anonymous. This project will provide useful information. Being aware of potential risk factors may help in implementing

protection strategies for radiation oncology professionals more prone to undergo BOS. Participants were asked to provide some general information and fill-in 3 different validated questionnaires (TAS-20, IRI, ProQoL) to investigate alexithymia trait, empathy and to quantify eventual BOS. The PRO-BONO initiative, is a valuable way to address an important issue, to analyze it and to define management strategies for individuals at risk of developing BOS.

#### Purpose or Objective

Burn-out syndrome (BOS) is a stress-related syndrome, particularly frequent within Oncology professionals and staff. It may affect performance within the working environment and impact on individual physical and mental well-being. Personality traits may predispose to develop BOS. Alexithymia is a psychological construct describing deficits in emotion processing and awareness. Empathy is the ability to share and understand another's 'state of mind' or emotion. The PROject on Burn-Out in RadiatioN Oncology (PRO BONO study) was developed to explore BOS in the field of radiation oncology and to investigate whether personality traits such as alexithymia and empathy may potentially affect the likelihood to develop BOS.

#### Material and Methods

An anonymous survey was conducted online using the web-based platform Survey Monkey (www.surveymonkey.com), addressed to ESTRO members, reached out via e-mail, social media or through the collaboration of National Societies. All professionals within ESTRO were involved (radiation oncologists, medical physicists, radiation therapists, radiobiologists). Participants were asked to provide specific individual and professional information and fill-in 3 different validated questionnaires to investigate alexithymia trait, empathy and to quantify BOS, namely the Toronto Alexithymia Scale (TAS-20), the Interpersonal Reactivity Index (IRI) and the Professional

Quality of Life Scale (ProQoL). Answers were collected and results analysed by the Young ESTRO Committee.

#### Results

The survey is still open for response. So far, a total of 1958 ESTRO members took part, from 94 different countries and 5 continents. Male were 56%, female 44%. Most of respondents were radiation oncologists (53%), while radiation technologists were 26%, medical physicists 20% and radiobiologists 1%. As for educational level of respondents, most of them were MD (44%), MSc (18%) or BSc (13%), being in the field of radiation oncology for < 5 year (28%) or between 11 and 20 years (27%). Up to 49% of them had on-call duties. Most of them (84%) pointed out that medical practice affected their private life. They felt valued by their patients in 88% of cases (not enough:12%) and by their supervisor in 72% (not enough:28%). Up to 32% had a 1-year leave from work. Preliminary results using Person correlation coefficient (PCC) showed a significant correlation (PCC=0.82) between a higher score (>61) on TAS-20 and a higher score (>57) on the burn-out subscale of the ProQoL questionnaire. A higher score for Empathy Concern within the IRI questionnaire was also significantly correlated (PCC =0.79) to higher burn-out on ProQoL.

#### Conclusion

The PRO BONO study provided an overview on BOS, alexithymia and empathy in radiation oncology professionals worldwide. Personality traits such as alexithymia and empathy seem to be correlated to the likelihood to develop BOS. After the upcoming end of the study, detailed analysis on subset population and individual domains within administered questionnaires will better clarify the scenario.

#### SP-0328 Report back from ESTRO mobility grants clinical: SRS and SBRT in the management of oligometastatic disease

I. Zumbadze<sup>1</sup>

<sup>1</sup>Research Institute of Clinical Medicine, Department of Radiation Oncology, Tbilisi, Georgia

#### Abstract text

Concept of oligometastatic state, proposed by Hellman and Weichselbaum, implies that "there exists a subset of patients with limited volume metastases in whom treatment of oligometastatic sites impacts survival". Randomized studies have demonstrated that surgical treatment of oligometastatic lesions can improve survival. Stereotactic body radiotherapy (SBRT) and Stereotactic Radiosurgery (SRS) has emerged as an attractive alternative or as an adjuvant to surgical resection. In this report we would like to review: the results of ablative radiotherapy for the intracranial and extracranial (lung, liver, spine) oligometastases; recent attempts to identify the patients with limited number of metastases who mostly benefit from aggressive local treatment; data addressing fractionation regimens in regard to feasibility and safety of ablative radiotherapy for various localization, volume and size of metastases and short summary of my experience at the University Hospital Turin. Aiming to develop the concept of stereotactic body radiotherapy and radiosurgery and introduce it in the clinical practice, we have set up collaborations and engaged discussion with Georgian colleagues. This process was enhanced by my visit to the department of Prof. Umberto Ricardi thanks to the mobility grant. Sharing the expertise of this department and inspiring our self from the irradiation protocols developed by Prof. Umberto Ricardi and his group, now we are treating this group of patients with oligometastatic disease and keeping institutional registry. The accumulating clinical data could be used in future to draw conclusions for safe and beneficial implementation of the existing guidelines.

#### SP-0329 Modelling Head and Neck Radiotherapy outcomes using radiomics biomarkers

P. Kalendralis<sup>1</sup>, Z. Shi<sup>1</sup>, J. Van Soest<sup>1</sup>, A. Ryczkowski<sup>2</sup>, J. Kazmierska<sup>2</sup>, J. Malicki<sup>2</sup>, A. Dekker<sup>1</sup>, L. Wee<sup>1</sup>

 Biology- Maastricht University Medical Centre+- Dr  
 Tanslaan 12- 6229et- Maastricht- The Netherlands,  
 Maastricht, The Netherlands ; <sup>2</sup>Radiotherapy Department  
 li- Greater Poland Cancer Center- Poznan- Poland,  
 Radiotherapy Department, Poznan, Poland

#### Abstract text

**Introduction:** Predictive models of radiotherapy (RT) treatment outcomes for head and neck cancer (HNC) patients have clinical value in personalized treatment. Presently, few externally validated models for HNC tumour control and treatment-related toxicity exploit the potential of quantitative image-derived biomarkers (i.e. radiomics) to individually characterize the tumor phenotype. Our primary hypothesis is that adding radiomic features from Planning CT scans improves predictive performance of models for Overall Survival, Xerostomia and Dysphagia, which can be tested by independent external validation between two RT centres. **Materials and methods:** A “personal health train” architecture

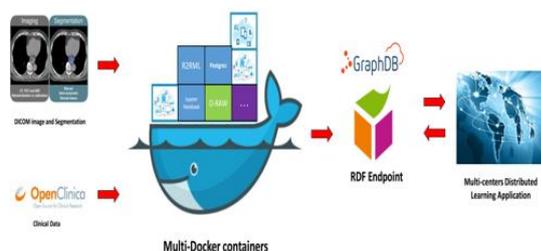

(<https://www.youtube.com/watch?v=mktAtHmy-FM> ) is implemented to connect Maastricht Clinic (Maastricht, Netherlands) and the Greater Poland Cancer Centre (GPCC-Poznan, Poland). The workflow of PHT is shown in Figure-1. These centres will independently develop and validate multi-variate prediction models on each other’s patient data without transferring any subject-level information. This methodology could maximally preserve medical data privacy because no individually-identifiable records are shared among centres. Instead, distributed machine learning algorithms shuttle between data sites to fit statistical models of outcome. The data from the two participated centres consist of retrospective clinical observation records and RT Computed Tomography (CT) planning scans approved for research from the Institutional Review Boards (IRBs) of each centre.

#### Results

We do not have preliminary results from our study as the workflow will be in progress during the visit to the GPCC. We aim to have local processing of retrospectively collected clinical and imaging data of H&N patients in combination with the development of a clinical prediction model in Poznan’s data performing distributed validation in MAASTRO’s dataset. Furthermore, as an extension of our results we are planning to distribute the final fitted models to a third RT centre for fully independent external validation of the models.

#### Conclusion

The collaboration between Maastricht and GPCC will potentially increase the sample size for model development, and provide essential alternative cohorts for fully independent external validation of prediction models. In addition, Maastricht’s technical infrastructure expertise establishes in return a long-term collaboration in Poland aiming to establish an innovative clinical research into the future.

#### SP-0330 Science slam: To breathe or not to breathe. ESTRO Mobility Grant report

S. Pracic<sup>1</sup>

<sup>1</sup>University Medical Centre Maribor, Department of Oncology, Maribor, Slovenia

#### Purpose

To learn about Voluntary Deep Inspiration Breath Hold radiotherapy technique.

#### Abstract text

Royal Marsden Hospital is one of the first hospitals which has implemented voluntary Deep Inspiration Breath Hold Technique (vDIBH) in a daily clinical practice. Their approach to this technique is unique, very simple and with no additional costs or investments in additional equipment, and therefore it is possible to copy their work onto our Department.

My primary goal was to learn how to train patients to breathe during the CT simulation and to learn the procedure of treatment delivery and treatment verification. It was also important to see the whole procedure and do some practical work for better understanding.

At the Pre-treatment Unit, I worked together with their radiographers during the CT simulation. Training the breathing technique with patient was of great benefit to further understand the principle of vDIBH. At the Treatment Unit, I was able to see what treatment delivery looks like in clinical practice. Working together with experienced radiographers and with patients, I was able to strengthen and further develop my knowledge gained through CT simulations, and better understand patient setup, treatment delivery and verification. I was also able to discuss outcomes of this technique, patient experience and satisfaction.

In a two week period, it was possible to see enough clinical cases and to overcome the challenges of such a technique.

#### SP-0331 Gut microbiota SCFAs modulate dendritic cell antigen presentation and impact radiotherapy

Andrea Facciabene<sup>1</sup>, S Rafail<sup>2</sup>, M Uribe-Herranz<sup>3</sup>, C Koumenis<sup>2</sup>

<sup>1</sup>University Of Pennsylvania,

Department Of Radiation Oncology-

Rand The Ovarian Canc. Res. Center\R, Philadelphia, Usa

<sup>2</sup>Upenn, Radiation Oncology, Philadelphia, Usa

<sup>3</sup>Upenn, Radiaiton Oncology, Philadelphia, Usa

#### Abstract text

Alterations in gut microbiota impact the pathophysiology of several diseases, including cancer. Radiotherapy (RT), an established curative and palliative cancer treatment, exerts potent immune modulatory effects, inducing tumor-associated antigen (TAA) cross-priming with anti-tumor CD8+ T cell elicitation and abscopal effects. Herein, we tested whether the gut microbiota modulates anti-tumor immune response following RT distal to the gut. Vancomycin, an antibiotic that acts mainly on gram-positive bacteria and is restricted to the gut, potentiated the RT-induced anti-tumor immune response and tumor growth inhibition. This synergy was dependent on TAA cross presentation to cytolytic CD8+ T cells and on IFN-g. Notably, butyrate, a metabolite produced by the vancomycin-depleted gut bacteria, abrogated the vancomycin effect. In conclusion, depletion of vancomycin sensitive bacteria enhances the anti-tumor activity of RT, which has important clinical ramifications.

**SP-0332 The Microbiome & Cancer Therapies**V. Paziienza<sup>1</sup><sup>1</sup>Fondazione IRCCS "Casa Sollievo della Sofferenza"  
Hospital, Gastroenterology, San Giovanni Rotondo, Italy**Abstract text**

Despite continuous advances in cancer related therapies, resistance to standard drugs and adverse effects still represent an important cause of therapeutic failure. Cancer is a major health burden worldwide being among the top two killing disease in the frame of non communicable diseases that are responsible of the 70% of deaths worldwide. There is a growing evidence that gut bacteria can affect the response to chemo, immuno and radiotherapeutic drugs by modulating either efficacy or toxicity. Moreover, intratumor bacteria have been shown to modulate chemotherapy response. At the same time, anticancer treatments themselves significantly affect the microbiota composition, thus disrupting homeostasis and exacerbating discomfort to the patient. In this lecture is presented the existing knowledge concerning the role of the microbiota in mediating chemo, immuno and radiotherapy efficacy and toxicity and the ability of these therapeutic options to trigger dysbiotic condition contributing to the severity of side effects. In addition, we discuss the use of probiotics, prebiotics, synbiotics, postbiotics, and antibiotics as emerging strategies for manipulating the microbiota in order to improve therapeutic outcome or at least ensure patients a better quality of life all along of anticancer treatments.

**SP-0333 Immune effects of the microbiome on cancer treatment**M. Nuti<sup>1</sup><sup>1</sup>Sapienza University of Rome, Division of Medical Oncology B- Department of Radiological- Oncological and Pathological Sciences- Policlinico Umberto I, Rome, Italy**Abstract text**

The microbiome is associated with immunity and the development of a healthy immune system. Several factors are known to influence the variable part of the microbiome such as host lifestyle, environment, diet, genotype, pathobiology, inflammation etc.. Parameters associated with a healthy and fit microbioma are essentially the high diversity and a resilient feature i.e the capacity to cope with a physiological stress. An unbalanced scenario together with a concomitant factors such as an inflammation process and/or presence of pathogens can cause complex diseases. It was not surprising the finding that outcome of immunotherapeutic strategies in cancer patients can be dependent on the gut microbiome. Treatment of cancer with check point inhibitors capable to unleash T cells to expand exponentially and kill transformed cells, is the newest and best treatment strategy being developed in the last decade. A true revolution in oncology is ongoing and we are seeing dramatic responses and long term overall survival in critical deadly tumors like advanced melanoma, non-small cell lung cancers, renal cell carcinomas. Not all patients respond and some of them show severe autoimmune toxicities. Data are now emerging suggesting that response to ICI therapy, particularly anti-CTLA4, is associated to microbioma composition and that restored immunity and antitumor activity of ICI could be achieved only with transplantation of stool samples from responder patients. Immunological mechanisms underlying these findings are still in the process of being fully elucidated. Significance of these findings is quite relevant for future strategies in oncology. We are today facing the possibility that modulation of microbioma with probiotics or fecal transplants can

increase the prevalence of bacteria linked to anticancer immunosurveillance and adapt bacteria ecosystem accordingly.

**SP-0334 The Microbiome and treatment side-effects**Y. Touchefeu<sup>1</sup><sup>1</sup>Institut des Maladies de l'Appareil Digestif- University Hospital- Nantes- France, Hepato-Gastroenterology, Nantes, France**Abstract text**

Radiation therapy and chemotherapy induce major changes in the composition of the gut microbiota. Basic and clinical data suggest that the intestinal microbiota may play an important role in the pathogenesis of chemo- or radiation-induced mucositis. Further metagenomic studies, investigating microbiota gene functions, are required to better understand the impact of microbiota disruption during cancer treatments. Strategies can be developed to prevent or treat potentially life threatening treatment complications, using manipulations of the intestinal microbiota. Probiotics may be beneficial to prevent chemo or radiation-induced diarrhoea. Gut microbiota identification could also be used as a predictive marker for radiation and chemotherapy adverse effects such as mucositis, diarrhoea, fatigue, pain and bacteremia, and could guide preventive strategies.

**SP-0335 Stem cell replacement to overcome RT induced xerostomia**C. Von Buchwald<sup>1</sup>, C. Groenhoej<sup>1</sup>, C.D. Lynggaard<sup>1</sup><sup>1</sup>Rigshospitalet- Copenhagen- Denmark, Department of Orl- H and N Surgery And Audology, Copenhagen, Denmark**Abstract text**

**Background:** Salivary gland hypofunction and xerostomia are major complications to head and neck radiotherapy. We have conducted a trial assessing the safety and efficacy of adipose tissue-derived mesenchymal stem cell (ASC) therapy for radiation-induced xerostomia. **Patient and Methods:** A randomized, placebo-controlled phase I/II trial included 30 patients, randomized in a 1:1 ratio to receive ultrasound-guided transplantation of ASCs or placebo to the submandibular glands. Patients had previously received radiotherapy for a T1-2, N0-2A, human papillomavirus-positive, oropharyngeal squamous cell carcinoma. The primary outcome was the change in unstimulated whole salivary flow rate, measured before and four months after the intervention. **Results:** No severe adverse events were detected. Unstimulated whole salivary flow rates significantly increased in the ASC-arm at one (33%; p=0.048) and four months (50%; p=0.003), but not in the placebo-arm (p=0.6 and p=0.8), compared to baseline. The ASC-arm symptom scores significantly decreased on the xerostomia and VAS questionnaires, in the domains of thirst (-22%, p=0.035) and difficulties in eating solid foods (-2%, p=0.008) after four months compared to baseline. The ASC-arm showed significantly improved salivary gland functions of inorganic element secretion and absorption, at baseline and four months, compared to the placebo-arm. Core-needle biopsies showed increases in serous gland tissue and decreases in adipose and connective tissues in the ASC-arm compared to the placebo-arm (p=0.04 and p=0.02, respectively). MRIs showed no significant differences between groups in gland size or intensity (p < 0.05). In addition, outcome from one-year follow-up study along with next the stem cell studies in the pipeline will be presented. **Conclusions:** We have conducted the first-in-man transplantation of

ASCs for radiation-induced salivary hypofunction and xerostomia and found it safe and significantly improved salivary gland functions and patient-reported outcomes.

**SP-0336 Reducing normal tissue damage by sparing of stem cells using protons**

P. Van Luijk<sup>1</sup>

<sup>1</sup>*University of Groningen- University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands*

**Abstract text**

Radiotherapy plays an important role in the treatment of many forms of cancer. However, dose to normal tissue frequently leads to damage, toxicity and reduction of quality of life of the patient.

Xerostomia is a frequently-observed side-effect of the treatment of head-and-neck tumors, associated with irradiation of the parotid gland. Recently it has been shown that the response of the parotid gland critically depends on dose to its major ducts, containing most of its stem cells. The observation that sparing of a relatively small substructure of an organ is important to preserve its function after radiotherapy opened new opportunities for reducing toxicity. In addition, recent pre-clinical work suggests that tissue-specific stem cells are particularly sensitive to low doses of radiation.

Interestingly, these findings coincides with an increasing availability of proton therapy world-wide. The precision of protons provides unique opportunities to specifically spare such substructures. In addition they offer more opportunities to limit the large volumes receiving low doses, as typically observed in Intensity Modulated Radiotherapy.

In conclusion, based on the unique properties of protons and available information from radiobiology, proton therapy may offer unique opportunities to reduce toxicity of radiotherapy.

**SP-0337 Mechanisms of radiotherapy-induced neurocognitive decline**

L. Barazzuol<sup>1,2</sup>

<sup>1</sup>*UMCG, Department Of Radiation Oncology, Groningen, The Netherlands;* <sup>2</sup>*umcg, Department Of Biomedical Sciences Of Cells And Systems, Groningen, The Netherlands*

**Abstract text**

Radiotherapy is an essential part of the treatment of paediatric and adult primary brain tumours. Although long-term survival rates are increasing, 50 to 90% of the surviving patients develop neurological dysfunction leading to a reduced quality of life. Symptoms include a progressive impairment in memory, executive function and processing speed. In particular, children and young adults suffer from significant loss of intelligence quotient, with an average IQ decline of over 2 points per year. The pathogenesis of radiation-induced neurocognitive dysfunction is not well understood and consequently no effective treatment or prevention strategy exist. My laboratory, by using a combination of methodologies, including cerebral organoids and *in vivo* models, aims to reduce radiotherapy-induced neurocognitive dysfunction. Radiotherapy mainly works by damaging the DNA. To date, the link between DNA damage and neuropathology is not fully understood. Yet it is widely accepted that diminished protein homeostasis can cause neurodegeneration in aging and protein-misfolding diseases (such as Alzheimer's and Parkinson's disease).

Our recent data provide the first evidence that radiation-induced DNA damage leads to loss of protein homeostasis. Using different model systems, from primary neuronal and glial cells, human ES/iPS-derived cortical organoids to mouse and rat models, we have shown elevated protein

aggregation levels after DNA damage caused either directly by radiation or indirectly by impairment of the DNA damage response. This imbalance in protein homeostasis can be reduced by modulating the protein quality control capacity. In this presentation, new molecular targets for the future development of interventions will be presented.

**SP-0338 Neurocognition and brain irradiation**

S. Deprez<sup>1</sup>

<sup>1</sup>*KULeuven, Imaging and Pathology, Leuven, Belgium*

**Abstract text**

Whole brain irradiation (WBRT) is an important treatment modality in the management of brain metastases. Additionally, WBRT in the form of prophylactic cranial irradiation (PCI) is often used to reduce the incidence of brain metastases in for example small-cell lung cancer. Although effective in cancer control, WBRT has important neurotoxic side effects. Fifty percent or more of patients who survive 6 months or longer after WBRT report cognitive dysfunction. Functional deficits including impairments in memory, attention and executive functioning can have a serious impact on quality of life. Mechanisms of radiation-induced cognitive impairment are still poorly understood. The pathophysiology of brain injury after RT is multifactorial and complex. Possible mechanisms include CNS-irradiation triggered neuroinflammation, decreased hippocampal neurogenesis and vascular injury. Both early stage (< 6m after RT) and late delayed (>6m) brain injury can contribute to the observed cognitive dysfunction. Various pharmacologic and non-pharmacologic strategies to prevent or alleviate these toxicities are being investigated. In this talk an overview will be given of current knowledge in the field of neurocognition and brain irradiation, possible mechanisms of radiation-induced cognitive impairment and strategies for preservation being investigated.

**SP-0340 Does normal tissue in elderly patients have different sensitivity and tolerance and do tumors require different treatment?**

C. Herskind<sup>1</sup>,

<sup>1</sup>*Universitätsmedizin Mannheim- Medical Faculty Mannheim- Heidelberg University, Department of Radiation Oncology, Mannheim, Germany*

**Abstract text**

In clinical practice patients are often considered elderly from the age of 65-70 years. However, in the developed world with high life expectancy, healthy persons of this age have an expected remaining life span of 15-20 years, and even persons with an attained age of 75-80 years are expected to live for another 8-12 years or longer. Therefore, long-term survival and quality of life is as important for cancer patients in this age group as in younger patients. It is a commonly made assumption that elderly patient show poorer tolerance and may not be eligible for radiotherapy protocols used in curative treatment of patients below this age. However, there is little high-level evidence to support this view. The

presentation will summarize the biological changes associated with increasing age and will emphasize the large individual variation observed. Clinical studies of the sensitivity and tolerance of normal tissue in elderly patients will be reviewed and the role of co-morbidities will be discussed. Furthermore, the available data on survival outcome of standard treatment protocols for different tumour entities will be considered. The bulk of the current evidence seriously questions the common practice of excluding cancer patients from study protocols solely on the basis of their chronological age

**SP-0341 Influence of age and comorbidity on outcome and compliance to RT**

C.R. Boeje<sup>1</sup>, J. Overgaard<sup>2</sup>

<sup>1</sup>Aalborg University Hospital, Dept of Oncology, Aalborg, Denmark; <sup>2</sup>Aarhus University Hospital, Dept. of Clinical Experimental Oncology, Aarhus, Denmark

**Abstract text**

Head and neck cancer (HNC) patients are often long term users of tobacco and/or alcohol. Besides the carcinogenic effect of these substances they also lead to other chronic diseases and thus contributes to a high prevalence of comorbidities among HNC patients. Due to demographic changes the general population becomes older and consequently more HNC patients may suffer from comorbidity. Severe comorbidity may impact on prognosis for HNC patients and may impact treatment decision, compliance and subsequent outcome. This talk will focus on comorbidity and age in HNC patients and the impact on survival. Data will be presented from different studies including large population based study from the DAHANCA group. These studies show that comorbidity is common among HNC patients and is a negative prognostic factor for overall survival. Comorbidity also have a negative impact on cancer specific survival, while age does not. Therefore, critical assessment of comorbidity can significantly improve the decision-making proces for clinicians and may influence and improve patient outcome.

**SP-0342 From geriatric assessment in radiation oncology to interventions: experience from the PIVOG trial**

D. Vordermark<sup>1</sup>

<sup>1</sup>Martin Luther University Halle-Wittenberg, Dept. of Radiation Oncology, Halle/Saale, Germany

**Abstract text**

The demographic development in Europe e. g. in Germany leads to increasing need of adapted care concepts for elderly cancer patients. General principles (e. g. "go-go, slow-go, no-go" for very fit, quite fit and unfit elderly patients, respectively) are difficult to translate into clinical treatment recommendations for individual patients. Maintaining quality of life is highly important for elderly cancer patients. Its measurement, however, has only become possible recently with established of normal reference values for elderly age groups (e. g. for the EORTC QLQ-C30 questionnaire) and the validation of an elderly-specific instrument (QLQ-ELD 14; Wheelwright et al., Br J Cancer 2013).

Using these tools, we could show in an observational study of n=50 very elderly (>80 years old) cancer patients undergoing radiotherapy, that general and elderly-specific quality of life remained stable from beginning to end of radiotherapy, but deteriorated in several domains, including physical function, role function and family support by 6 months after treatment (Kaufmann et al., Support Care Cancer 2015). A possible explanation was the good access to supportive treatment during radiotherapy, but lack thereof after treatment.

We interpreted this as a need to develop an intervention to stabilize quality of life of elderly cancer patients after

the end of treatment and developed a complex intervention containing (a) a clinically feasible comprehensive geriatric assesmentn (CGA) before the start of cancer treatment and (b) regular telephone contact with an oncology nurse during the first six months after treatment to counsel patients on the management of symptoms and provide additional ressources of care. This intervention was pilot tested in n=100 elderly patients over 70 years with at least one comorbidity and / or one functional impairment in the PIVOG trial (Patient-centered Interdisciplinary Care Concept for Geriatric Oncology Patients; Schmidt et al., J Geriat Oncol 2017). The geriatric assessment was feasible and took on average one hour. The nurse-led telephone contact was well accepted (used by 79% of patients, mean 7.8 calls per patient, mean duration 14 minutes). In the primary endpoint, global quality of life at 6-month follow-up, mean scores were stabilized compared to baseline. Clinically relevant improvement and deterioration were seen in 35% and 28% of patients, respectively, no change in 37%. Details on the experience with specific elements of the geriatric assessment and development in subscales of quality of life will be presented. Ongoing work is focussed on developing the complex intervention for evaluation in a randomized trial, on physical exercise to improve or stabilize physical function in elderly cancer patients and on the implementation of electronic patient-reported outcome measurement in geriatric oncology using the CHES platform.

**Debate: Which is the best brachytherapy technique to deliver partial breast irradiation? Pitfalls, results and current recommendations**

---

**SP-0343 Postoperative multicatheter brachytherapy**

J. Hannoun-Levi<sup>1</sup>

<sup>1</sup>Centre Antoine Lacassagne, Radiation Therapy, Nice, France

**Abstract text**

Whatever the breast brachytherapy indication (boost, APBI for primary or APBrI for salvage irradiation), breast brachytherapy can be performed intra or post-operatively. We listed the different point which can be positively or negatively impacted if the implant is performed intra or postoperatively. Regarding breast brachytherapy applicators, in case of intra-operative implant, both multicatheter and balloon devices (single or multilumen) can be used, while in case of postoperative implant multicatheter brachy is the only one possible technique. For patient comfort regarding to anesthesia, in case of intra-op implant, the patient is under general anesthesia which is more comfortable compare to a local one in a postoperative implant. Regarding to "Vectors in place" duration, in case of intra-operative implant, before starting the irradiation, it is warranted to obtain the full postoperative pathological report which takes between 5 to 8 days plus 4 to 5 more days for the treatment itself for a total duration ranged between 10 to 15 days (patient discomfort, risk of local infection and/or pain). However, in case of post-operative implant, the "Vectors in place" duration is reduced to the treatment duration itself plus/minus the delay between the implant and the first day of irradiation. For brachytherapist comfort regarding to anesthesia in case of intra-op implant, surgeon and brachytherapist can work together, with a full visibility of the tumor bed and the clip position. No pressure due to potential patient pain. In case of post-operative implant, it is sometimes difficult to perform the implant when the patient is not totally relaxed, obliging the brachytherapist to do the implant in a shorter time (potential stress). In terms of organization, in case of intra-operative implant, the brachytherapist must be available at the time of the

surgical procedure (which is often delayed for some reasons). However, in case of post-operative implant, the implant can be scheduled according to the brachytherapist activity/program. For vector implantation, in case of intra-operative implant, whatever the location of the tumor bed, it is always possible to place the vectors even if (in some cases) it is necessary to insert the needles in two times (for large breast, deep tumor bed, complex angulation ...). But in case of post-operative implant, it is sometimes possible to switch from brachy to external beam APBI in the clinical situations listed above (impossibility to properly place the vectors). For CTV delineation, in case of intra-operative implant, it is sometimes possible to (post-operatively) add some extra-needles in order to more accurately cover the target volume in regards to the clips and considering the delineation rules (SM = 2 cm = Surgical margin + brachy margin). In case of post-operative implant, it is possible to use all the imaging supports and mainly a pre-implant CT-scan allowing a pre-planning calculation considering all the delineation parameters. For treatment modification after post-op histology, according to the post-operative final pathological report, APBI is sometimes not possible in regards to the GEC-ESTRO APBI criteria. In this situation and after intra-operative implant, it is possible to remove applicator/vectors and continue the treatment either with WBI or systemic therapy. It is also possible to propose an anticipated boost which is acceptable only if there is no indication of chemotherapy. But in case of post-operative implant intent, if the final pathological data do not match with APBI criteria, no implant will be performed. The export of breast brachytherapy technique ( $\neq$  centers: surgery & brachy) is a very important point. In case of intra-operative implant, and if the surgeon works in a different place, the later must perform the lumpectomy in the brachytherapist hospital or, the brachytherapist must go to the surgeon hospital. Leading to consider that breast brachytherapy will be difficult to export because the surgeon, in the large majority of the cases, will not accept to refer his patient to another surgeon who works in the brachytherapist hospital. However, in case of post-operative implant, each doctor (surgeon and brachytherapist) will perform his procedure in his own hospital.

Abstract not received

#### SP-0345 Single catheter balloon brachytherapy (MammoSite, Contura)

P. Niehoff<sup>1</sup>

<sup>1</sup>Klinikum Offenbach GmbH, Dep. of Radiotherapy, Offenbach am Main, Germany

##### Abstract text

APBI is elegant method for treating low risk breast cancer patients. Single balloon catheter (MammoSite/ Contura) is the easiest way to treat pts. with APBI. If a open cavity method surgery has been used a geographic miss is extreme rare. Target definition is related to the applicator. The disadvantages are limited options for dose painting and covering the target volume. Another problem is the necessary for a minimum skin distance of 1.5 cm. Compared to other technique single lumen catheter have there limitation for breast size. The toxicity might be higher and the dose distribution worse compared to other techniques. But for deep sited small tumors and a large breast single lumen catheter are suitable.

#### SP-0346 Single catheter brachytherapy (SAVI) - Pitfalls, results and current recommendations.

A. Chichel<sup>1</sup>

<sup>1</sup>Greater Poland Cancer Centre, Department of Brachytherapy, Poznan, Poland

##### Abstract text

##### Introduction

Strut Adjusted Volume Implant (SAVI) serves as a single-entry Accelerated Partial Breast Irradiation (APBI) device that mimics, fastens and simplifies multicatheter interstitial brachytherapy (BT). In breast conserving therapy (BCT) radiation is mandatory, substantially reduces local recurrence rate and also improves overall survival. In low risk breast cancer patients APBI is proven safe alternative for whole breast irradiation. Amongst a number of possible techniques there is SAVI, which conforms with open cavity approach and fits the cavities easily with a set of applicator sizes. Single-entry device minimizes the risk of infection and improves patients' comfort.

##### Aim

The study is to report the long-term results in regard to loco-regional control and single institution experience in high-dose rate (HDR) BT APBI with the usage of single-entry applicator (SAVI) for early breast cancer patients treated with breast conserving approach.

##### Material and methods

Between Jan 2012 and Dec 2012, 11 stage I-IIA breast cancer patients (pT<sub>is</sub> - 1, pT<sub>1</sub> - 9, pT<sub>2</sub> - 1) were treated with BCT + adjuvant hormonal therapy and APBI HDR BT. All were implanted with SAVI in about 6 weeks after surgery and after receiving full pathological report. Each patient had a CT scan and treatment plan prepared on the day of implantation and started the treatment consisted of 10 daily fraction of 3,4 Gy. In this study overall survival (OS), disease-free survival (DFS), loco-regional control (LRC), cosmetic outcome (CO) and the tumor bed (TB) appearance were noted.

##### Results

Median follow-up was 58,5 months (range 19-78). One patient was lost from observation. Treatment plan parameters were as listed: PTV\_EVAL\_95 mean 96,89% (range 86,71 - 101,19%), PTV\_EVAL\_90 mean 101,74% (range 93,29 - 106,01%), skin 0,1 cc mean 60,9% (range 17,81 - 101,16%), chestwall 0,1 cc mean 72,1% (range 19,05 - 111,55%), lung 0,1 cc mean 51,99% (range 17,39 - 78,8%). In all cases treatment was completed without procedural complications and on time. OS was 10/10, DFS was 9/10 (1 case of multiple bone metastases), LRC was 100%. CO was excellent in 6/10 and good in 4/10. There were no outcomes assessed as satisfactory or poor. 5/10 patients resulted with soft breast and 5/10 had palpable painless TB (slight induration). No fat necrosis was identified on control mammograms. No superficial skin changes were observed.

##### Conclusions

APBI with HDR brachytherapy based on SAVI was feasible and well tolerated. As other APBI techniques SAVI results with perfect local control and itself saves very good breast appearance after proper surgery. SAVI application is fast and easy in experienced hands, needs only adequately prepared tumor bed, palpation and ultrasound. May be considered as intraoperative technique. SAVI offers better optimization abilities in comparison with single or multilumen balloon applicators, mimics and simplifies multicatheter interstitial BT. SAVI with its single entry minimizes the risk of infection and improves patients' comfort. Other advantages as well as important pitfalls, current recommendations and sights for future for SAVI will be discussed during the debate.

**Keywords:** SAVI, brachytherapy, APBI, breast cancer.

**SP-0347****The need and potential for use of big data for research and development of radiotherapy**

Leonard Wee<sup>1</sup>, J Van Soest<sup>2</sup>, I Bermejo<sup>3</sup>, R Fijten<sup>1</sup>, A Dekker<sup>2</sup>

<sup>2</sup>*Institute Of Data Science, Maastricht University, Maastricht, The Netherlands*

<sup>3</sup>*School Of Oncology And Developmental Biology, Maastric Clinic, Maastricht, The Netherlands*

**Abstract text**

Radiation oncology is an area of medicine that stands to benefit enormously from clinical knowledge extracted from “big data”. Radiotherapy departments worldwide generate a vast quantity and variety of data daily, due to the extensive use of medical imaging and a relative high degree of process automation already in place. It is important to understand the scope, type, quality and distribution of variegated oncology data if we wish to extract knowledge using machine learning and artificial intelligence. The potential benefits that can be addressed through utilization of big data approaches in healthcare generally fall into two domains - operational improvements and direct patient benefit. Among the major clinical needs in radiation oncology are : appropriate patient stratification, optimal treatment selection and reducing unjustified variation in procedures. Operational excellence, such as automating routine steps in clinical workflow, are more easily introduced into clinical practice but tend to have limited or indirect patient impact. Prediction of prognosis and treatment outcome (hence exerting direct influence on clinicians’ decision making) is much more cautiously being introduced into the clinic, but has immense future potential for substantial patient benefit. There are still major challenges impeding research and clinical utilization, chiefly focussed around issues of consent, privacy, generalizability and quality assurance.

**SP-0348 Challenges of collection, sharing and analysis of data at scale**

M. Modat<sup>1</sup>

Abstract not received

**SP-0349 Practicalities and issues of setting up the infrastructure to collect big data in a hospital environment**

G. Price<sup>1</sup>

<sup>1</sup>*The University Of Manchester, The Christie Nhs Foundation Trust, Manchester, United Kingdom*

**Abstract text**

Recent years have seen increased interest in the clinical value of routinely collected patient data. The migration to electronic patient record systems coupled with the increased ease with which powerful machine learning techniques can be employed has led to huge growth in the volume of retrospective observational studies reported in the radiation oncology literature. High quality studies can provide valuable insight where gold standard randomized trial evidence is lacking or where traditional methodologies are not appropriate.

The Christie NHS Foundation Trust in partnership with the Manchester Cancer Research Centre has invested significant effort in establishing an informatics infrastructure to enable such studies. Use of the system has underpinned a rapid expansion in the volume of related research within the institutes and streamlined

collaboration with international partners. In this talk we describe the practicalities of implementing this system, focusing on the organizational, resource and governance aspects as well as the technical detail. We explore both the barriers overcome and the remaining challenges, and consider, with examples and case studies, how the system fits into both the academic and clinical aspirations of the host institutions.

**Symposium: From grid therapy to microbeam radiotherapy****SP-0350 Introduction to microbeam radiation therapy: radiosurgical grid therapy at the microscopic scale**

E. Schültke<sup>1</sup>

<sup>1</sup>*Rostock University Medical Center, Radiooncology, Rostock, Germany*

**Abstract text**

Microbeam radiation therapy (MRT) is a still experimental concept of spatially fractionated radiotherapy. Clinically, it compares closets to radiosurgery and grid radiotherapy. In MRT, the irradiation target is covered by an array of quasi parallel microbeams. Microbeams are typically between 25 and 100 µm wide and spaced at center-to-center distances of several hundred micrometers. Thus, an inhomogeneous dose distribution with characteristic peak dose (high dose) and valley dose (low dose) zones is generated. The X-ray doses deposited in the peak dose zones are typically in the order of several hundred Gy. It has been shown in small animal models of malignant brain tumour that MRT allows a superior tumour control compared to current clinical radiotherapy concepts. The original concept of MRT has been developed in the 1980s by a group of researchers at the NSLS (synchrotron radiation source at Brookhaven, USA) with the experiences of classic clinical grid radiotherapy in mind. Since then, an increasing number of research groups has expanded the field to understand the therapeutic potential of MRT. Different irradiation schedules were tested, with MRT as single fraction treatment similar to clinical radiosurgery or with MRT integrated in a conventional radiotherapy schedule. Studies were designed to assess the tolerance of normal tissue and the potential adverse effects of MRT. During the first decade, MRT research focused mainly on brain tumours as target indications. More recently, there have been interesting developments within the MRT research community to include other tumour entities as possible targets, such as malignant melanoma and carcinoma of the lung.

This presentation will highlight key achievements of MRT research in preparation of its transition from bench to bedside.

**SP-0351 Spatial fractionation of the dose: from photons to charged particles**

Y. Prezado<sup>1</sup>

<sup>1</sup>*Imagerie et Modélisation en Neurobiologie et Cancérologie, New Approaches in Radiotherapy, Orsay, France*

**Abstract text**

The therapeutic use of ionizing radiation has been largely guided by the goal of directly eliminating all cancer cells while minimizing the toxicity to adjacent tissues. Nowadays, technological advances in radiation delivery, including image guidance and particle therapy (i.e. proton therapy), have notably improved tumor dose conformation, thus reducing the dose to the organs-at-risk. Despite remarkable advancements, the dose tolerances of normal tissues continue to be the main limitation in RT and still compromise the treatment of some radioresistant tumors, tumors close to a sensitive

structure (e.g. central nervous system (CNS)) and paediatric cancer. One possible way to overcome this limitation is to employ new modes of radiation dose deposition that activate biological processes different from those acting in standard radiotherapy. An example is the spatial fractionation of the dose. This lecture will give a general overview about this strategy. A particular focus will be put on minibeam radiation therapy (MBRT) and its advantages. MBRT, originated at synchrotrons, can now be explored outside large facilities thanks to its successful transfer into cost-effective equipment [1]. This allows a widespread implementation, the realisation of comprehensive and systematic biological studies and an easy transfer to potential clinical trials. In the recent years, the exploration of the possible synergies between the advantages of MBRT and the benefits of charged particles for therapy has started, with techniques like proton and heavy ions MBRT [2-7]. In particular, proton MBRT [2] has been implemented at a clinical center (Orsay proton therapy center) and it has already shown an effectiveness of tumor control equivalent or superior than that of standard PT without the important side effects observed in the latter, thus opening the possibility for more aggressive irradiation schemes [3-5]. Concerning heavy ions MBRT, the dosimetric data obtained supports the exploration of this radiotherapy approach [6,7]. Among the different ions species evaluated, Ne stands as the one leading to the best balance between high peak-to-valley dose ratio and peak-to-valley-LET ratio in normal tissues and high LET values in the target region [6]. The biological mechanisms in MBRT, which are not completely known, seem to contradict the classic RT paradigms. Its exploration offers a whole new horizon of both scientific research and potential future clinical practice. The spatial fractionation of the dose could especially benefit paediatric oncology (central nervous system), whose treatments are limited to the high risk of complications in the development of the infants.

#### SP-0352 Dosimetry measurement in microbeam therapy

J. Lye<sup>1</sup>, P. Harty<sup>2</sup>, D. Butler<sup>2</sup>

<sup>1</sup>Australian Radiation Protection And Nuclear Safety Agency, Australian Clinical Dosimetry Service, Melbourne- Victoria, Australia; <sup>2</sup>Australian Radiation Protection And Nuclear Safety Agency, Psdl, Melbourne-Victoria, Australia

##### Abstract text

Microbeam radiation therapy (MRT) with Synchrotron beams continues to evolve from promising research towards clinical or veterinary radiotherapy. The change from research to clinical applications requires many developments including dedicated treatment planning, image guidance, patient quality systems and high quality dosimetry. The focus of this presentation is on the challenge of absolute and relative dosimetry as performed at the Australian Synchrotron. The Synchrotron dosimetry chain consists firstly of absolute dosimetry in a "broadbeam"- in this context field sizes of a few centimetres. The next stage is relative dosimetry in the microbeams approximately 10-100 microns in

width. Secondary standard dosimeters such as ionization chambers require calibration in conventional x-ray sources with substantially different field sizes, dose-rates, polarizations and spectra to synchrotron beams. These differences add significant uncertainties to measurements of the dose in the synchrotron beam. Calorimeters and free air chambers can determine dosimetric quantities from first principles. Calorimetry has been successfully performed directly on Synchrotron beams as the high dose rates offers the advantage of increased temperature rise compared to conventional clinical linac calorimetry. Free air chambers (FAC) can also be used for absolute dosimetry, however they suffer from strong recombination and electron loss effects in Synchrotron beams. FAC are also useful tools for continuously monitoring in Synchrotron beams. The determination of the peak and valley dose of the microbeams is challenging. Understanding the valley dose is particularly important as this is a key parameter to spare the normal tissue, limiting the clinical dose delivered. Film and microdiamond detectors are commercially available and with careful use and analysis have had success in microbeam dosimetry. Other promising detectors are high spatial resolution fibre optic dosimeters (FOD) and silicon detector arrays.

#### SP-0353 Compact microbeam sources and microbeam treatment planning

S. Bartzsch<sup>1,2</sup>

<sup>1</sup>Klinikum Rechts Der Isar- Technical University Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Helmholtz-Zentrum Munich, Institute Of Innovative Radiotherapy, Munich, Germany

##### Abstract text

Microbeam radiation therapy (MRT) is an approach in radiation oncology that modulates radiation doses on a micrometre scale. Homogeneous radiation fields are collimated into 25-100 micrometre wide beamlets with a few hundred micrometre spacing between each other. Abundant preclinical research demonstrated that MRT has the potential to change radiotherapy treatment paradigms for certain tumour types. However, the technical demands of MRT on dosimetry, dose calculation, treatment planning and on the radiation source are high.

So far dose calculations in MRT have largely been based on Monte Carlo simulations. However, the small dimensions of the treatment fields, subsequent small voxel sizes and substantial dose differences between high and low dose regions entail long simulation times and often poor statistics. An alternative to Monte Carlo simulations are kernel based dose calculation approaches. Although these approaches are much faster they often lack accuracy at material boundaries due to the utilization of low energy photons in MRT. Hybrid dose calculation approaches use elements of both approaches and provide a very accurate and efficient way to calculate peak doses, valley doses and dose profiles. Even complicated cross-firing geometries can easily be calculated. Currently we implement a hybrid dose calculation engine in the popular treatment planning system Eclipse® (Varian), enabling treatment planning for first clinical trials in MRT.

The meaning of peak and valley doses in MRT on tissue reactions remains controversial. In order to plan and carry out first clinical trials in MRT, estimates on the biological effectiveness of microbeams based on the physical dose distribution are required. Recently, it has been suggested to use the concept of equivalent uniform dose (EUD). This concept can be calculated for arbitrary and complex beam geometries and our own in-vitro data demonstrates its applicability.

The major obstacle for a clinical application of MRT is the availability of adequate radiation sources. MRT requires high dose rates of more than 100 Gy/s, small beam divergence and photon energies of around 100 to 300

keV. Currently only a few large third generation synchrotrons around the world, such as the European Synchrotron in Grenoble (France) provide such beam properties. Various alternative approaches have been discussed in the past, including inverse Compton scattering sources and carbon nanotube x-ray tubes. Another strategy is the Line-Focus x-ray tube (LFxT), a source based on classical x-ray tubes, where the electron beam is focused to an extremely eccentric focal spot on a rapidly rotating tungsten target. The rapid relative movement between target and focal spot leads to a change in the energy transport within the target. Our simulations show that such a source can provide up to 200 Gy/s MRT peak entrance dose rate in a clinical setting.

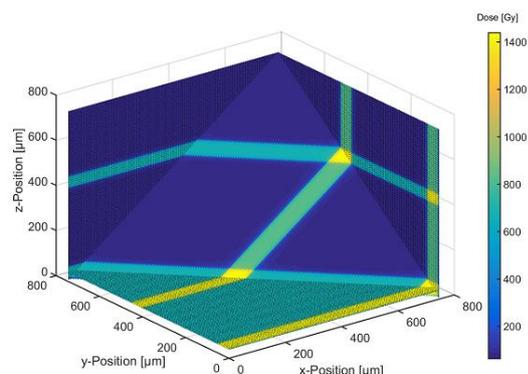

Figure 1: Hybrid dose calculation approaches can calculate complex MRT treatment geometries within a few minutes. The resulting dose distributions can be used to calculate the equivalent uniform dose a promising predictor for normal tissue reactions.

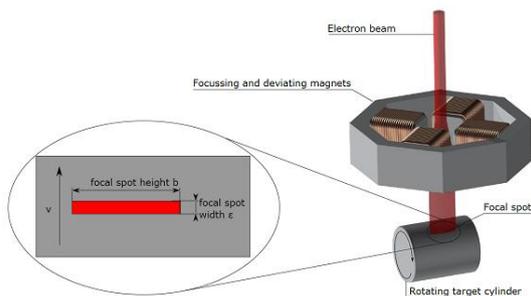

Figure 2: The concept of the line focus x-ray tube is based on conventional x-ray tube technology. An eccentric focal spot hits a fast rotating target cylinder.

## Symposium: Focus on the lung

### SP-0354 Image-guided adaptive radiotherapy in the treatment of lung cancer patients

M. Tvilum<sup>1</sup>, M. Marquard Knap<sup>1</sup>, L. Hoffmann<sup>2</sup>, A. Ahmed Khalil<sup>1</sup>, C.M. Lutz<sup>2</sup>, D. Sloth Møller<sup>2</sup>

<sup>1</sup>Aarhus University Hospital, Department Of Oncology, Aarhus C, Denmark; <sup>2</sup>Aarhus University Hospital, Department Of Medical Physics, Aarhus C, Denmark

#### Abstract text

Anatomical changes often occur during treatment of lung cancer patients with curative intended radiotherapy. These changes affect both the dose delivered to the tumour and to the normal tissue. By using the concepts of adaptive radiotherapy, the planned dose distribution can

be restored. Daily cone-beam CT scans based on soft tissue match are used for patient setup at Aarhus University Hospital. The combination of soft tissue match and an adaptive strategy allows for reduction in treatment margins, reduction in dose to normal tissue and enables dose escalation. This lecture focusses on the clinical implementation of image-guided adaptive radiotherapy in the treatment of lung cancer patients. It presents both the dosimetric and clinical outcome of the first patients treated with the strategy at Aarhus University Hospital.

### SP-0355 Selection of lung cancer patients for adaptive radiotherapy using cone-beam CT imaging

D. Hattu<sup>1</sup>

<sup>1</sup>Maastricht Radiation Oncology Maastricht Clinic, Radiotherapy, Maastricht, The Netherlands

#### Abstract text

Image-guided radiotherapy using cone-beam CT (CBCT) allows for precise patient set-up procedures and accurate treatment delivery. Besides image-guided patient set-up, CBCT can detect anatomical changes previously not visible on lateral port films. This additional information leads to an increased workload and decision criteria when to adapt need to be in place. Therefore in our department a traffic light protocol is part of the online matching protocol for lung cancer patients and is used for the evaluation of the correct positioning of the patient. It also serves as a decision support tool to guide Radiation Therapy Technologists (RTT) with potential follow-up investigations to be undertaken for e.g. changes in lung density, changes in tumor volume or tumor shifts. Requests for follow-up investigations are collected and reviewed offline by a dedicated RTT and a radiation oncologist specialized in lung cancer treatment to determine if further action is necessary (e.g. dose (re)calculation, new CT or even an adapted treatment plan). In this presentation an overview of the current protocol is given but also practical examples will be shown.

### SP-0356 Image-guided radiotherapy and motion management in lung cancer

V. Gram<sup>1</sup>

<sup>1</sup>University Hospital of Copenhagen- Rigshospitalet, section of Radiotherapy- Clinic of Oncology, Copenhagen, Denmark

#### Abstract text

Modern radiotherapy techniques as IMRT and VMAT have already contributed to a reduction of the radiation dose to the lungs and heart for patients with lung cancer, and there are still modern techniques that are being explored for this patient group today. Image guidance and motion management offer great advantages for lung cancer patients, including the ability of monitoring tumour size and motion. Motion management techniques, such as DIBH offer advantages including a reduced dose to the healthy part of the lung and the heart, improved image quality and intra-fractional motion management of the tumour and have been used for breast cancer patients for over a decade with good results, as this technique expands the lungs and pushes the heart down with the diaphragm. The use of breath hold techniques is however not a standard approach in lung cancer, despite its advantages. There are a number of considerations to be evaluated in the implementation of breath-hold techniques; both technical, practical and patient-related. This presentation will include clinical experience in implementing DIBH for lung cancer patients from the perspective of an RTT and include ethical aspects, choice of technique, patient selection, patient and staff training, patient compliance and extra time required for adding this technique.

**Symposium: Stronger together - news and projects in the young national societies**

**SP-0357 Perspective of an established young society: the Spanish Young Society**

V. Morillo<sup>1</sup>, R. Hernanz<sup>2</sup>

<sup>1</sup>*Consorcio Hospitalario Provincial De Castellon, Radiation Oncology, Castellon, Spain* ; <sup>2</sup>*ramon And Cajal Hospital, Radiation Oncology, Madrid, Spain*

**Abstract text**

The SYROG was formed about a decade ago, with the intention of fostering collaboration (research) and training (education) among young members of society as well as with other societies, both nationally and internationally. An executive committee was set up to oversee the objectives and functions of the group, made up of young specialists who wished to promote their spirit to the other doctors in training. We encountered many difficulties during our journey, but the ones that had the greatest impact were the lack of funding and recognition, slowing down our progress. In spite of this, numerous training courses have been carried out focused on the achievement of our objectives, the elaboration of articles with clinical impact, as well as the collaboration with fully constituted international societies. We promote the use of social networks as a means of disseminating evidence-based clinical guidelines, fundamental publications in healthcare practice, and reporting on scientific congresses and conferences. As far as future perspectives are concerned, it is necessary to be actively involved in young European society in order to be able to grow in opportunities, research and healthcare.

**SP-0358 An emerging young society: Young Romanian Radiotherapists and Oncologists Group (YRROG)**

M. Zerbea<sup>1</sup>

<sup>1</sup>*Institute of Oncology Prof. Dr. I. Chiricuta, Radiation Oncology, Cluj Napoca, Romania*

**Abstract text**

**Introduction**

The aim of a young society is to gain gratitude among the well known national and international societies. The Romanian residents in the oncology formed a society that is gaining members and visibility year by year. Projects Our society collaborates with the Romanian Surgery and Oncologic Gynecology Society in organizing the Multimodal Approach in Oncology, a conference held in Cluj Napoca once every month. It includes presentations on surgery, oncology, imaging, pathology, nuclear medicine for a better communication between all professionals in oncology. We also organize every week article presentations among residents. The goal is continuous medical education and improving qualities such as public speaking and presentation skills.

**Administration**

Our society is a non-profit organization managed by a representative, vice - representative and a secretary. It is holding over 500 members from diverse romanian medical fields. We promote our group through social media, national events such as the Romanian National Congress and international meetings such as ESTRO and ESMO Congress. The best papers presented by the residents are published in the society journal.

**Visión**

Our collaboration at ESTRO 38 with the other national societies is a step forward in organizing European projects, gaining better visibility in ESTRO and improving the medical education among the young residents.

**SP-0359 Creating a new young radiation oncology society - the case of Poland**

M. Spalek<sup>1</sup>

<sup>1</sup>*Maria Skłodowska-Curie Institute-Cancer Center, Department Of Soft Tissue/Bone Sarcoma And Melanoma, Warsaw, Poland*

**Abstract text**

Some young radiation oncology national societies (yNS) exist within Europe. However, the creation of a new yNS is a demanding task. Is it really important and worth this effort? The first step is to gather a group of enthusiastic people who will break the walls and face many legal issues. The presentation covers the process of creation of a new yNS in Poland, and also discusses ideas for first projects and possibilities of collaboration with the Young ESTRO Committee.

**SP-0360 Working together across borders: Young Academics in Radiation Oncology**

C. Ostheimer<sup>1</sup>

<sup>1</sup>*Universitaetsklinikum HalleSaale, Radiation Oncology, Halle, Germany*

**Abstract text**

Radiation Oncology is a crucial therapeutic pillar in modern Oncology, offering up-to-date and efficient treatment concepts for cancer patients. In cancer research, Radiation Oncology contributes with innovative research projects and approaches in clinical radiotherapy, radiation biology and physics.

In order to keep this status for the future, Radiation Oncology needs to stay attractive for young medical professionals and academics. As the "Motor of Innovation" in Radiation Oncology, research needs to motivate and support young academics to pursue own research activities - not only on the national level. In a world of globalization and internationalization, research needs to adapt to this trend and offer young academics and researchers structures, resources and platforms to collaborate on a multinational level. Only by establishing strong international research collaborations and networks already on the level of young academics can ensure and secure a lasting and significant impact of Radiation Oncology in cancer research.

This presentation gives an overview of the activities of the "Young Radiation Oncology Group" (YROG) of the EORTC ROG.

<sup>1</sup>*OncoRay - Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany*; <sup>2</sup>*Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology - OncoRay, Dresden, Germany* ; <sup>3</sup>*Department of Radiotherapy and Radiation Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Dresden, Germany*; <sup>4</sup>*National Center for Tumor Diseases NCT- Partner Site Dresden- Germany*; *German Cancer Research Center DKFZ- Heidelberg- Germany- Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden- Dresden- Germany- and Helmholtz* ; <sup>5</sup>*German Cancer Consortium DKTK- partner site Dresden, and German Cancer Research Center DKFZ, Heidelberg, Germany* ; <sup>6</sup>*German Cancer Research Center, Deutsches Krebsforschungszentrum DKFZ, Heidelberg, Germany*

### Purpose or Objective

To investigate changes in neurocognitive function and quality of life (QoL) and their association with dosimetric parameters of various brain structures as well as clinical cofactors in adult brain tumour patients following proton beam therapy (PBT).

### Material and Methods

Sixty-nine adult patients with primary brain tumours who received conventionally fractionated PBT were included in this study. Neurocognitive function according to the Montreal Cognitive Assessment (MoCA) test and QoL according to general EORTC-QLQ-C30 and brain tumour specific QLQ-BN20 questionnaires were scored prospectively at baseline and within 3-month-intervals up to one year after PBT. Dose-volume parameters of the retrospectively contoured structures hippocampus, thalamus, frontal and temporal lobes, amygdala, entire cerebellum, anterior cerebellum, and posterior cerebellum were extracted. Clinical parameters comprised age, sex, diagnosis and WHO grading, tumour volume, prescribed dose, concomitant chemotherapy, tumour resection and administration of corticosteroids. MoCA scores and differences to baseline values at different time points were correlated with self-reported QoL items (Spearman correlation  $r_s$ ), clinical and dosimetric parameters (Mann-Whitney  $U$  test, logistic regression). A change of  $\geq 3$  points of the MoCA total score compared to baseline was considered clinically relevant. Unless otherwise stated, differences at 3 months after PBT compared to baseline are given.

### Results

The MoCA total score remained stable over time for the majority of patients: Less than 10% of the patients had clinically relevant changes at respective time points. The QLQ-C30 items did not change over time. On the QLQ-BN20 symptom scale, significant increases were observed for the items hair loss ( $p=0.002$ ) and seizure ( $p<0.042$ , up to 9 months after PBT). However, future uncertainty decreased significantly ( $p<0.042$ ). MoCA scores were significantly correlated with self-reported QoL scores. At all time-points, MoCA total score correlated with QLQ-C30 cognitive function ( $r_s$ : 0.31-0.57) and MoCA language scores with QLQ-BN20 communication deficit ( $r_s$ : 0.36-0.59). Clinically relevant differences in the MoCA total score were significantly associated with high dose parameters in the anterior, posterior and entire cerebellum (V55Gy,  $p<0.05$ ), but not with clinical parameters.

### Conclusion

Neurocognitive function and QoL remained stable in the majority of brain tumour patients following PBT. Self-reported QoL was in accordance with the results of the objective MoCA test. Significant associations between dose-volume parameters and clinically relevant neurocognitive changes suggest that further sparing of organs at risk in treatment planning may lead to increased neurocognitive function and QoL for brain tumour patients. New planning constraints for further potential organs at risk, such as the cerebellum [1], should be discussed.

### PV-0362 Long term outcomes of high-dose single-fraction radiosurgery for chordomas of the spine and sacrum

C.J. Jin<sup>1</sup>, J. Berry-Candelario<sup>2</sup>, A. Reiner<sup>3</sup>, E. Lis<sup>4</sup>, M. Bilsky<sup>2</sup>, I. Laufer<sup>2</sup>, A. Schmitt<sup>1</sup>, D. Higgison<sup>1</sup>, Y. Yamada<sup>1</sup>  
<sup>1</sup>Memorial Sloan Kettering Cancer Center, Radiation Oncology, New York, USA; <sup>2</sup>Memorial Sloan Kettering Cancer Center, Neurosurgery, New York, USA; <sup>3</sup>Memorial Sloan Kettering Cancer Center, Biostatistics, New York, USA; <sup>4</sup>Memorial Sloan Kettering Cancer Center, Neuroradiology, New York, USA

### Purpose or Objective

To evaluate outcomes of patients with primary chordomas treated with spine stereotactic radiosurgery (SRS) alone or in combination with surgery, drawing from a single-institution database to elucidate treatment options associated with durable control of these conventionally radioresistant tumors.

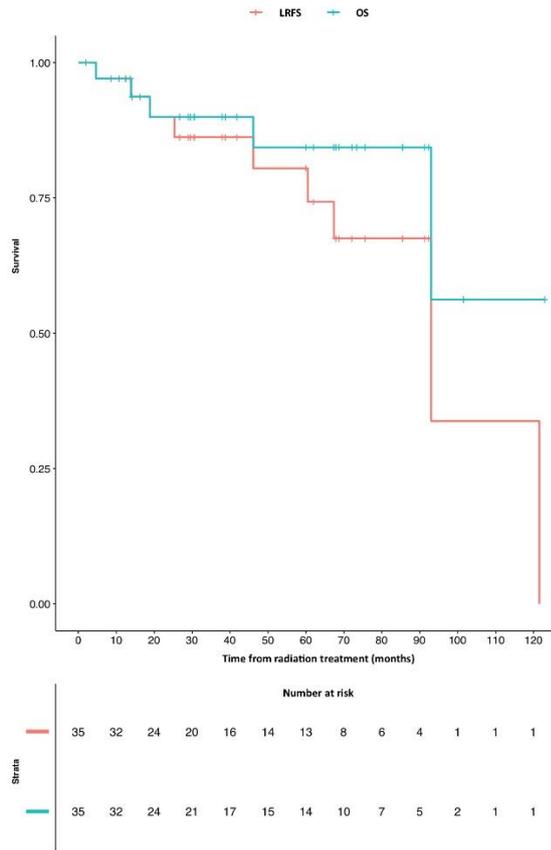

### Material and Methods

Clinical records were reviewed for outcomes of patients with primary chordoma of the mobile spine and sacrum who underwent single-fraction SRS between 2006 and 2017. Patients were followed with spine MRI to determine local recurrence-free survival (LRFS). LRFS and overall survival (OS) were analyzed using the Kaplan-Meier method. Tumor location and extent of surgery were analyzed for significance in relation to LRFS and OS using univariate Cox regression. CTCAE v. 5.0 toxicity in relation to extent of surgery was analyzed using Fisher's Exact Test.

### Results

In total, 35 patients with de novo chordoma of the mobile spine (46%) and sacrum (54%) received SRS, with a median post-SRS follow-up of 40.3 months (range 2.0-122.9). The median PTV volume was 155.6 cm<sup>3</sup> (29.2-903.8 cm<sup>3</sup>). The median PTV dose was 24 Gy (18-24 Gy), with a median V95 = 99.5% and D95 = 2395 cGy. Among 23 patients also undergoing surgery (66%), 39% underwent epidural decompression and instrumentation prior to SRS, while 61% underwent extensive resection including corpectomy or partial sacrectomy. One-third received SRS alone, including 4 patients who did not proceed to planned surgery based on lack of progression and patient preference. The 3- and 5-year LRFS rates were 86.2% and 80.5% respectively. Among 32 patients receiving 24 Gy (91%), the 3- and 5-year LRFS were 96.3% and 90.0%. Four developed metastatic disease (11%) at a median of 5.1 years (range 1.0-10.2). The 3- and 5-year OS rates were 90.0% and 84.3%. Spinal location (mobile spine, sacrum) and extent of surgery (none, epidural decompression, extensive resection) were not associated with LRFS or OS ( $p>.05$ ). Patients undergoing partial sacrectomy or corpectomy developed higher surgical toxicity rates compared to patients undergoing decompression surgery (85%  $\geq$ Grade 2; 54% Grade 3 vs. 22%  $\geq$ Grade 2; 0% Grade 3) ( $p=0.001$ ). The long-term  $\geq$ Grade 2 SRS toxicity rate was 31%, including 14% Grade 3 tissue necrosis, recurrent laryngeal nerve palsy, fracture, and secondary malignancy. Among 30 patients presenting with pain (100%), radiculopathy (23%), or neuropathy (34%), two-thirds reported symptom response to treatment, with rates of 40% complete response (CR), 23% partial response (PR), and 7% CR for pain with PR for neuropathy.

FIGURE: Kaplan-Meier estimate of local recurrence-free survival and overall survival.

### Conclusion

High-dose spine SRS can offer patients with chordoma the chance of durable radiographic control and effective symptom relief, with acceptable toxicity. SRS should be considered as definitive therapy for unresectable tumor due to surgical morbidity, neoadjuvant prior to resection, and adjuvant post-subtotal resection or for positive margins.

### PV-0363 Cognitive Outcomes after Conformal Radiotherapy in Pediatric Patients with Supratentorial Ependymoma

M. Mizumoto<sup>1</sup>, Y. Oshiro<sup>2</sup>, S. Wu<sup>3</sup>, T.E. Merchant<sup>1</sup>  
<sup>1</sup>St Jude Children's Research Hospital, Radiation Oncology, Memphis, USA; <sup>2</sup>Tsukuba Medical Center Hospital, Radiation Oncology, Tsukuba, Japan; <sup>3</sup>St Jude Children's Research Hospital, Biostatistics, Memphis, USA

### Purpose or Objective

This study investigated cognitive function after conformal radiotherapy (CRT) for pediatric supratentorial ependymoma.

### Material and Methods

From 1997 to 2009, 30 pediatric patients diagnosed with supratentorial ependymoma received photon-based CRT (54.0 or 59.4Gy) using a 0.5-1.0cm clinical target volume margin and were evaluated for change in cognitive function. The median age was 6 years (range 1 - 19 years). The tumor location was frontal (n=8), parietal (n=5), occipital (n=4), fronto-parietal (n=4), IIIrd ventricle (n=3) and other (n=6). The median follow-up period was 12.8 years (range, 2.2-19.0 years). 877 evaluations were performed including estimated IQ (n=209), WIAT Reading (n=174), WIAT Math (n=174), WIAT Spelling (n=173), and VAL (n=147).

### Results

Baseline mean neurocognitive scores were IQ (99.7±22.5), WIAT Reading (97.4±10.3), WIAT Math (98.2±12.2), WIAT Spelling (94.5±10.3), and VAL (97.3±22.2). Linear mixed models with random coefficients revealed no significant change over time and a slightly decline in WIAT reading scores during follow-up (WIAT Reading slope estimate -0.7444±0.3818 points/year; P=0.0631). Gender, age at time of radiotherapy, radiation dose to the supratentorial brain, temporal lobes and entire brain, the use of pre-CRT chemotherapy and number of surgeries was not significantly associate with cognitive function. Only tumor location (frontal vs. other) was significantly associated with WIAT Spelling (p=0.0223).

### Conclusion

In a cohort of children with supratentorial ependymoma and extended follow-up, CRT using photons spared cognitive function. These results challenge the premise that newer methods of radiation therapy will improve outcomes in these patients.

### PV-0364 Pulmonary function after high dose chemotherapy + total lung irradiation for pediatric Ewing sarcoma

B. Diletto<sup>1</sup>, E. Pecori<sup>1</sup>, N. Puma<sup>2</sup>, O. Alessandro<sup>3</sup>, S. Meroni<sup>4</sup>, M. Podda<sup>2</sup>, A. Busia<sup>5</sup>, F. Allegri<sup>5</sup>, A.C. Ogliari<sup>5</sup>, C. Materazzo<sup>6</sup>, R. Boffi<sup>5</sup>, E. Pignoli<sup>4</sup>, R. Luksch<sup>2</sup>, L. Gandola<sup>1</sup>  
<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy; <sup>2</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Pediatric Oncology, Milan, Italy; <sup>3</sup>Università degli Studi di Milano, Residency Program in Radiation Oncology, Milan, Italy; <sup>4</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Physics, Milan, Italy; <sup>5</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Pulmonary Unit, Milan, Italy; <sup>6</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Cardiology Unit, Milan, Italy

### Purpose or Objective

Total lung irradiation (TLI) following high dose chemotherapy with busulfan and melphalan (BuMel) and autologous stem cell transplantation (ASCT) is an intensive strategy improving outcomes of pediatric Ewing sarcoma (ES) pts with lung metastases. A critical issue regarding the combination of BuMel-ASCT and TLI is the supposed additional lung toxicity. Results of pulmonary function of a subgroup of metastatic ES children treated with this approach in a single Institution within a multicentric prospective study are reported.

### Material and Methods

Clinical records of lung metastatic ES children treated in our Institution were collected. Pts were treated according to 3 international and national protocols: ISG/SSG (Italian Sarcoma Group/Scandinavian Sarcoma Group) IV, ISG-AIEOP (Associazione Italiana Ematologia Oncologia Pediatrica) EW-2, ISG/AIEOP-Rel. TLI was administered at least 8 weeks after BuMel-ASCT, and the prescribed total dose was 15 Gy in 10 daily fractions. Lung and cardiac functions were assessed by pulmonary function tests (PFTs) (including spirometry, lung volume measurements and single-breath carbon monoxide-diffusion capacity - DLCO-) and echocardiogram before BuMel-ASCT, between BuMel-ASCT and TLI, after TLI and regularly during the F-UP. Ejection fraction (EF), forced vital capacity (FVC), forced expiratory volume in 1 second (FEV1), total lung capacity (TLC), and DLCO were recorded.

### Results

Data from 17 pts (ISG/SSG IV: 6, ISG-AIEOP EW2: 10, ISG/AIEOP-Rel: 1) were collected (10 F, 7 M, median age 15.3 y, range 3.9-20). All pts performed PFTs and echocardiogram regularly. Median time from BuMel-ASCT to TLI was 95 days (73-335). After BuMel-ASCT a mild restrictive syndrome was observed in 7 pts (41%) and a mild obstructive syndrome in 1 pts (6%). After TLI 9 (53%) patients presented a mild and 1 pts (6%) a moderate restrictive syndrome, 1 pts showed a mild obstructive

syndrome (6%). At last F-UP (median 70.8 mo, 14.3-207.9) 5 mild (30%), 1 moderate restrictive (6%) and 1 mild obstructive syndrome (6%) were recorded. No EF pathological reduction were observed. Mean trend of most significant PFTs (FVC, FEV1, DLCO) showed a rapid decline after BuMel-ASCT, reaching the lowest values (< 80% of basal value) after TLI, and they recovered gradually up to 90% of basal value over time. Only 1 reversible G2 interstitial pneumopathy was detected after BuMel-ASCT.

#### Conclusion

The combined strategy of BuMel-ASCT and TLI for treatment of lung and metastatic ES children seems to not compromise pulmonary and cardiac functions, demonstrating an acceptable toxicity profile. Nevertheless, it is mandatory to strictly and regularly assess pulmonary function before and after BuMel-ASCT to identify pts possibly ineligible for TLI, and during the F-UP.

#### PV-0365 Adoption of expansion margins to reduce the dose received by coronary arteries in lymphoma patients

V. De Luca<sup>1</sup>, S. Bartoncini<sup>2</sup>, M. Levis<sup>1</sup>, E. Gallio<sup>3</sup>, C. Cavallin<sup>1</sup>, G.C. Iorio<sup>1</sup>, R. Parise<sup>1</sup>, C. Palladino<sup>1</sup>, F.R. Giglioli<sup>3</sup>, C. Fiandra<sup>3</sup>, U. Ricardi<sup>1</sup>

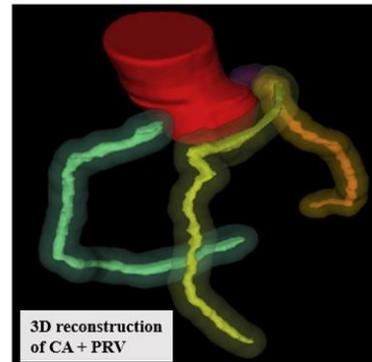

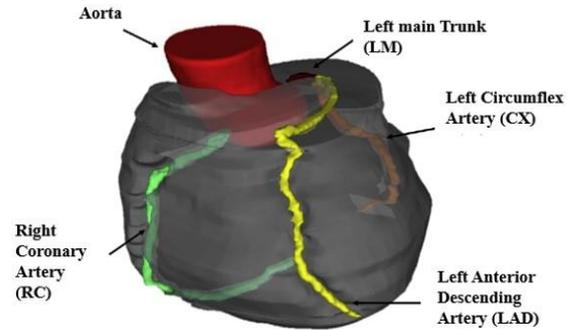

<sup>1</sup>University Of Turin, Department Of Oncology- Radiation Oncology, Turin, Italy ; <sup>2</sup>A.O.U. Citta' Della Salute E Della Scienza Di Torino, Department Of Oncology- Radiation Oncology, Turin, Italy ; <sup>3</sup>a.O.U. Citta' Della Salute E Della Scienza Di Torino, Medical Physics Unit, Turin, Italy

#### Purpose or Objective

Many studies have demonstrated a linear correlation between the heart dose and the risk of coronary artery disease in lymphoma patients receiving mediastinal radiotherapy (RT). In order to reduce long term ischemic events, a detailed contouring of cardiac structures - particularly of coronary arteries (CA) - is needed. Anyway, heart motion impacts on the precise estimation of the dose received by small volumes as CA. An isotropic margin (PRV) for CA may compensate the uncertainties due to their displacement during the heart cycle. In this study, we aimed to evaluate the potential dosimetric benefit obtained by the coronary tree with the optimization of the treatment plan on each PRV volume rather than just on CA volumes.

#### Material and Methods

We enrolled fifteen patients (mean age 30, range 16-54) affected with Hodgkin lymphoma or primary mediastinal B cell lymphoma (4 males and 11 females) with high prevalence of bulky presentation at baseline (13/15 patients: 87%). Median prescription dose to the PTV was 31 Gy (range 24-40). The following CA were contoured as organs at risk (OARs): left main trunk (LM), left anterior descending artery (LAD), left circumflex artery (CX) and right coronary artery (RC). We designed a dedicated PRV for each CA by applying an isotropic margin of 3 mm to LM, 4 mm to CX and 5 mm to LAD and RC, as suggested by a recent publication (Fig. 1).

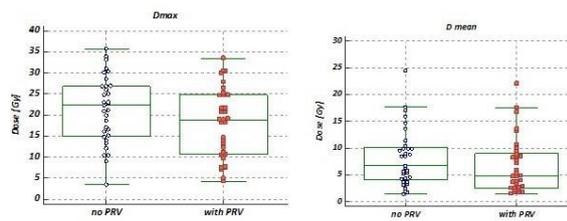

We then compared two care plans, either optimized on the original OARs (CA) or on their dedicated PRV in order to test potential dosimetric benefit conferred by the integration of PRV in the optimization process. Similar PTV coverage was deemed mandatory to proceed with the planning workflow. We included only those CA that were located in the close proximity of the target of treatment; we thus evaluated 33 CA and their relative PRVs. Seven patients (47%) had 3 CA, 4 (27%) had 2 CA and the remaining 4 (27%) had only 1 CA close to the PTV. Maximum and mean doses (Dmax and Dmean) were estimated for all the structures and were then compared with t-Student Test.

#### Results

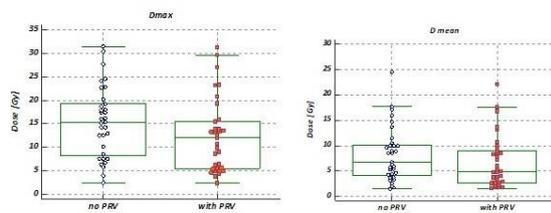

The plan optimization on PRVs shows a significant dosimetric benefit, both in terms of Dmax and Dmean, for the CA volumes, with a mean dose reduction of 20% for Dmax (12.3 vs 15.4 Gy,  $p < 0.05$ ) and of 16% for Dmean (6.8 vs 8.1 Gy,  $p < 0.05$ ). Moreover, we obtained a significant dosimetric gain also for the PRV volumes: in fact, we observed a mean dose reduction of 15,5% for Dmax (18.0 vs 21.3 Gy,  $p < 0.05$ ) and of 15,3% for Dmean (7.2 vs 8.5 Gy,  $p < 0.05$ ), respectively (Fig. 2).

## Plan optimized on PRVs

p - value	OAR PRV Dmax [Gy] [mean ± s.d.]		OAR PRV D mean [Gy] [mean ± s.d.]	
	NO	YES	NO	YES
	21.3 ± 8.0	18.0 ± 8.3	8.5 ± 8.5	7.2 ± 5.4
	< 0.05		< 0.05	

## Plan optimized on CAs

p - value	OAR PRV Dmax [Gy] [mean ± s.d.]		OAR PRV D mean [Gy] [mean ± s.d.]	
	NO	YES	NO	YES
	15.4 ± 7.5	12.3 ± 7.8	8.1 ± 5.4	6.8 ± 5.2
	< 0.05		< 0.05	

Notes: NO = OAR corresponds to Coronary Artery; YES = OAR corresponds to Coronary Artery's PRV.

## Conclusion

Our study shows that the optimization of the treatment plan to the PRV volumes of CA located in the proximity of the target volumes ensures a significant reduction (ranging from 15 to 20%) of the mean and maximal dose received by the coronary tree. We thus recommend to integrate PRVs in the optimization process of mediastinal RT for lymphoma patients because they decrease the dose received by CA and may potentially limit the risk of long term ischemic complications.

**PV-0366 Helical Total Lymphoid Irradiation: radiotherapy still works in lymphoma transplantation**  
S. Vagge<sup>1</sup>, F. Guolo<sup>2</sup>, A. Dominietto<sup>3</sup>, S. Agostinelli<sup>4</sup>, M. Gusinu<sup>4</sup>, A. Ibaticci<sup>3</sup>, F. Ballerini<sup>2</sup>, R.M. Lemoli<sup>2</sup>, E. Angelucci<sup>3</sup>, M. Gobbi<sup>2</sup>, R. Corvò<sup>5</sup>

<sup>1</sup>IRCCS Ospedale Policlinico San Martino- academic hospital, Radiation Oncology, Genova, Italy; <sup>2</sup>IRCCS Ospedale Policlinico San Martino, Clinica Ematologica, Genova, Italy; <sup>3</sup>IRCCS Ospedale Policlinico San Martino, Ematologia, Genova, Italy; <sup>4</sup>IRCCS Ospedale Policlinico San Martino, Medical Physics, Genova, Italy; <sup>5</sup>IRCCS Ospedale Policlinico San Martino, Radiation Oncology, Genova, Italy

## Purpose or Objective

Assessing feasibility and preliminary outcomes of a conditioning strategy based on high dose chemotherapy (HDC) and Helical Total Lymphoid Irradiation (HT-TLI) as preparation for autologous stem cell transplantation (ASCT) in patients affected by relapsed/refractory (R/R) Hodgkin's Lymphoma (HL) and non-Hodgkin lymphoma (NHL). Salvage chemotherapy followed by ASCT is the standard of care for patients with R/R. However conventional conditioning regimens have low efficacy in R/R patient and only a minority of them is cured by this approach. Promising results with a technical "old suite" total lymphoid irradiation (TLI) and with hyperfractionated schedules, followed by high-dose chemotherapy and ASCT have been reported in advanced HL patients, despite relevant toxicity due to radiation-induced damage of healthy tissues.

## Material and Methods

From February 2011 to December 2017, 15 patients with R/R HL (n=7), diffuse Large B Cell NHL (n=6) and T-cell NHL (n=2) were treated. Median age was 42 years (range 20-68) and median number of previous lines of therapy was 3 (range 2-4). Of note, 4 patients had already received prior ASCT. Salvage chemotherapy was decided case by case and clinical response was determined by functional imaging prior to ASCT. HT-TLI delivered 12 Gy in 3 daily fractions, by a dedicated setup, to all the body nodal chain with regards to the tumor burden area. HDC consisted of high-dose Bendamustine (400 mg/sqm) and Melphalan 140 (mg/sqm) for patients older than 40 years (n=10) and conventional FEAM (Fotemustine, Ethoposide, Cytarabine and Melphalan) for younger patients.

## Results

Salvage chemotherapy induced complete response (CR) in 7 patients (5 HL, 2 NHL), partial response (PR) in 5 (2 HL, 3 NHL), less than partial response (LPR) 3. Conditioning strategy was well tolerated. Six patients (40 %) experienced fever of unknown origin and 5 patients (33%) developed grade 3/4 mucositis. None experienced grade 3/4 extra-hematological toxicity. All patients showed complete engraftment and median time to neutrophil and platelet recovery was 11 (range 9-21) and 12 days (range 9-21) respectively. Median follow-up was 38 months (CI 95%: 1.3-66.1 months). All patients in PR or less before transplant achieved CR. There were no cases of treatment-related death. The 3-year overall PFS and OS were 78% and 93% (Fig. 1) respectively. Post-ASCT relapse occurred in 3 patients (HL=2 and NHL=1) at a median time of 8 months and 1 NHL patient subsequently died of progressive disease 7 months after ASCT.

## Conclusion

Our preliminary results show that HT-TLI can be safely used in advanced lymphomas with sequential high dose chemotherapy as combined conditioning. With the limit deriving from the small size of this series, we observe that all patients achieved CR after the procedure, even if heavily pretreated, and that relapse rate was low. Overall these results encourage the implementation of HT-TLI in the standard conditioning for R/R lymphomas.

**PV-0367 TMLI-based low-toxic myeloablative conditioning regimen in haploidentical HSCT for AML**

<sup>1</sup>Radiation Oncology Section- University of Perugia and Perugia General Hospital, Surgery and Biomedical Sciences, Perugia, Italy; <sup>2</sup>Division of Hematology and Clinical Immunology and Bone Marrow Transplant Program- University of Perugia and Perugia General Hospital, Medicine, Perugia, Italy; <sup>3</sup>Medical Physics Unit- Perugia General Hospital, Medical Physics, Perugia, Italy; <sup>4</sup>Radiation Oncology Section- Perugia General Hospital, Surgery and Biomedical Sciences, Perugia, Italy

## Purpose or Objective

Hematopoietic stem cell transplantation (HSCT) is elective post-remission treatment for patients with intermediate-high risk acute myeloid leukemia (AML). The best donor is the matched sibling which is available for 25% of cases. The 1-haplotype mismatched relative (haploidentical) is a valid alternative as it is immediately available for 95% patients. In haploidentical HSCT total body irradiation is an essential component of the myeloablative conditioning regimen which, in elderly or young unfit patients, is associated with high toxicity and non-relapse mortality rates. In order to reduce the treatment-related toxicity we designed a conditioning regimen with total marrow/lymphoid irradiation (TMLI) and low chemotherapy doses. Furthermore, to induce a Graft versus Leukemia (GvL) effect with a low incidence of Graft versus Host Disease (GvHD) the graft contained, as

adoptive immunotherapy, a ratio of conventional T cells (Tcons) and T regulatory cells (Tregs).

#### Material and Methods

From July 2015 to July 2018 26 AML patients (14 in first and 10 in second complete remission, 2 in partial remission) and 2 patients with myelodysplasia underwent haploidentical HSCT. There were 15 male and 13 female; median age was 60 years (range 42-70). Composite comorbidity/age scores were 1/2 in 10 patients and  $\geq 3$  in 18. TMLI target volumes were skeletal bones, major lymph node chains and spleen. TMLI was delivered by helical tomotherapy in 4 and half days (from day -15 to day -11) in 2 daily fractions of 1.5 Gy (TMI) and 1.3 Gy (TLI) (total doses 13.5Gy and 11.7Gy respectively). Chemotherapy schedule included tiothepa 2.5 mg/kg on days -10 and -9; fludarabine 30 mg/m<sup>2</sup> from days -10 to -6; cyclophosphamide 15 mg/kg on days -8 and -7. Haploidentical grafts consisted of 10x10<sup>6</sup>/kg purified CD34+cells, 1x10<sup>6</sup>/kg Tcons, 2 x10<sup>6</sup>/kg Tregs. No post-transplant immunosuppression was given.

#### Results

TMLI-related acute toxicity was G1-G2 in 23 patients, G3 in 4 and G4 in 1. All patients sustained primary full-donor type engraftment. Grade II-IV acute GvHD developed in 8 patients (29%) and chronic GvHD in none. Transplant-related causes of death in 6 patients were veno-occlusive disease (1), hemorrhage (1) sepsis (2) and acute GvHD (3). Immune reconstitution was good, with peripheral blood T cells rapidly increasing. Relapse did not occur in any patients. Twenty two (79%) patients are alive and relapse-free at a median follow up of 19 months (3-40 months).

#### Conclusion

This transplant strategy (TMLI, low doses of tiothepa, fludarabine, cyclophosphamide and adoptive immunotherapy with Tregs-Tcons) was successful in haploidentical transplantation for elderly and young unfit AML patients. TMI provides strong myeloablation and TLI provides efficient immunosuppression. The conditioning regimen was associated with low toxicity and mortality. The appropriate Tcon/Treg ratio was confirmed to exert a powerful T-cell dependent GvL effect with a low incidence of GvHD.

Radiotherapy, Arnhem, The Netherlands ; <sup>14</sup>Hospital of Navarra, Department of Radiation Oncology, Pamplona, Spain ; <sup>15</sup>Leiden University Medical Center, Department of Radiation Oncology, Leiden, The Netherlands

#### Purpose or Objective

Incidence methods and prevalence rates are commonly used statistical approaches for summarizing late side effects after radiotherapy. Incidence methods capture the first occurrence of an event; but are unable to distinguish transient from persistent symptoms. Prevalence rates contain information on persistence of symptoms in the cohort; but not on an individual patient level. A novel method to identify patients with LAte, PERsistent, Substantial and likely treatment related symptoms (LAPERS) is applied on patient reported outcomes (PRO) from the prospective, observational, and longitudinal study on MRI image-guided, adaptive brachytherapy in locally advanced cervical cancer (EMBRACE study).

#### Material and Methods

PRO (EORTC QLQ-C30 + CX24) were analyzed in 657 out of 1416 patients within the EMBRACE study who had a valid baseline, 3 months' assessment and at least 3 late follow ups (6 months and ongoing). A LAPERS event for an individual patient was defined when the median scoring over late follow-ups was "quite a bit" or "very much" (substantial symptoms). For organ-related symptoms (e.g. urinary frequency) baseline morbidity was taken into account by requiring the median to be worse than the minimum of baseline and 3 months scoring (treatment-related); whereas for more unspecific symptoms (e.g. tiredness) baseline correction was not applied. Crude incidences and median prevalence rates of substantial symptoms from 6 to 60 months were calculated in the same cohort and put into perspective with LAPERS via ratio calculations.

#### Results

Median follow-up was 42 months (IQR 30-59). Table 1 presents the outcome of the different methods for reporting. LAPERS was  $\geq 10\%$  in 10 out of 31 symptoms; amongst them swelling in one or both legs, tiredness, urinary frequency and trouble sleeping. LAPERS was below 2% in 8 symptoms for example pain/burning feeling passing urine and blood in stools. LAPERS/crude incidence ratios lower than 0.1 was seen in vaginal symptoms, pain/burning feeling passing urine, blood in stools, nausea and vomiting; indicating that less than 10% of patients experiencing substantial symptoms did so persistently. LAPERS/median prevalence ratios lower than 0.4 was seen in the same symptoms; indicating that the patients experiencing substantial symptoms do not consist of the same individuals over time. LAPERS/median prevalence ratios close to 1 (e.g. swelling in one or both legs) indicate that patients experiencing substantial symptoms over time

are the same.

	Symptom	Baseline	LAPERS	Crude incidence	LAPERS/ crude incidence ratio	Median prevalence 6-60 months	LAPERS/ median prevalence ratio

	Felt irritable	15.1%	<u>8.0%</u>	31.6%	0.25	10.40%	0.77
	Felt depressed	15.7%	<u>7.4%</u>	29.0%	0.26	9.20%	0.80

Table 1. Overview of LAPERS, crude incidence, prevalence rates of substantial symptoms (summarizing "Quite a bit" and "Very much") of the EORTC QLC30 and CX24. LAPERS calculation with baseline corrections applied are underlined. LAPERS ≥ 10% are marked with grey.

**Conclusion**

Incidence methods capture the first occurrence of an event; LAPERS in contrast excludes transient symptoms and identifies patients with persisting symptoms. When analyzing longitudinal morbidity data, a complementary approach combining the information of both methods improves the understanding of the morbidity profile of a treatment. LAPERS can be utilized to improve tools for informing patients about the burden and duration of toxicity (e.g. figure 1); thus improving the basis for shared

decision making.

**Difficulty controlling bowel**

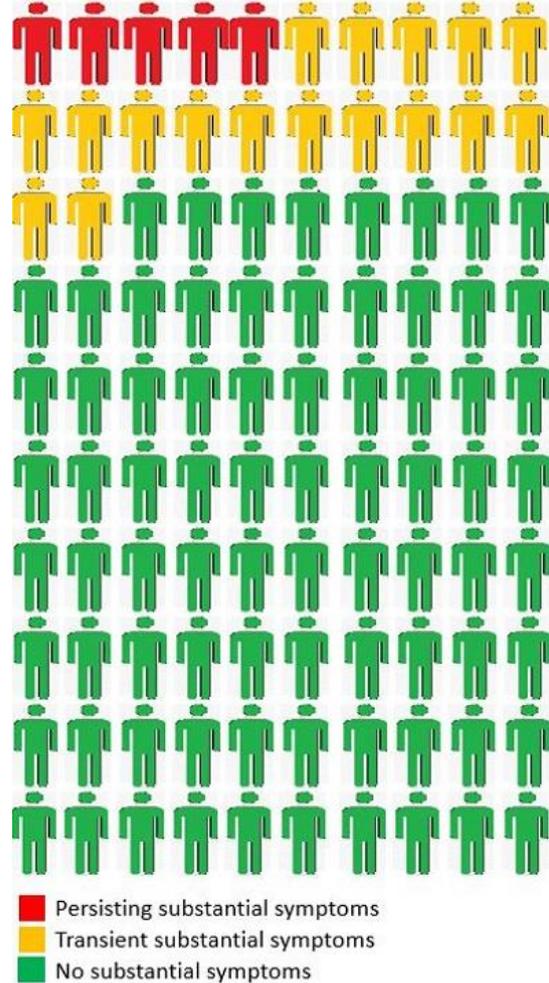

Figure 1. LAPERS events are the red persons, while crude incidence is the total of red and yellow persons.

**PV-0369 Radiomics in Magnetic Resonance Imaging for prediction of radiotherapy outcomes in cervical cancer**

N. Thanamitsomboon<sup>1</sup>, N. Kosaisawe<sup>2</sup>, K. Thephamongkhon<sup>1</sup>, P. Dankulchai<sup>1</sup>  
<sup>1</sup>Siriraj hospital, Division of Radiation Oncology- Department of Radiology, Bangkok, Thailand ;  
<sup>2</sup>University of California- Davis, Department of Molecular and Cellular Biology, Davis, USA

**Purpose or Objective**

The aim of this study is to investigate the predictive value of radiomics features from pre-treatment T2-weighted MR images for clinical outcome of radiotherapy with or without concurrent chemotherapy in cervical cancer patients. The primary and secondary clinical outcomes in this study were loco-regional recurrence (LRR) and overall survival respectively

**Material and Methods**

90 cervical cancer patients with stage IB-IVA between January 2015 to June 2016 were retrospectively enrolled in this study. All patients received definitive radiotherapy with or without concurrent chemotherapy as a primary treatment after underwent T2-weighted MRI simulation before the first fraction of external beam radiotherapy. Gross tumor volume (GTV) was delineated by a radiation oncologist who was an expertise in the gynecological field. Radiomics features [First orders, Gray level co-occurrence matrix (GLCM), and Gray level run length matrix (GLRLM)]

were extracted from GTV on pre-treatment T2-weighted MRI as a 3D contouring volume with MATLAB program. The association between radiomics features and loco-regional recurrence (LRR) were analyzed by T-Test and controlled by false discovery rate to reduce type I error from multiple testing. Then, the multivariable analysis was performed with significant radiomics features and known clinical prognostic factors using Cox-proportional hazard model.

### Results

The median follow-up time was 29.2 months in this study. 12 of 90 patients (13.3%) had LRR. 80 radiomics features were collected. The statistically significant association between each radiomics features with LRR showed as table below.

Table : P-value of T-test and Cox regression model with clinical factors

	P-value(t-test)	P-value(Cox)	Hazard Ratio	Lower CI	Upper CI
Max	0.00023	0.03818	1.002	1.0001	1.0039
Correlation135	0.00145	0.01305	1075.904	4.3454	266387.4092
Correlation90	0.00155	0.01522	1943.678	4.2945	879705.5522
Correlation45	0.00346	0.02480	915.340	2.3733	353027.4518
Correlation0	0.01062	0.05700	1345.319	0.8069	2242956.5340
HGRE0	0.01699	0.12562	1.100	0.9737	1.2424
Range	0.01791	0.04131	1.002	1.0001	1.0038
HGRE45	0.01888	0.13508	1.259	0.9307	1.7041
Entropy	0.02117	0.08858	7748.187	0.2588	232011519.3464
Contrast135	0.02129	0.04449	0.582	0.7810	0.9969

P-value(t-test) = P-value with t-test

P-value(Cox) = P-value of cox regression of radiomics feature and 6 clinical prognostic factors

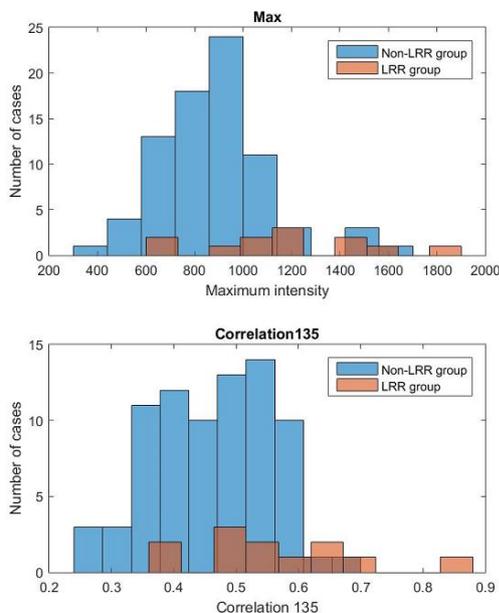

Max = Maximum intensity, Correlation135 = Correlation of gray-level co-occurrence matrix(GLCM) in 135 degree

Correlation90, Correlation45 and Correlation0 = Correlation of GLCM in 90, 45 and 0 degree,

HGRE0 and HGRE45 = High Gray-Level Run Emphasis in 0 and 45 degree, Range = Range of intensity,

Entropy = entropy of intensity, Contrast135 = Contrast of GLCM in 135 degree

The maximum intensity feature ( $p = 0.00023$ ) and correlation135 GLCM feature ( $p = 0.0015$ ) were the lowest p values.

Cox-regression analysis of radiomics features controlled for known clinical prognostic factors also confirmed significant hazard ratio for maximum intensity ( $p = 0.038$ ) and correlation135 GLCM ( $p = 0.013$ ) features. For overall survival outcome, there was no statistically significant association in any radiomics features

### Conclusion

The pre-treatment T2-weighted MR images in cervical cancer patients could provide additional information in predictive value of radiomics features with radiotherapy outcomes. Maximum intensity and correlation135 GLCM

features in our study were the most significant predictive values. To the best of our knowledge, this is the first work that shows predictive value of radiomics features in T2-weighted MRI for cervical cancer patients. These features need to be validated in subsequent more patients. Thus, the further investigation as comprehensive prediction model of LRR in cervical cancer patients would provide more statistical power and confirmation of these valuable features.

### Joint Symposium: ESTRO-ASTRO: Translating discovery to cure

#### SP-0370 Integrating Immunotherapy with Radiation

J. Schoenfeld<sup>1</sup>

<sup>1</sup>Dana Faber Cancer Institute, Radiation Oncology, Boston, USA

#### Abstract text

Immunotherapy has revolutionized the field of oncology. However, only a minority of patients with solid tumors respond to current immunotherapy treatments. Here, we will review the mechanism of action of immune checkpoint blockade and outcomes in recent seminal immunotherapy trials. Preclinical and an increasing amount of clinical data suggest that radiation can augment the clinical effectiveness of immune checkpoint blockade - we will review these data and discuss ongoing clinical trials.

#### SP-0371 A retrospective overview and future perspectives of developments in MRgRT

J. Lagendijk<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands

#### Abstract text

Currently, MR linacs systems are entering the clinic. Those systems move radiotherapy in the direction of real-time MRI guided treatment optimization, greatly reducing the targeting uncertainty in radiotherapy. This development puts great importance on all forms of high quality imaging needed for tumour localization and characterization; the step from relative large PTV volumes to stereotactic body irradiation requires better target definition. The reduction of the PTV both facilitates dose optimization and the further development of hypofractionation for the majority of tumours. This process transforms radiotherapy towards interventional radiology, re-inventing radiotherapy and finally allowing dose painting as pointed out by every TCP model. The impact on the organization of radiotherapy will also be discussed. The new focus on complex, large imaging departments with interventional treatments will steer away from the old model with small radiotherapy satellites with a focus on closeness to the patient.

#### SP-0372 Real Time Adaptive Radiation, Lessons from Clinical Practice Teams

M. Bassetti<sup>1</sup>

<sup>1</sup>University of Wisconsin School of Medicine and Public Health, Human Oncology, Madison, USA

#### Abstract text

Radiation treatment plans are traditionally created pre-treatment and are unchanged during the course of delivery. Recent advances in radiation treatment delivery systems, including integration of MRI and rapid treatment planning software, enable oncologists to adapt radiation treatment plans in real time. This capability to adjust treatment to account for daily anatomical position changes allows the potential to increase dose to tumors and minimize dose to normal organs. While opening

avenues for potentially safe dose escalation in difficult to treat anatomical locations such as pancreatic cancers, it also creates increased demand and time pressures on clinical care teams. Here we discuss examples from clinical practice highlighting the benefits, challenges, and practical solutions for clinical use of real time MR-guided adaptive radiation.

#### SP-0373 Fractionation and breast cancer: towards more efficient schedules

J.R. Yarnold<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Radiotherapy & Imaging Department, Sutton, United Kingdom

#### Abstract text

In 1952, Lionel Cohen, reported a retrospective analysis of fractionation parameters associated with local control in women treated in Johannesburg for locally advanced/recurrent breast cancer. He found that breast cancer is sensitive to fraction size, an interpretation confirmed in 1984 when Bruce Douglas re-analysed Cohen's data using the new L-Q model. This historical observation simulated a series of UK randomised trials that have generated direct estimates of alpha/beta (a/b) for breast cancer and late reacting normal tissues in patients irradiated after primary surgery. An a/b value of around 3 Gy has been generated for both endpoints. So, conventional 2 Gy fractions are equally sparing of cancer and the late reacting normal tissue and have no clinical advantages. 40 Gy in 15 fractions of 2.7 Gy in 3 weeks has become an international standard, but it may not represent the safe and effective limit of hypofractionation. The FAST randomised trial controlled for time by testing 5 fractions delivered once-weekly for 5 weeks against 50 Gy in 25 fractions in 5 weeks. The results informed the FAST forward randomised trial testing two dose levels of a 5-fraction regimen delivered in 1 week against 40 Gy in 15 fractions in 3 weeks and 3-yr late normal tissue responses have been presented. The UK trial designs, incorporating 2 test dose levels, enable interpolation, where needed, to identify test schedules iso-effective with the Control regimen for tumour and normal tissues without distinguishing fraction size and time-related effects.

Kingdom ; <sup>11</sup>Mount Sinai, Icahn School of Medicine, New York, USA

#### Purpose or Objective

There is a risk of long-term side-effects following radiotherapy for cancer. Identification of common genetic variants can provide information on susceptibility, and may lead to improve risk prediction and inform functional work to better understand biological mechanisms. The purpose of this Radiogenomics Consortium study was to expand our previous meta-analysis from ~1,600 patients to 4,000 patients in an attempt to identify new loci associated with risk of late toxicity following radiotherapy.

#### Material and Methods

An individual patient data meta-analysis was carried out in six European-ancestry genome-wide association studies (n=3,871) of radiotherapy-treated prostate cancer survivors. Radiotherapy side-effects were graded prospectively in all studies. Cox proportional hazards regression tested associations of ~6 million genotyped or imputed variants with urinary and rectal toxicity endpoints (time to first ≥grade 2 event).

#### Results

Individual patient data meta-analysis of the European ancestry cohorts identified three signals with genome-wide significance and low Bayesian false discovery probability (<2%): rs17055178 (p=6.2x10<sup>-10</sup>), rs10969913 (2.9x10<sup>-10</sup>), rs11122573 (p=1.8x10<sup>-8</sup>), associated with rectal bleeding, decreased urinary stream, and haematuria radiation induced risk, respectively. Fine mapping the regions containing these signals identified an additional independent signal associated with haematuria. Credible causal variants at the four signals lie in gene-regulatory regions and some modulate expression of nearby genes. All variants retained significance in multivariable models including clinical and dosimetric risk factors. Previously identified variants showed a consistent association effect in the new cohorts (*KDM3B*, *DHAH5*, *ATM*). Two new and two previously identified signals showed a similar effect in two Japanese ancestry cohorts.

#### Conclusion

Our study highlights the importance of common genetic variants as a determinant of long-term side-effects following radiotherapy, increases understanding of the architecture of common genetic variants affecting risk of late radiotherapy side-effects, and shows further multinational studies in larger cohorts are worthwhile.

#### OC-0375 Improving lung cancer outcome by reducing normal lung tissue toxicity

L. Giuranno<sup>1</sup>, E. Roig Moreno<sup>1</sup>, R. Iannone<sup>1</sup>, M. Vooijs<sup>1</sup>  
<sup>1</sup>Maastricht Radiation Oncology Maastricht, Radiotherapy, Maastricht, The Netherlands

#### Purpose or Objective

Lung cancer is the leading cause of cancer death in western countries. The current standard of care includes surgery, chemotherapy and radiotherapy. While significant progress has been made in terms of treatment modality radiotherapy is limited by dose-limiting side-effects which negatively affect tumour control and patient's quality of life. Reducing side-effects may improve tumor control by dose-escalation and treatment-time. The Notch signaling pathway plays an important role in lung cell differentiation and regeneration of the airway epithelium and its deregulation is associated with several cancers including lung cancer. Notch signaling pathway alteration leads to poor outcome and treatment resistance in patients and in preclinical models suggesting Notch signaling as a novel therapeutic target. However, the mechanism through which Notch inhibition integrates with airway repair and cellular differentiation is not fully understood. What is currently lacking are primary human lung tissue models that enable robust evaluation of normal

tissue effects prior to clinical studies. We hypothesize that Notch inhibition has a protective effect in cells exposed to radiotherapy and may represent a potential target for intervention to modulate normal tissue toxicity.

#### Material and Methods

We established and characterized primary lung organoids and air liquid interface system (ALI), pseudo-stratified cultures derived from primary human bronchial epithelial cells (PBEcs) from 6 different donors. In these cultures, basal cells proliferate and differentiate into ciliated and mucous/secretory cell types resembling the human bronchus. We irradiated lung epithelium with 2 and 4 Gy and early and late response to radiotherapy were evaluated. We investigated the consequences of blocking Notch signaling pathway using the pan-notch  $\gamma$ -secretase inhibitor DBZ (1 $\mu$ M) alone and when combined with irradiation (2, 4 Gy).

#### Results

Using immunofluorescence, western blot and q PCR we found that basal cells (p63<sup>+</sup>, CK5<sup>+</sup>) cease proliferation (Ki67, EdU) at day 21 and mucous cell differentiation (Muc1/5ac<sup>+</sup>) precedes ciliary differentiation (Ac-Tub<sup>+</sup>) and both complete at day 28. Proliferation decreases overtime but inhibiting Notch in undifferentiated progenitors and in differentiated cells at day 21 increases p63 proliferation alone and even more in combination with radiotherapy. In all the 6 donors and in murine cultures Notch inhibition increases p63+basal progenitors and ciliated cells and decreases mucous cells alone and in combination with radiation. In irradiated cultures we observed increased pATM and pCHK2 12h and 24h post-irradiation when Notch signaling was inhibited. 53BP1 staining shows reduced DNA breaks 24h and 3 days post-irradiation when Notch was inhibited.

#### Conclusion

These data support the use of normal patient tissue for predictive toxicity, screening of combination treatments and disclose important novel interactions between Notch inhibition and radiotherapy.

#### OC-0376 Radio-selective effects of natural occurring muscle-derived dipeptide in A549 and normal cell lines

N. Ybarra<sup>1</sup>, J. Seuntjens<sup>1</sup>

<sup>1</sup>McGill University, Oncology Department, Montreal, Canada

#### Purpose or Objective

Radiotherapy (RT) causes morbidity and long-term side effects. A challenge in RT is to maximize cancer cell killing while minimizing damage to normal tissue. The ideal radio-protector selectively improves survival and limits damage to normal tissues while reducing survival or proliferation of cancer cells. Muscle-derived dipeptide, L-carnosine (CAR) has been described as a potent antioxidant, with radio-protective, but also anticancer properties, affecting the cell cycle of cancer cells. We aimed to test CAR effects in 3 cell types affected by RT: cancer cells, differentiated and undifferentiated normal cells. We hypothesized that 1) CAR antioxidant properties will confer protection to normal cells against RT while preventing cancer cell proliferation, and 2) CAR may act as a radiosensitizer of cancer cells due to its effect on their cell-cycle progression.

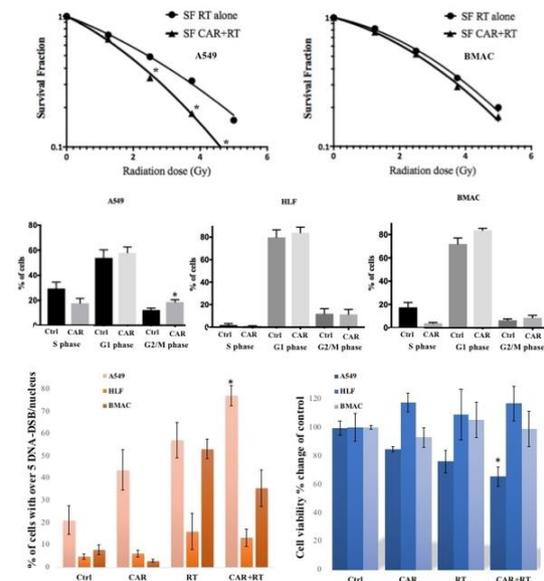

#### Material and Methods

The radio-selective effects of CAR were tested in cell lines: a) differentiated normal cells (human lung fibroblasts, HLF), b) normal undifferentiated cells (bone marrow adherent cells, BMAC), and c) lung cancer cell line (A549 cells). Treatment consisted of adding CAR to the media of growing cells. Cell cycle progression and short-term effects in proliferation were tested in control and CAR treated cells. Clonogenic assay, also performed in control and CAR-treated, was used to test CAR long-term effects in cells exposed to different radiation doses. In addition, the 3 cell lines were randomized in four groups:

control, CAR, RT, RT+CAR. Effects on cell viability were measured using XTT assay. DNA-DSB was done by quantifying foci of positive  $\gamma$ -H2AX staining. Cell bioenergetics were measured using Cell mitostress test (Seahorse Bioscience), and ROS production detected with the probe CM-H<sub>2</sub>DCFDA.

#### Results

Clonogenic assay: CAR reduced the number of colonies in non-irradiated cells, and decreased SF of A549 cells at increasing RT doses, not observed in BMACs. At short term, CAR reduced proliferation of the three cell lines and affected their cell cycle, but it only increased the percentage of A549 in the G2/M radiosensitive phase. In A549 cells CAR reduced cell viability, increased frequency of DNA-DSB, and production of ROS. These effects were exacerbated in RT+CAR; opposite effects were observed in normal cells. In terms of A549 cells bioenergetics, CAR reduced their metabolic potential (ability to meet energy demands via respiration/glycolysis), CAR did not induce negative effects on normal cells metabolic potential.

#### Conclusion

CAR increased radio-sensitivity of A549 cancer cells by selectively increasing ROS production and negatively affecting A549 cell bioenergetics, therefore reducing cells viability and DNA-DSB repair capacity. CAR had either no effect or reduced RT-induced damage in normal cells, depending on the cell type. CAR is a versatile naturally occurring compound, that could improve RT-induced cancer cell killing, while reducing the damage to normal differentiated and undifferentiated cells.

#### OC-0377 Individual radiation toxicity prediction, how does mtDNA influence normal tissue response?

<sup>3</sup>GROW - School for Oncology and Developmental Biology- Maastricht University Medical Centre, Department of Genetics and Cell Biology, Maastricht, The Netherlands

### Purpose or Objective

Mitochondria are structures within eukaryotic cells having their own genome. The mtDNA encodes for structural subunits of the OXPHOS chain, rRNAs and tRNAs. Although, variations in the mtDNA are very common (every individual carries variations), mtDNA variations can potentially lead to a stress-induced decrease in mitochondrial function. The main functions of mitochondria are ATP and ROS production, molecular properties important for radiotherapy (RT), suggesting that there is a role for mtDNA variations in RT response. We hypothesize that mtDNA variants are associated with RT response, and influence the DNA damage/repair capacity and/or induced ROS damage.

### Material and Methods

**Patient study:** Random forest modeling has been shown to perform well in situations where there are large numbers of predictor variables with complex interactions. We used this method to study the association between mtDNA variations of lung cancer patients and their dyspnea score as an outcome of radiation-induced lung toxicity (RILT). In our analysis, 137 patients with 3-month dyspnea score of 0 were marked to be not sensitive to RT and 41 patients with a change of at least 2 in the dyspnea score (3-month vs baseline) were marked as radiosensitive.

**In vitro study:** Primary fibroblasts were obtained from either healthy controls or mitochondrial patients, with a m.11778G>A mutation causative for a mild phenotype mitochondrial disease. Assays were performed using galactose containing medium in order to exhibit the mitochondrial phenotype of the cell lines.

### Results

Here, we performed a number of modeling efforts where each time we restricted the features to only a chosen subset of all mtDNA variants. We used a three-fold cross-validation (CV) on our data set and repeated the CV 100 times with random shuffling. We found predictive value when we restricted the features to all tRNA and rRNA variants together with the non-synonymous variants that:

1. are on genes COI, COII, COIII, and CYBT (AUC = 0.61±0.04)
2. are at positions that are at least 50% conserved (AUC = 0.59±0.04)

In our proof-of-concept study, trends in mitochondrial metabolism show that less mitochondrial spare capacity was present for the m.11778 G>A cells compared to the controls. Additionally, preliminary results show an upregulation of RT stress-induced genes (*NFKB*, *NRF2*). DNA damage (γH2AX foci) and apoptosis (cleaved PARP) were increased, although this needs to be further validated; also other stress response pathways are currently explored.

### Conclusion

Our data showed that mtDNA variation could be a valuable biomarker for RILT. Furthermore, we have preliminary data indicating that RT-induced stress response pathways are differently expressed in cells with a mild mtDNA phenotype.

### OC-0378 Regeneration after radiation and T cell-induced tissue injury is not enhanced by type III interferon

J. Fischer<sup>1</sup>, C. Lin<sup>2</sup>, S. Heidegger<sup>2</sup>, A. Wintges<sup>2</sup>, M. Schlapschy<sup>3</sup>, M. Beudert<sup>3</sup>, S.E. Combs<sup>1</sup>, F. Bassermann<sup>2</sup>, A. Skerra<sup>3</sup>, T. Haas<sup>2</sup>, H. Poock<sup>2</sup>

<sup>1</sup>Klinikum rechts der Isar- Technische Universität München, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Klinikum rechts der Isar- Technische Universität München, Klinik und Poliklinik für Innere Medizin III, Munich, Germany; <sup>3</sup>Technische Universität München, Munich Center for Integrated Protein Science CIPS-M and Lehrstuhl für Biologische Chemie, Freising, Germany

### Purpose or Objective

Type I interferon (IFN-I) and IL-22 modulate regeneration of the thymus and intestinal epithelial cells (IECs) after cytotoxic stress like irradiation. Radiation-induced damage to thymic tissues and IECs is a crucial aspect during the pathogenesis of inadequate immune reconstitution and acute graft-versus-host disease (GVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT) with myeloablative total body irradiation (TBI), respectively. IL-22 and IFN-I reduce severity of acute GVHD after allo-HSCT with myeloablative TBI. However, the role of biologically related type III interferon (IFN-III), also known as interferon lambda (IFN-λ) or IL-28, in this context is unclear. We therefore studied the role of the IFN-III pathway in thymic regeneration and GVHD after TBI and allo-HSCT.

### Material and Methods

Co-housed wild-type (WT) and IFN-III receptor-deficient (IL-28 receptor-alpha-deficient/IL-28Ra<sup>-/-</sup>) mice were analyzed in models of TBI-induced thymus damage and a model of GVHD after allo-HSCT with myeloablative TBI. PASylated IFN-III (PASylated IL-28A) was generated to prolong plasma half-life of IFN-III. Pharmacological activity and effects of PASylated IL-28A on radiation-induced thymus damage and the course of GVHD after allo-HSCT with myeloablative TBI were tested.

### Results

Course and severity of GVHD after myeloablative TBI and allo-HSCT in IL-28 receptor-alpha-deficient mice were comparable and not significantly different compared to WT mice. Also, activation of the IFN-III pathway with PASylated IL-28A did not significantly modulate GVHD after allo-HSCT with TBI. Furthermore, IL28Ra<sup>-/-</sup> mice and WT mice showed similar thymus regeneration after radiation, which could also not be significantly modulated by IFN-III receptor activation using PASylated IL-28A.

### Conclusion

We have analyzed the role of IFN-III signaling during radiation-mediated acute tissue injury. We found that despite molecular and biological homologies with IFN-I and IL-22, IFN-III signaling did not regulate thymus regeneration after irradiation or the course of GVHD after myeloablative TBI and allo-HSCT.

### OC-0379 Radiation response mechanisms of mesenchymal stem cells in dependence on their tissue of origin

N. Nicolay<sup>1,2</sup>, A. Rühle<sup>2</sup>, R. Lopez Perez<sup>2</sup>, R. Saffrich<sup>3</sup>, S. Sisombath<sup>2</sup>, T. Trinh<sup>4,5</sup>, J. Debus<sup>4,5</sup>, P.E. Huber<sup>2,4</sup>

<sup>1</sup>University of Freiburg Medical Center, Radiation Oncology, Freiburg, Germany; <sup>2</sup>German Cancer Research Center, Molecular Radiation Oncology, Heidelberg, Germany; <sup>3</sup>German Red Cross Blood Donor Service, Transfusion Medicine and Immunology, Mannheim, Germany; <sup>4</sup>Heidelberg University Hospital, Radiation Oncology, Heidelberg, Germany; <sup>5</sup>German Cancer Research Center, Clinical Cooperation Unit Radiation Oncology, Heidelberg, Germany

### Purpose or Objective

Human mesenchymal stem cells (MSCs) aid the regeneration of tissue damage caused by ionizing radiation (IR), and early clinical results indicate a potential of MSC-based therapies for the treatment of IR-induced toxicities. While MSCs can be harvested from different tissues, the influence of the tissue source on the radiation response of MSCs remains largely unknown.

### Material and Methods

Human MSCs were harvested from adipose tissue (adMSCs), bone marrow (bmMSCs) and umbilical cord Wharton's jelly (wjMSCs) from 9 voluntary donors and characterized according to the established defining criteria: Cellular adhesion was measured, and multi-lineage differentiation was assessed after IR. Proliferation and survival of MSCs were examined after IR, and IR-

induced cell cycle distribution was quantified by flow cytometry. Apoptosis and senescence levels were determined using caspase-3, annexin-V and  $\beta$ -galactosidase stainings. Immunofluorescence analyses of  $\gamma$ H2AX foci were performed to assess DNA double strand break (DSB) repair, and the expression and activation of various proteins involved in human damage signaling and DSB repair were elucidated by Western blot in MSCs from different tissues of origin.

### Results

All MSCs exhibited a relative radioresistance independent of their tissue source and comparable to adult fibroblasts. The defining stem cell characteristics and multi-lineage differentiation potential remained largely unaffected by IR independent of the MSCs' tissue source. While adMSCs and bmMSCs showed a strong IR-induced accumulation in the G2/M phase, wjMSCs exhibited virtually no G2/M phase arrest. Very low apoptosis levels were found in adMSCs and bmMSCs after IR, whereas IR induced apoptosis in up to 20% of wjMSCs as measured by caspase-3 activation. In adMSCs and bmMSCs,  $\gamma$ H2AX foci numbers induced by up to 8 Gy returned to baseline levels within 24 hours after treatment. In contrast, 8 Gy led to significant residual  $\gamma$ H2AX foci and hence unrepaired DSBs in wjMSC1. Expression of  $\beta$ -galactosidase cells was found to be unaffected in wjMSCs, while irradiated adMSCs and bmMSCs demonstrated an increase of  $\beta$ -galactosidase-positive cells. Levels of phospho-ATM and phospho-Chk2 observed after IR were found strongly decreased in all MSCs at 24 hours after IR. Contrary to adMSCs and bmMSCs, wjMSCs exhibited increased phospho-BRCA1 expression still at 24 hours after IR.

### Conclusion

Despite a comparable radiation resistance of MSCs derived from different human tissues, MSCs exhibited differential responses to IR regarding apoptosis, senescence and cell cycle distribution that depended on their tissue source. As the radiation resistance of human MSCs was found independent of their tissue of origin, MSCs from various tissues may aid the regeneration of radiation-induced tissue damages. However, the observed tissue-specific differences of MSCs may need to be taken into account in order to find the optimal tissue source when devising MSC-based clinical therapies for IR-induced tissue damage.

### Purpose or Objective

Curative treatment for locally advanced esophageal cancer (EC) consists of neoadjuvant chemoradiotherapy (nCRT) followed by surgery. Various chemotherapy and radiotherapy regimens are currently used worldwide. The aim of this study was to explore whether a higher total radiation dose leads to a higher probability to obtain a pathological major response (pMR).

### Material and Methods

All consecutive patients who underwent nCRT followed by surgery for locally advanced squamous cell carcinoma (SCC) or adenocarcinoma (AC) of the esophagus between 2000 and 2017 at four major university medical centres were included and stratified according to a prescribed dose of 36Gy, 40Gy, 41.4Gy, 45Gy or 50.4Gy in fractions of 1.8Gy or 2Gy. Clinical and treatment-related characteristics were collected from the prospectively obtained databases: age at diagnosis, sex, clinical tumor and nodal stage, histology, chemotherapy regimen, use of induction chemotherapy and the time interval from nCRT to surgery. The primary endpoint for the analysis was a pMR, defined as Mandard 1 (no residual tumor cells) or Mandard 2 (fibrosis with scattered tumor cells). A multivariable logistic regression analysis was used to analyse the relation between neoadjuvant radiation dose and pMR. Subgroup analysis was performed according to histology.

### Results

A total of 1102 patients were eligible for analysis, who received either 36Gy (162; 14.7%), 40Gy (79; 7.2%), 41.4Gy (211; 19.1%), 45Gy (271; 24.6%) or 50.4Gy (379; 34.4%). A pMR was achieved in 604 patients (54.8%). In multivariable analysis, the total radiation dose was the only factor increasing the probability of reaching a pMR (odds ratio (OR) 1.031), Table 1. Factors reducing this probability were a higher cT stage (cT1: reference; cT2: OR 1.030; cT3: OR 0.556; cT4: OR 0.448), the presence of an AC (OR 0.362) and the use of non-platinum versus platinum based chemotherapy (OR 0.294). The interaction between tumor type and chemotherapy regimen indicated that using non-platinum based chemotherapy for AC patients increases the likelihood of achieving a pMR (OR 4.336). The interaction between tumor type and the use of induction chemotherapy showed that the use of induction chemotherapy is beneficial to reach a pMR in AC patients (OR 1.731).

For AC, 417 of 819 patients (50.9%) achieved a pMR. Factors increasing the probability to achieve a pMR were total radiation dose (OR 1.027) and the use of induction chemotherapy (OR 1.702), Table 1. Tumor stage was the only factor reducing this probability (cT1: reference; cT2: OR 0.423, cT3: OR 0.260; cT4: OR 0.241).

For SCC, 187 of 283 patients (66.1%) achieved a pMR. No subgroup analysis with reliable adjustment of covariables was possible for the cohort of SCC patients.

Table 1: Explanatory model for pathological major response in the entire cohort and in patients with an adenocarcinoma.  
 n = number; OR = odds ratio; 95% CI = 95% confidence interval; SCC = squamous cell carcinoma; AC = adenocarcinoma; df = degrees of freedom.

\*51 and \*43 patients with a missing endpoint or variable were excluded for model building

	Entire patient cohort: n=1051*		Patients with AC: n=776*	
	OR (95% CI)	p-value	OR (95% CI)	p-value
Total dose	1.031 (1.007-1.056)	0.012	1.027 (1.001-1.053)	0.044
Histology (0=SCC; 1=AC)	0.362 (0.257-0.508)	<0.001	/	/
Tumour stage (cT1=reference)		0.011		0.025
cT2	1.030 (0.352-3.016)	0.957	0.423 (0.125-1.432)	0.167
cT3	0.556 (0.202-1.531)	0.256	0.260 (0.081-0.831)	0.023
cT4	0.448 (0.150-1.345)	0.152	0.241 (0.062-0.926)	0.039
Type of chemotherapy (0=platinum based; 1=non-platinum based)	0.294 (0.096-0.985)	0.031	/	/
Induction chemotherapy (0=no induction; 1= induction)	/	/	1.702 (1.261-2.296)	0.001
Interaction histology and induction chemotherapy	1.731 (1.281-2.340)	<0.001	/	/
Interaction histology and chemotherapy	4.336 (1.373-13.692)	0.012	/	/
	Hosmer-Lemeshow goodness: p=0.071 (df=7)		Hosmer-Lemeshow goodness: p=0.499 (df=7)	

### Conclusion

In this cohort of 1102 patients with EC who were treated with nCRT followed by surgery at four high volume institutes, it was demonstrated that the total radiation dose has a major impact on pathological response, especially in AC patients.

**OC-0381 Benchmark case in the ongoing PRODIGE 26 trial : quality assurance of dose escalated radiotherapy**

J. Boustani<sup>1</sup>, R. Rivin Del Campo<sup>2</sup>, J. Blanc<sup>3</sup>, D. Peiffert<sup>4</sup>, K. Benezery<sup>5</sup>, R. Pereira<sup>6</sup>, E. Rio<sup>7</sup>, E. Le Prisé<sup>8</sup>, G. Créhange<sup>1</sup>, F. Huguet<sup>2</sup>

<sup>1</sup>Centre Georges François Leclerc, Radiation Oncologist, Dijon, France ; <sup>2</sup>Tenon Hospital, Radiation oncology, Paris, France ; <sup>3</sup>Centre Georges François Leclerc, Biostatistics, Dijon, France ; <sup>4</sup>Institut de Cancérologie de Lorraine, Radiation Oncology, Vandoeuvre-Lès-Nancy, France ; <sup>5</sup>Centre Antoine Lacassagne, Radiation oncology, Nice, France ; <sup>6</sup>Centre Guillaume Le Conquérant, Radiation Oncology, Le Havre, France ; <sup>7</sup>Institut de Cancérologie de l'Ouest, Radiation Oncology, Saint Herblain, France ; <sup>8</sup>Centre Eugène Marquis, Radiation Oncology, Rennes, France

**Purpose or Objective**

The ongoing phase II/III PRODIGE 26 trial compares chemoradiotherapy with or without dose escalation in patients with locally advanced or unresectable oesophageal cancer. The results of a benchmark case procedure are reported here to evaluate the protocol compliance of participating centers as part of the radiation therapy quality assurance (RTQA) program.

**Material and Methods**

Volume delineation, target coverage, and dose constraints to the OARs were assessed on treatment plans performed by each participating center and compared to parameters defined in the protocol (Table 1). Centers were classified in three categories: per protocol (PP), minor acceptable deviation (MiD), or major unacceptable deviation (MaD). A plan was rejected if  $\geq 4$  MiD or one MaD were found.

**Results**

Thirty-seven centers submitted 52 plans. Among them, 17 (32.7%) were PP, 30 (57.7%) presented MiD, and 11 (21.1%) had MaD. Overall, 12 (23%) plans were rejected. One plan was rejected because the GTV was not correctly delineated. There were 8 (15.4%) MiD for CTV1 margins and 11 (21.2%) for CTV2 margins, due mostly to insufficient margins. The OARs delineation and the PTVs margins were respected in all cases. As for the target volume coverage, 10 plans had under-dosage among which 3 (5.8%) were major. Six plans had over-dosage among which 1 (1.9%) was major. When considering the maximal dose (Dmax) to the spinal cord, there were 2 (3.8%) plans with MiD and 1 (1.9%) plan with MaD. Regarding the lungs V20 and V30, 1 (1.9%) and 3 (5.8%) plans presented MiD and MaD, respectively. As for the heart V40, only 35 (67.3%) plans were PP, 13 (25%) had MiD and 4 (7.7%) had MaD. The liver V30 and the kidneys V20 were respected in all plans. Overall, 52% (n=27) of all treatments were planned with IMRT, while 48% (n=25) were planned with 3D-CRT. Deviations for target volume and OARs between 3D-CRT and IMRT plans are illustrated in Figure 1. The median PTV2 D2% was significantly lower in the IMRT group (p=0.01). The spinal cord Dmax was significantly lower in the IMRT group (median: 37.0 Gy (15.0-48.0), vs. 41.0 Gy (33.0- 46.0), respectively; p=0.003). The lungs V20 did not differ between groups (p=0.31), whereas the median V30 was significantly lower in the IMRT group, 9.0% (6.0-18.0) vs. 13.0% (7.0-28.0), respectively (p=0.003). The median heart V40 was significantly lower in the IMRT group (25.0% (14.0-36.0) vs. 30.0% (17.0-58.0), respectively; p=0.02). The liver V30 and the kidneys V20 did not differ significantly between groups. Overall, there were 13 (48.1%) and 4 (16%) PP plans in the IMRT and 3D-CRT groups (p=0.01), respectively. Significantly more plans in

the IMRT group were accepted (24 (88.9%) vs 16 (64%), respectively; p=0.03).

**Conclusion**

The high frequency of protocol deviations underlines the importance of a QA program in clinical trials. Further work should assess the impact of deviations on patient outcomes. IMRT might allow dose escalation without increasing normal tissue complications.

**OC-0382 Patterns of local failure after SBRT for pancreatic cancer: implications of target volume design**

X. Zhu<sup>1</sup>, C. Yangsen<sup>1</sup>, Z. Xianzhi<sup>1</sup>, S. Yuxin<sup>1</sup>, J. Xiaoping<sup>1</sup>, Q. Shuiwang<sup>1</sup>, C. Fei<sup>1</sup>, J. Zhen<sup>1</sup>, F. Fang<sup>1</sup>, G. Lei<sup>1</sup>, Z. Huojun<sup>1</sup>

<sup>1</sup>Changhai Hospital, Radiation Oncology, Shanghai, China

**Purpose or Objective**

To identify prognostic factors and patterns of local failure in patients with pancreatic cancer receiving stereotactic body radiation therapy (SBRT) plus chemotherapy as initial treatment, for the optimal design of target volumes encompassing a majority of local recurrences.

**Material and Methods**

Consecutive patients with resectable or borderline resectable but medically inoperable due to comorbidities and locally advanced pancreatic cancer undergoing SBRT and chemotherapy in our center were reviewed. Local recurrences were plotted with respect to the celiac trunk (CT), superior mesenteric artery (SMA) and splenic artery (SA) on 1 CT scan of a template patient.

**Results**

Five hundred and ten patients were included. Median follow-up of the entire group was 21.8 months (range: 3.1- 54.9 months). Two hundred and seventeen patients had locoregional recurrences while local and distant progressions were found in 293 patients. One hundred and sixty-nine (33.2%) and 144 (28.2%) patients had recurrences closer to the CT and SMA, respectively, while both invasions of the CT and SMA were found in 115 patients (22.5%). Additionally, 33 patients (6.5%) and 49 patients (9.6%) had recurrences at the hepatic hilum and invasions of the SA, respectively. Besides these patterns of failure, 138 patients (27.1%) also experienced retroperitoneal progressions. The mean distance to the CT, SMA and retroperitoneal recurrence was 9.0mm, 8.3mm and 11.7mm, respectively. Multivariable analysis demonstrated that advanced pancreatic cancer, recurrences at both the CT and SMA and the hepatic hilum, CA19-9 non-responders and BED<sub>10</sub> <60Gy were predictive of worse survival. Moreover, failures stratified by volumes of recurrences in the radiation field were also analyzed. In-field and outside-the-field recurrences alone were found in 127 (24.9%) 111 patients (21.8%), respectively, while 51 (10.0%) and 67 patients (13.1%) had in-field plus outside-the-field recurrences and marginal plus outside-the-field recurrences, respectively. Compared with patients with BED<sub>10</sub> <60Gy, fewer patients with BED<sub>10</sub>  $\geq$ 60Gy had in-field recurrence alone (68 patients vs. 59 patients, P=0.003) and in-field plus outside-the-field recurrences (29 patients vs. 22 patients, P=0.027). No differences were found in the incidences of margin recurrence alone (57 patients vs. 97 patients, P=0.108), outside-the-field recurrence alone (40 patients vs. 71 patients, P=0.128) and marginal plus outside-the-field recurrences (22 patients vs. 45 patients, P=0.091) between patients receiving BED<sub>10</sub> <60Gy and BED<sub>10</sub>  $\geq$ 60Gy, respectively.

**Conclusion**

Areas closer to the CT, SMA and retroperitoneal space were at a high risk of local recurrences. Non-uniform and enough expansions from gross tumor volumes may be necessary and the splenic vessels abutting to the tumor might also be included in the target volume without compromise of dose constraints of organs at risk.

### OC-0383 Randomised controlled trial for dose-escalated radiotherapy in locally advanced rectal cancer

#### Purpose or Objective

Patients with locally advanced rectal cancer (LARC) who achieve a good response following neoadjuvant chemoradiation (CRT) are potential candidates for organ-sparing treatment instead of surgery. As the response to radiotherapy is dose dependent, dose-escalated radiotherapy for LARC may render more patients eligible for organ preservation. In this trial, the RECTAL BOOST study, we have investigated the effect of a radiation boost to the primary tumour prior to standard CRT on complete tumour response in LARC patients.

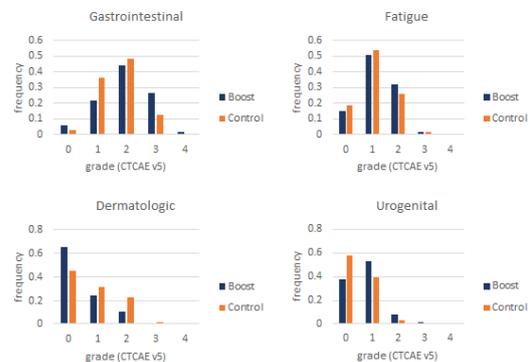

#### Material and Methods

This is a multicentre randomised controlled trial (RCT) nested within a cohort according to the cohort multiple RCT design (Figure 1). Patients with LARC participating in a prospective cohort, referred for CRT and with a tumour <10cm from the anorectal angle were randomised. The control arm received standard CRT (25x2Gy with capecitabine 825mg/m<sup>2</sup> bid). The intervention arm was offered a stereotactic, sequential radiation boost of 5x3Gy to the GTV prior to standard CRT. Dose planning for boost treatment involved equal dose constraints for organs at risk as in standard CRT. The primary endpoint was complete tumour response defined as pathological complete response (pCR), or, in patients who opted for a wait-and-see (WS) approach, 2-years local recurrence-free survival (2-yLRFS). We also assessed organ-sparing potential after CRT defined as (near-)pCR, ypT0-1N0, or wait-and-see with the hypothesis that ypT1N0 patients could have received local excision or could have waited longer. Acute toxicity was measured using CTCAE scores v5.0. Patients were included between Sept 2014 and July 2018. Because this abstract includes preliminary results, differences in outcomes were not tested for significance.

#### Results

Of the 64 patients who were offered boost CRT, 52 (81%) accepted and 51 (80%) received boost treatment. At abstract submission, 52 patients in the intervention group and 55 in the control group had complete follow up. In the boost group, 20/52 (38%) patients had a complete response (15 pCR and 5 2-yLRFS after WS) versus 20/55 (36%) patients in the control group (18 pCR and 2 2-yLRFS after WS). Organ-sparing potential was 50% in the boost arm (20 complete responses, 5 ypT1N0 and 1 ypTisN0) versus 36% in the control arm (20 complete responses, no ypT1N0). Grade 3/4 acute toxicity rate was 20/64 (31%) in the boost arm and 10/64 (16%) in the control arm, primarily due to gastrointestinal toxicity (Figure 2). No grade 5 toxicity was observed. Of all patients who underwent surgery, postoperative complications occurred in 21/46 (46%) in the boost arm versus 32/52 (62%) in the control arm.

#### Conclusion

Results suggest that the rate of complete tumour response is comparable between dose-escalated CRT and standard CRT. However, organ-sparing potential after dose-escalated CRT seems higher. Unfortunately, at the expense of an increase in grade 3-4 acute toxicity. Updated results on this RCT will be presented at the meeting.

### OC-0384 QoL after multimodal treatment of rectal cancer with/without oxaliplatin (phase 3, CAO/ARO/AIO-04)

#### Purpose or Objective

In a phase 3, open label randomised multicentre trial we previously confirmed that the inclusion of oxaliplatin (OX) into standard fluorouracil-based (5-FU) combined modality treatment for locally advanced rectal cancer (UICC II/III) was well tolerated and led to an improved disease-free survival (DFS) at 3 years. Here, we present 5-year results of patient reported quality of life (QoL).

#### Material and Methods

Between July, 2006, and February, 2010, 1236 patients aged 18 years or older with rectal carcinoma (clinically staged T3-4 or any node-positive) were randomly assigned to two groups at 88 participating German centres. Treatment was either standard 5-FU-based chemoradiotherapy (CRT) followed by total mesorectal excision (TME-surgery) and postoperative chemotherapy (CTx) with 5-FU, or preoperative CRT with 5-FU and OX, followed by TME-surgery and postoperative CTx with OX, leucovorin and 5-FU. 613 patients were randomised to the investigational group and 623 patients to the control group. The primary endpoint was DFS. QoL questionnaires (EORTC QLQ-C30, colorectal module CR38) were completed pretherapeutically, at the end of postoperative Ctx and during follow-up (1-, 3-, and 5-year visit). QoL assessment did not comprise specific questions on neurotoxicity. Analysis was done according to intention-to-treat. Recruitment and long-term follow-up are completed. ClinicalTrials.gov identifier: NCT00349076.

#### Results

Available questionnaires at baseline were 84,0% (n=515) in the investigational group and 82,5% (514) in the control group, 39,0% (239) vs. 36,8% (229) at 3 years, and 15,2% (93) vs. 16,4% (102) at 5 years (for all patients). General health status (GHS) for disease-free patients was stable in both groups (range 0 to 100): baseline: OX arm mean 63,2 (SD +/- 22; n=503) vs. standard arm 62,0 (+/- 21,6; n=491), 95% CI [-1,5;3,9]; at 5 years: OX arm 65,5 (+/- 22,4; n=83) vs. standard arm 64,9 (+/- 21,1; n=85), 95% CI [-6;7,2]. At the end of treatment and during follow-up, no moderate or large clinically relevant and statistically significant differences (differences of more than 10 points) between groups were found in QoL domains, including scales for diarrhea, gastrointestinal symptoms, chemotherapy side-effects or fatigue. Adjusting for age and gender, as well as including non-disease-free patients did not induce considerable changes. Regardless of the treatment arm, disease-free patients experiencing neurotoxic side-effects (grade 1-4) showed worse GHS at

3-year visit than patients without neurotoxicity (n=65 vs. n=296; mean 59,0 vs. 69,3; difference of means -10,4; 95% CI [-16,1;-4,6]).

#### Conclusion

The addition of oxaliplatin to a 5-FU-based preoperative CRT and postoperative CTx is not associated with worse overall QoL during follow-up. Given the benefit of improved DFS, our findings support the addition of oxaliplatin as a potential treatment option for patients with locally advanced rectal adenocarcinomas.

#### OC-0385 Gender associated differences in outcome after neoadjuvant chemoradiotherapy for rectal cancer

S. Meltzer<sup>1</sup>, K.M. Bakke<sup>1</sup>, K.L. Rød<sup>2</sup>, S. Dueland<sup>3</sup>, K. Flatmark<sup>4</sup>, A.T. Kristensen<sup>4</sup>, F.O. Larsen<sup>5</sup>, J.V. Schou<sup>5</sup>, A.J. Fuglestad<sup>6</sup>, C. Kersten<sup>6</sup>, K.R. Redalen<sup>2</sup>, A.H. Ree<sup>7</sup>  
<sup>1</sup>Akershus University Hospital, Department of Oncology, Lørenskog, Norway ; <sup>2</sup>Norwegian University of Science and Technology, Department of Physics, Trondheim, Norway ; <sup>3</sup>Oslo University Hospital, Department of Oncology, Oslo, Norway ; <sup>4</sup>Oslo University Hospital - Norwegian Radium Hospital, Department of Tumor Biology, Oslo, Norway ; <sup>5</sup>Herlev and Gentofte Hospital, Department of Oncology, Herlev, Denmark ; <sup>6</sup>Sørlandet Hospital, Center for Cancer Treatment, Kristiansand, Norway; <sup>7</sup>Institute of Clinical Medicine, University of Oslo, Oslo, Norway

#### Purpose or Objective

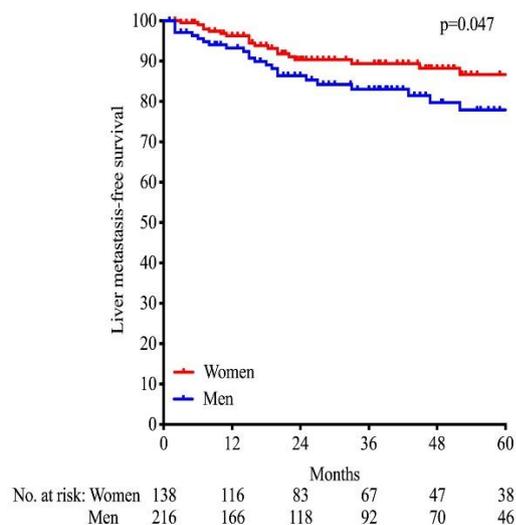

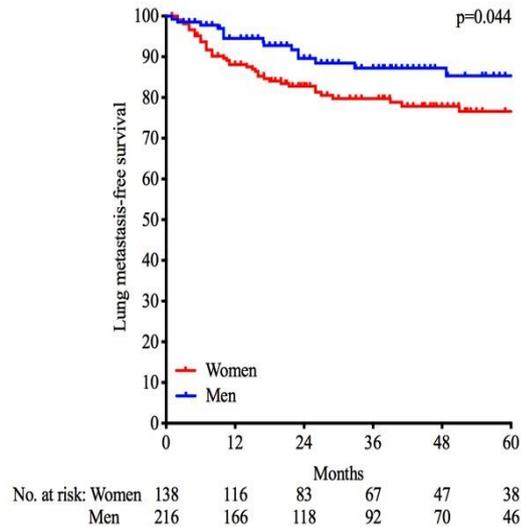

As combined-modality treatment of rectal cancer has resulted in high local control rates, dissemination to distant organs remains the foremost reason of treatment failure, disease-related morbidity, and impaired survival. While colon cancer primarily metastasizes to the liver, probably due to mesenteric venous drainage into the portal vein, rectal cancer is more prone to primarily spread to the lungs. We hypothesized that this may relate to anatomic and hemodynamic factors in the pelvic cavity.

#### Material and Methods

From 705 rectal cancer patients prospectively enrolled onto six clinical studies at four centers in Norway and Denmark between October 2005 and December 2017, 354 patients (216 men, 138 women) with locally advanced rectal cancer (LARC) were included for analysis of gender disparities in metastasis outcome. The selected patients had disease confined to the pelvic cavity at diagnosis and underwent study cohort-specific schedules of neoadjuvant chemoradiotherapy with curative intent. Progression-free survival was recorded as time from study enrolment until the first metastatic event or up to five years after surgery in the case of no event. In one of the study cohorts, dynamic susceptibility contrast-based magnetic resonance and computed tomography imaging at diagnosis enabled measurements of tumor blood perfusion (n=94) and the diameter of the inferior mesenteric vein (IMV; n=137), from patients who either proceeded directly to primary surgery or to standard neoadjuvant chemoradiotherapy. The IMV diameter was measured following the left colic, superior rectal and sigmoid veins to their confluence and then measuring the widest diameter of the IMV just after.

#### Results

Significantly more women than men developed lung metastasis (Figure 1), while the opposite was the case for liver metastasis (Figure 2). Women had both higher tumor blood perfusion than men (mean of 122.1 versus 99.83 ml/min/100g, p=0.004 by Student's t-test, parameters were normally distributed) and smaller IMV diameter (mean of 4.69 versus 5.48 mm, p<0.001 by Student's t-test). Finally, IMV diameter ≥5 mm was associated with progression to liver metastasis (p=0.016 by log-rank test, cutoff selected by receiver operating characteristics curve).

### Conclusion

Following neoadjuvant chemoradiotherapy for LARC, women had higher risk of developing lung metastasis, while men were more prone to develop liver metastasis. In a cohort consisting of rectal cancer patients that either proceeded directly to surgery or to standard neoadjuvant chemoradiotherapy, men's tumors had lower blood perfusion and wider IMV diameter. The latter was strongly associated with development of liver metastasis. Even though the LARC patients received study cohort-specific neoadjuvant treatments, the results indicate that women and men with rectal cancer have different outcomes of tumor-directed therapies, which may be related to hemodynamic factors in both the tumor and the pelvic cavity.

**OC-0386 A PET-based patterns of failure analysis in the context of contouring guidelines in anal cancer**  
 H. Dapper<sup>1</sup>, K. Schiller<sup>1</sup>, S. Münch<sup>1</sup>, J. Peeken<sup>1</sup>, K. Borm<sup>1</sup>, W. Weber<sup>2</sup>, S.E. Combs<sup>1,3,4</sup>

### Purpose or Objective

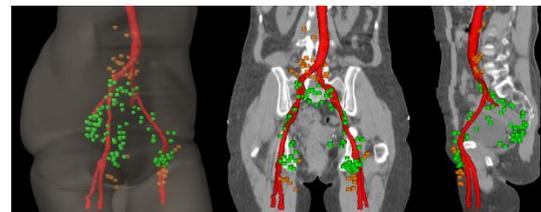

Definitive radiotherapy combined with chemotherapy (CRT) is the standard treatment for patients with loco-regional squamous-cell carcinoma of the anal canal. There are different contouring guidelines for anal cancer, which still vary concerning recommendations for radiation margins in different anatomical regions, especially on inguinal site. PET-imaging has become more important in primary staging of anal cancer, as it is a very sensitive method to detect lymph node (LN) metastases. Using PET-imaging, we evaluated patterns of LN spread, and examined the differences of the respective contouring guidelines on the basis of our results.

### Material and Methods

We carried out a retrospective study of 37 anal cancer patients treated with RCHT who underwent FDG-PET imaging for primary staging in our department between 2011 and 2018. Patients showing PET-positive LNs were included in this analysis. LN metastases of all patients were delineated in one patient's dataset. Using a color-code, LNs were divided indicating whether its location was in- or out-field of the standard clinical target volume as recommended by Radiation Therapy Oncology Group (RTOG), Australasian Gastrointestinal Trials Group (AGITG) or British National Guidance (BNG). Furthermore, a detailed analysis of the location of LNs of the inguinal region was performed.

### Results

Twenty-two out of 37 AC patients with pre-treatment PET-imaging had PET-positive LN metastases, accumulating to a total of 154 LNs. The most commonly affected anatomical region was inguinal (49 LNs, 32%). All para-rectal, external & internal iliac and pre-sacral LNs were covered by the recommended CTVs of the three different guidelines. Twenty-six out of the 154 positive LNs (17%) were above all three CTVs (13 para-iliac, 13 para-aortic). Of 49 involved inguinal LNs, 14 (29%), 7 (14%) and 5 (10%) inguinal LNs were outside the recommended CTVs by RTOG, AGITG and BNG. Inguinal LNs could be located up to 5.7cm inferiorly to the femoral saphenous junction and 2.8cm medial or laterally to the big femoral vessels.

**Table 2** PET-positive lymph nodes in anal cancer patients with number of misses using different contouring guidelines<sup>1</sup>

## Conclusion

In this study, we demonstrated patterns of LN involvement based on PET-imaging. In the pelvis, various recommendations are largely consistent and all LNs were covered by the recommended CTVs. LN "misses" appear generally cranially (common iliac or para-aortic) or caudally (inguinal) to the recommended CTVs. The established guidelines differ significantly, particular regarding the inguinal region. Based on our results, we finally presented our recommendation for contouring of the elective CTV of the inguinal region. Lymph node involvement of a larger number of patients should be investigated to enable final recommendations.

## Purpose or Objective

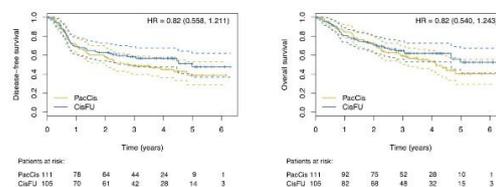

The utilization of taxanes has demonstrated promising results in squamous cell carcinoma of the head and neck (SCCHN) as induction chemotherapy prior to definitive chemoradiotherapy (CRT). The purpose of this multicenter, phase 3 trial was to investigate whether the incorporation of concurrent paclitaxel and cisplatin together with a slightly reduced total dose of radiotherapy (RT) is superior compared with standard fluorouracil-cisplatin based CRT.

## Material and Methods

Previously untreated patients with non-metastatic SCCHN, stage III-IVB, were randomized to receive paclitaxel/cisplatin(PacCis)-CRT (arm A; paclitaxel 20 mg/m<sup>2</sup> on days 2, 5, 8, 11 and 25, 30, 33, 36; cisplatin 20 mg/m<sup>2</sup>, days 1-4 and 29-32; RT to a total dose of 63.6 Gy) or fluorouracil/cisplatin(CisFU) -CRT (arm B; fluorouracil 600 mg/m<sup>2</sup>; cisplatin 20 mg/m<sup>2</sup>, days 1-5 and 29-33; RT: 70.6 Gy). Primary endpoint was 3-year-disease free survival (3y-DFS). Secondary endpoints included overall survival (OS), locoregional failure rate (LFR), distant failure rate (DFR), and toxicity.

## Results

A total of 221 patients have been enrolled in 14 sites between 2010 and 2015. With a median follow-up of 3.7 years, 3y-DFS in the CisFU arm and PacCis arm was 58.2% and 48.4%, respectively (HR 0.82, 95% CI 0.56-1.21, p=0.52). The 3y-OS amounted to 64.6% in the CisFU arm, and to 59.2% in the PacCis arm (HR 0.82, 95% CI 0.54-1.24, p=0.43). There were no significant differences for LFR and DFR. In the subgroup of p16-positive oropharyngeal carcinomas, 3y-DFS and 3y-OS was 84.6% vs 83.9% (p=0.653), and 92.3% vs. 83.5% (p=0.76) in arm A and B, respectively. Hematological toxicities grade 3-4 were significantly reduced in arm A (anemia, p=0.01; leukocytopenia, p=0.003).

## Conclusion

Paclitaxel/cisplatin-CRT with a slightly reduced total RT-dose is not superior to standard fluorouracil/cisplatin-CRT. Subgroup analyses indicate that a reduced radiation dose seems to be sufficient for p16+ oropharyngeal cancer and/ or in non-smokers.

### OC-0388 A prospective multicenter DAHANCA study of hyperfractionated accelerated RT for head and neck cancer

M. Saksø<sup>1</sup>, E. Andersen<sup>2</sup>, J. Bentzen<sup>2</sup>, M. Andersen<sup>3</sup>, J. Johansen<sup>4</sup>, J. Overgaard<sup>1</sup>, J.G. Eriksen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. of Experimental Clinical Oncology, Aarhus, Denmark ;

<sup>2</sup>Herlev Hospital, Dept. of Oncology, Herlev, Denmark ;

<sup>3</sup>Aalborg University Hospital, Dept. of Oncology, Aalborg, Denmark ;

<sup>4</sup>Odense University Hospital, Dept. of Oncology, Odense, Denmark

## Purpose or Objective

The DAHANCA9 hyperfractionation study and the MARCH meta-analysis (Bourhis et al, Lancet 2006) on altered fractionation showed that Hyperfractionated Accelerated Radiotherapy (HART) is superior in terms of loco-regional control (LRC) and overall survival (OS) compared to conventional or moderately accelerated radiotherapy for Head and Neck Squamous Cell Carcinomas (HNSCC). Since 2007, HART has been included as a treatment option in the Danish DAHANCA radiotherapy guidelines. The aim of the present study was to evaluate this treatment strategy using LRC, OS and late morbidity as endpoints.

## Material and Methods

Prospectively registered patients (pts) with HNSCC treated with HART according to national guidelines prescribed as 76Gy/56fx, 10 fx/week, as primary treatment were identified in the DAHANCA database and updated. The study was evaluated as intention to treat and elective neck-dissection was not an option.

## Results

From July 2007 to December 2017, 271 pts with HNSCC treated with HART were identified in four national cancer centers that on a regular basis offers HART according to treatment guidelines. The median age was 64 years (32-81 years) and 74% were males. The majority of pts were WHO PS 0-1 (94%) and only 6% were WHO PS  $\geq 2$ . Most (84%) were current or previous smokers with a smoking history of median 42 pack-years (1-140 pack-years). The primary site was larynx in 65 cases (24%); 176 cases were in the pharynx (65%) and 30 pts had oral cavity cancer (11%). In total, 62% of the cases were stage III-IV (UICC7). In the pharynx, 138 cases (78%) were of oropharyngeal origin and of those, 48% were HPV/p16+. The proportion of pts receiving HART as planned was 96%. No patients received adjuvant or concomitant chemotherapy. As per September 1<sup>st</sup> 2018, 50 loco-regional failures (19% of the pts) were detected with a median follow-up time of 29 months: 47 occurred in T-site and 15 in N-site. Among those, 12 pts had both T- and N-site failure. Three-year actuarial LRC was 81% and OS was 68%. LRC at three years was significantly different for stage I-II and stage III-IV HNSCC (90% vs. 74%, HR 0.44 (range 0.23-0.81)) but not significantly better for HPV/p16+ oropharyngeal carcinomas compared to the HPV/p16- oropharynx pts (94% vs 89%). The proportion of pts reporting severe late dysphagia was 16%, and 9% reported late, severe dryness of the mouth; 8% were observed with late tardive edema of the larynx, 10% with severe mucosal atrophy and 5% with severe fibrosis of the subcutaneous tissue in the neck region.

## Conclusion

Hyperfractionated accelerated radiotherapy is an attractive treatment approach in patients with HNSCC. Three-year loco-regional control as observed in this study is more than 80% and that is reflected in an acceptable overall survival. In this study, HART produced equally good results for HPV/p16+ and HPV/p16- oropharyngeal cancer patients. Severe late morbidity is reasonably low and comparable to treatment with chemo-radiotherapy.

## OC-0389 Individualized prophylactic irradiation based on sentinel lymph node(s) identification in cN0 HNSCC

E. Longton<sup>1</sup>, G. Lawson<sup>2</sup>, S. Deheneffe<sup>1</sup>, B. Bihin<sup>3</sup>, I.

Mathieu<sup>4</sup>, F. Hanin<sup>4</sup>, T. Vander Borgh<sup>5</sup>, J. Daisne<sup>1</sup>

<sup>1</sup>CHU UCL Namur- site Sainte-Elisabeth, Radiation oncology, Namur, Belgium; <sup>2</sup>CHU UCL Namur- site Godinne, Head and Neck Surgery, Yvoir, Belgium ;

<sup>3</sup>Namur Research Institute for Life Sciences Narilis, Unit of Biostatistics, Namur, Belgium ; <sup>4</sup>CHU UCL Namur- site Sainte-Elisabeth, Nuclear Medicine, Namur, Belgium ;

<sup>5</sup>CHU UCL Namur- site Godinne, Nuclear Medicine, Yvoir, Belgium

## Purpose or Objective

Due to a risk of occult nodal metastases in clinically node-negative (cN0) head and neck squamous cell carcinoma

(HNSCC) patients, prophylactic and often bilateral neck irradiation is mandatory. However, it leads to a large irradiation of healthy tissues and could miss unexpected nodal basins drained by the tumor. This prospective, non-randomized, interventional phase II study investigated how sentinel lymph node (SLN) mapping by SPECT/CT may help to individualize prophylactic neck irradiation and its potential impact on radiation-related toxicities and tumor control. The final results are presented.

## Material and Methods

Forty-four patients with newly diagnosed cN0 squamous cell carcinoma of the oral cavity, oropharynx, larynx or hypopharynx were included and treated with upfront (chemo)radiotherapy with a curative intent. After simulation, all patients were imaged in treatment position with SPECT/CT after <sup>99m</sup>Tc nanocolloid injection around the tumor. The neck levels containing up to four hottest SLN were selected for prophylactic irradiation (CTVn-LS). A comparative virtual planning was performed by including the levels selected on the basis of the current international guidelines (CTVn-IG). Dosimetric data to the different organs-at-risk (OAR) were compared between both plans. Normal tissue complication probability (NTCP) models for xerostomia and dysphagia as well as quality of life assessments (EORTC C30 and H&N35 scales) are being investigated to predict the clinical benefit of this technique.

## Results

Lymphatic migration was observed in all of the 44 patients. Four patients (9%) presented an unpredicted lymphatic drainage and 21 patients (48%) had only an unilateral drainage. The volumes of CTVn-LS and PTVn-LS (median volumes of 91.8 cc and 219.1 cc, respectively) were systematically smaller than CTVn-IG and PTVn-IG (median volumes of 188.3 cc and 405.3 cc, respectively). This led to a significant dose decrease in identified OAR, particularly to the contralateral parotid gland, contralateral submandibular gland, inferior constrictor muscle for oral/oropharynx tumors and superior constrictor muscle for larynx/hypopharynx tumors (Table 1). NTCP values and QoL data processing is still work in progress and will be presented during the congress. At a median follow-up of 42 months, 3 patients experienced a regional relapse: 2 in an irradiated area (4.5%) and 1 in a non-irradiated area (2.3%). Currently, 4 patients had a local recurrence and 6 patients died (2 patients from geriatric degradation and 4 patients experienced fatal local relapse).

Comparative dosimetry of clinically significant organs-at-risk

OARs	IG plan Median Dmean (Gy)	LS plan Median Dmean (Gy)	p-Value*	Median ΔDmean (Gy)
<b>Unilateral lymph drainage on SPECT/CT (n = 21)</b>				
Oral cavity and oropharynx carcinoma				
Parotid gland (ipsilateral)	28.5	29.7	0.69	-0.1

## Conclusion

SLN mapping using SPECT/CT allowed to significantly reduce the prophylactically irradiated neck volumes in cN0 HNSCC patients. This resulted in a significant dose decrease in OAR, especially in patients presenting an unilateral lymphatic drainage, while uncompromising the

oncological outcome. The final analysis of the clinical impact of dose reduction to OAR will be presented.

**OC-0390 TCGA molecular subclassification is prognostic for LRC of HNSCC after postoperative RCTx**

#### Purpose or Objective

The Cancer Genome Atlas (TCGA) recently provided a molecular subclassification of head and neck squamous cell carcinomas (HNSCC) including an atypical, classical, basal and mesenchymal subtype. The aims of the present study are to investigate (I) the impact of this subclassification on loco-regional control (LRC) in patients with locally advanced HNSCC who received postoperative radiochemotherapy (RCTx); and (II) the enrichment of those subtypes in radiobiologically relevant aspects such as hypoxia, epithelial-mesenchymal transition (EMT) and cancer stem cells (CSCs).

#### Material and Methods

In this retrospective multicentre study, 195 patients with locally advanced squamous cell carcinoma of the oral cavity, oropharynx and hypopharynx were included. All patients received surgery followed by postoperative RCTx between 2005 and 2011. Their median follow-up was about 26 months. Whole transcriptome analysis was performed using the HTA 2.0 Array (Affymetrix). Tumours were classified into the four subtypes atypical, classical, basal or mesenchymal, based on four cluster centres of the expressions of 838 genes that were previously reported. A clear classification was possible for 141 out of 195 patients. Hypoxia was assessed using an established hypoxia-associated 15-gene signature. For EMT, a previously developed 31-gene signature was applied and for the analysis of CSC markers, previously reported putative CSC markers *CD44*, *SLC3A2* and *MET* were used since no CSC signature is available to date. Primary endpoint was loco-regional control (LRC).

#### Results

Tumours were classified into all four subtypes (43% atypical, 19% classical, 15% basal and 23% mesenchymal). The atypical subtype represented the subgroup with the highest LRC, while the mesenchymal subtype showed the lowest LRC (p=0.002, log-rank test). The basal and classical subtypes represented intermediate subgroups. Interestingly, the atypical subtype showed low expressions of the EMT signature, the hypoxia signature as well as low expressions of CSC markers. In contrast, the mesenchymal subtype was associated with increased expression of the EMT signature as well as hypoxia-associated genes and CSC markers.

#### Conclusion

We have shown for the first time, that the molecular subclassification reported for the TCGA HNSCC cohort allows for stratification of patients who were treated with postoperative RCTx regarding their loco-regional control. This was further supported by the enrichment of radiobiologically relevant aspects within those subtypes.

#### OC-0391 Treatment outcome of 265 patients with sinonasal adenoid cystic carcinoma (ACC)

S. Akbaba<sup>1</sup>, D. Ahmed<sup>1</sup>, A. Mock<sup>2</sup>, K. Lang<sup>1</sup>, T. Held<sup>1</sup>, K. Herfarth<sup>1</sup>, S. Rieken<sup>1</sup>, P. Plinkert<sup>3</sup>, J. Debus<sup>1</sup>, S. Adebeg<sup>1</sup>  
<sup>1</sup>University Hospital Heidelberg, Radiation Oncology, Heidelberg, Germany ; <sup>2</sup>University Hospital Heidelberg, Oncology, Heidelberg, Germany ; <sup>3</sup>University Hospital Heidelberg, Otorhinolaryngology- Head and Neck Surgery, Heidelberg, Germany

### Purpose or Objective

The authors aimed to evaluate treatment outcome of primary and postoperative radiotherapy (RT) for 265 sinonasal adenoid cystic carcinomas, the currently available largest single-center patient collective for this cohort.

### Material and Methods

265 patients who received either an intensity modulated radiotherapy (IMRT) alone or a dose-escalated bimodal treatment with IMRT and carbon ion boost for sinonasal adenoid cystic carcinoma at the Department of Radiation Oncology, University Hospital Heidelberg and at the Heidelberg Ion-Beam Therapy Center (HIT) between 2003 and 2018 were analyzed retrospectively for local control (LC), distant progression-free survival (DPFS) and overall survival (OS) using Kaplan-Meier estimates. The majority of patients had tumors in advanced stages (T4 stage, n=208, 78.5%) or were irradiated for a macroscopic tumor disease (n=200, 76%). Overall, 35% of the patients received primary (n=93) and 65% postoperative RT (n=172). Additionally, toxicity was assessed according to the Common Toxicity Terminology Criteria for Adverse Events (CTCAE) v5.

### Results

Median follow-up was 49 months. At last follow up, 61% of the patients were still alive (n=90/231) while local recurrence occurred in 38% (n=84/231) and distant relapse in 39% (n=87/231), respectively. In univariate and multivariate analysis, we could identify three prognostic subgroups (postoperative bimodal RT vs. postoperative IMRT vs. definite bimodal RT) resulting in significantly different LC ( $p=0.003$ ), DPFS ( $p=0.005$ ) and OS rates ( $p<0.0001$ ). Best survival outcome could be achieved for the postoperative bimodal RT subgroup with a 5-year OS and DPFS of 78% and 72% vs. 69% and 70% for postoperative IMRT vs. 60% and 50% for definite bimodal RT, respectively. Bimodal RT resulted in a significantly increased LC compared to IMRT alone with a 5-year LC rate of 82% for postoperative bimodal RT vs. 76% for definite bimodal RT vs. 58% for postoperative IMRT alone. The majority of recurrences occurred in-field (n=37/84, 44%) and at critical structures where dose was spared (n=34/84, 40%). Toxicity was moderate with 29% acute and 16% late grade 3 toxicity.

### Conclusion

The authors conclude that bimodal RT in a primary or postoperative setting results in superior LC rates with moderate toxicity. Nevertheless, regarding overall survival outcome including OS, LC and DPFS, patients may profit the most from postoperative dose-escalated bimodal RT.

### OC-0392 Risk of ischemic cerebrovascular events is associated with carotid artery radiation dose

E. Van Aken<sup>1</sup>, H. Bijl<sup>1</sup>, H.P. Van der Laan<sup>1</sup>, L. Van den Bosch<sup>1</sup>, A. Van den Hoek<sup>1</sup>, M. Dieters<sup>1</sup>, R. Steenbakkers<sup>1</sup>, H. Langendijk<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

Radiotherapy in the head and neck area may cause vascular damage to the carotid arteries, increasing the risk of ischemic cerebrovascular events (ICVEs). However, limited data exists on the relationship between radiation dose and the risk of ICVE. This information is crucial to identify patients at risk and to optimize radiotherapy treatment plans. Therefore, the purpose of this study was to determine the relationship between radiation dose to the carotid arteries and anterior circulation ICVE risk and to identify the most relevant dose-volume parameters.

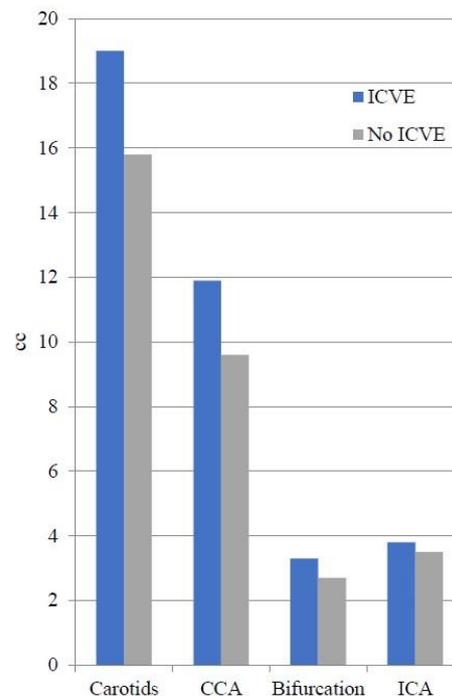

### Material and Methods

A retrospective analysis was performed using data of a prospective cohort study of 750 patients treated with definitive radiotherapy (either or not combined with

systemic treatment) for head and neck squamous cell carcinomas. Based on treatment planning CT scans, carotid arteries were delineated and dose-volume parameters were calculated bilaterally for the entire carotid arteries (external carotid arteries were excluded) and for the common carotid artery (CCA), bifurcation and internal carotid artery (ICA). ICVEs were scored prospectively and additional information was added by reviewing patient records. Cox proportional hazards analysis was performed to analyse the relationship between radiation dose and the risk of ICVE.

### Results

In the univariate analysis, anterior circulation ICVE risk was significantly associated with dose variables to the entire carotid arteries, particularly to the CCA and the bifurcation. Multivariable analysis showed that the absolute volume (cc) of the entire carotid arteries that receives at least a radiation dose of 10 Gy was the most important prognostic factor for ICVE (Figure 1), with a HR of 1.14 per cc (95% CI 1.064-1.222;  $p<0.001$ ). No relevant confounding patient and treatment characteristics were found, meaning that the absolute V10 to the entire carotid arteries can be considered as an independent prognostic factor for the cumulative incidence of ICVE.

**Figure 1.** Absolute V10 of the carotid arteries and the individual bilateral portions.

### Conclusion

This is the first prospective cohort study that demonstrates an independent dose-effect relationship between radiation dose to the carotid arteries and the risk of ICVE. These findings may lead to more adequate ICVE risk prediction and prevention in these patients. ICVE prevention can be achieved by radiotherapy treatment optimization, regular screening or pharmacological treatment.

### OC-0393 Impact of sarcopenia on survival and late toxicity in head and neck cancer patients treated with RT

I. Van Rijn - Dekker<sup>1</sup>, L. Van den Bosch<sup>1</sup>, A. Van den Hoek<sup>1</sup>, H. Bijl<sup>1</sup>, M. Dieters<sup>1</sup>, E. Van Aken<sup>1</sup>, H.P. Van der Laan<sup>1</sup>, H. Langendijk<sup>1</sup>, R. Steenbakkers<sup>1</sup>

<sup>1</sup>University Medical Centre Groningen UMCG, Radiotherapy, Groningen, The Netherlands

### Purpose or Objective

Sarcopenia, defined as the loss of skeletal muscle mass and strength, is emerging as an adverse prognostic factor for both survival and complication risk in cancer patients. The aim of this study was to determine the impact of sarcopenia on several survival parameters and late toxicity in a large cohort of patients with head and neck squamous cell carcinoma (HNSCC) treated with primary radiotherapy (RT).

### Material and Methods

Patients with HNSCC who were treated with definitive RT with or without systemic treatment from January 2007 to June 2016 were included. Prospectively collected variables were retrospectively analysed. The planning CT-scan was used to measure the cross-sectional area (CSA) of skeletal muscles at the level of the third cervical vertebra (C3). The prediction rule by Swartz et al. was used to estimate CSA at the third lumbar vertebra (L3). L3 skeletal muscle index (SMI) was calculated.

The impact of sarcopenia on overall survival (OS) and disease-free survival (DFS) was investigated using univariate (Kaplan Meier) and multivariate (Cox proportional hazards regression) analysis. To analyse the association of sarcopenia with physician-rated grade  $\geq 2$  toxicity (i.e. xerostomia and dysphagia) and with moderate-to-severe patient-rated xerostomia, multivariable logistic regression analyses were performed to create association models.

### Results

The study population was composed of 750 patients with HNSCC. The cut-off value of sarcopenia was set at SMI  $<42.4 \text{ cm}^2/\text{m}^2$  (men) and  $<30.6 \text{ cm}^2/\text{m}^2$  (women) corresponding with the lowest gender specific quartile. Patients with sarcopenia had significantly poorer survival rates than others. The 3-year OS in sarcopenic patients was 53% compared to 73% in non-sarcopenic patients ( $p < 0.001$ ) and the 3-year DFS was resp. 59% and 76% ( $p < 0.001$ ). However, sarcopenia was only significantly associated with OS and DFS in patients with WHO performance score (WHO-score)  $> 0$  (resp.  $p < 0.001$  and  $p = 0.003$ ) and in those with locally advanced disease (stage III-IV) (both  $p < 0.001$ ) (Figure 1 OS stratified by stage of disease). The multivariate analysis showed that sarcopenia was an independent adverse prognostic factor for OS ( $p = 0.004$ ), next to age, WHO-score, tumour stage and primary tumour site and for DFS ( $p = 0.013$ ), next to age, WHO-score and tumour stage (Table 1).

In the univariate analysis, sarcopenia was associated with more radiation-induced xerostomia and dysphagia at six and twelve months after treatment, but no such association was found in multivariate analysis after correcting for confounders.

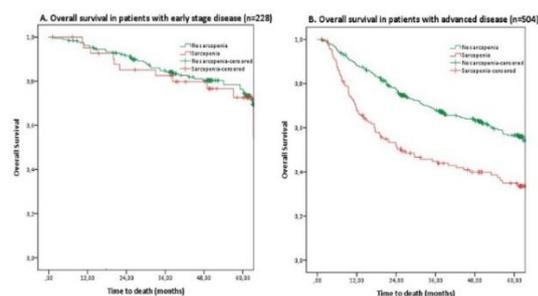

Figure 1 Kaplan Meier curves of overall survival in HNSCC patients treated with radiotherapy. A. OS of patients with early stage disease (I-II) ( $p = 0.596$ ) B. OS of patients with locally advanced disease (III-IV) ( $p < 0.001$ ) HNSCC = head neck squamous cell carcinoma, OS = overall survival

Table 1 Cox regression analysis of overall survival and disease-free survival in HNSCC patients treated with radiotherapy

Variable	Overall survival (n=729)		Disease-free survival (n=641)	
	HR (95% CI)	p-value	HR (95% CI)	p-value
<i>Univariate analysis</i>				
Gender (male vs. female)	1.103 (0.853 - 1.425)	0.456	1.058 (0.794 - 1.409)	0.700
Age	1.014 (1.003 - 1.025)	0.011	1.024 (1.012 - 1.037)	$< 0.001$
WHO-score (0 vs. 1-3)	0.374 (0.299 - 0.467)	$< 0.001$	0.426 (0.333 - 0.546)	$< 0.001$
Sarcopenia (no vs. yes)	0.533 (0.421 - 0.675)	$< 0.001$	0.566 (0.433 - 0.740)	$< 0.001$
Smoking history (never vs. ever)	0.758 (0.520 - 1.105)	0.150	0.950 (0.644 - 1.402)	0.797
Tumour stage (I-II vs. III-IVb)	0.472 (0.360 - 0.617)	$< 0.001$	0.629 (0.479 - 0.827)	0.001
Primary tumour site (larynx vs. other)	0.521 (0.412 - 0.659)	$< 0.001$	0.662 (0.515 - 0.851)	0.001
Treatment modality (RT alone vs. RT with systemic treatment)	0.663 (0.531 - 0.828)	$< 0.001$	0.852 (0.662 - 1.096)	0.214
Technique (conventional vs. IMRT)	0.593 (0.417 - 0.843)	0.004	0.695 (0.484 - 0.997)	0.048
<i>Multivariate analysis</i>				
Age	1.020 (1.009 - 1.032)	0.001	1.024 (1.011 - 1.038)	$< 0.001$
WHO-score (0 vs. 1-3)	0.442 (0.352 - 0.556)	$< 0.001$	0.501 (0.387 - 0.647)	$< 0.001$
Sarcopenia (no vs. yes)	0.697 (0.545 - 0.892)	0.004	0.705 (0.535 - 0.930)	0.013
Tumour stage (I-II vs. III-IVb)	0.601 (0.440 - 0.821)	0.001	0.624 (0.467 - 0.835)	0.001
Primary tumour site (larynx vs. other)	0.674 (0.515 - 0.883)	0.004		

HNSCC = head neck squamous cell carcinoma; HR = hazard ratio; 95% CI = 95% confidence interval; WHO-score = WHO performance score; RT = radiotherapy; IMRT = intensity modulated radiotherapy

### Conclusion

In this prospective cohort study, sarcopenia was significantly associated with poorer OS and DFS, for patients with lower performance (WHO-score  $> 0$ ) and locally advanced disease (stage III-IV), with similar prognostic value as WHO-score, tumour stage and primary tumour site. Given that the SMI can be easily assessed on planning-CT scan, clinical introduction is easy and adds important and clinically relevant information to assess patient outcome.

### Purpose or Objective

The international multicenter PORTEC-4a trial investigates molecular-integrated risk profile guided adjuvant treatment for women with high-intermediate risk (HIR) endometrial cancer (EC). As part of the quality assurance (QA) program, all participating centers had to pass a mandatory vaginal brachytherapy (VBT) dummy run procedure before site activation. Subsequently, QA review of one VBT treatment plan is done annually for each site to verify protocol adherence. Aims of the current study

were to evaluate VBT planning quality and protocol adherence.

#### Material and Methods

Each participating center was asked to provide anonymised CT or MRI scan data used for a VBT plan for a randomly selected case. Quality review included the delineation of organs at risk (OAR) and clinical target volume (CTV), applicator reconstruction, dose plan, DVH parameters and printouts of the dose plan including the dose to the reference points (see Figure 1). In an additional questionnaire, changes in type of afterloader, applicator set and software used were recorded. Data was imported into Oncentra Brachytherapy at Leiden University Medical Center. A local expert panel reviewed all information and scored the compliance of plans according to a QA item checklist. After the review, feedback was sent to the study PI and physicist of each participating site.

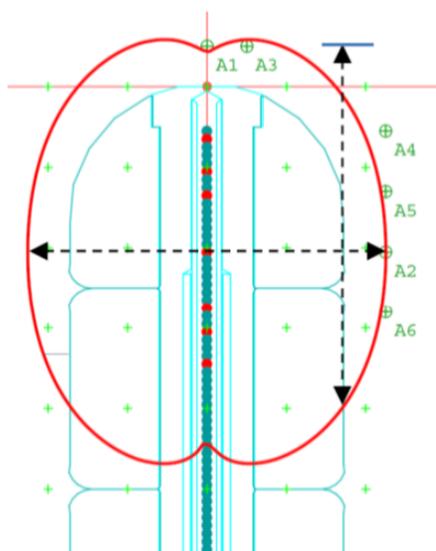

Figure 1. Dose distribution for a vaginal cylinder diameter 3.5cm. 100% isodose line (red). Dose is specified to point A2; average dose of A1+A3 should be approximately 100%; dose to A1 >90% and A3 <110%; A4-6 aim for dose reporting with the aiming to reach 100%. Reference length/width (dotted arrows), reference length should aim for 4.5 cm.

#### Results

Currently a total of 152 patients have been included in the PORTEC-4a trial and 14 sites are actively recruiting. In total, 21 cases were requested for the annual QA review, five in the first and eight in the second round were evaluated; eight data requests are pending. 12 centers used CT planning, two used MRI planning. Three different treatment planning systems and HDR afterloaders were used. During the trial, two centers changed to a different cylinder applicator and two centers changed their planning software. Compliance results of the QA checklist are shown in Table 1. Seven out of thirteen evaluable plans were fully compliant. Most common reasons for feedback were related to target (CTV was not a ring structure or too long) and OAR delineation, and applicator positioning (applicator not horizontal or in optimal contact). Feedback concerning the symmetry of the loading pattern and the reference length (when > 5cm) was provided for six plans (mean reference length 5.0cm, range 4.3 - 5.6; Figure 1). The mean % dose (7Gy = 100%) in A2 was 100.7% (SD 2.4, range 99.3-108.7); in A1: 90.4% (SD 7.1, 67.8-95.7); and in A3: 105.3% (SD 7.7, 81.7-110.0).

Table 1. Checklist QA

Items	Fully compliant	Partly compliant
<b>Applicator positioning</b>		
Position and angle of cylinder	8	5
Contact of cylinder to vaginal mucosa	10	3
<b>Delineation</b>		
CTV delineation	6	7
OAR delineation	9	4
<b>Treatment planning</b>		
Reconstruction	10	3
Position of A points	9	4
Prescribed dose in point A2	12	1
Symmetry of loading pattern	7	6
<b>Evaluation of dose distribution</b>		
Average dose in A1+A3 = 100%	8	5
Dose in point A1 >90% and A3 <110%	10	3
Reference length/width	7	6
CTV D90/D98	11	2
OAR D2cm <sup>3</sup>	13	0

#### Conclusion

Most feedback during the continuous QA of VBT planning in the PORTEC-4a trial was related to target and OAR delineation, applicator positioning, symmetry of the loading pattern and reference length. Changes in type of afterloader, applicator and planning software were recorded and can affect VBT protocol compliance. Annual QA contributes to protocol compliance, to ensure uniform high quality VBT in all participating centers.

#### OC-0395 Bi-objective optimization of dosimetric indices for HDR prostate brachytherapy within 30 seconds

A. Bouter<sup>1</sup>, T. Alderliesten<sup>2</sup>, B.R. Pieters<sup>2</sup>, A. Bel<sup>2</sup>, Y. Niatsetski<sup>3</sup>, P.A.N. Bosman<sup>1</sup>

<sup>1</sup>Centrum Wiskunde & Informatica, Life Sciences and Health, Amsterdam, the Netherlands; <sup>2</sup>Amsterdam UMC-University of Amsterdam, Radiation Oncology, Amsterdam, The Netherlands; <sup>3</sup>Elekta, Physics and Advanced Development, Veenendaal, the Netherlands

#### Purpose or Objective

In clinical practice, plan quality is judged based on dosimetric indices. However, for the purpose of efficiency, typical automated planning methods do not directly optimize dosimetric indices. This creates a mismatch between what is optimized and what is evaluated. A bi-objective optimization approach was recently proposed that directly optimizes dosimetric indices, finding many high-quality plans with different trade-offs between target coverage and organ sparing. This allows for insightful comparison of high-quality plans and patient-specific plan selection. We now aim to accelerate this approach to the extent that it can be used in clinical practice by applying parallelization on a Graphics Processing Unit (GPU).

#### Material and Methods

The two objectives of our bi-objective optimization are the dosimetric indices having the largest deviations from the clinical protocol (see Table 1) in terms of aspired target coverage and organ sparing, the Least Coverage Index (LCI) and Least Sparing Index (LSI), respectively. Optimization is done using the Gene-pool Optimal Mixing Evolutionary Algorithm (GOMEA). The main acceleration is obtained by calculating dosimetric indices on an NVIDIA Titan Xp GPU, programmed in CUDA.

We perform bi-objective planning for 18 HDR prostate brachytherapy cases. Prior to acceleration, results for these cases after 1 hour of optimization were found to be clinically superior to manually optimized plans. We optimize on 20,000 dose calculation (DC) points, whereas typical planning methods (e.g., IPSA, HIPO) use in the order of 5,000 DC points for the purpose of efficiency. All

final reported dosimetric indices are computed on 500,000 DC points, the standard setting in Oncentra Brachy. Bi-objectively optimized plans are compared to clinical plans obtained by experienced planners using IPSA/HIPO, followed by graphical optimization, in 30 to 60 minutes.

**Results**

For all cases, a trade-off curve of plans similar to or better than the clinical plan was found. The clinical plans satisfied all clinical criteria for only 4 cases. Our optimization found plans satisfying all clinical criteria for 15 cases, including these 4. Optimizing for more than 30 seconds did not substantially improve results.

Figure 1 shows plans generated in 30 seconds by the bi-objective planning for 3 patients.

In Table 1, we highlight selected plans for the same patients. Plans with maximum coverage while satisfying all sparing constraints were selected. To satisfy the clinical constraint on the urethra for patient 2, dose to rectum and bladder are increased compared to the clinical plan. For patient 3, all dosimetric indices of the optimized plans are better than the clinical plan.

**Conclusion**

Bi-objective planning allows for insightful plan selection from a large set of high-quality plans, each with a different trade-off between target coverage and organ sparing. We can now generate such sets computer-aided in as little as 30 seconds by applying GPU acceleration, which permits use in clinical practice.

**Purpose or Objective**

Recently, a bi-objective optimization model has been introduced, to automatically create a set of clinically good HDR prostate brachytherapy (BT) plans. The model uses separate objectives for target coverage and organ sparing, based solely on dose-volume indices (DVIs). To calculate DVIs, a reconstruction algorithm is used to determine the 3D organ shape from 2D contours, containing settings that influence the result. In this work, we augment the automatic planning model to find plans that are robust to differences in 3D reconstruction. We investigated the impact on the resulting plans.

**Material and Methods**

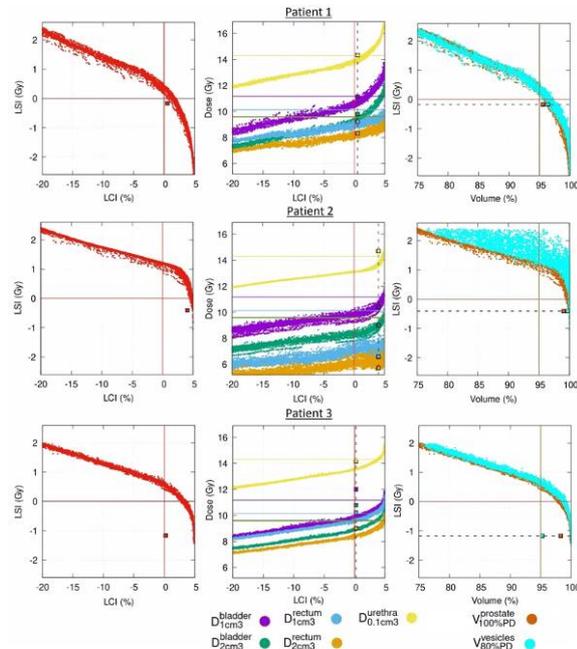

The original model is based on the clinical protocol (Table). DVIs of the protocol are combined into two objectives: Least Coverage Index (LCI) and Least Sparing Index (LSI), and a hard optimization constraint value C. Studied reconstruction settings were:

1. The urethra is considered as part of the prostate, or not.
2. Contours fill the volume spanned by their slice, or interpolation is used.

3. Top/bottom contours span the half-slice-thickness towards the other contours, or the full-slice-thickness.

Combinations of these settings yield 8 possible 3D organ reconstructions per patient, hence 8 combinations of (LCI<sub>i</sub>, LSI<sub>i</sub>, C<sub>i</sub>) per plan. We define the robust model as  $LCI = \min_{i=1, \dots, 8} \{LCI_i\}$ ,  $LSI = \min_{i=1, \dots, 8} \{LSI_i\}$ ,  $C = \min_{i=1, \dots, 8} \{C_i\}$ .

Both models were tested on data of 5 prostate cancer patients consecutively treated with HDR BT, with contours delineated on axial MRI scans (slice thickness: 3.3mm). For the original model, settings were based on the standard of our TPS (Oncentra Brachy version 4.5: urethra as part of the prostate, interpolation, half-slice-thickness). Plans were optimized using the evolutionary algorithm GOMEA, which previously obtained excellent results for the original model. Optimization was performed on 20,000 dose-calculation points, and re-evaluation on 500,000 points. To compare the two models, all optimized plans were re-evaluated both in the original, and in the robust model.

**Figure 1:** All optimized plans of 30 runs (to show variation) of bi-objective planning for 30 seconds. Leftmost figures show the LCI and LSI for all plans. Plans with positive LCI and LSI satisfy all clinical coverage and sparing constraints, respectively. Middle figures show each plan in 5 different colors, aligned parallel to the dashed line, to indicate the 5 different dose indices for a plan with a given LCI. Rightmost figures show each plan in 2 colors, and corresponding volume indices for a given LSI. Clinical constraints are shown as solid lines in corresponding colors. The clinical plan is shown as a square in all plots, colored corresponding to the displayed dosimetric index.

$$LSI = \min\{86 - D_{1cm3}^{bladder}, 74 - D_{2cm3}^{bladder}, 78 - D_{1cm3}^{rectum}, 74 - D_{2cm3}^{rectum}, 110 - D_{0.1cm3}^{urethra}\}$$

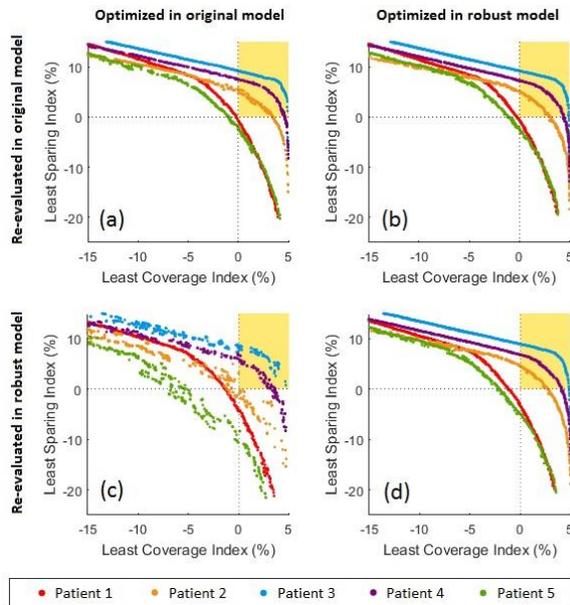

$$C = \min\{50 - V_{150\%}^{prostate}, 20 - V_{200\%}^{prostate}\}$$

**Table:** The DVIs and the clinical protocol for HDR prostate BT used at our center, and the original bi-objective optimization model used. The unit of each DVI is either percentage of total organ volume for volume indices V, or percentage of planning-aim dose (13Gy) for dose indices D. During optimization, only plans with a positive constraint violation index (C) are considered feasible. For feasible plans, the clinical protocol is satisfied if the two objectives Least Coverage Index (LCI) and Least Sparing Index (LSI) are positive.

**Results**

Re-evaluated in the original model, differences were negligible for all patients between plans optimized using the original model (fig. (a)), and plans optimized using the robust model (fig. (b)), hence the cost for robust optimization as observed in the original model was negligible. Re-evaluated in the robust model, the difference between the original model (fig. (c)) and the

robust model (fig.(d)) was large for 2 of the 5 patients (2,5), hence the benefit of robust optimization could be large. For patient 2, plans that appeared good when optimized in the original model, often violated the clinical protocol when considering different settings. This was not the case for robustly optimized plans.

**Figure:** Original and (new) robust bi-objective HDR prostate BT planning results for 5 patient cases. All plans, optimized with either the original (a, c) or robust (b, d) bi-objective model, are re-evaluated in the original (a, b) or the robust (c, d) bi-objective model. Plans in the yellow rectangle where the LCI and LSI are both larger than zero satisfy the clinical protocol.

## Conclusion

Different settings for organ reconstruction can have a non-negligible impact on automatically optimized plans. Robust optimization generated plans of high quality, irrespective of organ reconstructions, and therefore offers a solution to accounting for dosimetric uncertainties.

## OC-0397 Intensity modulated brachytherapy for prostate cancer: plan quality, robustness and delivery time

G. Famulari<sup>1</sup>, S.A. Enger<sup>1,2,3</sup>

<sup>1</sup>McGill University, Medical Physics Unit, Montreal, Canada; <sup>2</sup>McGill University, Department of Oncology, Montreal, Canada; <sup>3</sup>McGill University Health Centre, Research Institute, Montreal, Canada

### Purpose or Objective

Intensity modulated brachytherapy (IMBT) is a novel high dose rate brachytherapy (HDR-BT) technique which incorporates rotating metallic shields inside brachytherapy catheters to dynamically direct the radiation towards the tumor and away from healthy tissues. A delivery system that can enable IMBT for prostate cancer was proposed in a previous study. The purpose of this study is to evaluate the plan quality, robustness and delivery time for IMBT.

### Material and Methods

The IMBT delivery system dynamically controls the rotation of platinum shields placed inside interstitial catheters (Fig. 1). The platinum shield partially collimates the radiation emitted from an <sup>169</sup>Yb source to produce a highly anisotropic dose distribution. The shield contains an emission window of 180° and a groove which guides the translation of the source through the catheter. The device can be connected to the standard 6F transfer tubes for interstitial brachytherapy. Conventional <sup>192</sup>Ir-based HDR-BT and <sup>169</sup>Yb-based IMBT plans were generated for 12

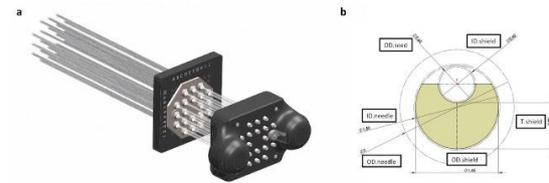

prostate cases using an in-house column generation-based optimizer coupled to a Geant4-based dose calculation engine, RapidBrachyMC. The optimized treatment plans were normalized to match the same PTV D<sub>90</sub> coverage as the original clinical plans. A sensitivity analysis was performed to evaluate the impact of longitudinal source positioning errors ( $\pm 1$  mm,  $\pm 2$  mm and  $\pm 3$  mm) and rotational errors ( $\pm 5^\circ$ ,  $\pm 10^\circ$  and  $\pm 15^\circ$ ) on plan quality indices (PTV D<sub>90</sub> and urethra D<sub>10</sub>).

## Results

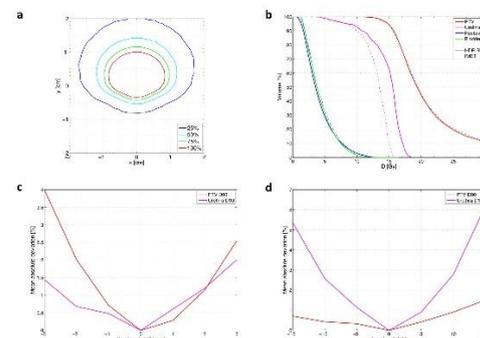

The platinum shield reduced the dose on the shielded side at 1 cm off-axis to 18.1% of the dose on the unshielded side (Fig. 2a). For equal PTV D<sub>90</sub> coverage, the urethral D<sub>10</sub> was reduced by 12.9% $\pm$ 4.6%, without change to other plan quality indices (Fig. 2b). The maximum decrease for a single case was 21.3%. Delivery times for IMBT using a 3.1 Ci <sup>169</sup>Yb source, which has the same dose rate at 1 cm off-axis as a 10 Ci <sup>192</sup>Ir source, were, on average, 35% higher compared to conventional HDR-BT. Systematic translational and rotational shifts led to a decrease (increase) in PTV coverage (urethral dose). In general, the PTV D<sub>90</sub> was more sensitive to source positioning errors, while the urethral D<sub>10</sub> was more sensitive to rotational errors (Fig. 2cd). For a typical range of delivery errors ( $\pm 1$  mm,  $\pm 5^\circ$ ), the plan quality indices varied by <2%.

## Conclusion

A system was developed to deliver IMBT for prostate cancer. IMBT has the potential to create a low dose tunnel within the urethra. Delivery times for IMBT with a 4 Ci <sup>169</sup>Yb source are comparable to that of conventional HDR-BT with a 10 Ci <sup>192</sup>Ir source. Treatment plans are robust with respect to delivery errors.

**Figure 2:** (a) Relative dose distribution in the transverse plane of a shielded <sup>169</sup>Yb source. (b) Average DVH for prostate cancer treated with conventional HDR-BT and IMBT. Impact of (c) source position errors and (d) rotational shield errors on plan quality indices.

## OC-0398 Clinical introduction of 3D printed applicators for endocavitary and interstitial brachytherapy.

W. Bazen<sup>1</sup>, P. Kroon<sup>1</sup>, R. Moerland<sup>1</sup>, S. Van de Vegt<sup>1</sup>, P. Mulder<sup>1</sup>, R. Schokker<sup>1</sup>, K. Van Vliet - van den Ende<sup>1</sup>, S. Kloosterman<sup>1</sup>, H. Dehnad<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

In our institute, we used handmade applicators and needle templates for brachytherapy of head and neck tumors. The needle entry points were defined on the template according to a clinical drawing of anatomy and clinical target volume (CTV). The drawback of this method is the difficulty of finding the optimal needle configuration. The introduction of 3D printing based on CT and/or MR imaging gives the opportunity to create more conformal applicators and templates.

The aim of this work is:

- to compare simulated dose distributions based on 3D printed applicators with clinically achieved dose distributions
- to demonstrate the clinical workflow and to share our first clinical experiences with 3D printed applicators.

### Material and Methods

Before introduction of 3D printed applicators and templates, an in-silico treatment plan study was performed using the Oncentra Brachy (OCB) treatment planning system (Elekta).

In 4 patients treated for cancer of the vestibulum nasi, a plan based on a 3D printed template was compared to the clinical plan (Figure 1).

Subsequently, a clinical workflow for the use of 3D printed applicators and templates was developed, which consists of the following steps (Figure 2):

- 1) A CT and/or MRI is made for defining the CTV and the body contours;
- 2) The virtual placement of catheters is simulated in the TPS and optimized until an adequate dose distribution is achievable;
- 3) In a 3D design program (Autodesk, Fusion 360) the preplanned catheters and the lock inserts (Elekta) to fix the needles are subtracted from the applicator;
- 4) The applicator is fitted on the patient and a CT scan is made for reconstruction and dose planning;
- 5) The applicator is sterilized and used for treatment;
- 6) The treatment plan is made;
- 7) The treatment plan is executed;
- 8) During treatment a position verification CT is made;
- 9) The applicator is removed.

Between November 2017 and September 2018 17 patients (10 lip, 4 vestibulum nasi, 3 other) have been treated using 3D printed applicators).

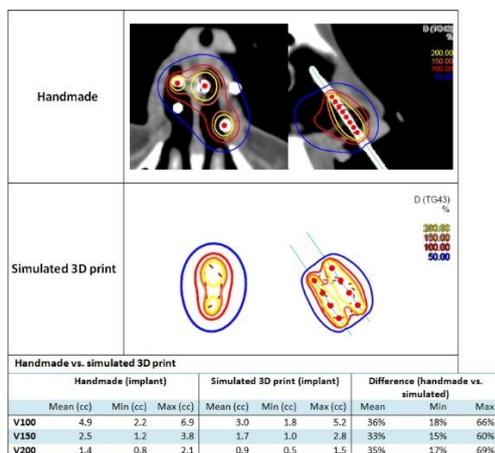

Figure 1: In-silico comparison handmade applicator vs. 3D printed applicator

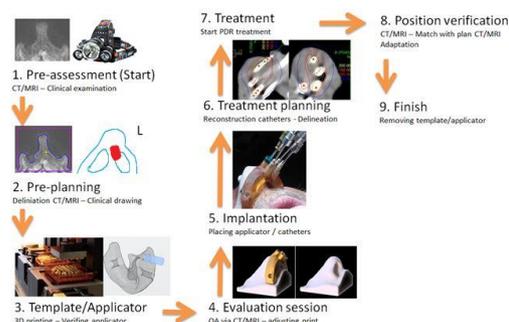

Figure 2: Workflow of creating individual templates and applicators (example vestibulum nasi)

### Results

The in-silico study showed a reduction of the dose volumes V100, V150 and V200 when using 3D printed applicators without compromising CTV coverage (Figure 1). 17 patients were treated according to the new workflow (Figure 2). The applicators fitted well in and on the patients and the needles were placed according to the preplanned positions resulting in adequate CTV dose coverage. On average it took about 3 hours to create a 3D model for printing, whereas handcrafting a template may take up to 6 hours.

### Conclusion

The possibility to optimize needle positions based on CT and/or MR imaging in a single implant gives the advantage to adapt to a wide range of tumor shapes and anatomy constraints. This translates into a reduction of dose volumes when using 3D printed applicators without compromising CTV coverage. The clinical workflow using 3D printed applicators for brachytherapy was successfully implemented and resulted in a reduction of production and processing time.

### OC-0399 Comparison of high-dose interstitial brachytherapy vs. stereotactic treatment in patients with HCC

F. Walter<sup>1</sup>, S. Gerum<sup>1</sup>, J. Well<sup>1</sup>, R. Shpani<sup>1</sup>, N. Lukas<sup>1</sup>, M. Cornelius<sup>1</sup>, F. Streitparth<sup>2</sup>, J. Ricke<sup>2</sup>, C. Belka<sup>1</sup>, S. Corradini<sup>1</sup>

<sup>1</sup>Radiation Oncology, Department of Radiation Oncology LMU, Munich, Germany; <sup>2</sup>Radiology, Department of Radiology, Munich, Germany

### Purpose or Objective

The role of brachytherapy (BT) in hepatocellular carcinoma is under investigation. Objective of the study was to evaluate and compare normal liver tissue exposure of CT-guided high-dose interstitial BT to SBRT.

### Material and Methods

The treatment plans of 11 patients (m:f 9:2) with a median age of 65 years (47-82) who received high-dose BT for hepatocellular carcinoma between 07/17 and 06/18 were retrospectively analysed. Lesions with a maximal diameter of <6cm were included. In all cases a prescription dose of 15Gy in single fraction was aimed. SBRT plans prescribing 37.5Gy in 3 fractions to the 65%-Isodoseline were retrospectively planned using the BT planning CT images. Regarding liver exposure, the V5 and V10 Gy of the single BT treatment was compared to the V15, V15.9 and V20Gy of SBRT in 3 fractions (EQD2;  $\alpha/\beta = 3\text{Gy}$ ).

### Results

A total of 13 lesions were treated with high-dose CT-guided interstitial BT using 1 catheter in 7 patients (pts), two in 5pts and three in one case. GTV had a median diameter of 2.73cm (1.17-6.53cm), and a median volume of 5.03ccm (1.39-66.43ccm). The total liver volume ranged from 832.55-2194.46ccm (median 1461.88ccm). A medium dose of 15.1Gy was achieved in D100 (11.4-

15.5Gy), D98=18Gy (14.2-19.1Gy), D95=19.5Gy (15.8-21.5Gy), and D90=21.5Gy (17.8-24.2Gy). In BT 5Gy was administered to 87.7ccm (19.28-570.75ccm) of the liver, 10Gy (EQD2 26Gy,  $\alpha/\beta$ 3) to 35.92ccm (8.38-254.42ccm). Correspondingly in SBRT normal liver tissue received 15Gy median 135.53 (56.88-827.2ccm), 15.9Gy (EQD2 26.4Gy,  $\alpha/\beta$ 3) 120.93 ccm (51.18-734.91ccm), and 20Gy to 73.11ccm (16.59-390.73ccm) of normal liver tissue.

Figure: plan comparison

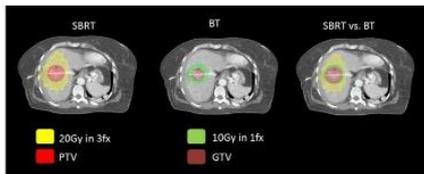

Table: Comparison of delivered doses to normal liver tissue:

Pts	Brachytherapy		SBRT		
	5Gy	10Gy	15Gy	15.9Gy	20Gy
1	39.66	18.17	34.23	30.98	21.58
2	31.14	136.62	335.25	363.35	215.8
3	88.52	31.38	136.37	120.51	75.11
4	87.7	85.92	58.89	49.49	34.88
5	217.64	135.88	387.38	287.13	218.47
6	45.48	20.01	115.15	101.88	50.5
7	970.79	124.42	610.29	382.88	200.19
8	81.85	33.57	49.19	44.86	32.82
9	147.78	47.04	140.5	181.55	145.75
10	27.38	8.88	29.22	24.09	28.59
11	120.02	108.49	91.71	284.81	179.78
12	18.38	8.81	54.94	49.05	32.45
13	272.28	114.27	395.46	322.87	299.99

### Conclusion

Compared with SBRT, high-dose interstitial brachytherapy in patients with hepatocellular carcinoma allows for a good dose coverage while sparing normal liver tissue.

### OC-0400 Are prostate contours affected by the RO's clinical experience in prostate HDR brachytherapy?

H. Lavoie<sup>1</sup>, E. Poulin<sup>1</sup>, A. Martin<sup>1</sup>, L. Pilote<sup>1</sup>, E. Vigneault<sup>1</sup>, W. Foster<sup>1</sup>, L. Archambault<sup>1</sup>, F. Lacroix<sup>1</sup>

<sup>1</sup>CHU de Quebec, Radiation Oncology, Quebec, Canada

### Purpose or Objective

The aim of this study was to compare the prostate contours for two imaging modalities, computed tomography (CT) and trans-rectal ultrasound (TRUS), used in HDR brachytherapy. The authors hypothesized that the contour variability was affected by the radiation oncologists (ROs) clinical experience.

### Material and Methods

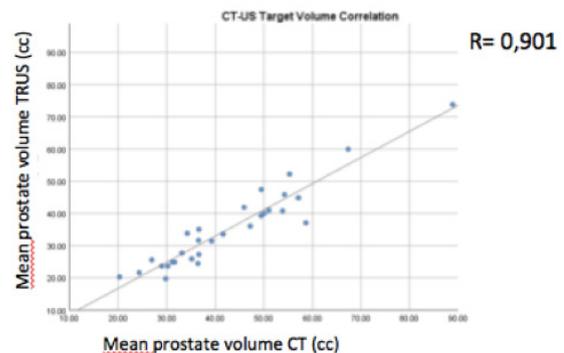

CHU de Québec is a high volume prostate brachytherapy center (>250 patients/year) employing multiple ROs that have performed CT-based HDR brachytherapy since 1999. A TRUS-based HDR procedure was introduced in 2016. The first thirty patients to undergo the TRUS procedure were given a 15 Gy HDR boost. While still under general anesthesia, a CT on rails located in the brachytherapy suite was used to image the pelvis after the treatment. The treating RO (RO1, 2 or 3 in 2016) then contoured the prostate on both modalities. Two years later, four ROs (RO4 started in 2017) re-contoured the prostate on the CT and TRUS images for each patient. The RO's CT clinical experience was as follow: RO1=13, RO2= 18 RO3=7 and

RO4= 1 (years). In 2018, all 4 ROs had 2 years of experience in TRUS. A volume comparison between both modalities and between ROs was performed. A rigid registration between CT and TRUS images was completed for 16 patients using gold fiducial markers. The Jaccard Index (JI) was computed to evaluate the inter-observer variability. In addition, the intra-observer variability was evaluated by comparing the volumes contoured in 2016 and 2018. Paired t-tests were used to evaluate the volume and JI differences.

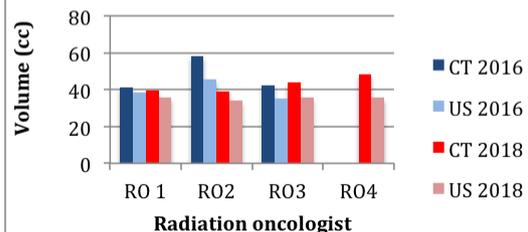

### Results

The mean CT and TRUS volumes showed a significant correlation for the prostate of 0.95 ( $p<0.001$ ). The volume ratio of TRUS/CT was 0.82 (95% interval 0.79-0.87), meaning the volume was 18% bigger on CT. The mean JI was 87% for CT and 92% for TRUS when comparing all 4 ROs; CT and TRUS JIs were significantly different ( $p<0.001$ ). The mean JI for the prostate on CT was significantly better ( $p<0.05$ ) when comparing RO1, 2 and 3 together (RO1-2, RO1-3, RO2-3, mean=89%) than when comparing RO4 to the others (RO1-4, RO2-4, RO3-4, mean=85%). For TRUS planning, the mean JI was not significantly different ( $p>0.05$ ) when comparing all ROs (91-93%). The intra-observer volume variability between 2016 and 2018 for CT and TRUS was evaluated and revealed a bigger mean difference for CT than for TRUS, 6.9 cc vs 4.5 cc respectively ( $p<0.001$ ). The average ROs intra-observer variability was not significant in TRUS ( $p>0.05$ ).

### Correlation between CT and TRUS mean prostate volume (2018)

### Mean prostate volume by RO and imaging modality

### Conclusion

Contoured prostate volumes were 18% bigger on CT compared to TRUS. In CT, the inter-observer variability is significant even for ROs with more than 7 years' experience. Interestingly, the inter-observer and intra-observer variability were significantly smaller in TRUS

compared to CT-based planning, despite different clinical experiences. Finally, the superior soft tissue contrast offered by TRUS seems to insure a RO independent prostate planning, which might lead to more homogeneous clinical outcomes.

#### OC-0401 Pre-treatment radiomic features predict individual nodal failure in head and neck cancer

T. Zhai<sup>1,2</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, L.V. Van Dijk<sup>1</sup>, J.G.M. Vemer-van den Hoek<sup>1</sup>, H.P. Bijl<sup>1</sup>, M. Dieters<sup>1</sup>, W. Noordzij<sup>3</sup>, A. Van der Schaaf<sup>1</sup>, N.M. Sijtsema<sup>1</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands ;

<sup>2</sup>Cancer Hospital of Shantou University Medical College, Department of Radiation Oncology, Shantou, China ;

<sup>3</sup>University Medical Center Groningen, Department of Nuclear Medicine and Molecular Imaging, Groningen, The Netherlands

#### Purpose or Objective

Optimal management of neck nodes after definitive radiotherapy for head and neck cancer patients is still under debate. The main concerns are how to identify patients that need neck dissection and lymph nodes that need super-selected neck node resection after treatment. The main objective of this study was to test whether the addition of pre-treatment radiomic features of pathological lymph nodes to clinical prediction models improves the prediction of nodal failure for individual lymph nodes.

#### Material and Methods

This was a retrospective analysis in a prospective cohort study, which was composed of 277 node-positive head and neck squamous cell carcinoma patients with 1025 pathological neck nodes treated with definitive radiotherapy with or without systemic treatment. A total of 165 patients with 558 pathological lymph nodes treated before January 2013 were enrolled in the training cohort and 112 patients with 467 pathological lymph nodes treated between January 2013 and June 2016 were enrolled in the validation cohort. Overall 82 pre-treatment CT radiomic features and 8 clinical features from each positive lymph node were analyzed. The endpoint was the cumulative incidence of nodal failure. Clinical, radiomic and combined models were created from the multivariable Cox proportional hazard analysis based on clinical features, radiomic features, and both clinical and radiomic features, respectively. The performances of the models were assessed in the validation cohort. A nomogram was constructed for individualized nodal failure estimation.

#### Results

There were 71 and 28 lymph node failures in the training and validation cohorts with 31.1 and 29.0 months median follow up, respectively. Multivariable analysis revealed two radiomic features (Least axis length (LALLN,  $p < 0.001$ ) and Correlation of Grey level co-occurrence matrix (Corre-GLCM,  $p = 0.039$ ) and three clinical risk factors (WHO performance score (PS,  $p < 0.001$ ), T stage ( $p = 0.009$ ) and gender ( $p = 0.005$ )). LALLN means the shortest diameter and Corre-GLCM represents the heterogeneity of the lymph node. The combined model showed good discrimination with a c-index of 0.87 (95% CI: 0.80 to 0.95) in the training cohort and 0.79 (95% CI: 0.78 to 0.80) in the validation cohort and was significantly better than models based on clinical features ( $p < 0.001$ ) or radiomics ( $p = 0.002$ ) only (Fig.1). The relation between the risk of nodal failure for male patients with WHO PS > 0 and the radiomic features is shown in Fig.2. Lymph nodes with a

high risk to persist or recur could be identified before treatment by using the nomogram constructed for this model to guide decisions on the preferred treatment strategies such as neck dissection or treatment intensification.

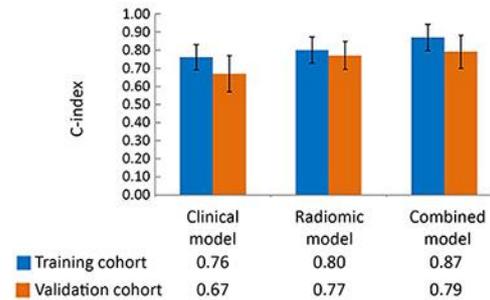

Fig.1. The performance of clinical, radiomic and combined models.

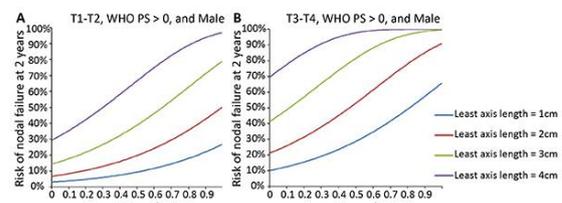

Fig.2. The risk of nodal failure for male patients with worse WHO PS at 2 years as a function of the radiomic features (Correlation of GLCM and Least axis length) for different tumor stages: (A) T1 and T2 and (B) T3 and T4. Abbreviations: WHO PS = WHO performance score; GLCM = Grey level co-occurrence matrix.

#### Conclusion

A pre-treatment prediction model was developed to predict the risk of individual lymph node failure based on non-invasive radiomic and clinical features. This model may support personalized lymph node treatment adaptations in clinical practice after further multi-center validation.

#### OC-0402 Tumour blood perfusion from baseline contrast-based MRI predicts radiation outcome in rectal cancer

<sup>1</sup>Akershus University Hospital, Department of Oncology, Lørenskog, Norway; <sup>2</sup>University of Oslo, Department of Physics, Oslo, Norway; <sup>3</sup>Oslo University Hospital, Department of Diagnostic Physics- Division of Radiology and Nuclear Medicine, Oslo, Norway; <sup>4</sup>University of South-Eastern Norway, Department of Optometry-Radiography and Lighting Design, Drammen, Norway; <sup>5</sup>Akershus University Hospital, Department of Radiology, Lørenskog, Norway; <sup>6</sup>University of Oslo, Institute of Clinical Medicine, Oslo, Norway; <sup>7</sup>Norwegian University of Science and Technology, Department of Physics, Trondheim, Norway

#### Purpose or Objective

To evaluate the prognostic and predictive potential of parameters obtained from baseline intravoxel incoherent motion (IVIM) diffusion-weighted MRI and multi-echo contrast-based dynamic MRI in locally advanced rectal cancer.

#### Material and Methods

192 patients with suspected rectal cancer were enrolled onto a prospective biomarker study. 45 of these patients scheduled for neoadjuvant radiation consisting of either short-course radiotherapy (5 Gy x 5) (n = 10) or long-course chemoradiotherapy (2 Gy x 25 with concomitant capecitabine) (n = 35) were selected for analysis. At baseline, patients underwent routine MRI followed by an extended diffusion weighted sequence for IVIM analysis and a multi-echo contrast-based dynamic sequence with

gadolinium injection (Dotarem® 279.3 mg/ml, Guerbet Roissy, France). From the multi-echo data both the  $T_1$ -weighted dynamic curve and the  $R_2^*$ -weighted curve were extracted for dynamic contrast enhanced (DCE) and dynamic susceptibility contrast (DSC) analysis, respectively. The extended Tofts model was applied for DCE analysis, estimating transfer constants ( $K^{trans}$ ,  $k_{ep}$ ) and plasma- and interstitial volumes ( $V_p$ ,  $V_e$ ). The model-free deconvolution approach was used for DSC analysis, calculating tumour blood flow (BF). For both DCE and DSC analysis, individual arterial input functions were used. A bi-exponential model was used for IVIM analysis, estimating perfusion fraction ( $f$ ), pseudo-diffusion ( $D^*$ ) and diffusion ( $D$ ). Tumours were delineated by two radiologists on  $T_2$ -weighted images and co-registered to parametric images before median tumour values were extracted. Pearson correlation coefficients were estimated to evaluate correlations between parameters, Student's  $t$ -test to assess differences between patients with good and poor tumour response to the neoadjuvant radiation and Cox-regression for survival analysis. The median follow-up for the selected patients was 21 months (range 3 - 51 months).

### Results

BF was significantly higher in tumours with good response to the treatment (ypT0-1,  $n = 9$ ; BF = 120 ml/min/100 g) compared to those with poor response (ypT2-4,  $n = 34$ ; 96 ml/min/100 g) ( $p = 0.014$ ). High BF was also significantly associated with overall survival (hazard ratio = 0.97,  $p = 0.017$ ), Figure 1. Further, BF was correlated to both  $D^*$  ( $r = 0.46$ ,  $p = 0.001$ ) from IVIM and  $v_p$  ( $r = 0.57$ ,  $p < 0.001$ ) from the DCE analysis.

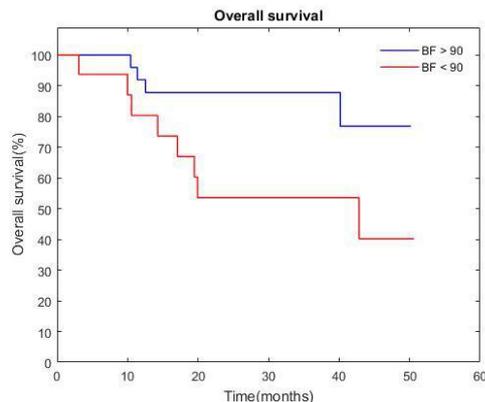

Figure 1: Kaplan-Meier plot showing overall survival for patients with low (< 90 ml/min/100 g) versus high (> 90 ml/min/100 g) tumour blood flow (BF) at baseline.

### Conclusion

In this cohort of rectal cancer patients, BF from DSC acquired at baseline, reflecting tumour perfusion, predicted both local tumour response to neoadjuvant radiation as well as overall survival.

### OC-0403 Type 4 TRIPOD external validation of a larynx survival model

C. Rønn Hansen<sup>1,2,3,4</sup>, N. Sarup<sup>1</sup>, R. Zukauskaitė<sup>4,5</sup>, J. Johansen<sup>3</sup>, J.G. Eriksen<sup>5,6</sup>, S.L. Krogh<sup>1</sup>, A. Bertelsen<sup>1</sup>, D.I. Thwaites<sup>2</sup>, U. Bernchou<sup>1,4</sup>, C. Brink<sup>1,4</sup>

<sup>1</sup>Odense University Hospital, Laboratory of Radiation Physics, Odense, Denmark; <sup>2</sup>The University of Sydney, Institute of Medical Physics- School of Physics, Sydney, Australia; <sup>3</sup>Aarhus University Hospital, Danish Centre for Particle Therapy, Aarhus, Denmark; <sup>4</sup>University of Southern Denmark, Department of Clinical Research, Odense, Denmark; <sup>5</sup>Odense University Hospital, Department of Oncology, Odense, Denmark; <sup>6</sup>Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus, Denmark

### Purpose or Objective

Prediction of overall survival is important to select appropriate treatment for the individual patient. In order to use prediction models clinically, they require independent validation to check their robustness between different institutions (Type 4 TRIPOD external validation). The aim of this study was to validate the larynx survival model published by Egelmeier et al 2011 in an external cohort from one institution.

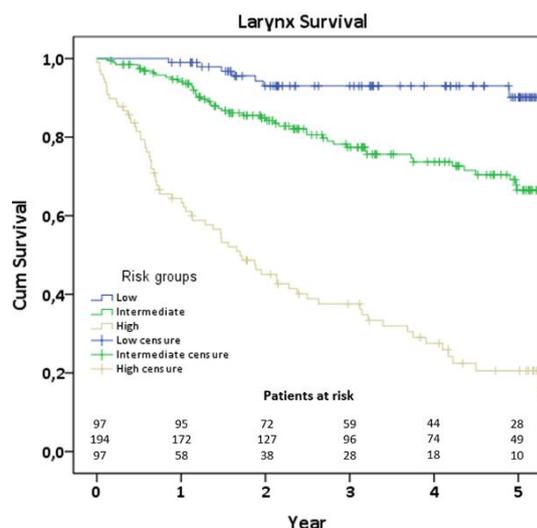

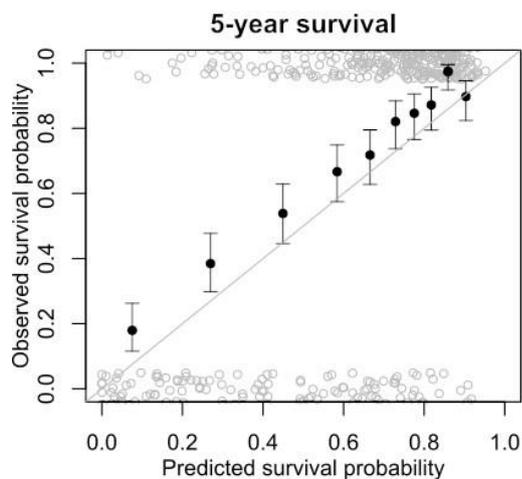

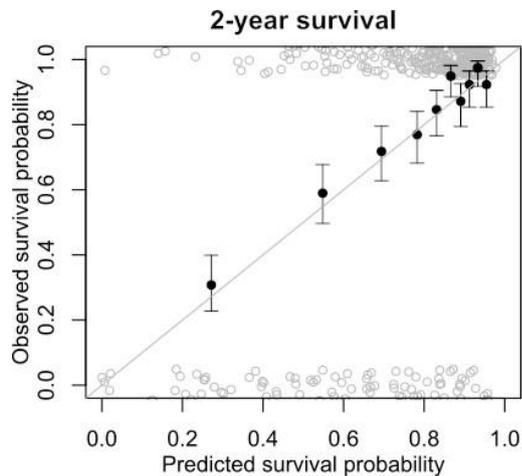

### Material and Methods

Using the Computer Assisted Theragnostics (CAT) approach all ( $n=615$ ) patients treated for larynx cancer were retrieved from the Danish DAHANCA database from 2005-2015 and using the CAT system combined with data from our local Record and Verify system (Mosaik). Patients that received surgery alone ( $n=58$ ) or those with missing data ( $n=169$  - predominantly hemoglobin at start of RT) were excluded. In total, 388 patients were used for the validation. All patients were treated according to the DAHANCA guidelines and followed up yearly until year 5. The median follow-up of the 388 patients was 2.6 years. The parameters used in the model were: age, hemoglobin and equivalent dose (EQD2T) as continuous variables, and T-classification (1-4), N- classification (-/+), sex (F/M) and tumor site (glottis/other) as categorical variables.

The 2-year and 5-year model performance was validated using calibration plots with the patients grouped in 10 equal sized groups. The plots contain raw data as open circles (1 = alive) and group averages as filled circles. The error bars represent one standard deviation. The validation cohort was split into three groups (two outer quartiles and the inner quartiles as one group) according to the risk assessment of the published model in a Kaplan-Meier plot. The Harrell C-index, the equivalent of AUC for a survival model, was calculated. Bootstrap was used to calculate a 95% confidence interval.

### Results

The external model validation shows a very good calibration for the 2 year survival, while the 5-year survival model underestimates the survival (offset), however with a good calibration slope (fig. 1). The three risk groups showed highly significant ( $p < 0.001$ ) different survival rates in the Kaplan-Meier plot (fig. 2), validating that the model discriminates this larynx patient cohort well. The 2- and 5-year survival rates for the three risk groups were: low risk  $93.0 \pm 2.8\%$  and  $90.1 \pm 3.9\%$ , intermediate risk  $84.9 \pm 2.7\%$  and  $66.5 \pm 4.3\%$ , and high risk  $45.1 \pm 5.2\%$  and  $20.6 \pm 4.8\%$  (std error). The model has a high Harrell C-index of 0.78 [0.74-0.82] compared to 0.73 [0.70-0.77] from the original article.

### Conclusion

The data collection and merging in the CAT-system work smoothly and show good potential. The models perform very well on this external patient cohort and could provide doctors and patients with valuable information on patient-specific survival. The model does not include smoking status of the patients, which has been shown to have a major impact on tumor control and survival and therefore could potentially improve the model predictions further.

### OC-0404 Dose to vascular calcifications is predictive for overall survival in lung cancer patients

E.M. Vasquez Osorio<sup>1</sup>, F. Brewster<sup>2</sup>, A. McWilliam<sup>1</sup>, A. Scaife<sup>3</sup>, K. Banfill<sup>1</sup>, A. Abravan<sup>1</sup>, D. Cobben<sup>1</sup>, C. Faivre-Finn<sup>1</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>The University of Manchester, Division of Cancer Studies- School of Medical Sciences- Faculty of Biology-Medicine and Health, Manchester, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Christie Medical Physics & Engineering, Manchester, United Kingdom; <sup>3</sup>The University of Manchester, Jodrell Bank Centre for Astrophysics - School of Physics and Astronomy - Faculty of Science and Engineering, Manchester, United Kingdom

### Purpose or Objective

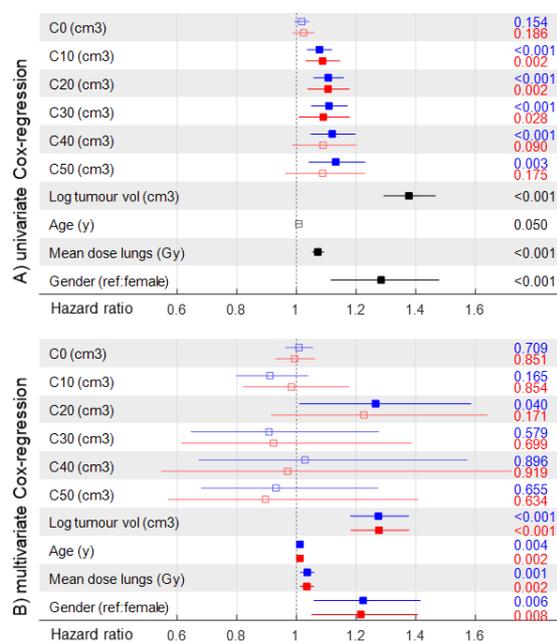

Recent studies suggest that incidental dose to the heart can have an early detrimental effect on overall survival for lung cancer patients receiving radiotherapy. We investigated whether irradiation of vascular calcifications, identified on the radiotherapy planning CT, also affects overall survival.

### Material and Methods

Data from 1002 unselected non-small cell lung cancer patients, all treated with 55Gy in 20 fractions, were used. Calcifications within the thoracic cavity were automatically segmented in the planning CT scans using standard image processing algorithms, including morphological operations, connected pixel analysis and shape analysis. Calcifications for 10 CT scans were manually segmented to evaluate the quality of the automatic segmentation. To explore the interaction of the identified calcifications and the radiation dose on overall survival prediction, the volume of calcifications receiving  $\geq 0$ , 10, 20, 30, 40 and 50 Gy was determined. We subsequently refer to them as Cx. These variables were included in a Cox-regression analysis alongside log tumour volume, age, mean dose to the lungs, and gender. Heart structures were created for all patients using atlas-based segmentation in ADMIRE v2.0 (Elekta AB, Stockholm, Sweden). The analysis was repeated for calcifications within the heart only.

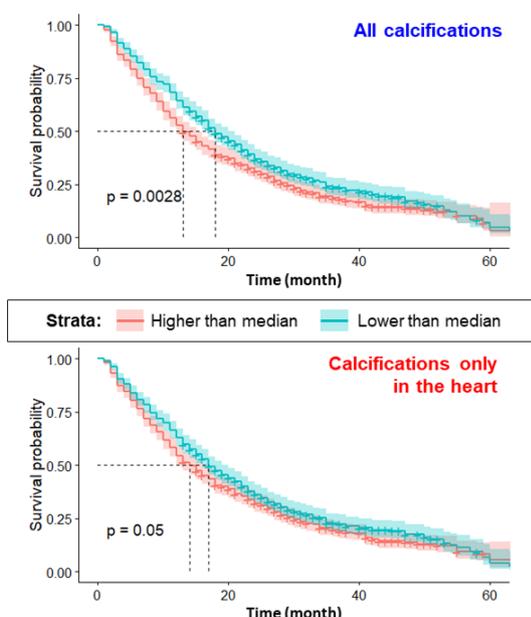

### Results

The average calcification volume found was 2.6 cm<sup>3</sup> (SD 2.8 cm<sup>3</sup>), of which 1.3 cm<sup>3</sup> (SD 2.0 cm<sup>3</sup>) was within the heart. The success rate of the algorithm for identifying calcifications was 81.8%, with an error rate of 8.8%. Figure 1 shows the hazard ratios and significance levels for univariate and multivariate Cox-regressions. Univariate analysis of C10, C20, C30, C40 and C50 were significant for all calcifications, but only C10, C20 and C30 for calcifications within the heart. Tumour volume, age, mean dose to the lungs, and gender were significant in all models. In the multivariate analysis, C20 remained significant when using all calcifications (HR=1.27, CI=1.01, 1.59, p=0.04) but only borderline significant for calcifications within the heart.

**Fig 1:** Forest plots of the hazard ratios for A) univariate and B) multivariate survival analysis. Blue indicates all calcifications, red only in the heart and black other variables. Filled markers represent significance at 0.05 threshold. n=1002,803 events for all variables.

Using median C20 to stratify the patient data resulted in two significantly different survival distributions when all calcifications were used ( $p=0.003$ , log-rank test) but border-line for calcifications only in the heart. Figure 2 shows the corresponding Kaplan-Meier survival estimates.

**Fig 2:** Kaplan-Meier survival estimators for the univariate models for calcification volume receiving  $\geq 20$  Gy. Median survival times across groups are significant different when stratifying based on all calcifications but border-line for calcifications only in the heart.

## Conclusion

Our results suggest that the risk of death increases by 27% for every extra  $\text{cm}^3$  of calcifications receiving at least 20 Gy. Moreover, the loss of significance when analysing data to only the calcifications within the heart suggest an important dose/effect relation for calcifications outside the heart and these should not be ignored. We are planning to validate of our findings in an external cohort.

## OC-0405 Registry-based modelling of early mortality following radiotherapy of lung cancer

## Purpose or Objective

To demonstrate registry based outcome modeling using multivariable models of 90- and 180-day mortality rates following conventionally fractionated, curative radiotherapy treatments (RTs) for non-small cell lung cancer (NSCLC) as exemplar.

## Material and Methods

The scripting capabilities of a modern oncology information system was used to automatically identify patients and extract dose volume information. We considered all patients available in the oncology information systems diagnosed with NSCLC treated with conventionally fractionated, curative RT between 2002 and 2017 at two Danish and two Swedish hospitals. Date of death was available through national registries or hospital records. Exclusion criteria were previous dose exposure in the thoracic region, another RT concurrently or during the observation period for early mortality (90- or 180-days), and/or dose or treatment time outside of normal range (see Figure 1).

Maximum likelihood estimation and univariable logistic regressions (LRs) for the binary endpoints death within 90- and 180-days from the treatment start were used. Predictor variables with a p-value for the regression coefficient less than 0.1 in likelihood ratio tests were considered eligible for multivariable LR to model the same endpoints. The statistical significance of each multivariable model as a whole was evaluated with likelihood ratio tests.

## Results

Data were automatically extracted for 2018 patients. Applying exclusion criteria, 1721 patients and 1621 patients remained for modelling of the 90- and 180-day mortality rate, respectively. Figure 1 shows a CONSORT diagram of the patient cohort. The 90- and 180-day mortality rates were 2.9% (50/1721) and 10% (170/1621), respectively. MLD and patient age were significantly associated with mortality after both 90 and 180 days (all  $p<0.01$ ). Predicted 90-day mortality rate (Figure 2, upper panel) of 5% for patients aged 50, 60, 70 and 80 years were reached at MLD of 34, 28, 22 and 16 Gy, respectively. Calibration plots showed a good agreement between observed and modelled 90- (Figure 2, lower panel) and 180-day mortality rates.

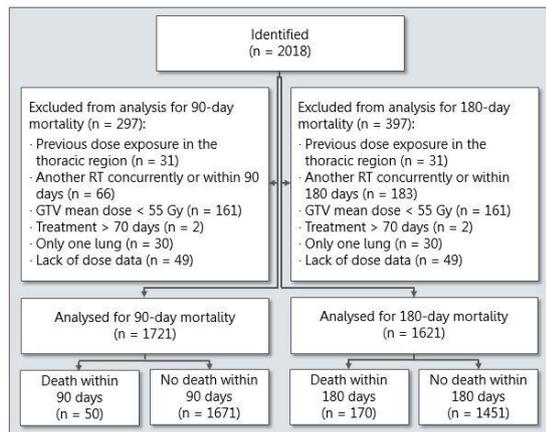

Figure 1. CONSORT diagram of the patient cohort.

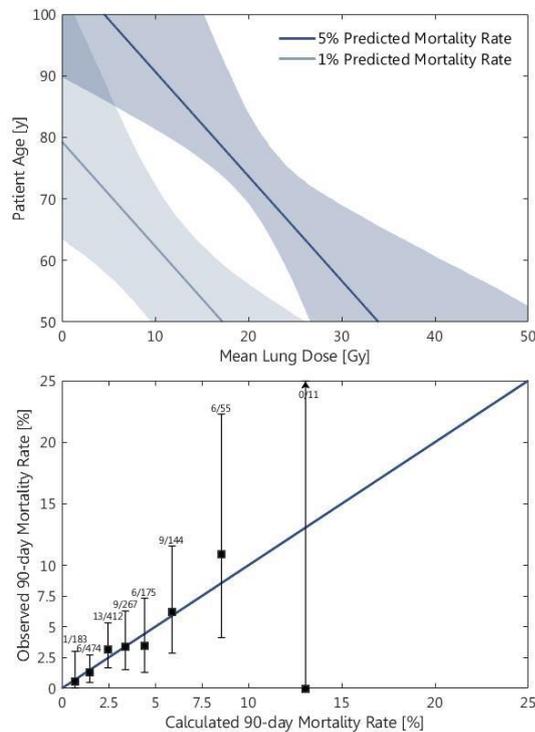

Figure 2. Upper panel: Isocurves of the predicted 90-day mortality rates 1% and 5% as a function of the mean lung dose and patient age. The shaded areas corresponds to the 95% confidence intervals. Lower panel: Calibration plot comparing observed and modelled 90-day mortality rates. The vertical error bars are the 95% binomial confidence interval and the numbers above are the observed data in each bin.

#### Conclusion

We demonstrated registry based outcome modeling as a means to predict the infrequent endpoint of early mortality following curative intended radiotherapy for NSCLC. Age and MLD were found to be associated with a higher risk of early mortality.

#### OC-0406 Early survival prediction in non-small cell lung cancer with PET/CT size aware longitudinal pattern

M. Astaraki<sup>1,2</sup>, C. Wang<sup>1</sup>, G. Buizza<sup>3</sup>, I. Toma-Dasu<sup>2,4</sup>, M. Lazzeroni<sup>2,4</sup>, Ö. Smedby<sup>1</sup>

<sup>1</sup>KTH Royal Institute of Technology, Department of Biomedical Engineering and Health Systems, Stockholm, Sweden ; <sup>2</sup>Karolinska Institutet, Department of

Oncology-Pathology, Stockholm, Sweden ; <sup>3</sup>Politecnico di Milano, - Department of Electronics- Information and Bioengineering, Milan, Italy; <sup>4</sup>Stockholm University, Department of Physics, Stockholm, Sweden

#### Purpose or Objective

Recently, numerous studies have developed advanced imaging biomarkers in order to capture cancer imaging phenotypes. By extracting large numbers of quantitative features, radiomics offers new opportunities in cancer outcome modeling. However, radiomic features are quite sensitive to different factors, and it is often difficult to interpret their physiological meanings. The objective of this study was to develop a novel physiologically interpretable feature set describing intra-tumor heterogeneity in patients with lung cancer and test it as an imaging biomarker for survival prediction.

#### Material and Methods

Longitudinal PET-CT images from 30 patients diagnosed with non-small cell lung cancer were analyzed. After preprocessing the images, gross target volumes (GTV) were segmented semi-automatically. Inspired by the assumption that partial tumor response to the therapy would be explained by the existence of sub-regions within the GTV, we introduced the size-aware longitudinal pattern (SALoP), which aims at quantifying variations in the structure and function of the tumor. To compute SALoP, we partitioned the GTVs into separate subregions based on the distance of each voxel inside the GTV from the tumor border, i.e. for every 0.5cm of distance from the tumor border, one region was added. Then, the change in average intensity of each subregion between the two scans was calculated. For comparison, radiomic analysis was performed by extracting 451 features. Reproducibility of SALoP and radiomic features were investigated on an external test-retest dataset. Dimensionality reduction was performed by applying a forward feature selection (FFS) algorithm, and a support vector machine (SVM) was employed as the prediction model.

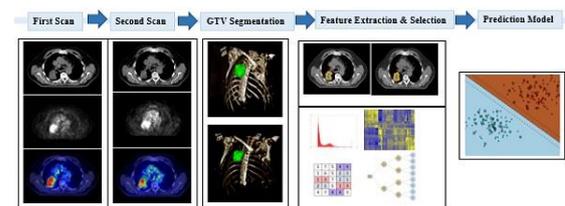

Figure 3. Schematic illustration of the study pipeline.

#### Results

Reproducibility of the SALoP set was substantiated by achieving a high agreement when it was applied on test-retest dataset. Without FFS, SALoP features outperformed radiomics significantly. Feeding the prediction model with only selected features, the combination of SALoP and radiomics resulted in the highest predictive values. For SALoP, a combination of PET and CT features led to higher predictive values than CT and PET features separately either with or without FFS. Applying FFS contributed an improvement of 15 percent (0.71 to 0.86) in predictive power of radiomics and 5 percent (0.90 to 0.95) for the SALoP. This implies that large numbers of radiomic features were either redundant or lacking informative value, whereas the SALoP features were more consistent

with each other.

Table1. Predictive values of SALoP feature set, radiomics and their combination with and without Forward Feature Selection (FFS), in terms of area under the receiver operating characteristic curve (AUROC) calculated on leave one out cross validation. For each case, the highest values are marked in bold. AUROC values significantly different from randomness (0.5) are indicated with \*

Modality	Therapy	AUROC					
		Without FFS			With FFS		
		SALoP	Radiomics	SALoP+ Radiomics	SALoP	Radiomics	SALoP+ Radiomics
CT	Sequential	0.87*	0.80	<b>0.92*</b>	0.92*	0.76	<b>0.95*</b>
	Concurrent	<b>0.70</b>	0.49	0.50	0.53	0.50	<b>0.70</b>
	All	0.66	0.56	<b>0.69</b>	0.71*	0.87*	<b>0.89*</b>
PET	Sequential	<b>0.85*</b>	0.73	0.73	0.91*	0.97	<b>0.99</b>
	Concurrent	<b>0.80*</b>	0.63	0.65	0.90*	<b>1*</b>	<b>1*</b>
	All	<b>0.86*</b>	0.61	0.63	0.89*	0.87*	<b>0.96*</b>
PET-CT	Sequential	<b>0.94*</b>	0.78	0.76	0.95*	0.96*	<b>0.98</b>
	Concurrent	<b>0.83*</b>	0.65	0.69	0.91*	<b>1</b>	<b>1*</b>
	All	<b>0.90*</b>	0.71	0.66	<b>0.95*</b>	0.86*	<b>0.95*</b>

### Conclusion

Assuming that the sensitivity of tumor cells to treatment may vary as a function of distance from the tumor border, dividing the tumor volume into subregions can characterize tumor cells and identify them from more homogeneous regions. The proposed novel feature set was capable of describing intra-tumor heterogeneity with only 20 features and outperformed conventional radiomics.

### OC-0407 CT-based Radiomics for Risk Stratification in Prostate Cancer

S. Osman<sup>1,2</sup>, R.T.H. Leijenaar<sup>3</sup>, A.J. Cole<sup>1,4</sup>, A.R. Hounsfield<sup>2</sup>, K.M. Prise<sup>1</sup>, J.M. O'Sullivan<sup>1,4</sup>, P. Lambin<sup>3</sup>, C.K. McGarry<sup>1,2</sup>, S. Jain<sup>1,4</sup>

<sup>1</sup>Queen's University Belfast, Centre for Cancer Research & Cell Biology, Belfast, United Kingdom; <sup>2</sup>Northern Ireland Cancer Centre, Medical Physics, Belfast, United Kingdom; <sup>3</sup>The D-Lab: Decision Support for Precision Medicine- GROW- Maastricht University Medical Centre- The Netherlands, School for Oncology and Developmental Biology, Maastricht, The Netherlands; <sup>4</sup>Northern Ireland Cancer Centre, Department of Clinical Oncology, Belfast, United Kingdom

### Purpose or Objective

The prognostic and predictive value of MRI- based radiomics imaging features for prostate cancer (PCa) has been demonstrated in a number of publications. However, there is no clear consensus on the most important imaging biomarkers for prostate or their clinical applicability. This could be due to the lack of interoperability (i.e. variable imaging protocols, scanners, software or uncertainties in the manual definition of tumours). Planning CT scan protocols for PCa are typically standardised for all patients treated with external beam radiation therapy (EBRT). This study explored the role of CT-based radiomics features in PCa Gleason score (GS) and risk group classification.

### Material and Methods

The study population consisted of 506 PCa patients from a clinically annotated database all treated in a single centre using EBRT. After applying exclusion criteria (available CT scans with 2.5mm slice thickness and no artefact), 342 patients were included in the final analysis. CT-based radiomics features were extracted for prostate gland only (PO) structure. CT scans were re-sampled to 2.5mm isotropic voxels and the range of Hounsfield Units (HU) discretised to 10 HU bins prior to feature extraction. For 20 patients with scan and re-scan data the interclass correlation coefficient ICC was used to identify a set of robust features to use for our analysis. Features with ICC > 0.8 were considered reproducible. Pairwise correlation testing was also employed to remove redundant features. Penalized regression analysis using LASSO generalized linear model was used. Optimal lambda was estimated using 10-fold cross validation (CV) repeated 100 times, the lambda value one standard error away was used. Models were evaluated through 10-fold CV repeated 100 times.

Models' discriminatory performance was assessed using receiver operating characteristic (ROC) area under the curve (AUC) analysis, accuracy, and Youden index (YI = specificity + sensitivity - 1).

Table 1(a): Patient grouping based on Gleason Score (GS)

Gleason Score	Number of patients
6(3+3)	100
7(3+4)	87
7(4+3)	49
>7	106

Table 1(b): Patient grouping based on Risk Group (RG)

Risk Group	Criteria	n
Low risk	T1 or T2a and Gleason score 6 and PSA <10 ng/ml	33
Intermediate risk	T2b or T2c or Gleason score 7 or PSA 10-20ng/ml	76
High Risk	>T2c Gleason score 8-10 or PSA > 20ng/ml	233

### Results

Classifiers employing CT-based radiomics features distinguished between GS ≤ 6 vs. GS ≥ 7 with (AUC = 0.83, YI = 0.16) and GS=7(3+4) vs. GS=7(4+3) with (AUC = 0.98, YI = 0.80). Excellent performance was observed for radiomics-based classification of PCa risk groups for low vs. high risk group (AUC = 1.00, YI = 0.81), low vs. intermediate risk (AUC = 0.97, YI = 0.58). Models showed poor performance in distinguishing between GS 7 vs. GS > 7 (AUC = 0.65, YI = 0.02) as well as intermediate vs. high risk patients (AUC = 0.66, YI = 0.00). Applying augmentation methods to balance the data improved classifiers' performance in all cases.

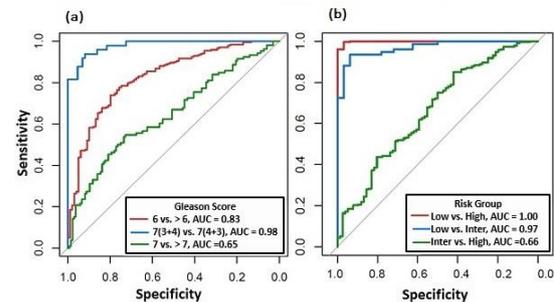

Figure 1: ROC curves for (a) Gleason score and (b) risk group classification.

### Conclusion

Results show that radiomics features from routinely acquired planning CT scans may provide insights into prostate cancer aggressiveness (i.e. Gleason score and risk-group) in a non-invasive manner. Our classifiers were especially accurate in identifying high-risk patients. External validation, and prospective studies are warranted to verify the presented findings.

OC-0408 Impact of bladder filling on the magnitude of prostate intra-fraction motion assessed in 3D Cine-MR  
H. De Boer<sup>1</sup>, D.M. De Muinck Keizer<sup>1</sup>, J.R.N. Voort van Zyp<sup>1</sup>, N.A.T. Van den Berg<sup>1</sup>, F.J. Pos<sup>2</sup>, U.A. Van der Heide<sup>2</sup>, B.W. Raaymakers<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, L.G.W. Kerkmeijer<sup>1</sup>

<sup>1</sup>University Medical Center Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands ;  
<sup>2</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

We have collected and analyzed an extensive 3D cine-MR dataset to study the visualization of intrafraction motion of the prostate and surrounding organs in MR-guided RT. Here we report on a remarkable relationship of prostate intrafraction motion with initial bladder volume.

### Material and Methods

Fifty-nine patients had repeated weekly cine-MR imaging sessions over five weeks in a multicenter Medical Ethics Review Board approved study. Each session was scheduled shortly after a radiotherapy fraction. 30 patients were instructed to drink 400 mL prior to irradiation as well as scanning, while 29 patients were instructed to drink 200 mL only prior to irradiation. A cine-MR session consisted of 55 sequentially obtained 3D datasets ('dynamics'), using a balanced 3D gradient echo sequence. Each dynamic was acquired over a 11 second period, with the complete cine-MR session covering a ten minute period, similar to the duration of RT fraction delivery. The bladder volume (BV) in each dynamic was obtained with an in-house developed bladder segmentation algorithm. In total, 238 sessions were available for analysis. Prostate intrafraction motion results were obtained with an in-house developed automatic soft-tissue tracking algorithm that was validated with an independent marker tracking algorithm (success rate > 98%, ESTRO 37). We assigned cine-MR sessions to either a group with a BV in the first dynamic below the overall mean BV (Group 1) or to a group with a BV above the group mean (Group 2). We analyzed differences in prostate intrafraction behavior between these two groups.

### Results

Deviations between the automatic segmentation of the bladder and manual delineations were typically < 10 mL. The mean bladder volume  $\pm$  SD was  $0.17 \pm 0.07$  L,  $0.12 \pm 0.03$  L and  $0.24 \pm 0.05$  L in respectively all sessions, group 1 (135 sessions) and group 2 (103 sessions). BV increase during the ten minute sessions was small ( $0.014 \pm 0.013$  L). The distributions of intrafraction translations in AP as well as CC directions were significantly different between groups 1 and 2 for all time points > 2 minutes ( $p < 0.05$ , Kolmogorov-Smirnov test). Particularly the magnitude of motions in the AP direction was markedly larger in group 2 (Fig. 1). The distributions of 3D displacements were equally different between the two groups, as illustrated by Fig. 2. The frequency of displacements > 5 mm almost doubled in group 2 relative to group 1 near the end of the sessions.

### Conclusion

We have found a significant and clinically meaningful increase of prostate intrafraction motion in patients with an initial high bladder volume. Our working hypothesis is that this is due to increased discomfort for larger BV. The presented results suggest that caution should be applied with too strict drinking instructions for prostate cancer patients as full bladder conditions may deteriorate targeting accuracy even after daily on-line corrections.

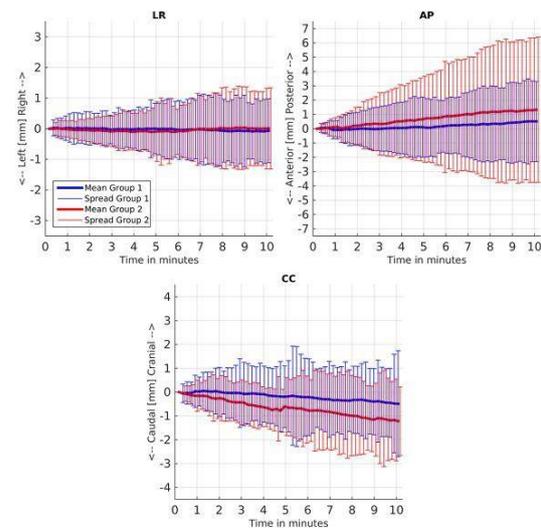

Figure 1: The time evolution of group mean translations (bold) and spread (95 percentile error bars) for both groups.

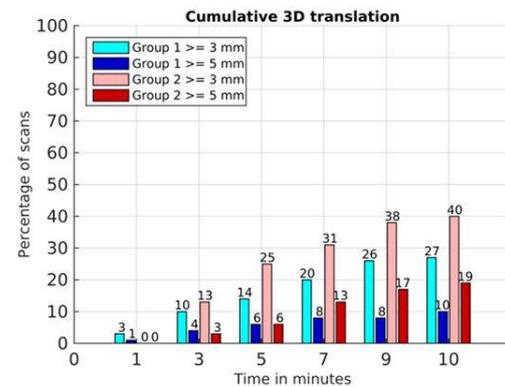

Figure 2: Cumulative distribution of 3D intrafraction translations of group 1 and 2, for various time points.

### OC-0409 Comparison of different strategies to derive time-resolved volumetric MRI in MRI-guided radiotherapy

C. Paganelli<sup>1</sup>, S. Portoso<sup>1</sup>, N. Garau<sup>1</sup>, G. Meschini<sup>1</sup>, R. Via<sup>2</sup>, P. Keall<sup>3</sup>, M. Riboldi<sup>4</sup>, G. Baroni<sup>1</sup>

<sup>1</sup>Politecnico di Milano, Dipartimento di Elettronica- Informazione e Bioingegneria, Milano, Italy; <sup>2</sup>Paul Scherrer Institute, Center for Proton Therapy, Villigen, Switzerland; <sup>3</sup>University of Sydney, ACRF Image X Institute- Sydney Medical School, Sydney, Australia ; <sup>4</sup>Ludwig-Maximilians-Universität München, Department of Medical Physics, Munich, Germany

### Purpose or Objective

MRI-Linacs enable 2D cine-MRI centred in the tumour for motion detection in radiotherapy. However, they lack 3D information due to temporal-spatial limits. To derive time-resolved 3D information, different approaches have been proposed in the literature, but a rigorous comparison between these strategies has not yet been performed. The goal of this study is to quantitatively investigate published strategies to derive time-resolved volumetric MRI in MRI-guided radiotherapy.

### Material and Methods

Five published strategies to derive time-resolved 3DMRI were selected: propagation (PROP)<sup>1</sup>, out-of-plane motion

compensation (OOPM)<sup>2</sup>, Fayad model (FAY)<sup>3</sup>, ROI-based model (ROI)<sup>4</sup> and Stemkens model (STEM)<sup>5</sup>. Comparison among these methods was performed by means of a digital phantom. 3D Digital XCAT-based MRI phantoms were generated from six patient-measured tumour shapes, positions and motion signals: 4DMRI (mean cycle) was generated prior to treatment, with sagittal/coronal 2D cine-MRI acquired during treatment (1x1x3mm<sup>3</sup> resolution, 300ms acquisition). Quantitative analysis was performed by comparing the estimated 3D volume to the ground truth available for each 2D cine-MRI using the centre of mass distances (CD) and dice coefficient (DSC) for the tumour and the apex distance for the diaphragm (Dd).

### Results

Figure A shows the boxplot for each method over the six cases (Friedman test for statistical analysis). For the tumour region (patient motion of 0.4-6.3mm) better results were achieved by PROP and ROI with an overall median CD of 1.14mm and 1.44mm, respectively. Higher errors and variabilities were instead quantified for OOPM, FAY and STEM, with CD>2mm (DSC<0.90) for patients with irregular breathing patterns (CD<1.8mm and DSC>0.92 for PROP and ROI). All methods presented median errors on Dd below 2.5mm (patient motion of 2.2-9.3mm), with PROP and ROI being the most accurate (Dd<3.1mm for irregular patients). Figure B shows a qualitative result for a regular and irregular patient.

### Conclusion

A comparison between different strategies to derive time-resolved 3DMRI is proposed, with PROP and ROI outperforming other methods due to the capability to directly compensate for in-room variations and to account for regional changes, respectively. Future analysis will evaluate the performance of each method according to relevant patient-specific characteristics.

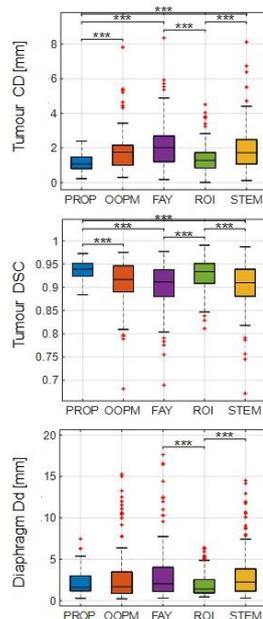

Figure A. Error distributions for tumour (CD and DSC) and diaphragm (Dd) in case of Propagation, OOPM compensation, Fayad model, ROI-based model and Stemkens model. \*\*\* for significant difference ( $p < 0.001$ ).

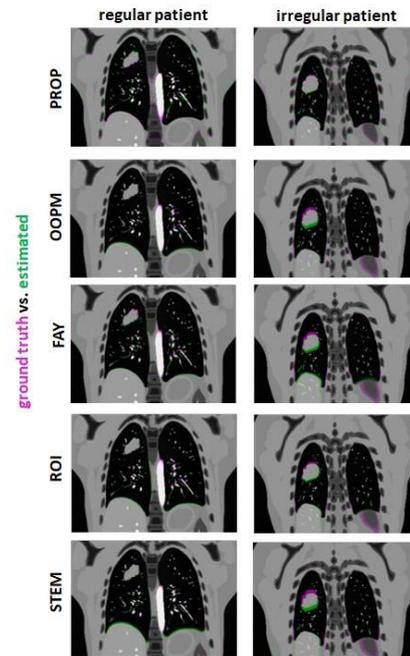

Figure B. Performance of the considered methods on a regular and irregular case: overlap between the estimated volume and the ground truth. Patient-specific signals and tumours animate the phantom.

### OC-0410 Soft-tissue based on-line prostate motion assessment in 4D Cine-MR for MR-Linac treatments

D. De Muinck Keizer<sup>1</sup>, L.G.W. Kerkmeijer<sup>1</sup>, M. Maspero<sup>1</sup>, J.R.N. Van der Voort van Zyp<sup>1</sup>, C.A.T. Van den Berg<sup>1</sup>, B.W. Raaymakers<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, H.C.J. De Boer<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

#### Purpose or Objective

We develop real-time MR-guided extremely hypofractionated (HF) prostate radiotherapy (RT) with active correction for prostate intrafraction motion. We have collected an extensive 4D cine-MR dataset to study the intrafraction motion of the prostate during the period of a RT fraction. Previously, we have presented a method for accurate automatic prostate tracking based on fiducial gold markers (ESTRO 37). Now we present a method for soft-tissue contrast based tracking that obviates the need for fiducial markers on an MR-Linac.

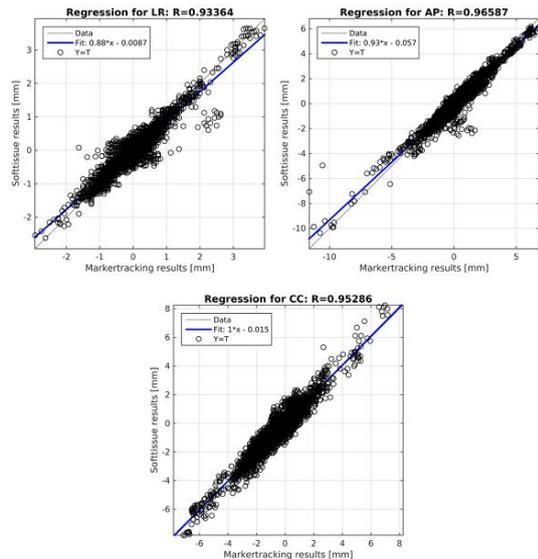

#### Material and Methods

Thirty patients undergoing HF prostate RT had repeated cine-MR imaging sessions after each of five weekly fractions in a multicenter Medical Ethics board approved study. Each cine-MR session consisted of 55 sequentially obtained 3D datasets ('dynamics'), acquired with a balanced 3D gradient echo sequence and a voxel spacing of 0.96x0.96x2mm<sup>3</sup>. Each dynamic was acquired over an 11 second period, with the cine-MR session covering a 10 minute period, similar to the duration of a RT fraction. A clinician delineated the prostate on the first dynamic from

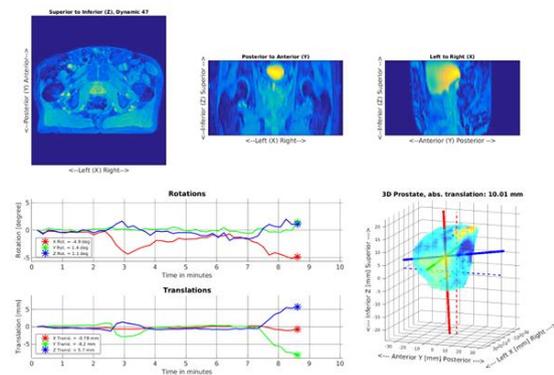

which in-house developed Python code performed soft-tissue (ST) tracking of the prostate in subsequent dynamics using a mutual information metric and rigid transformations. We validated the performance of the ST algorithm with previously obtained, ground truth marker tracking (MT) data of the same dataset.

**Results**

The algorithm was applied to 7645 dynamics from 139 sessions with a mean processing time of  $5.47 \pm 0.77$  sec (mean $\pm$ stdev) per dynamic. The success rate (difference between MT and ST result < 1 mm) was 98.93%. We found group translations after 10 minutes of  $0.05 \pm 0.81$ mm for X (LR),  $0.83 \pm 1.90$ mm for Y (AP),  $-0.90 \pm 1.85$ mm for Z (CC) and corresponding rotations of  $-0.49 \pm 2.13^\circ$  about X,  $0.09 \pm 0.58^\circ$  Y and  $0.09 \pm 0.73^\circ$  for Z. After 10 min, 12% of all sessions had demonstrated a 3D displacement > 5 mm. Linear regression and Pearson correlation analysis indicated a good correlation and non-significant difference with all p-values <  $1e^{-5}$  between the ST and MT algorithm in the X (R=0.934), Y (R=0.966) and Z (R=0.953) directions as shown in Fig. 1. An overview of the ST intrafraction visualization tool is provided in Fig. 2, showing the rotation, translation and full 3D segmentation of the prostate at a specific time point.

**Figure 1:** Overview of the linear regression analysis between the ST and MT algorithm results in the three translation directions.

**Figure 2:** Overview of the prostate intrafraction visualization tool, showing the different slices of the prostate, the found rotations and translations and the current 3D segmentation of the prostate.

**Conclusion**

We have developed a fast, robust and accurate ST tracking algorithm in cine-MR data which was validated against marker tracking. The presented method for soft-tissue contrast based tracking obviates the need for surgically implanted fiducial markers during MR-guided prostate RT on an MR-Linac.

**OC-0411 Geometric efficacy of breath-hold gated MR-guided SABR for adrenal metastases**

J. Van Sornsen de Koste<sup>1</sup>, M. Palacios<sup>1</sup>, A. Bruynzeel<sup>1</sup>, F. Spoelstra<sup>1</sup>, B. Slotman<sup>1</sup>, F. Lagerwaard<sup>1</sup>, S. Senan<sup>1</sup>  
<sup>1</sup>Amsterdam UMC- Vrije Universiteit Amsterdam- VU Medical Center, Department of Radiation Oncology, Amsterdam, The Netherlands

**Purpose or Objective**

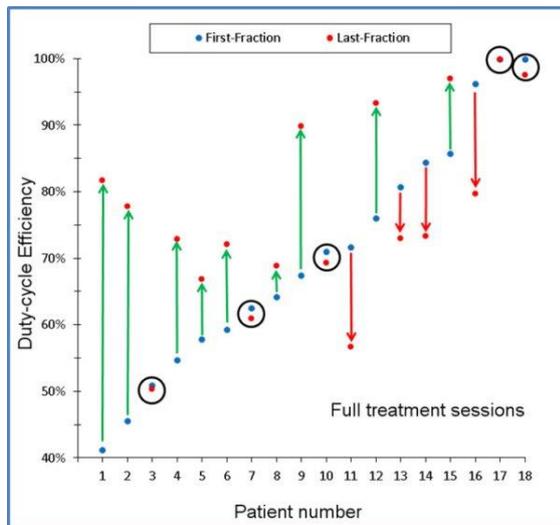

Magnetic Resonance (MR) guided stereotactic ablative radiotherapy (SABR) improves target coverage and reduces organ-at-risk doses. We studied target coverage and breath-hold performance in patients undergoing MR-guided adrenal SABR.

**Material and Methods**

Breath-hold SABR data from 18 patients treated on a MRIdian unit (ViewRay Inc) was analyzed. Real-time tumor tracking during SABR was performed using repeated fast planar MR imaging in a single sagittal plane, at 4 frames-per-second with 3.5mm x 3.5mm in-plane resolution via deformable image registration. An in-room MR-compatible monitor projects sagittal images to allow patient visualization of tracked GTV (GTV<sub>t</sub>) and PTV (GTV+3mm) contours. Simulation MR-imaging is performed in quiet inspiration. A delivery threshold-ROI% determines the maximum permitted percentage of GTV<sub>t</sub>-area that can be outside the PTV-area, before a beam-hold is triggered. Breath-hold related tumor coverage during SABR was analyzed for 82 fractions (40 hours of MR-cine series). For each fraction, we analyzed: [1] geometric coverage of GTV<sub>t</sub> within PTV; [2] duty-cycle efficiency; [3] stability of breath-holds during each session [4] beam-off latency effects on target coverage using a 500msec system-latency time as a worst case scenario.

**Results**

Different threshold-ROI% settings were used (range 7-20%), but 75% of fractions used a 15% threshold-ROI. Mean geometric GTV<sub>t</sub> coverage was 94.2% (5<sup>th</sup>-95<sup>th</sup> Percentile range: 90.6%-96.7%); corresponding mean duty-cycle efficiency was 71.7% (range: 45.5%-99.5%). Average duty-cycle efficiency increased from 70.5% during the first fraction, to 76.7% during the last fraction (Figure), and treatment delivery times decreased from 32.4 to 28.6 minutes, respectively (p<0.04). Gating efficacy in patients during the initial 10 minutes of SABR delivery correlated with efficacy during the full SABR session (~ 31 minutes). On average, beam latency effects had marginal impact on GTV<sub>t</sub> coverage during repeated inspiration breath-holds, leading to a reduction in mean GTV<sub>t</sub> coverage by only -0.9%. Increased latency effects were seen when (i) relatively short breath-hold gates occurred in combination with mean large tumor motion (>15mm, Peak-to-Peak), (ii) both very short and high frequent gates occurred, and (iii) different breathing phases were used during gating (e.g. mid-ventilation), leading to system-latency effects causing up to -3.0% in mean GTV<sub>t</sub> coverage. Analysis of the first, middle and last fractions revealed that some patients used different breathing phases than light inspiration in 10/54 fractions; in those patients latency effects increased for tumors showing an initial mean motion >12mm.

Comparison of first and last SABR fractions: Duty-cycle efficiency increased in nine patients (green arrows), decreased in four patients due to an increase tumor motion amplitude (red arrows), and remained stable in five other patients in both low and high efficiency ranges (black circles). Small tumor motion amplitude generally results high duty cycle efficiency.

### Conclusion

In breath-hold adrenal SABR, use of visual MR feedback achieved high geometric tumor coverage, but beam latency effects increased in patients who performed subsequent breath-holds in other phases of respiration.

**OC-0412 Dosimetric impact of marker-based intrafraction motion from cine-MRI in prostate SBRT**  
 C. Kontaxis<sup>1</sup>, D. De Muinck Keizer<sup>1</sup>, L. Kerkmeijer<sup>1</sup>, H. De Boer<sup>1</sup>, B. Raaymakers<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy department, Utrecht, The Netherlands

### Purpose or Objective

To investigate the effect of intrafraction translation and rotation motion, as extracted from 3D cine-MRI based on fiducial marker tracking, on the dose distributions of extremely hypofractionated (SBRT) prostate patients.

### Material and Methods

Twenty prostate patients treated with extremely hypofractionated radiotherapy (4 mm CTV to PTV margin,  $5 \times 7$  Gy, with focal boosts up to  $5 \times 10$  Gy) underwent weekly cine-MRI within an Ethical Review Board approved study. Fiducial marker-based online corrections were applied during treatment. Each cine-MRI session consisted of a balanced 3D gradient echo sequence, acquiring one volume every 11 sec over 10 min. A marker tracking algorithm was used to obtain the prostate marker-based intrafraction motion in subsequent dynamics for each session (ESTRO 37). The fiducial positions from the first cine-MR dynamics were registered to the planning CT, thus transferring the local cine-MRI motion to the CT coordinate system. Then for each patient fraction, the treatment plan delivery consisting of two VMAT arcs was played back, by proportionally splitting the MUs into 11 sec intervals leading to 33 partial plans during a 6 min delivery. For each partial plan, the corresponding volume was generated by applying the cine-MRI rigid transformation to the CT, the partial dose was calculated using our research treatment planning system and was then warped back to the reference volume by using the inverse transformation. The mean $\pm$ SD translations (mm) were  $0.04 \pm 0.79$  (LR),  $0.4 \pm 1.9$  (AP),  $-0.5 \pm 1.73$  (CC) and rotations (degrees) were  $-0.84 \pm 2.91$  (LR),  $0.13 \pm 1.15$  (AP),  $0.25 \pm 1.84$  (CC) among all patients and timepoints. For each fraction the 33 partial doses were summed leading to the accumulated fraction and total treatment dose

(INTRA) which was compared to the original reference (REF) dose.

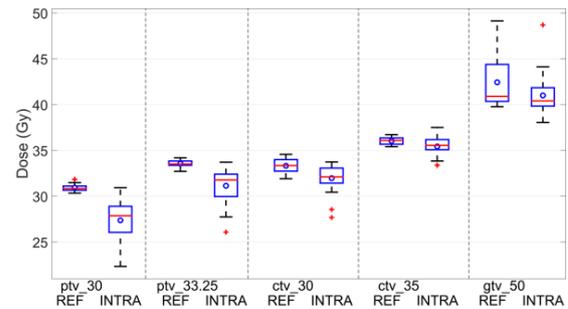

Figure 1: Boxplots including the D99% DVH point of the different target structures: CTV\_35 corresponds to the prostate, CTV\_30 to the seminal vesicles along with their corresponding PTV expansions and integrated GTV\_50

### Results

Figure 1 shows the D99% point of the target structures between REF and INTRA dose for these 20 patients. The PTVs (average decrease of  $9.4 \pm 6.8\%$ ) ensured the full CTV/GTV coverage for 80% patients. The average drop in D99% coverage for CTV\_35 (prostate) and CTV\_30 (seminal vesicles) was  $1.7 \pm 2.8\%$  and  $4.1 \pm 4.7\%$  respectively while the GTV dropped by  $3.2 \pm 3.6\%$  with a mean dose reduction of  $2.8 \pm 2.4\%$ . Figure 2 shows boxplots of the Dmax for rectum and urethra respectively. Rectum Dmax (40 Gy) was exceeded in 4 cases while V35Gy was stable ( $0.1 \pm 1.1\%$ ).

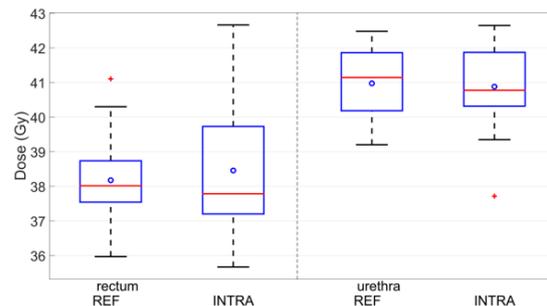

Figure 2: Boxplots including the Dmax DVH point of Rectum and Urethra OARs

### Conclusion

We have simulated the dosimetric impact due to prostate intrafraction motion as extracted by marker-based tracking on cine-MRI for extremely hypofractionated treatments. Evaluating the impact of intrafraction motion with such high spatial and temporal resolution has now become possible with MRI-linacs. The analysis presented is essential to establish the optimal inter/intrafraction adaptation strategies for MRI-guided radiotherapy, which will ensure continuous online target coverage while safely decreasing margins. We are now working towards a full dosimetric analysis of both targets and OARs for more patients.

**OC-0413 MR-derived signals for respiratory motion models evaluated using sagittal and coronal datasets**  
 E.H. Tran<sup>1</sup>, B. Eiben<sup>1</sup>, A. Wetscherek<sup>2</sup>, U. Oelfke<sup>2</sup>, G. Meedt<sup>3</sup>, D.J. Hawkes<sup>1</sup>, J.R. McClelland<sup>1</sup>

<sup>1</sup>University College London, Medical Physics and Biomedical Engineering, London, United Kingdom ; <sup>2</sup>The Institute of Cancer Research and the Royal Marsden NHS Foundation Trust, Joint Department of Physics, London, United Kingdom; <sup>3</sup>Elekta, Medical Intelligence Medizintechnik GmbH, Schwabmünchen, Germany

### Purpose or Objective

MR-Linac systems can provide 2D cine-MR images to monitor the motion of a tumour during beam delivery, enabling gated or tracked radiotherapy treatments.

Respiratory motion models can potentially estimate the motion of the full 3D anatomy using internal surrogate signals extracted from the real-time 2D images. In this study, we used 2D motion models to quantitatively evaluate potential surrogate signals with data from lung cancer patients.

#### Material and Methods

Surrogate cine-MR images from a fixed location and with sagittal orientation were used to generate surrogate signals by tracking the diaphragm motion, and performing principal component analysis (PCA) on image intensities, or PCA on deformation fields (DFs) resulting from deformable registration of the images. The surrogate images were interleaved in time with motion images from another fixed location. The motion images had sagittal orientation for 8 datasets and coronal orientation for 4 datasets. Deformable image registration was used to measure the motion in the motion images relative to an end-exhale reference image. The registration algorithm can account for sliding motion by taking a sliding interface (manually defined for each dataset) as input. The motion images were divided into a training set and a test set. Linear correspondence models were fit to the motion measurements using a variable number of training images and the corresponding interpolated surrogate signals. The models driven by the surrogate signals were used to estimate the motion for the test images. The different surrogate signals were evaluated by calculating the deformation field error (DFE) which is the difference between the DFs estimated by the model and the DFs from the sliding registration.

#### Results

The motion models are able to model the sliding motion. Figure 1 shows an example of the estimated DFs for a sagittal and a coronal dataset respectively. Figure 2 reports the mean of the L2 norm of the DFE against the number of training images for the different surrogate signals. For each dataset the mean DFE was computed over all pixels of all test images within the sliding interface (excluding the gastrointestinal organs) and averaged over all datasets for each slice orientation. The mean DFE when not using a motion model was equal to 3.41 mm for the sagittal datasets and 4.54 mm for the coronal datasets. The models for the different surrogate signals all give good results when using 8 or more training images, with mean DFEs below the in-plane pixel size (1.98 mm).

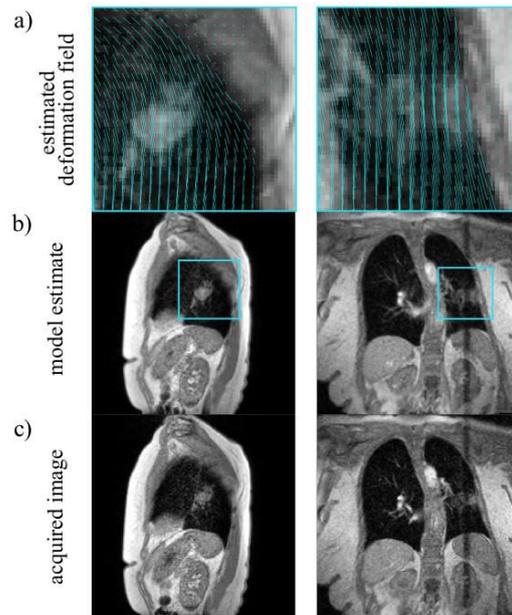

Figure 1. Model estimates using PC1 and PC2 on DFs as surrogate signals for a sagittal (left) and a coronal (right) dataset. a) DF estimated by the model in a region containing the tumour, showing the sliding motion of the lung. b) Motion image estimated by the model and obtained by warping the reference image with the estimated DF. c) Corresponding acquired motion image.

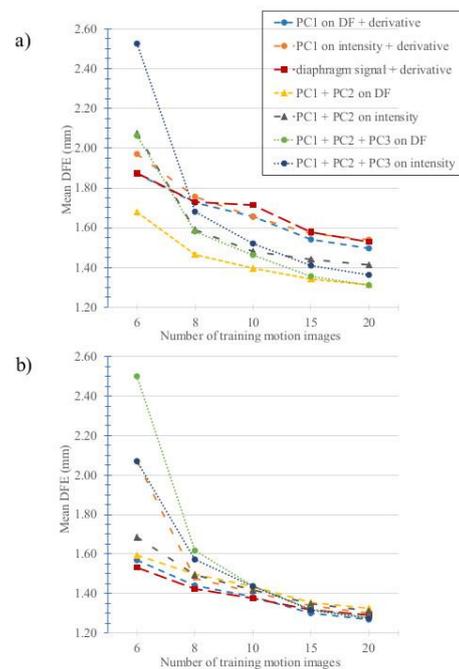

Figure 2. Mean of the L2 norm of the DFE for different numbers of training motion images with sagittal (a) and coronal (b) orientation. The different combinations of signals used to build and drive the motion models are indicated with different lines and colors.

#### Conclusion

The investigated surrogate signals are suitable to model the 2D motion, including sliding, in both sagittal and coronal planes, using few training images. Future work will extend the study to 3D motion models from multi-slice MR images. The 3D models can potentially estimate the motion of the tumour as well as the organs-at-risk during treatment on an MR-Linac from 2D cine surrogate images, and facilitate accurate dose calculations.

**OC-0414 Intrafraction displacement of breast tumor (bed) and individual axillary lymph nodes on cine MRI**  
 M. Groot Koerkamp<sup>1</sup>, H.J.G.D. Van den Bongard<sup>1</sup>, M.E.P. Philippens<sup>1</sup>, J.J.W. Lagendijk<sup>1</sup>, A.C. Houweling<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

The purpose of this study was to evaluate intrafraction displacement of breast tumor (bed) and individual axillary lymph nodes (LN) on cinematic MRI (cine) scans. Evaluation of displacement in local and regional target regions will help us to assess the potential impact of these displacements on future MRI-guided (stereotactic) RT for breast cancer patients.

### Material and Methods

2D cine scans (0.3-0.6s/slice) of 25 breast cancer patients participating in an MR imaging study were acquired on a 1.5T MRI scanner. Transverse-sagittal interleaved imaging of the breast was performed in both prone and supine position. Coronal-sagittal interleaved imaging of regional LNs was performed in supine position only. Additionally, sagittal cine scans (0.3s/slice) of LNs of 7 healthy volunteers were assessed. All cine scans were acquired during 1-3 minutes of free breathing.

Intrafraction displacement in the cine scans was investigated with an optical-flow algorithm. With this method we applied a deformable registration of the cine scan frames to a reference frame of the same cine series. The mean displacement of pixels within a region of interest was calculated to determine tumor (bed) or LN displacement with respect to the reference frame. In preoperative patients the visible tumor or biopsy marker was chosen as the region of interest; in postoperative patients the best visible surgical clip was used. The maximum peak-to-peak difference (Figure 1) was determined in left-right (LR), superior-inferior (SI), and anterior-posterior (AP) direction.

### Results

In total 40 cine scans of LNs (17 patients, 7 volunteers), and 21 cine scans of the breast (6 pre- and 4 postoperative patients) in prone (12) and supine (9) position were analyzed (Figure 1). The median maximum displacement for LNs was around 2mm in all directions (Table 1). Tumor or surgical clip position in prone position was very stable (median maximum displacements around 1mm in all directions). In supine position median maximum displacements were 1.5mm in LR, 2.6mm in SI, and 3.7mm in AP direction.

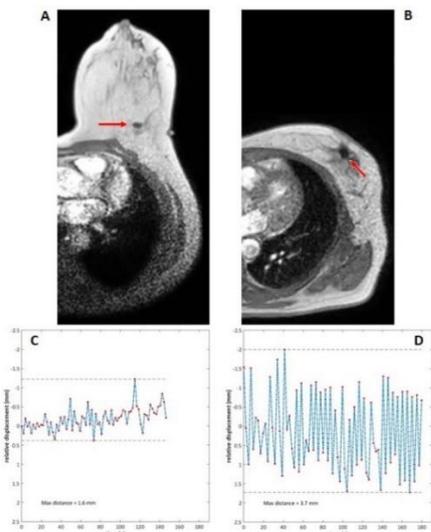

Figure 1. Prone (A) and supine (B) cine scans for intrafraction tumor displacement analysis with AP displacements (C and D) in two different breast cancer patients. This example illustrates that on average the maximum displacement in AP direction was larger in supine position than in prone position.

Table 1. Median maximum [range] intrafraction displacements [mm] in individual axillary lymph nodes and breast tumor (bed).

	Lymph nodes		Tumor (bed)*			
	Median (range)	# cine scans	Prone median (range)	# cine scans	Supine median (range)	# cine scans
Left-Right	1.9mm (1.2 – 4.1mm)	33	1.0mm (0.2 – 1.9mm)	12	1.5mm (0.8 – 3.4mm)	7
Superior-Inferior	2.1mm (0.9 – 3.9mm)	34	0.9mm (0.1 – 1.4mm)	11	2.6mm (1.1 – 3.1mm)	9
Anterior-Posterior	1.9mm (0.7 – 3.8mm)	34	1.2mm (0.7 – 1.9mm)	12	3.7mm (2.6 – 6.5mm)	7

\* In preoperative patients: tumor or biopsy marker depending on visibility;  
 In postoperative patients: best visible surgical clip

### Conclusion

Intrafraction displacement of both the tumor (bed) and axillary lymph nodes was small. With the current PTV margins (5-8mm) these displacements are not clinically relevant. However, the displacements should be considered for future MRI-guided stereotactic (single fraction) breast RT with smaller PTV margins, e.g. for tumor-positive LNs or partial breast irradiation. For local stereotactic breast RT, prone positioning might be beneficial, since the displacements in the breast were smaller in prone than in supine position, especially in AP direction.

### Purpose or Objective

Diffusion-weighted MRI (DW MRI) enhances anatomical imaging obtained from MR, by providing information on the cellularity of tumours by measuring Brownian motion. Studies show promising results in defining a threshold change in ADC that predicts non-responders to treatment. However, these studies have; low patient numbers, include a number of sub-sites, and often don't describe the delineation method. The overall aim of the MERINO study is to determine threshold change in ADC that determines responders from non-responders, which may allow intensification of RT treatment for those who require it [1].

The aim of this work is to:

- Quantify primary gross target volume (GTV) change between; baseline MR (GTV\_T1\_Base) to repeat MR (GTV\_T1\_Rpt) as defined on T1 post contrast fat sat (T1PCFS) anatomical imaging, and baseline MR (GTV\_b0\_Base) to repeat MR (GTV\_b0\_Rpt) on DW MRI.
- Describe a standardised method of defining a region of interest (ROI) to allow repeated measurements within clinical studies

### Material and Methods

This is a prospective observational imaging study (REC approval (15/WS/0159). Patients with intermediate and high risk, locally advanced SCC oropharynx (OPSCC)

receiving radical RT or chemo-RT(65Gy in 30 fractions) were eligible for the study.

DW- MRI images were acquired immediately prior to fraction 1, and repeated immediately before 11. MRI scans were acquired on a GE Signa 1.5T HDxT scanner including T1PCFS image with slice thickness of 3mm. Diffusion weighted images were acquired using a single shot EPI sequence with five b-values between 0 and 1000 s/mm<sup>2</sup>. Parallel imaging was utilised to reduce distortion in the images. Apparent diffusion coefficient (ADC) maps were calculated using a monoexponential fit.

A clinical oncologist, radiologist and RTT delineated GTV on axial slices on MR baseline and repeat MR to evaluate volume change. For ADC measurements, a ROI was defined on T1PCFS, copied to DW b=0 image, slightly adjusted for artefacts and patient motion. This volume was then copied to the ADC map. To ensure ROI include only disease, an inner margin of 1mm was created. ADC was recorded for each ROI, and % ADC change was calculated.

**Results**

20 patients with intermediate-high risk, locally advanced OPSCC were included in the analysis. Primary GTV volumes were successfully delineated in 18/20 patients using the described method Figure 1. Mean (SD,range) GTV\_T1\_Base was 15.1cm<sup>3</sup> (8.5, 3.3-34.2) with GTV\_T1\_Rpt volume reducing to 8.3cm<sup>3</sup> (6.3, 0.1-18.1). On b value 0 images, GTV\_b0\_Base volume was 12.4cm<sup>3</sup> (8.1, 2.1-26.1), reducing to 6.9cm<sup>3</sup> (5.6, 0.1-17.0) on GTV\_b0\_Rpt.

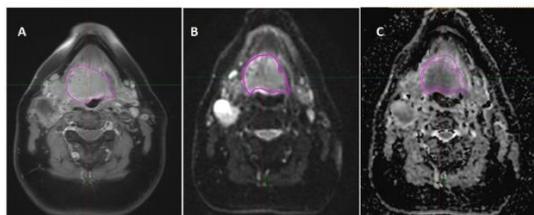

Figure 1. Images showing method of delineation used to define ROI. Primary GTV on: A - T1PCFS image, B – b=0 image, C – ADC map. Primary GTV with inner margin of 1mm shown on C.

**Conclusion**

There are many challenges in quantifying ADC as a predictor of outcome. We imported MR scans into the treatment planning system, allowing 3D ROI to be created. Here we described a standardised method of creating a ROI for repeated assessment of volume change and ADC within a large clinical study. MERINO study will use these analytical method for all patients.

**OC-0416 Assessing the quality of oesophageal cancer target volume delineation in the SCOPE1 trial**

S. Cox<sup>1</sup>, S. Gwynne<sup>1</sup>, J. Staffurth<sup>2</sup>, T. Crosby<sup>2</sup>  
<sup>1</sup>South West Wales Cancer Centre, Oncology Department, Swansea, United Kingdom; <sup>2</sup>Velindre Cancer Centre, Oncology Department, Cardiff, United Kingdom

**Purpose or Objective**

The SCOPE1 trial, which standardised RT planning within the UK, demonstrated survival rates for oesophageal cancer patients treated with definitive chemoradiotherapy (dCRT) comparable with the best published results worldwide. We present the planned retrospective analysis of adherence to the trial protocol for target volume delineation (TVD).

**Material and Methods**

A single RT plan was selected at random from each of the 32 centres. Using the Global Harmonisation Group’s (GHG) system for classifying RT protocol adherence, each step (protocol item) of TVD was retrospectively assessed. RT

plans without deviations were graded as ‘acceptable-per protocol’. Variations in TVD which were unlikely to affect the trial outcome were graded as ‘acceptable’, whilst those with a potential impact graded as ‘unacceptable’. Unacceptable deviations were further categorised according to their potential impact on tumour control probability (TCP) and toxicity. An initial review was conducted by an experienced RTQA reviewer; plans with deviations underwent a secondary review by the RTQA lead for the SCOPE2 trial. Reviewers were blinded to the trial treatment arm & recruiting centre.

**Results**

32 RT plans were reviewed (19 upper/mid and 13 lower third oesophageal tumours) with 463 protocol items in total (figure 1). Overall, 15 (47%) plans were deemed to have either acceptable or no deviations, the majority of which had upper/mid oesophageal tumours; 9 (28%) such plans did not have any deviations at all. 17 (53%) plans had at least one unacceptable deviation, the majority being lower third oesophageal tumours. The pre-trial benchmark test case was for a mid-oesophageal tumour; lower third TVD and elective lymph node irradiation (ELNI) is more complex and was not assessed with a benchmark case which may explain the higher number of unacceptable deviations for this sub site. When the total number of protocol items was assessed, 413 (89.2%) were acceptable-per protocol; 18 (3.9%) were graded as acceptable deviations. 28 (6.0%) protocol items were graded as unacceptable, 8 (1.7%) of which were deemed unlikely to affect tumour control probability (TCP) or treatment-related toxicity rates (table 1).

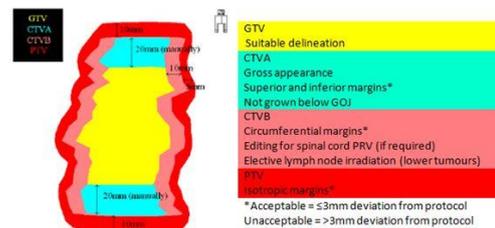

Figure 1: TVD protocol for SCOPE1 and assessment criteria for deviations  
 Abbreviations: GTV – gross tumour volume; CTV – clinical target volume; GOJ – gastro-oesophageal junction; PRV – planning risk volume; TV – planning target volume

	Potential to increase treatment-related toxicity n (%)	Unlikely to affect treatment-related toxicity n (%)	Total n (%)
Potential impact on TCP n (%)	2/463 (0.4%) <i>Most commonly relating to inadequate ELNI</i>	11/463 (2.4%) <i>Most commonly relating to inadequate ELNI</i>	13 (2.8%)
Unlikely to affect TCP n (%)	7/463 (1.5%) <i>Most commonly relating to CTVa stopping at GOJ</i>	8/463(1.7%) <i>Most commonly relating to CTVa inferior margin</i>	15 (3.2%)
Total n (%)	9/463 (1.9%)	19/463 (4.1%)	28 (6.0%)

Table 1: Frequency of unacceptable deviations according to potential impact on clinical outcomes  
 Abbreviations: CTV – clinical target volume, ELNI – elective lymph node irradiation; GOJ – gastro-oesophageal junction; TCP – tumour control probability

**Conclusion**

Adherence to the TVD protocol in this sample from SCOPE1 was high with only 4.3% of protocol items graded as unacceptable deviations with potential clinical impact. Our results show that even with a detailed TVD protocol and benchmark case, clinically significant errors still occur. As RTQA programmes are being streamlined appropriate benchmark cases need to be carefully considered, especially for trials that may introduce a new standard of care.

<sup>3</sup>Memorial Sloan Kettering Cancer Center, Neuroradiology, New York, USA ; <sup>4</sup>Dana-Farber Cancer Institute- Harvard Medical School, Radiation Oncology, Boston, USA

#### Purpose or Objective

Accurate identification of spinal cord and cauda equina is paramount for spine stereotactic radiosurgery (SRS). This study investigates the inter-observer variability in contouring spinal cord (SC), cauda equina (CE) and thecal sac (TS) using CT myelogram vs. MRI T2 sequences.

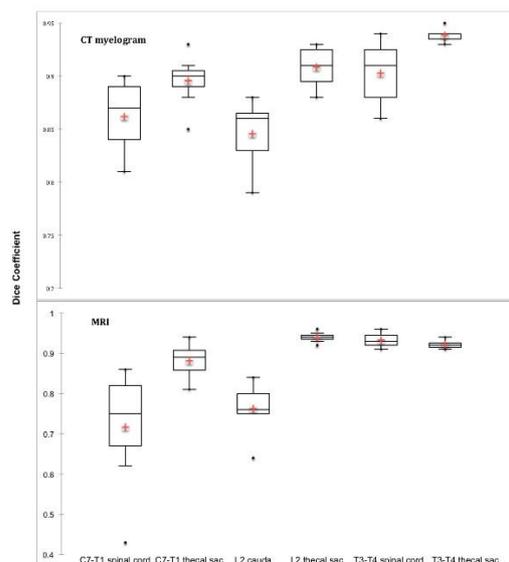

#### Material and Methods

7 radiation oncology (RO) observers (3 ROs and 4 RO residents) and 1 diagnostic neuroradiologist (DR) delineated SC, CE, and TS in the regions of interest for 6 spine SRS cases. Cases included 3 with CT myelogram pre-simulation and 3 with diagnostic MR spine fusion. Cases were evenly distributed between the junctional (C7-T1), mobile (L2), and semirigid (T3-T4) spine. Inter-observer variability was quantified using volumetric coefficient of variation (VCV), mean Hausdorff distance (HD), and the Dice coefficient (DSC). Segmentation variability in relation to imaging modality and spinal region was analyzed using the Wilcoxon rank sum test.

#### Results

In total, 96 contours were analyzed within the CT myelogram and MRI datasets. Across the 6 cases, no significant difference was found in mean VCV for CT myelogram vs MRI (10.7% vs 12.3%  $P = .675$ ). The mean HD between RO and DR contours was significantly lower for CT vs MRI (0.32 vs 0.46 mm  $P = .008$ ). The mean DSC agreement between RO and DR contours was  $0.89 \pm 0.04$  for CT and  $0.89 \pm 0.11$  for MRI ( $P = .063$ ). Substantial differences in contour variability were seen in different spine locations. The mean VCV for SC/CE contours based on MRI varied across the junctional (21.1%), mobile (25.5%), and semirigid (10.1%) spine, while there was less variability based on CT myelogram (14.0%, 13.4%, and 16.3% respectively). TS volumes were less variable across all spine locations (mean VCV 6.3% TS vs 16.7% SC/CE,  $P = .036$ ). Mean HD between RO and DR contours was significantly greater in the junctional vs semirigid spine for both SC (0.57 vs 0.19 mm,  $P = .002$ ) and TS (0.49 vs 0.26 mm,  $P = .005$ ), and this difference persisted across imaging modalities (CT: 0.37 vs 0.21 mm,  $P = .002$ ; MR: 0.68 vs 0.24 mm,  $P = .003$ ). Similarly, the DSC agreement was significantly lower in the junctional vs semirigid spine for SC (0.78 vs 0.92,  $P = .003$ ) and TS (0.89 vs 0.93,  $P = .001$ ), for both imaging modalities (CT: 0.88 vs 0.92,  $P = .001$ ; MR: 0.79 vs 0.93,  $P = .003$ ). Compared to RO volumes, DR volumes were larger for SC/CE ( $P = .036$ ) and TS ( $P = .036$ ), particularly for the MRI dataset ( $P = .036$ ), with a similar trend for the CT myelogram dataset ( $P = .059$ ).

Figure: DSC agreement between RO and DR contours based on CT myelogram and MRI.

#### Conclusion

Inter-observer variability differences in contouring SC, CE, and TS between CT myelogram and MRI were minor. CT myelogram produces slightly better agreement between RO and DR contours, but similar segmentation can be achieved from either imaging modality when there is no registration error. Contouring uncertainties that need to be considered include the greater inter-observer variability in the junctional spine, and the comparatively larger DR volumes.

### OC-0418 Residual misalignment of supraclavicular lymph nodes for NSCLC patients, to determine GTV-PTV margin

J. Stam<sup>1</sup>, S. Gerrets<sup>1</sup>, R. De Haan<sup>1</sup>, J. Belderbos<sup>1</sup>, E. Damen<sup>1</sup>, P. Remeijer<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Purpose or Objective

For locally advanced non-small cell lung cancer (NSCLC) patients besides the primary tumor, the mediastinal lymph nodes and supraclavicular lymph nodes (SLN) are often involved. In case of SLN involvement a thermoplastic mask is used for immobilization. For the SLN a GTV-PTV margin of 1-1.2 cm in all directions is used in our institute. In this analysis the positioning-errors of the SLN were evaluated to determine the optimal GTV-PTV margin to cover involved SLN adequately.

#### Material and Methods

A total 720 CBCT's of 30 patients with a fractionated treatment dose > 44Gy were analyzed. All patients were positioned on a thorax support and immobilized with a thermoplastic mask. The IMRT treatment plan included the primary tumor, mediastinal lymph nodes and SLN in one isocenter. For each fraction online CBCT registrations were performed using a 3D rectangular shaped region-of-interest (ROI) around the vertebrae (Clipbox 1) and a ROI around the carina (Clipbox 2) followed by an online table shift to correct for the carina misalignment. When the spinal cord dose was critical, the table shift was performed based on the vertebrae registration instead. To measure the residual set up error of the SLN, a grey value registration was performed using an additional ROI around the SLN (Clipbox 3), see figure 1. After the automatic grey

value registration of Clipbox 3, the position of the SLN was visually checked. If necessary, the registration was manually adapted to make sure the position of the SLN was correct.

Next, the residual errors of the SLN lymph nodes relative to the carina and vertebrae registration were analyzed. For both residuals the grand mean ( $M$ ), systematic errors ( $\Sigma$ ) and random errors ( $\sigma$ ) were calculated. From these results the required GTV to PTV margins were derived using the margin recipe from van Herk et. al., taking delineation uncertainty and intra-fraction motion [1] in account as well.

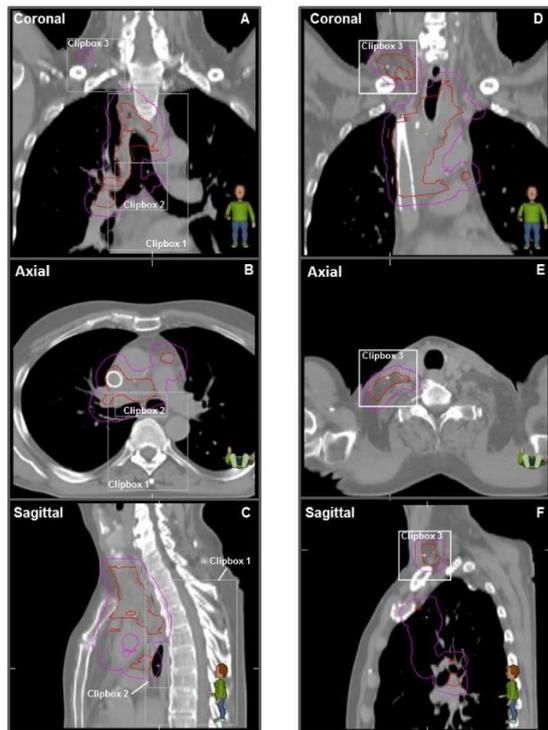

Figure 1. Example of the three clipboxes used for the CBCT registrations. Clipbox 1 (vertebrae) and Clipbox 2 (carina) are shown in a coronal, axial and sagittal view in respectively picture A, B and C. Clipbox 3 (SLN) is shown in a coronal, axial and sagittal view in respectively picture D, E and F.

**References** 1. A. Licup, Data mining in RT: Intrafraction motion and treatment time analysis for SBRT lung cancer patients (ESTRO37 2018)

**Results**

For all CBCT's a successful SLN registration was performed, automatically or either after manual adaptation. The mean, systematic and random error (translations and rotations) for the SLN in relation to the correction based on the vertebrae or carina are summarized respectively in table 1. A and B.

Table 1: Grand mean, systematic ( $\Sigma$ ) and random error ( $\sigma$ ) for the SLN relative to the Vertebrae (A) and the Carina (B) position. LR: left-right, CC: cranial-caudal, AP: anterior-posterior							
		LR (mm)	CC (mm)	AP (mm)	Roll (deg)	Pitch (deg)	Yaw (deg)
A Vertebrae	Mean	0.28	0.65	0.29	0.39	-0.18	0.05
	$\Sigma$	0.87	1.70	1.67	0.85	1.01	0.77
	$\sigma$	1.30	1.45	1.45	1.03	1.14	1.07
	Margin	7	9	9			
B Carina	Mean	-0.11	0.85	0.68	-0.09	0.29	-0.22
	$\Sigma$	1.39	3.27	1.92	0.90	0.97	0.63
	$\sigma$	1.45	1.73	1.57	0.98	1.04	0.97
	Margin	8	12	9			

**Conclusion**

Positioning errors of the SLN lymph nodes were analyzed for locally advanced NSCLC patients using a thermoplastic mask. Based on the found results the initial GTV-PTV margin of 1-1.2 cm in our institute could be reduced as following: in case the table correction was based on the vertebrae registration, the required GTV-PTV margin for

the SLN was LR: 7 mm, CC: 9 mm and AP: 9 mm. When the table correction was based on the carina registration, the required GTV-PTV margin for the SLN was LR: 8 mm, CC: 12 mm and AP: 9 mm.

**OC-0419 Evaluation of Metabrain: a semi-automated delineation tool for edema surrounding brain metastasis**

Y. Pin<sup>1</sup>, D. Antoni<sup>1</sup>, A. Keller<sup>1</sup>, P. Truntzer<sup>1</sup>, J. Clavier<sup>1</sup>, O. Schaeffer<sup>1</sup>, M. Schmitt<sup>1</sup>, W. Waissi<sup>1</sup>, G. Noël<sup>1</sup>  
<sup>1</sup>Centre de Lutte Contre le Cancer Paul Strauss, Radiation Oncology, Strasbourg, France

**Purpose or Objective**

The edema surrounding brain metastasis (BM) was the subject of several studies but the measurement methods remain controversial. The edema volume is an objective and relatively reproducible feature but its determination by contouring is time consuming which can limit its use. In this study, we propose and test a semi-automated tool to segment brain edema and measure its volume in patients with BM.

**Material and Methods**

We developed Metabrain, a threshold based automated segmentation tool to extract edema surrounding BMs on FLAIR sequence MRI. Developed in Python, the software imports image datasets and BMs GTV contours. Each edema, corresponding to a BM, is segmented and its volume measured based on a windowing (level and width) manually defined by the user. A contouring study was performed to assess the reliability and similarity of Metabrain contours. Ten BM edemas were contoured two times by 9 radiation oncologists: manually (MC) and with Metabrain (AC). A Dice index (DI) was calculated in the MC and AC groups, compared to the intersection of all contours in each group. The DI was also calculated between each manual and automated contour of each edema for each radiation oncologist. The volume of each edema and the total time for manual and automated contouring were recorded. DI, volumes and contouring time were compared using a paired Wilcoxon signed rank test. Contouring time and DI were compared between experimented physicians and residents.

**Results**

Ninety manual and semi-automated edemas were delineated. One edema on ten was removed because it was in contact with the skull and lead to an aberrant segmentation. In the AC group, the DI was significantly better than in the MC group (median DI of 0.95 vs 0.81,  $p < .001$ ) and the contouring time significantly shorter (18 vs 40 minutes,  $p = 0.01$ ). The median volume was significantly lower in the AC group than in the MC group (respectively a median volume of 1.89 and 2.16 mL,  $p < .001$ ). The median DI between manual and Metabrain contours from a same radiation-oncologist was 0.80. No significant difference was found in DI and contouring time between experimented physicians and residents.

**Conclusion**

Metabrain is an efficient tool to measure the volume of edema surrounding brain metastasis. It performs contours more similar, accurate and time saving than manual contouring. Its use would make it easier to include the volume of cerebral edema in BM studies.

**OC-0420 How accurate is automatic determination of the Mid-Ventilation position and tumour motion?**

A. Van Nunen<sup>1</sup>, D. Schuring<sup>1</sup>  
<sup>1</sup>Catharina hospital, Radiotherapy, Eindhoven, The Netherlands

**Purpose or Objective**

Different approaches can be applied to determine target position and PTV margins for lung cancer patients. In our hospital the Mid-Ventilation (MidV) approach is used. For quantifying the MidV position (MidV-P) and tumour motion,

several manual actions have to be performed which are time consuming, and interobserver variation can occur. An automatic procedure can reduce the workload and variability. Aim of this study was to compare the results of the manual approach with the automatic approach using the Deformable Image Registration (DIR) module in RayStation.

#### Material and Methods

For 23 patients, the automatic procedure was applied and compared to the manually determined MidV. The tumour was delineated at one of the 10 reconstructed phases of the 4D CT-scan. This delineation is then copied to the other phases and translated manually to the correct position. For the automatic approach, all phases were registered deformably to the 0% phase scan using the Anaconda algorithm. To improve the DIR in the close proximity of the tumour, a 2 cm expansion was used as focus region. After visually inspecting the DIRs (figure 1), the delineated tumour was propagated automatically to the other phases. The center of mass position of the translated or propagated contour was used for calculating the MidV-P and tumour motion.

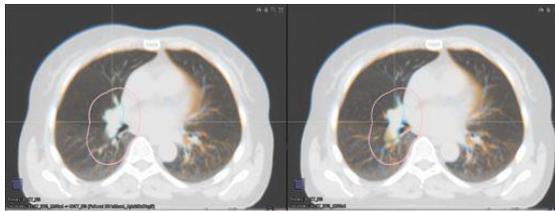

Figure 1: Transversal CT slice with the results of a DIR (left) compared to the rigid registration (right). (pink = focus region and lightblue = tumour)

#### Results

For all patients, the DIRs were considered acceptable for calculating the MidV-P and tumour motion. The difference in MidV-P was  $0.0 \pm 0.5$  mm in LR direction,  $0.4 \pm 1.0$  mm in CC direction and  $0.1 \pm 0.6$  mm in AP direction (mean  $\pm$ SD). For 22/23 patients the maximum difference in position was 2 mm and a high correlation was found in all directions. For 4/23 patients a difference in tumour motion larger than 2 mm was observed (figure 2). The mean difference in tumour motion was  $0.6 \pm 0.8$  mm in LR direction,  $0.1 \pm 1.4$  mm in CC direction and  $0.2 \pm 0.9$  mm in AP direction (mean  $\pm$ SD). These variations are similar to the interobserver variation for the manual procedure. For one patient, manual determination of the MidV-P and tumour motion was difficult due to poor soft tissue contrast between tumour and surrounding tissue. This resulted in a difference in MidV-P in the CC direction of 3.6 mm and a difference in tumour motion in LR and CC direction of 2.4 and 4.4 mm respectively. By using the automatic approach with the enlarged focus region, the surrounding vessels are included in this region to obtain more consistent results compared to the manual approach.

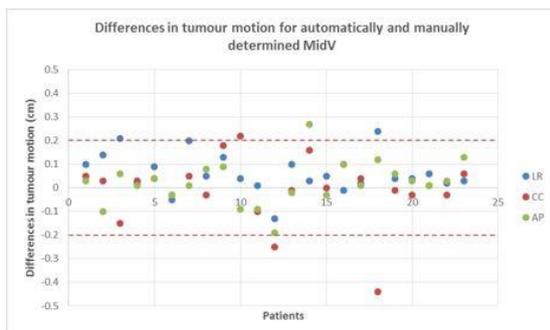

Figure 2: difference in tumour motion for automatically and manually determined MidV for all directions.

#### Conclusion

MidV determination based on DIR is accurate. A high correlation was found in MidV-P for the evaluated methods and the differences in tumour motion were small. Different results were found for patients with poor soft tissue contrast between tumour and surrounding tissue. For these patients, the automatic approach can reduce the interobserver variation and can obtain more consistent results by using an enlarged focus region. The automated method is now clinically used to determine tumour motion and MidV-P.

#### OC-0421 Stage migration in planning PET/CT scans in lung cancer patients referred to radiochemotherapy

S. Kivistik<sup>1</sup>, L. Randle<sup>1</sup>, M. Vardja<sup>1</sup>, A. Aasa<sup>1</sup>, J. Jaal<sup>1</sup>  
<sup>1</sup>Tartu University Hospital, Dept of Radiotherapy and Oncological Therapy, Tartu, Estonia

#### Purpose or Objective

With recent advances in immune-oncology and the introduction of checkpoint inhibitors into clinical practice, the treatment landscape of lung cancer has changed dramatically. Immune checkpoint inhibitors can be used as adjuvant therapy after completion of radiochemotherapy in stage III non-small cell lung cancer (nsclc) and as systemic treatments in stage IV nsclc as well as small-cell lung cancer (sclc). Cancer treatment costs are rising, therefore, it is extremely important to assure that patients receive most effective treatment at the right time based on the exact stage of the disease. In our institution, 18-fluoro-deoxyglucose positron emission tomography (FDG-PET) is mostly used for patients that are considered to have stage III disease based on previous computed tomography (CT) findings and are consequently referred to receive radiochemotherapy. The aim of this study was to assess the impact of radiotherapy planning PET-CT on stage migration in these patients.

#### Material and Methods

The stage migration after PET-CT was evaluated in 82 patients referred to our department to receive radiochemotherapy. All patients were previously assessed in multidisciplinary team meetings (including radiologist) and had stage III disease based on available CT scans.

#### Results

Out of 82 patients, 65 had nsclc (79%) and 17 sclc (21%). After planning PET-CT, metastatic stage IV disease was detected in 31 lung cancer patients (38%). The stage migration was seen in 22 patients (34%) with nsclc and in 9 patients (53%) with sclc. In nsclc, metastases were most frequently found in bones (55%), lymph nodes (55%), lungs (32%), pleura (23%), adrenal glands (18%) and liver (9%). In sclc, metastases were most frequently detected in lymph nodes (67%), bones (22%), lungs (11%), pleura (11%) and liver (11%). Radiochemotherapy was given to 45 patients (88%) with locoregional disease. Some patients did not receive radiochemotherapy due to refusal (n=1), treatment in another hospital (n=1), or not acceptable mean lung dose (n=4).

#### Conclusion

In the situation, where PET-CT is not routinely used for staging of all lung cancer patients and it is mainly utilized for radiotherapy planning, significant stage migration can be detected. Big proportion (38%) of lung cancer patients that were previously considered to have stage III disease showed metastatic lesions after planning PET-CT. This study confirms that proper selection of patients with PET-CT is mandatory to guarantee optimal use of cancer care resources.

PV-0422 Consequences of respiratory motion variability in lung 4DMRI datasets

M. Krieger<sup>1,2</sup>, A. Giger<sup>3</sup>, D.C. Weber<sup>1,4</sup>, A.J. Lomax<sup>1,2</sup>, Y. Zhang<sup>1</sup>

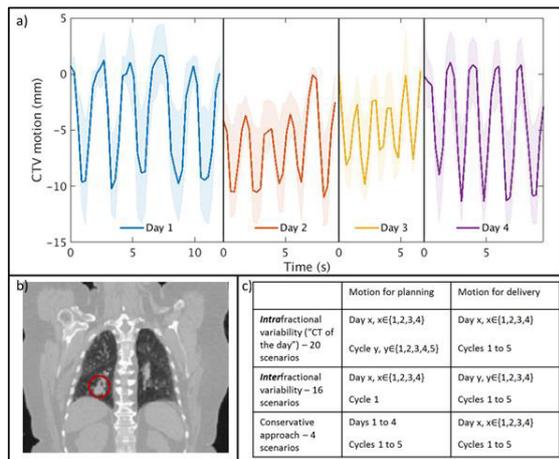

<sup>1</sup>Paul Scherrer Institute, Centre for Proton Therapy, Villigen PSI, Switzerland ; <sup>2</sup>ETH Zurich, Department of Physics, Zurich, Switzerland ; <sup>3</sup>University of Basel, Center for medical Image Analysis and Navigation CIAN-Department of Biomedical Engineering, Basel, Switzerland ; <sup>4</sup>University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland

### Purpose or Objective

To investigate the consequences of respiratory motion pattern variability on ITV definition for treatment planning and 4D dosimetric evaluation.

### Material and Methods

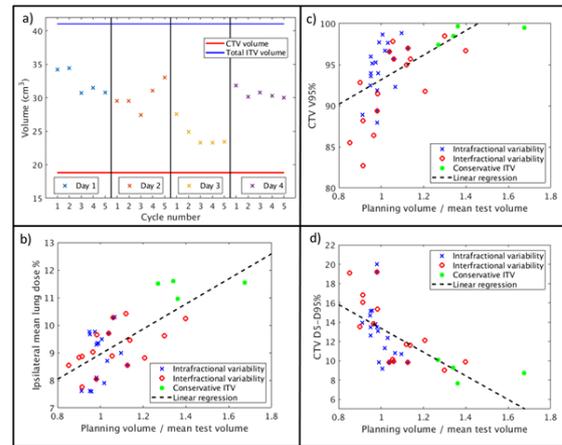

Synthetic 4DCT (4DCT(MRI)) data sets (Fig. 1b) have been generated by warping a single phase 3DCT using multiple motions extracted from 4DMRI datasets of a single subject (Boye et al 2013, Med.Phys. 40(6)). 20 such 4DCT(MRI) data sets have been generated from 20 respiratory cycles (128 phases) with large amplitude/period variations (Fig. 1a), which were then sorted as 4 sub-datasets (each of 5 cycles), each of which simulates motions that might occur on four different fractions. To evaluate the influence of *intra*- and *inter*-fractional motion variabilities from this data, two field PBS proton treatment plans were optimised on different geometric ITVs by considering several definitions (see Fig. 1c for details of each scenario). 4D dose calculations were applied to quantify the dosimetric effects by assuming different motion scenarios during dose delivery, using 9 volumetric rescans in order to minimise the influence of the interplay effect. Additionally, a ‘conservative’ ITV was calculated as a reference by considering all cycles together. Planning was performed on phase-averaged 4DCT(MRI) data sets, but using maximum intensity projections within the ITV. The resulting 4D dose distributions were analysed in terms of CTV coverage and homogeneity (V95%, D5-D95%) as well as mean lung dose. Linear regression was used to extract trends between relative ITV volumes and the aforementioned dose parameters.

### Results

Based on 4DMRI extracted motions, mean ITV size (29.4cc) was 156% of the static CTV (18.8cc), with large variations of ITV size of up to ±20% (range: 23.3-34.4cc) observed depending on the considered motion cycle during treatment planning (see Fig. 2a). Coverage (range: 82.7%-99.7%) and homogeneity (range: 7.7%-20.0%) for all 4D plan scenarios (Fig. 2c-d) show a clear trend of improved coverage and homogeneity for plans optimised on the larger ITVs and encountering smaller motions during delivery ( $R^2=0.39$  for D5-D95%, 0.28 for V95%). Moreover, considering the conservative ITV, the volume is between 16% and 43% larger than any individual ITV and induced a

significantly ( $R^2=0.46$ ) increased mean lung dose of up to 57% (range: 7.6%-11.6%, Fig. 2b). Generally, dosimetric impacts due to the variation of ITV volume definition are larger for *inter*-fractional than *intra*-fractional variability.

### Conclusion

The ITV defined at treatment planning phase can vary up to ±20% depending on the motion cycle considered by a 4DCT and could become invalid when motions are considerably different during dose delivery, thus substantially compromising the quality of the dose delivered in a fraction. Thus, careful consideration of motion variability is required for 4D treatments at both planning and delivery phase.

### PV-0423 Fast automated IMRT sequencing using deep-learned dose from generative adversarial networks

C. Kontaxis<sup>1</sup>, G. Bol<sup>1</sup>, J. Lagendijk<sup>1</sup>, B. Raaymakers<sup>1</sup>

<sup>1</sup>UMC Utrecht, Radiotherapy Department, Utrecht, The Netherlands

### Purpose or Objective

In this work we utilize generative adversarial networks (GANs) to perform fast dose prediction along with a two-step IMRT optimization pipeline capable of fast automated plan optimization for prostate radiotherapy.

### Material and Methods

A conditional GAN network was trained to predict the 3D clinical dose distributions from data of previously treated patients in our clinic. For 291 prostate patients the masks of the relevant optimization volumes, including bladder, rectum, femur heads, PTV and EBV were calculated. Then, for each 3 mm transversal PTV slice, a 256x256 image of the combined masks and background Hounsfield Units was extracted along with its corresponding slice from the clinical dose distribution of that patient (Figure 1). For each input mask slice  $i$ , a three-channel image was formed by placing slice  $i-1$  into red, slice  $i$  into green and slice  $i+1$  into blue channel respectively; in a caudal-to-cranial direction encoding the local 3D anatomical information into the 2D image. Then, the pix2pix framework was used to train the network with the data of 215 patients, totalling 5907 images. The resulting network was used to predict the dose distribution for the remaining independent 76 patients per slice. The 2D slices are then concatenated into the final predicted 3D dose distribution and fed into our previously developed Adaptive Sequencer (ASEQ) to perform IMRT optimization generating deliverable plans targeting that input dose. ASEQ is an IMRT optimizer which uses a per-voxel dose prescription along with minimum/maximum weights to penalize under- and overdosage. For automated planning a generic weights set is selected following the clinical structure priority:

bladder (low), rectum, PTV, EBV (high).

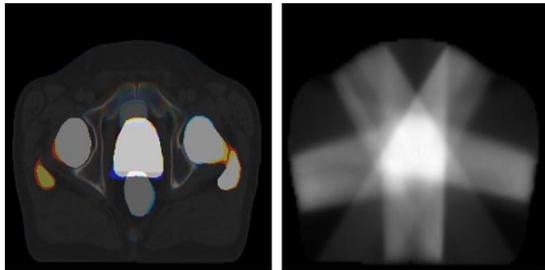

Figure 1: Input (left) / target (right) pair for one 2D transversal slice

## Results

The GAN network was trained over 75 epochs. The average difference between the 3D predicted and clinical dose distributions was  $0.1\% \pm 2.6\%$  and  $0.9\% \pm 1.9\%$  for PTV and EBV among 76 patients. For 5 patients, ASEQ was used to generate automated IMRT plans targeting the predicted dose (Figure 2). The average difference between the clinical and ASEQ dose was  $-1.1\% \pm 3.1\%$  and  $-0.3\% \pm 2.4\%$  for PTV and EBV while bladder and rectum were more spared ( $10.7\%$  and  $3.6\%$  on average). Total time per patient for dose prediction and plan optimization was 47 and 109 sec respectively.

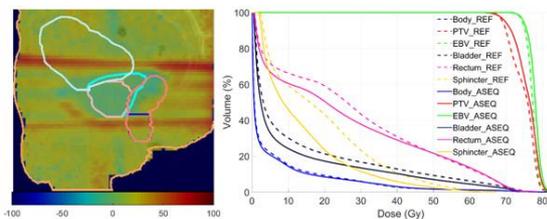

Figure 2: Central sagittal slice of the relative dose difference (%) between the clinical (REF) and ASEQ dose distribution (positive value means REF is higher) (left) and DVH plot of the relevant structures (right) for one case

## Conclusion

We demonstrate that conditional GAN networks can be used to accurately predict the 3D dose distribution of prostate patients. Moreover, the GAN output can be directly used into our fast automated optimization as a voxel-by-voxel prescription to generate deliverable plans closely matching the clinical plans. Application of this pipeline can be twofold: the initial dose prediction could assist the radiation therapist during the offline plan generation, while in an MRI-linac setting the ASEQ pipeline can be used for fast plan generation on an online inter/intrafraction basis. We are now evaluating automated plan generation for all test patients and further exploring both the network and ASEQ-specific parameters.

### PV-0424 Deliverable multi-criteria navigation for VMAT in RayStation

R. Bokrantz<sup>1</sup>

<sup>1</sup>RaySearch Laboratories, Research, Stockholm, Sweden

#### Purpose or Objective

To develop and evaluate a method for deliverable multi-criteria VMAT navigation: a form of real-time planning based on exploration of a Pareto surface represented by a set of plans and their linear combinations. Navigation has conventionally relied on Pareto surface representations composed of plans generated by fluence map optimization. Such a representation necessitates a post-processing step where the navigated dose is converted to control points, which can degrade the dose. Deliverable navigation, in contrast, uses plans that are segmented into control points in combination with a control point interpolation technique that after the navigation is used

to collapse the Pareto surface plans into a single deliverable plan. The goal is to make the navigated dose as realistic as possible representation an achievable dose distribution.

#### Material and Methods

The multi-criteria optimization (MCO) module of RayStation (RaySearch Laboratories) was augmented with the capability to generate Pareto surfaces composed of VMAT plans represented by control points. All plans were made to satisfy a movement pattern where the MLC leaves sweep back and forth across the target volume as the gantry rotates, defined such that the leaf motion was unidirectional within sub-sectors of an arc. A deliverable plan was, following navigation, constructed by interpolation of the leaf trajectories of the Pareto surface plans. The interpolated trajectories were sampled into control points at equispaced gantry angles and the control points optimized towards minimization of any dose error relative to the navigated dose.

#### Results

The new form of MCO was evaluated for three patients (head and neck, lung, and brain with multiple metastases). All patients were planned for treatment with a 360-degree arc. For each patient, a Pareto surface was generated using a fast optimization dose algorithm. A navigated dose satisfying the patient's clinical goals was then identified and this dose converted to a deliverable plan. Final dose for the deliverable plan was calculated using an accurate dose algorithm and the accuracy between this dose and the navigated dose then assessed. The resulting differences are quantified in Table 1 and summarized qualitatively as DVHs in Figure 1.

Table 1. Voxelwise dose differences between the navigated dose and the deliverable plan, with differences corresponding to an improved dose (a dose closer to the prescription level for targets and closer to zero otherwise) truncated to zero.

	Average (cGy)	90 <sup>th</sup> percentile (cGy)	98 <sup>th</sup> percentile (cGy)
<b>Head and neck</b>			
PTV 69	16	52	91
PTV 50	24	76	129
Healthy tissues $\geq 20$ Gy	31	101	366
<b>Lung</b>			
PTV 70	12	37	65
Healthy tissues $\geq 20$ Gy	15	17	247
<b>Brain</b>			
PTV 54	11	30	43
PTV 48	9	20	30
PTV 42	4	13	35
Healthy tissues $\geq 20$ Gy	13	24	202

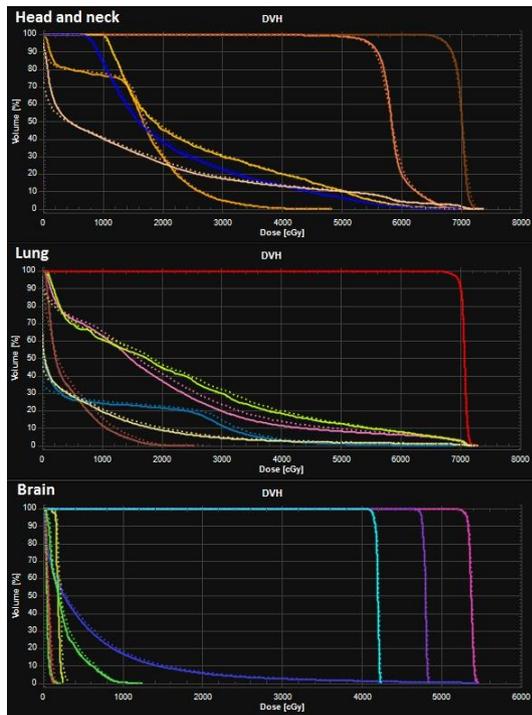

Figure 1. DVH comparison between the deliverable plan (solid lines) and the navigated dose (dotted lines).

**Conclusion**

A form of multi-criteria navigation for VMAT that gives only minor or negligible errors between the deliverable plan and the navigated dose has been demonstrated. A highly realistic navigated dose has the potential to simplify clinical decision making and improve planning efficiency thanks to a decreased or eliminated need for manual tuning after the conversion of the navigated dose into a deliverable plan.

**PV-0425 Automated configuration of an algorithm for fully automated Pareto-optimal treatment planning**  
 R. Van Haveren<sup>1</sup>, B. Heijmen<sup>1</sup>, S. Breedveld<sup>1</sup>  
<sup>1</sup>Erasmus Medical Center Rotterdam Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, The Netherlands

**Purpose or Objective**

The Lexicographic Reference Point Method (LRPM) is a novel algorithm for automated, fast and consistent generation of clinically favourable Pareto-optimal treatment plans. Current configuration of the LRPM requires manual tweaking of the algorithm’s parameters. This is a labour-intensive and time-consuming trial-and-error procedure. We propose a novel configuration method to automatically tune the algorithm’s parameters based on historical treatment plans. We demonstrate the method for prostate, and head and neck (HN) cancer.

**Material and Methods**

The LRPM for fast automated multi-criterial treatment planning has previously been introduced for generating Pareto-optimal plans with clinically favourable trade-offs between all plan criteria. The proposed novel configuration method generates a single LRPM configuration per treatment site. Validation was performed with patient/plan databases for prostate cancer (287 plans) and HN cancer (105 plans). All database plans were generated with an in-house developed clinically applied algorithm for automated multi-criterial planning (other than LRPM).

Configuration of the LRPM was based on 90 training plans for prostate cancer and 30 plans for HN cancer. For each criterion, differences between the training plans and

LRPM generated plans were compared. To steer towards relevant trade-offs between all criteria for all training patients, the user specifies preferences for each criterion. E.g., for prostate cancer, the preferences encourage reducing high rectum dose and mean bladder dose, while retaining similar PTV coverage and allowing slight degradation in mean anus dose. The quality of the automatic LRPM configurations was tested by comparing database plans with LRPM generated plans for 197 prostate cancer evaluation patients (not used for training) and 75 HN evaluation patients.

**Results**

With the automatically generated LRPM configurations, all automatically LRPM generated plans had sufficient PTV coverage ( $V_{95\%} \geq 99\%$  for prostate,  $V_{95\%} \geq 98\%$  for HN). For the evaluation patients, differences in OAR doses between database plans and LRPM generated plans (both Pareto-optimal) are shown in fig. 1 (prostate) and fig. 2 (HN) using boxplots. Medians of criteria differences marked with \* were statistically significantly different from zero (paired two-sided Wilcoxon signed-rank test,  $p < 0.05$ ). For prostate cancer, the LRPM generated plans had on average a decreased high rectum dose at the cost of slight increases in mean anus dose and maximum dose to the femoral heads (while still within constraints). For HN, we found more variation: generally, the LRPM generated plans had large improvements for some criteria at the cost of slight degradations for other criteria.

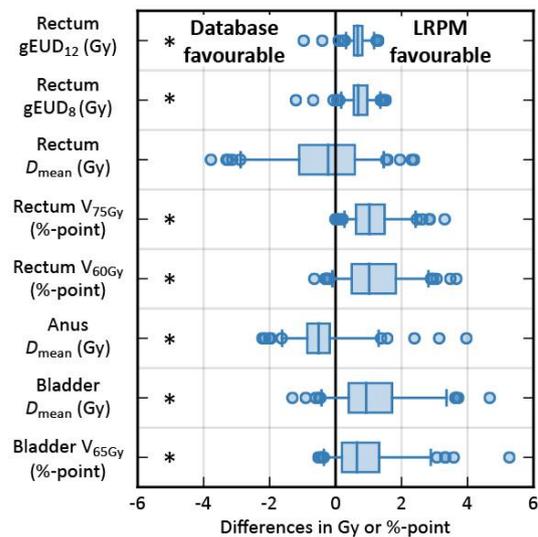

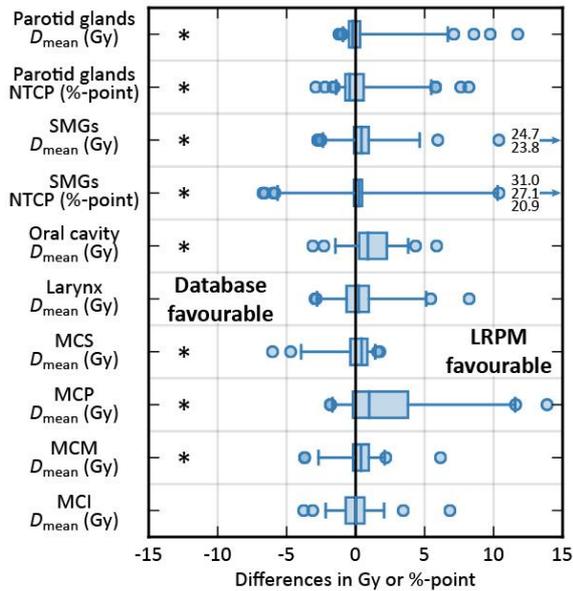

Figure 1. Plan parameter differences between database plans and LRPM generated plans for the 197 prostate evaluation patients. Vertical lines in boxes are medians, boxes are within 1<sup>st</sup> and 3<sup>rd</sup> quartile, whiskers are between the 2.5<sup>th</sup> and 97.5<sup>th</sup> percentile, and circles are outliers.

**Figure 2.** Plan parameter differences between database plans and LRPM generated plans for the 75 HN evaluation patients. Vertical lines in boxes are medians, boxes are within 1<sup>st</sup> and 3<sup>rd</sup> quartile, whiskers are between the 2.5<sup>th</sup> and 97.5<sup>th</sup> percentile, and circles are outliers. Arrows display values of large outliers outside of the specified range.

### Conclusion

The novel method for automatic configuration of the LRPM resulted in clinically favourable Pareto-optimal treatment plans. Due to the vast reduction in configuration workload, a major obstacle for introducing large-scale automated multi-criterial planning with the LRPM has been overcome.

### PV-0426 First system for fully automated multi-criterial planning for an MR-Linac applied to rectal cancer

<sup>1</sup>Erasmus MC Cancer Center, Radiation Oncology, Rotterdam, the Netherlands ; <sup>2</sup>The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

High-quality Pareto-optimal treatment plans are mandatory for MR-Linac (MRL) treatment units to maximally benefit from the offered high geometrical accuracy. In this study we have adapted our system for fully automated multi-criterial planning on regular linacs for plan generation on a 1.5T MRL. We evaluated automated MRL planning for rectal cancer by comparing automatically and manually generated plans regarding planning workload and plan quality.

### Material and Methods

A fully automated planning workflow for generation of clinically deliverable Pareto-optimal plans was implemented by coupling the in-house Erasmus-iCycle optimizer to a dedicated version of the Monaco TPS (Elekta AB, Sweden). The integrated system can handle the dosimetric impact of the magnetic field, enlarged source-isoc. distance, etc. 15 rectal cancer patients were manually planned for a 9-beam Step and Shoot IMRT treatment, delivering 50 Gy in 25 fractions. The 9 fixed beam directions were selected to avoid irradiation through the MRL cryostat pipe and the high attenuation regions of the MRL treatment couch. Automated plans were generated with the same beam directions as used for

the manual plans. The clinical protocol was leading in both manual and automated plan generation and evaluation. For the healthy tissues the goal was to maximally reduce the mean dose in a composite OAR consisting of small-bowel-bag + bladder excluding overlaps with the PTV. For consistent plan comparisons based on the OAR sparing, all plans were rescaled such that 95% of the PTV received 99% of the prescribed dose, as required by the clinical protocol. The two-sided paired Wilcoxon signed rank test was applied for statistical analyses.

### Results

Differences in plan quality are presented in Table 1. With equal PTV coverage and PTV D<sub>99%</sub>, automated plans had favourable V<sub>107%</sub> and homogeneity index (HI). Compared to the manual plans, the OAR D<sub>mean</sub> was reduced in the automated plans by 1.2 Gy (6.4%) on average and a maximum reduction of 4.2 Gy (21.3%). A large reduction in planning time was obtained, going from ~4-6 hours per patient for manual plans (mainly hands-on time) to ~1-2 hours per patient (mainly computational time).

**Table 1** Comparison of dosimetric parameters for manual plans and automated plans for 15 rectal cancer patients.

PTV	Parameter	Manual		Manual – Automated			
		Mean	SE	Mean	Range	SE	P (Wilcox)
PTV	V <sub>99%</sub> [%]	99*	-	0*	-	-	-
	D <sub>99%</sub> [Gy]	95*	-	0*	-	-	-
	V <sub>107%</sub> [%]	0.3	0.04	0.2	[-0.4 – 0.5]	0.06	0.02
	D <sub>mean</sub> [Gy]	50.2	0.03	-0.1	[-0.8 – 0.8]	0.1	0.3
	CI	0.5	0.01	-0.05	[-0.3 – 0.3]	0.04	0.2
	HI [%]	9.5	0.08	0.8	[-0.7 – 2.5]	0.2	0.003
Composite OAR	D <sub>mean</sub> [Gy]	19.1	0.5	1.2	[-1.0 – 4.2]	0.8	0.004

\* all plans normalized to 99%, \* related to plan normalization, SE = standard error, PTV = planning target volume, OAR = organ at risk, CI = conformity index, HI = homogeneity index

### Conclusion

A system for fully automated multi-criterial planning for a high magnetic field MR-Linac has been developed and tested for rectal cancer patients. Plan quality of automated plans was better with an improvement in OAR dose. Automated planning resulted in a major reduction in manual planning workload.

### PV-0427 Improving cumulative dose evaluation for re-irradiation: first results from the STRIDeR project

L. Murray<sup>1,2</sup>, S. Gregory<sup>3</sup>, M. Nix<sup>3</sup>, M. Aldred<sup>3</sup>, L. Aspin<sup>3</sup>, J. Uzan<sup>4</sup>, J. Lilley<sup>3</sup>, B. Al-Qaisieh<sup>3</sup>, A. Appelt<sup>1,3</sup>

<sup>1</sup>University of Leeds, Leeds Institute of Cancer and Pathology, Leeds, United Kingdom ; <sup>2</sup>Leeds Cancer Centre, Department of Clinical Oncology, Leeds, United Kingdom ; <sup>3</sup>Leeds Cancer Centre, Department of Medical Physics, Leeds, United Kingdom ; <sup>4</sup>Raysearch Laboratories, Service Department, Stockholm, Sweden

### Purpose or Objective

Accurately evaluating cumulative doses in the re-irradiation (reRT) setting is challenging due to anatomical and positional changes between radiotherapy courses. Furthermore, treatment planning systems (TPS) do not routinely incorporate radiobiology (e.g. fraction size correction) into dose summation. The STRIDeR (Support Tool for Re-Irradiation Decisions guided by Radiobiology) project aims to develop a software tool for use in a commercially available TPS to address these issues and so facilitate more informed reRT. We evaluated three approaches to dose summation, incorporating anatomical change and radiobiology to differing extents.

### Material and Methods

Ten patients who received pelvic reRT were included. All originally had conventionally fractionated radiotherapy. ReRT was Stereotactic Ablative Radiotherapy (SABR, 30Gy/5 fractions) to oligometastatic nodal disease in the previously irradiated pelvis. For clinical reRT planning, permitted doses to organs at risk (OAR) were at the

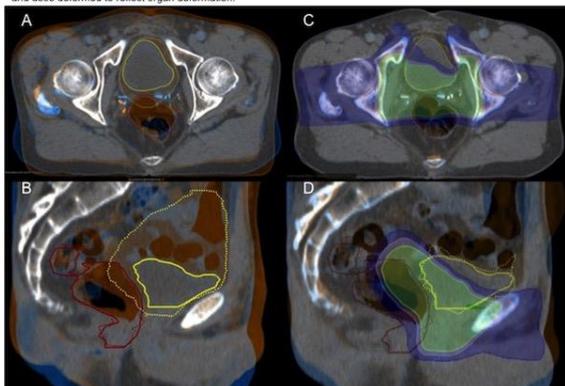

clinicians' discretion, after review of the former treatment plan.

Using RayStation (RaySearch Laboratories, Stockholm, Sweden), cumulative doses were calculated in 3 ways:

1. Rigid image registration (RIR) of former and reRT plans with physical dose summation (current clinical standard)
2. RIR with full radiobiological dose
3. e summation (i.e. each dose distribution converted to equivalent dose in 2Gy fractions (EQD2), then summated, using  $\alpha/\beta=3\text{Gy}$  for all tissues, except nerves, where  $\alpha/\beta=2\text{Gy}$ )
4. Deformable image registration (DIR) with dose mapping and radiobiological dose summation as per 2. above (Fig. 1).

Registrations were assessed by two clinicians who considered all DIR images of greater clinical relevance than RIR images.

Figure 1. Example case. A and B: rigid registration: solid line represents reRT contours and dotted line represents former radiotherapy contours. Substantial difference in bladder volume between courses apparent. C and D: deformable registration with dose mapping and radiobiologically summed dose distribution: solid line represents reRT contours and dotted line represents deformed former radiotherapy contours. Bladder volumes now more similar and dose deformed to reflect organ deformation.

## Results

Table 1 shows cumulative OAR doses based on each strategy. Summated physical doses (Strategy 1) should not be evaluated against constraints given the different dose per fraction from each treatment course, potentially masking OAR overdose. For example, incorporating radiobiology (Strategy 2) revealed that one patient received cumulative maximum EQD2 of 94.8/106.9/119.5Gy to colon/small bowel/sacral plexus, not appreciated at the time of clinical plan prescription, or identified by physical dose summation. By incorporating DIR and radiobiology (Strategy 3), for 11/114 threshold/maximum doses, there was  $\geq 20\%$  difference in cumulative EQD2 (range -33 to +43%) compared to RIR with radiobiology, affecting at least one OAR in 7/10 cases: cumulative doses were lower based on DIR in 5/7.

Table 1. Cumulative doses

	Threshold volume (used in addition to maximum dose constraints for selected OAR)	Strategy 1: Rigid registration with physical dose summation		Strategy 2: Rigid registration with dose summation in EQD2		Strategy 3: Deformable registration with dose summation in EQD2	
		Median of Dose to threshold volume (range)	Median of Maximum doses to 0.5cm <sup>3</sup> * (range)	Median of Dose to threshold volume (range)	Median of Maximum doses to 0.5cm <sup>3</sup> ** (range)	Median of Dose to threshold volume (range)	Median of Maximum doses to 0.5cm <sup>3</sup> ** (range)
Small bowel	5cm <sup>3</sup>	19.4 (4.6-63.4)	26.2 (6.1-77.8)	21.0 (3.2-73.8)	33.1 (4.4-106.9)	15.3 (2.9-58.6)	31.4 (4.2-90.1)
Colon	-	-	52.6 (17.5-73.5)	-	55.9 (18.9-94.8)	-	53.3 (18.4-70.0)
Rectum	-	-	53.1 (36.4-73.8)	-	59.7 (42.1-73.5)	-	59.2 (41.9-72.1)
Vessels	-	-	35.1 (27.7-79.3)	-	61.8 (36.5-116.6)	-	61.6 (37.1-86.9)
Sacral plexus*	5cm <sup>3</sup>	24.0 (13.6-62.3)	35.6 (23.7-79.2)	21.6 (10.2-82.5)	53.2 (23.5-119.5)	20.6 (9.4-78.2)	53.8 (25.2-95.6)
Cauda equina*	5cm <sup>3</sup>	9.7 (2.4-14.6)	9.0 (3.2-34.1)	9.1 (1.3-14.3)	8.1 (1.6-40.5)	9.0 (1.2-14.4)	8.1 (1.6-34.6)
Bladder	15cm <sup>3</sup>	53.1 (35.0-65.6)	54.0 (35.8-83.0)	59.8 (39.8-66.6)	61.3 (41.2-110.1)	54.6 (36.4-67.1)	61.1 (41.3-110.7)
Left femoral head**	10cm <sup>3</sup>	38.7 (19.3-48.1)	-	35.8 (16.9-44.9)	-	35.5 (16.7-42.1)	-
Right femoral head**	10cm <sup>3</sup>	40.2 (7.7-50.2)	-	38.8 (5.5-46.0)	-	38.9 (5.6-45.5)	-

\*Dose to 0.1cm<sup>3</sup> presented for neural structures; \*\*Maximum doses to femoral heads not used clinically so not reported

## Conclusion

Evaluation of cumulative doses in the reRT setting has traditionally been crude. Physical dose summation is radiobiologically meaningless, thus clinically unhelpful. An approach that incorporates radiobiology has revealed cases where OARs received higher doses than intended. DIR substantially influenced dosimetry in 70% of cases. We have developed a clinically implementable solution for radiobiological dose summation. This can be applied in many situations, including reRT and adaptive radiotherapy.

## PV-0428 A multi-centre study for implementation of MRI-only prostate planning

P. Greer<sup>1,2</sup>, P. Pichler<sup>1</sup>, T. Young<sup>3</sup>, J. Martin<sup>1,4</sup>, P. Hunter<sup>1</sup>, C. Wratten<sup>1,4</sup>, J. Denham<sup>1,4</sup>, L. Holloway<sup>3,5</sup>, M. Sidhom<sup>3,5</sup>, J. Dowling<sup>6</sup>

<sup>1</sup>Calvary Mater Newcastle Hospital, Department of Radiation Oncology, Newcastle, Australia; <sup>2</sup>University of Newcastle, School of Mathematical and Physical Sciences, Newcastle, Australia; <sup>3</sup>Liverpool Hospital, South Western Sydney Radiation Oncology, Sydney, Australia; <sup>4</sup>University of Newcastle, School of Medicine and Public Health, Newcastle, Australia; <sup>5</sup>University of New South Wales, South Western Sydney Clinical School, Sydney, Australia; <sup>6</sup>CSIRO, E-Health Research Centre, Brisbane, Australia

## Purpose or Objective

MRI-only planning is a departure from conventional CT based planning practice where dose calculations are performed on artificially created pseudo-CT (pCT) scans. It is paramount that procedures and processes are developed to ensure the safe implementation of this new technology. This project aims to investigate whether MRI-only prostate planning can be implemented effectively and safely in a prospective multi-centre study.

## Material and Methods

The protocol was a 2 phase design, where for phase 1 centres that had not previously validated MRI-only plans recruited 5 patients for retrospective analysis. Following successful completion of this phase centres then recruited to the prospective MRI-only treatment phase. To date 22 patients have been recruited and analysed across two treatment centres with 17 prospective. Whole-pelvic MRI scans were converted to pCT using an established atlas-based method. Dose plans were generated using MRI-based anatomy and pCT dose calculations. A conventional QA CT scan was acquired subsequent to MRI-only plan

development. Comprehensive QA procedures and tolerances were developed to evaluate pCT dose calculation accuracy and gold fiducial marker positions for image guidance prior to treatment. 3D Gamma evaluation was performed between pCT calculated plan dose and recalculation on QA CT following image registration. Distances of each of three gold fiducial markers to the centroid and isocentre were compared between pCT and QA CT scan.

### Results

Isocentre dose differences between pCT and QA CT were (mean=-0.1%, SD=1.1%). The 3D Gamma dose comparison pass-rates were (mean=99.3%, SD=0.7%) with mean gamma (mean=0.239, SD=0.074) for 2%, 2 mm criteria with 20% low dose threshold and QA CT as reference dose distribution. Results were similar for the two centres using two different scanners. All gamma comparisons exceeded the 90% pass-rate tolerance with a minimum gamma pass-rate of 97.6%. In all cases the gold fiducial markers were correctly identified on MRI and the distances of all seeds to centroid were within the tolerance of 1.0 mm of the distances on QA CT (mean=0.1 mm, SD = 0.5 mm). Differences in distances to isocentre were larger (mean=1.8 mm, SD=5.4 mm). This reflects displacements due to the image registration of QA CT to the pCT scan to copy the plan to the QA CT. All MRI-only treatment plans passed the QA criteria. All 17 prospective MRI-only plans were approved by the radiation oncologist and used for patient treatment.

### Conclusion

To our knowledge this is the first multi-centre study examining prospectively the implementation of MRI-only radiotherapy planning. The results to date support the hypothesis that MRI-only prostate planning can be implemented safely and accurately. Alternatives to comparison to QA CT scans for quality assurance of MRI-only planning are currently under development.

### PV-0429 A machine learning method to improve duodenum dose prediction for pancreatic cancer radiotherapy

Z. Feng<sup>1</sup>, K. Ding<sup>1</sup>

<sup>1</sup>John Hopkins School of Medicine, Department of Radiation Oncology and Molecular Radiation Sciences, Baltimore, USA

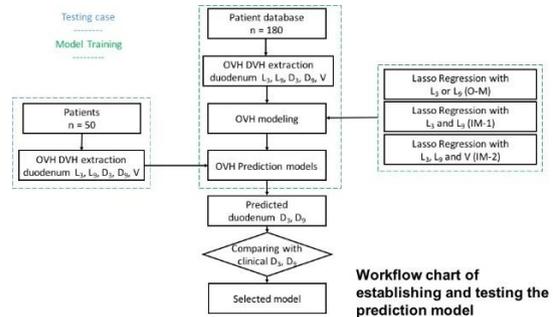

### Purpose or Objective

Our goal is to use machine learning based method to improve the accuracy of overlap-volume-histogram (OVH) based duodenum dose prediction for pancreatic cancer radiotherapy. We have previously proposed a method to reduce duodenum dose using biodegradable pancreas-duodenum spacer and accurate dose prediction is an important step to understand if a patient needs spacer.

### Material and Methods

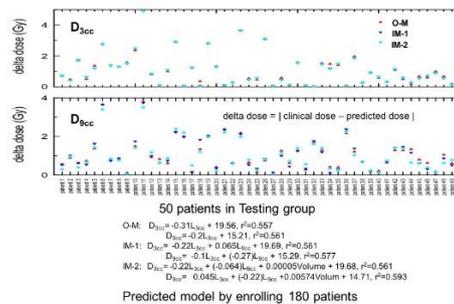

A database of OVH and dose-volume-histogram (DVH) metrics, was collected from the stereotactic body radiation therapy (SBRT) plans of 230 previous patients with unresectable pancreatic cancer (33Gy in 5 fractions). OVH metrics L9cc and L3cc were defined as the tumor volume expansion distance at which 9cc and 3cc volume of the duodenum overlap with tumor. DVH metrics D9cc and D3cc of the duodenum were defined as the dose to 9cc and 3cc of the duodenum. We randomly selected 180 patients in the database as the training group and the rest of the 50 patients as testing and validation group. Our previously published prediction model, a linear regression model (O-M) between Lx and Dx, where x=3cc and 9cc, served as the baseline for comparison. For machine learning based method, we used multivariate regression model with Least Absolute Shrinkage and Selection Operator (LASSO). We included OVH data (L9cc, L3cc, duodenum volume) as explanatory variables to predict Dx of duodenum: I-Model-1 was a linear equation in two variables which is to model the relationship between L3cc,

L9cc and Dx. I-Model-2 included L3cc, L9cc and volume of duodenum as explanatory variables to establish a linear equation in three variables to predict the response variable, Dx. For validation, the difference between the predicted dose (D3cc, D9cc) from these three models and the achieved dose of clinical plans, was defined as delta dose (Gy) to evaluate the prediction accuracy.

### Results

For the training group, the ANOVA results of these models showed that the predicted accuracy of D9cc was significantly improved by including one or two parameters data in the IM-1 (p=0.048) and IM-2 (p=0.014) compared with O-M. Furthermore, by comparing between IM-1 and IM-2, adding volume of duodenum could lead to a significantly improved fit over the I-Model-1 (p= 0.0087). For the testing group, the goodness of fitting between predicted dose and clinical dose was higher in IM-1 (r<sup>2</sup>=0.366 and 0.289 for D3cc and D9cc, respectively) and IM-2 (r<sup>2</sup>=0.366 and 0.324 for D3cc and D9cc, respectively), compared to the O-M (r<sup>2</sup>=0.358 and 0.282 for D3cc and D9cc, respectively). All the predicted doses of D3cc and D9cc were in corresponding predicted ranges of three types predicted models. The root mean square error (RMSE) of D3 is lower in IM-1(1.50) and IM-2(1.50) compared to the O-M(1.51). IM-2 produces the lowest RMSE value of D9(1.31) than O-M(1.35) and IM-1(1.35).

### Conclusion

By utilizing machine learning method, the multivariate regression models can more accurately predict achievable duodenum planning dose.

### PV-0430 automated IMRT planning integrating knowledge-based model with Auto-Planning for cervical cancer

C. Tao<sup>1</sup>, B. Liu<sup>1</sup>, C. Li<sup>1</sup>, J. Zhu<sup>1</sup>, J. Lu<sup>1</sup>, Y. Yin<sup>1</sup>

<sup>1</sup>Shandong Cancer Hospital Affiliated to Shandong University, Department of Radiation Oncology, Jinan, China

### Purpose or Objective

In this study, a fully automated hybrid IMRT planning platform, integrating knowledge-based model and Auto-Planning engine, were established by Pinnacle scripts and Python codes for cervical cancer. And the advantages of this hybrid planning platform were investigated.

## Material and Methods

60 patients with clinical approved IMRT plans for cervical cancer were selected into establishing a knowledge-based model by linear fitting the equivalent uniform dose (EUD,  $a=1$ ) and equivalent uniform distance (EUL,  $a=1$ ), developed from the overlap volume histograms (OVH) method. Another 20 patients were used as the test group. By integrating the EUD-EUL model with Auto-Planning module, a fully automated hybrid IMRT planning platform was developed based on Pinnacle scripts and python codes. IMRThy plans, generated this hybrid planning platform, were compared with corresponding IMRTap plans, generated by Auto-Planning module with default pre-setting objectives from a template. The quality and consistency of IMRThy plans produced by this hybrid planning platform were evaluated by dose/volume indices and EUD-EUL metrics.

## Results

The linear regression between EUD and EUL for bladder and rectum of 60 previous clinical approved plans were shown in figure 1. Therefore, correlation functions between EUD and EUL for bladder and rectum were obtained:

$$\text{EUD}_{\text{bla}} = 45.37 - 5.78 \cdot \text{EUL}_{\text{bla}} \text{ with } R^2 = 0.79$$

$$\text{EUD}_{\text{rec}} = 44.23 - 5.38 \cdot \text{EUL}_{\text{rec}} \text{ with } R^2 = 0.69$$

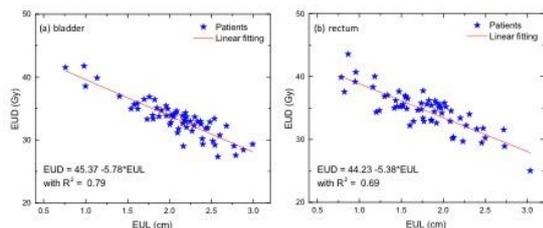

Figure 1: Linear regression between EUD and EUL for bladder and rectum of 60 previous clinical approved plans.

The dose/volume indices of IMRThy plans and IMRTap plans were listed in table 1. For PTV, V95 of IMRThy plans were a little worse than that of IMRTap plans with significant differences (IMRThy:  $95.38 \pm 0.92\%$ , IMRTap:  $96.04 \pm 0.73\%$  with  $p=0.02$ ). While HI and CI of IMRThy and IMRTap plans were very similar without significant differences. Considering bladder and rectum, the organs predicted by the EUD-EUL model, dose/volume indices including V20, V30, V40 and Dmean of IMRThy plans were dramatically reduced than IMRTap plans with significant differences. While V50 and V60 of IMRThy plans were lower than that of IMRTap plans without significant differences. For femoral heads, which were not considered in the predicting model, all dose/volume indices were comparable between these two type plans.

Table 1: Evaluation of dose/volume indices of IMRThy plans and IMRTap plans.

Structures	Parameters	IMRThy plans	IMRTap plans	p value
PTV	V95	95.38±0.92	96.04±0.73	0.02
	HI	0.11±0.01	0.11±0.01	0.06
	CI	0.74±0.04	0.74±0.04	0.94

	V40	2.42±2.11	2.61±2.41	0.81
	V50	0.16±0.37	0.14±0.35	0.91
	V60	0.00±0.00	0.00±0.00	-
	Dmean	19.81±1.84	19.96±1.58	0.78

## Conclusion

The fully automated hybrid IMRT planning platform, combining knowledge-based model and Auto-Planning module, could generate clinical accepted plans and significantly improve the quality and consistency of IMRT plans.

## Proffered Papers: BT 6 : Innovative and uncommon indications

### OC-0431 Esophageal brachytherapy: Institut Gustave Roussy's experience

M. Kissel<sup>1</sup>, E. Chirat<sup>1</sup>, P. Annede<sup>1</sup>, P. Burtin<sup>2</sup>, I. Fumagalli<sup>1</sup>, E. Bronsart<sup>1</sup>, F. Mignot<sup>1</sup>, A. Schernberg<sup>1</sup>, I. Dumas<sup>1</sup>, C. Haie-Meder<sup>1</sup>, C. Chargari<sup>1</sup>

<sup>1</sup>Institut Gustave Roussy, Radiotherapy, Villejuif, France;

<sup>2</sup>Institut Gustave Roussy, Gastroenterology, Villejuif, France

### Purpose or Objective

Esophageal cancer is characterized by its propensity to local evolution, which conditions prognosis but also quality of life. Brachytherapy may be a therapeutic option for all stages of esophageal cancer, especially for inoperable patients.

### Material and Methods

This retrospective unicentric study included all consecutive patients treated for an esophageal high dose rate brachytherapy in our institution from 1992 to 2018.

### Results

90 patients were included. They were treated in four distinct indications : exclusive (7 patients), boost after external beam radiotherapy (41), reirradiation (36) or palliative aim (6). Most frequently prescribed schemes were 3x5Gy (boost) or 6x5Gy (exclusive treatment and reirradiation). At the end of follow-up, 50% of patients had presented with local recurrence : 46% in the boost setting, 71% for exclusive brachytherapy, 47% for reirradiation and 100% for palliative treatment. 17% of patients had a metastatic relapse. Median overall survival (OS) was 15 months in the whole cohort : 22 months in the boost setting, 25 months for exclusive brachytherapy, 15 months for reirradiation and only 2 months for palliative treatment. Tumor length at brachytherapy, brachytherapy dose and interfraction response were significantly associated to OS. 40% of patients presented with grade 2+ toxicity, mostly esophagitis, including 3 toxic deaths.

### Conclusion

Phase III trial RTOG9405, showing the absence of dose-effect on esophageal cancer, has led teams to progressively give up the technique in the boost setting. Although local control outcomes are still poor, one must remember that patients are unfit for any curative therapeutic option and that palliative chemotherapy offers mediocre results. The most promising setting probably is reirradiation since brachytherapy offers a remarkable dose gradient allowing best OAR sparing. Esophageal brachytherapy deserves to be further investigated since some patients, even unfit, may benefit from it in some indications, with acceptable toxicity. Prospective studies are warranted.

### OC-0432 Endoluminal brachytherapy with induction chemotherapy and definitive chemoradiation in Ca. Esophagus

S. Raghunath<sup>1</sup>, R. Tiwari<sup>1</sup>, G. Narayanan<sup>1</sup>, B. Vishwanathan<sup>1</sup>, R. Sultana<sup>1</sup>

<sup>1</sup>Vydehi Institute of Medical Sciences and Research Center, Radiation Oncology, Bangalore, India

### Purpose or Objective Need for the Study:

Over 75% of people with cancer worldwide have no access to safe surgery. Access is worse in low income countries where 95% of people with cancer do not receive basic cancer surgery.

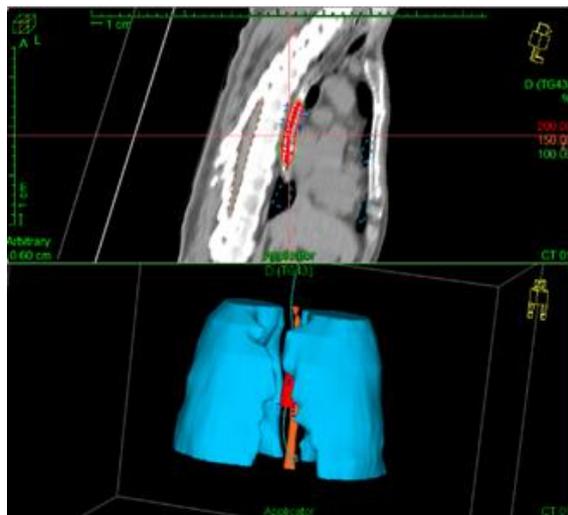

Patients in remote areas in Rural India, South Asia, Africa and Poorer EU Member States do not have access to surgical infrastructure or qualified personnel to deliver high quality surgery in locally advanced esophageal carcinoma. Further, Esophageal Cancer has an abysmal response despite multimodality treatment. Endoluminal Brachytherapy is an under-utilized modality in the curative setting and an elegant tool to escalate the dose to improve the clinical response and clinical symptoms.

This study examines if Dose Escalation with Endoluminal Brachytherapy after Induction Chemotherapy and Definitive Chemoradiation is feasible in the background of the above scenarios in underserved populations.

### Objective:

To evaluate Dysphagia Free Interval (DFI), Disease Free Survival (DFS), Overall Survival (OS) and Toxicity Profile in Endoluminal Brachytherapy in Ca. Esophagus with Induction Chemotherapy and Definitive Chemoradiation.

### Material and Methods

31 patients with biopsy proven Esophageal Carcinoma Stage IIA-IVA with Node (-) Status were enrolled at our Institute from June 2007 to July 2018. ILRT 10Gy/2# was delivered following Definitive CRTT 50.4Gy/28# with 3-weekly CDDP/5-FU after 6-10 cycles of Pacli/Carbo.

Proximal and Distal borders were marked from the Prechemotherapy tumor volume on OGD. Patients were simulated in a GE Multislice CT scanner to confirm accurate coverage of the pre-chemotherapy disease.

Positions were marked and secured to prevent any shift in placement before and during treatment. ILRT Dose was prescribed to 1 cm from the center of the source.

Swallowing Status was established on follow up. OS and DFS was censored at death or last follow up. Statistical Analysis was performed using SPSS.

### Results

Patient Characteristics	
Total No. of Patients	31
Median Age of Recruitment	62.5 years
Distribution by Sex	
Male	20
Female	11
Distribution by Stage	
T2N0M0	3.22%
T3N0M0	87.09%
T4N0M0	9.6%
Histology	
Squamous Cell Carcinoma	87.09%
Adenocarcinoma	12.91%

- Median Age of Recruitment was 62.5 years. All 31 Patients completed treatment and were clinically stable at discharge. 83.97% Completed Chemotherapy, 96.77% completed Radiation Therapy according to protocol. 35.48% patients were alive on last follow up.
- Median OS was 21 months. OS at 2 years was 53.6% . Median DFI was 10.7 months. Those with a Cumulative EQD2 >60 Gy had a significant 5 year OS of 59.1% vs. 33.3% for those who received EQD2 <60 Gy (p=0.061, CI=76.3-91.4). 5 year DFS for EQD2 >60 Gy was 56.1% vs. 16.7% for those who received Cumulative EQD2 <60Gy (p=0.079, CI=74.2-93.8).
- There were no Grade III/IV acute toxicities. There were no Fistulas on follow up. 2 patients required stenting within 1 year of treatment and died within 2 months thereafter. 2 Patients developed CHF at 4 years.1 Patient Developed Left Breast Fibrosis at 4.5 years.

### Conclusion

Endoluminal Brachytherapy with Induction Chemotherapy and Definitive Chemoradiation is a feasible option in the absence of conventional alternatives.

### OC-0433 Feasibility and early clinical response of interstitial BT for hepatocellular carcinoma

S. Corradini<sup>1</sup>, F. Walter<sup>1</sup>, C. Maihöfer<sup>1</sup>, M. Rottler<sup>1</sup>, J. Well<sup>1</sup>, L. Nierer<sup>1</sup>, M. Seidensticker<sup>2</sup>, R. Seidensticker<sup>2</sup>, T. Streitparth<sup>2</sup>, F. Streitparth<sup>2</sup>, J. Ricke<sup>2</sup>, C. Belka<sup>1</sup>  
<sup>1</sup>Radiation Oncology, Department of Radiation Oncology LMU, Munich, Germany; <sup>2</sup>Radiology, Department of Radiology LMU, Munich, Germany

### Purpose or Objective

Several local approaches for hepatocellular carcinoma have been evaluated in clinical practice. Interstitial CT-guided brachytherapy (BT) has been shown to be a safe and effective treatment option in various sites, but remains under investigation in the setting of hepatocellular carcinoma.

### Material and Methods

Between 07/2017-07/2018 patients treated with CT-guided high-dose interstitial brachytherapy for hepatocellular carcinoma were evaluated. All patients with a minimum follow-up of 2 months were included in the present Analysis.

### Results

Between 07/2017-07/2018 patients treated with CT-guided high-dose interstitial brachytherapy for hepatocellular carcinoma were evaluated. All patients with a minimum follow-up of 2 months were included in the present analysis.

### Results

Overall, 82 hepatocellular carcinoma lesions were treated with BT in 36 patients. Median age was 66 years (range 46-85 years). 29 patients presented with a liver cirrhosis Child-Pugh A and 11 patients with Child-Pugh B cirrhosis at the time of brachytherapy. Prior treatments were: transarterial chemotherapy embolization (TACE), radiofrequency ablation (RFA), surgical resection, selective internal radiotherapy (SIRT), SBRT. In 22 patients more than one lesion was treated per fraction (mean 1.6, range 1-5 per fraction). Mean liver volume was 1654cc (range 800-2488cc). Brachytherapy was performed in a single fraction with an aimed prescription dose of 15Gy, taking into account constraints of organs at risk. A mean dose of D100: 14.4 Gy was reached, D95: 18.9 Gy, D90: 21.0 Gy. Mean CTV volume of single lesions was 14cc (range 0.2-103cc) and cumulative CTV volume per fraction of 36cc (range 1.4-282cc). Mean liver volume receiving > 5Gy was 326cc (range 21-1330cc).

After a mean follow-up of 6 months (2-12months), 3 patients who received brachytherapy as a bridging treatment, had undergone liver transplantation after 2-5month. Regarding overall local control of treated lesions, 26 complete responses, 24 partial responses and 1 progression were recorded. 15 patients developed new HCC lesions within the liver and 5 patients developed distant metastases. 4 patients died during the follow-up period, resulting in a 6- and 12-months overall survival of 96% and 74%, respectively.

### Conclusion

Interstitial CT-guided BT showed to be an effective treatment option due to its good rate of local control. However, longer follow-up is needed to definitively assess its role in this Setting.

### OC-0434 Sphincter function after EBRT and Pulsed Dose Rate Brachytherapy (PDR-BT) in anal cancer patients

T. Brahmi<sup>1</sup>, A.A. Serre<sup>1</sup>, F. Gassa<sup>1</sup>, M. Sandt<sup>1</sup>, F. Lafay<sup>1</sup>, P. Pommier<sup>1</sup>

<sup>1</sup>Centre Léon Bérard, Radiation Therapy, Lyon, France

### Purpose or Objective

One of the objectives of the anal canal cancer treatment is the preservation of the pelvic sphincter system to avoid a definitive stoma. However, the sphincter function is poorly evaluated, especially regarding patients' perspective.

### Material and Methods

Between 2005 and 2017, 179 consecutive patients with anal canal cancer (all histological types) received PDR-BT as a boost after EBRT (+/- concomitant chemotherapy) in our institution. 79 out of 131 of them eligible for the study (alive with a minimum 7 months follow-up; no recurrence) were included.

Sphincter function was self-evaluated by the Wexner questionnaire, that assess different types of incontinence (solids, liquids, gases) and their impact on the quality of life, leading to a score from 0 to 20. Interpretation of Wexner's score was defined as follows: None (0), Minimal (1 to 4), Moderate (5 to 9), Important (10 to 16) and Severe (17 to 20). Threshold of 9 has also been used, associated in the literature to a poorer quality of life. Additional items issued from the questionnaire developed by Vaizey (impact on sexuality, faecal urgency and self-medication) were also assessed.

### Results

Patients who responded to the questionnaire had similar characteristics to those of the whole cohort, except for average follow-up (43 vs 23 months, p<0.001). Average Wexner score was 4.1 (25%IQ: 0 - 75%IQ: 7). 19% had a score > 9. 41.8% of this cohort did not report any symptoms (score 0). Only 2.5% had severe symptoms. Regarding sexual symptoms, 56.5% of our patients have expressed no discomfort. Faecal urgency was present in 45.6% of our cohort. Only 11.4% of patients have used drugs for a constipation purpose.

No pre-therapeutic or therapeutic factors have been identified as associated with the occurrence of anal incontinence. The occurrence of a late gastrointestinal or cutaneous toxicity (> grade 2) does not have a significant influence on the occurrence of these symptoms (HR: 1.693 [95%CI: 0.573 - 5.008], p=0.357).

We observed a non-significant (p=0.185) decrease of the average score with the delay between the BT and the evaluation: 6.3, 3.8 and 3.5 respectively when the questionnaire was applied less than 2; 2 to 5; or more than 5 years after BT. Incontinence for solid stools was statistically reducing with time (average score: 1.3, 0.4 and 0.3 respectively, p=0.011) as well as the proportion of patients without symptoms (13.3%, 40% and 55.9% respectively, p=0.019).

### Conclusion

Anal incontinence after conservative treatment of the sphincter system remains a poorly explored pathology, with multiple scores available in the literature. Our homogeneous retrospective cohort reports a low incidence of incontinence, but faecal urgency remains important with a definite impact on the quality of life of these patients. With reservation of confounding factors (modifications of the indications and treatments' modalities during the period of observation), the function of the sphincter may improve over time.

### OC-0435 Contact X-Ray Brachytherapy (CXB) after local excision (LE) for early rectal adenocarcinoma.

J. Gérard<sup>1</sup>, S.M. Arthur<sup>2</sup>, F. Antoine<sup>3</sup>, D. Amandeep<sup>4</sup>  
<sup>1</sup>Centre Antoine Lacassagne, Radiotherapy - University Côte d'Azur, Nice, France ; <sup>2</sup>Clatterbridge Cancer Centre, Radiotherapy Papillon Suite, Liverpool - Clatterbridge, United Kingdom; <sup>3</sup>Centre Antoine Lacassagne, Biostatistiques - University Côte d'Azur, Nice, France ; <sup>4</sup>East Yorkshire Hospitals, Radiotherapy Oncology, Hull, United Kingdom

### Purpose or Objective

Early rectal cancers, increasingly diagnosed through screening programmes, are often treated using local excision (LE). In case of pathological pejorative features a radical surgery (TME) is the standard recommendation. The risks and sequelae of TME have stimulated alternative option using radiotherapy to preserve the rectum. We present the results of adjuvant CXB with or without external beam radiotherapy (EBRT) after LE in a multicenter cohort.

### Material and Methods

Between 2009-2017 CXB was given after LE in three centers to 197 patients (Clatterbridge :120, Hull: 35, Nice:34). All patients were M0. Negative pathological features were: lymphovascular invasion (LVI), sm2-3

kikuchi level, budding, pT2, R1. CXB was performed with the Papillon50™ machine and dose was 40 to 60 Gy in 2 or 3 fractions (depending on association with EBRT) over 2 to 4 weeks. Kaplan Meier estimates was used for outcomes measures.

**Results**

Median age was: 70 years. Male:127, Female :70. cN0: 189, cN1: 8 (4%). pT staging was : pT1: 146, pT2: 46, pT3: 5 . CXB alone was given in 27 pts and combined with EBRT in 170 (EBRT alone(45 -50 Gy/ 5 weeks):35, chemoRT :107, EBRT “short course”: 28 pts. Median follow-up time was 41 months. Local relapse rate at 5 years was 8% and distant metastases 11%. Organ preservation was achieved in 95% with good bowel function in nearly all patients. Main toxicity was rectal bleeding due to radiation mucosal telangiectasia. Due to small number of events only few prognostic parameters were observed: LVI for local relapse (4% vs 19% out of 63 pts with LVI reported ) and sm3 vs sm1-2 for distant metastases (DM). A local relapse was associated with a higher risk of DM (5% vs 44%, p< 0.0001)

**Conclusion**

This appears to be the largest ever presented multicenter cohort study using adjuvant CXB for early rectal cancer with pejorative features after local excision. This strategy brings high rate of local control and rectal preservation with good bowel function. It appears to be a good option for well-informed patients to avoid safely the risks of a radical TME after LE.

**OC-0436 13 SCC penis treated with HDR brachytherapy, results and dosimetric analysis**

M. Marban Orejas<sup>1</sup>, J. Crook<sup>1</sup>, M. Keyes<sup>2</sup>, D. Batchelar<sup>1</sup>, R. Dubash<sup>2</sup>, F. Bachand<sup>1</sup>  
<sup>1</sup>BCCA, Radiation Oncology, Kelowna BC, Canada ; <sup>2</sup>BCCA, Radiation Oncology, Vancouver BC, Canada

**Purpose or Objective**

We report a retrospective analysis of treatment features and results for 13 localized penile SCC treated with HDR brachytherapy (BT)

**Material and Methods**

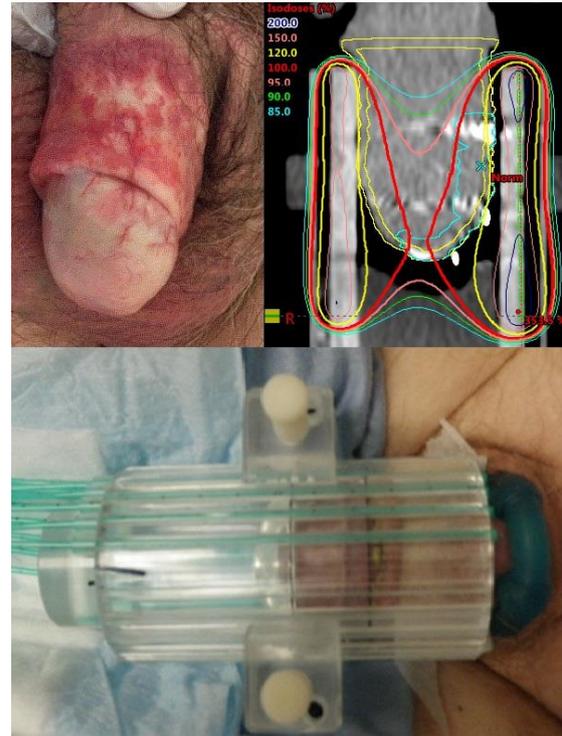

6 patients (T1a-b) received plesiotherapy and 7 (T1-2) interstitial BT. CTV was defined as GTV+5mm, or 3mm below the skin after excisional biopsy (n=2). Skin refers to a 2mm rind on the penis within the applicator and urethra is a central 1cm circle or the catheter contoured on CT. We performed a descriptive analysis to correlate dosimetry with clinical outcomes

**Results**

HDR mold BT was used for 5 T1a tumors and 1 T1b(G3 pN0) between 11/15-02/17. Median age was 68(51-78) 40Gy/10 was prescribed BID 6hours apart. Median CTV was 4.4cc(2.6-11.8)

Median dosimetric parameters were CTV V100 80.3%, V125 0.2%; skinD5 118%(125-107); urethral Dmax 102%(118-75), D5 95% and D30 89%.

Median follow up is 29.3months(20-35). All patients are alive and free of disease(NED). 1 patient had a local failure at 17months presenting as a non-healing ulcer and urethral stricture. He had a partial penectomy for pT3 recurrence, and remains NED 15months later. No other urethral or soft tissue toxicity occurred. First 2patients treated have G2 telangiectasias on the shaft(image1), proximal to treated site, attributed to redundant penile skin sliding into treatment volume. Subsequently, a Lucite applicator allowed visual position check and a constriction ring at the penile base immobilized the skin(image3). All sexually active patients remain potent.

HDR interstitial BT was used for 7patients between11/09-05/18. Median age was 51.7(33-77). 2patients had T1 and 5 had T2 disease. 2 underwent inguinal LND, one for G3(pN0) and one cN1(pN2) Dose prescribed was 42Gy/12 in 3patients while the other 4 received 42/14, 45/12, 53/17 and 38.4/12, BID 6h apart.

Interstitial HDR dosimetric parameters

				median	21.05	98.60	75.40	26.80	9.30	128.00	98.50	207.90	134.85	74.15	0.96

Table1 summarizes dosimetric parameters

Median follow up is 98 months(5-106). All patients are alive and NED at last follow up, 5 with intact penis, and 3 remain potent 1patient failed locally at 21months with a non-healing ulcer unresponsive to hyperbaric oxygen. 6 years after partial penectomy and pelvic/groin dissection(pN1), he is alive and NED. The first 4 patients had G2necrosis, 3 received hyperbaric oxygen. The implant had catheter spacing >12mm(14-17mm) and unacceptable inhomogeneity (V150mean 47%, V125mean 85%). For the final 2patients, catheter spacing 9-12mm was used and V150 limited to<20%,V125 to-45% 1 patient presented with G1 meatal stenosis, 1 with urethral stenosis requiring dilatations(G2) and 1 perineal urethrostomy(G3). There was no correlation between toxicity and implant geometry in those cases, but BED, considering urethral α/β=3, was higher(101.2 and 108.2Gy), and they had diabetes.

**Conclusion**

HDR brachytherapy is effective treatment for SCC penis either as a surface mold or interstitial. Homogeneity parameters should be followed. There may be a correlation between urethral BED and complications. A constriction ring is advisable in mold treatment to avoid skin toxicity More prospective analyses are warranted

**OC-0437 Update of moderate dose-escalation with perioperative HDR brachytherapy in soft tissue sarcomas**

Fernandez-Leton<sup>3</sup>, C. Rubio<sup>1</sup>

<sup>1</sup>University Hospitals HM Sanchinarro - Puerta del Sur, Radiation Oncology, Madrid, Spain; <sup>2</sup>University Hospitals HM Sanchinarro, Orthopaedic Surgery, Madrid, Spain; <sup>3</sup>University Hospitals HM Sanchinarro - Puerta del Sur, Medical Physics, Madrid, Spain

**Purpose or Objective**

Conservative surgery in combination with local radiation therapy is considered a standard approach for soft tissue sarcomas (STS). A close relationship exists between total radiation dose and local control. We report our experience about the feasibility of perioperative brachytherapy (PoBT) with a moderate dose-escalation in the multidisciplinary management of soft tissue sarcoma.

**Material and Methods**

From May 2015 to October 2018, 22 patients (p), 13 men and 9 women, with a median age of 61.5 years (range 7 - 77 years) underwent perioperative brachytherapy (PoBT). Histology: 7 p (32%) liposarcoma, 5 p (23%) fusocellular sarcoma, 3 p (14%) desmoids tumor, 5 p (23%) fibroblastic sarcoma, 1 p (4%) pleomorphic sarcoma and 1 p (4%) malignant glomus tumour. Tumor location: thigh 14 p (63%), trunk 4 p (18%), arm 3 p (14%), neck 1p (4%). Tumor staging according to the AJCC 8th ed (2016): 5 p IA, 9 p IB, 5 p II, 2 p IIIA and 1 p IIIB. PoBT procedure was performed by using 6F plastic catheters placed on the surgical bed at the time of tumor excision. Sixteen (73%) patients obtained R0 resection and 5 p (23%) R1 resection. Plastic catheters were placed either parallel or perpendicular to the surgical incision at 1.5- 2 cm intervals to ensure adequate dosimetry. CT simulation with 1.5 mm slice thickness was done in the fourth or fifth day after surgery once the sewer system was retired. A total 16.5 Gy was delivered to the PTV in 3 fractions of 550 cGy in 20 p; 1 p received 4 fractions of 400 cGy and 1p received 3 fractions of 500 cGy. Fractions were separated at least 6 hours. Catheters were retired after the last fraction.

**Results**

All p received external beam radiotherapy (EBRT) before or after brachytherapy at a mean dose of 50 Gy in 25 fractions. Conformal 3D radiotherapy planning was used in 7 p (32%), intensity modulated radiotherapy (IMRT) in 10 p (45%) and volumetric modulated arc therapy (VMAT) in 4 p (18%). Six p (27%) underwent pre-operative radiotherapy whereas 16 p (73%) post-operative radiotherapy. One of the biological characteristics of sarcoma is their relatively low  $\alpha$ -B ratio. Assuming an  $\alpha$ /beta ratio of sarcoma cells as 4 our calculation of tumor BED is as following: (2Gy x 25fx) + (5.5Gy x 3fx) = 114.19Gy which corresponds to an accumulated EQD2Gy for tumor of 76.12Gy. With a median follow-up of 16 months (range 0.2 - 37.5 months), 1 p had developed marginal local relapse at 7.6 months of follow-up. In-field local control, distant-metastases free survival and overall survival are of 100%. No grade 3 or higher toxicity was observed.

**Conclusion**

Peri-operative brachytherapy is feasible and well tolerated and allows a moderate dose-escalation in patients with soft-tissue sarcomas.

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

**Abstract text**

Radiation Oncology is unique as a field, where excellence in care and advances in research are only possible by closest collaboration of multiple professions: medical physics, nursing, radiation oncology, radiation technologists and radiobiology. The progress in our field is documented by significantly and clinically relevant improved outcome over time and this has been achieved in all frequent cancer sites of lung cancer, prostate cancer, breast cancer, rectal cancer and many small cancer sites. Medical physics has been a key driver of these advances and has strongly contributed to reshape the way radiation oncology is practiced and perceived today: clinically effective, well tolerated and cost-effective. Both innovation AND translation are responsible for these success stories. Intensity-modulated radiotherapy, image-guidance and stereotactic-body radiotherapy are just some exemplary innovations which all improve outcome of our today's cancer patients: these advances have been (co-)developed by Medical Physics, jointly implemented by all professions, successfully evaluated in clinical trials, incorporated into international and multidisciplinary guidelines and are today standards of care in our societies. All innovations can be summarized under the umbrella of precision medicine: to adapt radiation oncology to the patient-individual disease aiming to deliver the right treatment to the right patient and the right time. Consequently, radiation oncology has practiced precision medicine long before this "buzz-word" was adopted in medicine and oncology. This is a huge opportunity for radiation oncology in general and medical physics in particular: to be at the forefront of current research and clinical advances in oncology and medicine. Precision medicine is fundamentally based on individual patient and disease characterization: digitalization, standardization, collection, analysis and interpretation of various patient and disease characteristics within multi-level prognostic and predictive models has already been established in radiation oncology. More comprehensive patient and disease characterization beyond currently available biomarkers has been pioneered by Medical Physics using e.g. quantitative image analysis - Radiomics. Artificial intelligence and machine learning will be mandatory for handling and interpretation of these massive data and are already today routine in radiation oncology. Medical physics has therefore a lot to offer to the progress of precision medicine in general, not only in the field of radiation oncology and also not restricted to oncology. It will be critical to distribute and balance the limited resources between these different fields of research, between "traditional" radiation oncology medical physics and "beyond borders" radiation oncology. This will strengthen Medical Physics. However, if Radiation Oncology overall is open for these developments, our discipline and finally our cancer patients will benefit from continuing our multi-professional nature.

---

#### SP-0439 Extreme hypofractionation in the treatment of localized prostate cancer

R. Valdagni<sup>1</sup>

<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori, Radiation Oncology 1, Milan, Italy

#### Abstract text

Over the past two decades, the radiation oncology community is being experiencing a major technical evolution in the radical irradiation (RT) of localized prostate cancer. Most significant improvements consist of the routine utilization of IMRT, of IGRT, also including active (e.g. electromagnetic transponders) or passive (e.g. gold fiducials markers) localization systems, of devices aimed to improve dosimetry in the perirectal space (e.g. rectal spacer and endorectal balloons) as well advances in prostate imaging.

Such technical sophistication facilitates the definition, localization and monitoring of the tumor position, size and shape before and during treatment, together with the possibility of higher, targeted radiation doses to improve tumor control and decreased radiation exposure to normal tissues surrounding the tumor. Highly precise treatment delivery is leading to safely administer very conformal treatment at increased total doses in small volumes. This allows to overcome conventional fractionation (CF) and to routinely utilize moderate hypofractionation (M-HF) as well as to explore feasibility and safety of extreme hypofractionated (E-HF). The recently published guidelines on localized prostate cancer by ASTRO, ASCO, and AUA define M-HF as the daily fraction of 2.40-3.4 Gy and of  $\geq 5$  Gy for E-HF; this guideline underlines that, being HF a "spectrum" of fraction sizes and lacking a "universally accepted definition", the above mentioned subdivision between M-HF and U-HF is "necessarily arbitrary" and pragmatically reflects most of the available clinically experience with M-HF and E-HF. The almost acquired evidence that the  $\alpha/\beta$  ratio of prostate cancer is in the range of 1.5-2 Gy and that surrounding critical organs (rectum and bladder) tend to exhibit lower fractionation radiosensitivity (i.e.  $\alpha/\beta$  range: 3-5 Gy), suggest the use of hypofractionated schemes to improve the therapeutic gain, exploiting high doses per fraction to achieve better tumor control probability.

E-HF, particularly at single doses  $\geq 8$ Gy, shows further radiobiological advantages with respect to C-F and M-HF, tumor microvasculature induced disruption appearing to be a significant ablative determinant which concurs in considerably increasing tumor cell death. Beside radiobiological and clinical considerations, E-HF implies additional advantages in terms of economical cost reduction and patients' convenience (mainly but not only related to the possibility of gaining time), over CF- and M-HF, brachytherapy, proton irradiation and, because of non-invasiveness and of the evidence that radio-induced toxicities do not depend on patient's age, over radical prostatectomy. To date, E-HF in localized prostate cancer has been used in low, intermediate and high risk tumors and appears very attractive for intermediate risk and potentially for high risk patients (the non malignant nature of GG I/GPS 3+3 strongly suggests to avoid overtreatment in low risk patients), showing good biochemical control and, with few exceptions, limited toxicities in the early-mid term follow up. However, the long survival of prostate cancer patients with localized disease and the present

lack of published randomized trials comparing E-HF with C-F and/or M-HF, suggest that E-HF should remain an area of investigation.

The aim of this teaching lecture is to review the present clinical experience of extreme hypofractionation in localized prostate cancer, discussing patient and disease selection, different fractionation schemes, major technical features of available treatments, the present evidence re toxicities and oncologic outcomes, and future developments in the use of E-HF.

#### SP-0440 Immunotherapy and Radiotherapy: challenges and opportunities

S. Formenti<sup>1</sup>

<sup>1</sup>Weill Cornell Medical Center of Cornell University, Radiation Oncology, New York- NY, USA

##### Abstract text

Radiotherapy has revealed an ideal adjuvant to cancer immunotherapy, because of its ability to convert the irradiated tumor into an individualized, in situ vaccine. When successful at immunizing, radiotherapy evokes T cell memory, and induces effects outside the treated field, defined as abscopal effects (responses at a distant, synchronous, un-irradiated established tumor or metastasis). In the setting of clinical cancer, however, abscopal effects are extremely rare, because of immune-suppressive characteristic of established solid tumors (Curr Probl Cancer 40:25-37, 2016). Thus, strategies to exploit the pro-immunogenic effects of radiotherapy require combination with immunotherapy: experiments in several syngeneic mouse models that mimic the setting of advanced cancer have demonstrated promise of combining radiation with immune checkpoint blockade (Clin Cancer Res. 2005;11:728-734). Radiation can compensate tumors with a low mutational load, by inducing de novo T cell priming to multiple tumor antigens and therefore, achieve responses in the absence of pre-existing neoantigens with anecdotal clinical examples confirming the preclinical data (Trends Cancer 2016;2,6:286-294). Currently, multiple clinical trials are exploring optimal regimes of radiotherapy and immunotherapy, with some initial success. The issue of dose and fractionation seems to be particularly relevant to abscopal responses. A mechanism underlying the dose dependence of abscopal response was recently elucidated (Nature Communications 2017; Jun 9;8:15618 ). In mice bearing bilateral TSA murine breast carcinoma when combined with ICB a single dose of 20 or 30Gy achieved comparable in field control to that of a regimen of 8GyX3 fractions, but only the fractionated regimen induced abscopal responses. Radiation-generated double strands (ds) DNA fragments reach the cytoplasm of irradiated cells where they are "sensed" by the cGAS/STING pathway (cGAS=cyclic GMP-AMP synthase and its adaptor protein STING= stimulator of interferon genes, aka transmembrane protein 173 - TMEM173). cGAS binds cytosolic dsDNA to initiate interferon (IFN-I) responses upon STING stimulation, resulting in dendritic cell recruitment and cross-priming of effector T-cells, the key steps to convert the tumor into an in situ vaccine. When tested in multiple carcinoma murine and human carcinoma cells as the radiation dose per fraction increases, cytosolic dsDNA was found to accumulate to a threshold above which induction of three prime repair exonuclease 1 (Trex1) occurred, an enzyme that degrades cytoplasmic DNA. Single doses in excess of 10-12Gy induced Trex1 to rapidly degrade cytosolic dsDNA, the substrate for cGAS/STING. As a result, signaling to induce IFN was abrogated, impairing RT-induced abscopal effects. Consideration to these findings suggest that a

hypo-fractionated regimen, ideally with 3-5 doses of less than 10-12 Gy each, should be used when radiotherapy is combined with immunotherapy. Recent clinical data confirms the use of this dose and fractionation regimens, demonstrating efficacy in human cancers (Nature Medicine 2018:24, 1845-51).

##### Abstract text

Lactate exchange between glycolytic and oxidative cancer cells optimizes tumor growth. Blocking lactate uptake through monocarboxylate transporter 1 (MCT1) thus represents an attractive therapeutic strategy but may in turn stimulate glucose consumption by oxidative cancer cells. Here, we found that inhibition of mitochondrial pyruvate carrier (MPC) activity could fulfill the tasks of blocking lactate use while preventing glucose oxidative metabolism. Using *in vitro* <sup>13</sup>C-glucose and *in vivo* hyperpolarized <sup>13</sup>C-pyruvate, we identified TACC2 as a potent inhibitor of mitochondrial pyruvate transport which consecutively blocks extracellular lactate uptake by promoting intracellular pyruvate accumulation. Also while in spheroids MCT1 inhibition leads to cytostatic effects, pharmacological inhibition of MPC activity induces profound cytotoxic effects together with glycolysis stimulation and uncompensated inhibition of mitochondrial respiration. Hypoxia reduction obtained with TACC2 was further shown to sensitize tumor xenografts to radiotherapy. Hence, this study positions MPC as a control point not only for pyruvate but also lactate metabolism and expands on the radiosensitizing potential of MPC inhibition.

---

#### SP-0442 Machine learning in radiomic analyses to predict radiotherapy outcome

S. Löck<sup>1</sup>

<sup>1</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden-Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

##### Abstract text

This lecture will focus on specific methods for the development and validation of prognostic or predictive models based on features extracted from medical imaging. The radiomic workflow, starting from available medical images to finally validated models, will be presented. Different machine-learning algorithms for the tasks of feature selection and model development will be explained in detail. Furthermore, the steps of hyperparameter tuning and model validation will be discussed. The results of systematic comparisons between machine-learning algorithms for the tasks of feature selection, patient classification or survival analysis allow for selecting suitable methods, which is an important step to increase the robustness of radiomic studies. After this lecture the participants may have a general impression on the radiomic workflow and on specific machine-learning algorithms applied for radiomic analyses.

B. Maciejewski<sup>1</sup>

<sup>1</sup>*Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Dept. Radiotherapy, Gliwice, Poland*

**Abstract text**

Basic biological aim of radiotherapy is to kill tumour cells (stem and clonogenic cells) and kill them all to achieve the highest TCP. Therefore, dose fractionation should be tailored to the initial number of tumour cells, which strictly corresponds with tumour volume. However, fractionation schedule is still individually designed based on quasi-quantitative rank - TNM system, which radiobiologically sounds illogical. Within a given T stage, i.e. T<sub>2</sub>N<sub>0</sub>M<sub>0</sub>, there is at least one decade difference in tumour cell number between the smallest and the largest tumours within this T category but practically, prescribed total dose is usually the same. This problem is discussed in details and illustrated with own data and the published results. Simple methods, how to convert tumour volume into the number of tumour cells and to tailor dose-fractionation for the highest TCP as possible, using single parameter D<sub>10</sub> is presented. The use of Volumetric Staging instead of the TNM to plan optimal radiotherapy is documented by practical examples. In the era of the 3D, 4D-IMRT, IGRT, SHRS, Fowler strongly recommended to plan D<sub>100</sub> instead of D<sub>95</sub> for the GTV. Results of the own pilot study clearly show, that even small “cold spots” within GTV subvolume can ruin the TCP initially predicted. The study shows how important is to convert physical DVHs into Biologically Normalized Histograms (BNDVHs) and the way how to replan dose distribution within GTV to eliminate biological “cold spots” in order to estimate real TCP to be close or even equal to that initially prescribed. Main goal of the lecture is to convince the audience that clinical radiobiologic principles are undoubtedly a basic requirement of all 3D conformal radiotherapy strategies. Key words: 3D-IMRT, Volumetric Staging, biological dose fractionation planning, D<sub>100</sub> instead of D<sub>95</sub>, BNDVHs

**Teaching Lecture: In-vivo dosimetry : Possibilities and Pitfalls**

---

**SP-0444 In-vivo dosimetry: Possibilities and Pitfalls**

V.N. Hansen<sup>1</sup>

<sup>1</sup>*Odense University Hospital, Laboratory of Radiation Physics, Odense C, Denmark*

**Abstract text**

In-vivo dosimetry (IVD) is the final verification of correct radiotherapy delivery. IVD is verifying that the radiotherapy plan, as designed within the treatment planning system (TPS), is delivered correctly to the individual patient, at the time of treatment. Historically IVD has focused on correct output of the linear accelerator and the focus has been point dose measurements. This is often measured as entrance dose verification, which does give assurance that at the specific point the output of the linac is correctly calibrated. This worked well in an era of simple open beams. However, the focus has changed from the “simple” output of the linac due to the fact that most TPS plans are IMRT or VMAT. Hence a point dose is no longer representative of the treatment. In addition the focus is not only on the capability of the linac delivery, but it is increasingly the patient anatomy and the possible

changes of the individual’s anatomy. The lecture will review options for IVD based on 2D detectors either place at the head of the linac for forward projected 3D IVD, or EPID detectors for back-projected 2D or 3D IVD. Clinical examples and challenges of IVD will be discussed.

**Teaching Lecture: The vital role of physicists in clinical trials: from design to data analysis**

---

**SP-0445 The vital role of physicists in clinical trials: from design to data analysis**

A.L. Appelt<sup>1</sup>

<sup>1</sup>*University of Leeds & St James’s University Hospital, Leeds Institute of Medical Research and Leeds Cancer Centre, Leeds, United Kingdom*

**Abstract text**

Medical physicists are vital players in the conducting of radiotherapy trials. Evidence clearly points to the importance of treatment quality assurance in clinical trials [1,2], where protocol violations and sub-optimal radiotherapy results in worse patient outcomes [3]. Consequently, the need for medical physics expertise for trial QA is well-recognised, and major organisations directly employ physicists to conduct multi-centre QA, e.g. in EORTC, IAEA, RTOG, TROG, and the UK RTTQA [4].

This lecture will argue, however, that the role to be played by physicists is considerably more extensive and more impactful than “just” thorough trial QA. Through specific trial examples, the impact of physicists on hypothesis generation, trial design, protocol development, and imaging / treatment delivery sub-studies will be demonstrated - and a case will be made for physics leadership on trials. Trials discussed will include an early phase dose finding trial [5] in head & neck cancer and a large multi-centre phase III trial in NSCLC [6]. Furthermore, the added scientific depth offered by radiotherapy physicists from exploratory secondary analysis of trial data will be touched upon (see e.g. [7]). Finally, we will go through some practical tips and tricks on how to get involved in clinical trials work - all directly sourced from physicists actively working on clinical trials.

**SP-0446 New developments in the treatment of brain metastases: better prognostic tools, improved outcomes**

C. Nieder<sup>1</sup>

<sup>1</sup>Nordlandssykehuset HF, Dept. of Oncology and Palliative Medicine, Bodoe, Norway

**Abstract text**

Compared to previous decades where treatment options for brain metastases were limited to surgical resection and whole-brain radiotherapy, with stereotactic radiosurgery as an emerging modality, the current era is characterized by highly individualized treatment concepts, often combining different modalities and also integrating systemic drug therapy. Unprecedented CNS activity has been reported for different drugs, e.g., in subsets of patients with non-small cell lung cancer and malignant melanoma. It also appears possible to extend the survival of patients with oligometastatic disease by adding consolidative, ablative radiotherapy to extracranial metastatic sites after standard of care systemic treatment. On the other hand, many patients still present with widespread metastases and sometimes additional adverse prognostic features. These patients are at risk of early death and may be managed with optimal supportive care. Therefore, the invited lecture will focus on recent clinical studies and refined prognostic models, e.g., for non-small cell lung cancer, malignant melanoma and renal cell cancer.

**Abstract text**

Nowadays a radical cystectomy is still the golden standard for patients with muscle invasive bladder cancer although there is growing interest in bladder sparing approaches as an alternative for radical cystectomy. Level 1 evidence has clearly demonstrated the superior effect in outcome by combining chemotherapy and radiotherapy in a trimodality approach compared to radiotherapy alone. Similarly adding the tumour radiosensitizers carbogen and nicotinamide to radiotherapy results in increased permanent control of bladder disease. In the meanwhile several publications have proven the efficacy and safety of these trimodality therapies. Randomised trials comparing the outcome after radical cystectomy and trimodality therapy are lacking and one attempt to randomise patients between both treatment options failed due to poor accrual. Several retrospective analyses have tried to resolve the issue whether or not trimodality therapy is a valuable alternative for radical cystectomy. Conflicting results have been published. However it is of importance to point out that these analyses are not free from limitations. Misclassification and selection bias impair the interpretation of these data leading to overstated results and misleading conclusions. Rather than seeing both modalities as competing strategies one should regard them as complementary approaches in a very heterogenous population and one must absolutely avoid to deny a curable treatment with a bladder sparing

approach to patients who are unfit for surgery. This is of specific interest in an increasing elderly population.

**SP-0448 Bladder brachytherapy: an undoubtable importance of close multidisciplinary collaboration**

E. Van Der Steen-Banasik<sup>1</sup>, B. Oosterveld<sup>1</sup>, M.A.D.

Haverkort<sup>1</sup>, C. Wijburg<sup>2</sup>, G. Smits<sup>2</sup>

<sup>1</sup>Radiotherapy Group, Radiotherapy, Arnhem, The Netherlands ; <sup>2</sup>Rijnstate Hospital, Urology, Arnhem, The Netherlands

**Abstract text**

The first report of brachytherapy (BT) as part of a bladder-sparing treatment in MIBC appeared in 1915, followed by hundreds of treatments in the US and since the 50s in Europe with the majority of patients treated in the Netherlands. The biggest population was published by Koning et al in 2012, reporting a cohort of 1040 patients with a 5-years local control of 75 %. Two other bladder sparing modalities: partial cystectomy (PC) and chemoradiation report resp. 5-years DFS of 39%-67% and 60-73%. In a match-controlled study, comparing open radical cystectomy with BT in solitary MIBC, we have shown superior recovery, less complications and at least equal oncological outcome in the BT group. BT catheter placement was then performed by open surgery. Since 2009, we uniquely transformed the open technique in minimal invasive laparoscopy, in 2010 modified to a robot assisted approach. Here we show data of 130 consecutive, minimal invasively treated and prospectively monitored patients.

**Methods**

The indication is <5cm unifocal MIBC, no CIS, staged  $\leq$ T3a (CT and MRI.)

Ca 8 wks after TURB external beam irradiation EBRT starts, 40 Gy, 20 fractions in 4 weeks, including bladder and regional lymph nodes.

10 days afterwards the surgery consists of BT catheter implantation and (PC) if thicker than 1 cm residual tumor, localization in urachus, diverticulum or tumor nearby distal ureter/ostium.

The HDR (Ir-192) scheme is 25 Gy in 10 fractions, 3 fractions/day, starting 3hrs after surgery. In 2016 the decision was made to de-escalate the brachytherapy dose to 17.5 Gy in 7 fractions if PC was performed.

**Results**

130 consecutive patients (2% recurrent pT1, 98% MIBC) were treated. 5 patients were excluded from final analysis. PC was performed in 42 patients, with the last 16 receiving a reduced BT dose. Selective Lymph node dissection was performed in 42 patients, we found 7 positive of 252 resected nodes. Median hospitalization was 5.0 days, significantly reduced compared to the previous published open procedure (13.5 days). The average FU was 2.9 year (1 month - 9 year). 16 patients developed toxicity (CTCAEv4): acute G3-4: delirium(3), ileus(1), pulmonary embolism(1), late G2-3: hematuria(3), urinary urgency(3), lymphedema(2), bladder necrosis(1), recurrent cystitis(1), hydronephrosis(1). No changes in sexual functions nor late deterioration of bladder functions were

observed. Survival analysis: Kaplan-Meier method; 2y local control is 82%, 2y disease specific survival is 89%. No in-field local recurrences are observed in the PC group. This subgroup consists of 49% pT0, 11% pT1, 40% pT2 or more and showed 97% cancer specific survival, 97% loco-regional control and 94% NED (median follow-up of 2,5y). Fortunately this method is adopted: the group from Amsterdam recently reported 3 in-field recurrences in a cohort of 26 patients, treated between 2011 - 2016 and in the group from Lisbon reported on feasibility and reproducibility of the treatment.

**Conclusions:**

In these selected MIBC patients this minimally invasive multi-modality treatment results in excellent oncological

and functional outcomes. We consider this bladder sparing treatment as the gold standard in bladder preserving therapies. A multidisciplinary collaboration is indispensable.

**Abstract text**

The introduction of new technology has revolutionized the way radiotherapy is delivered for bladder cancer: developing from the use of basic conventional techniques to a high precision, personalized approach. In order to demonstrate that the new technology is beneficial to the patient and to ensure its safe implementation, there is a need to integrate clinical expertise, patient values and research evidence into the development of evidence-based best practices (EBP). Since 2005, a series of prospective and retrospective studies were conducted to investigate different aspects of bladder radiotherapy, such as the accurate definition of treatment volumes, quantification of inter- and intrafractional bladder volumes changes and surface displacements, conformity and normal organ avoidance for dose distributions, mode and frequency of image-guidance interventions, reliability of image guidance surrogates and the cost/benefit of adaptive strategies. At each stage, the impact on geometric and dosimetric precision was quantified as evidence to substantiate the use of EBPs. Currently all bladder patients at our institution are treated with daily image guidance using CBCT with soft tissue alignment, with dose delivered to an individualized clinical target volume and planning target volume using IMRT.

**SP-0450 Radiosensitization strategies for the treatment of bladder cancer**

A. Choudhury<sup>1</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom

**Abstract text**

Bladder preservation is increasingly being accepted as an important alternative to radical cystectomy for muscle-invasive urothelial cancers. This talk will cover the evidence for bladder preservation using radiotherapy with radiosensitisation, dose, fractionation and radiotherapy technique. There are no robust ways to stratify patients for treatment, but there are a number of promising candidates. An overview of novel biomarkers for stratification will be presented.

**Abstract text**

To increase cancer immunotherapy success, PD-1 blockade must be combined with rationally selected treatments. Here, we examined in a poorly immunogenic mouse breast cancer model the potential of antibody-based immunomodulation and conventional anti-cancer treatments to collaborate with anti-PD-1 treatment. One important requirement to improve anti-PD-1-mediated tumor control was to promote tumor-specific cytotoxic T cell (CTL) priming, which was achieved by stimulating the CD137 costimulatory receptor. A second requirement was to overrule PD-1-unrelated mechanisms of CTL suppression in the tumor micro-environment (TME). This was achieved by radiotherapy and cisplatin treatment. In the context of CD137/PD-1-targeting immunotherapy, radiotherapy allowed for tumor elimination by altering the TME, rather than intrinsic CTL functionality. Combining this radioimmunotherapy regimen with low-dose cisplatin improved CTL-dependent regression of a contralateral tumor outside the radiation field. Thus, systemic tumor control may be achieved by combining immunotherapy protocols that promote T cell priming with (chemo)radiation protocols that permit CTL activity in both the irradiated tumor and (occult) metastases.

**Abstract text**

Colorectal, ovarian, endometrial and other tumors carrying defects in DNA mismatch repair often show favorable prognosis and indolent progression. The genomes of these tumors bear hundreds of thousands of somatic mutations, a feature which fosters cancer progression and might lead to rapid evolution of resistance to targeted therapies. Recent evidences that a subset of MSI (microsatellite instable) tumors respond prominently to immune checkpoint blockade led to the hypothesis that the presence of high number of somatic mutations may be responsible for effective immune-surveillance. However, several reports indicate that a relevant fraction of hyper-mutated tumors have unfavorable prognosis and do not respond to immune-modulators. To understand the molecular and functional bases of response to immune checkpoint inhibitors, we genetically inactivated MutL homolog 1 (MLH1) in colorectal, breast and pancreatic mouse cancer cells. The growth of MMR deficient cells was comparable to their proficient counterparts in vitro and upon transplantation in immune-compromised mice. However, isogenic MMR deficient cancer cells, acquiring alterations over time, were unable to form tumors when

injected subcutaneously or orthotopically in syngeneic mouse models according to cell-passage number. Moreover, we found that MMR-driven dynamic generation of neoantigens, when restricted to a clonal population, further increases immune detection. Mechanistically, MLH1 inactivation increased the mutational burden and led to dynamic mutational profiles, resulting in persistent renewal of neoantigens *in vitro* and *in vivo*, while control cells exhibited stable mutational loads and neoantigen profiles over time. These results led us to hypothesize that enforced increase of the number of mutations in cancer cells could restrict cancer growth and might be beneficial for therapeutic purposes. We therefore performed a pharmacological screen to identify agents capable of permanent inactivation of MMR in colorectal, breast and PDAC cancer cells. We found that temozolomide triggers MLH1 inactivation in cancer cells that -as a result- are unable to form tumors in syngeneic animals. Genomic analysis of temozolomide resistant cells revealed that fluctuating levels of neoantigens, rather than the absolute number of mutations, might be critical to provoke immune surveillance. Overall, these results provide the rationale for developing innovative anticancer therapies based on inhibition of DNA repair mechanisms.

**SP-0454 Trial design: early clinical studies and learning from the laboratory**

T. Illidge<sup>1</sup>

<sup>1</sup>The University of Manchester, Manchester Cancer Research Centre- Christie NHS Foundation Trust, Manchester, United Kingdom

**Abstract text**

Radiotherapy (RT) is a highly effective cancer treatment and research for much of the last century focused on understanding the mechanisms underlying its tumoricidal properties. Only relatively recently have the local and systemic immunomodulatory properties of RT been investigated. RT is now known to stimulate an immune response by inducing a variety of immunogenic and phenotypic changes in malignant cells that can recalibrate the immune contexture of the tumour microenvironment. If the immunoregulatory effects could be harnessed this could significantly increase the anti-cancer effect of RT. The recent major breakthrough of the immune checkpoint inhibitors (ICI) anti-CTLA-4 (cytotoxic T-Lymphocyte-associated protein 4) and anti-PD1/PD-L1 (programmed death-ligand 1) has led to durable remissions and improved survival in a number of incurable cancers including metastatic malignant melanoma, Non Small Cell lung cancer, renal cell cancer and other cancers. This remarkable clinical efficacy has established immunotherapy as another effective form of cancer therapy and stimulated the “immunotherapy revolution” leading to the large scale development of a new class of therapeutics termed immuno-oncology (IO) agents. Given that both RT and IO agents are potentially immunomodulatory combining RT with IO agents provides a unique opportunity to increase systemic anti-tumour immunity and transform cancer therapy. This goal would be achieved with RT and IO agents combinations by improving the outcomes for those patients who present with localised disease and who currently fail with localised recurrence or the development of metastatic disease as well as tackling those with oligometastatic disease who are currently incurable and thus converting RT into an effective part of systemic therapy. Proof of principle preclinical studies using RT in combination with Immune check point inhibition (ICI) using anti-CTLA-4 and PD-1/PD-L1 blockade have demonstrated “abscopal” systemic anti-tumour immune responses in tumours outside of the RT field leading to long term clearance. These systemic immune responses have also been reported in a number of clinical case reports. This preclinical evidence and these interesting clinical reports led to hundreds of clinical trials

being launched with the aim of testing the efficacy of radiotherapy in combination with immunotherapy to improve outcomes. However converting clinical responses seen with in a minority of patients in solid tumours with ICI using a single site of RT for “abscopal” responses and expecting the majority of patients to respond to ICI in combination with RT is unlikely to happen. In order to see more durable responses to RT and IO agent combinations we need firstly to further understand how RT influences the tumour cells, tumour microenvironment and surrounding immune effector cells. We also need to explore irradiation of multiple lesions in order to enhance the likelihood of obtaining meaningful clinical outcomes in some clinical situations. Secondly we need to partner RT with the optimal immunomodulatory IO agent to generate the most effective systemic anti-tumour immune responses. For tumours rich in T cell infiltrates, RT and anti-PD1 might be effective combinations overcoming T cell exhaustion and increasing systemic T cell anti-tumour immunity. For those with more immunosuppressive microenvironments that might be devoid of T cell and / or rich in myeloid cells other types of immunostimulatory agents are likely to be required. In this presentation the current challenges in translating recent findings with RT and IO agents in the laboratory into the clinic and a review of the progress made to date in clinical trials will be discussed.

**SP-0455 Inhibition of glycolysis and redox metabolic pathways in cervical cancer**

J. Schwarz<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Department of Radiation Oncology, St. Louis, USA

**Abstract text**

One third of locally advanced cervical cancers treated with standard of care chemoradiation (pelvic irradiation plus concurrent cisplatin chemotherapy) fail this treatment, and there is currently no cure for recurrent or metastatic disease. Our previous work has shown that the results of <sup>18</sup>F-fluoro-deoxy-glucose positron-emission-tomography (FDG-PET) can be used to identify treatment-resistant cervical cancers. Cervical tumors that take up large quantities of FDG, a glucose analog, prior to treatment are resistant to radiation, and tumors that maintain high levels of FDG uptake after radiation is complete are likely to recur. Given these clinical observations, a reasonable hypothesis is that inhibiting cervical tumor glucose metabolism may improve radiation sensitivity. The hexokinase inhibitor, 2-deoxyglucose (2-DG), has been evaluated in *in vitro* and *in vivo* as a radiosensitizer in a number of cancer models, and 2-DG has been administered to patients in the context of clinical trials. The results of these studies show that while inhibition of glucose metabolism with 2-DG can transiently increase radiation sensitivity, long term therapeutic gains are limited by the normal tissue toxicity that occurs at the doses required to maintain effective inhibition of glycolysis in tumors. In addition, new concerns have arisen over the capacity of tumor cells to rewire their metabolism in response to metabolic therapy (metabolic plasticity). Glycolytic tumor cells exist in a relative state of oxidative stress due to increased levels of reactive oxygen species (ROS) and compensate for this by upregulating redox metabolic pathways. Indirect effects of irradiation also result in transient increases in ROS that are metabolized by tumor cells. We hypothesized that simultaneous inhibition of glycolysis and the redox metabolic pathways would be more effective as a radiation sensitizer than inhibition of glycolysis alone. Using a panel of cervical cancer cell lines, we

demonstrate that sensitivity to 2-DG monotherapy is increased in tumor lines that are highly glycolytic, and that 2-DG enhances the efficacy of cisplatin chemotherapy and radiation in glycolytic tumor cells. When 2-DG is combined with L-buthionine sulfoximine (BSO), an inhibitor of glutathione biosynthesis, and auranofin (AUR), a thioredoxin reductase inhibitor, glycolytic cervical cancer cells are unable to proliferate. Detailed analysis of intracellular redox parameters indicates that these effects are mediated primarily by increases in intracellular reactive oxygen species, which can promote autophagic and non-autophagic forms of cell death depending on the oncogenic context. In cervical tumor models in the mouse, this drug strategy can be used to limit tumor growth for highly glycolytic cancers and to radio-sensitize cancers that display intermediate levels of Warburg-related glucose metabolism. Consistent with our hypothesis, combined treatment with 2-DG, BSO and AUR is more effective as a radio-sensitizer in vivo than 2-DG alone. Most recently, we have found that glutamine deprivation or treatment with glutaminase inhibitors can also be used to promote increases in intracellular oxidative stress that facilitate radiation therapy efficacy.

**SP-0456 Sex differences in cancer metabolism: implications for therapy**

J. Ippolito<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, Radiology, Saint Louis, USA

**Abstract text**

There is a sex disparity in many cancers throughout the body where males have a higher incidence and mortality compared to females. Moreover, these effects are independent of age suggesting that cell-intrinsic phenomena, rather than the effects of sex hormones, may play a key role in this clinical phenotype. Metabolism is one potential factor underlying this disparity where nutrient uptake and metabolism are enhanced in males relative to females beginning at the earliest stages of embryogenesis and are carried into adulthood. Because of the established inverse correlation between enhanced glucose metabolism and patient survival in many cancers, we hypothesized that sex differences in central carbon metabolism underlie sex differences in cancer patient survival. We developed a data mining algorithm using The Cancer Genome Atlas (TCGA) to identify metabolic gene expression patterns that correlated with poor sex-specific outcomes. We applied this algorithm to the lower grade glioma (LGG) transcriptome and identified numerous enzymes involved in glycolysis, glutamine-fueled tricarboxylic acid (TCA) cycle metabolism, and oxidative phosphorylation that uniquely identified men, but not women, with poor outcomes. We validated these findings using an established mouse model for sex differences in gliomas, the *Nf1*<sup>-/-</sup>*DNp53* model, where transformed mouse astrocytes are deficient for neurofibromin 1 (*Nf1*) and express dominant negative p53 (*DNp53*) protein. We identified that a critical metabolic sex difference was glutamine-fueled TCA cycle metabolism that was significantly higher in transformed male astrocytes. We also identified that transformed male astrocytes were more susceptible to inhibition of glutamine metabolism with glutaminase inhibitors compared to females. Together, these findings highlight sex-specific dependencies of specific nutrients and metabolic pathways on tumor growth that may potentially be exploited for therapy. Moreover, clinically-relevant metabolic imaging modalities such as fluorodeoxyglucose-PET, fluoroglutamine-PET, or hyperpolarized carbon-13 MRI may identify prognostic sex differences in patients.

TBC

**SP-0458**

**Targeting metabolism to sensitize hypoxic tumor cells**

M. Koritzinsky<sup>1</sup>

<sup>1</sup>University Health Network, Princess Margaret Cancer Centre, Toronto, Canada

**Abstract text**

Tumor hypoxia has long been recognized as a limiting factor for radiotherapy response due to the strong radiosensitizing effect of oxygen. Although randomized clinical trials have demonstrated some benefit of increasing the oxygen supply or replacing oxygen with radiosensitizers during radiotherapy, these strategies have not resulted in widespread clinical adoption. Over the last few years, a common theme has emerged from experimental studies, highlighting the potential for various clinically approved drugs to enhance tumor oxygenation through inhibition of the oxygen consumption of tumor cells close to blood vessels. These studies have hence led to several ongoing randomized clinical trials in which these drugs are repurposed to enhance tumor oxygenation during radiotherapy. A complimentary approach to sensitize hypoxic tumors is to target hypoxia adaptation mechanisms that render cancer cells vulnerable to the lack of oxygen. Many aspects of metabolism are altered or specifically required under hypoxic conditions, including the cellular metabolism of reactive oxygen species (ROS). Cancer cells frequently have high ROS production due to deregulated proliferation and metabolism. Hypoxia further increases overall cellular levels of ROS, and reoxygenation triggers substantial ROS bursts. Together, this renders tumor cells vulnerable to targeting anti-oxidant defense systems. Here we will present data demonstrating that the protein peroxiredoxin 4 (PRDX4) is essential in both normoxia and fluctuating oxygen conditions in vitro and in experimental tumor models. Loss of PRDX4 leads to increase ROS and DNA damage, resulting in cell toxicity and radiosensitization. These data support the potential for combining disruption of redox homeostasis with radiotherapy for improved therapeutic ratio.

**SP-0459 Clinical status of MR-integrated photon therapy**

L. Boldrini<sup>1</sup>

<sup>1</sup>Fondazione Policlinico Universitario "A. Gemelli" Ircs, Radiation Oncology, Rome, Italy

**Abstract text**

The introduction of MR integrated delivery units represents one of the most significant and promising innovations of the last years in radiotherapy delivery technology. The advantages assured by the better visualization of the therapy volumes allowed by on board MR imaging and the possibility to use active gating and motion management solutions embedded in this novel workflow need to be further explored and quantified both from a technical and a clinical perspective. Aim of this talk is to describe the current clinical status of the MR-integrated photon radiotherapy and to present the clinical evidence to date available. Its most common applications will be reported, ranging from the patient selection methods to the choice of the most appropriate therapy delivery protocol. Furthermore, the possibility to implement innovative hypothesis generating approaches (movement management, radiomics, new delivery techniques) in clinical MR-integrated radiotherapy will be presented.

**SP-0460 Integration of MR and particle therapy - how far are we?****A. Hoffmann<sup>1</sup>**<sup>1</sup>*OncoRay - Center for Radiation Research in Oncology, Medical Radiation Physics, Dresden, Germany***Abstract text**

Precise targeting in proton therapy (PT) is even more important than in conventional photon-based radiation therapy (XT), because the usage of fewer radiation fields make PT dose distributions more sensitive to anatomical variations (e.g., organ motion and deformation) and patient set-up inaccuracies than XT. This is due to the steep dose fall-off behind the Bragg peak and to the fact that the range of the proton beam strongly depends on the material composition in the beam path. Especially for moving tumours, these uncertainties translate into relatively large safety margins, thus compromising the dosimetric benefit of PT. This urges the need for real-time image guidance during PT dose delivery. Magnetic resonance imaging (MRI) offers real-time image guidance with unparalleled soft-tissue contrast and absence of radiation dose. PT is therefore expected to benefit even more from the integration with real-time MRI than XT. Hence, in recent years there has been a growing interest to investigate the potential of MR-integrated PT (MRiPT), but so far no hybrid system has been realized due to a number of hitherto open technological problems. To study the technological feasibility of MRiPT, mutual interactions between the PT and MRI system have to be taken into account, some of which have already been addressed or are subject of ongoing research. Lorenz-force induced dose distortions (i.e. beam deflection and electron return effect for transverse magnetic fields and beam focussing effect for longitudinal magnetic fields) need to be quantified and taken into account during treatment planning and dose delivery. The magnetic interaction with dosimetry detectors may compromise the results of such measurements. Methods and procedures for proton beam dosimetry in the presence of magnetic fields have to be established. The mutual electromagnetic interaction between the MRI scanner and the PT system needs to be assessed and understood as this can compromise both the beam and image quality. For simultaneous operation of both systems, magnetic shielding may be required in addition to RF shielding. For on-line adaptive treatment planning, the proton dose distribution needs to be calculated directly from MR images. Fast and accurate methods that translate MR image information into electronic stopping power need to be developed.

Recent research efforts have realized a proof-of-concept system where first MR images of tissue-mimicking phantoms have been successfully acquired with a clinical in-beam MR scanner during proton beam irradiation. This offers the prospect that the development of a clinical prototype MRiPT system within the next 5 years should not be considered beyond the realms of possibility.

The contribution provides an overview of the current status of MRiPT research achievements and discusses technology issues that need further investigation. Implications for future developments and clinical treatment workflow are also addressed.

**SP-0461 MR-based functional imaging****R. Beets-Tan<sup>1</sup>**<sup>1</sup>*Maastricht Radiation Oncology (Maastricht), Maastricht, The Netherlands*

Abstract not received

**SP-0462 Adaptive workflow - current status and challenges****S. Kharuzhyk<sup>1</sup>**<sup>1</sup>*N.N. Alexandrov National Cancer Center, Department of Radiology, Minsk, Belarus***Abstract text**

MRI is used at different stages of oncological patient management including tumor staging, treatment (surgery, radiation therapy) planning and tumor response assessment. Traditional radiation therapy planning workflow integrates high contrast resolution and anatomical details provided by MRI with electron density values obtained from CT. More recently MRI-only radiotherapy planning workflow has been implemented with synthetic CT images generated from MRI data. On-treatment MRI-guidance is a new paradigm of precision radiotherapy that enables a scan-plan-treat approach or adaptive radiotherapy. MRI linac machines integrating clinical MRI scanner with linear accelerator are current reality in some cancer centers around the globe.

**Symposium: Improved outcome by smarter use of radiotherapy****SP-0463 Towards less radiotherapy in breast cancer treatment****I. Meattini<sup>1</sup>**<sup>1</sup>*University of Florence - Azienda Ospedaliero Universitaria Careggi, Radiation Oncology Unit - Oncology Department, Florence, Italy***Abstract text**

Overdiagnosis and overtreatment represent great challenges in modern treatment for breast cancer. During the last decades several trials aiming less radiotherapy have been performed: reduction of overall treatment course (hypofractionation), reduction of overall treatment courses and breast target volumes (partial breast irradiation), omission of radiotherapy (whole breast and/or tumour bed boost). Hypofractionated whole breast irradiation, based on precedent studies over the past two decades, offers an opportunity for improved patient convenience, lower healthcare costs, and greater access to care without sacrificing treatment outcomes. Four randomized trials fully supported the use of hypofractionated whole breast irradiation as standard of treatment: the RMH/GOC trial, the UK START trial A and B, and the Canadian trial [1-6]. Partial breast irradiation has been introduced as an alternative treatment method for selected patients with early stage breast cancer. Potential advantages include shorter treatment time (accelerated), improved cosmesis secondary to a reduction in volume of breast tissue treated, and cost reduction compared with standard fractionation. Initial trials investigating partial breast irradiation showed conflicting results. The recent new high-level evidence provided by the results of the IMPORT-LOW trial clearly showed that adequate patients' selection led to low LRR. Tumour biology seems to play a crucial role on treatment outcome, thus it should always be considered together with disease stage, comorbidities, and patient's quality of life. Breast cancer should be always considered as a heterogeneous disease, for which a one treatment fit all strategy rarely represented the best option e giving the patients the final word in the shared decision-making process [7-10]. Whether radiotherapy is beneficial in elderly patients undergoing conservative surgery for early breast cancer has long been controversial. In the PRIME II trial, patients  $\geq 65$  years with tumours  $< 3$  cm in size with primarily grade I/II disease, all oestrogen receptor-positive and pathologically node-negative, were randomly assigned to whole-breast radiation therapy plus hormone therapy vs hormone therapy alone. The findings parallel those of CALGB 9343, which included an even lower-risk cohort of

patients ( $\geq 70$  years with tumours  $\leq 2$  cm, clinically node-negative, oestrogen-positive). Both studies showed significantly higher rates of local relapse in the endocrine therapy alone arms; though these differences, the addition of whole-breast radiation therapy did not result in differences in breast cancer-specific survival. The BASO II trial confirmed that patients treated with either exclusive adjuvant radiotherapy or endocrine therapy with tamoxifen had an equivalent local relapse rate per annum of 0.8%. These data suggest that radiation or endocrine therapy alone resulted in excellent disease control in older women with early breast cancer, and that the combination of treatments may have less benefit than expected. A direct comparison between radiation or endocrine therapy omission as adjuvant treatment is lacking in the existing literature [11-13]. The use and dose of a boost on the tumour bed has been largely investigated. In a phase 3 randomised controlled trial, the effect of a radiation boost of 16 Gy on overall survival, local control, and fibrosis for patients with stage I and II breast cancer compared with patients who received no boost has been evaluated. At a 20-year follow-up time, a radiation boost has no effect on long-term overall survival, but can improve local control, with the largest absolute benefit in young patients, although it increases the risk of moderate to severe fibrosis. Conversely, boost can be avoided in most patients older than age 60 [14,15].

#### SP-0464 Image-guided elective neck irradiation in head and neck cancer

A. Al-Mamgani<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Abstract text

Because of the rich lymphatic supply of the head and neck region, head and neck squamous cell carcinoma (HNSCC) has the tendency to metastasize to the regional lymph nodes, also to the contralateral side. The concept of elective nodal irradiation (ENI) was introduced in the sixties by Fletcher and supported later on by others. Since then, there is a long-standing empirical convention to irradiate the vast majority of HNSCC electively to both

sides of the neck (with the exception of T1 laryngeal and small lateralized tonsillar fossa cancer), in order to reduce the risk of contralateral RF (cRF). Meanwhile, there is slowly growing evidence that the incidence of cRF in well-selected HNSCC is very low (<5%). Furthermore, unilateral ENI will result in significant decrease in the incidence and severity of acute and late toxicity and improve QoL. In different studies, large treated volumes, chemoradiation and bilateral neck irradiation were the most important predictors for radiation-related toxicity. Therefore, there is increasing need for selection tools to expand the indication for unilateral ENI to reduce toxicity and improve QoL. As a consequence of the improved prognosis and increased incidence of HPV-positive oropharyngeal cancer among young people, these issues are becoming increasingly important since these young patients will live longer with the burden of troublesome late toxicities. At the Dutch Cancer Institute, we initiated a proof-of-concept study, the SUSPECT study (mapping of sentinel lymph node drainage using SPECT to tailor ENI in node-negative neck of patients with head and neck cancer) (ClinicalTrials.gov Identifier NCT02572661). The aim of this study was to investigate the role of SPECT/CT for the lymph drainage mapping (LDM) and to explore the incidence of cRF in patients electively treated to one side of the neck, based on SPECT/CT-guided LDM. In this study, 50 patients with primary HNSCC, T1-3N0-2bM0 located in the oral cavity, oropharynx, larynx (except T1 glottic), and hypopharynx, not crossing the midline and planned for treatment with (chemo)radiotherapy in curative setting, were included. LDM was performed using SPECT/CT scan 2-4 hours after injection of the primary tumor with radioactive Tc-Albumin (80MBq). Patients without any contralateral drainage, only the ipsilateral neck was electively irradiated. In case a contralateral tracer accumulation was identified, the elective treatment included the ipsilateral neck and only the level containing tracer accumulation, instead of the whole contralateral neck. The preliminary results are very promising. The dosimetric analysis showed highly significant reduction of dose to the salivary glands, swallowing muscles, speech structures, larynx, supraglottic region and thyroid glands. These dosimetric advantages was translated in significant reduction of the frequency, severity, and duration of acute and late toxicities such as grade 3 dysphagia (tube-feeding) and dry mouth, compared to a historical cohort of 50 consecutive patients treated bilaterally, outside the framework of the study. The first 40 patients included have meanwhile a follow-up time of at least 1 year. Only one patient with cRF was seen (2.5%). This patient was successfully salvaged by ND and is still alive with NED, 1.5 years after treatment.

#### SP-0465 Adapting RT in soft tissue sarcoma: the influence of anatomy, biology and response

B. O'Sullivan<sup>1</sup>

<sup>1</sup>Princess Margaret Cancer Centre, Radiation Oncology, Toronto, Canada

#### Abstract text

Traditional combined modality approaches to the local management of soft tissue sarcoma have used post-operative radiotherapy (RT) in a "shrinking field" concept to deliver an elective dose (e.g. 50 Gy) to a clinical target volume (CTV2) encompassing potential microscopic involvement beyond the original location of the gross tumour volume (GTV) and a higher dose to the originally site of the GTV (CTV1). These CTVs can be treated simultaneously or sequentially and generally are facilitated by the use of IMRT to deliver a dose of 60-66 Gy to the combined volume. Alternatively, pre-operative RT to CTV2 alone is often favored with RT reserved for CTV1 as a "boost" if involved resection margins occur at the resection. However, adequate and safe RT administration may not be feasible in some sites such as

skull base or retroperitoneum occupied by vulnerable anatomy. Therefore, modifications have been introduced by some groups in the interest of dose reduction to spare late morbidity. For example, a post-operative “boost” of 10-16 Gy to CTV1 to complete the 66 Gy total dose prescription was traditional in pre-operative radiotherapy but has generally been omitted in recent years when resection margins are not involved. Moreover some centres now also omit this “boost” when the margins are involved if this was a “planned positive” margin in a very small region juxtaposed to a vulnerable structure. Some colleagues, e.g. in Scandinavia and France, have also restricted post-operative radiotherapy courses to approximately 50 Gy in 25 fractions or equivalent rather than delivering an additional boost to CTV1 for a total of 66 Gy if the resection margins are uninvolved. The concept of restricting the dose to 50 Gy pre-operatively and post-operatively is currently being tested in the Canadian 50/50 randomized trial (NCT02565498). Differences in RT response of different sarcoma histological subtypes exists and has been shown to convert to improved local control in myxoid liposarcoma, with further potential for treatment with lower pre-op RT doses (36 Gy) in this pathological subtype currently under evaluation in the Doremy study (NCT02106312). There is also evidence that RT volume adaptation may be facilitated based on on-treatment response during pre-operative RT evident in patients treated in the first clinical trial of IMRT in extremity (STS NCT00188175). With daily CBCTs online, we have seen incremental changes in volume, and a 1 cm change affects dosimetry and coverage. This may be facilitated by implementation of MRgRT systems, with eventual potential generation of new IMRT plans for patients while still on treatment. Additional possibilities for RT dose reduction with shorter overall treatment time seem possible using RT regimens combined with chemotherapy or targeted agents. Finally, RT doses may be reduced through volume restriction by modification of RT delivery including use of particle beam, intra-operative RT, or pathological response following intratumoral injection of hafnium oxide nanoparticles with RT.

**Symposium: Quantitative Imaging for Radiation Oncology**

---

**SP-0466 A Critical Look of Quantitative Dynamic Contrast Enhanced MRI: From QIBA guidelines to Clinical Implementation**

**C. Chung<sup>1</sup>**

<sup>1</sup>MD Anderson Cancer Center, Radiation Oncology, Houston, USA

**Abstract text**

The promise of dynamic contrast-enhanced MRI (DCE-MRI) as a prognostic and predictive biomarker in solid malignancies is not a new concept. There have been efforts over several decades to investigate the methods and clinical value of DCE-MRI in oncological assessment. Many studies from individual institutions have suggested that DCE-MRI can characterize tumor angiogenesis and serial measurements may reflect changes in tumor vascular physiology in response to treatment or with further tumor progression. In Radiation Oncology, DCE-MRI has frequently been investigated in conjunction with tumor hypoxia, which has been associated with greater tumor aggressiveness and metastatic potential. In Medical Oncology, DCE-MRI was of particular interest when anti-angiogenic and anti-vascular therapies were discovered, but remain of interest in the context of drug delivery and early biomarkers of response.

Despite strong interest and promising single site studies, there have been great challenges in using DCE-MRI as a

quantitative imaging measure, particularly in multisite trials. This motivated the Quantitative Imaging Biomarker Alliance (QIBA), which initially formed in 2007, to write one of their earliest profiles on DCE-MRI. The DCE-MRI Quantification QIBA Profile places requirements on the acquisition device, the actors (technologists, radiologists, physicists), reconstruction software and image analysis tools involved in image acquisition, image data reconstruction, and image analysis. As QIBA recognized that the clinical and research environment for these quantitative imaging tools is ever evolving, the Profile sits online as a living document and there are current ongoing revisions to address the increasing use of 3.0T magnets and parallel imaging. The Profile requirements are determined based on published literature on repeatability and reproducibility. Despite a long history of interest by the oncology community in using DCE-MRI as a quantitative imaging biomarker, the recent systemic review of clinical literature by the DCE-MRI Committee within QIBA discovered a very limited number of publications on repeatability and reproducibility data.

In the era of precision medicine, the community-at-large is starting to understand that variability in measurement limits our ability to quantitatively characterize tumors or evaluate treatment response. Only through standardized processes of image acquisition, quality assessment, processing and analysis will there be the potential for collaborative, quantitative investigation. As part of this standardization process, the community will need to come together to determine shared nomenclature and define reporting standards that ensure enough transparency to enable cross-validation as well as supportive data collection, including repeatability and reproducibility data.

**SP-0467 Quality assurance for quantitative MRI in a multicenter trial**

**P. Van Houdt<sup>1</sup>**

<sup>1</sup>The Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

**Abstract text**

Quantitative MRI (qMRI) is promising as a biomarker for prediction of treatment outcome and for treatment response monitoring. However, current evidence is mainly built on small patient cohorts. Large, multi-center studies are necessary to investigate the clinical application of qMRI. However, these studies typically involve a wide variety in MRI systems, with different vendors, field strengths, and generations. As a result novel sequences may be available in one institute, but not in another. One approach to reach consistency would be to use standardized MRI protocols in all centers. The drawback is, however, that this will force us to design the sequences for the oldest system. Therefore, we have built a framework where we deal with this variety by optimizing the trial sequences on each system individually. In this way all institutes are free to choose the sequence to their preference and system possibilities. We have set up a quality assurance (QA) procedure using calibration phantoms to assess consistency of the trial sequences between institutes. This includes the measurement of benchmark sequences to investigate whether deviations between institutes result from protocol differences in the trial sequences or from system variations. These benchmark sequences are well known reference standards that are available on all systems using identical parameter settings.

In this talk, we will illustrate how we applied this framework in the IQ-EMBRACE trial and for treatment response monitoring studies using MR-linac systems. IQ-EMBRACE (sub-study of the EMBRACE-II trial) is a large, multi-center trial in which patients with cervical cancer will undergo an MRI exam prior to radio(chemo)therapy to investigate qMRI as a potential biomarker for treatment

outcome. So far, measurements have been performed in ten institutes. With the QA procedure we were able to identify inaccurate results and optimize the sequences such that consistent results were obtained. Similar results were obtained with measurements on MR-linac Unity systems, where we compared the repeatability and reproducibility in comparison to standard diagnostic systems.

**SP-0468 Quality assurance and validation for Quantitative PET in Multicenter Trials**

M. Lubberink<sup>1</sup>

<sup>1</sup>*Uppsala University, Department Of Surgical Sciences-Radiology, Uppsala, Sweden*

**Abstract text**

In recent years, a lot of effort has been put into harmonization of clinical PET procedures with <sup>18</sup>F-fluorodeoxyglucose (FDG) in oncology. For example, the European Association of Nuclear Medicine's EARL accreditation program aims to ensure comparable quantitative results among patients and sites, and as such provide quality assurance for multi-center trials. This lecture will cover the use quantitative imaging with PET-CT and PET-MR, especially related to the use of PET in multi-center trials concerning dose planning and treatment response monitoring.

First, the concept of quantitative PET will be discussed. PET is unique amongst medical imaging techniques in its ability to absolutely measure a wide range of molecular and physiological biomarkers. These quantitative measurements are based on time-varying measurements of radioactivity concentrations and the tracer kinetic models that describe the in-vivo behaviour of PET tracers. This will be illustrated using its most common application, measurement of glucose metabolism using FDG. The simplifications necessary to use these methods clinically in radiation oncology will be addressed, such as standardized uptake values (SUV), and the challenges associated with them both in terms of biology and instrumentation. Then, the harmonization efforts to ensure comparable SUV measurements between different scanners and hospitals will be discussed. PET-MR provides additional challenges in quantification associated with the limitations of MR-based attenuation correction. Improvements in quantification using recent developments in instrumentation, such as digital PET detectors and time-of-flight, and novel image reconstruction methods, will be reviewed in the context of multi-center studies in oncology.

Finally other tracers than FDG and their possible quantitative applications in radiation oncology will be presented, such as those measuring hypoxia, proliferation, blood flow and oxygen consumption.

**SP-0469 Mitigation of range uncertainties with probabilistic IMPT optimization**

M. Bangert<sup>1,2</sup>, N. Wahl<sup>1,2</sup>, H. Wieser<sup>2,3,4</sup>

<sup>1</sup>*German Cancer Research Center Dkz, Medical Physics In Radiation Oncology, Heidelberg, Germany* ; <sup>2</sup>*Heidelberg Institute Of Radiation Oncology Hiro, Heidelberg, Germany*; <sup>3</sup>*German Cancer Research Center, Medical Physics in Radiation Oncology, Heidelberg, Germany*; <sup>4</sup>*Heidelberg University, Faculty For Medicine, Heidelberg, Germany*

**Abstract text**

At the time of planning it is impossible to estimate the range of charged particles within a patient with absolute certainty. Due to, among others, inevitable limitations in

computed tomography imaging and patient motion, particles stop at different geometric locations during treatment than predicted during dose calculation. This may heavily compromise the quality of the computed treatment plan.

Conventional radiation therapy planning does not explicitly model this range uncertainty, usually relying only on a single "best-guess" scenario for dose optimization. Probabilistic optimization, in contrast, may incorporate explicit assumptions about the probability distribution over range uncertainty. Thereby it is possible to reduce a potentially deteriorating impact of uncertainties within a structured probabilistic optimization process.

The first part of the presentation will give a thorough introduction to the fundamentals of probabilistic optimization in radiation therapy planning. This includes (1) intuitive visualizations on how uncertainty in particle ranges translate into uncertainty in the dose, depending on different correlation and fractionation assumptions, and (2) a brief overview of facilitated objective functions for probabilistic optimization.

Within the second part of the presentation we will discuss advantages and disadvantages associated with probabilistic optimization in radiation therapy as compared to conventional optimization and robust ("worst case") optimization. In particular, this includes an illustration of the challenges associated with probabilistic and robust optimization regarding the exact control of the robustness level of the optimized treatment plans. In the third part of the presentation we will elaborate on prerequisites for exact uncertainty control within probabilistic radiation therapy optimization with regard to (1) the underlying uncertainty models, (2) the facilitated uncertainty quantification pipeline, and (3) the mathematical formulation of the uncertainty minimization algorithms. We will show how this issue is currently addressed within the academic community using e.g. Gaussian Processes, Polynomial Chaos Expansion, and Analytical Probabilistic Modeling.

**Abstract text**

*Introduction*

Dual energy CT (DECT), Multi energy CT (MECT) and Photon Counting Detector CT (PCD-CT) have been investigated for their ability to improve the accuracy of the stopping power ratio (SPR) estimation, which is used in the treatment planning process for proton therapy. Especially DECT has been intensively investigated. Most DECT based methods have been shown to provide better results for the SPR estimation than the conventional method based on single energy CT (SECT). The CT number and the SPR are both proportional to the electron density of the tissue whereby they are also proportional to each other. This is exploited in the standard SECT based SPR estimation. However, the proportionality factor is not constant. This has been considered by making a piecewise linear fit between the single energy CT number and the SPR, approximating the proportionality factor with a local constant. Using DECT or even MECT and PCD-CT this approximation is not needed, directly, but approximations are still exploited. Some of these SPR methods are more empirical than others, but often their parameter fitting is

less ambiguous than the empirical SECT based stoichiometric method.

#### Methods and Materials

To investigate the accuracy of SPR estimation methods, experimental validation was performed on organic tissues. Measurements of the proton range were made with pristine pencil beams, and CT scans were acquired in SECT and DECT mode, as well as PCD-CT mode. Firstly, the SECT scans were evaluated with a clinical stoichiometric conversion curve, and the DECT scans were evaluated with commercial DECT software. The SECT and DECT scans were later re-evaluated with our own implementation of (other) SPR methods. No software is available for evaluation of SPR estimation based on PCD-CT scans and these were therefore evaluated with our own implementation of different SPR estimation methods. The accuracy of the methods was evaluated based on the root-mean-square error (RMSE) and the mean error, with main focus on the RMSE as too few tissues were examined to assume Gaussian distributed errors.

#### Results

It was found that DECT was superior to SECT, following the trend of other recent investigations. However, re-evaluation using another implementation of the stoichiometric curve, it was found that the SECT based SPR estimation error could be significantly reduced (Table 1). The mean errors stayed lower for the DECT based methods. The same tissues (a subset) were scanned with a PCD-CT scanner, acquired in four, two and one energy bin mode. For the one-bin images the stoichiometric method was applied, here the result was consistent with the second implementation for SECT (compare Table 1 and 2). Two different SPR methods developed for MECT and a DECT method were tested. The results for all the methods were comparable (Table 2).

#### Discussion

In the comparison of SECT and DECT (Table 1), the fitting of the second stoichiometric curve was not guided by the measurements of the organic tissues. This shows that when comparing any DECT or MECT based SPR method to the SECT based stoichiometric method an effort should be made to improve the stoichiometric curve to have a fair comparison. More importantly, it shows that SECT based SPR estimation as applied in most proton centers today can provide fairly good results, but the curve fit should be carefully considered. At best, it should be experimentally validated to ensure the connection points between the individual line sections are placed appropriately; generally, more than two line sections are needed. Moreover, it was found that the stoichiometric curve could also be improved by implementing different methods for estimating the CT numbers of the literature data for the reference human tissues (first step of the stoichiometric method). The standard stoichiometric method was based on an empirical parametrization of the linear photon attenuation coefficient, which is less accurate for high density tissues. The second method applied a CT number estimation was based on effective energies for the x-ray energy spectrum, which improved the accuracy (Table 3). DECT and PCD-CT provided low errors for the SPR estimation of the organic tissues, but it was found that two-bin PCD-CT images were sufficient, and a further increase of the number of energy bins was not needed. It has previously been shown that three or four CT numbers improved the accuracy above the results for DECT. However, for our experimental results this was not the case, which most likely can be explained by the favorable energy separation which can be obtained using two-bin PCD-CT scans. In conclusion, DECT, MECT and PCD-CT can improve the SPR accuracy compared to SECT. But until these CT techniques can be used in commercial treatment planning software, improvements of the SPR estimation can be obtained by carefully fitting the stoichiometric method, and optimization of the CT scanning protocols.

**Table 1:** SPR accuracy in experimental evaluation based on fourteen organic tissues for comparison of SECT vs DECT. The results are stated as root-mean-square errors (RMSE) and mean errors.

SPR methods – SECT vs DECT	RMSE (%)	Mean (%)
SECT version 1	2.8	-0.6
DECT method 1	1.3	-0.3
SECT version 2	0.8	-0.6
DECT method 2	0.9	0.2

**Table 2:** Results for SPR estimation based on PCD-CT compared to measured SPR for nine organic tissues.

SPR methods – PCD-CT	RMSE (%)	Mean (%)
4 energy bins, PCD method 1	1.0	0.3
4 energy bins, PCD method 2	0.8	-0.7
2 energy bins, PCD method 1	0.8	0.1
2 energy bins, DECT method	1.3	0.1
1 energy bin, SECT method	0.8	-0.1

**Table 3:** CT estimation accuracy. Results presented in the upper part of the table is based on the accuracy of the CT number estimation for tissue equivalent phantom materials. The lower part of the table present SPR accuracy for the stoichiometric method applying the two different CT number estimation methods, evaluated on the fourteen organic tissues.

CT number estimation	RMSE (%)	Mean (%)
X-ray attenuation parametrization	3.1	-1.2
Effective energies	0.2	0.0
SPR estimation	RMSE (%)	Mean (%)
X-ray attenuation parametrization	0.7	-0.2
Effective energies	0.5	-0.1

#### SP-0471 Treatment Planning and Verification with Proton CT and Proton Radiography to Reduce Range Uncertainties in Proton Therapy

R. Schulte<sup>1</sup>

<sup>1</sup>Loma Linda University, Division of Biomedical Engineering Science- Department of Basic Sciences, Loma Linda, USA

#### Abstract text

Proton CT was originally proposed as a low-dose imaging modality by physicist Allan M. Cormack, winner of the 1979 Nobel Prize in Physiology or Medicine. Cormack had in mind to use protons for diagnostic imaging instead of x-rays but was discouraged by the need for large accelerators, rotating gantries, and other expensive equipment, besides the difficulties imposed by multiple Coulomb scattering. The real value of pCT became apparent with the expansion of proton therapy; currently, there are 27 proton treatment centers operational in the United States. Proton CT (pCT) provides artifact-free images of the true relative stopping power values of the patient tissues (not converted from x-ray CT HU), thus avoiding the uncertainties in HU-to-RSP conversions. The use of pCT in treatment planning would reduce distal margins added to clinical proton beams and allow the use of beam directions where the beam stops near critical organs at risk like brain stem and optic chiasm. In this presentation, the possible technological realizations of proton CT scanners, all still at the preclinical stage and ranging from single-particle tracking systems operating in list-mode data acquisition to simpler technology using equipment already in use in the clinic. Proton radiography can be used as a pre-treatment verification of water-equivalent range-checking tool for each treatment field. In addition, proton CT may be used for pretreatment volumetric imaging and treatment adaptation, thus closing the gap in image guidance with respect to photon therapy.

#### SP-0472 Accounting for organ motion in proton therapy at the planning stage

**SP-0473 Stereotactic radiosurgery for brain metastases: treating multiple lesions**

A. Williamson<sup>1</sup>

<sup>1</sup>Beatson West Of Scotland Cancer Centre, Radiotherapy, Glasgow, United Kingdom

**Abstract text**

Stereotactic radiosurgery (SRS) has become an increasingly utilised treatment option in the initial management of patients with brain metastases. Its efficacy has been well demonstrated with a local control rate of >75% at 1 year with minimal treatment related toxicity. Novel plan optimisation and treatment delivery platforms for linear accelerator-based SRS techniques have shown that single isocentre SRS for multiple targets can be efficiently delivered without increasing the dose to organs at risk. Evolving radiation therapy and imaging technology has increased interest in SRS for hypofractionated stereotactic radiotherapy (HFSRT) for large metastases and for lesions close to organs at risk (e.g. the brainstem).

The aim of this presentation is to review and discuss results of selected SRS studies in light of technological advances and the emerging clinical needs. The session will include discussion on the optimal technique for delivery, including; different treatment platforms and technologies, treatment planning methods, methods of dose prescribing and calculation of appropriate margins. New and emerging evidence will be presented with an overview of future areas of interest.

**SP-0474 Linac isocentric accuracy and its influence on treatment margins**

<sup>2</sup>Haaglanden Medical Centre, Medical Physics, Den Haag, The Netherlands

**Abstract text**

The majority of linear accelerators used for radiotherapy is isocentric. Their design is such that the three major rotation axes, for rotation of collimator, gantry and table, pass through one point, the isocenter. Several factors hinder the ideal situation of an isocenter having a fixed position in space. As a result the location of the tumor with respect to the beam's central axis is displaced due to gantry, table or collimator rotation. The isocentric accuracy is an important parameter in stereotactic treatment, as it is a major determinant of the treatment accuracy.

Measurement of isocentric accuracy is part of the quality assurance program. Ideally, it should be carried out quickly, and, considering the requirements on accuracy, have high spatial resolution.

We developed a procedure to measure isocentric accuracy, based on the Winston-Lutz test. To quantify isocentric accuracy due to gantry rotation (no table rotation) a ball bearing was imaged at various gantry and collimator angles. The accuracy of the procedure was established and found to be better than 10 µm. Several system quality parameters could be derived from these measurements, such as:

-Lateral vs. longitudinal excursion of isocenter due to gantry rotation

- EPID tilt
- Field size
- Position of beam focus, and the influence of beam steering
- MLC symmetry

The influence of inaccuracies of table rotation are mainly due to differences in location of collimator rotation axis vs. table rotation axis, as a function of table rotation angle. A simple procedure to measure this distance is discussed. The consequences of such an inaccuracy are variations in coincidence of the beam central axis and the target position in the patient. These should be accounted for by including its effect in the treatment margins that are applied. A procedure to calculate the contribution to treatment margins is given and discussed using results of our linacs.

**SP-0475 Communication care and side effect - brain radiotherapy - What's the role of the RTT?**

H. Simonsen<sup>1</sup>

<sup>1</sup>Nurse, Radioterapi, Aarhus, Denmark

**Abstract text**

Abstract Estro April 2019 Presenter: Hanne Simonsen, Department of Oncology, Aarhus University Hospital, Denmark. Topic category: Cancer care. Key words: Patient care, side effects and communication. Presentation preference: Oral, I am an invited speaker. Title: Individual network meetings in cancer care -From young people with cancer to adults with brain tumours Purpose/objective: The aim of the network meetings is to facilitate the involvement of a supportive social network around the patient and relatives. A malignant brain tumour often includes cognitive impairment. This affects both patients and families. Compared to other cancer patients, studies show that they are significantly in more need of social support and help for everyday activities. A network focused approach offering individual network meetings with and for young people with cancer has shown to facilitate the involvement of a social network around the patient and the family, with can assist them in keeping their world together. Methods: A participatory action research design was employed to develop and implement a researched based service that would promote and encourage a supportive social network for patients with primary brain tumours and their families. Patients and close relatives preferences and attitudes towards an offer of a network meeting were explored. The study involved parallel processes of interviews with patients and usually their spouses, education and interaction between the researcher and a group of ten clinical nurses. Results: Based on the findings the individual network meeting for patients with brain tumours has been shaped to fit their needs and wishes and are now fully implemented in the clinic. A group of nurses has been trained in planning and leading network meetings and acts as implementation agents. Early presentation of individualised network meetings is welcomed as an opportunity and accepted by about 40 % of the patients and relatives. Conclusion: Network meetings are feasible in clinical practice. They are highly valued by patients, who has participated and their social network. The interactive approach in action research has supported the implementation of the complex service - a service which has potential in other nursing areas. The presentation will focus on preparing and conducting network meetings.

**PV-0476 Effect of updated ICRU90 data on Monte Carlo kQ calculations: results from the Australian PSDL**  
M. Hanlon<sup>1</sup>, C. Oliver<sup>1</sup>, T. Bailey<sup>1</sup>, J. Lye<sup>2</sup>, D. Butler<sup>1</sup>

<sup>1</sup>Australian Radiation Protection and Nuclear Safety Laboratory, Primary Standards Dosimetry Laboratory, Melbourne, Australia ; <sup>2</sup>Australian Radiation Protection and Nuclear Safety Laboratory, Australian Clinical Dosimetry Service, Melbourne, Australia

### Purpose or Objective

The publication of the updated key data for ionizing-radiation dosimetry in ICRU90<sup>1</sup> includes changes to the mean excitation energy (I-value) of graphite and water, and the renormalised photoelectric cross sections. Both of these changes will affect the Monte Carlo calculated beam quality correction factor  $k_Q$ , which is being considered with the update to TRS-398. Here, we have modelled the change that the ICRU90 data has on  $k_Q$  for several common ionisation chambers.

### Material and Methods

All modelling was done in the EGSnrc c++ user code egs\_chamber. Various ionisation chambers commonly calibrated by the Primary Standards Dosimetry Laboratory (PSDL) at ARPANSA were modelled (Including the NE 2571, PTW 30013, IBA FC65-5, ICA CC-13, and the Exradin A12) according to detector specifications from obtained from the manufacturers, including accurate modelling of the stem. Two source inputs have been used; a commissioned full linac head model (6, 10, 18 MV) and tabulated photon source spectra from both published results (4-25 MV) and results from the ARPANSA modelled linac. The dose to the air cavity in the chamber and the dose to water were scored at 5 cm depth in <sup>60</sup>Co beams and at 10 cm depth in MV photon beams, as per the IAEA TRS-398 protocol, and the ratio used to calculate  $k_Q$ . The simulations were repeated with the previous (ICRU37) and updated (ICRU90) key datasets.

### Results

All simulations were run until a combined uncertainty from all four measurements was <0.1%. All simulations compare well to TRS-398, agreeing within similar ranges to other published studies. When using the ICRU37 data, results agreed with published values<sup>2</sup> to within 0.4%. When comparing the same inputs with the updated ICRU90 data, the values for  $k_Q$  were on average 0.2% higher/lower, indicating that the impact of the updated data from ICRU90 has a small effect on  $k_Q$ , which agrees with other published works. Figure 1 shows the calculated values for the NE-2571 ionisation chamber, including the difference. The difference of 0.2% is small, and within the 1% uncertainty quoted in TRS-398.

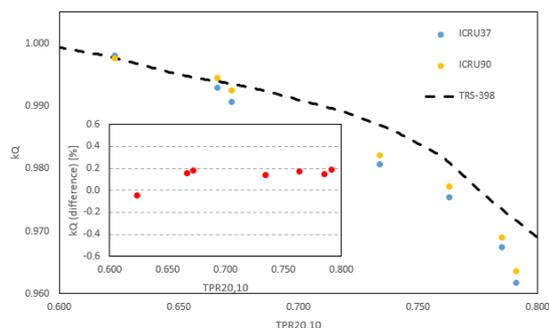

Figure 1: Calculated  $k_Q$  values for the NE-2571 ionisation chamber using ICRU37 and ICRU90 data, with the differences (positive shows ICRU 90 is higher than ICRU37) between the two datasets.

### Conclusion

Several ionisation chambers have been successfully modelled, allowing for the beam quality correction  $k_Q$  to be calculated. We have shown good agreement with published protocols and published Monte Carlo studies.

The updated ICRU90 data has a small effect on  $k_Q$ , in the order of 0.2%, but this is well within the quoted uncertainty associated with  $k_Q$  in TRS-398 of 1%.

### PV-0477 A Monte Carlo study of collimator angle dependence of extra focal dose during VMAT

F. Ghareeb<sup>1</sup>, J. Lencart<sup>2</sup>, J. Oliveira<sup>1</sup>, J. A. M. Santos<sup>1,2,3</sup>  
<sup>1</sup>Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Medical Physics- Radiobiology and Radiation Protection Group- IPO Porto Research Center CI-IPOP, Porto, Portugal; <sup>2</sup>Instituto Português de Oncologia do Porto Francisco Gentil- EPE, Medical Physics, Porto, Portugal; <sup>3</sup>University of Porto, Instituto de Ciências Biomédicas Abel Salazar ICBAS, Porto, Portugal

### Purpose or Objective

Patients undergoing 3DCRT radiotherapy using linac head equipped with HD120MLC are subjected to out-of-field transmitted localized extra-focal dose (LEFD) in a very specific region in the direction perpendicular to the MLC leaves motion direction [1]. The goal of this work is to study the effect of collimator rotation angle on the location and the magnitude of the extra-focal dose regions in case of VMAT using Monte Carlo (MC) technique.

### Material and Methods

Several VMAT treatment plans were created using Varian Eclipse TPS for the same hypothetical abdominal lesion. The plans were based on a whole-body CT dataset of a pediatric anthropomorphic phantom (CIRS, ATOM model 705-C, Norfolk, VA). Each plan consisted of two 6 MV full arcs and they were optimized to achieve the same PTV and OAR objectives with different collimator rotations ranged from 0°(360°) to 50°(310°). The treatment plans were then simulated with Monte Carlo (MC) technique using PRIMO software. The dose out of the treatment field was evaluated using 10 spherical structures (1 cm<sup>3</sup>) located along the central axis at several distances from the isocenter (5 spheres) and along the lateral axis (5 spheres) located 7.5 cm to the right of the isocenter (Figure 1a). For each collimator angle all the mean dose values inside each spherical structure were normalized to the corresponding mean dose value inside an identical spherical structure located at the isocenter.

### Results

The localized extra focal dose distribution is located after 11 cm from the isocenter in the direction perpendicular to the leaves motion direction. At 0° of collimator rotation a cylindrical dose distribution with a diameter equal to the Y-jaws aperture is noticed (as shown in Figure 1b). The dose inside the cylinder is up to 3 folds of the background dose. As the collimator angle increases, the dose distribution start to decrease along the central axis and to increase at the peripheral regions (as shown in Figure 1c for a collimator rotation of 30°) until the extra focal dose disappears from all the evaluated structure at a collimator rotation > 40°. The collimator angle dependence of dose in points 1, 9 and 10 are shown in Figure 2.

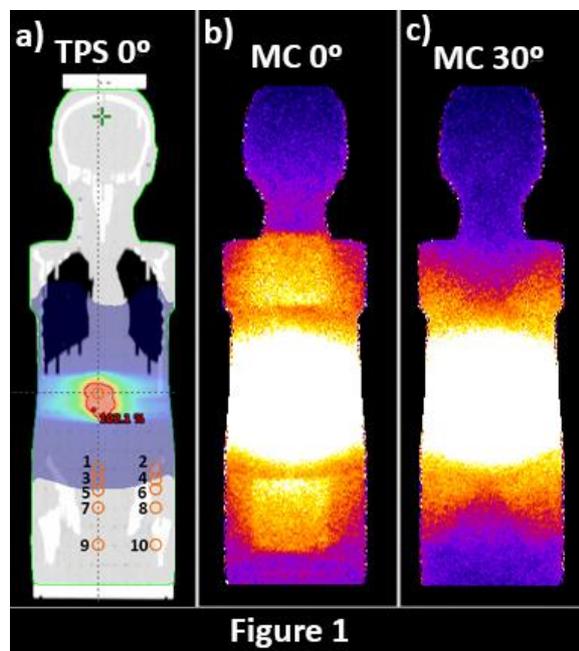

Figure 1

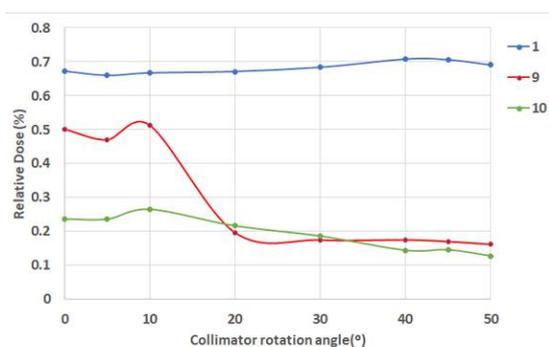

Figure 2

### Conclusion

From the above results, one notices that highly inhomogeneous out-of-field distributions in the patient can easily be achieved for different collimator rotations during VMAT irradiations. Extra precautions can be taken into consideration when treating patients with HD120MLC or other devices presenting the same behavior. To avoid directing the extra-focal radiation into a radiosensitive organ during VMAT treatment, the collimator angle can be optimized as described to avoid sensitive organs at risk. This issue is of major importance in pediatric patients.

### Purpose or Objective

To report on an upgrade of the Anthropomorphic Dynamic breAthing Model (ADAM) phantom for QA of real time respiratory tracking systems.

### Material and Methods

ADAM is a 3D printed human torso with realistic embedded ribs and spinal cord, a moving upper chest wall and simulated lungs. An Arduino programmable board, integrated in the phantom body, drives movements of lung along linear or elliptical paths and of upper chest wall up and down. Linear paths dephasing thorax motion and signals based on real patient breathing traces are implemented.

In the current version a new Tracking Tool (TT) (fig 1A) has been realized to enable accuracy tests of tracking systems based on fiducial-less tumor detection. The TT consists in four blocks, each hosting a quarter of sphere, simulating a lung-tumor structure, built using a 3D printer and different filling percentage. This results in X rays images with realistic contrast between the target and the surrounding material. The TT can host two small films and can be inserted in any position inside the phantom thorax enabling to simulate different tumor detection uncertainties, as observed in real patient cases (fig 1 B). The TT is moved by the same system used to move lungs.

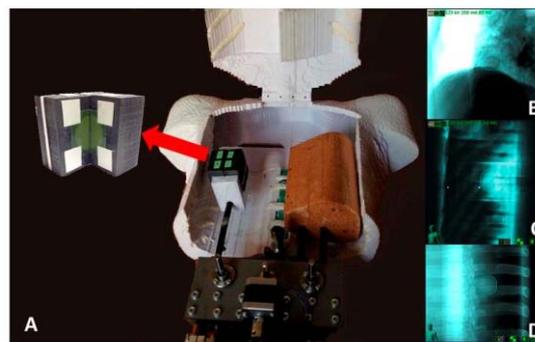

Figure 1. ADAM and a zoomed view of the Tracking Tool containing radio-chromic films. A. X-rays projections acquired with the Cyber-Knife imaging system showing detected structures in patient B, in ADAM C, and in a commercial phantom D.

ADAM and the new TT were used to perform end-to-end tests of a CyberKnife® System (Accuray, USA). An isocentric plan was created targeting the beams on the TT. Two orthogonal EBT3 films were inserted in the sphere and the plan was delivered while moving the sphere and the thorax according to: Linear, Elliptical, Linear no sync (thorax and TT motion not always synchronized), Linear patient (based on a real patient breathing) and Linear patient no tracking (with the tracking system deactivated) respiratory traces. The same plan was delivered also in static condition.

Films were analyzed using an E2E dedicated software (Accuray, USA), which provides the distance between the centroid of planned and delivered dose distributions as global tracking error. Films irradiated in static and moving conditions were compared with FilmQA™ Pro (Ashland Inc., USA).

### Results

The TT was detected by the tracking algorithm with an uncertainty (range 10%-20%) close to what observed in real patient treatments (mean 15.5%; range 5%-32). In one of the two projections, uncertainty was higher (15%-20%) due to the superimposition of a radiopaque heart-like structure (fig 1C). Tracking errors derived by the E2E software were all below 0.95 mm (range 0.6-0.9 mm). The maximum difference in tracking error between two repeated tests was 0.4 mm. In table 1 gamma passing rates obtained by comparing films acquired in dynamic and static conditions are reported. In particular  $GI_{3\%/1mm}$  (local criteria) pass-rates scored above 90% for all respiratory

traces using tracking, while dropping below 50% when the tracking system was deactivated.

Table 1. Gamma passing rates of films (lying on the sagittal plane) acquired in different dynamic conditions using films irradiated in stationary conditions as reference.

path	TT amplitude in CC [mm]	Chest wall amplitude in UD [mm]	Breathing frequency [bpm]	GI <sub>25%/2mm</sub>	GI <sub>50%/2mm</sub>
Linear	10	10	11.2	96%	97%
Linear no sync	10	10	11.2	90%	97%
Elliptical	10 (5 AP)	10	10.4	96%	99%
Linear patient	10 (max)	10 (max)	11 (max)	94%	97%
Linear patient no tracking	10 (max)	10 (max)	11 (max)	30%	45%

TT tracking tool, CC craniocaudal, AP anterior-posterior, UD up and down

## Conclusion

The new ADAM's tool demonstrates suitable performances to test, in realistic patient-like conditions, tracking systems based on soft tissue detection.

## PV-0479 Development of an anthropomorphic multimodality pelvis phantom for PET/MRI- and CT-based RT planning

## Purpose or Objective

The aim of the study is the further development of an anthropomorphic multimodality pelvis phantom (ADAM, [1]) for the integration of PSMA-PET/MRI-based treatment planning of prostate cancer patients.

## Material and Methods

CT and 3T-MRI characteristics of different tissue types are mimicked using agarose gels (Agarose NEO Ultra-Qualität Carl Roth GmbH + Co. KG, Germany) mixed with different concentrations of Gadolinium (Gd, MultiHance® 0.5 M, Bracco Imaging Deutschland GmbH) and sodium fluoride (NaF, Carl Roth GmbH + Co. KG). Gels were scanned using a 3T PET/MRI (Biograph mMR, Siemens Healthineers, Erlangen, Germany) using a saturation recovery sequence with multiple inversion times and a spin-echo sequence with multiple echo times. Based on the resulting images, T1- and T2-relaxation times were determined using in-house written software. CT scans of the agarose mixtures were performed on a stand-alone CT scanner (Somatom Definition Flash, Siemens Healthineers) at 120 kV and 390 mAs.

Agarose mixtures that agreed best with reference values derived from literature data [2-4] were subsequently doped with patient-specific activity concentrations of <sup>18</sup>F and <sup>68</sup>Ga (e.g. 3 kBq/ml <sup>68</sup>Ga and 11 kBq/ml <sup>18</sup>F for the primary tumor). Organ shells (prostate with two

intraprostatic lesions, lymph nodes and bone metastases) were printed using a 3D printer (Stratasys Objet 300 Connex 3, print material: VeroClear). The doped, liquid agarose gels were filled into the organ shells where they solidified within seconds. Organ shells were scanned at the 3T PET/MRI scanner (PET acquisition time: 10 min, MRI: T2-weighted morphological sequence).

## Results

The final compositions of agarose gels are the following (given as mass fractions of agarose/NaF/Gd): Prostate (1.35%/3.2%/0.011%), lesions (2.25%/3.2%/0.0085%) and lymph nodes (3.2%/1.4%/0.025%).

T1- and T2-relaxation times and CT numbers of the developed agarose gels fit well to reference values (Figure 1). Exemplary PET- and MR-images of a prostate with two intraprostatic lesions doped with 11 kBq/mL <sup>18</sup>F are shown in Figure 2. The PET signal can be detected and the tumors appear hypointense on T2-weighted MRI.

## Conclusion

Agarose gel mixtures with organ-specific MR-relaxation times at 3T and CT numbers have been developed and doped with radioactive tracers. The gels will be used in the pelvis phantom which will be central to simulate and optimize the technical workflow for the integration of PSMA-PET/MRI-based RT planning of prostate cancer patients.

## PV-0480 Plastic-scintillator based PET detector for proton beam therapy range monitoring: preliminary study

A. Rucinski<sup>1</sup>, J. Baran<sup>1</sup>, M. Garbacz<sup>1</sup>, M. Pawlik-Niedzwiecka<sup>1</sup>, P. Moskal<sup>2</sup>

<sup>1</sup>Institute of Nuclear Physics PAN, Proton Radiotherapy Group, Krakow, Poland ; <sup>2</sup>Jagiellonian University, Faculty of Physics- Astronomy and Applied Computer Science, Krakow, Poland

## Purpose or Objective

Proton beam therapy (PBT) range monitoring is required to fully exploit the advantages of a proton beam in the clinic. In PBT the distribution of beta+ emitters induced

by a proton beam in a patient can be detected by PET scanners, the emission distribution can be reconstructed and used for monitoring of the beam range. A prototype of a diagnostic strip-based whole-body PET scanner (J-PET) has been developed and tested at the Jagiellonian University in Krakow (Moskal et al. Phys. Med. Biol. 61 (2016) 2025-2047). The advantages of the system over commercial PET scanners is that it increases the geometrical acceptance and facilitates integration in the treatment room, off-line or in the treatment position. The aim of this work is to study a feasibility of the J-PET technology for range verification in PBT.

#### Material and Methods

A single detection module of the strip-PET scanner is constructed out of thirteen 50-cm long organic scintillator strips. The light pulses produced in a strip by gamma quanta are propagated to its edges and converted into electrical signals by silicon photomultipliers (see Fig. 1). They are read-out by fast on-board front-end electronics allowing excellent overall coincidence resolving time (CRT) of about 300 ps, which shows a significant improvement compared to the standard LSO-based PET scanners. Three different configurations of the modular system were investigated: (i) a single layer consisting of 24 modules, (ii) a two-layer consisting of 20 and 24 modules, and (iii) three-layer consisting of 20, 24 and 28 modules. GATE Monte Carlo (MC) toolkit has been used to investigate the modular JPET system efficiency for detection of beta+ annihilation back to back photons induced in PMMA target by a proton beam (see Fig. 2). A MC based comparison of a J-PET based dual head system consisting of 2x5 modules configured as two opposing heads with the clinically operated inter-spill dual-head PET system installed at CNAO (V. Ferrero et al. Sci. Rep. 8:4100 2018) has been performed.

Fig. 1.

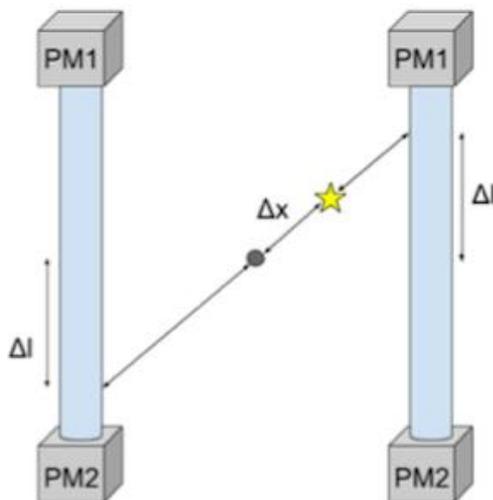

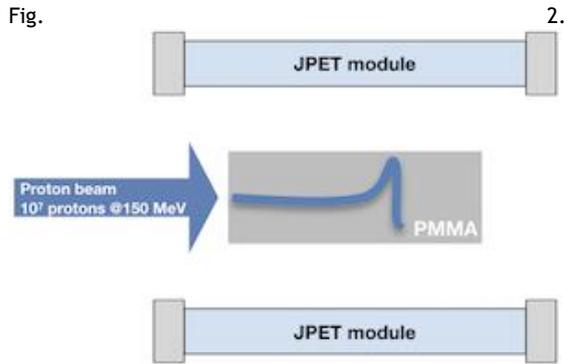

Fig.

#### Results

The efficiency of the system in the proton beam simulation increases quadratically with the number of detector layers. It ranges from 0.12% for single layer setup to 0.75% for three-layer setup. Detected coincidences per primary proton for the single layer, two and three layer modular JPET configurations is  $4.0 \cdot 10^{-5}$ ,  $1.3 \cdot 10^{-4}$  and  $2.5 \cdot 10^{-4}$ , respectively. The comparison of the dual head JPET and PET system installed at CNAO reveals comparable results.

#### Conclusion

Performed simulations suggest the signal obtained with the J-PET detector technology during proton beam therapy is sufficient for range monitoring. The results revealed that inter-spill beam range monitoring is achievable with both, dual-head and multi-layer JPET configurations. Experimental verification of the performed simulations is planned.

**PV-0481 IMRT/VMAT QA in heterogeneous media: first experience with a 2D solid-state detector prototype**  
G. Biasi<sup>1</sup>, N. Stansook<sup>1,2</sup>, M. Petasecca<sup>1</sup>, M. Carolan<sup>3</sup>, V.L. Perevertaylo<sup>4</sup>, P. Metcalfe<sup>1</sup>, M.L.F. Lerch<sup>1</sup>, T. Kron<sup>5,6</sup>, A.B. Rosenfeld<sup>1</sup>

<sup>1</sup>University of Wollongong, Centre for Medical Radiation Physics, Wollongong, Australia; <sup>2</sup>Mahidol University, Department of Radiology, Bangkok, Thailand;

<sup>3</sup>Wollongong Hospital, Illawarra Cancer Care Centre, Wollongong, Australia; <sup>4</sup>SPA-BIT, n/a, Kiev, Ukraine;

<sup>5</sup>Peter MacCallum Cancer Centre, Department of Physical Sciences, Melbourne, Australia; <sup>6</sup>University of Melbourne, Sir Peter MacCallum Cancer Institute, Melbourne, Australia

#### Purpose or Objective

Under-sampling dose distributions in IMRT/VMAT QA may potentially lead to incorrect gamma index analysis. At the present time, the spatial resolution of commercially available phantom-based array detectors is generally larger than 3 mm.

These devices are also not designed for measurements in heterogeneous media.

In this context, the present study aimed at introducing the use of a high-resolution (2 mm) 2D solid-state detector prototype 'MP512' embedded into a customized (in terms of density, dimensions, shape and location of inhomogeneities with respect to the active area of the detector) heterogeneous phantom.

#### Material and Methods

The MP512 has diode-sensitive volumes with a square area of 0.5 m side each.

They are uniformly distributed with a pitch of 2mm over a square area of 52 mm side.

The MP512 and Gafchromic™ EBT3 films were lodged into a phantom (cedar wood,  $\rho=0.38 \text{ g/cm}^3$ , to simulate lung tissue) of total thickness 5 cm with a small solid water insertion (0.5 cm radius,  $\rho=1 \text{ g/cm}^3$ , to simulate the tumour target).

We considered a lung treatment plan delivered with step-and-shoot IMRT, and a lung treatment plan delivered with VMAT.

We used the Pinnacle<sup>3</sup> treatment planning system (TPS), version 14 (Philips Medical Systems, Eindhoven, The Netherlands) and dose calculations were performed with Pinnacle's adaptive convolution-superposition (CS) algorithm with a 2 mm grid.

In all cases, fields were produced by a 6 MV flattened photon beam delivered by a Varian Clinac® iX linear accelerator equipped with a Millennium 120-multi-leaf collimator (MLC).

To assess the performance of the MP512, we used a gamma index analysis (acceptance criteria: 3%/3 mm and 2%/1 mm) considering absolute dose map measurements with the detector, with films and calculations with the TPS.

### Results

3%/3 mm: gamma passing rates (%GP) were >99% for all plans when comparing the MP512 and films, and =100% when comparing the MP512 and TPS.

2%/1 mm: %GP were >95% for all plans when comparing the MP512 and films, and >96% when comparing the MP512 and TPS.

For %GP, we found a better agreement between the MP512 and TPS than with films and TPS.

This may be explained by noise artefacts created by scanning procedures and/or film handling, heterogeneities affecting film response, or the higher spatial resolution of films.

Selected dose profiles measured with the MP512 and with films are in Figure 1.

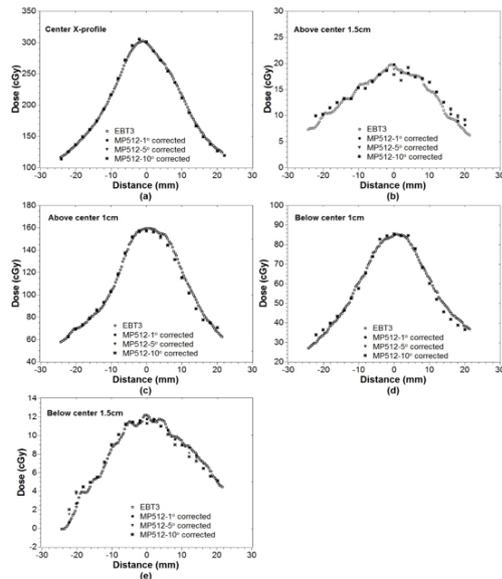

Figure 1. VMAT plan, lung: superior-inferior dose profiles measured with the MP512 and with films. Profiles are shown at the centre (a) and for different distances from the latter: 1.5 cm above (b), 1 cm above (c), 1 cm below (d), 1.5 cm below (e). The response of the MP512 was corrected for its angular dependence by applying correction factors calculated at either 10°, 5° or 1° intervals. However, results were not significantly different.

### Conclusion

Results suggest that the MP512 system has the required characteristics for high-resolution (2 mm) absolute dose maps measurements in fully-customizable heterogeneous phantoms in the context of IMRT/VMAT QA. The MP512 could potentially be used to verify dose calculations with a TPS in heterogeneous media.

### PV-0482 Dosimetric verification of Elekta MR-linac adaption workflow using 3D dosimeters

F. Costa<sup>1</sup>, I. Hanson<sup>1</sup>, S. Doran<sup>2</sup>, J. Adamovics<sup>3</sup>, S. Nill<sup>1</sup>, U. Oelfke<sup>1</sup>

<sup>1</sup>The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Joint Department of Physics,

London, United Kingdom ; <sup>2</sup>Institute of Cancer Research, CRUK and EPSRC Cancer Imaging Centre, London, United Kingdom ; <sup>3</sup>Rider University, Department of Chemistry and Biology, Lawrenceville, USA

### Purpose or Objective

The Elekta MR-linac (Elekta Unity, AB, Stockholm, Sweden) system comprises a 1.5T Phillips magnet, a 7 MV Linac and a treatment table which cannot be used to correct for target miss-positioning. An MRI scan of the patient position and anatomy is used to localize the target and adapt the treatment plan. In this work, PRESAGE® 3D dosimeters are used together with a lung phantom as an end-to-end test to verify the dose distributions obtained by following this daily adaptation workflow.

### Material and Methods

A CT scan of a dummy PRESAGE® sample (3.5 cm diameter and 5.7 cm length) placed in the central cylinder of the QUASAR™ MRI4D motion phantom was performed. The scan was transferred to Monaco (version 5.4, Elekta AB, Stockholm, Sweden) and an IMRT plan with 5 beams was calculated with a maximum dose to the target of 9.4Gy. Three irradiations were performed using different PRESAGE® samples. One sample (sample 1) was placed at the linac isocenter, verified via EPID images acquired at gantry 0° and 90°, and irradiated as per the plan. The two other samples were irradiated with the phantom away from the isocenter to test the “adapt segments” option of the MR-linac, in which the isocenter shift is accounted for by repositioning the MLC leaves to match the original plan aperture shapes. Prior to the adaptation an MRI scan of the phantom on the table was taken and registered with the planning CT. Sample 2 was irradiated with the phantom placed 3 cm away from the isocenter in the sup-inf direction, while for sample 3 the phantom was moved an additional 3 cm in the left-right direction (Figure 1).

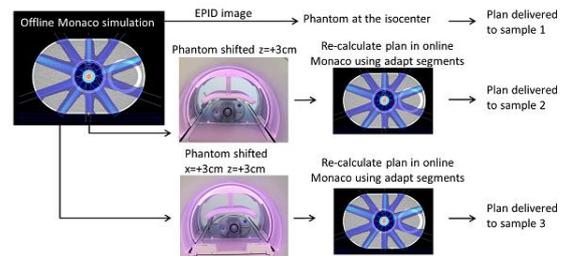

Figure 1. Scheme of the study workflow

Samples were imaged before and after irradiation with an in-house telecentric optical-CT scanner with a voxel size of  $-0.2 \text{ mm}^3$ . PRESAGE® samples have shown a higher sensitivity to radiation at the axial edges, so a correction image, which was obtained previously by uniformly irradiating samples from the same batch, was applied here.

### Results

PRESAGE® measured and Monaco simulated dose distributions agreed well with adapted plans (Figure 2). For a local gamma criterion of 2%, 2mm and 10% threshold, the gamma passing rate was 98.5% for sample 1, 99.7% for sample 2 and 98.4% for sample 3.

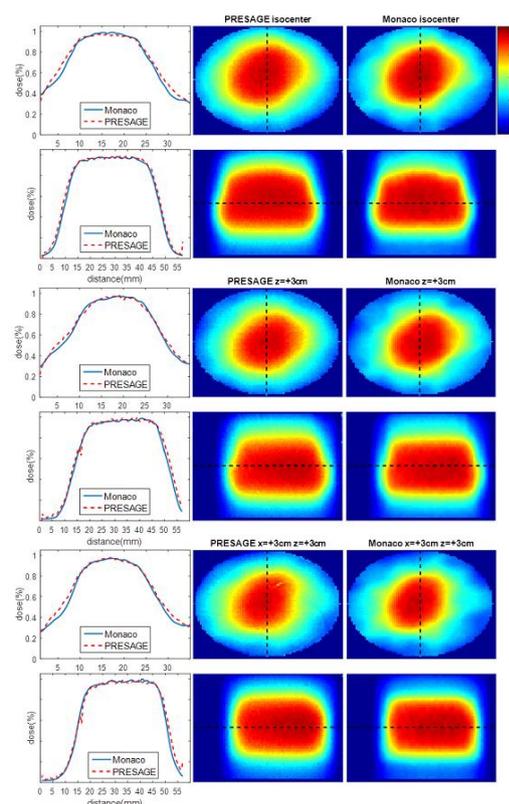

Figure 2. Axial and sagittal slices showing normalized 2D colour coded measured (PRESAGE) and simulated (Monaco) dose distribution and respective profiles given by the black dashed lined.

## Conclusion

The dosimetric accuracy of the MR-linac online adaption workflow was tested for the first time using PRESAGE® dosimeters and a phantom mimicking a tumour in the lungs. The dose distributions were accurately delivered to the target by positioning the phantom at the isocenter and by shifting it and applying the adaptive planning workflow. Complex IMRT plans will be evaluated in the future using larger samples of PRESAGE®.

## PV-0483 Pre-treatment portal dosimetry for the MR-Linac

I. Torres Xirau<sup>1</sup>, I. Olaciregui-Ruiz<sup>1</sup>, A. Mans<sup>1</sup>, U. A. van der Heide<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

## Purpose or Objective

The implementation of MRI-guided radiotherapy systems has become a reality in our clinic with the first patients being treated in the Elekta's Unity MR-Linac (Elekta AB, Stockholm, Sweden). The system introduces the possibility of real-time adaptation of the plan based on the actual anatomy of the patient during treatment. Given the complexity of the system, in combination with novel techniques for daily re-planning, the verification of the dose delivered to the patient is very important. For this purpose, the use of an Electronic Portal Imaging Device (EPID) for independent *in vivo* dose verification in the MR-Linac is being developed and the first phantom validation results are presented.

## Material and Methods

An existing back-projection algorithm used with conventional linacs was adapted for the Unity system, accounting for the increased amount of scatter received by the panel and the extra attenuation by the MR elements in the beam. The algorithm parameters were determined

by performing square field measurements under a variety of different phantom setups (varying SSD, phantom thickness and field size), which were semi-empirically fitted to EPID images of the corresponding fields. The algorithm was commissioned for three gantry angles (0, 90 and 180 degrees) and a solution to adapt the back-projection to arbitrary intermediate gantry angles was introduced and validated with phantom experiments. Phantom verification was performed for 75 IMRT fields irradiated to a solid water slab phantom at gantries 0, 90 and 180 degrees. The EPID images were back-projected to the isocenter at 10 cm depth using the model commissioned at its corresponding gantry angle. The reconstructed dose distributions were compared to 2-D measurements acquired at 10 cm depth with an ionization chamber (IC) array (OCTAVIUS 1500 PTW array).

The same IMRT fields were back-projected using a model commissioned at a different gantry angle and incorporating the gantry angle adaptation in the algorithm, and compared to 2-D measurements.

## Results

In the phantom study, the gamma results (global, 3%, 2mm, within the 10% isodose) averaged over 75 IMRT fields were  $\gamma_{\text{mean}} = 0.37 \pm 0.07$  and  $\gamma_{\text{passrate}} = 98.1 \pm 2.4$ , with an average dose difference in reference point of  $\Delta\text{DRP} = -0.5\% \pm 1.8\%$ . Gamma results for the fields reconstructed from a different commissioned gantry angle were  $\gamma_{\text{mean}} = 0.39 \pm 0.08$  and  $\gamma_{\text{passrate}} = 97.6 \pm 3.3$ , with an average  $\Delta\text{DRP} = -0.1\% \pm 1.8\%$ .

## Conclusion

We have successfully demonstrated the feasibility of back-projection portal dosimetry for the MR-Linac. Verification of IMRT fields irradiated to a phantom shows good agreement between EPID reconstructed and IC array dose distributions. The first MR-Linac prostate and rectum patients are being treated in our clinic and EPID images acquired during treatment for validation of the described method.

This research was partly sponsored by Elekta AB, Stockholm, Sweden.

## PV-0484 In vivo dosimetry using CBCT and EPID device: analysis of sources of errors in VMAT treatments

S. Bresciani<sup>1</sup>, L. Botez<sup>1</sup>, A. Miranti<sup>1</sup>, M. Stasi<sup>1</sup>

<sup>1</sup>Candiolo Cancer Institute - FPO- IRCCS, Medical Physics, Candiolo TO, Italy

## Purpose or Objective

*In vivo* dosimetry (IVD) using an electronic portal imaging device (EPID) combined with CBCT imaging may provide an effective means for quantify dose discrepancies and preventing errors in radiotherapy. The aim of this work is to evaluate the daily dose delivery discrepancies catching sources of errors in VMAT treatments with a 3D EPID-based IVD system

## Material and Methods

The IVD software PerFRACTION (Sun Nuclear Corporation) was used.

PerFRACTION is based on the information concerning MLC and collimator positions obtained by EPID images and on the information of log files, such as the MUs and the gantry angles. From these informations, a collapsed-cone/superposition algorithm (SDC) is used to calculate the dose distribution on daily CBCT images. It also uses the SDC to produce an entire dose volume to check against that from the TPS. First of all we calculated the dose discrepancies (DD%) at the isocenter (ID) and the 3D 2%/2mm gamma passing rate (% GP) between our reference (AAA) and SDC algorithm for 180 plans. About IVD, 3D dose distributions were reconstructed for 961 fractions of 133 patients, including prostates (17%), lungs (15%), Head & Neck (6%), PBI (17%), and palliatives (28%). We evaluated DD% between reference and daily

dose distribution in terms of dose to 95% of the volume ( $D_{95\%}$ ), dose to 2% of the volume ( $D_{2\%}$ ) and average dose to the target.

#### Results

We obtained for ID an average DD% equal to  $(1.8 \pm 0.9)\%$  and an average %GP equal to  $(98 \pm 2)\%$ . For IVD, the mean DD% was equal to  $(-1.6 \pm 5.4)\%$  for  $D_{95\%}$ ,  $(1.0 \pm 1.7)\%$  for  $D_{2\%}$ , and  $(0.3 \pm 1.8)\%$  for average dose. 74% of fractions showed DD% inferior to 2%. For 16% and 5% of the analyzed dose points, DD% was greater than 3% and 5%, respectively. Dose failures occur mainly in air-tissue interfaces and in superficial regions, in fact the deviations greater than 5% were observed in lung patients (30%), partial breast irradiation plans (27%) and palliative treatments (20%). For the 57% of fractions the delivered dose is higher than calculated one. For the fractions that exceed 3%, the errors are due to setup (29%), patient anatomy (40%), setup + anatomy (27%) and bolus positioning (4%). Among set-up errors, 48% is due to SSD variations, 5% are rotational errors, 12% are errors due to difficult art and shoulder positioning, and 35% is due to weight variation. No machine-based errors were observed for these patients.

#### Conclusion

EPID-based IVD is a powerful method to catch and quantify delivery discrepancies during radiotherapy process.

---

#### SP-0485 Hypofractionation from a radiobiological perspective

M.R. Horsman<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. Experimental Clinical Oncology, Aarhus C, Denmark

#### Abstract text

Hypofractionation is the application of dose fractions larger than the conventional 2 Gy per fraction. It includes moderate doses per fraction of approximately 3.5 Gy routinely used with curative intent, as well as stereotactic treatments with a few large fractions that has been widely applied in palliative radiotherapy, but now suggested to have a curative application, especially for oligometastases. Radiobiologically, when compared to conventional fractionation, hypofractionation would be expected to lower the therapeutic ratio between tumors and late-responding normal tissues. However, technological advances in image guidance and treatment delivery can reduce the dose delivered to normal tissues, allowing tumors to receive higher doses per fraction. There are reports that in addition to direct cell killing seen with high doses per fraction, one also finds dose-dependent secondary cell death that occurs following the induction of vascular damage. However, this is controversial, because changes to the tumour microenvironment (i.e., increased hypoxia) seen following vascular damage are not always apparent after stereotactic irradiation. In fact, hypoxia in tumours, a known factor for resistance to conventional radiotherapy, may play a more significant role with stereotactic radiation. These vascular and microenvironmental effects may depend on the dose per fraction. Recent studies suggest that high-doses per fraction has the potential to induce an immune response that not only improves response of the primary tumor, it also has the potential to cause an abscopal effect. However, the radiation dose and number of fractions necessary to induce this effect is unclear. In this presentation, we will review some of these radiobiological issues associated with hypofractionation and discuss how they can play a role in future radiation therapy.

Abstract not received

#### SP-0487 How we deliver extreme-hypofractionated radiotherapy with current technology - a physicist perspective

J. Cuijpers<sup>1</sup>

<sup>1</sup>Amsterdam University Medical Centers, Radiation Oncology Department, Amsterdam, The Netherlands

#### Abstract text

The successful clinical implementation of hypofractionated radiotherapy is strongly connected to current advances in treatment technology that enable the safe and precise delivery of high fraction doses to the target with optimal sparing of the adjacent healthy tissue. This starts with a reliable definition of the target volumes and organs at risk using multimodality pretreatment imaging incorporating breathing motion for tumors in the lung or abdomen. Advanced dose delivery techniques, like multiple field IMRT or VMAT, using complex shaped beam portals are applied to achieve steep dose gradients outside the target. This sets high demands on dose planning, especially for small targets in low density lung tissue, and machine performance. Due to the multi-directional or rotational beam setup high beam energies are becoming of less importance, but instead the use of flattening filter free modalities will be important for reduction of treatment times for the delivery of high fraction doses. Of utmost importance is a reliable positioning of the tumor before but also during treatment using on-line image guidance, setting high standards in accuracy and precision for IGRT equipment. This is even more important in the case of hypo-fractionation since the dose averaging effect of geometric random errors does not occur if only a few fractions are administered. Ultimately, if the superior soft tissue contrast of MRI is required, an integrated MR-treatment unit will allow to meet these requirements. Also, demands for quality assurance programs and the necessary equipment will be affected by the requirements for high-precision hypo-fractionated treatments. The consequences on how this affects the program of requirements for radiotherapy equipment will be discussed in this presentation.

#### SP-0488 What's the impact of extreme-hypofractionated radiotherapy in operating a radiotherapy department - an RTT perspective

Y.M. Tsang<sup>1</sup>

<sup>1</sup>Mount Vernon Cancer Centre, Radiotherapy, Northwood Middlesex, United Kingdom

#### Abstract text

Radiotherapy plays a key role in cancer management. The conventional radiotherapy treatment course is divided into a number of small doses called fractions, which are usually given once a day, Monday to Friday, over a number of weeks. Currently, there is a wide range of radiotherapy fractionation schemes available clinically based on treatment intents and disease sites. Hypofractionation, the delivery of a course of radiotherapy using a smaller number of fractions with a higher dose of radiation within each fraction than what is given conventionally as 1.8 - 2Gy, is increasingly studied and adopted for clinical use. In the last decade, there have been rapid changes and progressive developments in the technology used for

planning and delivery of radiotherapy. Intensity modulated radiotherapy and volumetric modulated arc therapy are now commonly implemented for clinical use. Combining the concept of hypofractionated radiotherapy and the use of image guided radiotherapy, these advanced highly precise treatment techniques can be utilised to deliver ablative doses of radiation to tumours while sparing the surrounding normal tissues as commonly known as stereotactic radiotherapy.

Hypofractionated high dose per fraction requires greater clinical, dosimetric and geometric accuracy. Interval between fractions and gaps in radiotherapy schedules can be critical in maintaining the overall treatment outcome. With the introduction of advanced radiotherapy technology, this has increased the complexity of the treatment process resulting in a shift in types and levels of responsibility taken between clinicians, physicists and radiation therapists (RTTs). It provides an opportunity for RTTs to extend their roles and scopes of practice. RTTs should understand the scientific basis and clinical rationale of extreme-hypofractionated radiotherapy and the importance of accurate delivery to tackle both systematic and random errors in this setting. Development of a comprehensive training and competency assessments is an essential aspect of introducing a culture of accuracy in the advanced hypofractionated radiotherapy delivery, irrespective of resource constraints. Before implementing advanced hypofractionated radiotherapy, an institution should review its resources and working practices to define the level of accuracy that is realistically achievable. The number of patients who can be treated accurately within a given time frame and the level of complexity that can be safely implemented into daily practice should be considered. All of these will be discussed in this presentation with the aim to explore the perceived impact of extreme-hypofractionated radiotherapy in operating a radiotherapy department with a RTT's perspective.

**Debate: Which is the best technique for the delivery of APBI?**

---

**SP-0489 This house believes that the EBRT is the best technique**

C. Coles<sup>1</sup>

<sup>1</sup>University of Cambridge, Oncology, Cambridge, United Kingdom

**Abstract text**

External beam partial breast radiotherapy: Is non-inferior to whole breast radiotherapy with excellent local control rates, DFS and OS and is the only technique whereby patients have reported better breast appearance and less late side effects<sup>1</sup>.

Can be given in just 5 daily outpatient treatments as illustrated by the UK FAST Forward trial 3-year toxicity results and is non-invasive.

Does not require specialist training and is therefore far more accessible for patients.

Uses existing standard equipment and this simple technique can be implemented in all radiotherapy centres worldwide with no/minimal additional resources.

Partial-breast radiotherapy after breast conservation surgery for patients with early breast cancer (UK IMPORT LOW trial): 5-year results from a multicentre, randomised, controlled, phase 2, non-inferiority trial. *Lancet* 2017 Sep 9;390(10099):1048-1060.

**SP-0490 This house believes that the multicatheter brachytherapy is the best technique**

V. Strnad<sup>1</sup>

<sup>1</sup>University Hospital Erlangen, Dept. Radiation Oncology, Erlangen, Germany

**Abstract text**

**Purpose:** To analyze the facts about adjuvant interstitial brachytherapy-based Accelerated Partial Breast Irradiation (APBI) after breast conserving surgery in terms of clinical experience, quality assurance and clinical results. **Methods and Materials:** The multicatheter brachytherapy is unique among the different techniques of APBI for a lot of reasons. The author analyses in a matter-of-fact and detailed fashion the facts in this context: 1. *High Quality assurance and reproducibility*; 2. *Technique with the longest experience among all APBI techniques*; 3. *Level 1 evidence - excellent efficacy - the same whole breast irradiation (WBI)*; 4. *Level 1 evidence - lower incidence of late side effects in comparison to WBI*; 5. *Level 1 evidence - better Quality of Life (QoL) in comparison to WBI*; 6. *In comparison to APBI using different external beam therapy techniques the multicatheter brachytherapy reduces in majority of anatomic scenarios significant doses to all relevant organs at risk.*

**Results**

The published data imposingly demonstrate the very long experience of brachytherapy as a technique for APBI. The first Phase II APBI-trials were started more than 20 years ago and over the same time the basic rules of image-guided multicatheter brachytherapy techniques have been developed and guidelines published. Long-term follow-up outcomes in two Phase 3 trials show that APBI using multicatheter brachytherapy yields equivalent local control, disease-free survival, and overall survival after breast-conserving treatment compared with conventional whole-breast irradiation. In large multicentre GEC-ESTRO trial after median follow-up of 6.6 years exceptionally low overall recurrence about 1% at 5 years in both treatment arms has been reported (p=0.4). Analogous also 5-year disease-free survival was 94,5% with whole-breast irradiation and 95% with APBI (p=0.8) and breast cancer-related mortality did, hitherto, not differ between groups (four events vs four events; p=0.8). Furthermore 5-year toxicity profiles and cosmetic results were similar in patients treated with breast-conserving surgery followed by either APBI with interstitial brachytherapy or conventional whole-breast irradiation, with significantly fewer grade 2-3 late skin side-effects after APBI with interstitial brachytherapy. APBI with multicatheter brachytherapy is also associated in general with equal quality of life (QoL) compared with whole-breast irradiation, but in details moderate, statistically and clinical significant difference of QoL between the groups was found in the breast symptoms scale in favour for brachytherapy based APBI. In addition to it the published dosimetric comparisons of different APBI techniques described, that the multicatheter brachytherapy in comparison to external beam based APBI-techniques reduces in majority of anatomic scenarios significant the mean doses to all relevant organs at risk and in consequence the multicatheter-based APBI is able to reduce significant as well deterministic as the stochastic late side effects in all surrounding organ at risk as heart and lung.

**Conclusions**

Summarizing the facts available to date it is obvious that APBI using brachytherapy techniques works excellently. No other technique of APBI is supported by such robust, broad positioned and encouraging data. In addition to it comparing the dose distributions of different APBI techniques, and given the long-term experience and excellent clinical results the high adaptability, versatility, precision, quality and reproducibility of brachytherapy

based APBI is also proven. All these facts should be a stimulus for radiation oncologists to make available brachytherapy based APBI worldwide for each suitable patient with early breast cancer.

**SP-0491 For which patient which technique is the best from view of the physicist?**

T. Major<sup>1</sup>

<sup>1</sup>National Institute of Oncology, Radiotherapy, Budapest, Hungary

**Abstract text**

Accelerated partial breast irradiation (APBI) can be performed with various techniques including both brachytherapy (BT) and external beam radiotherapy (EBRT) having different dosimetric characteristics. All methods are clinically feasible and there is no „one size fits all” technique. The best technique depends on patient anatomy and tumour location. However, the choice for treatment in the institutions mostly depends on the physician's preference and the technical availability.

Among all techniques multicatheter interstitial BT (MIBT) has the longest experience. MIBT can provide highly conformal dose distribution, large dose gradient at target edge, low doses to organs at risk (OARs), but a possible geometric miss can result in significant under dosage of the target.

Technically, the use of single-entry intracavitary applicators is easier. With balloon-type applicators no geometric miss can occur, but proper tissue conformance is not always guaranteed. With multi-lumen balloons sphere-like target volume with limited asymmetric margins can be irradiated, and the dose modulation potential is modest. In some anatomical situation the balloon can be asymmetric resulting in asymmetric target coverage. The intracavitary hybrid applicators are more flexible regarding shaping the dose distribution and reducing dose to OARs without compromising the target volume coverage.

During intraoperative radiotherapy (IORT) large dose is given in one fraction without imaging and 3D treatment planning. In intraoperative electronic BT using spherical applicator the dose distribution is also spherical and a large dose inhomogeneity develops due to the sharp dose fall-off of the low energy X-ray beam. The margin is always symmetric, but the geometric accuracy is always ensured.

At IORT with electron beam dose modulation possibility to shape the dose distribution is very limited. Standard dose distributions are used, the thoracic wall is protected with a physical device and the skin with retraction.

Linear accelerator based EBRT techniques expose relatively large volumes of non-target breast to high dose mainly due to the extended target volume created from CTV. In three-dimensional conformal radiotherapy (3D-CRT) dose to contralateral breast, lung or heart can be reduced with proper selection of beam orientations. With intensity modulated radiotherapy (IMRT) highly conformal dose distribution can be achieved, but volumes irradiated by low doses can be larger than with 3D-CRT. Regarding the dose to OARs, with MIBT the critical structures can be better spared than with 3D-CRT/IMRT except for the heart. The dose to heart in BT is strongly dependent on the location of the PTV. With image guidance in EBRT the dose to OARs can be significantly reduced due to smaller target volume. At left sided lesion the dose to heart can be considerably decreased with deep inspiration breath-hold technique.

With special EBRT devices such as Cyberknife or Tomotherapy which are equipped with image guidance smaller CTV-PTV margin can be applied which reduces the dose to OARs while maintaining proper target coverage. Real-time tracking with Cyberknife can provide good target volume coverage and spares nearby critical organs, but the treatment time is too long.

Proton beam irradiation, due to the more favourable dose characteristics of proton beam, can provide the least dose to organs at risk, but the accessibility of the technique is limited and the available data are scarce.

**SP-0492 Radiobiology of APBI: aspects and limitations**

<sup>1</sup>Fundación Instituto Valenciano De Oncología,

Department Of Radiation Oncology, Valencia, Spain;

<sup>2</sup>Fundación Instituto Valenciano De Oncología,

Department Of Radiation Physics, Valencia, Spain

**Abstract text**

Accelerated partial breast irradiation (APBI) has become a standard in early low-risk breast carcinomas. Alfa/beta around 4 is accepted for breast, what means that higher doses per fraction are recommended, and are favourable for patients due to a shorter total time of treatment in five days or less. Several techniques are being used, but with different dosimetries and different biological effects. Intracavitary procedures limit the irradiation to a certain margin from the cavity edge, but with a high gradient of dose on the surface. The volume of treatment is several times larger with external beam radiotherapy (EBRT) compared with multicatheter interstitial brachytherapy (MIBT) because a PTV must be added due to positional uncertainties. The skin and ribs cannot be easily preserved with EBRT. The accelerated schemes of EBRT with 38.5Gy in ten fractions or 30 Gy in 5 five fractions, correspond to a higher EQD2 dose than MIBT for alfa/beta 4, but the difference is greater for alfa/beta 2, chosen for late effects. We do not know if it has some impact on long term results and complications, as it happens with intracavitary devices, where rib fractures and skin necrosis are described in a small amount. On the other hand, the prescription dose with EBRT is quite homogeneous. With MIBT it corresponds with the peripheral dose, and the gradient of dose around every catheter supposes a higher biological effect inside the treated volume, but a higher risk of fibrosis. Five-year results are only the first step to know the efficacy of APBI, and longer follow-up is needed to be sure that the low total EQD2 doses are similar for EBRT and MIBT. Shorter number of fractions are under investigation, and will probably be implemented in the next future, to increase the comfort and compliance of APBI. The extremely low percentage of recurrences, under 2-3% at five years, indicates that low total doses are enough to control the remaining tumour cells after conserving surgery. Very accelerated partial breast irradiation (VAPBI) in a few or even a single fraction are promising. But the radiobiological effect is not well known and we must wait for the clinical trials to find the best option. Probably, several approaches will be useful and must be offered to each patient according to the availability, experience and preferences.

**OC-0493 CTCs in patients with brain metastases under radiotherapy: do they indicate treatment response?**

C. Petersen<sup>1</sup>, Y. Goy<sup>1</sup>, A. Krüll<sup>1</sup>, K. Pantel<sup>2</sup>, H. Wikman<sup>2</sup>, K. Borgmann<sup>3</sup>

<sup>1</sup>University Medical Center Hamburg - Eppendorf UKE, Department of Radiation Oncology, Hamburg, Germany ;

<sup>2</sup>Institut of Tumor Biology, Center of Oncology, Hamburg, Germany; <sup>3</sup>Laboratory of Radiobiology & Experimental Radio-Oncology, Department of Radiotherapy, Hamburg, Germany

### Purpose or Objective

Circulating tumor cells (CTCs) are detectable in many cancers, including breast and lung cancer, where they can have prognostic significance. However, because of the lack of a suitable detection method, there are no useful data on CTCs in patients undergoing radiotherapy. The only US Food and Drug Administration-approved methodology, the CellSearch platform, uses epithelial cellular adhesion molecule EpCAM, exploiting the positivity of carcinomas to common epithelial markers. The monitoring of CTCs under chemotherapy showed a correlation of persistent CTCs and shorter survival in breast cancer. This indicates stronger defense mechanisms in the remaining CTCs. More efficient DNA repair capacity could contribute to such stronger resistance. The aim of this study is to identify relevant DNA damage response pathways in CTCs and peripheral blood lymphocytes under radiotherapy and their possible implications for the adjustment of future therapies.

### Material and Methods

Up to now 47 patients with brain metastases of breast and lung cancer (n=21/26) receiving radiotherapy were included in the study. Blood samples were collected before, at the end of radiotherapy and at the first follow-up (87 blood samples so far). The number of CTCs at the first follow-up was compared with clinical treatment response (e.g. MRI/CT and performance status). Enumeration and characterization of CTCs were done using the CellSearch® system. Apoptosis was measured in CTCs (*in vivo* irradiation) with the help of the M30 antibody in the CellSearch® system and DNA damage repair analyzed by γH2AX and 53BP1 foci detection was analyzed in primary lymphocytes (*ex vivo* irradiation).

### Results

CTCs were detectable in 19% of lung cancer and 38% of breast cancer patients with brain metastases before start of radiotherapy. Quantitative changes in the number of CTCs under local radiotherapy were measurable in all patients. In the lung cancer group, 40% of patients showed an increase of CTCs after irradiation. This percentage was much higher in the breast cancer group with 75%. To specify whether the observed increase in number was due to vital or lethal CTCs an apoptotic marker (M30) was stained in addition in the same samples. In 82% the increase in CTC number was accompanied by apoptosis. After correction for this the number of vital CTCs decreased, indicating treatment response. This is mirrored by the clinical follow up via MRI/CT (evaluation under way) after different radiation schedules (whole brain vs. stereotactic treatment). The same treatment response was detectable in the DNA-damage response assessment parameters.

### Conclusion

The results indicate that monitoring DNA repair in CTCs and primary lymphocytes is already showing promising potential for judging treatment response after radiotherapy in the metastatic state of disease. The increase in apoptotic cells under radiotherapy suggests ineffective DNA repair and thus a local response to therapy. On the other hand, if persistent CTCs are present, this indicates efficient DNA repair and a poor prognosis.

### OC-0494 Genetic variants associated with radiation-induced xerostomia in head and neck cancer: a GWA study

E. Naderi<sup>1,2</sup>, A.P. Crijns<sup>1</sup>, R.J. Steenbakkers<sup>1</sup>, H.P. Bijl<sup>1</sup>, J.F. Van den Hoek<sup>1</sup>, M. Dieters<sup>1</sup>, M.H. Boezen<sup>2</sup>, B.Z. Alizadeh<sup>2</sup>, J.A. Langendijk<sup>\*1</sup>

<sup>1</sup>The University of Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>The University of Medical Center Groningen, Epidemiology, Groningen, The Netherlands

### Purpose or Objective

We aimed to find genetic variants associated with radiation-induced late Xerostomia in head and neck cancer (HNC) patients population treated with definitive or postoperative radiotherapy (RT).

### Material and Methods

We included 1,061 HNC patients treated with definitive or postoperative RT with or without chemotherapy from a prospective cohort study. All baseline patient- tumor- and treatment characteristics and acute and late toxicity was prospectively scored. Patients were followed up to 5 years after treatment. Patient phenotype data were imputed to correct for missingness of samples. Patients were genotyped on Illumina human hap 550k v.3.0 (n=607) or Illumina global screening array (n=464). Genotypes were imputed on Haplotype Reference Consortium reference panel version R1.1. Principal component analysis (PCA) was performed to identify population substructures among samples. Eventually, 957 patients and 6,334,277 SNPs passed quality controls which were included in the final analysis. Xerostomia was defined as moderate to severe xerostomia at 6 months (XER6M). We fitted first a phenotype model (model I) to identify the significant non-genetic clinical and baseline factors associated with XER6M by using imputed samples. Next logistic regression was used to estimate the association of the additive effect of genetic variants with XER6M while adjusting for other predictors from the model I and the top four eigenvectors obtained from PCA analysis. A p-value<0.05 for clinical co-variable, and a genome-wide p-value<5.0x10<sup>-8</sup> for genetic variants was considered statistically significant.

### Results

Full data were available in 763 patients, of whom 280 (36.7%) had XER6M. These cases were compared to 483 patients without XER6M. Clinical factors including N stage (OR=0.29; 95%CI 0.12 to 0.68; p=0.004), volume surrogate (5.97; 3.11 to 11.46; p=7.16x10<sup>-8</sup>), definitive radiotherapy (0.22; 0.15 to 0.32; p=1.61x10<sup>-15</sup>) and baseline xerostomia (2.60; 2.00 to 33.36; p=5.48x10<sup>-13</sup>) were significantly associated with XER6M. In total, 26 variants across eight genomic regions showed a suggestive association at (5.0x10<sup>-8</sup><p<5.0x10<sup>-6</sup>) to XER6M, including one variant on chr1.q41 at p=7.8x10<sup>-7</sup> with an OR of 2.5 (95%CI 1.74 to 3.61).

### Conclusion

We found suggestive genetic variants associated to in XER6M, independent of clinical predictors of XER6M. Further replication is required in independent cohorts while also adjusting for dose distributions in related organs at risk. Identification of genetic variants associated with radiation-induced XER6M may eventually improve predictive models for radio-toxicity in HNC patients.

### Purpose or Objective

To analyze the recurrence patterns and reasons in patients with head and neck cancer (HNC) treated with intensity-modulated radiotherapy (IMRT) and to investigate the feasibility of radiomics for analysis of nasopharyngeal carcinoma (NPC) radioresistance.

### Material and Methods

We analyzed 504 HNC patients treated with IMRT from Jul-2009 to Aug-2016, 26 of whom developed with recurrence. For the HNCs with recurrence, CT, MR or PET/CT images of recurrent disease were registered with the primary

planning CT for dosimetry analysis. The recurrences were defined as in-field, marginal or out-of-field, according to dose-volume histogram (DVH) of the recurrence volume. To explore the predictive power of radiomics for NPCs with in-field recurrences (NPC-IFR), 16 NPCs with non-progression disease (NPC-NPD) were used for comparison. For these NPC-IFRs and NPC-NPDs, 1117 radiomic features were quantified from the tumor region using pre-treatment spectral attenuated inversion-recovery T2-weighted (SPAIR T2W) magnetic resonance imaging (MRI). Intraclass correlation coefficients (ICC) and Pearson correlation coefficient (PCC) was calculated to identify influential feature subset. Kruskal-Wallis test and receiver operating characteristic (ROC) analysis were employed to assess the capability of each feature on NPC-IFR prediction. Principal component analysis (PCA) was performed for feature reduction. Artificial neural network (ANN), k-nearest neighbor (KNN) and support vector machine (SVM) models were trained and validated by using stratified 10-fold cross validation.

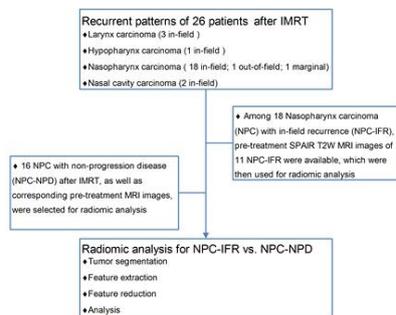

Figure 1. Flowchart of using radiomic analysis in recurrent pattern.

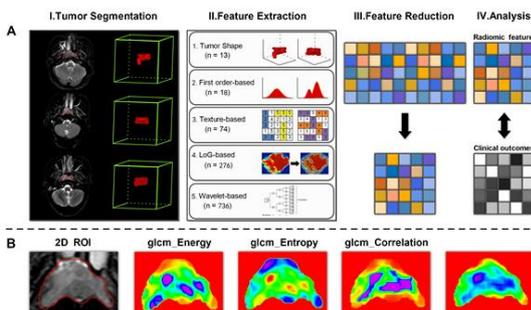

Figure 2. (A) Workflow of radiomic analysis for nasopharyngeal carcinoma (NPC) with in-field recurrence (IFR). (B) Examples of feature maps computed from the tumor region by using GLCM method (e.g. Energy, Entropy, Correlation, InverseDifferenceMoment [IDM]).

## Results

The median follow up was 26 (range 3-65) months. 13/26 (50%) occurred in the primary tumor, 8/26 (31%) occurred in regional lymph nodes, and 5/26 (19%) patients developed a primary and regional failure. Dosimetric and target volume analysis of the recurrence indicated that there were 24 in-field, and 1 marginal as well as 1 out-of-field recurrence. Among the HNCs with recurrence, 20 NPCs developed in-field failure (NPC-IFR). With pre-therapeutic SPAIR T2W MRI images available, 11 NPC-IFRs (11 of 20 NPC-IFRs who had available pre-therapeutic MRI) and 16 NPC-NPDs were subsequently employed for radiomic analysis. Results showed that NPC-IFRs versus NPC-NPDs could be differentiated by 8 features (AUCs: 0.727-0.835). The classification models showed potential in prediction of NPC-IFR with higher accuracies (ANN: 0.812, KNN: 0.775, SVM: 0.732).

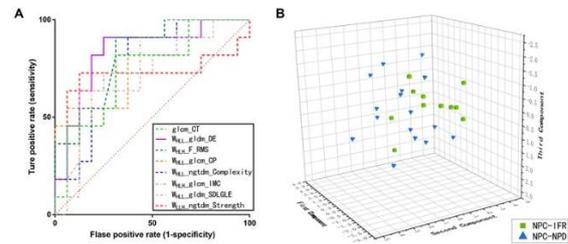

Figure 3. (A) Receiver operating characteristics (ROC) curves on the basis of the significant features. (B) Three-dimensional scatter plot of the NPC-IFR and NPC-NPD by using three principal components derived from the above eight significant features.

## Conclusion

In-field and high-dose region relapse were the main recurrence patterns which may be due to the radioresistance. After integration in the clinical workflow, radiomic analysis can be served as imaging biomarkers to facilitate early salvage for NPC patients who are at risk of in-field recurrence.

## OC-0496 Deep-learning based estimation of loco-regional control for patients with locally advanced HNSCC

### Purpose or Objective

In order to improve radiotherapy outcomes, further treatment personalisation is considered beneficial. Radiomics analyses aim to predict treatment outcomes based on medical imaging data. Commonly, hand-crafted imaging features are used that require domain knowledge and further feature selection steps. This may cause relevant information to be lost. Deep convolutional neural networks (CNNs) on the other hand can act as automatic feature detectors and are able to learn highly nonlinear relationships directly from imaging data, thus addressing the drawbacks of conventional radiomics approaches and enabling end-to-end learning. We investigated whether CNNs are capable of quantifying loco-regional tumour control (LRC) based on CT imaging of patients with locally advanced head and neck squamous cell carcinoma (HNSCC).

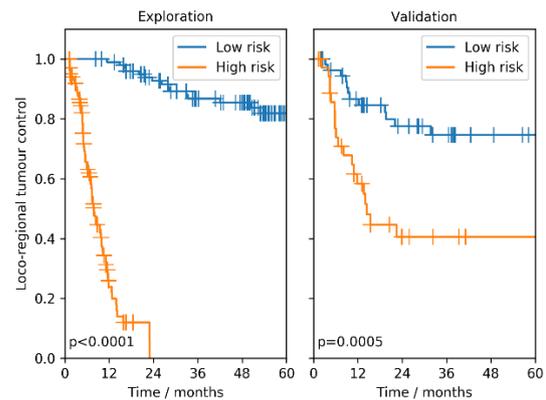

### Material and Methods

A multicentre cohort consisting of 302 patients with locally advanced HNSCC was collected and divided into an exploratory and a validation cohort (207 and 95 patients, respectively). All patients received a CT scan for treatment-planning and were treated by primary radio(chemo)therapy. 9725 transverse CT slices from the exploratory cohort were used to train a CNN with eight convolutional layers. For every patient (with one exception) we used 23 CT slices cranial and caudal of the slice with the largest tumour area, resulting in 47 slices per patient. Discriminative performance was evaluated using 4465 slices of the validation data set. The hazard of loco-regional recurrence was estimated by the CNN maximising the likelihood of the Cox proportional hazards model, which allows for incorporation of nonlinear relationships between the imaging features and the hazard prediction. The final hazard for every patient was obtained by averaging the results of the individual slices. The prognostic value of the model was evaluated by the concordance index (C-Index). Patients were stratified into groups of low and high risk of recurrence using the median hazard in the exploratory cohort.

### Results

The validation of our CNN model revealed a C-Index of 0.68 (95% confidence interval: 0.57-0.79) for the prognosis of LRC. The estimated hazards were used to stratify patients into two risk groups. LRC significantly differed between these groups, both in the exploratory and the validation cohort (log-rank  $p < 0.0001$  and  $p = 0.0005$ , respectively). Compared to previously published results with an average validation C-Index of 0.62 based on conventional radiomics [1], prognostic performance was slightly improved.

[1] Leger et al. Sci Rep 7: 13206 (2017).

### Conclusion

We showed that CNNs are capable of automatically stratifying patients with locally advanced HNSCC into high and low-risk groups for loco-regional tumour recurrence. The obtained results suggest that deep-learning based approaches can become useful for non-invasively evaluating individual recurrence risks encouraging future research in this area.

### OC-0497 Predictive modelling of risk of breast fibrosis at >10 years after radiotherapy using the RILA assay

C. Herskind<sup>1</sup>, P. Seibold<sup>2</sup>, I. Helmbold<sup>2</sup>, E. Sperk<sup>1</sup>, F.A. Giordano<sup>1</sup>, S. Behrens<sup>2</sup>, F. Wenz<sup>1</sup>, J. Chang-Claude<sup>2</sup>, M.R. Veldwijk<sup>1</sup>

<sup>1</sup>Universitätsmedizin Mannheim- Medical Faculty Mannheim- Heidelberg University, Department of Radiation Oncology, Mannheim, Germany ; <sup>2</sup>German Cancer Research Center, Division of Cancer Epidemiology, Heidelberg, Germany

### Purpose or Objective

The radiation-induced lymphocyte apoptosis (RILA) assay has shown associations with the risk of late adverse reaction in cohorts of radiotherapy patients with mixed and single-entity tumors. However, most published studies have scored late reactions up to three years only. The purpose of the present study was to test the assay in breast cancer patients who had undergone radiotherapy after breast-conserving surgery (BCS) more than 10 years earlier. A particular aim was to compare the predictive value of RILA for fibrosis within and outside the surgical area, as well as for telangiectasia, and to assess the influence of other clinical risk factors.

### Material and Methods

Patients from the German ISE cohort (BCS and adjuvant radiotherapy without chemotherapy) with median 11.6 years of follow-up were included in the analysis. RILA for CD4<sup>+</sup> and CD8<sup>+</sup> T cells was determined by flow cytometry of peripheral blood cells 48h after irradiation with a dose of 8 Gy (6 MV X-rays). Late reactions scored by LENT-SOMA were dichotomized as moderate-severe (grade 2-3) vs non-mild (grade 0-1). Fibrosis was scored outside and within the surgical area. Multivariate logistic regression model included: Age at surgery, BMI, hypertension, smoking status, total dose (EQD2), and hormonal treatment. Multivariate predictive modelling was performed by bootstrapping using c statistics to evaluate discrimination of risk.

### Results

High CD4<sup>+</sup> RILA values were inversely correlated with the risk of fibrosis ( $p = 0.011$ ) and telangiectasia ( $p < 0.001$ ) while CD8<sup>+</sup> RILA showed a trend ( $p = 0.06$ ) for telangiectasia only. Univariate ROC analysis and multivariate analysis showed higher AUC and c-stat values outside than within the surgical area. Notably, the improvement by including CD4<sup>+</sup> RILA in the multivariate analysis relative to including

only the clinical factors was larger outside than inside the surgical area. The data showed better discrimination for predicting resistance than sensitivity to developing late reaction. In univariate analysis of the upper RILA tertile versus the lower and middle tertiles, the positive predictive value (PPV) for resistance to fibrosis was 95.1% outside and 73.2% within the surgical area whereas the negative predictive values (NPV) were 21.0% and 16.0%, respectively. For resistance to telangiectasia, PPV was 97.5% and NPV was 12.7%.

#### Conclusion

CD4<sup>+</sup> RILA predicted fibrosis and telangiectasia although it seemed better at predicting resistance. The higher PPV for resistance to fibrosis outside the surgical area supports that CD4<sup>+</sup> RILA is indeed associated with risk of radiation-induced fibrosis whereas fibrosis within the surgical area could be partly explained by clinical factors. Although the patients in this study were recruited prospectively and had a long follow-up (>10y), the predictive modeling is limited by blood samples being taken at the time of follow-up rather than prospectively. Future prospective studies are needed to validate the present findings.

#### Purpose or Objective

Monocentric cohorts suggested that radiation-induced CD8 T-lymphocyte apoptosis (RILA) can predict late toxicity after curative intent radiotherapy (RT). We assessed the role of RILA as a predictor of pelvic toxicities (pt+) after localized prostate RT in a prospective multicentre trial.

#### Material and Methods

A total of 383 prostate-cancer patients (pts) treated by RT were recruited at eight centres. Before the amendment (2014), only favourable stage prostate cancers were included (n=205). The amendment allowed inclusions of prostate cancers treated with pelvic irradiation for higher risk disease or postoperative RT (n=179). RILA was assessed before RT by flow cytometry. Impact of RILA on pt+ (primary endpoint) or relapse was assessed using a competing risks method. Receiver-operator characteristic (ROC) curve analyses were also performed in intention to treat. This study is registered with ClinicalTrials.gov, number NCT00893035 and analyses of the 205 localized prostate-cancer pts are presented here.

#### Results

All pts received 80 Gy to the planning target volume defined as the prostate only plus a margin of 10 mm except in regard to the rectum (5 mm). Concomitant

hormonotherapy was administered to 91 pts (44.4%). With a median follow-up of 38 months (179 pts presented a minimum follow-up of 36 months), acute and late grade  $\geq 2$  pt+ was observed in 95 pts (46.3%) and 60 pts (29.3%), respectively. No correlation was observed between values of RILA and acute pt+. A decreased incidence of late grade  $\geq 2$  pt+ was observed for increasing values of RILA (p = 0.04). The area under the ROC curve was 0.60. For cut-off values of RILA  $\geq 24\%$  and  $< 14\%$ , sensitivity and specificity were 75% and 37%, 45% and 74%, respectively. Negative predictive value for grade  $\geq 2$  pt+ was equal to 76% for RILA  $\geq 24\%$  and positive predictive value was equal to 45% for RILA  $< 14\%$  where the overall prevalence of grade  $\geq 2$  pt+ was estimated at 29%. A significant increase in the risk of grade  $\geq 2$  pt+ was found if patients had pre-treatment urinary symptoms (sHR = 1.90, p = 0.016) and decreased if pts presented a RILA  $\geq 14\%$  (sHR = 0.58, p = 0.04).

#### Conclusion

RILA significantly predicts the risk of pt+ in case of prostate radiotherapy associated with pre-treatment clinical symptoms. This study validates the use of RILA in a predictive multiparametric nomogram as a rapid screening test before RT delivery and may guide physicians in personalizing radiation therapy scheme.

#### OC-0499 Neutrophilia as prognostic factor for outcome in the CAO/ARO/AIO-04 phase 3 rectal cancer trial

#### Purpose or Objective

Peripheral blood leukocytosis and neutrophilia reflect cancer inflammation and have been proposed as prognostic immunological biomarkers in various malignancies. However, previous studies were limited by their retrospective nature and small patient numbers.

#### Material and Methods

The CAO/ARO/AIO-04 randomized phase 3 trial accrued 1236 patients with locally-advanced rectal adenocarcinoma. Patients were randomized to receive either fluorouracil-based preoperative chemoradiotherapy alone (5-FU CRT) or with oxaliplatin (5-FU/Oxaliplatin CRT) followed by surgery and adjuvant chemotherapy. The baseline level of peripheral blood leukocytes, neutrophils, hemoglobin, platelets, lactate dehydrogenase (LDH) and carcinoembryonic antigen (CEA) was correlated with clinicopathologic characteristics and clinical outcome. Multivariable analyses adjusted for treatment arm, pathologic stage, resection status and blood biomarkers were performed using Cox regression models.

#### Results

After a median follow-up of 50 months, neutrophilia remained an independent adverse prognostic factor for disease-free survival (DFS; HR 1.528; 95% CI 1.181-1.977;

P=0.001), the cumulative incidence of distant metastasis (HR 1.957; 95% CI 1.388-2.761; P<0.001) and overall survival (OS; HR 2.161; 95% CI 1.507-3.10; P<0.001) in multivariable analysis. Similar significant findings were observed for leukocytosis and high CEA levels, whereas thrombocytosis was an independent prognostic factor for local recurrence (HR 2.731; 95% CI 1.308-5.701; P=0.007) in multivariable analysis. Conversely, treatment-induced leukopenia correlated with significantly better DFS (P=0.037). Addition of oxaliplatin to 5-FU CRT resulted in a significant DFS improvement only in patients with neutrophilia and leucocytosis (both P=0.005).

#### Conclusion

We here demonstrate that peripheral blood leukocytosis and neutrophilia were associated with adverse clinical outcome in patients with rectal cancer treated within the CAO/ARO/AIO-04 phase 3 trial. Our findings have important implications for the daily clinical practice and provide high-level evidence on the prognostic role of leukocytes and neutrophils. These data could help guide patient stratification to escalation or de-escalation strategies, also as part of the increasingly explored concept of non-operative management, and provide a rationale for neutrophil inhibition with CRT and chemotherapy in future trials in rectal cancer.

#### Purpose or Objective

Total neoadjuvant therapy (TNT) is a new paradigm for locally-advanced rectal cancer treatment. Two TNT

sequences have emerged: induction chemotherapy (CT) followed by chemoradiotherapy (CRT), and CRT followed by consolidation CT. Despite the increasing interest in the concept of TNT, optimal scheduling of preoperative CRT and CT remains to be established.

#### Material and Methods

We conducted the CAO/ARO/AIO-12 multicentre, randomised, phase 2 trial using a “pick the winner” design to select the better TNT sequence. Patients with stage II-III rectal cancer were randomly assigned to group A for induction CT prior to CRT, or to group B for consolidation CT following CRT. CRT consisted of 50.4 Gy in 28 fractions plus infusional fluorouracil (250 mg/m<sup>2</sup> days 1-14 and 22-35) and oxaliplatin (50 mg/m<sup>2</sup> days 1, 8, 22, and 29). Induction-/consolidation CT consisted of oxaliplatin (100 mg/m<sup>2</sup> day 1), leucovorin (400 mg/m<sup>2</sup> day 1), and infusional fluorouracil (2400 mg/m<sup>2</sup> days 1-2) repeated every 15 days for a total of 3 cycles. Total mesorectal excision surgery was scheduled on day 123 after start of TNT. Randomisation was done with computer-generated block randomisation codes stratified by centre and clinical N category (cN0 vs cN1-2) without masking. The primary endpoint was pathological complete response (pCR). Secondary endpoints included toxicity, compliance and surgical complications (ClinicalTrials.gov, registration number NCT02363374).

#### Results

Of the 311 patients enrolled, 306 patients were evaluable (156 in group A and 150 in group B). CRT-related grade 3-4 toxicity was lower (37% vs 27%) and compliance to CRT higher in group B (91%, 78%, and 76% vs 97%, 87%, and 93% received full dose radiotherapy, fluorouracil, oxaliplatin in group A and B, respectively); 92% vs 85% completed all CT cycles. The longer interval between completion of CRT and surgery in group B (median 90 vs 45 days in group A) did not increase surgical morbidity. A pCR in the intention-to-treat population was achieved in 17% (95% CI [12%; 24%]) in group A and in 25% (95% CI [18%; 32%]) in group B. Thus, only group B (p=0.0002) but not group A (p=0.210) fulfilled the predefined statistical hypothesis of significantly increased pCR versus 15% expected after standard CRT. In an exploratory analysis, comparison between groups yielded an odds ratio for pCR of 1.69 in favour of group B (95% CI [0.96; 2.99], p=0.0705).

#### Conclusion

In summary, this is, to our knowledge, the first randomised trial to report safety and efficacy of TNT sequences. CRT followed by consolidation CT was feasible and led to more patients achieving a pathological complete response. This TNT sequence fulfilled the predefined trial hypothesis of an increased pCR rate of 25% based on the “pick the winner” design, and has been selected for further phase 3 comparison with standard preoperative CRT in the CAO/ARO/AIO-18 trial.

**Purpose or Objective**

Neurocognitive decline after Prophylactic Cranial Irradiation (PCI) may be related to the dose in the hippocampus. This multicenter randomized phase III trial (NCT01780675) investigated hippocampus dependent memory functioning and safety after PCI with or without hippocampus sparing in Small Cell Lung Cancer (SCLC) using the Hopkins Verbal Learning Test-Revised (HVLTR).

**Material and Methods**

Patients with limited or extensive stage SCLC who received PCI (25 Gy in 10 fractions) were randomized to standard PCI or hippocampus avoidance PCI (HA-PCI), using IMRT or VMAT. In the HA-PCI group the objective was to get the mean dose in the right and left hippocampus  $\leq$  8.5 Gy (biological dose  $\leq$  6.1 Gy for  $\alpha/\beta=2\text{Gy}$ ) and  $D_{1\%}$

hippocampus  $\leq$  10 Gy,  $D_{\text{max}}$  PTV  $<$  28.75 Gy (115%) and  $V_{115\%}$  PTV  $\leq$  1%. Neurocognitive functioning was assessed by a neuropsychological test battery at baseline, 4, 8, 12, 18 and 24 months after the irradiation. The primary endpoint was a decline in the HVLTR total recall at 4 months, where a decline of 5 or more out of a possible 36 points was considered a failure. Secondary objectives were other cognitive outcomes/quality of life, radiological brain abnormalities on MRI (baseline, 4 and 12 months) and evaluation of the incidence and location of brain metastases following HA-PCI compared with standard PCI and overall survival (OS) using the Kaplan-Meier method.

**Results**

From April 2013 until March 2018 a total of 168 patients were randomized in 10 centers in the Netherlands and Belgium. The median follow-up time was 24.6 months. Median age was 64 years, 51% was female, and performance score at baseline was WHO 0-1 in 93%. The stage distribution was comparable in both arms (70% limited- and 30% extensive stage). All patients were treated using 25 Gy in 10 fractions. A total of 75% of all patients alive and treated had neurocognitive tests at 4 and this was 66% at 8 months. The HVLTR total recall score was  $\geq$  5 points lower compared to baseline in 28% PCI and 29% HA-PCI at 4 months ( $P=0.99$ ) and 34% PCI and 26% HA-PCI at 8 months ( $P=0.46$ ). Compared to baseline, the average HVLTR total recall score dropped 2 points for both arms at 4 months and 3 points in the PCI arm and 1 point in the HA-PCI arm at 8 months. Nineteen patients developed brain metastases of which 50% were multiple. No patient developed an isolated brain metastasis in the HA zone. The OS at 18 months was 54% in the PCI arm and 53% in the HA-PCI arm.

**Conclusion**

This randomized phase III trial investigating the neurocognitive decline at 4 and 8 months after treatment of HA-PCI compared to conventional PCI revealed a decline by  $\geq$  5 points at HVLTR total recall score in 28% of the total group. However, no significant difference between the two arms was seen. The incidence of brain recurrences was not increased in the avoidance region.

**OC-0504 Randomized phase 2 trial of adaptive dose painting vs. standard IMRT for head and neck cancer.**

F. Duprez<sup>1</sup>, J. Daisne<sup>2</sup>, D. Berwouts<sup>3</sup>, W. De Gerssem<sup>1</sup>, I. Goethals<sup>3</sup>, L. Olteanu<sup>1</sup>, T. Vercauteren<sup>1</sup>, W. De Neve<sup>1</sup>  
<sup>1</sup>Universitair Ziekenhuis Gent, Radiotherapie-Oncologie, Gent, Belgium; <sup>2</sup>CHU-UCL Namur, Radiotherapie, Namur, Belgium; <sup>3</sup>Universitair Ziekenhuis Gent, Nuclear Medicine, Gent, Belgium

**Purpose or Objective**

We report final results of a randomized phase 2 trial comparing adaptive dose painting by numbers (A-DPBN) using <sup>18</sup>F-FDG-PET with standard IMRT (S-IMRT) in 2 centres.

**Material and Methods**

Patients were stratified per centre before randomisation. Ninety-five patients were randomized: 47 in A-DPBN and 48 in S-IMRT. Patient characteristics can be found in Table 1.

The dose prescription protocols for both arms are given in Figure 1. As we unexpectedly observed late grade 3 and 4 mucosal ulcers in 1/7 and 3/7 A-DPBN-patients, respectively, in the first dose prescription protocol for A-DPBN, the levels of dose-escalation in A-DPBN have been adapted in 2 steps during the trial.

Kaplan-Meier statistics were used to estimate local (LC), regional control (RC) and overall survival (OS).

Acute toxicity was assessed during radiotherapy in all patients. Late toxicity could be assessed in 83 patients (DPBN-arm 42 and S-IMRT 41) from 3 months after radiotherapy.

	3-phase adaptive DPBN (n = 47)	Standard IMRT (n = 48)	p-value
Median age (range) (in years)	60 (40-74)	58 (43-81)	
Male / female	40/7	40/8	1

- 2	39	9	

local recurrence); spontaneous healing was seen in 3/3 patients of S-IMRT and in 9/14 of A-DPBN. Post-hoc analysis revealed more grade ≥3 late mucosal toxicity in active smokers (29% vs. 3%, p=0.005) and alcohol drinkers (33% vs. 13%, p=0.024) at diagnosis. For grade ≥4 late mucosal toxicity, comparable results were observed in active smokers at diagnosis (19% vs. 0%, p=0.013) but not in active alcohol drinkers at diagnosis.

There was no patient with grade 3 late dysphagia or xerostomia, but 1 patient presented with grade 4 dysphagia in S-IMRT due to esophageal stenosis (primary hypopharyngeal carcinoma).

**Conclusion**

Superior local control was achieved with A-DPBN compared to standard-IMRT, at the cost of more late grade ≥3 mucosal toxicity in active smokers/drinkers at diagnosis. An appropriately powered multicenter phase-3 trial comparing A-DPBN with S-IMRT in non-smokers could lead to better OS or disease-free survival without high rates of mucosal ulcers.

**OC-0505 Evidence-based practice in the global setting: an international survey of hypofractionation**

**D. Rodin**<sup>1</sup>, M. Osama<sup>2</sup>, B. Tawk<sup>3</sup>, S. Grover<sup>4</sup>, F. Moraes<sup>5</sup>, M.L. Yap<sup>6</sup>, E. Zubizarreta<sup>7</sup>, Y. Lievens<sup>8</sup>

**Purpose or Objective**

Multiple large clinical trials have established the equivalence or non-inferiority of hypofractionated radiotherapy compared to conventionally fractionated treatment. The objective of this study is to determine real-world variations in the adoption of hypofractionation across different geographic regions and practice settings for cancers of the breast, prostate, and cervix, and for bone metastases, and barriers and facilitators to such adoption.

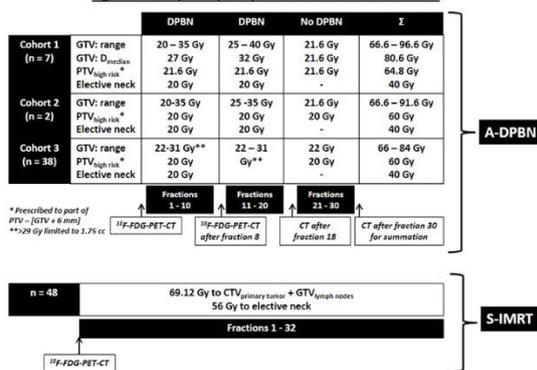

**Material and Methods**

An anonymous, electronic survey was distributed internationally from January to December 2018 in English, Spanish, and Mandarin to radiation oncology consultants through the ESTRO Global Impact of Radiotherapy in Oncology initiative. There were 2,259 respondents from Europe (56%), Asia Pacific (19%), Middle East (5%), 12% Latin America, (12%), North America (6%), and Africa (2%). This survey assessed preference for hypofractionation and specific fractionation regimens across 4 disease sites (breast, prostate, and cervical cancer, and bone metastases) in curative and palliative scenarios. Perceived barriers and facilitators to adoption were evaluated. In regression analyses, hypofractionation preference was defined as the use of hypofractionation for >75% of patients within each disease site and in >50% of clinical scenarios overall.

**Results**

Hypofractionation preference was more common in node-negative than in node-positive breast cancer (83% vs 46%, respectively; p<0.001), in low- and intermediate- vs. high-risk prostate cancer or that requiring pelvic irradiation (56% vs. 32%, respectively; p=0.00001); hypofractionation

Figure 1. Dose prescription protocols in A-DPBN and S-IMRT

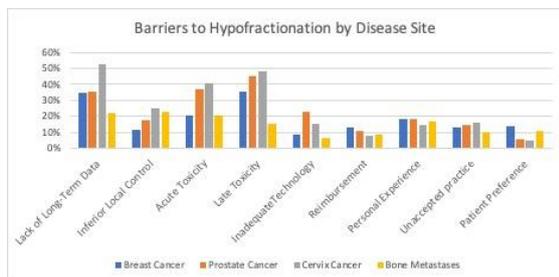

**Results**

Table 1 shows an imbalance in site distribution. Median follow-up was 25 months. Better local control was achieved in A-DPBN: 1- and 2-year local control were 91% and 88% vs. 78% and 75% in A-DPBN vs. S-IMRT (p=0.033). One- and 2 year regional control were equal in A-DPBN vs. S-IMRT: 86% and 84% vs. 84% and 82%, respectively (p=0.8). One- and 2 year OS were equal in A-DPBN vs S-IMRT: 85% and 80% vs. 90% and 70%, respectively (p=0.2). There was no difference in grade ≥3 acute dermatitis, dysphagia or mucositis between both arms. More grade 3 acute dysphagia was observed in patients with concomitant chemotherapy (13/42; 49% vs. 3/41; 22%, p=0.016) and depended from site (oral cavity 100%, oropharynx 42%, larynx 25% and hypopharynx 28%, p=0.036). We observed more grade ≥3 late mucosal toxicity (33% vs. 7%, p=0.003) and grade ≥4 late mucosal toxicity (19% vs. 5%, p=0.047) in A-DPBN than S-IMRT. One grade 5 toxicity was observed in A-DPBN (mucosal blow-out in absence of

was more common in North America and Europe than in other regions. In cervix cancer, hypofractionation was preferred in 30% of locally advanced cervical cancer cases in Africa, but in <10% of cases in other regions. For palliative symptom control, hypofractionation was preferred by 93%, 91%, and 84% of respondents for breast cancer, prostate cancer, and cervix cancer respectively, and in 95% for bone metastases ( $p < 0.001$ ) across geographic regions. Lack of long-term data, inferior local control, toxicity, and inadequate technology were the most commonly cited barriers. In adjusted analyses, hypofractionation preference was associated with age <55 (odds ratio [OR] = 1.46, 95% CI 1.23 to 1.88), practice in a high-income country (OR=2.72, 95% CI 2.12 to 3.49), in a university setting (OR=1.30, 95% CI 1.04 to 1.67), in a centre with a catchment area with >1,000,000 population (OR=1.57, 95% CI 1. to 2.0), and with intensity modulated radiotherapy (OR=1.70, 95% CI 1.22 to 2.34).

Table 1. Preference for hypofractionation by indication and by region

	Africa (N=64)	North America (N=117)	Asia-Pacific (N=433)	Europe (N=1254)	Latin America (N=269)	Middle-East (N=122)
<b>Breast Cancer</b>						
Lumpectomy, node negative	40%	100%	73%	89%	77%	79%
Lumpectomy, node positive	37%	48%	43%	48%	36%	61%
Mastectomy, node negative	49%	62%	33%	49%	38%	70%
Mastectomy, node positive	49%	40%	23%	34%	25%	51%
Palliative symptom control	80%	98%	90%	95%	91%	96%
<b>Prostate Cancer</b>						
Low-Risk	18%	92%	42%	66%	45%	32%
Intermediate-Risk	21%	92%	41%	64%	37%	32%
High-Risk	30%	65%	35%	49%	25%	23%
Pelvic Irradiation	27%	31%	16%	28%	15%	11%
Palliative symptom control	85%	100%	91%	93%	83%	81%
<b>Cervix Cancer</b>						
Locally advanced	30%	0%	5%	9%	10%	6%
Palliative symptom control	79%	100%	79%	85%	82%	81%
<b>Bone Metastases</b>						
Bone Metastasis, Uncomplicated	100%	100%	96%	98%	90%	96%
With Fracture	93%	98%	96%	95%	92%	98%
With Cord Compression	97%	97%	98%	95%	92%	91%
With Soft Tissue Component	93%	96%	91%	94%	85%	89%

### Conclusion

Significant variation was observed in preference for hypofractionation across indications and between geographic regions, with greater concordance in preference for palliative indications. Improving the cost-effectiveness of radiotherapy and the quality of care delivered requires greater international attention to continuing medical education and policy reform that aligns evidence-based practice with physician incentives.

### Purpose or Objective

To evaluate the pattern of sexual activity and its associations to sexual/vaginal functioning within the prospective, observational, multi-center EMBRACE study (An international study on MRI-guided brachytherapy in locally advanced cervical cancer).

### Material and Methods

From 2008-2015, 1416 patients from 22 centers were included and treated with combined EBRT±chemotherapy and image-guided adaptive brachytherapy (IGABT) following the GEC-ESTRO guidelines.

Sexual outcomes were prospectively assessed according to EORTC-QLQ-CX24 questionnaires at baseline and follow-ups (FUP) every 3 months (1<sup>st</sup> year), every 6 months (2<sup>nd</sup>, 3<sup>rd</sup> year) and yearly thereafter. Prevalence rates over time were displayed. Associations between pain during intercourse (dyspareunia) and vaginal functioning were evaluated with Spearman's rank correlations, pooling observations over all FUP (N=2670).

Longitudinal analyses of individual patterns for sexual activity and dyspareunia were performed in patients with at least 3 FUP (N=850). Frequent dyspareunia was defined, if ≥50% of all sexual encounters were "quite a bit" or "very much" painful; occasional dyspareunia if less than half of all encounters were experienced painful.

### Results

Information on baseline sexual activity was available in 1027, in FUP in 1044 patients, with a median FUP time of 36 months. Sexual functioning was assessed in sexually active patients (incidence in FUP: 611 patients, 58.5%). Prevalence rates (figure 1A-F) revealed a slow increase of sexual activity during the 1<sup>st</sup> year of FUP, reaching a plateau up to 5 years. Vaginal functioning problems such as dryness, shortening, tightening and dyspareunia showed a substantial increase after treatment and remained either elevated or showed signs of slight improvement during the observation period. Sexual enjoyment was impaired over all time points, with a range of 37-48% of patients reporting to have "not at all" or "a little" sexual enjoyment.

The vaginal functioning problems dryness, shortening and tightening were significantly correlated with dyspareunia to  $r=0.407$ ,  $0.539$ ,  $0.552$ , respectively (figure 2A-C). The analysis of individual longitudinal pattern revealed 179 patients reporting dyspareunia at least once during FUP (incidence). Of those, the symptom was experienced frequently by 89 (49.7%), but only occasionally by 90 (50.3%) patients, with significant impact on the sexual frequency. 28.1% of patients with frequent dyspareunia showed lower sexual activity (to less than 50% of FUPs). In contrary, only 6.7% of patients with occasional dyspareunia reported a low sexual frequency to the same degree.

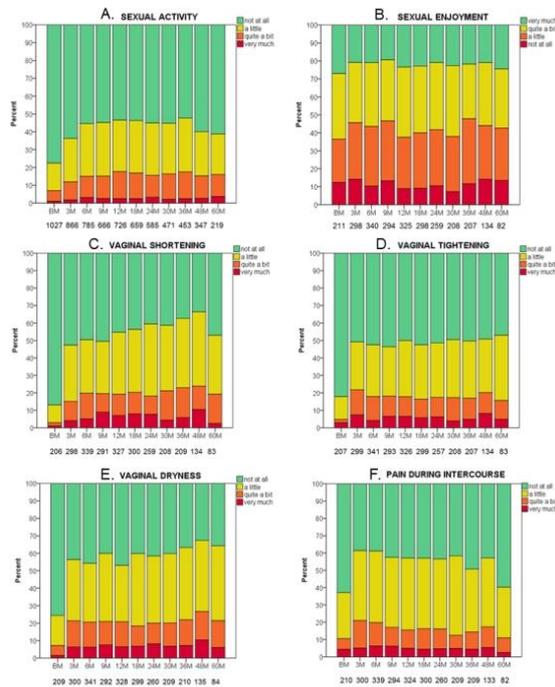

Figure 1: Prevalence rates of A. sexual activity, B. sexual enjoyment, C. vaginal shortening, D. vaginal tightening, E. vaginal dryness and F. pain during intercourse. BM = baseline, M = months in follow-up

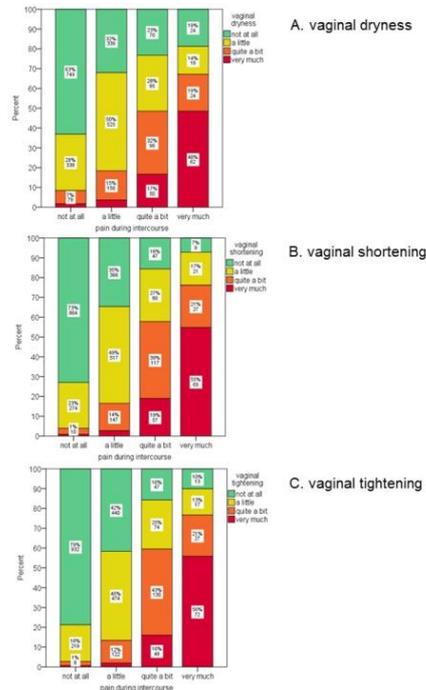

Figure 2: Association between pain during intercourse and A. vaginal dryness, B. vaginal shortening and C. vaginal tightening. Observations pooled over all follow-ups.

**Conclusion**

More than half of locally advanced cervical cancer patients are sexually active after definitive radiochemotherapy plus IGABT. Treatment-induced vaginal changes, such as patient-reported vaginal dryness, shortening and tightening can be associated with pain during intercourse and can impact sexual functioning and frequency.

### Purpose or Objective

To identify risk factors for bladder fistula, bleeding and cystitis within the prospective, multi-institutional, observational EMBRACE I study (An international study on MRI-guided brachytherapy in locally advanced cervical cancer) that enrolled 1416 patients treated from 2008 to 2015.

### Material and Methods

Bladder fistula, bleeding and cystitis (CTCAEv.3) were analysed in Locally Advanced Cervical Cancer (LACC) patients treated with radiochemotherapy and Image-Guided Adaptive Brachytherapy (IGABT). Adverse events arising at any time in the course of follow-up were considered. Patient, disease and treatment characteristics were tested as risk factors for moderate grade (G)  $\geq 2$  with univariate (UVA) and multivariable (MVA) analyses (Cox proportional hazards model) in patients without bladder involvement. UVA and MVA were also performed for severe G $\geq 3$  incidence pooled over the three endpoints. The cumulative (EBRT+IGABT) minimal dose to the most exposed 2cm<sup>3</sup> of the bladder (D2cm<sup>3</sup>) and ICRU Bladder Point dose (EQD2) were considered as continuous variables in UVA and MVA. Urinary frequency and incontinence were not included in the analysis.

### Results

In 1146 patients without bladder involvement, the crude incidences for G $\geq 2$  fistula, bleeding and cystitis were 0,7% (n=8), 2,0% (n=23) and 7,4% (n=84), respectively. The pooled incidences for G $\geq 2$  and G $\geq 3$  were 8,5% (n=97) and 1,4% (n=16), respectively, with 15% of symptomatic patients experiencing more than one endpoint. In 67 patients with bladder involvement, the incidences for G $\geq 2$  fistula, bleeding and cystitis were 2,5% (n=8), 12% (n=2) and 17% (n=11), respectively, and G $\geq 3$  in 15% (n=10) (pooled incidence). Mean (SD) bladder D2cm<sup>3</sup> was 75,8 $\pm$ 9,7Gy and 83 $\pm$ 11,5Gy in patients without and with bladder involvement, respectively. Median follow-up was 35 (range:1-97) months, median age was 49 (range:22-91) years, and 31% were smokers. Table 1 shows the covariates tested in UVA and MVA for G $\geq 2$  fistula, bleeding and cystitis, and G $\geq 3$  for pooled symptoms in patients without bladder involvement. The Hazard Ratios (HR) are shown for significant variables in UVA (p $\leq$ 0.10) and MVA (p $\leq$ 0.05). Bladder D2cm<sup>3</sup> was significant on MVA for all individual and pooled endpoints. ICRU Bladder Point dose was significant in UVA for fistula and pooled incidence, but was not included in the MVA because of correlation with bladder D2cm<sup>3</sup> and a lower HR. Smoking status was predictive for bleeding, cystitis and pooled incidence, with smokers at higher risk. Younger patients had a higher risk for cystitis compared to older patients.

**Table 1:** Covariates tested in UVA and MVA for G $\geq 2$  fistula, bleeding and cystitis and for G $\geq 3$  pooled incidence. HRs are shown for variables significant in UVA. Significant HRs in MVA are highlighted in bold.

### Conclusion

In the present study, bladder D2cm<sup>3</sup> was a dominant risk factor for developing bladder fistula, bleeding or cystitis

after IGABT in LACC patients. The risk of bleeding and cystitis was considerably higher in smokers. Finally, age was a predictor for cystitis, with younger patients at higher risk.

### OC-0508 MRI guided chemoradiation and brachytherapy for postsurgical vaginal recurrences: A phase II study

S. Chopra<sup>1</sup>, R. Engineer<sup>2</sup>, U. Mahantshetty<sup>2</sup>, S. Mechanery<sup>3</sup>, T. Dora<sup>3</sup>, R. Shukla<sup>4</sup>, P. Popat<sup>5</sup>, J. Swamidas<sup>3</sup>, J. Ghosh<sup>3</sup>, S. Gupta<sup>3</sup>, S. Shrivastava<sup>2</sup>

### Purpose or Objective

To report outcomes of prospective phase II study that integrated MRI for planning external radiation and brachytherapy for postsurgical recurrences of cervical cancer.

### Material and Methods

The prospective phase II study (NCT 01391065) recruited patients from January, 2011 until December, 2016. Patients with local residual or recurrent tumour after hysterectomy without any evidence of distant metastasis were included. All patients underwent baseline T2 MR imaging to define the extent and volume of disease and were planned for external radiation (50 Gy/25#/5weeks (IMRT or 3DCRT)) with concurrent weekly cisplatin (40mg/m<sup>2</sup>). Response assessment MRI was performed in all patients at completion of brachytherapy. While patients with baseline parametrial disease received interstitial high dose rate brachytherapy including vagina and parametrium (16-20Gy/4-5#) those with only central disease at presentation received only central vaginal brachytherapy (12-14 Gy/2-4#). Information from MR was utilized to delineate clinical target volume on CT obtained for planning interstitial or intracavitary brachytherapy. MRI was done at first follow up followed by clinical examination with additional imaging as and when indicated. Kaplan Meier Analysis was performed to evaluate Locoregional Relapse, Disease Free and Overall Survival. Univariate and multivariate analysis was performed to evaluate impact of known prognostic factors.

### Results

A total of 60 patients were included of which 51 were identified to have nonmetastatic disease. The median age of the cohort was 48 years (35-65 yrs). The median and mean tumour volume on T2W MRI was 25 cc (IQR 8.4-145 cc) and 118 cc ( IQR8.4-145) cc[A1] ). A vast majority of patients had squamous carcinoma (82.4%). Overall 16/50 (31.4%) patients had radiologically positive lymph nodes prior to treatment initiation. Overall 40 patients (78%) had complete response after external radiation, 8 had partial response and 3 patients had progressive disease. Planned treatment was completed in 47/50 patients. The median EQD2 was 70.8Gy (50-73 Gy). The median D 2cc for rectum, bladder and sigmoid was 65.8 Gy, 68 Gy and 62 Gy respectively. At a median follow up of 60 months (5-93) local control was 88%. Of the 6 patients (12%) with local relapse 4 were local only and another 2 also had distant metastasis. Five patients (10%) had distant relapse in the absence of local relapse leading to 5 and 7 year disease free and overall survival of 72% and 69% and 88% and 77% respectively. Grade III proctitis and cystitis was observed in 4% and 2% patients respectively. Of the known prognostic, predictive and treatment related factors only baseline tumour volume >20 cc adversely impacted 7 year

DFS (91% vs 65%,  $p=0.03$ ) and overall survival (96% vs 77%,  $p=0.06$ ).

**Conclusion**

MRI assisted external radiation and brachytherapy results in excellent 7-year disease free and overall survivals in patients with post surgical vaginal recurrences

**OC-0509 MRI radiomics analysis for predicting prognosis of cervical cancer after definitive radiotherapy**

A. Takada<sup>1</sup>, H. Yokota<sup>1</sup>, M. Watanabe<sup>1</sup>, T. Horikoshi<sup>1</sup>, T. Uno<sup>1</sup>  
<sup>1</sup>Chiba University, Department of Radiology, Chiba, Japan

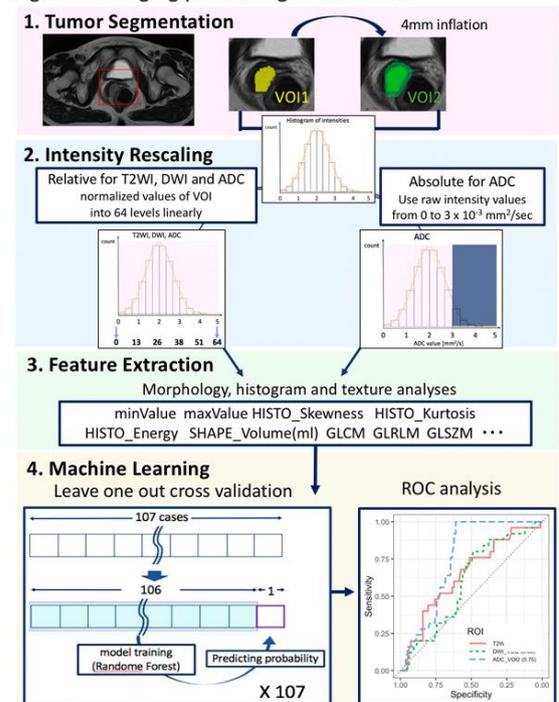

**Purpose or Objective**

Although many clinical prognostic factors for uterine cervical cancer have been reported, prediction accuracy is still insufficient. Radiomics is a method to construct predictive machine learning models for treatment prognosis or benign/malignant using many image features, which are extracted from a lesion site on medical images such as MRI, CT, and PET. However, machine learning is theoretically weak for differences in imaging acquisition conditions. The purpose of this study was to investigate whether radiomics analysis with MRI images of different scanners can predict the prognosis in cervical cancer after definitive radiotherapy.

**Material and Methods**

Totally 107 patients ( $58.8 \pm 13.5$  years) were included. All underwent MRI of 16 multi-center scanners and definitive radiotherapy for cervical cancer between April 2012 and March 2016. Spatial resolution of MRI was converted into  $0.5 \times 0.5 \times 5.0$  mm for T2-weighted image (T2WI), and  $1.0 \times 1.0 \times 5.0$  mm for diffusion-weighted image (DWI) and apparent diffusion coefficient map (ADC). A radiologist delineated the volume of interest (VOI) within each tumor region on axial T2WI, DWI and ADC map (VOI1). In addition, VOI2 was created by expanding the entire circumference by 4 mm. Using open-source software (LIFEx: <https://www.lifexsoft.org>), two intensity rescaling methods were applied; i.e. relative rescaling for T2WI and DWI, and relative and absolute rescaling for ADC. The Relative method can be applied for any imaging modalities, whereas the absolute method is robust for outliers although it is available for images with absolute values such as ADC. From T2WI, DWI and ADC each, 45 imaging features of morphology, histogram and texture analyses in the VOIs were extracted. The prognosis was defined based on whether recurrence within the irradiation field within two years after treatment. We constructed prediction models for locoregional recurrence with leave-one-out cross-validation using random forest algorithm, and receiver operating characteristic (ROC) analysis to evaluate diagnostic performance.

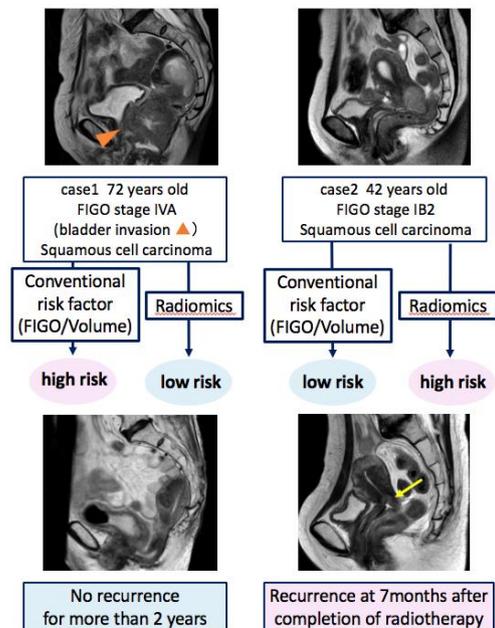

Figure 1. Imaging processing of radiomics

**Results**

Cervical cancer relapsed in 25 of 107 patients within the irradiation field. The area under the curve (AUC [95% confidence interval]) calculated by ROC analysis was summarized in Table. Absolute rescaling improved AUC of ADC into 0.79 (sensitivity 69.5% and specificity 88.0% at the closest top-left point of ROC curve) on VOI2. AUCs of conventional risk factors such as volume (AUC=0.52) was significantly lower than that of ADC with radiomics ( $p=0.001$ , Delong test).

Figure2. An example with discrepancy between conventional risk factor and Radiomics

**Conclusion**

Radiomics machine learning approach for ADC with absolute rescaling and VOI delineation including tumor surroundings was useful for predicting locoregional recurrence of cervical cancer after definitive radiotherapy even using multi-center MRI data.

Intensive Rescaling	VOI	T2WI	DWI	ADC
Relative	VOI1	0.52 [0.390-0.65]	0.70 [0.59-0.80]	0.68 [0.57-0.79]
Relative	VOI2	0.66 [0.53-0.79]	0.73 [0.63-0.84]	0.5 [0.43-0.70]
Absolute	VOI1	N/A	N/A	0.67 [0.56-0.79]
Absolute	VOI2	N/A	N/A	0.79 [0.70-0.87]

### OC-0510 MRI radiomics to predict tumour response in patients with locally advanced rectal cancer

P. Bulens<sup>1</sup>, A. Couwenberg<sup>2</sup>, M. Intven<sup>2</sup>, A. Debucquoy<sup>1</sup>, V. Vandecaveye<sup>3</sup>, M. Philippens<sup>2</sup>, P. Mukherjee<sup>4</sup>, O. Gevaert<sup>4</sup>, K. Haustermans<sup>1</sup>

<sup>1</sup>University Hospital Gasthuisberg, Radiation Oncology, Leuven, Belgium ; <sup>2</sup>University Medical Center Utrecht, Radiation Oncology, Utrecht, The Netherlands;

<sup>3</sup>University Hospital Gasthuisberg, Radiology, Leuven, Belgium; <sup>4</sup>Stanford University, Center for Biomedical Informatics Research, Stanford, USA

#### Purpose or Objective

To implement organ-sparing strategies into the multimodality treatment of patients with locally advanced rectal cancer (LARC), response prediction to select eligible patients is needed. In this research, we investigate the use of different multiparametric MRI-based radiomics models that predict (near-)complete response to chemoradiotherapy (CRT) in patients with LARC and compare their performances with the performance our previously developed and validated semantic model based on two volumetric and two ADC parameters.

#### Material and Methods

Radiomics models were developed in a cohort of 70 patients with LARC, prospectively recruited between 2012 and 2015. The external validation cohort consisted of 55 patients, recruited between 2008 and 2011. All patients were treated with CRT followed by surgery and underwent T2-weighted and diffusion-weighted imaging (DWI) before CRT and before surgery. The outcome measure for this study was (near-)complete pathological tumour response (ypT0-1N0).

The tumour was segmented on T2-images and the ROI was transferred to DWI b800 images and ADC maps, after which radiomics features were extracted. Also, the two volumetric and two ADC parameters of the semantic model were calculated. Principal component analysis was used to linearly combine the radiomics and semantic features and regression analysis with LASSO was applied to develop the models. The best three models based on performance using receiver operating characteristic (ROC) and precision were selected for external validation and for comparison with the four-feature semantic model.

#### Results

21/70 patients (30%) achieved ypT0-1N0 in the development cohort versus 13/55 patients (24%) in the validation cohort. The four-feature semantic model had a predicting performance of AUC 0.86 (95% confidence interval (CI) 0.76-0.95) on the development cohort and

AUC 0.87 (95% CI 0.76-0.97) on the validation cohort. The best three models using radiomics with or without semantic features (semantic\_dwi\_post, semantic\_dwi\_adc\_pre, t2\_dwi\_pre\_post) were identified with performances on the development cohort with an AUC of 0.84 (95% CI 0.75-0.94), 0.85 (95% CI 0.75-0.98) and 0.83 (95% CI 0.70-0.95) respectively. Two models (semantic\_dwi\_post, t2\_dwi\_pre\_post) validated well in the external patient cohort with an AUC of 0.86 (95% confidence interval 0.76 - 0.97) and 0.83 (95% confidence interval 0.70 - 0.95) respectively.

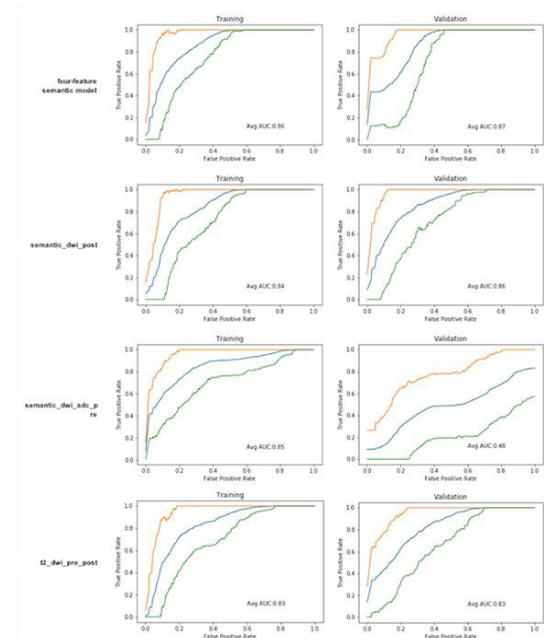

Figure 1. Receiver operating characteristic curves for the four-feature semantic model and the three radiomics models on both the training and the validation cohort. Orange and green curves represent the 95% confidence interval.

	Development Cohort	Validation Cohort
semantic	AUC	0.857 (0.765 – 0.950)
	PPV	77%
	Sensitivity	53%
	Specificity	94%
semantic_dwi_post	AUC	0.842 (0.747 – 0.936)
	PPV	67%
	Sensitivity	63%
	Specificity	88%
semantic_dwi_adc_pre	AUC	0.864 (0.749 – 0.979)
	PPV	92%
	Sensitivity	52%
	Specificity	98%
t2_dwi_pre_post	AUC	0.828 (0.728 – 0.929)
	PPV	67%
	Sensitivity	50%
	Specificity	90%

Table 1. Performance and operating points of the selected models that predict response to chemoradiation for patients with rectal cancer, for both the development and the validation cohort. Data between brackets represents the 95% confidence interval. Abbreviations: AUC = Area Under the Curve; PPV = Positive Predictive Value.

### Conclusion

Prediction models based on T2- and DW-MRI radiomics can be used for adequate non-invasive detection of patients with rectal cancer that will achieve a (near-)complete response after CRT. These radiomics models, however, do not outperform a previously reported prediction model based on two volumetric and two ADC parameters.

### OC-0511 Organ Preservation with Image Guided and Adaptive Brachytherapy for Patients with Rectal Cancer

A. Garant<sup>1</sup>, S. Magnan<sup>2</sup>, S. Devic<sup>3</sup>, A. Martin<sup>2</sup>, M. Boutros<sup>4</sup>, C. Vasilevsky<sup>4</sup>, S. Ferland<sup>5</sup>, A. Bujold<sup>6</sup>, S. Desgroseilliers<sup>7</sup>, H. Sebahang<sup>8</sup>, C. Richard<sup>9</sup>, T. Vuong<sup>10</sup>

<sup>1</sup>UT Southwestern Medical Center, Radiation Oncology, Dallas, USA ; <sup>2</sup>Laval University, Radiation Oncology, Quebec City, Canada ; <sup>3</sup>McGill University, Medical Physics, Montreal, Canada ; <sup>4</sup>Jewish General Hospital, Colorectal Surgery, Montreal, Canada ; <sup>5</sup>Gatineau Hospital, Radiation Oncology, Gatineau, Canada ; <sup>6</sup>Maisonneuve-Rosemont Hospital, Radiation Oncology, Montreal, Canada ; <sup>7</sup>Pierre-Boucher Hospital, Surgery, Longueuil, Canada ; <sup>8</sup>University of Montreal Hospital Center, Surgery, Montreal, Canada ; <sup>9</sup>University of Montreal Hospital Center, Colorectal Surgery, Montreal, Canada ; <sup>10</sup>Jewish General Hospital, Radiation Oncology, Montreal, Canada

### Purpose or Objective

Organ preservation or non-operative management (NOM) of rectal cancer is of growing interest among colorectal experts. Image guided and adaptive endorectal brachytherapy (IG-AEBT) is a radiation dose escalation modality: we explored its role as a tumor-response adaptive therapy in elderly patients unfit for surgery and patients refusing surgery.

### Material and Methods

In this prospective registry study, patients with rectal cancer who were ineligible for surgery began treatment with pelvic external beam radiotherapy (EBRT) to a dose of 40 Gy in 16 fractions; in patients refusing surgery, EBRT was prescribed at a dose of 45- 50 Gy in 25 fractions with concurrent 5-FU. This was followed by three weekly IG-AEBT boosts of 10 Gy to the residual clinical target volume, for a total of 30 Gy in 3 weekly fractions. Complete clinical response (cCR) was the primary endpoint.

### Results

A total of 118 patients were included; the median age was 81 years. With a median follow-up of 2.5 years for living patients, the proportion of cCR was 86.4%, the tumor regrowth proportion was 12.8%, and the cumulative incidence of local relapse was 4.3% at 1 year and 16.4% at 2 years. When considering responders and non-responders, the 2-year local control was 72.8%. The overall survival at 2 years was 66.1%. Acute rectal grade 1-2 toxicity included all patients: 25.5% of patients had late rectal bleeding requiring iron replacement, or blood transfusions and/or argon plasma therapy.

### Conclusion

The results of our registry study exploring IG-AEBT as a boost modality for an elderly medically unfit patient population with unselected tumors reveal that a high proportion of patients achieved cCR with a reasonable toxicity profile. Consequently, it is our belief that this technology will contribute to the challenging NOM paradigm of rectal cancer.

### OC-0512 Radiochemotherapy and hyperthermia in locally advanced rectal cancer - A prospective phase II trial

C. Gani<sup>1</sup>, U. Lamprecht<sup>1</sup>, M. Bitzer<sup>2</sup>, J. Gellermann<sup>3</sup>, O. Voigt<sup>1</sup>, A. Ziegler<sup>4</sup>, M. Moll<sup>1</sup>, A. Königsrainer<sup>5</sup>, D. Zips<sup>1</sup>  
<sup>1</sup>University Hospital Tübingen, Radiation Oncology, Tübingen, Germany ; <sup>2</sup>University Hospital Tübingen,

Gastroenterology, Tübingen, Germany; <sup>3</sup>Zentrum für Strahlentherapie und Radioonkologie, Radiation Oncology, Berlin, Germany ; <sup>4</sup>Städtische Kliniken Esslingen am Neckar, Oncology, Esslingen am Neckar, Germany ; <sup>5</sup>University Hospital Tübingen, Surgery, Tübingen, Germany

### Purpose or Objective

Despite excellent local control rates after preoperative radiochemotherapy and total mesorectal excision there is growing interest in local treatment escalation strategies which could increase pathological complete response rates and therefore qualify more patients for non-operative management. Therefore, the goal of the present study was to evaluate tumor regression after preoperative radiochemotherapy combined with deep regional hyperthermia in locally advanced rectal cancer.

### Material and Methods

A total of 78 patients with locally advanced rectal cancer, UICC stage II or III, were enrolled in this prospective phase 2 study. Radiotherapy consisted of 50.4 Gy and concomitant chemotherapy with 5-Fluorouracil (1000mg/m<sup>2</sup> CVI) during the first and fifth week of treatment. Deep regional hyperthermia was applied biweekly with a target of at least eight treatments. Tumor regression was graded according to the Dworak classification with "Dworak 4" corresponding to a pathological complete response. The primary endpoint was the pathological complete response rate, a good response (GR) was defined as Dworak grades three and four.

### Results

All patients completed radiotherapy as prescribed. Sixty of 78 patients (77%) completed eight or more hyperthermia treatments, all patients underwent surgery. Five patients experienced grade three or higher hyperthermia related toxicity (Three with claustrophobia, two with bolus pressure). Dworak grades 1/2/3 and 4 were 11.5% / 38.5% / 34.6% and 15.4%. A GR to treatment was achieved by 50% of all patients. Patients with a GR had significantly higher cumulative equivalent minutes at 43 degrees (CEM43) compared with patients with Dworak grades 1 and 2 (7.22 vs 4.47, p=0.012).

### Conclusion

Our study showed a very favorable toxicity profile of deep regional hyperthermia and a promising proportion of patients with a high degree of tumor regression. The higher CEM43 in good responders suggests a causal relationship between temperature and tumor regression. We will further investigate the potential of hyperthermia to maximize pathological complete response rates in the ongoing multicentric CAO/ARO/AIO-16 organ preservation trial.

(Parts of the study results were presented at the "European Society of Hyperthermia in Oncology" Meeting in 2018)

### OC-0513 Cone-beam CT intensity correction using a generative adversarial network and unpaired training

C. Kurz<sup>1,2,3</sup>, M. Maspero<sup>3</sup>, M.H.F. Savenije<sup>3</sup>, G. Landry<sup>2</sup>, F. Kamp<sup>1</sup>, M. Li<sup>1</sup>, K. Parodi<sup>2</sup>, C. Belka<sup>1,4</sup>, C.A.T. Van den Berg<sup>3</sup>

<sup>1</sup>University Hospital- LMU Munich, Department of Radiation Oncology, Munich, Germany ; <sup>2</sup>Faculty of Physics- Ludwig-Maximilians-Universität München, Department of Medical Physics, Munich, Germany ; <sup>3</sup>Universitair Medisch Centrum Utrecht, Center for Image Sciences, Utrecht, The Netherlands; <sup>4</sup>DTK, German Cancer Consortium, Munich, Germany

### Purpose or Objective

In adaptive photon and proton radiotherapy (RT and PT) it is desirable to utilize pre-treatment CBCT images for online dose calculation and adaptation. Due to various imaging artifacts CBCTs are, however, not suitable for accurate dose determination and current correction methods lack speed for online application. This work aimed at investigating the feasibility of using a cycle-consistent generative adversarial network (cycleGAN) for CBCT intensity correction to enable fast and accurate RT and PT dose calculation. The dedicated loss-function of the network allowed for using unpaired (not registered) training data despite inter-scan anatomical deviations.

### Material and Methods

Planning CT (pCT) and daily CBCT imaging data of 25 prostate cancer patients were used for training in this study. A cycleGAN was trained using 18/25 patients and 4-fold cross-validation, aiming at translating the uncorrected CBCT images ( $CBCT_{org}$ ) to a pCT-like image ( $CBCT_{cycleGAN}$ ) in 2D (slice-by-slice). No initial matching of the data was performed (unpaired). A previously validated CBCT correction method ( $CBCT_{cor}$ ) applying corrections in projection space on the basis of a prior virtual CT, obtained from pCT to CBCT deformable image registration (DIR), served as reference.  $CBCT_{cycleGAN}$  was compared to  $CBCT_{cor}$  in terms of mean Hounsfield Unit (HU) error within the body outline. Dose calculation accuracy was evaluated using volumetric modulated arc therapy (VMAT) photon and opposing single field uniform dose (OSFUD,  $90^\circ/270^\circ$  gantry angle) proton plans generated on  $CBCT_{cor}$  and recalculated on  $CBCT_{cycleGAN}$ . Single-sided SFUDs were utilized to compare the proton range in beam's eye view (BEV).

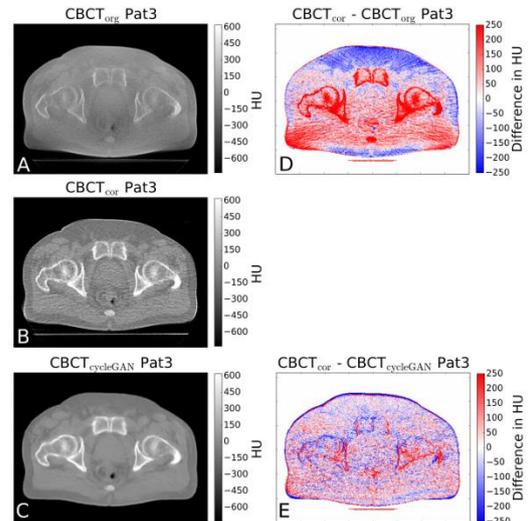

### Results

The average (over all patients) HU error comparing  $CBCT_{cor}$  and  $CBCT_{cycleGAN}$  was -0.5 HU. In comparison,  $CBCT_{org}$  showed an average deviation of 33HU with respect to  $CBCT_{cor}$  (Fig. 1). For VMAT the average pass-rates for a 2%/1% dose-difference criterion were 100%/94%. For the OSFUD plans the 2% pass-rate was lower, at 77% (Fig. 2). Using a 2%/2mm gamma criterion the pass-rate increased to 94%. In terms of the proton range 87% of all analyzed BEV profiles agreed better than 3mm on  $CBCT_{cor}$  and  $CBCT_{cycleGAN}$ . The average range difference was 0.4mm. Application of the cycle consistent GAN allowed for a considerable increase in speed: time to correct a 3D CBCT was reduced from 8-10 min ( $CBCT_{cor}$ ) to about 3 s ( $CBCT_{cycleGAN}$ ).

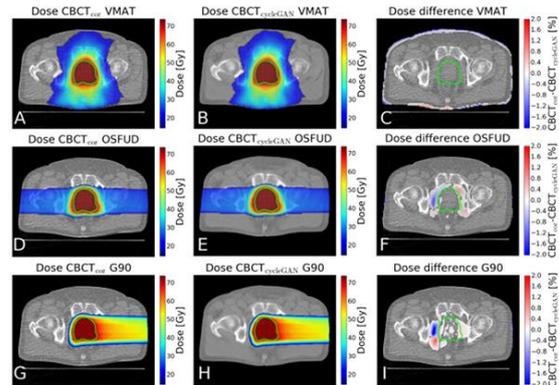

### Conclusion

Our study demonstrated for the first time the feasibility of using a cycleGAN and unpaired training for CBCT intensity correction. Results suggest high RT dose calculation accuracy. In PT, agreement to the reference  $CBCT_{cor}$  was reduced due to the sensitivity of the proton range on HU values. The substantial speed-up with respect to the reference method renders  $CBCT_{cycleGAN}$  particularly interesting in the scope of online adaptive therapy approaches. Due to unpaired training the method is independent from anatomical inconsistencies in the training data.

**Figure 1.** CBCT images used in this study: Original CBCT ( $CBCT_{org}$ , A), reference corrected CBCT ( $CBCT_{cor}$ , B) and CBCT corrected using the cycle-consistent GAN ( $CBCT_{cycleGAN}$ , C). Panels D and E illustrate the difference between  $CBCT_{cor}$  and  $CBCT_{org}$  (D), as well as  $CBCT_{cycleGAN}$  (E).

**Figure 2.** Dose distribution optimized on  $CBCT_{cor}$  (A, D, G) and recalculated on  $CBCT_{cycleGAN}$  (B, E, H) for the VMAT (A, B) the OSFUD (D, E) and the single-sided SFUD plan at  $90^\circ$  gantry angle (G, H). Deviations between  $CBCT_{cor}$  and  $CBCT_{cycleGAN}$  based dose calculations are depicted in panels C, F and I.

### OC-0514 Unsupervised deep learning for fast and accurate CBCT to CT deformable image registration

S.R. Van Kranen<sup>1</sup>, T. Kanehira<sup>1</sup>, R. Rozendaal<sup>1</sup>, J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands

### Purpose or Objective

CBCT based online adaptive radiotherapy requires fast deformable image registration (DIR) to facilitate plan adaptation within a reasonable timeslot. Deep learning convolutional neural networks (CNNs) have demonstrated fast and accurate alignment of MR datasets of brain images[1]. The goal of this study is to train such networks for head & neck CBCT-to-CT DIR and to compare the accuracy with our clinically implemented bSpline method.

### Material and Methods

VoxelMorph [1], a U-net based CNN with a spatial transformation block for image registration, was modified to capture deformations up to 3 cm. Networks were trained unsupervised on 7899 CBCT-CT scan pairs of 232 patients. The loss function consisted of local cross correlation regularized on the bending energy to enforce smooth deformations. Several trainings were performed to determine the optimal weighting ( $\lambda=0.1-10$ ). An independent set of 10 CBCT-CT pairs was regularly evaluated during training to determine convergence (no improvement during 200 iterations). Training typically took 1.5 days on a single GTX 1080 GPU.

The accuracy of both methods was determined with a modified distance discordance metric[2] (DDM): a deformation vector field (DVF) between a planning CT (pCT) and a repeat CT (rCT) was constructed by concatenating DVFs between the pCT and a CBCT and the CBCT and the rCT. With 35 CBCTs per patient, the distribution of the DVF end points was determined (per pCT voxel as the vector length of the standard deviation per direction). Finally the accuracy for relevant structures was quantified. The DDM was collected over a held-out test set of 5 patients.

### Results

Training typically converged within three epochs. Regularization weights in the range 0.5-2 showed a shallow optimum and resulted in an absence of folding effects and unrealistic micro deformations. Applying trained models to scan-pairs took ~10 sec, vs minutes with our bSpline method. Figure 1 shows an example DDM color overlay. VoxelMorph generally showed accurate mapping, but failed at occasional large deformations (weight loss, shoulders) and areas with sliding tissue (uvula, epiglottis) or (dis)appearing air gaps (nose, oral cavity). Figure 2 shows the distribution of DDM vector lengths of target areas and various organs. Both deformation methods showed excellent mapping-accuracy: 50% of voxels within the patient-external lay within 0.5mm, 90% within 1.5mm. Outliers within the external were found to correspond with above mentioned failures. Specified per structure, bSplines DIR was more accurate than VoxelMorph.

[1] Balakrishnan G, CVPR, 2018

[2] Saleh ZH, PMB, 2014

### Conclusion

CNN based DIR resulted in fast and accurate head & neck CBCT-to-CT mappings, creating opportunities for on the fly DIR for online plan adaptation. Accuracy was acceptable but less than our clinically applied bSpline DIR and failed at occasional large deformations. Diversifying the training with large deformations and other tumor sites may improve accuracy and robustness, and prevent failures.

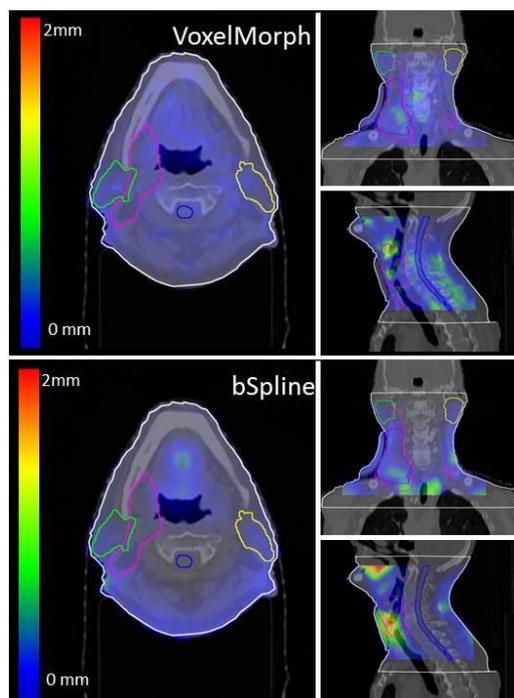

Figure 1. DDM color overlay for an example patient. Tumor regression, sliding tissue and (dis)appearing airgaps are challenges to both VoxelMorph and bSpline DIR.

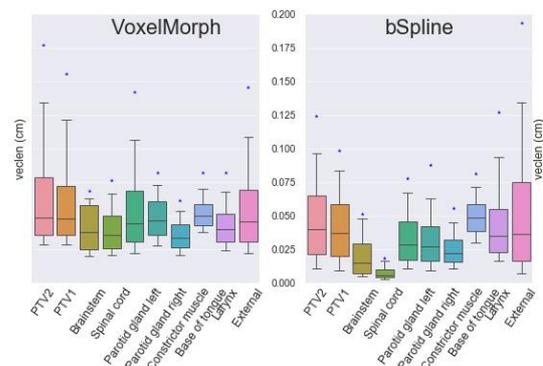

Figure 2. DDM comparison of the DIR accuracy of VoxelMorph vs. bSpline. The boxes represent the median and interquartile ranges, the whiskers the 10/90-percentile, the stars the 95-percentile.

### OC-0515 Synthetic CT generation for Head and Neck radiotherapy by a 3D convolutional neural network

A. Dinkla<sup>1</sup>, M. Florkow<sup>2</sup>, M. Maspero<sup>1</sup>, M. Savenije<sup>1</sup>, F. Zijlstra<sup>2</sup>, P. Doornaert<sup>1</sup>, M. Van Stralen<sup>2</sup>, M. Philipppens<sup>1</sup>, P. Seevinck<sup>2</sup>, N. Van den Berg<sup>1</sup>

<sup>1</sup>UMC Utrecht, Department of Radiation Oncology, Utrecht, The Netherlands; <sup>2</sup>UMC Utrecht, Centre for Image Sciences, Utrecht, The Netherlands

### Purpose or Objective

Synthetic CT generation is required for MR-only simulation workflow where CT-MRI registration can be avoided. More recently, also sCTs are becoming desirable for MRI-guided Radiotherapy where planning is performed based on daily MR images.

In the Head and Neck region (H&N), atlas-based methods have been adopted. However, their robustness is limited as in H&N abnormal patient anatomies can occur due to large tumors or surgical excision. Therefore, here a patch-based deep learning method was chosen to improve robustness. In particular, we used a 3D patch-based convolutional neural network (CNN) to generate sCTs based on T2-weighted Turbo Spin echo (TSE) images and evaluated its image and dosimetric performance.

### Material and Methods

We conducted a retrospective study on 34 patients with Head and Neck cancer who underwent CT (Philips Brilliance Big Bore) and MR imaging (3T Philips Ingenia) for radiotherapy simulation. To generate the sCTs, a large field-of-view (FOV) transverse T2-w TSE mDixon MRI, originally used for tumor/OAR contouring, was selected from the clinical protocol. 83 transverse slices with 3 mm thickness were acquired with a FOV of 45x45 cm<sup>2</sup> and 0.94x0.94 mm<sup>2</sup> resolution in 5min24s and readout bandwidth of 876 Hz/px. Cases with severe image artefacts from dental implants (CT) or motion (MRI) were excluded from the training. To align images for training and evaluation, CT scans were non-rigidly registered (CTreg) to the in-phase MR images (Elastix 4.7) and all images were resampled to 1x1x1 mm<sup>3</sup> isotropic resolution. The CNN was based on a U-net architecture and consisted of 14 layers with 3x3x3 filters. Patches of 48x48x48 were randomly extracted and fed into the training. sCTs were created for all patients using three-fold cross validation. The CT-based treatment plan was recalculated on sCT using Monaco TPS (Elekta).

### Results

sCT generation took 4 min. on a single GPU. The patch-based approach allowed proper sCT generation for non-standard anatomies (fig. 1). Mean absolute error (MAE) over the patient population of the sCT within the intersection of body contours was 75±9 HU, and the mean error (ME) was 9±11 HU. Dice scores of the air (<200HU) and bone (>250HU) masks (CTreg vs sCT) were 0.79±0.08 and 0.70±0.07 respectively. Dosimetric analysis showed mean differences of -0.03±0.05% for dose within the body

contours and  $-0.07 \pm 0.22\%$  inside the high dose region (dose  $>90\%$ ). Dental artefacts obscuring the CT, could be circumvented in the sCT by the CNN-based approach in combination with TSE MRI sequence that typically is less prone to susceptibility artefacts (fig. 2).

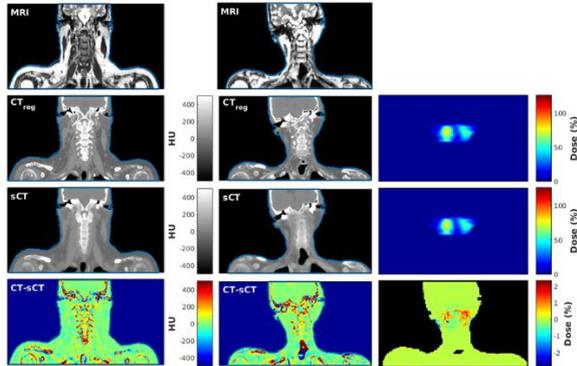

Figure 1: Coronal slice through the MRI, CT<sub>reg</sub>, sCT and HU difference map of a regular case (left) and for a postoperative case with non-standard anatomy (centre). For the latter, the dose maps calculated on the CT<sub>reg</sub>, sCT and dose difference map are shown (right).

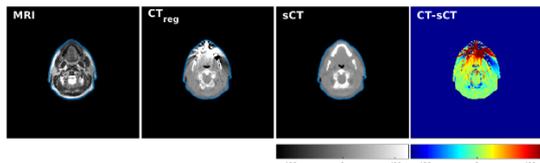

Figure 2: Example of a patient with streaking artefacts on the CT from dental implants. Since no artefacts are present on the MRI, the sCT can be reconstructed without artefacts.

## Conclusion

The 3D patch-based CNN generated sCTs of the H&N region that were dosimetrically accurate. The sCT were generated based on T2W TSE images already used for tumor/OAR contouring and thus no extra scan time was added. Moreover, for H&N cancers, the use of TSE as input for sCT generation has as particular advantage that it is less affected by dental artefacts compared to commonly used gradient echo sequences.

## OC-0516 Whole-frame 2D cineMR prediction using deep neural networks

P. Borman<sup>1</sup>, L. Kerkmeijer<sup>1</sup>, B. Raaymakers<sup>1</sup>, M. Glitzner<sup>1</sup>  
<sup>1</sup>UMC Utrecht, Radiotherapy, Utrecht, The Netherlands

### Purpose or Objective

Accurate target localization during radiotherapy treatments is becoming increasingly feasible with the recent clinical introduction of MR-guided radiotherapy systems such as the Elekta Unity and ViewRay MRIdian. These systems will facilitate real-time treatment adaptation based on continuous MR imaging, to correct for e.g. respiratory motion. It is important to minimize the latency of this control loop, which is largely determined by the MR imaging due to its relatively long acquisition time [1]. The control loop latency may be reduced by predicting the next state based on previous states, a concept that has been previously applied to 1D respiratory signals [2]. In this work we present full frame, image-based, prediction results using the readily available deep learning library pix2pix [3].

### Material and Methods

MR images were acquired on a 1.5T Philips Ingenia system in five renal cell carcinoma patients, with IRB approval. A 2D balanced gradient echo sequence was used consisting of 300 sagittal frames, with a frame rate of 2 Hz. A TensorFlow implementation of pix2pix was used to train a model that predicts a frame based on three previous frames. For each frame (n), the input images consisted of frames (n-2), (n-1), and (n), while the target image was set to frame (n+1). The model was trained and tested on

a per patient basis, where the first 200 frames were used for training and the last 100 frames for testing. The training time was 45 minutes using a nVidia Titan Xp GPU. For evaluation, motion fields of 1) the predicted frames (n+1)' and 2) the most current frames (n) were calculated with respect to the ground truth frames (n+1). The motion fields were then used to calculate per-voxel displacement curves and RMSE maps, with and without prediction.

## Results

The RMSE maps show that the error with prediction is substantially lower than without prediction in almost all areas of the image (figure 1). Displacement curves at points around the tumor (figure 2) show that phase and baseline of the predicted signal correspond with the ground truth, reducing the RMSE from 2.4 mm with no prediction to 1.1 mm with prediction, in this patient. Averaged over all patients, the RMSE was reduced from 1.47 mm to 0.74 mm, an average reduction factor of 2.0.

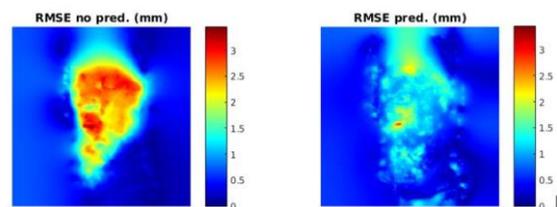

Figure 1: Root mean squared error maps without prediction (left) and with prediction (right).

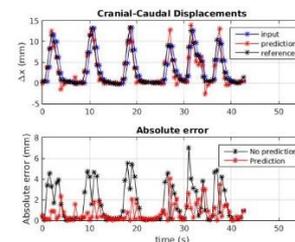

Figure 2: Displacement curves of the tumor for the input, prediction, and ground truth reference (top). The absolute error with and without prediction is shown in the bottom graph.

## Conclusion

A deep learning based prediction model is indeed able to learn a patients breathing pattern and predict a full frame 500 ms ahead. This may help to reduce the influence of imaging latency, which is important for real-time MR-guided treatment applications.

## OC-0517 Automatic tumor delineation in rectal cancer using functional MRI and machine learning

F. Knuth<sup>1</sup>, A. Rosvoll Grøndahl<sup>2</sup>, T. Torheim<sup>3,4</sup>, A. Negård<sup>5,6</sup>, S.H. Holmedal<sup>5</sup>, K.M. Bakke<sup>7,8</sup>, S. Meltzer<sup>7</sup>, C. Futsaether<sup>2</sup>, K.R. Redalen<sup>1,7</sup>

<sup>1</sup>Norwegian University of Science and Technology, Department of Physics, Trondheim, Norway; <sup>2</sup>Norwegian University of Life Sciences, Faculty of Science and Technology, Ås, Norway; <sup>3</sup>University of Oslo, Department of Informatics, Oslo, Norway; <sup>4</sup>Oslo University Hospital, Institute for Cancer Genetics and Informatics, Oslo, Norway; <sup>5</sup>Akershus University Hospital, Department of Radiology, Lørenskog, Norway; <sup>6</sup>University of Oslo, Institute of Clinical Medicine, Oslo, Norway; <sup>7</sup>Akershus University Hospital, Department of Oncology, Lørenskog, Norway; <sup>8</sup>University of Oslo, Department of Physics, Oslo, Norway

### Purpose or Objective

Tumor delineation is a time- and labor-intensive procedure both for radiotherapy planning and for quantitative imaging biomarker purposes. In addition, it is

prone to inter- and intra-observer variations. The movement towards a plan-of-the-day approach further intensifies this issue and increases a need for fast and automatic tumor delineation methods. The objective of our study was to use functional magnetic resonance imaging (MRI) to develop and evaluate a voxelwise tumor classification method in rectal cancer utilizing a machine learning approach.

#### Material and Methods

Eighty-nine patients with rectal cancer were subjected to MRI scans at baseline. Routine T2-weighted (T2w) MRI was performed before an extended diffusion-weighted (DW) sequence with b-values of 0, 25, 50, 100, 500, 1000 and 1300 s/mm<sup>2</sup>. In addition, static R2\* (1/T2\*) MR data was acquired using a sequence with five different echo times. Intensity and spatial information extracted from the different image series served as input to an image voxel classification based on Fisher's linear discriminant analysis (LDA) model. The model was trained and assessed using tumor delineations from two radiologists as reference. Their tumor delineations were defined on T2w-images but guided by T2w and DW images.

The ability to distinguish tumor from healthy tissue was assessed by using the Dice similarity coefficient (DICE), kappa statistics (K) as well as sensitivity (Sens) and specificity (Spec) as performance measures. In addition, the receiver operating characteristic (ROC) curve was inspected for each model adjustment by use of the area under the curve (AUC). The effect of combining the different image series was investigated as well as the effect of different pre- and postprocessing options.

#### Results

LDA models based on T2w images alone resulted in an AUC of 0.72 (DICE: 0.24; K: 0.19; Sens: 0.82; Spec: 0.67). R2\* images alone resulted in similar performance measures (AUC: 0.76; DICE: 0.23; K: 0.18; Sens: 0.78; Spec: 0.66). Models based on DW images or a combination of DW and T2w and/or R2\* images improved the performance measures (AUC: 0.86-0.88; DICE: 0.42-0.43; K: 0.39-0.40; Sens: 0.75-0.78; Spec: 0.88-0.89). Inclusion of spatial information in the form of intensity information of neighboring voxels improved the performance as well as preprocessing by calculating the standardized z-scores. A further improvement was achieved by postprocessing the binary tumor mask utilizing morphological closing and opening.

#### Conclusion

We demonstrate an automatic method for MR-based classification of tumor voxels in rectal cancer using a machine-learning approach. The classification results improved significantly when functional MRI sequences were added to the anatomical sequences.

#### OC-0518 Feasibility of MRI-guided VMAT: investigating image quality during gantry rotation on an MR-linac

S. Jackson<sup>1</sup>, M. Glitzner<sup>2</sup>, R.H.N. Tijssen<sup>2</sup>, B.W. Raaymakers<sup>2</sup>

<sup>1</sup>The Christie NHS Foundation Trust, Christie Medical Physics and Engineering, Manchester, United Kingdom ;

<sup>2</sup>University Medical Hospital, Department of Radiotherapy, Utrecht, The Netherlands

#### Purpose or Objective

During a step and shoot or VMAT radiotherapy treatment the linac gantry is repositioned many times. On the Elekta Unity MR-Linac if the patient is continuously MR imaged then the active shimming of the magnet will no longer be correct as soon as the gantry moves away from its original position. Incorrect shimming can result in inhomogeneity of the principal (B0) magnetic field, leading to geometric distortion that could affect real-time treatment plan adaptation.

For a static linac gantry it has been shown that the inhomogeneity difference is negligible between a shimmed and unshimmed magnet, using a clinical pulse

sequence at several gantry angles. Our objective was to measure B0 inhomogeneity changes during linac gantry rotation and to measure geometric distortion in MR images during linac gantry rotation using a clinical balanced steady state (bFFE) sequence and a single shot spin echo EPI (SS-SE-EPI) sequence.

The clinical bFFE sequence has high receive bandwidth to minimise geometric distortion caused by B0 inhomogeneity. The EPI sequence was chosen to demonstrate the sensitivity of the method due to its susceptibility to geometric distortion and because it is often used in diffusion weighted imaging (DWI).

#### Material and Methods

**Continuous rotation:** Sequential single slice acquisitions were obtained while the gantry completed one rotation around the magnet. The centre point of a 10cm diameter spherical phantom was estimated for both the bFFE and SS-SE-EPI pulse sequences, with a temporal resolution of <1s/frame. These were compared to the static gantry cases.

**Inhomogeneity:** Analysis of the root-mean-squared deviation from perfect magnetic homogeneity was obtained for sequential, single slice B0 maps obtained coronally using a dual echo FFE sequence with a temporal resolution of 1.5s/frame during continuous gantry rotation for a 35cm diameter ROI in a flood phantom. This was compared to the static gantry case.

**Step-and-shoot:** the average of fifty coronal, dynamic, single-sliced SS-SE-EPI MR images was calculated with the gantry static at 12 gantry angles spaced 30° apart, with the magnet shimmed for the first gantry position only. The centre point of a 10cm diameter spherical phantom on the resulting images was estimated and plotted against gantry angle.

#### Results

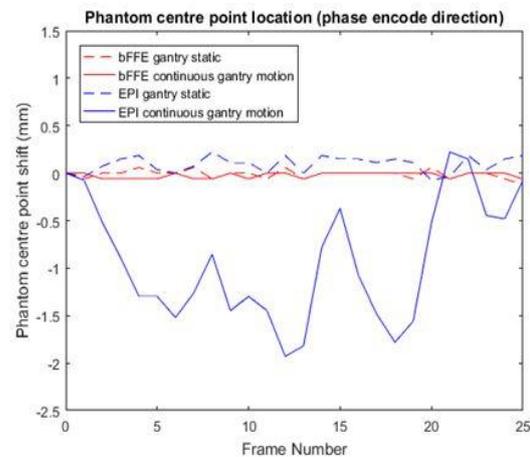

Figure 1 Measured phantom centre point position during static and continuous gantry motion for the clinical bFFE and EPI sequences

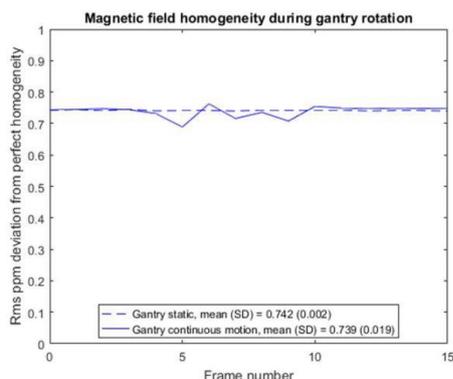

Figure 2 Rms ppm deviation from perfect homogeneity during static and continuous gantry motion using the B0 map.

The 10cm diameter spherical phantom deviated by less than 1mm in the phase encode direction between different gantry angle positions during the step and shoot SS-SE-EPI test.

#### Conclusion

We conclude that VMAT with real-time MR monitoring is feasible, SS EPI-based DWI is permitted as the geometric shifts measured are sub-pixel sized for this sequence and re-shimming the magnet is not required during continuous monitoring of step and shoot treatments.

#### OC-0519 Registration and image quality of T2w 3D TSE scans of the Unity MR-linac

V. Van Pelt<sup>1</sup>, T. Janssen<sup>1</sup>, I. Walraven<sup>1</sup>, C. Liskamp<sup>1</sup>, D. Lambregts<sup>2</sup>, U. Van der Heide<sup>1</sup>, M. Nowee<sup>1</sup>  
<sup>1</sup>Netherlands Cancer Institute, Radiation Oncology, Amsterdam, The Netherlands; <sup>2</sup>Netherlands Cancer Institute, Radiology, Amsterdam, The Netherlands

#### Purpose or Objective

With the Unity MR-linac (Elekta AB, Stockholm, Sweden) a new paradigm in radiation oncology has emerged allowing daily adaptive radiotherapy. Currently, a 3D TSE sequence with an acquisition time of over 6 minutes is used clinically as pre-beam MR. The aim of this study was to investigate the impact of the acquisition time and scan quality on the accuracy in registration of the pre-beam MR for plan adaptation.

#### Material and Methods

After informed consent, 8 patients with prostate cancer were scanned on the Unity MR-linac. Four T2w 3D TSE sequences were acquired with different acquisition times and resolutions (Table 1). Seven experienced observers independently registered the MR sequences on the planning CT using Monaco 5.4 (Elekta AB). Automatic prostate matching was performed and manually adjusted when necessary. Sequences were compared on 3 measures. 1) Registration accuracy for each sequence was quantified by the standard deviation of the registrations per patient. 2) Differences between the sequences was quantified by the mean deviation from the mean registration. 3) A dedicated radiation oncologist and radiologist assessed the overall image quality using a 5 point scale (1: poor; 2: moderate; 3: satisfactory; 4: good; 5: excellent).

#### Results

Acquisition times ranged between 6.25 and 1.27 minutes (Table 1) and an example of corresponding image quality is presented in Figure 1.

Mean deviation from the mean registration per sequence was maximally 0.3mm (sequence A) and the root mean square of the standard deviations of each registration per sequence was <0.7mm. Comparing the different sequences, only small differences were seen, where

deviations in registration of sequence A seem to be slightly larger compared to the other sequences (Table 1).

The qualitative assessment by radiologist and radiation oncologist is listed in Table 1. Median scores per patients ranged from 1.5 - 4.0.

	Voxel size	Acquisition time	Mean deviation of the mean (mm)			RMS of standard deviation (mm)			Median qualitative assessment (range)	
			LR	AP	CC	LR	AP	CC	Rad. Onc.	Radiologist
A	1.2x1.2x1.2 mm	6.25 min	+0.3	+0.3	+0.2	0.50	0.41	0.66	3 (1-3)	3 (3-4)
B	1.2x1.2x2.4 mm	3.12 min	-0.2	0.0	0.0	0.35	0.28	0.69	3 (1-3)	3 (1-4)
C	1.7x1.7x1.7 mm	3.15 min	0.0	-0.2	-0.2	0.45	0.25	0.56	3 (2-3)	3 (2-4)
D	1.8x1.8x1.8 mm	1.27 min	-0.1	-0.1	0.0	0.45	0.30	0.63	2 (2-3)	2 (1-3)

Table 1. voxel size and acquisition time of the T2w 3D TSE sequences. LR: left-right, AP: anterior-posterior, CC: cranial-caudal.

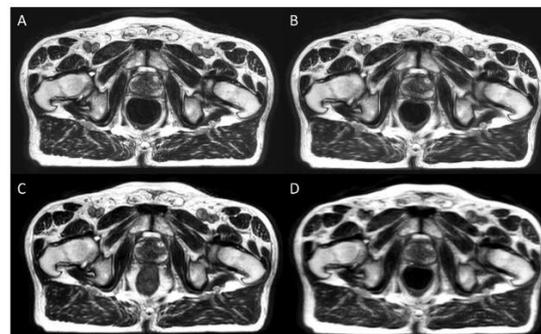

Figure 1. Example of a prostate cancer patient scanned with different acquisition times (A: 6.25 min; B: 3.12 min; C: 3.15 min; D: 1.27 min)

#### Conclusion

We studied scan quality and registration accuracy comparing a 6.25 minute T2w 3D TSE scan with shorter sequences of up to 1.27 minutes. We found registration accuracy was on average high (sub-millimetre) and changed only mildly for the different sequences. A qualitative assessment shows only a lower judgement for the shortest (1.27 minute) sequence and variation of image quality between patients is larger than between the different acquisition times. These results can be used to effectively improve overall fraction time for adaptive treatment on the MR-linac, by optimising the imaging sequence used for registration.

#### OC-0520 Inter-observer variations in plan evaluation

L.P. Kaplan<sup>1</sup>, A.I.S. Holm<sup>1</sup>, U.V. Elstrøm<sup>1</sup>, J.G. Eriksen<sup>2</sup>, K. Jensen<sup>3</sup>, H. Primdahl<sup>3</sup>, C.N. Andreassen<sup>2</sup>, S.S. Korreman<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. of Medical Physics, Aarhus C, Denmark ; <sup>2</sup>Aarhus University Hospital, Dept. of Experimental Clinical Oncology, Aarhus C, Denmark ; <sup>3</sup>Aarhus University Hospital, Dept. of Oncology, Aarhus C, Denmark

#### Purpose or Objective

Use of dose-volume parameters is the standard way of quantifying plan quality. Secondary plan characteristics can be quantified using metrics such as dose gradient or dose homogeneity but are in practice often evaluated qualitatively. Subjective qualitative evaluation and comparison of RT treatment plans can be arbitrary and hence suffer from inter-observer variations. The aim of this study was to compare subjective vs. quantitative evaluations and determine how much consistency there is between the two.

**Material and Methods**

Twenty head-and-neck cancer pts were included. Two planning strategies were used for all pts: one with and one without using the knowledge-based planning (KBP) software RapidPlan included in the Eclipse TPS (v13.7 Varian Medical Systems). All plans were three-arc VMAT plans, made to be clinically acceptable according to current national guidelines. Four radiation oncologists performed a blinded clinical evaluation of the plans. Each chose which plan they preferred for each patient, giving scores for target coverage and OAR doses, respectively, from six (good) to one (bad). In addition, they gave scores for importance in choosing between two plans, from six (important) to one (not important), for five different secondary plan characteristics. Corresponding quantitative metrics from the literature were calculated. Subjective scores and quantitative metrics are shown in table 1. Consistency between the score-metric pairs was evaluated and the calculated metrics were compared for KBP vs. non-KBP plans.

Subjective scores	Metrics	Definitions	Significant difference KBP/non-KBP?
Target score	Target coverage index	$TCl = TV_{PD} / TV \times 100$	No
	Cold volume	$CV = TV < 95\% PD$	No
OAR score	OAR mean dose		Yes, KBP lower for: PCM <sub>sp</sub> $p = 0.025$ PCM <sub>int</sub> $p < 0.001$ PCM <sub>low</sub> $p < 0.001$ Thyroid $p = 0.036$ GI larynx $p = 0.003$
Dose homogeneity in target	Homogeneity index	$HI = (D_{2\%} - D_{98\%}) / D_{95\%}$	Yes, KBP dose less homogenous in low-risk target $p < 0.001$
Steep dose fall-off	Gradient index	$GI = R_{eff,50\%PD} - R_{eff,PD}$	Yes, steeper gradient for KBP $p = 0.004$
	Conformity index	$CI = TV_{90\%} / (TV \times PDV)$	Yes, KBP plans less conformal to high-risk target $p < 0.001$
Hot spots outside target	Hot volume	$HV = HT > 95\%PD$	Yes, larger for KBP for High-risk target: $p < 0.001$ Low-risk target: $p = 0.033$ Elective target: $p = 0.019$
Low-dose bath	$V_{X\%}, X = 1, 5, 10, 15$	Volume given a minimum dose of X Gy	Yes, smaller for KBP for 10 Gy $p = 0.030$ 15 Gy $p = 0.002$
Integral dose	Body mean dose times body volume		Yes, lower for KBP $p = 0.019$

Table 1: List of the plan characteristics which were scored subjectively. Each has one or more quantitative metrics associated with it. If the quantitative metrics differ significantly from KBP to non-KBP plans this is noted in the rightmost column.  $D_{X\%}$ : minimum dose given to the hottest X% of a volume, HT: healthy tissue volume, PD: prescription dose, PCM: pharyngeal constrictor muscle,  $R_{eff,50\%PD}$ : effective radius of the 50% prescription isodose volume,  $R_{eff,PD}$ : effective radius of the prescription isodose volume, TV: target volume,  $TV_{PD}$ : target volume given at least 95% of the prescription dose.

**Results**

All plans complied with critical OAR (spinal cord, brainstem) and target coverage constraints. KBP plans were preferred in 65% of all evaluations. In only six cases did all physicians prefer the same plan. Mean[SD] scores given for target coverage were 5.28[0.70] (KBP) and 5.40[0.54] (non-KBP). For OAR dose they were 5.16[0.66] (KBP) and 4.71[0.67] (non-KBP). For all scores except OAR for non-KBP plans a Friedman's ANOVA test showed significant ( $p < 0.05$ ) variations between observers. Table 1 shows for which quantitative metrics KBP and non-KBP plans differed significantly (Wilcoxon signed rank test,  $p < 0.05$ ). Subjective scores and corresponding metrics are shown in fig. 1 for dose gradient and conformity. The figure shows little consistency between the subjective scores and the quantitative metrics. The same was found for all score-metric pairs investigated. Spearman's  $\rho$  for correlations in each score-metric pair (including scores from all physicians) ranged from -0.34 to 0.20 (median -

0.07).

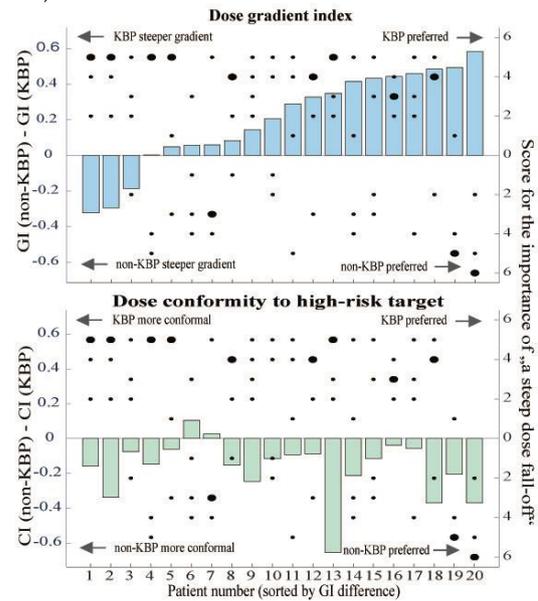

Figure 1: The bars (left y-axes) show the gradient (upper) and conformity (lower) index for non-KBP plans minus the same index for KBP plans for each patient. The black dots (right y-axes) show subjective scores given for the importance of a steep dose fall-off outside the target in the choice between two plans for a patient. A dot in the upper half of the figure indicates the corresponding physician preferred the KBP plan for this patient, a dot in the lower half that the non-KBP plan was preferred. Large dots mark where two physicians gave the same score.

**Conclusion**

There were substantial inter-observer variations in subjective scores. Little to no consistency was seen between qualitative scores and corresponding quantitative metrics. Often physicians gave a high importance score to a plan characteristic but chose the plan which scored worse on the quantitative metric. Consistent use of quantitative metrics in addition to subjective plan evaluation should be investigated as a way of mitigating such inconsistencies and variations.

**OC-0521 SRS plan quality with variation in modality: Results of an international planning competition**

N. Hardcastle<sup>1</sup>, B. Nelms<sup>2</sup>, L. O'Connor<sup>3</sup>, J. Shakeshaft<sup>4</sup>, A. Haworth<sup>5</sup>, O. Cook<sup>6</sup>, M. Harris<sup>6</sup>, C. Phillips<sup>7</sup>  
<sup>1</sup>Peter MacCallum Cancer Centre, Physical Sciences, Melbourne, Australia ; <sup>2</sup>ProKnow Systems, Development, Madison, USA ; <sup>3</sup>Calvary Mater Hospital, Radiation Therapy, Newcastle, Australia ; <sup>4</sup>Radiation Oncology Centres, Medical Physics, Brisbane, Australia ; <sup>5</sup>University of Sydney, School of Medical Physics, Sydney, Australia ; <sup>6</sup>Trans-Tasman Radiation Oncology Group, Quality Assurance, Newcastle, Australia; <sup>7</sup>Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia

**Purpose or Objective**

Stereotactic radiosurgery (SRS) delivers highly conformal doses cranial targets. There is large variation in treatment planning and delivery technology, with recent linac developments enabling treatment of complex and multiple targets. In this study, we evaluate the treatment plan quality for plans submitted to an international competition for a case of SRS to multiple brain metastases.

**Material and Methods**

A single SRS patient was used, with five brain metastases of volumes 0.07-2.82 cm<sup>3</sup> located throughout the brain including adjacent to the brainstem. A planning CT scan with tumour and OAR contours was provided via the ProKnow system. Targets were provided as PTVs, without margin adjustment for SRS delivery technology. A dosimetry scoring matrix based on the TROG 16.02 Local-

HERO trial protocol was created in which approximately equal points were allocated to target dosimetry including conformity index (CI), and to OAR dosimetry. Where applicable, progressive scoring was used; for example, participants received a minimum score for meeting trial protocol and increasing points when OAR dose was reduced further below protocol. In addition to dosimetry metrics, delivery parameters including treatment plan geometry, delivery time and monitor units were analysed for the top 50 plans.

### Results

A total of 160 plans were submitted from 28 countries. Treatment devices included linacs, CyberKnife (CK), GammaKnife (GK), TomoTherapy and particle therapy. The majority of plans were VMAT (101), followed by GK (20), CK (16) and IMRT (7) (Figure 1). The median score was 124.8 (out of 150) and maximum was 146.2, achieved with CK. The top 50 plans scored 134.5-146.2. Of these, VMAT/IMRT plans had superior CI100% compared with CK and GK, however VMAT was inferior to IMRT, CK and GK for CI50%. IMRT achieved lower normal brain receiving 12 Gy compared with VMAT, CK and GK (Figure 2). It should be noted that GK PTV margin in practice may be lower than for linac plans. For all techniques, all top 50 plans had at least 125% target maximum dose. Top 50 linac plan score was independent of monitor units, but all had at least three couch angles. Median VMAT delivery time was 14 minutes, compared with 25, 120 and 169 minutes for IMRT, CK and GK respectively (Figure 2).

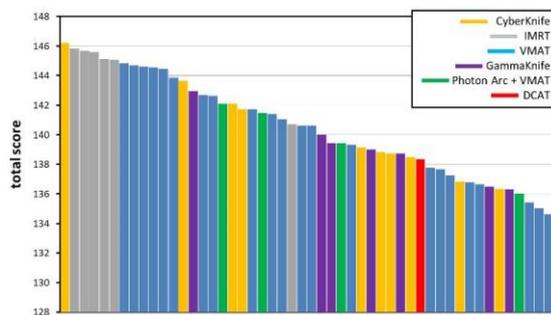

Figure 1: Waterfall plot of plan scores for the top 50 plans with delivery or planning technique denoted by colour

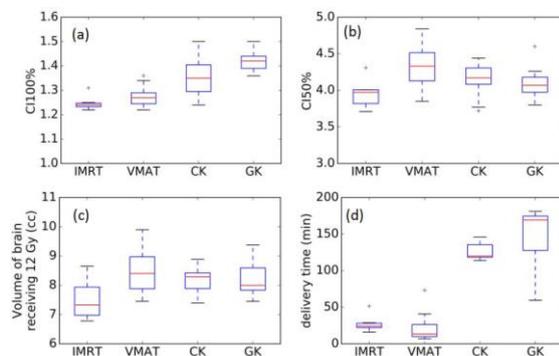

Figure 2: (a) 100% CI (b) 50% CI (c) volume of normal brain receiving 12 Gy and (d) delivery time for IMRT, VMAT, GammaKnife and Cyberknife in the top 50 scoring plans

### Conclusion

In this international multi-metastases SRS planning competition, similar plan quality was achieved with across various SRS delivery systems. There was a vast range in delivery time required between different SRS delivery systems. This study did not however collect planning and QA time, or QA results, for which large variations between systems may be present.

### OC-0522 Characterising dose changes due to unplanned gas cavities in Magnetic Resonance guided Radiotherapy

J. Shortall<sup>1</sup>, E. Vasquez Osorio<sup>1</sup>, A. Green<sup>1</sup>, R. Chuter<sup>2</sup>, A. McWilliam<sup>1</sup>, K. Kirkby<sup>1</sup>, R. Mackay<sup>2</sup>, M. Van Herk<sup>1</sup>

<sup>1</sup>The University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom ; <sup>2</sup>The Christie NHS Foundation Trust, Medical Physics and Engineering, Manchester, United Kingdom

### Purpose or Objective

Due to Lorentz Forces, electron dose deposition within patients is altered during Magnetic Resonance guided Radiotherapy (MRgRT). Effects of the magnetic field are of particular interest at air-tissue boundaries, named the Electron Return Effect (ERE). Little work has been done on characterising the dosimetric effects of unplanned gas cavities in MRgRT on Organs At Risk (OAR), which could affect their dose constraints, depending on beam directions and the frequency of gas cavity presence. Here we characterise superficial dose changes around unplanned spherical air cavities during MRgRT in a single beam, as part of development a simulation platform for the dosimetric accuracy of MRgRT.

### Material and Methods

Three cuboid water phantoms containing varying spherical air cavities (0.5, 3.5, 7.5cm diameter) and a reference phantom without an air cavity were created. Monte Carlo dose calculations of a single 7MV photon beam under the influence of a 1.5T transverse magnetic field were produced using research Monaco 5.19.02 treatment planning system (Elekta AB, Stockholm, Sweden). Calculated dose distributions of phantoms with and without air cavities were compared using a spherical coordinate system originating in the centre of the cavity. Dose changes over the surface of the cavities,  $\Delta D\%(\theta, \Phi)$ , were fit to a modulated sinusoidal function of the form:  $\Delta D\%(\theta, \Phi) = A \sin(k_1 \theta + \psi_1) \sin(k_2 \Phi + \psi_2) + E$ .

Absolute residual errors, defined as simulated-fitted delta dose, for the fit were quantified and reported.

### Results

Figure 1 shows  $\Delta D\%(\theta, \Phi)$  for all tested cavities. Hot and cold spots of up to +/- 70% are observed for larger cavities, with the largest effects observed about 12° off-axis.

The fitted  $\Delta D\%(\theta, \Phi)$ , fitting parameters and absolute residual error of the fit for the cavities are presented in Figure 2. All fits have a mean error <3% of the dose at the air cavity (<0.3% for the two larger cavities), and standard deviation of <6%, i.e., the sinusoidal function characterises the effect well. However, for all cavities the fit deteriorates at the sides of the cavities (indicated by the blue areas in figure 2(panels D-F)), mainly due to lack of attenuation by the cavity. Calculating the dosimetric effect for multiple beams is done by applying the equation per beam, while rotating the coordinate system according

to the beam direction.

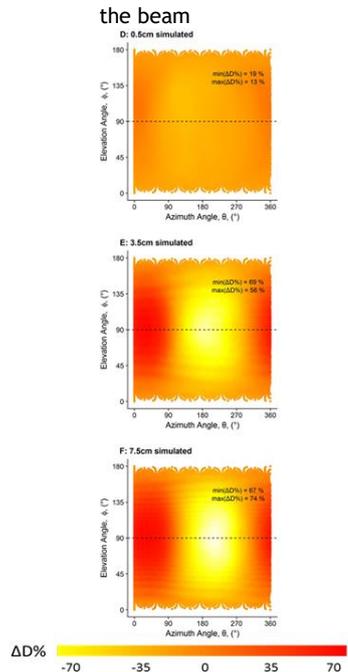

Figure 1: The dose changes,  $\Delta D\%(\theta, \phi)$ , occurring due to unplanned spherical air cavities (diameter 0.5, 3.5, 7.5 cm respectively) forming in the path of a single beam during MRgRT using a 1.5 T transverse magnetic field. Clear areas of dose increase (red) and decrease (yellow) are observed around the cavities. Minimum and maximum dose changes become larger for larger air cavities, increasing from the region of 15% in small cavities to 70% in the largest cavity for cavities.

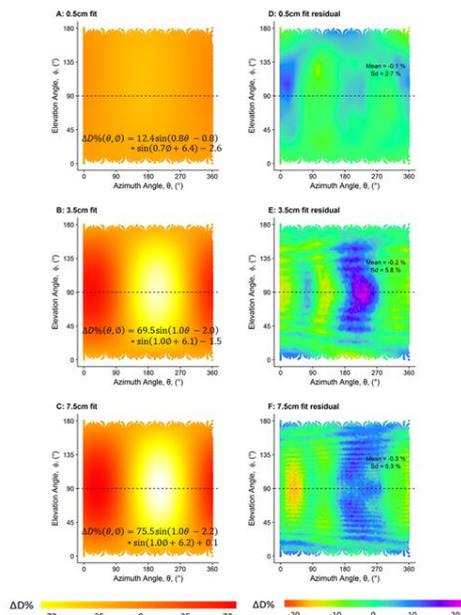

Figure 2: A-C: The fitted dose change maps for the surface of the cavities, produced using reduced-squared optimization to fit simulated data (figure 1) to a modulated sinusoidal function. The fitting parameters for each cavity are shown. D-F: The residual error of the fit for each cavity. The sinusoidal function fits the simulated data well overall, with all mean errors  $<3\%$  and the standard deviation  $<6\%$ . The fit deteriorates in the same location around the larger cavities however, indicated by the blue area. This could be due to the lack of attenuation through the cavity, which does not appear to follow a sinusoidal pattern as effects due to ERE do.

## Conclusion

We quantified dosimetric changes due to unplanned gas cavities in MRgRT using Monte Carlo dose calculations. Dose changes around the surface of unplanned spherical air cavities can be well characterised as a modulated sinusoidal function. The fit does deteriorate slightly in a consistent place around each cavity. Work is currently being done to extend the model beyond the cavity surface, create a generalised form for the relevant cavity diameters, and to implement the fit function into a

simulation platform that takes multiple beam directions into account.

## OC-0523 $^3\text{He}$ MRI for functional lung avoidance VMAT treatment planning in lung cancer

## Purpose or Objective

Radiation-induced lung toxicity (RILT) is a dose limiting complication of thoracic radiotherapy that impacts on the clinical benefits of dose escalation strategies in lung cancer. Lung dose volume parameters have a limited ability to identify patients at risk of RILT and recent studies suggest functional dosimetric parameters provide stronger predictive values than conventional anatomical parameters. The incorporation of regional ventilation information obtained via hyperpolarised gas MRI has been shown to reduce functional lung dose in conformal (3D-CRT) and fixed-field intensity-modulated radiotherapy (ff-IMRT) planning. Here we report the effects of hyperpolarised  $^3\text{He}$  MRI for volumetric modulated arc therapy (VMAT) in a cohort of lung cancer patients.

## Material and Methods

Ten non-small cell lung cancer (NSCLC) patients being planned for radical radiotherapy underwent inspiratory breath-hold CT and same-breath anatomical  $^1\text{H}$  MRI and hyperpolarized  $^3\text{He}$  MRI ventilation at the same inflation state as CT. The ventilated lung was segmented using a fuzzy c-means clustering algorithm. Binary ventilation maps were registered to breath-hold CT via its same-breath anatomical  $^1\text{H}$  MRI. VMAT plans with two partial arcs that minimised dose to the anatomical lung volume were compared with plans that minimised dose to the  $^3\text{He}$  defined functional lung volume. For each pair of plans, the volume of functional lung receiving  $\geq 10\text{Gy}$  ( $fV_{10}$ ) and  $\geq 20\text{Gy}$  ( $fV_{20}$ ), mean functional lung dose ( $fMLD$ ) and percentage of planning target volume (PTV) receiving 95% of the prescription dose ( $PTV_{95}$ ) were compared.

## Results

Incorporation of  $^3\text{He}$  MRI ventilation information led to statistically significant median reductions in  $fV_{10}$  of 1.3% (range: -0.1-2.4%;  $p=0.016$ ) and  $fV_{20}$  of 0.8% (range: -0.2-1.1%;  $p=0.007$ ). A small but significant reduction in  $fMLD$  of 0.3Gy (range: 0.1-0.4 Gy;  $p=0.005$ ) was also observed. There was no difference in target coverage: median difference in  $PTV_{95}$  of 0.0% (range: -0.2-0.1%;  $p=0.447$ ). Patients with the largest individual reductions in  $fV_{10}$  and  $fV_{20}$  demonstrated large functional defects either in close proximity to the target volume or at the periphery of the ipsilateral lung. Significant negative correlation between the percentage of ventilated ipsilateral lung and both  $fV_{10}$  and  $fV_{20}$  was also observed ( $R_s = -0.707$ ,  $p = 0.022$  and  $R_s = -0.665$ ,  $p = 0.036$  respectively).

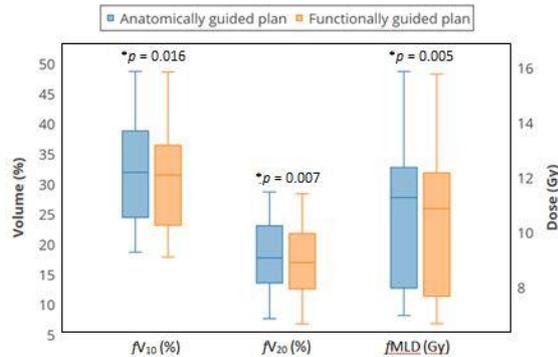

Fig1: Boxplot of functional dosimetric parameters for anatomically and functionally guided VMAT plans.

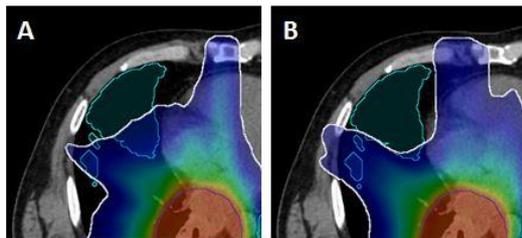

Fig2: Transverse views of anatomically guided (A) and functionally guided (B) VMAT plans for a representative patient. Cyan contour indicates the ventilated volume within the lung as defined via  $^3\text{He}$  MRI. White contour shows the 20Gy isodose, which can be seen to preferentially avoid the ventilated volume in the functionally guided plan.

## Conclusion

Functionally-guided VMAT plans incorporating regional ventilation information from hyperpolarised  $^3\text{He}$  MRI can permit dosimetric reduction to the ventilated lung volume without compromising PTV coverage. The degree of reduction is however less than that previously reported for 3D-CRT and ff-IMRT planning, which may be attributable to increased dose conformity with VMAT. The location of ventilation defect in relation to target volume is an important factor in reducing function lung dose, with the greatest reduction possible in patients with significant ventilation defects located in the ipsilateral lung.

## OC-0524 A two-beam non-coplanar class solution to supplement VMAT in prostate SBRT

A.W. Sharfo<sup>1</sup>, L. Rossi<sup>1</sup>, M. Dirckx<sup>1</sup>, S. Aluwini<sup>2</sup>, S. Breedveld<sup>1</sup>, B. Heijmen<sup>1</sup>

<sup>1</sup>Erasmus MC Cancer Institute, Radiation Oncology, Rotterdam, The Netherlands ; <sup>2</sup>University Medical Center Groningen, Department of Radiation Oncology, Groningen, The Netherlands

## Purpose or Objective

An advantage of coplanar VMAT in SBRT is short delivery time. It also avoids long planning times related to optimization of non-coplanar beam arrangements, and most commercial TPSs lack advanced options for beam angle optimization (BAO). On the other hand, optimized non-coplanar setups can often significantly improve SBRT dose distributions. In this study we used automated planning with integrated BAO to explore advantages of VMAT supplemented with  $\leq 5$  noncoplanar IMRT beams, aiming at plan quality improvement relative to VMAT while limiting the increase in treatment time. The analyses resulted in a proposal for a two-beam noncoplanar class solution to supplement VMAT.

## Material and Methods

For 20 prostate SBRT patients with a prescribed dose of 38 Gy in 4 fractions, our platform for fully automated multi-criterial treatment planning was first used to generate dual-arc VMAT plans supplemented with five non-coplanar

IMRT beams with optimized patient-specific beam orientations (VMAT+5). Next, based on the selected non-coplanar beam directions in the patient group (20x5 beams in total), two preferred non-coplanar beam directions were selected as class solution (CS), and for each of the 20 patients a VMAT+CS plan was automatically generated. The VMAT+CS plans were benchmarked against a) dual-arc coplanar VMAT plans, b) the VMAT+5 plans, and c) IMRT plans with 30 computer-optimized non-coplanar beams (30NCP). For comparison, all plans were normalized to have identical PTV coverage. Deliverability of generated plans was verified with QA measurements by executing plans at the linac, where treatment delivery times were also measured.

## Results

Fig. 1 shows treatment plan parameters for the four treatment approaches normalized to the values of VMAT. Overall the quality of VMAT+CS plans is similar to VMAT+5, while optimization times were reduced by a factor of 25 due to the omission of BAO. Compared to VMAT, VMAT+CS significantly reduced doses to rectum and bladder and dose bath, showing median percentage differences from 1-24% for rectum  $D_{1cc}$ ,  $D_{mean}$ ,  $V_{40GyEq}$ , and  $V_{60GyEq}$ , bladder  $D_{mean}$ , and patient  $V_{xGy}$  (all  $p < 0.001$ , Fig. 1). All VMAT and VMAT+CS plans passed the dosimetric QA tests (3%/1 mm criteria) with average Gamma passing rates of  $98.3 \pm 1.0\%$  and  $98.3 \pm 0.7\%$ , respectively. Compared to VMAT, VMAT+CS plans required 3% less MU on average and only  $1.9 \pm 0.7$  min longer total delivery time. Compared to 30NCP, VMAT+CS plans were considered clinically equivalent with respect to high doses in the rectum and bladder (Fig. 1A) and much faster to deliver, while 30NCP had more favorable low dose bath (Fig. 1B).

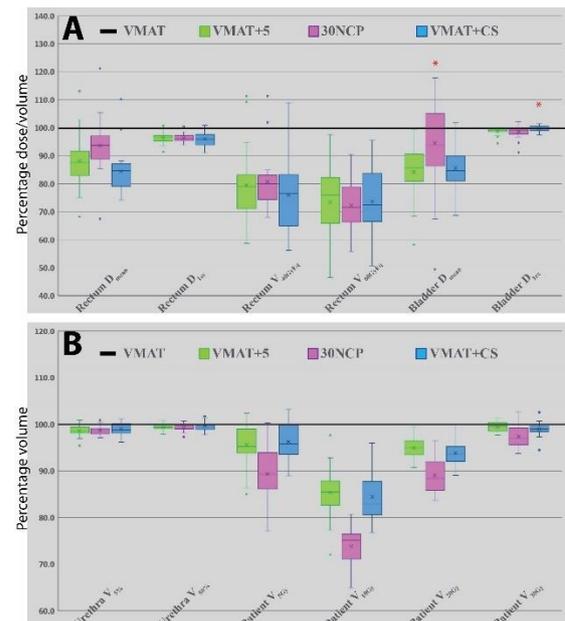

Fig 1. Percentage dose/volume values for healthy tissues across the 20 study patients, relative to VMAT. The central line of each box represents the median value, and its upper and lower edge the 25<sup>th</sup> and 75<sup>th</sup> percentiles, respectively. The x mark inside each box represents the mean value. The whiskers extend to the minimum and maximum values, or to 1.5 times the inter-quartile range from the top/bottom of the box. Values outside this range are plotted individually as outliers.

\* indicates no statistically significant difference compared to VMAT.

## Conclusion

Using an algorithm for fully automated multi-criterial beam profile and beam angle optimization (BAO), we derived a two-beam non-coplanar class solution (CS) to supplement VMAT for prostate SBRT. Adding the CS beams to a coplanar VMAT plan resulted in substantial improvements in treatment plan quality with a minimal increase in treatment time. The fixed CS avoids the need for patient-specific BAO.

### OC-0525 4D Monte Carlo dose calculations on different CT image sets for SBRT using patient breathing data

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>German Cancer Research Center DKFZ, CCC Molecular Radiation Oncology, Heidelberg, Germany; <sup>3</sup>National Center for Radiation Research in Oncology NCRO, Heidelberg Institute of Radiation Oncology HIRO, Heidelberg, Germany; <sup>4</sup>German Cancer Research Center DKFZ, Division of Medical Image Computing, Heidelberg, Germany; <sup>5</sup>Heidelberg University Hospital, Department of Radiation Oncology, Heidelberg, Germany; <sup>6</sup>Comprehensive Pneumology Center Munich CPC-M, Member of the German Center for Lung Research DZL, Munich, Germany; <sup>7</sup>DKTK, German Cancer Consortium, Munich, Germany; <sup>8</sup>LMU Munich, Department of Experimental Physics - Medical Physics, Munich, Germany

#### Purpose or Objective

The need for four-dimensional treatment planning becomes indispensable for radiation therapy of tumors with breathing-induced motion. In this study, we combined the actual patient breathing trace with the Linac's log file and a Monte Carlo (MC) dose engine to recalculate a 4D dose distribution for 3D-conformal radiation therapy (3D-CRT) and volumetric modulated arc therapy (VMAT) for lung SBRT and compared the 4D dose to MC dose calculations based on different CT image datasets.

#### Material and Methods

For 5 lung patients, 3D-CRT and VMAT treatment plans were calculated on four different 3DCT image datasets: a three-dimensional CT (3DCT), an average intensity projection (AIP) and a maximum intensity projection (MIP) CT both generated from a 4DCT, and a 3DCT with density overrides (DO) in the internal target volume (ITV) and planning target volume (PTV) based on the 3DCT. The MC 4D dose has been calculated on each 4DCT phase using the Linac's log file and the patient's breathing trace (acquired during clinical treatment). Dose calculation on 10 4DCT breathing phases was performed using MCverify, a scriptable sub-module XVMC dose engine of Hyperion V2.4.5 (University Tübingen, Germany; research version of Elekta MONACO 3.2). Dose was accumulated to the gross tumor volume (GTV) at the 50% breathing phase (end of exhale) using deformable image registration with AVID (Analysis of Variations in Interfractional Radiotherapy, DKFZ, Germany). Dose-volume-histograms (DVHs) were created and  $\Delta D98\%$  and  $\Delta D2\%$  were calculated as the difference between 4D recalculated and planned dose.

#### Results

For 3DCT-based planning,  $\Delta D98\%$  is higher in mean over all patients for all treatment plans while  $D2\%$  is lower for 3D-CRT. AIP-based planning increases the low dose areas in the GTV in 3D-CRT and slightly less using VMAT, while  $D2\%$  stays within the same range for both treatment planning methods. Absorbed dose in high dose areas is in good agreement for MIP-based planning over the patient cohort, although less dose was calculated and both treatment techniques. DO-based planning leads to a lower  $D2\%$  in the GTV due to the higher density in ITV and PTV but also to fewer cold spots for low dose areas ( $D98\%$ ) in the GTV.

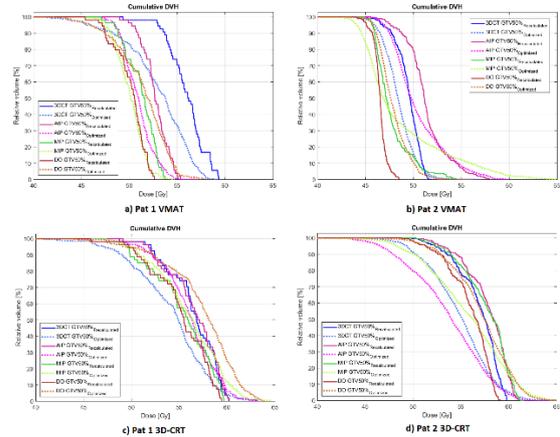

Fig. 1: GTV<sub>50%</sub> DVHs of 4D MC recalculated (solid) and optimized dose (dashed) for 2 patients: 3DCT (blue), AIP (magenta), MIP (green), DO (brown)

#### Conclusion

AIP and MIP served as the most stable base for treatment planning and both tend to be superior to DO, but the results indicate a dependency on breathing variability, tumor motion, and size. Both methods can be recommended for SBRT treatment planning but DO could perform better in individual cases due to the highly patient-specific character of breathing motion. An interplay effect could not be observed in the small patient cohort. Our workflow, after adaptation for clinical use, could help to provide a 4D dose calculation tool in modern treatment planning systems, where evaluation tools for the effects of tumor motion have not been incorporated adequately.

### OC-0526 Dependency of the interplay effect on the fractionation for proton therapy of pancreatic cancer

<sup>1</sup>German Cancer Research Center DKFZ, Medical Physics in Radiation Oncology, Heidelberg, Germany; <sup>2</sup>University of Heidelberg, Department of Physics and Astronomy, Heidelberg, Germany; <sup>3</sup>National Center for Radiation Research in Oncology, Heidelberg Institute for Radiooncology, Heidelberg, Germany; <sup>4</sup>Paul Scherrer Institute, Center of Proton Therapy, Villigen, Switzerland; <sup>5</sup>Heidelberg Ion-Beam Therapy Center HIT, Heidelberg Ion-Beam Therapy Center HIT, Heidelberg, Germany; <sup>6</sup>German Cancer Research Center DKFZ, Division of X-Ray Imaging and Computed Tomography, Heidelberg, Germany; <sup>7</sup>ETH Zurich, Department of Physics, Villigen, Switzerland; <sup>8</sup>University Clinic Heidelberg, Department of Radiation Oncology, Heidelberg, Germany

#### Purpose or Objective

In particle therapy treatments of pancreatic cancer, interplay effects between the scanning pencil beam and intrafractional abdominal organ motion may lead to pronounced hot and cold spots in the resulting dose distributions. These effects can be assessed and quantified by means of 4D dose calculations. To furthermore account for interfractional motion variability, repeated 4D image acquisitions are required. In this study, we performed 4D dose calculations based on repeated time-resolved volumetric MR images (4D-MRI) to investigate both the magnitude and the mitigation effectiveness of the interplay effect by means of fractionation for pancreatic cancer patients.

#### Material and Methods

For a cohort of 9 pancreatic cancer patients (P1-P9), up to six repeated 4D-MRI were acquired, which were

reconstructed by an iterative algorithm which provides 20 breathing phases per measurement. The deformation vector fields between the breathing phases were used to warp a 3D planning CT of the corresponding patient to obtain multiple synthetic 4DCTs per patient. These synthetic 4DCTs were used to perform single field uniform dose 4D dose calculations with 1.8 Gy (RBE) per fraction and two oblique proton beams. The interplay effect was quantified by means of the homogeneity index  $d5/d95$  and CTV coverage  $v95$  for gradually increasing numbers of treatment fractions. This was realized by randomly accumulating single fraction dose distributions with both variable initial breathing phases and underlying synthetic 4DCTs. Moreover, correlations between the interplay effect and pancreatic motion amplitudes were analyzed.

### Results

Variable initial breathing phases and day-to-day organ motion variations lead to an incremental mitigation of the interplay effect. For single fractions, pronounced underdosage down to  $v95=70\%$  with heterogeneous dose distributions were observed. On average, after 7 fractions, sufficient CTV coverage of 95%-107% was obtained for the patients. However, for patients with large underlying motion amplitudes, more fractions were needed to mitigate the interplay effect sufficiently. Despite of the pronounced interplay impact on the CTV, no significant differences were found for the organs at risk, comparing static and 4D dose distributions. Significant correlations were found between the CTV motion amplitudes and the resulting interplay effect.

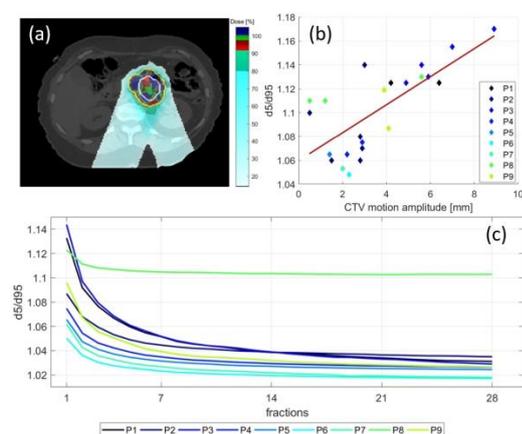

Figure 1: (a) 4D dose distribution of a single fraction. (b) The interplay effect, quantified by  $d5/d95$  is correlated with the CTV motion amplitudes. (c) By means of fractionation, the interplay effect is mitigated patient-specifically.

### Conclusion

4D dose evaluations, based on repeated 4D-MRI images, are a promising tool to investigate interplay effects and their dependency on the number of fractions. Without exposing the patients to additionally ionizing radiation, repeated 4D-MRI are useful to include motion variability into 4D dose analyses. Generally, for hypofractionated treatments, the interplay effect showed to be more pronounced than for standard fractionation schemes for pancreatic cancer treatments.

### Proffered Papers: RTT 5: Improving accuracy in patient positioning

**OC-0527 Evaluation of AlignRT for deep inspiration breath hold positioning and intrafraction monitoring**  
 V. Hamming<sup>1</sup>, C. Visser<sup>1</sup>, D. Busz<sup>1</sup>, E. Batin<sup>1</sup>, J.A. Langendijk<sup>1</sup>, S. Both<sup>1</sup>, N.M. Sijtsema<sup>1</sup>  
<sup>1</sup>UMCG University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

To determine the accuracy of a surface imaging system (AlignRT) for positioning of breast cancer patients in breath hold (BH) by comparison with conebeam computed tomography (CBCT) data. Second, to evaluate with AlignRT the intrafraction variability and stability of the breast surface position during BHs guided with the active breathing coordinator (ABC) system.

### Material and Methods

eighteen consecutive left-sided breast cancer patients treated with deep inspiration breath hold radiotherapy (DIBH-RT) were included. During CBCT acquisition and treatment, AlignRT monitored the breast surface. CBCT registrations were performed both on the target volume and on the patient's surface. The setup error differences between the CBCT and AlignRT were analyzed in terms of the group mean ( $M$ ), the systematic error ( $\Sigma$ ), the random error ( $\sigma$ ) and the 95% limits of agreement (LOA). A linear regression analysis was performed to determine the correlation. Furthermore, the intrafraction variability and stability of the ABC guided BHs were evaluated with AlignRT. The variability was determined as the average over the maximum differences between different BH levels within a treatment fraction for a patient. The stability was determined as the difference between the start and end position of a BH.

### Results

In total 143 treatment fractions were included with an average of  $7.9 \pm 3.6$  CBCTs per patient. Figure 1 shows the Bland-Altman plots for the setup errors of AlignRT and the CBCT registrations. The LOA values are on average tighter when the CBCT is registered to the patient's surface. The LOA values (mean  $\pm$  2SD) were  $0.1 \pm 3.0$ ,  $0.6 \pm 4.1$  and  $0.4 \pm 3.4$  mm in left-right, craniocaudal and anterior-posterior directions respectively for the CBCTs registered to the patient's surface. Systematic and random errors of the setup error differences were  $\leq 2$  mm in all directions. AlignRT data showed higher correlations with CBCT data for the patient's surface than for the target volume (0.61 vs 0.44 respectively). This was as expected as AlignRT monitors the same surface as was registered during the CBCT surface registration. For the variability and stability a total of 1705 BHs were analyzed. The results are presented in Table 1. The average intrafraction variability between BHs was 2.2, 2.8 and 2.3 mm whereas the average stability was -1.0, 2.1 and 1.5 mm in left-right, craniocaudal and anterior-posterior directions respectively. The largest error in intrafraction variability was 12.4 mm (craniocaudal direction) and in stability it was 11.7 mm (anterior-posterior direction).

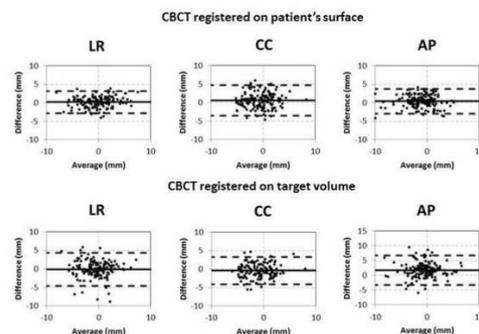

Figure 1: Bland-Altman plots for the setup errors of AlignRT and the CBCT registrations. The top and bottom dashed lines represent the 95% limits of agreement. The central solid line represents the mean of the differences between the AlignRT and CBCT setup errors. LR: left-right, CC: craniocaudal, AP: anterior-posterior.

Table 1. Intrafraction BH variability and stability evaluation

	LR (mm)	CC (mm)	AP (mm)
<u>Average (<math>\pm</math> 1SD)</u>			
BH deviation with planning CT	0.2 ( $\pm$ 3.1)	-1.0 ( $\pm$ 2.6)	-1.2 ( $\pm$ 2.9)
Variability	2.2 ( $\pm$ 1.4)	2.8 ( $\pm$ 1.5)	2.3 ( $\pm$ 1.3)
Stability	-1.0 ( $\pm$ 1.3)	2.1 ( $\pm$ 2.5)	1.5 ( $\pm$ 2.8)
<u>Maximum</u>			
Variability	7.5	12.4	6.4
Stability	-5.8	9.6	11.7

### Conclusion

With AlignRT, left-sided breast cancer patients can be positioned accurately (on average  $0.4 \pm 1.3$  (1SD) mm) based on comparison with CBCT data. Low intrafraction variability and good stability were observed for the active breathing coordinator guided breath holds.

### OC-0528 A clinical evaluation of the stability, patient comfort and ease in use of the new Nanor mask

L. Mesch<sup>1</sup>, M. Essers<sup>2</sup>, T. Rozema<sup>1</sup>

<sup>1</sup>Dr. Bernard Verbeeten Instituut, Department of Radiation Oncology, Tilburg, The Netherlands; <sup>2</sup>Dr. Bernard Verbeeten Instituut, Department of Medical Physics and Engineering, Tilburg, The Netherlands

### Purpose or Objective

The Nanor mask (Orfit Industries) is a mask with a “thin thermoplastic material that makes use of nanotechnology to improve the mechanical properties of the thermoplastic material”. The goals of this study were to compare the stability and patient comfort of the Nanor Mask with two Efficast mask materials, as well as the ease in use for the RTT.

### Material and Methods

From January 2017 until December 2017, 48 patients referred for radiotherapy of the brain for at least 10 fractions were randomized to 3 categories:

1. Orfit Efficast mask 2 mm maxi perforation (16, 1 stopped)
2. Orfit Efficast mask 1,6 mm micro perforation (16, 2 stopped)
3. Orfit Nanor mask 1,6 mm micro perforation (16, 2 stopped)

Each patient was immobilized with a mask in combination with Raycast® Head supports regular density with lateral neck flaps (Orfit Industries).

### Stability

Two orthogonal kV images were acquired for daily image-guided patient setup (Varian Medical Systems). After the online correction, CBCT1 was acquired. After delivery of the treatment fields, CBCT2 was acquired to determine the intra fraction error. Proper PTV margins were determined taking these intrafraction errors into account<sup>1</sup>.

### Patient comfort

After the treatment, the RTT marked the straining zones on a picture of the head and asked the patient where they felt any discomfort or pressure, which was also marked on another picture of the head. Figure 1 shows the colour scale (0-100%): 0% means there was no straining on any day and 100% means patient felt straining zones on each treatment day.

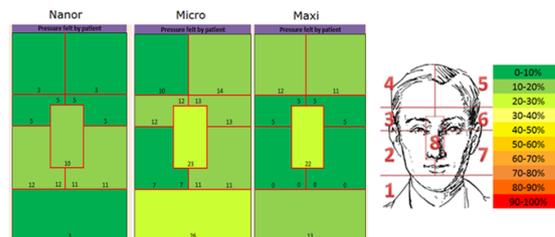

Figure 1: patient comfort

### Questionnaire

A questionnaire about ease in moulding, positioning and removing the mask was answered by:

- 4 Mouldroom RTTs
- 5 CT RTTs
- 38 Treatment room RTTs

1. van Herk M, Remeijer P, Rasch C, et al: The probability of correct target dosage: Dose-population histograms for deriving treatment margins in radiotherapy. Int J Radiat Oncol Biol Phys 47:1121-1135, 2000

### Results

#### Stability

The stability of the Nanor mask is slightly better than the Efficast Maxi and Micro mask. A reduction in intrafraction margin of 5mm is possible (Table 1).

Table 1: Intrafraction motion margin

	Margin			
	Vrt (mm)	Lng (mm)	Lat (mm)	Proper PTV Margin (mm)
Nanor mask	1,5	1,5	1,7	1,5
Efficast mask Micro	2,2	1,7	1,8	2,0
Efficast mask Maxi	1,8	2,2	1,7	2,0

### Patient comfort

Patient comfort of all masks is good. The pressure felt by the patient is comparable for the Efficast Maxi and Nanor masks and slightly less for Efficast Micro mask. Similar results were found for compression seen by the RTT. Patient comfort is slightly better for the Nanor mask for fractions where patients use dexamethasone (figure 1).

### Questionnaire

User friendliness is comparable for all masks. There is a slight preference for Nanor mask, especially for positioning the patient in the mask at the CT and the treatment unit.

### Conclusion

The stability and patient comfort for the Nanor, Efficast micro and Efficast maxi mask are good. Although the Nanor mask feels more comfortable and softer than the Efficast micro mask, in fact the stability is slightly improved.

### OC-0529 Evaluation of the potential treatment delivery benefits of Varian HyperArc for brain metastases

A. Williamson<sup>1</sup>, A. James<sup>1</sup>, A. Chalmers<sup>2</sup>, R. Carruthers<sup>2</sup>, S. Nowicki<sup>1</sup>, P. McLoone<sup>3</sup>

<sup>1</sup>Beatson West of Scotland Cancer Centre, Radiotherapy, Glasgow, United Kingdom; <sup>2</sup>Institute of Cancer Sciences-University of Glasgow, Radiotherapy, Glasgow, United Kingdom; <sup>3</sup>University of Glasgow, Statistics, Glasgow, United Kingdom

### Purpose or Objective

Varian HyperArc is a stereotactic radiosurgery solution, designed to automate and simplify sophisticated treatments which became clinically available in October 2017. HyperArc uses the Encompass immobilisation device and 6DOF couch, with a single button delivery and automated couch movement eliminating the need to re-

enter the room during treatment. Before the implementation of HyperArc, patients were immobilised with BrainLab mask system and planned using 10X FFF VMAT.

#### Objective

- Compare the positioning accuracy of Encompass and the BrainLab frameless mask system
- Determine the potential treatment delivery advantages of HyperArc
- Investigate the intrafraction motion for the Encompass device

#### Material and Methods

50 patients with brain metastases were treated with SRS. Lesions were <3cm and treated with a dose between 18-24Gy.

25 patients, set up with Brainlab, were planned using mono-isocentre 10XFFF VMAT with co-planar arcs. These were compared to 25 subsequent patients, set up with Encompass, and planned with Hyperarc using a mono-isocenter technique with multiple non-coplanar arcs. CBCT imaging was acquired immediately before treatment and registered to the reference CT using a 6DOF automatching procedure. All corrections were applied before delivery. Beam on time (BOT) (min:sec) is defined as the aggregate time for delivery of total MU for all arcs in a given plan. Time In Room (TIR) (min:sec) is measured from the first alignment image to last beam off, inclusive of all pre-treatment imaging and/or shifts to correct patient position. Post treatment CBCT scans were acquired for Encompass to assess intrafraction motion. Two sample t-tests (two-tailed with a significance level of < 0.05) were used to test for differences between the techniques.

#### Results

Brainlab patients were treated with 2 coplanar arcs. Encompass patients were treated with 4 arcs delivered at floor rotation angles of 0, 45, 315 and 270. Mean setup shifts for Encompass and Brainlab were 1mm or less (Table 1). There was no statistically significant difference in mean set-up shifts comparing Encompass with BrainLab patients, although the mean values for Brainlab patients were slightly smaller and sub 1 mm.

Mean BOT for HyperArc was on average 0.6 minutes less than 10XFFF VMAT ( $p=0.0005$ ) - a 20% reduction (Table 2). Mean TIR for HyperArc was on average 7.1 minutes shorter ( $p<0.0001$ ) - a 41% reduction.

Intrafraction motion for Encompass is shown in Table 3.

	Vrt mm Mean (SD)	Lng mm Mean (SD)	Lat mm Mean (SD)	Pitch° Mean (SD)	Roll° Mean (SD)	Rot° Mean (SD)
Encompass	1.18 (0.76)	1.04 (0.74)	0.87 (0.60)	0.43 (0.50)	0.55 (0.48)	0.74 (0.62)
BrainLab	0.78 (0.68)	0.79 (0.72)	0.78 (0.62)	0.61 (0.52)	0.34 (0.31)	0.44 (0.34)
P value	0.06	0.23	0.58	0.22	0.08	0.06

	Mean BOT (SD) (mins)	Mean TIR (SD) (mins)
HyperArc	2.5 (0.3)	10.1 (1.1)
10X FFF VMAT	3.1 (0.6)	17.2 (5.0)

	Vrt mm	Lng mm	Lat mm	Pitch°	Roll°	Rot°
Mean	0.18	0.23	0.12	0.13	0.11	0.15
SD	0.12	0.26	0.12	0.10	0.05	0.17

#### Conclusion

To our knowledge this is the first study to evaluate the benefits of Varian Hyperarc for treatment delivery. The setup accuracy of Encompass is comparable to BrainLab, and treatment position with Encompass is maintained during the delivery of non-coplanar beams. HyperArc delivers linac based SRS efficiently, with a faster treatment time than 10XFFF VMAT and a statistically significant improvement in TIR. This significant reduction in delivery time (TIR) could result in a clinically

meaningful reduction in risk of intrafraction motion than previous technique.

#### OC-0530 Improving OAR volumes during prostate RT using daily patient feedback and standardized protocols

I. Gagne<sup>1</sup>, K. Earnshaw<sup>2</sup>, S. Cowan<sup>2</sup>, J. Goulart<sup>3</sup>, A. Alexander<sup>3</sup>

<sup>1</sup>BC Cancer - Victoria, Medical Physics, Victoria, Canada ;

<sup>2</sup>BC Cancer - Victoria, Radiation Therapy, Victoria, Canada; <sup>3</sup>BC Cancer - Victoria, Radiation Oncology,

Victoria, Canada

#### Purpose or Objective

Prostate radiotherapy accuracy is impacted by inter- and intra-fraction volume variations associated with proximal organs at risk (OARs) such as bladder and rectum. Patients are therefore often advised to have a comfortably full bladder and empty rectum at the time of CTsim and treatment. The optimal hydration and bowel preparation is a topic of many studies and there exists to date no consensus. The goal of this study was to evaluate the impact of a standardized hydration and bowel preparation protocol (SHBPP) in conjunction with daily patient engagement on bladder and rectum volumes.

#### Material and Methods

In 2018, 32 patients with prostate cancer were sent a SHBPP advising them to administer a micro-enema 2-3 hours before CTsim and the first 10 treatments and to empty their bladder 1hour before CTsim and treatment and consume within 15 minutes, 750 ml of water. At the time of CTsim and treatment, radiation therapists (RTs) recorded the details of the preparation in the patient's technical notes. Daily CBCT was performed and the consistency of bladder and rectal volumes in comparison to CTsim was assessed and recorded using a locally developed bladder and rectum scoring system. Scores and CTsim volumes obtained for this cohort were compared to 20 patients treated in 2013 who had CBCT on days 1,2,3 and weekly, and no SHBPP and daily feedback. In this non-SHBPP cohort, therapists were instructed to ensure bladder filling at time of CTsim placed the bladder dome at least 2 cm above the femoral head.

#### Results

To date, 19 patients on SHBPP have completed treatment, leading to 19 CTsim volumes and 533 CBCT scores for analysis. Using the Mann-Whitney test, the median bladder (279cc vs 387cc) and rectal (57cc vs 79cc) volumes were found to be statistically different at the  $P=0.05$  level, with CTsim bladder and rectal volumes being on average, 15% and 30% smaller, respectively with SHBPP. While rectal volumes were found to have less variability (SD: 20cc vs 37cc), bladder volumes had slightly larger variability (SD: 200cc vs 180cc). The smaller variability in the non-SHBPP cohort could be due to the bladder filling requirement at CTsim. On treatment, the fraction of treatments with rectal volumes within "rectum+5mm" where the same (75%) while the fraction of treatments with anterior rectal distensions >10mm decreased by 3% (8% vs 11%) for the SHBPP group. The fraction of treatments with bladder volumes <2/3 decreased by 28% (13% vs 41%). On average, the difference in bladder filling scored by measuring the dome location difference between CBCT and CTsim was  $-0.3\text{cm}\pm 0.9\text{cm}$  for the SHBPP group vs  $-2.0\pm 2.5\text{cm}$  for the non-SHBPP group.

#### Conclusion

The implementation of SHBPP resulted in significantly smaller and less variable rectal volumes and slightly smaller bladder volumes at CTsim. The use of daily feedback significantly reduced the variability of bladder volumes at treatment and also reduced the fraction of treatments with rectal distensions >10mm by 3%.

### OC-0531 Can SGRT be used with open masks to set-up HNC patients and reduce intrafractional motion?

A. Moreira<sup>1</sup>, N. Weitkamp<sup>1</sup>, M. Zamburlini<sup>1</sup>, H.I. Garcia Schüler<sup>1</sup>, M. Guckenberger<sup>1</sup>

<sup>1</sup>University hospital Zurich, Radiation Oncology, Zurich, Switzerland

#### Purpose or Objective

To evaluate the set up and treatment of head and neck cancer patients in an open mask with the aid of surface guided radiotherapy (SGRT). We investigated the initial setup accuracy of an open mask (OM) with SGRT vs. traditional closed mask (CM) system. Additionally, data from the SGRT system was used to evaluate intrafractional motion.

#### Material and Methods

14 Patients being treated for T1 or T2 larynx carcinomas were evaluated in this study. Patient setup at planning CT was performed using a CIVCO Posifix® thermoplastic mask. For 7 patients the mask was cut out around the face (from 2-5cm above the eyebrow, until 1cm above the lips and on the sides until their ears) as well as over the neck (Fig 1.). Patients' reference surface was imported from the CT scan and regions of interest for both the face and the neck were selected. The patients were positioned until all pre-shift deltas displayed on the SGRT system were as close to zero as possible. After positioning, CBCT imaging was performed to verify the patient's position. The residual set up error as defined by shifts seen on the CBCT image were compared to a control group of 7 patients who were treated using the standard closed mask to evaluate any loss in stability as well as set up accuracy. For the 7 patients treated with an open mask, the intra-fractional motion caused by swallowing was also evaluated using SGRT to monitor the neck area. Gating margins on the SGRT system were set at  $\pm 2\text{mm}/2^\circ$  in each direction and log files were retrospectively analyzed to determine how often the patients swallowed during treatment and how large this motion was.

#### Results

In total, 153 CBCTs were analyzed: 80 from the OM group and 73 from the CM group. Mean post-match shifts based on CBCT PTV match was  $-0.1 \pm 0.2\text{cm}$ ,  $0.2 \pm 0.4\text{cm}$ ,  $-0.04 \pm 0.13\text{cm}$ ,  $0.4 \pm 1.8^\circ$ ,  $0.7 \pm 2.7^\circ$ ,  $0.6 \pm 2.5^\circ$  in the OM plus SGRT group and  $0.0 \pm 0.3\text{cm}$ ,  $-0.1 \pm 0.5\text{cm}$ ,  $-0.1 \pm 0.4\text{cm}$ ,  $0.2 \pm 1.4^\circ$ ,  $0.6 \pm 1.4^\circ$ ,  $0.7 \pm 1.2^\circ$  in the CM group, in the VRT, LNG, LAT, Rotation, Roll and Pitch directions respectively. In 27% out of the 211 fractions monitored using SGRT, the radiotherapy delivery was interrupted at least once during treatment due to motion caused by swallowing. During this time, the mean absolute shifts were  $1.5 \pm 2.6\text{ mm}$ ,  $3 \pm 7\text{ mm}$ ,  $1.7 \pm 1.9\text{ mm}$  in VRT, LONG, LAT directions. This proves that treatment disruption is due to longitudinal motion. Mean absolute motion observed during beam delivery were  $0.27 \pm 0.23\text{ mm}$ ,  $0.3 \pm 0.3\text{ mm}$ ,  $0.3 \pm 0.4\text{ mm}$  in the VRT, LNG, LAT directions.

#### Conclusion

Our study shows that SGRT allows for HNC treatment in an open mask with clinically acceptable setup accuracy of less than 2mm in each direction. An open mask creates a better treatment experience for patients with claustrophobia and any potential benefit of increased patient comfort will be investigated in future studies. Additionally, OM allows monitoring and if necessary gating of radiotherapy delivery for swallowing motion, which could influence future PTV definition.

### OC-0532 Virtual reality animations, a new strategy to reduce patients' anxiety induced by radiotherapy

G. Van Ooteghem<sup>1,2</sup>, X. Geets<sup>1,2</sup>

<sup>1</sup>Institut de Recherche Expérimentale et Clinique, Molecular Imaging- Radiotherapy and Oncology - MIRO, Brussels, Belgium; <sup>2</sup>Cliniques Universitaires Saint Luc, Radiation Oncology, Brussels, Belgium

#### Purpose or Objective

Patients facing medical and technological interventions such as radiotherapy, mechanically-assisted and non-invasive ventilation (MANIV), or MRI can experience a high level of anxiety and discomfort in addition of the stressful background linked to cancer. This can lead to negative impacts on their mental status but also have deleterious consequences during radiation treatments (difficulties in positioning, movements during irradiation, impaired breathing) and thus also impact the treatment efficacy. Virtual reality and hypnosis are stress management strategies that showed encouraging results in different medical fields. The efficacy on anxiety of a dedicated hypnotising Virtual Reality Animation (VRA) commercialised by Oncomfort® was evaluated in patients included in a trial assessing MANIV. This trial aimed to demonstrate the safety and the efficacy of MANIV to stabilize and modulate the breathing pattern without any sedation. Patients were therefore connected to a mechanical ventilator and asked to give up control on their breathing. They could thus experience anxiety.

#### Material and Methods

VRA lasted for 10 to 20 minutes and was proposed before each MANIV session (one coaching session, one simulation session and 2 MRI sessions) (Figure 1).

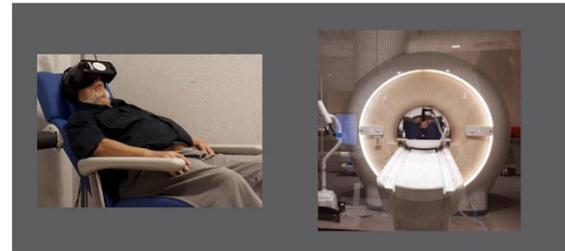

Figure 1: The Oncomfort® device was used for a hypnotising Virtual Reality Animation (VRA) with the aim to decrease the patient anxiety level before that he underwent a MRI acquisition session with Mechanically-assisted and non-invasive ventilation (MANIV).

VRA assessment was done with questionnaires fulfilled at each session. Patients answered first to multiple choice questions (MCQ), then to the same questions but with a Visual Analogic Scale (VAS) ranging from 0 to 100. On VAS, an effect on anxiety was considered when a difference greater than 10 was observed between two scores.

#### Results

Twenty-one patients (49-83 years old) participated to the trial. Comfort level obtained during the coaching and simulation sessions and rated before the VRA, after the VRA and during MANIV were 54, 67 and 66 respectively. During the 2 MRI sessions, the comfort level before the VRA, after the VRA were similar (57.5 and 66.5 respectively) but was clearly decreased during the MRI acquisitions (50), raising a probable MRI-driven loss of comfort.

Based on the MCQ, 17 patients (81%) appreciated the VRA experience. Nine patients (43%) felt an improvement of their comfort while 9 patients (43%) did not and 3 (14%) experienced a comfort degradation. VAS scores led to identical conclusions, with only one patient having discrepancies in his answers. Patients with the lowest VAS scores in comfort before the trial were those with the greatest improvement after the VRA. Eight patients (38%) stopped the trial at their request for convenience reasons or due to the degradation of comfort.

#### Conclusion

The hypnotising Virtual Reality Animation proposed by Oncomfort® can be a good support, especially in very anxious patients. However, some patients may not benefit of this strategy, highlighting the need to adapt to each patient and to further enlarge our stress management strategies.

**PV-0533 HPV16 viral load may explain gender differences in treatment outcome of anal squamous cell carcinoma**

D. Martin<sup>1</sup>, P. Balermphas<sup>1</sup>, R. Winkelmann<sup>2</sup>, U. Wieland<sup>3</sup>, M. Rave-Fränk<sup>4</sup>, J. Kitz<sup>5</sup>, C. Rödel<sup>1</sup>, E. Fokas<sup>1</sup>, F. Rödel<sup>1</sup>  
<sup>1</sup>Klinikum der Johann Wolfgang Goethe Univ, Department of Radiotherapy and Oncology, Frankfurt, Germany ;  
<sup>2</sup>Klinikum der Johann Wolfgang Goethe Univ, Senckenberg Institute for Pathology, Frankfurt, Germany ;  
<sup>3</sup>University of Cologne, Institute of Virology- National Reference Centre for Papilloma- and Polyomaviruses, Cologne, Germany ;  
<sup>4</sup>University Medical Center Göttingen, Department of Radiotherapy and Radiation Oncology, Göttingen, Germany ;  
<sup>5</sup>University Medical Center Göttingen, Department of Pathology, Göttingen, Germany

**Purpose or Objective**

Female gender is a well-established favorable prognostic factor after definitive chemoradiotherapy (CRT) for patients with anal squamous cell carcinoma (ASCC), however, no clear explanation for this gender difference has been elucidated so far. ASCC is associated with high-risk strains of human papilloma virus (HPV) infection and HPV-positive patients have improved treatment outcomes. We hypothesized that the differences in outcome according to gender are due to differences in HPV infection parameters.

**Material and Methods**

We examined pretreatment tumor samples of 141 patients (64 male/77 female) with ASCC treated with standard chemoradiotherapy. Expression of p16<sup>INK4a</sup> was measured semiquantitatively by a immunohistochemical score. The HPV16 viral load was assessed via a quantitative PCR approach. Clinical outcomes of these patients were correlated with clinicopathological factors and p16 expression/HPV16 viral load.

**Results**

After a median follow-up of 46 months, the 5-year locoregional control rate (LRC) and disease-free survival (DFS) was 80.4% and 75.3%, respectively. There were no significant differences in age, cT/N-categories, pretreatment white blood cell and platelet count according to gender, but female patients had significantly lower hemoglobin levels at baseline. A high HPV16 viral load (using maximally selected rank statistics) was associated with a favorable LCR ( $p < 0.01$ ), DFS ( $p < 0.01$ ), and overall survival ( $p < 0.01$ ). A high expression of p16<sup>INK4a</sup> (score >6) was associated with a favorable LRC ( $p < 0.01$ ) and DFS ( $p < 0.05$ ). Female patients showed a significantly higher HPV16 viral load ( $p = 0.012$ ) at baseline. In a multivariate cox regression model, including gender and HPV16 viral load, only the viral load was significantly associated with LRC (HR 0.3,  $p < 0.01$ ) and DFS (HR 0.39,  $p < 0.05$ ).

**Conclusion**

A high HPV16 viral load in pretreatment tissue was associated with better treatment outcome and significantly higher in female patients. Multivariate analyses revealed that HPV16 viral load remained as a significant predictor of treatment outcome when combined with gender. These data suggest a possible biological background for gender differences after CRT in ASCC.

**PV-0534 Carbon ions and microRNAs: new insights into hadrontherapy biology in prostate cancer**

I. Salido<sup>1</sup>, R. El Bezawy<sup>1</sup>, M. Ciocca<sup>2</sup>, F. Valvo<sup>2</sup>, A. Facchetti<sup>2</sup>, P. Gandellini<sup>1</sup>, R. Valdagni<sup>3</sup>, N. Zaffaroni<sup>1</sup>  
<sup>1</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Applied Research and Technological

Development, Milan, Italy; <sup>2</sup>Fondazione CNAO- Centro Nazionale di Adroterapia Oncologica, Clinical Department, Pavia, Italy; <sup>3</sup>Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Department of Radiation Oncology 1, Milan, Italy

**Purpose or Objective**

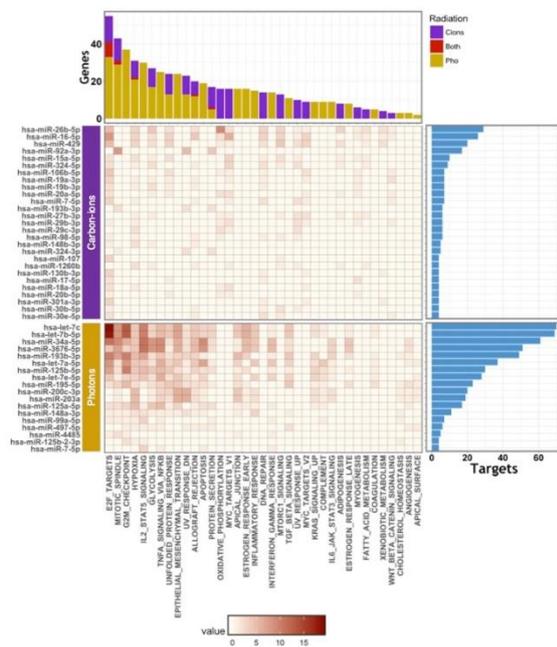

Considering the relative radioresistance of prostate cancer (PCa) to conventional photon therapy, a novel form of external radiation therapy, hadrontherapy, has been recently proposed. Hadrontherapy uses high-linear energy transfer (LET) particle beams, such as carbon ions, and exhibits favorable results for several malignancies that poorly respond to conventional radiotherapy, including PCa. However, from a radiobiological perspective, the molecular basis underlying carbon ions is not yet fully understood. In this regard, among the various molecular determinants of response to radiotherapy are microRNAs (miRNAs).

**Material and Methods**

We explored changes in the miRNome and gene expression profile of PCa cell lines (LNCaP and DU145) upon carbon ion beam and photon irradiation -a study never pursued in the available literature- to search for commonalities and differences between the two irradiation sources. Considering the higher relative biological effectiveness (RBE) of carbon ions, PCa cells were exposed to different doses of photons (10 Gy) and high-LET carbon ion beams (5 Gy) delivered by a <sup>137</sup>Cs irradiator and a synchrotron (at CNAO, Pavia), respectively. miRNA and gene differential expression following irradiation was assessed by microarray analyses at different time points and then validated by qRT-PCR.

**Results**

We found that, among the 102 miRNAs modulated by photons and the 186 miRNAs affected by carbon ions, only 6 (2%) were shared by the two irradiation sources in both LNCaP and DU145 cell lines. Accordingly, the analysis of miRNA targets, selected from the intersection of targets predicted by in silico tools and genes found anticorrelated among those modulated upon irradiation, revealed that there was only a partial overlap (4%) between photons and carbon ions. These findings suggest that, unexpectedly, the two irradiation sources act by affecting different miRNAs and genes, still producing the same biological effect. Paradoxically, GSEA analyses revealed that genes significantly modulated by photons and/or carbon ions were prevalently enriched for common biological processes, including mitotic spindle and UV response, known to be strictly related to radiation response. This provides the first evidence that photons and carbon ion beams modulate different factors still converging on common cell processes, thus determining a comparable final biological effect.

### Conclusion

Overall, our findings show that photons and carbon ions may modulate the expression of different miRNAs still affecting the same biological processes. While photon radiobiology has been extensively characterized, a deeper understanding of the biological dynamic underlying the modus operandi of carbon ions might contribute to the design of more precise and honed hadrontherapy treatment schedules on the basis of patient miRNA expression patterns. In addition, miRNAs may be envisaged as a novel class of predictive biomarkers also for this promising frontier in radiotherapy.

### PV-0535 Pilot study on immunomodulation role of radiotherapy in oropharyngeal cancer: preliminary results

<sup>1</sup>University of Genoa and IRCCS Ospedale Policlinico San Martino, Department of Health Science DISSAL and Radiation Oncology, Genoa, Italy; <sup>2</sup>IRCCS Ospedale Policlinico San Martino, Department of Radiation Oncology, Genoa, Italy; <sup>3</sup>University of Genoa, Department of Otorinolaringology- Head and Neck Surgery, Genoa, Italy; <sup>4</sup>University of Genoa and IRCCS Ospedale Policlinico San Martino, U.O. Immunologia Clinica and Centro di Eccellenza per le Ricerche Biomediche CEBR, Genoa, Italy; <sup>5</sup>IRCCS Ospedale Policlinico San Martino, Department of Medical Oncology, Genoa, Italy

### Purpose or Objective

The discovery of the key role of the immune system in the pathogenesis of tumors prompted studies aimed at identifying immunological prognostic biomarkers. The encouraging results of immunotherapy in recurrent non-resectable head and neck cancer may indicate its potential efficacy, combined to conventional therapies, also as primary treatment. The aim of our prospective study is to perform a comprehensive analysis of the circulating and intratumoral T cell compartments in patients affected by Oropharyngeal Squamous Cell Carcinoma (OSCC) to search for new prognosticators and

to get insights on new possible immunotherapeutic strategies.

### Material and Methods

From May to November 2017 20 untreated patients affected by moderately to advanced stage OSCC and treated by radiotherapy or chemo/bio-radiotherapy have been enrolled in the study. Peripheral blood and tumor biopsies were collected and evaluated by multiparametric flow cytometry panels to delineate: CD4+ and CD8+ T cell maturation stages, frequency of CD4+ and CD8+ T regulatory cells (Treg), expression of exhaustion/immune checkpoints (CD39, PD-1, CTLA-4, TIM3).

### Results

The results showed: a) CD4+ and CD8+ effector memory cells were the most represented population among tumor infiltrating lymphocytes (TIL) but not among peripheral blood lymphocytes; b) CD4+ and CD8+ TIL showed decreased expression of co-activatory receptors, as CD28 molecule, and increased expression of inhibitory receptors, as PD-1, TIM-3, CTLA-4, than circulating CD4+ and CD8+ T cells; c) intratumoral CD4+ and CD8+Treg frequencies resulted statistically increased in cancer specimens with respect to blood; d) Treg exhibited an active functional phenotype, as demonstrated by their elevated FoxP3, CTLA-4 and CD39 expression and high expression of immune checkpoints (PD1, CTLA-4 and TIM3).

### Conclusion

Collectively, the results highlight expansion in the tumor of T cells in advanced stage of maturation, characterized by high expression of immune checkpoints and enrichment of Treg, suggesting a pressure by tumor toward regulatory function induction. Interestingly, immune checkpoint expression only partially overlapped in the different intratumoral T cell subsets indicating that immunotherapy by immune checkpoint inhibitors might develop new combinatorial protocols associating at least 3 different agents targeting CTLA-4, PD1-PDL1 and TIM3-Galectin-9 axes in order to be effective in HNSCC patients.

### PV-0536 On the impact of HPV status and radiation dose on survival in a large cohort of anal cancer patients

R. Kabarriti<sup>1</sup>, P. Brodin<sup>2</sup>, R. Narang<sup>3</sup>, R. Huang<sup>3</sup>, J. Chuy<sup>3</sup>, L. Rajdev<sup>3</sup>, S. Kalnicki<sup>2</sup>, C. Guha<sup>2</sup>, M. Garg<sup>2</sup>  
<sup>1</sup>Montefiore Medical Center- Albert Einstein College, Radiation Oncology, New York, USA ; <sup>2</sup>Montefiore Medical Center, Radiation Oncology, Bronx, USA; <sup>3</sup>Montefiore Medical Center, Oncology, Bronx, USA

### Purpose or Objective

To determine whether patients with anal cancer with human papilloma virus (HPV) infections have different overall survival compared to those without HPV infections, and to elucidate the radiation dose-response relationship in a large retrospective cohort of anal cancer patients.

### Material and Methods

We utilized the National Cancer Database (NCDB) registry to identify a cohort of non-metastatic anal cancer patients treated with curative intent between 2008 - 2015 with available treatment data and follow-up for vital status. HPV status was dichotomized into positive vs. negative for those with available HPV markers from diagnostic work-up. For patients receiving definitive radiation therapy (RT), the total dose delivered to the tumor was used for analysis. Multivariable Cox proportional hazards regression models were used to determine the association between HPV status and overall survival (OS), as well as varying levels of total RT dose delivered. Kaplan-Meier survival analysis with log-rank test was used to illustrate and compare actuarial survival estimates between groups.

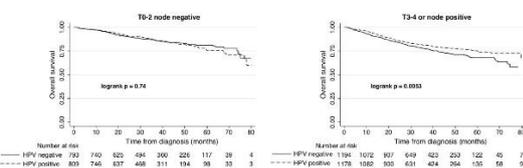

### Results

We identified 33,537 patients for this analysis, of which 5,961 patients had information on HPV infection. Of those, 3,550 (59.6%) were HPV positive and 2,411 (40.4%) were

HPV negative. In a propensity-matched analysis adjusted for age, sex, Charlson-Deyo score, systemic therapy use, treatment facility, income, ethnicity and race; HPV positive patients had significantly better OS, but only in patients with locally advanced disease (T3-4 or node positive; HR = 0.77 (95% CI: 0.64-0.93),  $p=0.005$ ), whereas for patients with early stage disease (T1-2 and node negative) there was no association with OS (HR = 1.08 (95% CI: 0.83-1.42),  $p=0.56$ ). Similar results were found in unmatched multivariable analysis (Locally advanced disease: HR: 0.79;  $p=0.005$  and early-stage disease HR: 1.12;  $p=0.34$ ). The table shows the results from the propensity-matched multivariable analysis and the figure the propensity-matched unadjusted Kaplan-Meier curves, illustrating HPV infection as a prognostic marker in locally advanced disease. The multivariable model for radiation dose showed a clear dose-response for all patients with decreasing HRs for increasing total RT dose up to 55 Gy (compared to total RT doses less than 40 Gy, 40-45 Gy- HR: 0.71;  $p<0.001$ ; >45-50 Gy- HR: 0.74;  $p<0.001$ ; >50-55 Gy- HR: 0.60,  $p<0.001$ ; >55-60 Gy- HR: 0.69;  $p<0.001$ ; >60-65 Gy- HR: 0.78;  $p=0.003$ ; >65 Gy- HR: 0.84;  $p=0.11$ ). A stronger dose-response was seen for locally advanced patients who were HPV negative (HR: 0.43 for >50-55 Gy), compared to those that were HPV positive (HR: 0.72 for >50-55 Gy).

Patients with T3-4 or node positive disease	Hazard ratio (95% CIs)	p-value

\*also adjusted for income, ethnicity and race

## Conclusion

We found that HPV infection is a positive prognostic marker for patients with locally advanced anal cancer, but not for those with early stage disease. We further found that higher radiation dose up to 55 Gy was associated with better survival, especially for locally advanced disease in HPV negative patients, and less so in those with HPV positive disease.

## PV-0537 Optimized fractionated radiotherapy with anti-PD-L1 and anti-TIGIT: a promising combination

M. Grapin<sup>1</sup>, E. Limagne<sup>2</sup>, C. Richard<sup>2</sup>, R. Boidot<sup>2</sup>, M. Thibaudin<sup>2</sup>, V. Morgand<sup>1</sup>, G. Créhanche<sup>1</sup>, F. Ghiringhelli<sup>2</sup>, C. Mirjoret<sup>1</sup>

<sup>1</sup>Centre Georges-François Leclerc, Radiation Oncology, Dijon, France ; <sup>2</sup>Centre Georges-François Leclerc, Platform of Transfer in Biological Oncology, Dijon, France

## Purpose or Objective

Radiotherapy (RT) is able to induce an immunogenic antitumor response, but also to increase some

immunosuppressive barriers. It is still unclear how each fractionation protocol can modulate the immune microenvironment. Nevertheless, it is essential to determine the best RT fractionation protocol to associate with checkpoint inhibitors (CPI). Currently, in the setting of localized rectum cancer, RT can be delivered before surgery according to two validated schemes with a different dose per fraction. Clinical studies are ongoing to evaluate CPI (such as anti-PD-L1) in association with RT. However, only few trials aim to optimize the RT fractionation to improve efficacy of these associations. Here we wanted to characterize different fractionation protocols effect on immune response and associate them with CPI.

## Material and Methods

Mice bearing subcutaneous CT26 colon tumors were irradiated using SARRP device according to different radiation schemes (1, 3 or 18 fractions) with a same biologically effective dose. The mice were monitored for tumor growth. The radiation immune response (lymphoid, myeloid cells, lymphoid cytokines and immune checkpoints) was monitored by flow cytometry at different time points after treatment. The same fractionation protocols were performed with or without CPI against immune checkpoints modulated by RT.

## Results

In absence of CPI, we showed that 18x2Gy and 3x8Gy induced the longest tumor growth delay compared to 1x16.4Gy. While 3x8Gy and 1x16.4Gy induced a lymphoid response (CD8<sup>+</sup>T cells, Regulators T cells (Treg) and natural killer cells); 18x2Gy induced a myeloid response (MDSC, neutrophils, tumor-associated macrophages 2). The secretion of granzyme B by CD8<sup>+</sup>T cells and interferon  $\gamma$  by CD4<sup>+</sup>T cells was more importantly increased with 3x8Gy. The expression of PD-L1 by tumor cells was moderately increased by RT but the most durably with 18x2Gy. While TIGIT expression by CD4<sup>+</sup>, CD8<sup>+</sup>T and NK cells was increased or maintained by 3x8Gy compared to control group, it was decreased or maintained by 18x2Gy and 1x16.4Gy. There was a synergistic effect of any CPI with RT whatever the dose per fraction compared to RT and IgG. The 18x2Gy protocol did not seem to benefit from anti-TIGIT when associated with anti-PD-L1. RT was dramatically more effective with 3x8Gy compared to all the other treatments schemes when associated with anti-TIGIT and anti-PD-L1 with more than 90% of the tumor in complete response.

## Conclusion

Each fractionation scheme induced different lymphoid and myeloid responses as well as various modulation of PD-L1 and TIGIT expression. Furthermore, 3x8Gy was the most effective protocol when associated with anti-PD-L1 and anti-TIGIT. This is the first study combining RT and anti-TIGIT with promising results; further studies are warranted.

In order to describe mechanisms, which may explain differential effects of the different fractionation protocols on immune response, RNA sequence-analysis is still ongoing.

## PV-0538 Prostaglandin related distinct regenerative activities in hair follicles following radiation injury

S. Lai<sup>1,2</sup>, W. Huang<sup>3</sup>, S. Chen<sup>1</sup>, S. Lin<sup>1,4,5</sup>

<sup>1</sup>National Taiwan University, Institute of Biomedical Engineering- College of Medicine and College of Engineering, Taipei, Taiwan ; <sup>2</sup>National Taiwan University Hospital and College of Medicine, Division of Radiation oncology- Department of Oncology, Taipei, Taiwan ; <sup>3</sup>National Taiwan University, Institute of Biomedical Engineering- College of Medicine and College of Engineering-, Taipei, Taiwan ; <sup>4</sup>National Taiwan University, Research Center for Developmental Biology and Regenerative Medicine, Taipei, Taiwan ; <sup>5</sup>National Taiwan University Hospital and College of Medicine, Department of Dermatology, Taipei, Taiwan

### Purpose or Objective

The highly proliferative hair follicles are sensitive to radiation and hair loss (alopecia) often develops. We found, local prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) pretreatment could reduce hair loss from radiation injury by preventing entry into catagen (regression phase) and telogen (resting phase) (Figure 1a). Whether and how anagen hair follicles attempt to repair themselves in response to ionizing radiation (IR) under PGE<sub>2</sub> local treatment has not been characterized. In this work, we try to investigate the proceeding regenerative process in hair follicle cells following radiation injury under prostaglandin treatment.

### Material and Methods

The dorsal hair of female C57BL/6 mice on postnatal day 32 when hair follicles were in the early full anagen (growth phase) was carefully shaved. Single dose of 8.5Gy was given from dorsal side 2 hours after dmPGE<sub>2</sub> (A stabilized derivative of prostaglandin E<sub>2</sub>, 16,16-dimethyl-PGE<sub>2</sub>) locally injected. Skin specimen was harvested at multiple time points after radiation exposure. H&E staining, Immunohistochemical analysis and double staining with hair follicle cell markers were used to monitor the dynamics of cell differentiation at different time points. The fluorescence ubiquitination cell cycle indicator (FUCCI) system, which can easily determine G1 and/or S/G2/M phases of the cell cycle through analyzes living cells in a spatio-temporal manner using a dual color scheme of orange and green, is used for evaluating cell cycle condition.

### Results

Severe dystrophic change of anagen hair follicles were observed after 8.5Gy radiation injury. We found anagen hair follicles were able to initiate spatially and temporally repair activities to restore their structure under PGE<sub>2</sub> pretreatment after radiation injury. The hair follicle bulge stem cells were not activated during the repair process. (Figure 1b) Continuous BrdU pulse labeling after PGE<sub>2</sub> local pretreatment revealed that the proliferation of hair follicle bulb matrix cells (hair follicle transit amplifying cells (TACs) ) was transiently halted (Figure 2a). Immunostaining of cell cycle marker of cyclin D showed decrease level after PGE<sub>2</sub> pretreatment. (Figure 2b). These suggested PGE<sub>2</sub> might reduce the radiosensitivity of TACs through cell cycle G1 phase arrest. We further took advantage of the fluorescence ubiquitination cell cycle indicator (FUCCI) system and confirmed the process.

Figure. 1

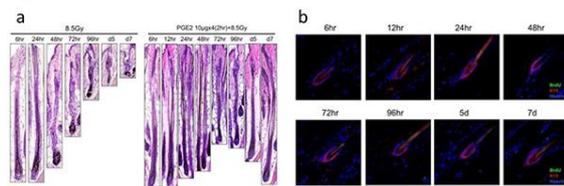

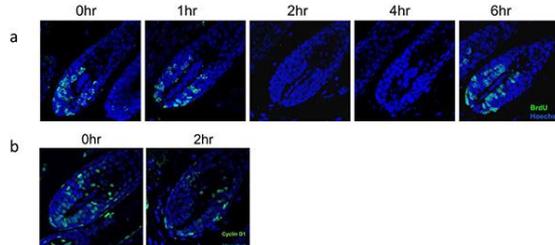

Figure. 2

### Conclusion

Under radiation injury, anagen hair follicles were able to initiate distinct repair activities to restore their structure after PGE<sub>2</sub> pretreatment through cell cycle modification.

Radiation-induced alopecia might be prevented by modulating cell cycle associated signaling to enhance spontaneous repair.

### PV-0539 Antidiabetic biguanides radiosensitize hypoxic cancer cells through a decrease in oxygen consumption

S. De Mey<sup>1</sup>, H. Jiang<sup>1</sup>, C. Corbet<sup>2</sup>, H. Wang<sup>1</sup>, I. Dufait<sup>1</sup>, K.L. Law<sup>1</sup>, T. Gevaert<sup>1</sup>, O. Feron<sup>2</sup>, M. De Ridder<sup>1</sup>  
<sup>1</sup>University Hospital Brussels, Radiotherapy, Jette, Belgium; <sup>2</sup>Université catholique de Louvain, Pole of Pharmacology and therapeutics, Brussels, Belgium

### Purpose or Objective

The anti-diabetic biguanide drugs metformin and phenformin exhibit antitumor activity in various models. However, their radiomodulatory effect under hypoxic conditions, particularly for phenformin, is largely unknown. This study therefore examines whether metformin and phenformin as mitochondrial complex I blockades could overcome hypoxic radioresistance through inhibition of oxygen consumption.

### Material and Methods

A panel of colorectal cancer cells (HCT116, DLD-1, HT29, SW480, and CT26) was exposed to metformin or phenformin for 16 h at indicated concentrations. Afterward, cell viability was measured by MTT and colony formation assays. Apoptosis and reactive oxygen species (ROS) were detected by flow cytometry. Phosphorylation of AMP-activated protein kinase (AMPK) was examined by western blot. Mitochondria complexes activity and oxygen consumption rate (OCR) were measured by seahorse analyzer. The radiosensitivity of tumor cells was assessed by colony formation assay under aerobic and hypoxic conditions. The *in vitro* findings were further validated in colorectal CT26 tumor model.

### Results

Metformin and phenformin inhibited mitochondrial complex I activity and subsequently reduced OCR in a dose-dependent manner starting at 3 mM and 30  $\mu$ M, respectively. As a result, the hypoxic radioresistance of tumor cells was counteracted by metformin and phenformin with an enhancement ratio about 2 at 9 mM and 100  $\mu$ M, respectively. Regarding intrinsic radioresistance, both of them did not exhibit any effect although there was an increase of phosphorylation of AMPK and ROS production. In tumor-bearing mice, metformin or phenformin alone did not show any anti-tumor effect. While in combination with radiation, both of them substantially delayed tumor growth and enhanced radioresponse, respectively, by 1.3 and 1.5-fold.

### Conclusion

Our results demonstrate that metformin and phenformin overcome hypoxic radioresistance through inhibition of mitochondrial respiration, and provide a rationale to explore metformin and phenformin as hypoxic radiosensitizers.

### PV-0540 Tumor modifications recorded with IVIM and DCE-MRI after Neoadjuvant radiotherapy

F. Lallemand<sup>1,2,3</sup>, N. Leroi<sup>3</sup>, M. Bahri<sup>2</sup>, E. Balteau<sup>2</sup>, A. Noël<sup>3</sup>, P. Coucke<sup>1</sup>, A. Plenevaux<sup>2</sup>, P. Martinive<sup>1,3,4</sup>  
<sup>1</sup>C.H.U. - Sart Tilman, Department of Radiotherapy-Oncology, Liège, Belgium; <sup>2</sup>University of Liège, Cyclotron Research Centre, Liège, Belgium; <sup>3</sup>University of Liège, Laboratory of Tumor and Development Biology, Liège, Belgium; <sup>4</sup>Institut Jules Bordet, Department of Radiotherapy-Oncology, Brussels, Belgium

### Purpose or Objective

Neoadjuvant radiotherapy (NeoRT) improves tumor local control and facilitates tumor resection in many cancers. We hypothesized anti-cancer treatments (i.e. radiotherapy) modify tumor microenvironment and could potentially impact distant metastases occurrence.

Previously, we developed a pre-clinical model demonstrating an impact of NeoRT schedule and the timing of surgery on metastatic spreading (Leroi et al. *Oncotarget* 2015). Here, we aim to identify by fMRI non-invasive markers reflecting NeoRT related tumor microenvironment modifications that could predict the best timing for performing surgery and avoiding tumor spreading.

#### Material and Methods

To briefly delineate the NeoRT model, MDA-MB 231 tumor cells implanted in the flank of SCID mice were locally irradiated with 2x5Gy when tumor reached 100mm<sup>3</sup> and then surgically removed at different time points. We performed fMRI, Diffusion Weighted (DW) and Dynamic Contrast enhancement (DCE) - MRI, before RT and every 2 days between RT and surgery. We acquired 8 slices of 1 mm thickness and 0.5 mm gap with an "in plane voxel resolution" of 0.5 mm. For DW-MRI, we performed FSEMS (Fast Spin Echo MultiSlice) sequences, with 9 different B-value (from 40 to 1000) and B0. We performed IVIM (IntraVoxel Incoherent Motion) analysis to obtain information on intravascular diffusion, related to perfusion ( $F$ : perfusion factor) and subsequently tumor vessels perfusion. For DCE-MRI, we performed a T1 mapping with multiple TR and DCE acquisition with 200 repetitions of 3 sec each and gadolinium IV injection after 10 repetitions. We performed semi-quantitative analysis. We validated tumor perfusion by immunohistochemistry with injection of FITC-dextran IV 3 min before surgery and CD31 labelling. Human Ki67 was used for lung metastases labelling and quantification.

#### Results

After the tumor irradiation, we observed a significant and transient increase at day 6 (60% of the basal value ( $n=6$ ,  $p<0,05$ )) of  $F$  and  $D^*$  parameters related to perfusion. The other parameters of the DW-MRI, ADC and  $D$  presented no modifications. The sham irradiated tumors used as control showed no modifications of all fMRI parameters. At the same timing, 6 days post-radiotherapy, DCE-MRI significantly demonstrated a WashinSlope ( $n=13$ ,  $p<0,05$ ) increase. Immunohistochemistry confirmed the increase of tumor perfusion when surgery is performed at day 6. The sham irradiated tumors never demonstrated such changes. Finally, when surgery is performed on tumor increased perfusion measured by fMRI, it demonstrated a burst of lung metastasis compared to the other timings.

#### Conclusion

We showed a significant difference in perfusion-related parameters with fMRI and immunohistochemistry at a specific time point after NeoRT. These modifications are correlated with an increase of metastasis spreading related to surgery procedure. These results open new perspectives in the personalized medicine and MRI guided surgery timing after NeoRT.

#### PV-0541 Immune modulation by brachytherapy in peripheral blood

M.A. Berenguer Francés<sup>1</sup>, I. Linares Galiana<sup>1</sup>, R. Cañas<sup>2</sup>, C. Gutierrez<sup>1</sup>, D. Najjari<sup>1</sup>, A. Slocker<sup>1</sup>, S. Marin i Borrás<sup>1</sup>, C. Bellobi<sup>1</sup>, F. Guedea<sup>1</sup>

<sup>1</sup>Instituto Catalan De Oncologia, Radiation Oncology, Hospitalet De Llobregat, Spain; <sup>2</sup>Idibell-Oncobell, Radiobiology and cancer, Hospitalet De Llobregat, Spain

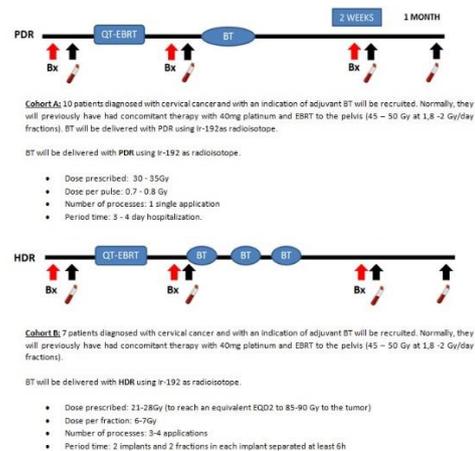

#### Purpose or Objective

Treatment with brachytherapy, either High Dose Rate (HDR) or Pulsed Dose Rate (LDR), is an effective treatment with consolidated results in cervical cancer, but its effect on the immune system is unknown. The effect of HDR-BQT as well as SBRT or IORT, can generate an individual immunity that can lead to lasting systemic responses, causing superior tumor control in these patients. These changes should be greater in HDR than in LDR. Our objective was to compare the effect on the immune system of both treatment in cervical cancer with the idea

of being able to find predictive and prognostic factors for diagnosis in these patients.

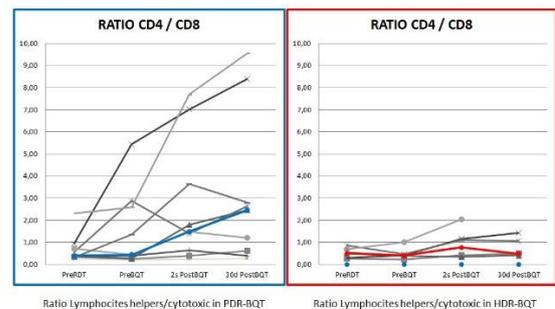

#### Material and Methods

We studied immunological factors in peripheral blood of 17 patients diagnosed with cervical cancer, 10 were treated with LDR-BQT and 7 with HDR-BQT. Four blood samples were obtained at different times of chemotherapy + radiotherapy and LDR / HDR-BQT. A blood sample was obtained prior to the start of treatment with RT, second sample before the start of the BQT, another sample at 2 weeks after the end of the BQT and a fourth sample one month after the end of the treatment. These samples were studied by flow cytometry in 3 panels. In the first panel the lymphocyte phenotype is studied; B lymphocytes, T lymphocytes, NK cells and monocytes. In another panel the regulatory T cells (Treg) were studied and in the third panel the suppressor cells derived from myeloid cells (MDSC). Subsequently, the effect on the tumor microenvironment will be analyzed with biopsies taken at different times of treatment.

#### Results

In the phenotyping panel there was an increase in TCD8 cell values and a decrease in TCD4 cells in BQT-HDR with a CD4 / CD8 ratio favorable to the BQT-HDR arm. An increase of NK cells in HDR-BQT was observed. At the Treg cell level there was a decrease in the HDR-BQT arm. In the MDSC panel an increase of the CD4 + CD45Ra-CD25 + and FOXP3 + cells in the HDR-BQT arm was evidenced.

#### Conclusion

Radiation doses delivered with HDR-BT in cervix cancer patients could trigger immune stimulation by modulating immune cells in plasma and tumor microenvironment. Deciphering immune-responses to treatment in cervix cancer patients could introduce new biomarkers helpful for treatment choice in the future.

**SP-0542 A stroll in Rome, together**V. Valentini<sup>1</sup><sup>1</sup>Fondazione Policlinico Universitario A.Gemelli IRCCS, Diagnostica Immagini- Radiation Oncology And Hematology, Roma, Italy**Abstract text**

In Rome every period of history has written pages of great artistic beauty.

These testimonies are randomly distributed throughout the city, sometimes one inside the other. What makes it unique to walk through the streets of Rome is that you never lose the sense of unity that there is, however, among all these beauties.

Radiation oncology is like Rome: it has pages of great beauty that combine together in great unity. The interweaving of basic sciences with clinical activity, of the relationship with the patient and technological innovation, of the molecular world with value-based medicine make this profession as unique and fascinating as Rome.

Being able to reread one's professional career in the light of this unified perspective helps me and perhaps the youngest to predict the future of our discipline.

**OC-0543 First clinical real-time motion-including tumor dose reconstruction during radiotherapy delivery**S. Skouboe<sup>1</sup>, T. Ravkilde<sup>2</sup>, J. Bertholet<sup>3</sup>, R. Hansen<sup>2</sup>, E. Worm<sup>2</sup>, C.G. Muurholm<sup>1</sup>, B. Weber<sup>1</sup>, M. Høyer<sup>4</sup>, P.R. Poulsen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; <sup>2</sup>Aarhus University Hospital, Department of Medical Physics, Aarhus, Denmark; <sup>3</sup>The Institute of Cancer Research and the Royal Marsden Hospital, Joint Department of Physics, London, United Kingdom; <sup>4</sup>Aarhus University Hospital, Danish Center for Particle Therapy, Aarhus, Denmark

**Purpose or Objective**

Organ and tumor motion during radiotherapy delivery can deteriorate the planned dose. Real-time reconstruction of the delivered dose to a moving tumor may be used for quality assurance (QA) or dose-guided decision-making during treatment. This study presents the first clinical real-time motion-including tumor dose reconstruction performed during radiotherapy delivery.

**Material and Methods**

Seven liver SBRT patients with 2-3 implanted gold markers were treated using 3-arc VMAT.

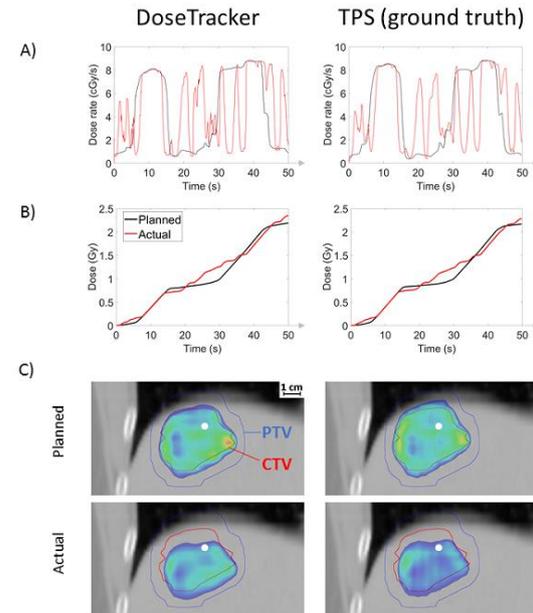

The 3D tumor motion was monitored in real time during one fraction per patient by our in-house developed software that used continuous monitoring of an external marker block combined with x-ray images acquired every 3 seconds by a gantry-mounted imager. The monitoring relied on a correlation model between external block motion and internal marker motion that was established just before treatment from setup cone-beam CT projections and updated during treatment by the x-ray images. The tumor position and all accelerator parameters were streamed at 9.5Hz to another in-house program, DoseTracker, that reconstructed the actual motion-including dose and the planned static dose to the same calculation points as used by the treatment planning system (TPS) within the PTV. A modified pencil beam algorithm that assumes water density inside the patient contour was used.

Post-treatment, the real-time tumor localization accuracy was estimated by comparing the real-time 3D marker positions at the time of x-ray imaging with ground truth

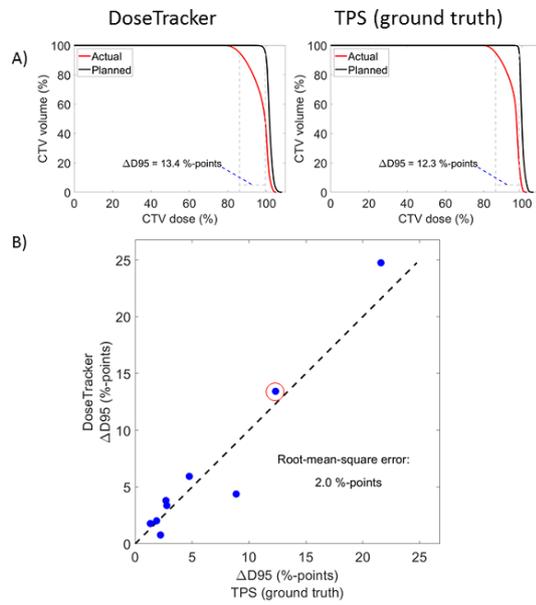

3D positions obtained from accurate post-treatment marker segmentations in all intra-treatment x-ray images. The real-time DoseTracker doses were compared with ground truth doses obtained with post-treatment TPS calculations that emulated tumor motion as multiple isocenter shifts.

**Results**

The mean 3D root-mean-square error (RMSE) of the real-time tumor localization was 1.90mm as estimated from a mean of 174 intra-treatment x-ray images per fraction. DoseTracker reconstructed pairs of actual and planned doses at a mean frequency of 9.5Hz with a mean of 3194 calculation points per patient. The time-resolved dose in single points and the reconstructed dose distributions generally agreed well with the ground truth TPS doses (see examples in Fig 1). The actual transient point dose deviated substantially from the planned dose as the point moved in and out of the beam (Fig 1A). The motion-induced reduction in CTV D95 (minimum dose to 95% of the CTV) as reconstructed by DoseTracker was in most cases in very good agreement with that of the TPS (Fig 2A) with a RMSE over all patients of 2.0%-points (Fig 2B). Outliers were mainly caused by approximations such as water density in the current version of DoseTracker.

**Figure 1:** Example of planned (black) and actually delivered (red) transient (A) and cumulative (B) dose to one out of 4200 calculation points as determined in real time during treatment by DoseTracker (left) and after treatment by the treatment planning system (right). The doses are only shown for the first 50s of treatment. (C) Planned and actually delivered dose distribution in the coronal plane through the isocenter after delivery of the whole plan (dose range of 95%-107% is shown, 67% was prescribed to the PTV). The white dot indicates the calculation point presented in (A) and (B).

**Figure 2:** (A) DVH for the planned (black) and actually delivered (red) CTV dose for the same case as in Fig 1 determined in real time during treatment by DoseTracker (left) and after treatment by the treatment planning system (right). The specified  $\Delta D95$  is the reduction in CTV D95 caused by motion. (B)  $\Delta D95$  from DoseTracker plotted against the ground truth from the TPS for all nine tumors (two of the seven patients had two tumors). The red circle indicates the patient in Fig 1 and Fig 2A. The black, dotted unity line indicates perfect agreement of dose error reconstruction.

## Conclusion

The world's first clinical real-time motion-including tumor dose reconstruction during radiotherapy was demonstrated. This milestone marks a significant step towards real-time monitored radiotherapy with important potential applications for real-time QA and dose-guided treatment adaptation.

## Purpose or Objective

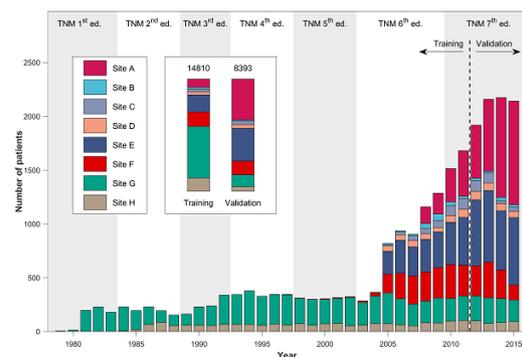

Access to healthcare data is crucial for scientific progress and technological innovation. Sharing healthcare data is time-consuming and notoriously difficult due to privacy and regulatory concerns (e.g., GDPR). Leaving health data at its source and bringing research questions to the data overcomes these privacy issues. Our infrastructure connects FAIR (Findable, Accessible, Interoperable, Reusable) data sources and allows distributed data analysis and machine learning. The infrastructure facilitates assembling study consortia and executing analyses in a short time frame, therefore paving the way for the era of *rapid learning healthcare*. We present results of the infrastructure's application across 8 healthcare institutes in 5 countries on 20 000+ patients: a registered study to predict 2-year survival in non-small cell lung cancer (NSCLC) patients executed and analyzed in 4 months.

## Material and Methods

NSCLC-specific databases (tumor staging and post-treatment survival information) of oncology departments were translated according to FAIR principles. Distributed learning software was installed on-site to receive machine learning algorithms. An iterative alternating direction method of multipliers-based logistic regression (LR) algorithm and data analysis procedures were implemented in MATLAB. These algorithms are privacy-preserving by design as only summary statistics and LR coefficients are exchanged between healthcare institutes and the central server. The LR algorithm was trained to predict post-treatment 2-year survival on 2/3 of the eligible patient data. The LR model performance was evaluated on the remaining 1/3 by receiver operating characteristic curves (ROC) per site and their area under the curve (AUC), and root mean square error (RMSE).

## Results

Eight healthcare institutes in Europe and Asia supplied data of 37 090 patients on which descriptive statistics were computed. Strong variation in patient cohorts across sites was observed. Inclusion criteria for prediction modelling of 2-year survival were met for 23 203 patients (Fig. 1). An LR model was distributively trained on 14 810 patients diagnosed between 1978-2011. The LR training algorithm converged after 81 iterations (25 minutes). When applying the final LR model on the validation cohort of 8 393 patients diagnosed between 2012-2015, the total RMSE was 0.43 and the AUCs ranged between 0.58-0.85 across sites (Fig. 2).

**Figure 1:** The number of patients available for training or validation per year per site.

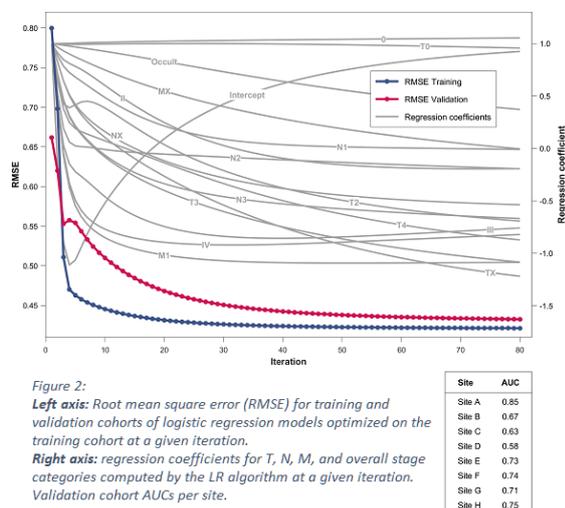

Figure 2:

Left axis: Root mean square error (RMSE) for training and validation cohorts of logistic regression models optimized on the training cohort at a given iteration.

Right axis: regression coefficients for T, N, M, and overall stage categories computed by the LR algorithm at a given iteration.

Validation cohort AUCs per site.

## Conclusion

Our infrastructure was deployed across 8 healthcare institutes in 5 countries in 4 months. A 2-year survival prediction model was trained and validated in more than 20 000 NSCLC patients. This infrastructure demonstrably overcomes patient-privacy barriers to healthcare data sharing and allows training population-based predictive models. Scaling up and combining future imaging and genomic data analyses via the infrastructure will bring us closer to the ultimate goal of model-based treatment individualization.

## Symposium: Adaptive RT: reactive or proactive?

### SP-0545 Clinical perspective and evidence on RT adaptation, has it improved outcome?

M. Guckenberger<sup>1</sup>

<sup>1</sup>University Hospital Zürich, Department of Radiation Oncology, Zurich, Switzerland

#### Abstract text

Already in 1997, Di Yan et al. described the aims and process of adaptive radiotherapy “Adaptive radiation therapy is a closed-loop radiation treatment process where the treatment plan can be modified using a systematic feedback of measurements. Adaptive radiation therapy (ART) intends to improve radiation treatment by systematically monitoring treatment variations and incorporating them to re-optimize the treatment plan early on during the course of treatment”. More than 20 years later, we have predominantly been working on solving the methodological challenges of ART, in particular improving in-room image quality, fast and automatic image segmentation, re-define adaptive planning objectives, fast and robust treatment plan optimization and quality assurance. Many in-silico planning studies have been conducted, focusing in particular on conventionally fractionated radiotherapy of lung cancer and head and neck cancer; whereas most studies reported a clinically relevant benefit of ART - organs-at-risk sparing or iso-toxic dose escalation - the magnitude of benefit varies substantially, most likely because of variation in ART methodology and endpoints. Clinical results of ART are still very rare, because its clinical implementation has only recently accelerated due to the commercial availability of the MRI-Linac technology and advances in software for image processing and treatment planning. On 12/2018, a total of 15 clinical trials are listed in clinicaltrials.gov with ART as the intervention: head and neck cancer is the most frequent indication (4/15 trials).

Results of these trials are eagerly awaited to evaluate the true clinical benefit of ART.

### SP-0546 Physics perspective on RT adaptation including role of predictive modelling in RT adaptation

J. Sonke<sup>1</sup>

<sup>1</sup>Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, The Netherlands

#### Abstract text

Adaptive radiotherapy (ART) utilizes an imaging feedback loop and replanning to 1) improve target coverage, 2) reduce toxicity and/or 3) improve tumor control after radiation therapy. Firstly, when adequate PTV margins are used to account for geometrical uncertainties, ART is only required for a limited number of patients with large variability to restore target coverage. On the other hand, more extensive use of ART allows for margin reduction with constant target coverage and reduced organ at risk exposure. Secondly, ART can be utilized to modify the treatment plan for patients where the delivered dose deviates from the planned dose. Effective use of such strategies requires normal tissue complication probability (NTCP) models to discriminate clinically relevant from irrelevant changes. Most NTCP models available, however, are based on the planned dose instead of the delivered dose. These models need to be updated using delivered dose to effectively use such adaptive strategies. Similarly, in the context of daily adaptive replanning, dose objectives and constraints should be reevaluated. Thirdly, adaptive strategies utilizing repetitive biological imaging aim to characterize treatment response and modify the treatment plan accordingly. Such strategies also require predictive models to translate (heterogeneous) treatment response to modified dose prescription between patients or even within the target itself.

### SP-0547 Role of the RTT in the clinical implementation of adaptive radiotherapy

A. Baker<sup>1</sup>, H. Mcnair<sup>2</sup>

<sup>1</sup>Oxford University Hospitals NHS Foundation Trust, Radiotherapy, Oxford, United Kingdom; <sup>2</sup>The Royal Marsden NHS Foundation Trust, Radiotherapy, London, United Kingdom

#### Abstract text

In the UK we are aiming for adaptive radiotherapy (ART) to be the standard of care<sup>1</sup> with IGRT as a core, essential component. These national recommendations define a roadmap to modern 4D-ART within a multi-professional team (MPT) environment with each profession bringing different perspectives to the development and implementation process. ART can be reactive, proactive, scheduled and real-time. Each have workflow considerations which should be carefully considered including roles and responsibilities of the MPT. Standardisation of clinical practice is essential for the delivery of safe, accurate radiotherapy treatments. New protocols and processes for ART should be developed which can be at both local and national levels. These can be established using existing evidence, through clinical trial participation and driven by technology. Examples of these approaches, from a radiation therapist (RTT) perspective, will be discussed.

Clinical trials enable new technologies to be evaluated with regard to outcome, in a controlled environment. There have been a number of ART clinical trials in the UK which use a proactive plan of the day technique for bladder treatments. This assisted the centres involved to develop ART standards within their departments within a quality assured clinical trial. One such standard was the competency of RTT's to select the plan of the day. Clearly defined guidelines within the protocol and the advice and support of the QA team enabled successful implementation throughout the UK.

It is important to consider the role of QA together with audit programmes both during the implementation phase and also on a routine basis following the implementation of the new evidence based standards. This should include process mapping and resource assessments for each step in the ART process. RTTs are a key component of this process within the MPT.

The advent of real-time ART techniques, particularly utilising the MR-linac technology, presents an opportunity to improve outcomes for a number of disease sites and for RTTs to further extend their role within the patient pathway. However, this also presents challenges from a training perspective for RTTs to ensure correct interpretation of on-line image guidance, now with both CBCT and MR modalities.

#### Conclusion

Utilisation of national recommendations or clinical trial processes ensure that ART can be developed and implemented safely and accurately within a multi-professional team environment. Advanced ART techniques provide an opportunity for RTTs to extend their roles and scope of practice. This can be achieved by developing an educational framework which includes ART.

#### SP-0548 Adaptive and Real-time Approaches in Brachytherapy

T.P. Hellebust<sup>1</sup>

<sup>1</sup>Oslo University Hospital/University of Oslo, Department of Medical Physics/Physics Department, Oslo, Norway

#### Abstract text

For the last 25 years radiotherapy treatment planning has evolved from a 2-dimensional (2D)-approach using radiographic films to an approach where the planning is based on 3D imaging showing the target volumes and the normal tissue. This enables conformation of the dose distribution to the target volume(s) and avoidance of high dose to organs at risk (OARs). Broad implementation of 3D planning in external beam radiotherapy (EBRT) already took place around the end of the 90ties and was considered as state of the art rather soon. In brachytherapy (BT), however, the transition from 2D to 3D based planning started much later and is not until recently considered as the state of the art, especially for GYN, prostate and breast BT. The 3D imaging approach for treatment planning is rather different for EBRT and BT. In EBRT the treatment is traditionally based on pre-treatment imaging acquired typically a few days or up to a week before treatment start. Due to development of on board anatomical imaging, using cone beam CT and lately MR imaging, many groups have for the last years worked on procedures for treatment plan adaptation during the EBRT treatment schedule. In BT, on the other hand, many centres developed procedures with a dedicated imaging procedure for each fraction already from the beginning of the 3D area. Such procedure facilitates the opportunity to prepare a new fraction specific treatment plan taking into account the dose distribution in previous fractions, in fact the core principle of adaptive radiotherapy. Additionally, the limited requirement of tissue density to have accurate dose calculation, means that MR and/or ultrasound (US) based treatment planning has played an important role since 3D planning was introduced in brachytherapy more than a decade ago.

Image guidance in BT is used for navigation of the implant and individual dose adaptation. In fact, when image guided brachytherapy is given as boost at the last part an EBRT schedule, an adaptive target volume is identified. This means that the dose is delivered to the residual limited sized target volume and not to the initial target volume which may be significantly larger. Such approach has successfully been applied in definitive treatment of

cervical cancer the last decade [Sturdza et al 2016]. Several studies have addressed the added value of fraction specific imaging and re-planning, e.g. for breast [Altman et al 2018], bladder [Bus et al 2018], cervix [Nesvacil et al 2013 and Skliarenko et al 2018] and prostate [Simnor et al 2009]. Skliarenko et al suggested for example that the first implant, used for delivering two fractions, could be performed only with intracavitary applicators and that the addition of needles in the second implant could be performed if the dosimetry of the first implant was suboptimal.

Another important principle of adaptive radiotherapy is to record the actual dose distribution that is delivered to the patient. In EBRT the CBCT is performed in room with the patient on the treatment couch. Except for US-guided brachytherapy, such in room imaging systems is usually not used in brachytherapy centers, even though some centers has developed in room MR and CT facilities. This means that the patient is moved from the brachytherapy suite to the imaging device and then to the treatment room with inherent risk of altering the position of the applicator. Therefore, the need of treatment monitoring and verification has emerged. Some very interesting technology has been developed and implemented recently. One of them is electromagnetic (EM) tracking where the position and orientation of one or several small coils (sensors) are detected within a known electromagnetic field. Additional, new developments in real-time in vivo dosimetry are also promising and it has been demonstrated that it can be used for source tracking during treatment delivery. However, the limitation of source tracking is of course that it tracks the source in relation to the detector, and not in relation to the anatomy. The ultimate goal would be to combine the source tracking with imaging, which some groups are working on. Moreover, at the end of the day the ability to perform true adaptive BT treatment requires fast recalculation algorithms/procedure, which is rather similar to challenges seen in EBRT.

---

#### Symposium: Predictive models of toxicity and big data, big open issues

---

#### SP-0549 How to organise your department to have a structured way of collecting toxicity data

J. Widder<sup>1</sup>

<sup>1</sup>Medical University Vienna, Radiation Oncology, Vienna, Austria

#### Abstract text

Reducing toxicity is a central paradigm for all local treatment modalities in oncology. Minimally invasive and robot assisted surgery, local ablation options, increasing conformality and beam modulation in radiotherapy as well as the implementation of protons all intend to reduce toxicity. RT has highly quantitative, modellable, and actionable causal data of toxicity, more than any other discipline: this renders RT a paradigm discipline of precision medicine striving towards improving the fit between oncological condition of a patient and tailored treatment. Why then are actionable RT toxicity data still relatively scarce? How to assess toxicities is navigating between specificity (is this toxicity radiation-induced?) and relevance-for-patients (does this toxicity actually bother patients?). Quality-of-life, functioning, symptoms, toxicity scores: which outcomes matter most, and which are actually used in treatment decisions. Clinical relevance is crucial, and any threshold-level of clinical relevance will require consensus. In order to be effective, collecting toxicity data at a department need to be part of a larger endeavour of collecting patient-data, data about the disease and comorbidity, surgery and systemic treatments and detailed

radiotherapy data: dose-matrix, dose administered, and time. Survival and patterns of recurrence are essential to render toxicity data interpretable. This requires a department policy commitment as it will change workflows and even clinical routine (e.g., organisation of patient follow-up). Using common terminology for regions-of-interest is a prerequisite, just like adequate software and IT-support, which is crucial as data incompleteness and inconsistencies are an issue.

**SP-0550 Dreams and reality of toxicity data-sharing/farming: quality vs quantity?**

A. Dekker<sup>1</sup>

<sup>1</sup>*Department Of Radiation Oncology Maastrro- Grow School For Oncology And Developmental Biology- Maastricht University Medical Centre+, Maastrro, Maastricht, The Netherlands*

**Abstract text**

Big, real world data has opened a new paradigm of modeling. The large quantity and diversity of data becoming available, may enable new predictive models of toxicity after radiation therapy which are better in terms of performance and more holistic (i.e. taking into account data elements from a wide variety of domains such as biological, clinical, imaging and treatment factors). But big, real world data is usually of much lower quality compared to clinical trial data that was until now used to derive toxicity prediction models. The hypothesis is that knowing and planning for data quality problems, using data quantity to our advantage and ensuring proper validation strategies will enable big real world data to start playing a larger role in toxicity prediction models.

Typical big, real world data quality problems include unstructured data, incomprehensible data, missing data, incorrect/implausible data, contradicting data, biased data and biased-missing data. Being aware of and identifying these data quality problems is a first step towards addressing them.

There are a number of ways to improve and mitigate quality once the problems are known. E.g. tools are becoming available to convert unstructured and incomprehensible data into FAIR (Findable Accessible Interoperable Reusable) data; missing data can be imputed; incorrect data removed; contradictions solved by a trust hierarchy of sources; biased data can be transformed to a common, unbiased data domain. Besides improving the data quality, careful selection of the modeling approach taking into account the approach's sensitivity to data quality problems is also important. In almost all the above data quality improvement approaches, a high data quantity is an important enabler. Finally, even if the toxicity prediction model is based on low quality data, it does not necessarily mean the model is bad nor vice versa (a model on good data may be bad). It is therefore important to validate the model on locally recorded data so that confidence and trust in the model is increased. Such acceptance and commissioning of models requires effort on the implementing site to capture their toxicity data and other data elements required for model validation. This effort leads to more and high quality data to become available which can then be fed back for the development of a new iteration of the prediction model. Such a learning system, which implements the model development - validation - development cycle, is expected to lead to both improved data quality and data quantity and finally better toxicity prediction models.

**SP-0551 Exploiting large data base to build robust predictive models: validation issues**

T. Rancati<sup>1</sup>

<sup>1</sup>*Fondazione IRCCS Istituto Nazionale dei Tumori, Prostate Cancer Program, Milan, Italy*

**Abstract text**

The final purpose of any predictive model in the oncological domain is to provide valid outcome predictions for new patients. Essentially, the data set used to develop a model is not of interest other than to learn for the future.

Validation hence is a crucial aspect in the process of predictive modelling. Validation is the process of determining the degree to which a model is an accurate representation of the real world from the perspective of the intended uses of the model. It is a process that accumulates evidence of a model correctness or accuracy for specific scenarios, with external validation providing a measure of "generalizability" and "transportability" of the prediction model to populations that are "plausibly related".

"Plausibly related" populations can be defined as cohorts that could be slightly different from the one used for model development, e.g. treated at different hospitals, at different dose levels, with different RT techniques, in different countries or in different time frames. Generalizability and transportability are desired properties from both a scientific and practical perspective.

Quantifying the confidence and predictive accuracy of model calculations provides the decision-maker with the information necessary for making high-consequence decisions.

The more often a model is externally validated and the more diverse these settings are, the more confidence we can gain in use of the model for prospective decision-making and its possible use in interventional trials. Within this frame, the following specific issues will be considered:

1. Detecting signal from noise: the importance of model validation
2. Internal vs external validation
3. External validation: homogeneity vs heterogeneity issues, harmonization issues
4. Using large distributed datasets vs large benchmark datasets
5. Extrapolation of models: defining model applicability domain
6. Using models: continuous refinement opportunity

**SP-0552 Radiogenomics: big data to understand genetic risk factors of toxicity**

C.N. Andreassen<sup>1</sup>

<sup>1</sup>*Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus C, Denmark*

**Abstract text**

The ability to predict normal tissue radiosensitivity has been a long sought goal in radiobiology. During the last 15 years, efforts were made to identify genetic germline alterations that affect the risk of toxicity after radiotherapy. This research is to an increasing extent undertaken by international cooperative research groups. Certain challenges relate research in radiogenomics: Large cohorts are needed to identify genotype-phenotype associations. Furthermore, normal tissue radiosensitivity is a relatively complex phenotype in several respects. It is made up by a number of sub-phenotypes that are not necessarily strongly associated. In addition the risk of normal tissue toxicity is dependent on complicated and not entirely understood dose-volume relationships. Some sequence alterations are likely to be specifically associated with certain types of normal tissue toxicity whereas others are likely to have a general impact on normal tissue toxicity.

In order to meet these challenges, 'big data approaches' will be needed. These include development of detailed NTCP-models, machine learning algorithms to analyze

complex genotype data and approaches that combine biological knowledge with genotype data.

#### Abstract text

Cytotoxic T-cells play an important role in the response to cancer treatment. T-cells can be (re)activated by e.g. immunotherapy, chemotherapy or radiotherapy and subsequently contribute to the destruction of the tumor. Insight in the immune response in the tumor can facilitate optimal treatment with minimal side effects. Non-invasive imaging of infiltrating activated T-cells would be very useful for monitoring the immune response within the tumor. Positron Emission Tomography (PET) could be such a tool, provided that a suitable tracer is available. Therefore, we have developed the PET tracer, [<sup>18</sup>F]FB-IL2, that binds specifically to interleukin-2 (IL2) receptors, that are predominantly expressed by activated T-cells. Since chemokine receptors direct the migration of T-cells to the tumor, we have also developed the PET tracer N-[<sup>11</sup>C]methyl-AMD3465 for imaging of CXCR4 receptors on T cells. The imaging properties of both tracers were successfully evaluated in several rodent models. To demonstrate the feasibility of the imaging methods to monitor the immune response to treatment, PET imaging with [<sup>18</sup>F]FB-IL2 and N-[<sup>11</sup>C]methyl-AMD3465 was performed in TC-1 tumor-bearing mice. Mice were treated with sham-irradiation (control), with a single 14Gy dose of tumor irradiation alone, or with tumor irradiation in combination with vaccination against human papilloma virus antigens that are expressed by the tumor cells. To investigate whether infiltration of lymphocytes is mediated by the CXCR4 receptor signaling pathway, a group of animals were treated with radiotherapy in combination with the CXCR4 antagonist Plerixafor (AMD3100).

PET imaging of IL2 receptors on activated T-cells 4 days after (sham-)irradiation showed a 10-fold increase in [<sup>18</sup>F]FB-IL2 uptake in the tumor of mice treated with radiotherapy alone, when compared to controls. When radiotherapy was combined with vaccination, the tumor uptake of [<sup>18</sup>F]FB-IL2 was even further increased by another 2.7-fold. These results were in line with flow cytometry data of CD8+ T-cells in the tumor. Interestingly, the combination of radiotherapy and vaccination - but not tumor irradiation alone - significantly increased the [<sup>18</sup>F]FB-IL2 uptake in various organs, indicating that the immune response to tumor irradiation is restricted to the tumor, whereas the addition of vaccination induced a more widely spread immune response. PET imaging of CXCR4 receptor expression showed similar results as [<sup>18</sup>F]FB-IL2 PET, with N-[<sup>11</sup>C]methyl-AMD3465 uptake being increased 2.5- and 4-fold in mice treated with radiotherapy alone, or radiotherapy in combination with vaccination, respectively. Moreover, [<sup>18</sup>F]FB-IL2 PET showed that blocking of the CXCR4-mediated signaling pathway with the antagonist Plerixafor, resulted in a 2.8-fold reduction tracer uptake in the irradiated tumor,

indicative of a reduction in T-cell infiltration. These results suggest that tumor irradiation and vaccination increase the influx of activated T-cells and that CXCR4 receptor-mediated signaling is involved in the migration and infiltration of these T-cells. Taken together, this study demonstrates the potential of PET imaging for non-invasively monitoring of the immune response to anti-cancer treatments, like immunotherapy and radiotherapy. Currently, the first clinical studies evaluating the feasibility of [<sup>18</sup>F]FB-IL2 PET to detect the immune response in tumor lesions during immunotherapy and chemo-radiotherapy are in progress.

#### SP-0554 Imaging DNA damage response

B. Cornelissen<sup>1</sup>

<sup>1</sup>Oxford Cancer Center - Churchill Hospital Oxford inst for RO, Radiopharmaceuticals and Molecular Imaging Group, Oxford, United Kingdom

#### Abstract text

DNA integrity is continuously challenged by endogenous and exogenous factors that can damage or alter the DNA sequence, leading to mutagenesis, aberrant transcriptional activity, and cytotoxicity. Left unrepaired, damaged DNA can ultimately lead to the development of cancer. To overcome this threat, a series of complex mechanisms collectively known as the DNA damage response (DDR) are able to detect the various types of DNA damage that can occur and stimulate the appropriate repair process. Each DNA damage repair pathway leads to the recruitment, upregulation, or activation of specific proteins within the nucleus, which, in some cases, represent attractive targets for molecular imaging. Given the dominant involvement of DNA damage and its repair during radiotherapy, the ability to monitor these repair processes non-invasively using nuclear imaging techniques may facilitate monitoring response to DNA damaging treatments. The aim of this talk is to provide an overview of recent efforts to develop PET and SPECT radiotracers for imaging of DNA damage repair proteins.

#### SP-0555 MRI-CEST Imaging of tumor acidosis

D. Longo<sup>1</sup>

<sup>1</sup>Italian National Research Council (CNR) Institute of Biostructures and Bioimaging (IBB)

#### Abstract text

Up-regulated glucose metabolism, upon hypoxia-induced shift toward glycolysis, leads to enhanced acidification of the extracellular pH (pHe) to values in the range 6.5-7.0, which is a salient feature of the tumor microenvironment. Consequently, tumor cells have evolved several sophisticated mechanisms to regulate pH homeostasis: they eliminate acidic catabolites by ion transporters and pumps to preserve a slightly alkaline intracellular pH (pHi), which is optimal for cell proliferation and tumor survival. Imaging based methods are already been established, at a clinical level, to assess glucose metabolism (by positron emission tomography - PET imaging of 18F-fluorodeoxyglucose FDG tumor uptake) providing a formidable tool for evaluating treatment response.

Conversely, despite the excellent studies regarding tumor acidosis, we still do not have an effective imaging protocol that allow to quantify extracellular tumor pH and to assess pHe related changes following therapeutic treatment. Furthermore, new anticancer drugs that, upon inhibiting one or more of these pH regulators causing both the pHi and the pHe values to return to normal, with the consequent impairment of tumour growth, cannot be in vivo evaluated both at preclinical and clinical level. We have developed innovative MRI-based approaches for assessing in vivo tumor acidosis by exploiting already clinically-used x-ray contrast agents that are translatable to the clinical scenario. We have exploited tumor pH

imaging for assessing its relationship with cancer metabolism and metastatic potential as well as for assessing treatment response to novel anticancer therapies.

We will discuss different MRI-based approaches developed for imaging tumor acidosis, using examples from our own research and from recent literature. Based on these data, tumor pH imaging may be a potential innovative diagnostic tool for characterizing tumor metabolism and to evaluate treatment response.

#### SP-0556 Tracing Tumor Hypoxia

##### Abstract text

Hypoxia is known to play a role in many types of cancer and is linked to metastasis, genetic instability, resistance to therapy and poor prognosis. Despite the overwhelming prognostic and predictive significance of tumor hypoxia, hypoxia modification strategies have been mostly unsuccessful in patients. There is a knowledge gap in the characterization and behavior of hypoxic tumor cells during tumorigenesis and treatment. We have optimized a system that allows hypoxic cells to be lineage traced using genetically encoded fluorescent sensors and cytotoxins to investigate their dissemination within the primary tumor and in distant metastasis. I will present data showing the application of these systems to the intravital imaging of hypoxic tumor cells.

#### Symposium: New developments for breast cancer irradiation

---

#### SP-0557 Neoadjuvant radiotherapy in breast cancer

Y. Kirova<sup>1</sup>  
<sup>1</sup>Institut Curie Ensemble Hospitalier, Department of Radiation Oncology, Paris cedex 05, France

##### Abstract text

Previous experience with preoperative RT with or without systemic treatment was reported with long term results. The studies have shown the excellent response rate, increasing the breast conserving surgery. These studies helped to numerous patients to preserve their breasts. Conventional scheduling in breast cancer treatment has been challenged in recent years with primary systemic therapy now widely used. The potential advantages of delivering RT before surgery are now under investigation, with current and upcoming trials. These new studies are asking new questions: how to optimize timing with mastectomy and reconstruction when the breast conserving surgery is not feasible, as well as the interest of combination with novel drugs to improve the response rates in chemo resistant tumours. The associations between radiotherapy and systemic treatments are also useful in patients who did not responded to primary systemic therapy as salvage treatment. Technically the neoadjuvant radiotherapy is interesting option because the radiation oncologist can visualize and directly delineate the tumour. Other advantage of the preoperative radiotherapy is that it can avoid the challenging techniques after oncoplastic and reconstruction surgical techniques in terms of volumes definition, as well as the sparing of organs at risk (OAR). With the hypofractionation regiments, the toxicity is

lower and the postoperative complications can be decreased. There is also currently increased interest of association between neoadjuvant irradiation and new targeted molecules as PARP inhibitors, immunotherapy agents with the aim to improve the treatment results. These associations realized in clinical trials open the door for the translational research with understanding the mechanisms of tumour resistance, as well as the discovery of new biomarkers to permit individualized optimal treatment.

Abstract not received

#### SP-0559 Nodal irradiation with or instead axillary lymph node dissection

M. Molla<sup>1</sup>  
<sup>1</sup>Hospital Clinic Barcelona, Radiation Oncology, Barcelona, Spain

##### Abstract text

The management of the node positive axilla in breast cancer remains a controversial topic.

A negative finding on examination of the axilla identifies patients who are candidates for axillary staging with SLNB. The absence of cancer cells in the SLNB confirms that no further surgical management of the axilla or nodal RT is warranted.

Clinical trials (EBCTCG metaanalysis /EORTC 22922/10925 and NCIC MA209) support the use of regional nodal irradiation (RNI) in breast cancer patients with 1-3 axillary nodal metastases following ALND. However, the controversy lies in regarding the need for ALND and/ or RNI in T1-2 clinically node negative breast cancer undergoing conservative breast surgery and systemic therapy and have metastases in 1 or 2 sentinel nodes. Ten year results of ACOSOG Z0011 (ALND or no further axillary treatment) and 5 year results of AMAROS (ALND or axillary radiotherapy) confirm no differences in nodal recurrence, disease-free survival or overall survival. The presence of risk factors such as: younger patient age, large tumor size, extent of nodal involved, lymphovascular invasion, and high tumor grade strongly support the use of RNI in this group of patients. Future work is ongoing to examine whether genes that are frequently associated with risk of recurrence can be used to assign patients to the most appropriate loco-regional treatment.

In those patients with T1-2 and sentinel node metastases undergoing mastectomy, there is little evidence to support omitting ALND and/or RNI. There are some scenarios in which axillary treatment could be omitted, such as: sentinel node micrometastases (AATRM 048/13/2000 and IBCSG 23-01) and the use of neoadjuvant chemotherapy (NAC).

The increasing use of NAC has significantly affected local-regional decision-making. Higher rates of loco-regional recurrence was seen in patients with extensive disease at presentation or nodal positive after NAC, which could decrease with RNI. However, there are some clinical data suggesting that in women who experience a complete response with NAC, ALND and/ or RNI could be omitted. Achieving a pathological response following NAC has been associated with improved survival. The NSABP B-18 and B-27 trials and data from retrospective studies found that the incidence of locoregional recurrence failure is less than 10% in patients with stage II and non residual lymph node disease. However, there are other factors that have to be taken into consideration, such as: presence of residual disease in the breast, young age and

the presence of lymphovascular invasion. In patients with these risks factors RNI would be recommended. Currently, there are two prospective trials (Alliance A11202 and RTOG 1304) that will potentially allow us to optimize nodal treatment.

**SP-0560 Radiotherapy after breast reconstruction**  
B. Offersen<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Department Of  
Experimental Clinical Oncology, Aarhus, Denmark

**Abstract text**

Immediate breast reconstruction (IBR) rates are increasing in high risk breast cancer patients having postmastectomy radiation therapy (PMRT). PMRT combined with reconstruction increases the rate of complications regardless of the type (implant or autologous) and the timing of reconstruction. Fewer complications and better long-term cosmetic outcome are seen with autologous flap-based reconstruction compared to implant-based reconstruction, however, implant-based reconstruction is increasing in combination with PMRT. Despite thousands of women are treated, contouring guidelines for target volumes in the setting of IBR are lacking. Therefore, many patients who have IBR receive PMRT to target volumes similar to CT-simulator based conventional breast irradiation. The aim of this presentation is to present a delineation guideline for PMRT after IBR with implant endorsed by a consensus among a global multidisciplinary group of breast cancer experts. If a consensus for patients having autologous IBR is reached before the ESTRO38 conference, this will also be presented.

**SP-0561 EORTC State of Science in Radiation Oncology: Overcoming barriers to practice change by collaboration; why now, and how....**

R. Bristow<sup>1</sup>

<sup>1</sup>Manchester Cancer Research Centre University of Manchester, Division of Cancer Sciences, Manchester, United Kingdom

**Abstract text**

The EORTC conducted a State of Science in Radiotherapy Workshop in September 2018 to explore collaborative research in radiobiology as applied to radiation oncology. The workshop was attended by clinicians, medical physicists and basic scientists in order to delineate areas of innovative research potential in the biological sciences that could augment technologic approaches within the speciality of radiation oncology. This was particularly of interest in an era where the cost-effectiveness of new technologies, including particle therapies, are being evaluated for their ability to step-change clinical practice in relation to biological approaches. The latter approaches include stratified medicine approaches using big data and genomics, immuno-modulation of treatment response using radiotherapy, molecular predictive assays married to molecular drug treatments in combination with precision radiotherapy for localised and (oligo)metastatic disease. Using an interactive group discussion approach, a number of new areas for clinical trials were explored that marry technology with best biology in a multidisciplinary manner: these will be discussed in the session. Other important elements were the interactive team science approaches to novel ideas generation and implementation across disparate health care jurisdictions and competing health resources within the EORTC. Exciting areas for collaboration can come from discrete team science approaches which focus on specific clinical impact and

routes that afford rapid translation from the basic through discovery to clinical trials sciences.

**SP-0562 Cohorts studies versus randomised controlled trials: can we combine the best of both worlds?**

L. Verkooijen<sup>1</sup>

<sup>1</sup>UMC Utrecht, Imaging Division University Medical Center Utrecht, Utrecht, The Netherlands

**Abstract text**

Randomised controlled trials (RCTs) provide the best evidence for effectiveness of new interventions. RCTs are often hampered by slow and time-consuming recruitment, and complicated informed consent procedures. RCTs may also suffer from limited generalisability, due to strict in- and exclusion criteria, and enrolment of healthier and more educated individuals. In cohort studies, recruitment of large groups of representative patients is more straightforward. However, the cohort study design is less suitable for evaluation of treatment effectiveness, due to the 'selection by indication' phenomenon. The 'Trials within Cohorts' (TwiCs) design, also known as the cohort multiple RCT (cmRCT) design, aims to combine the advantages of RCTs and cohorts and is increasingly being applied as an alternative for classic RCTs. The basis of TwiCs is a prospective cohort of people with a condition of interest, in which trials can be embedded. According to the classic cohort study design, characteristics and outcomes of participants (eg. demographics, clinical data, laboratory findings, patient-reported outcomes etc.) are collected at baseline and at fixed time intervals during follow-up. In addition, at cohort entry, participants provide broad consent to be either randomly selected to be approached for experimental interventions, or to serve as control without further notice. In a second stage, at the start of an RCT, cohort participants eligible for an experimental intervention are identified within the cohort and randomized to the intervention or control arm. Only those randomized to the intervention arm are informed about the trial, and offered the intervention, which they can accept or refuse. Participants randomized to the control arm are not informed about the trial and receive treatment as usual. Relevant outcomes of participants who have been offered the the intervention are compared with those of participants who were not offered the intervention and who received standard care. Starting in 2013, several radiotherapy TwiCs cohorts have been set up including patients with breast cancer (2400+), bone metastases (1400+), oligo lymph nodes (n=20), brain metastases (starting), and rectal cancer (700+). Of those patients, 80-85% provided broad consent for future randomization. Response rates of patient-reported outcome questionnaires varied from >85% at baseline to 60-70% at 3 years follow-up. Three RCTs have now been completed: RECTAL BOOST (n=128), VERTICAL (SBRT for vertebral metastases, n=110) and FIT (exercise trial, n=260).

Advantages of the TwiCs design included easier and more representative recruitment (>60% of all eligible patients were enrolled), and prevention of contamination and cross-over in the control arm. One of the main challenges of TwiCs was the selective drop-out in the intervention arm (i.e. patients refusing to undergo the experimental intervention), which was substantial in some of the trials. This presentation will address the above challenges, as well as other practical, ethical, and statistical issues associated with the TwiCs design.

**OC-0563 First experience with the model-based selection of head and neck cancer patients for proton therapy**

M. Tambas<sup>1</sup>, H.P. Van der Laan<sup>1</sup>, J.G.M. Van den Hoek<sup>1</sup>, H.P. Bijl<sup>1</sup>, M. Dieters<sup>1</sup>, R.G.J. Kierkels<sup>1</sup>, D. Scandurra<sup>1</sup>, S. Both<sup>1</sup>, R.J.H.M. Steenbakkers<sup>1</sup>, J.A. Langendijk<sup>1</sup>

<sup>1</sup>Department of Radiation Oncology- University of Groningen- University Medical Center Groningen, Radiation Oncology, Groningen, The Netherlands

### Purpose or Objective

In the Netherlands, head and neck cancer (HNC) patients are selected for intensity modulated proton therapy (IMPT) according to so-called 'model-based selection' approach (MBS). In this approach, a VMAT-plan and IMPT-plan is generated per patient, to determine the differences in dose to the OARs ( $\Delta$ Dose), and to translate  $\Delta$ Dose into the differences in normal tissue complication probabilities ( $\Delta$ NTCP-profile), which can be considered as a biomarker for the expected reduction in toxicity. The aim of this study was to evaluate the first experience in MBS of HNC patients.

### Material and Methods

According to the Dutch National Indication Protocol, three NTCP-models are used for the selection for IMPT, including NTCP models for tube feeding dependence, grade 2 xerostomia and dysphagia. These models include the following predictors:  $D_{\text{mean}}$  contralateral parotid gland, superior and inferior pharyngeal constrictor muscles, cricopharyngeal muscle and oral cavity, T stage, treatment modality, baseline weight loss, xerostomia and dysphagia status. The  $\Delta$ NTCP-thresholds to be selected for IMPT were defined as  $\geq 10\%$  and  $\geq 5\%$ , for grade  $\geq 2$  and grade  $\geq 3$ , respectively; or  $\geq 15\%$  for the summed risk reduction ( $\Sigma$ ANTCP) for grade 2 side effects.

63 consecutive patients with HNC who were treated with definitive RT alone (conventional or accelerated RT) with or without systemic treatment at our center since January 2018 and were subject to the MBS were evaluated. Most patients had either oropharyngeal (42%) or laryngeal (42%) carcinoma.

First, a VMAT plan was created for each patient with optimal sparing of OARs relevant for the  $\Delta$ NTCP-profile (model-based optimization). Then the subsequent NTCP-profile was calculated. An IMPT-plan with robustness evaluation was only created if the NTCP-values were beyond the thresholds. The  $\Delta$ NTCP-profile was derived from the VMAT and IMPT plans. If the  $\Delta$ NTCP-profile met the decision criteria, the patient was selected for IMPT (Fig. 1).

### Results

10 patients were excluded from the MBS plan comparison since they were not eligible for IMPT for various reasons and 5 patients because NTCP values in the VMAT plan were already below the thresholds (Fig. 1).

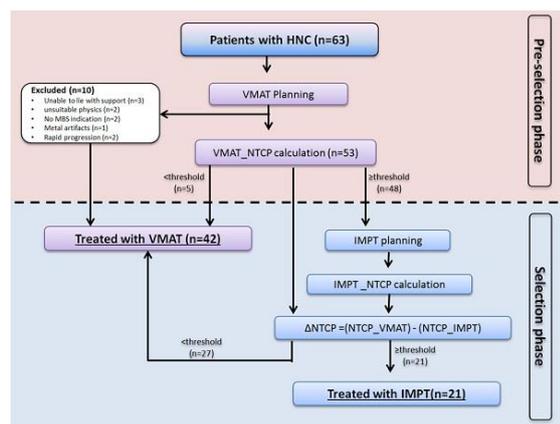

Figure 1. Selection of patients with model-based approach for proton therapy.

A planning comparison was performed for 48 patients, of which 27 were not selected since their  $\Delta$ NTCP-profile did not meet the MBS criteria (Fig. 1). Among the 21 patients who were selected for IMPT, 3 patients qualified based on  $\Delta$ NTCP xerostomia, 11 based on  $\Delta$ NTCP dysphagia, 6 based

on  $\Delta$ NTCP tube feeding dependence and 14 based on  $\Sigma$ ANTCP of  $\geq 15\%$ . Three patients were selected for IMPT based on only  $\Sigma$ ANTCP value. The NTCP values of patients with a plan comparison are summarized in Fig.2.

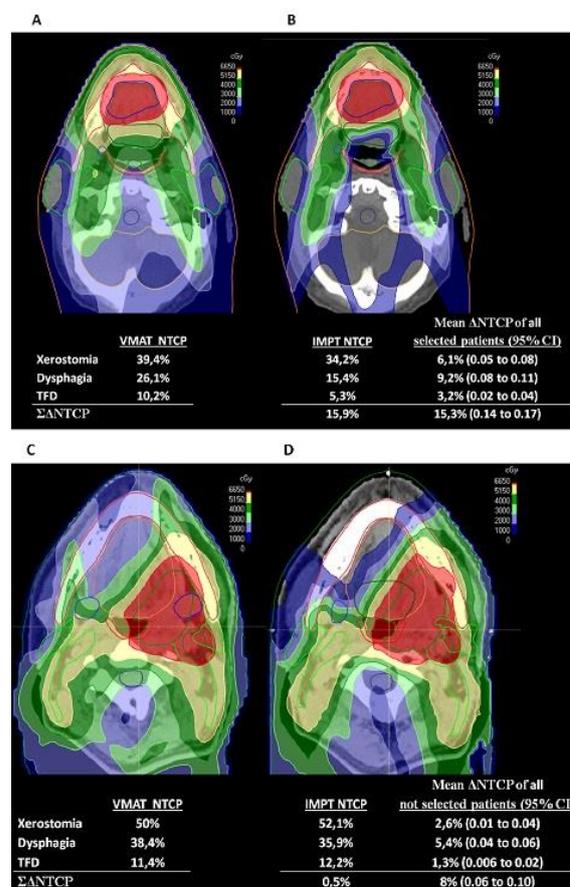

Fig. 2. The dose distributions of two patients who were selected for proton therapy (VMAT=A, IMPT=B) and photon therapy (VMAT=C, IMPT=D). The  $\Delta$ NTCP and  $\Sigma$ ANTCP values of all the patients for whom a plan comparison was performed were also shown.

### Conclusion

Our first experience is that MBS is logistically time consuming but feasible. Of the 63 patients included in this procedure, 21 were selected for IMPT. Using MBS for IMPT, only patients who most likely benefit from IMPT are selected. Our next step is to develop highly efficient pre-selection tools and new (updated) NTCP models.

### Proffered Papers: PH 11: Proffered paper: Proton range and dose verification

#### OC-0564 A novel range probing-based optimization of CT calibration curve for Proton Therapy

A. Meijers<sup>1</sup>, J. Free<sup>1</sup>, D. Wagenaar<sup>1</sup>, S. Deffet<sup>2</sup>, A.C. Knopf<sup>1</sup>, J.A. Langendijk<sup>1</sup>, S. Both<sup>1</sup>

<sup>1</sup>University of Groningen - University Medical Centre Groningen, Department of Radiation Oncology, Groningen, The Netherlands ; <sup>2</sup>Université catholique de Louvain, Icteam, Louvain-la-Neuve, Belgium

### Purpose or Objective

Proton therapy is affected by range uncertainty. CT calibration curves (CC) are institution specific and may be a source of systematic errors for proton treatment planning. Therefore, a novel range probing method to optimize and validate a CT CC for proton treatment planning using an end-to-end approach is proposed.

### Material and Methods

An initial CT CC was determined according to the stoichiometric approach. The CC consists of 5 segments: 3 lines that each describe organ-like, fat-like and bone-like tissues respectively and 2 lines as transitions between the primary segments. Unlike in routine practice, 3 types of vacuumed “fresh” animal tissue phantoms were made, consisting of (1) a pig’s head, (2) “thorax”, consisting of ribs, fat, liver and muscle, and (3) femoral bone. These phantoms were scanned on the CT (Somatom, Siemens) and transferred to the treatment planning system (RayStation, RaySearch) to calculate individual pencil beams directed through each phantom. On the CT scans a water slab was added behind the tissue samples to simulate the detector that was used for integral depth dose curve measurements. Tissue phantoms were positioned in the planned position at the proton therapy system (ProteusPlus, IBA) isocenter using the on-board x-ray imaging. A set of shot-through pencil beams of a 210 MeV energy was delivered, and depth dose profiles were measured using a multi-layer ionization chamber (Giraffe, IBA). Measured depth dose curves were compared to TPS calculated ones and the residual range error per spot was defined. Additionally, based on the WEPL of every spot through the tissue, the range error margin according to the published uncertainty recipe of 2.4% + 1 mm was defined. Ratios between measurement based and theoretical range error margins per spot were calculated (fig 1). The CT CC optimization was performed by identifying systematic shifts of the mean range error value per phantom type and minimizing the spread of ratios between residual range errors and range uncertainty margins.

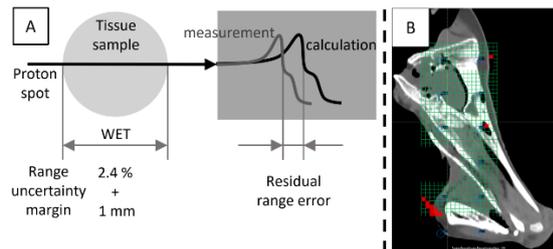

Fig 1. A illustrates the principle of the experiment, where proton beam is shot through a tissue sample and depth profile is measured behind the sample by the detector. Afterwards residual range error is defined as discrepancy between measurement and TPS calculation. The WEPL through tissue is defined for every spot and range uncertainty margin is calculated. A ratio between range error and uncertainty margin is defined. B Shows an overlay between pig’s head and measured spots, where every green square is a measurement; red squares indicates spots for which range error exceeds uncertainty margin.

## Results

When performing the analysis using the initial CT CC, increased range errors were observed for the femoral bone measurement set. Therefore, the slope of the CT CC line segment representing bone-like tissues was adjusted to ensure better agreement between measurements and calculations. Afterwards an independent measurement set for another femoral bone was included in the analysis and all data sets were recalculated using the optimized CT CC. For a full data set (about 1600 spots over all phantoms) the ratio of the actual range error and the uncertainty margin for 1.5 $\sigma$  did not exceed 0.75, indicating that the theoretical uncertainty recipe overestimates the actual range errors (fig 2).

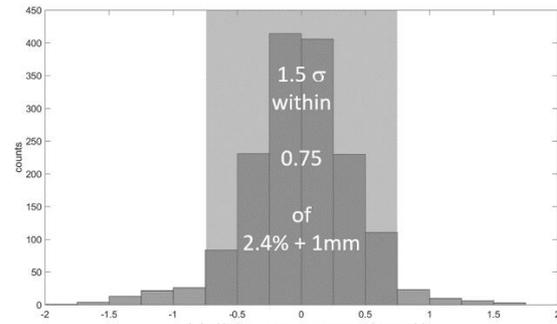

Fig 2. Histogram of ratios between measured residual range errors and range uncertainty margin as defined per individual spot. 1.5 $\sigma$  of ratios are within 0.75, which indicates that theoretical uncertainty margin is an overestimation.

## Conclusion

The feasibility of using range probing to assess the residual range errors was demonstrated in an institution specific setup. As a result, the published uncertainty margins may be reduced by ~25%, allowing for potentially more conformal proton plans in the future.

## OC-0565 The optimization of prompt gamma based range estimation in proton therapy using Cramér-Rao theory

E. Lens<sup>1</sup>, E. Tolboom<sup>1</sup>, D. Schaart<sup>1</sup>

<sup>1</sup>Delft University of Technology, Radiation Science and Technology, Delft, The Netherlands

## Purpose or Objective

Various methods for *in vivo* range estimation during proton therapy based on the measurement of prompt gamma (PG) photons have been proposed. However, optimizing the method of detection by trial-and-error is a tedious endeavor. Here, we demonstrate the use of the Cramér-Rao lower bound (CRLB) to more quickly, and more objectively, arrive at an optimal detector design.

## Material and Methods

The CRLB is based on the Cramér-Rao inequality and can be used to find the lower bound on the variance of any unbiased estimator of a parameter, given a statistical model of the observables. In this study the CRLB was used to derive the smallest possible variance on the proton range obtained from the detected PG photons, making use of the fact that the PG emission process is covered by Poisson statistics. The observables considered are the position, energy, and time of detection of the detected PG photons.

We used the TOPAS (Geant4 based) Monte Carlo code to simulate a clinical proton pencil beam with  $4 \cdot 10^9$  protons targeting a cylindrical, soft-tissue equivalent phantom. PG photons were scored on a cylindrical surface (i.e. detector;  $\varnothing=40$  cm) coaxially surrounding the phantom. Spatially-, temporally-, and spectrally-resolved PG emission profiles corresponding to different proton ranges were generated by changing the initial proton energy. The detected photons were selected and tallied based on the location, energy, time, and angle of incidence on the simulated ideal detector. From the resulting signals, we calculated the CRLB as a function of several detector setup parameters such as detector size and location, bin size, energy resolution, and photon acceptance angle.

## Results

We obtained relations between the CRLB and different detector setup parameters that allowed us to determine the optimal values for these detector properties. For most detector parameters there is a clear optimal value while the energy resolution and proton bunch width were preferably kept as small as possible.

We found comparable CRLB values for proton range estimation based on either spatial, spectral, or temporal information, of 0.26 mm, 0.24 mm and 0.25 mm, respectively, if the detection parameters were optimized

for each case (Table). The figure illustrates this optimization when using the PG photon energy. The table lists the optimal detection parameters for all (combinations of) observables. Combined detection of spatial and energy information yielded the lowest CRLB values.

**Conclusion**

We conclude that the CRLB is a promising tool for the optimization of the detector setup for PG based range estimation in particle therapy. With the current, idealized detector setup, similar accuracy could be achieved when using either the position, energy, or time of detection of the detected PG photons. Moreover, simultaneous measurement of the spatial information and energy of the PG photons yielded the highest accuracy when determining the proton range.

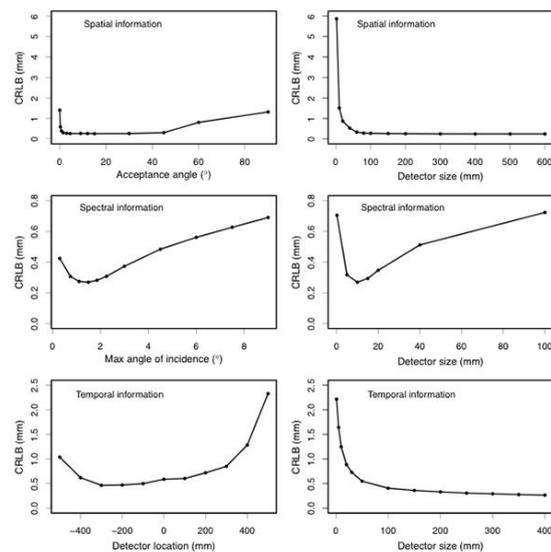

Figure: CRLB values as a function of different detection parameters when using the spatial, spectral or temporal information of incoming prompt gamma photons.

Table: Optimized CRLB values and detection parameters for the different observables

	Spatial	Energy	Timing	Spatial + energy	Spatial + timing
Max. angle of incidence <sup>1</sup> (°)	9.0	1.5	90.0	3.0	3.0

**OC-0566 Range verification in proton therapy: Can prompt-gamma imaging identify the source of deviation?**

C. Khamfongkhrua<sup>1</sup>, G. Janssens<sup>2</sup>, J. Petzoldt<sup>2</sup>, J. Smeets<sup>2</sup>, G. Pausch<sup>1,3,4,5</sup>, C. Richter<sup>1,3,4,5</sup>

<sup>1</sup>OncoRay - National Center for Radiation Research in Oncology, Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden-Helmholtz-Zentrum Dresden - Rossendorf, Dresden, Germany ; <sup>2</sup>Ion Beam Applications SA, Research, Louvain-la-Neuve, Belgium; <sup>3</sup>Helmholtz-Zentrum Dresden - Rossendorf, Institute of Radiooncology - OncoRay, Dresden, Germany ; <sup>4</sup>German Cancer Consortium DKTK-partner site Dresden, German Cancer Research Center DKFZ- Heidelberg, Dresden, Germany; <sup>5</sup>Faculty of Medicine and University Hospital Carl Gustav Carus- Technische Universität Dresden, Department of Radiotherapy and Radiation Oncology, Dresden, Germany

**Purpose or Objective**

In-vivo prompt-gamma imaging (PGI) is a promising method for directly assessing deviations in the proton

range during proton therapy. However, several effects that can cause range shifts in patients need to be distinguished, e.g. global range errors in CT conversion to stopping power ratio (SPR), variations in patient setup, and changes in the patient anatomy. Here, we evaluate if the source of range deviation in proton pencil-beam scanning (PBS) can be distinguished based on PGI information using a slit camera [1].

**Material and Methods**

For a virtual head-and-neck tumor in an anthropomorphic head phantom, a PBS treatment plan with simultaneous integrated boost (3 beams, 70Gy and 57Gy in 33 fractions) was generated. For all PBS spots in the investigated beam, PGI profiles were simulated using a verified analytical model of the slit camera [2, 3] for the reference scenario as well as for different error scenarios: SPR change of ±1.0, ±2.0 and ±3.5%, setup error in beam direction of ±1mm and ±3mm, and 10 scenarios of realistic anatomical changes (Fig. 1). A decision-tree approach was proposed to classify different groups of error sources. This included preceding filtering of PBS spots containing reliable PGI information for range verification. For simplification and better hypothesis generation, the head phantom was first overridden with water density. Afterwards, the real phantom anatomy including all heterogeneities was analyzed. It was evaluated whether the different error scenarios could be classified correctly.

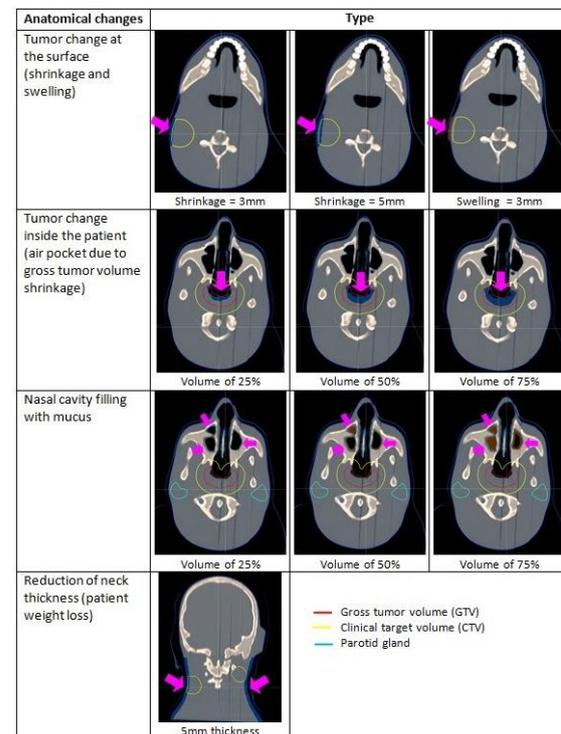

Figure 1: Simulated anatomical changes based on modified CT images of an anthropomorphic head phantom.

**Results**

An automated filter to identify reliable PBS spots was developed, e.g. assuring that the spot position is within the effective field of view (FOV) of the camera and that the fall-off of the PGI profile is completely included in the FOV - even in case of range shifts. For subsequent decision-tree-based error source classification (Fig. 2), the following parameters were selected: The coefficient of determination (R<sup>2</sup>), the slope and intercept of the linear regression between range shift and penetration depth as well as the 2D range shift map. With this approach, 27 of 30 error scenarios could be identified correctly. However, the three error scenarios with anatomical changes in the nasal cavity could not be identified because the

automated filtering approach had removed most relevant spots in this region.

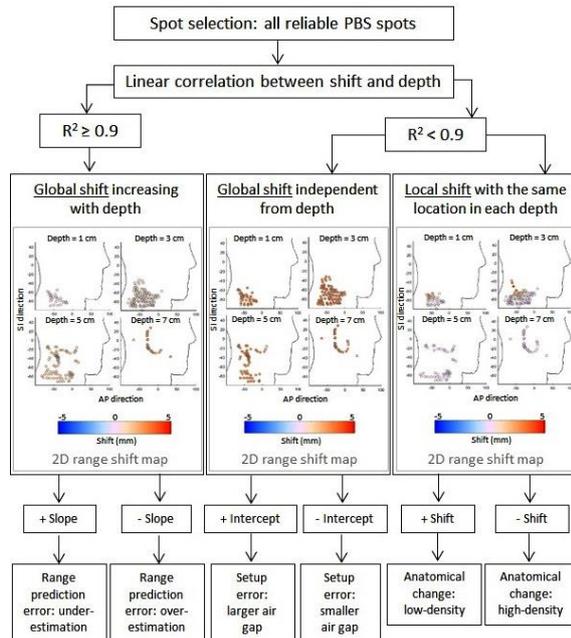

Figure 2: Decision tree to identify the source of range deviation based on PGI information.

## Conclusion

An automated classification approach was introduced to identify the source for range deviation solely from prompt-gamma information. Based on phantom data, including simulation of realistic anatomical variation, the results are promising. Further refinement of this initial approach might be beneficial. An extension of the validation with patient CT data is in preparation. In the future, an application of the approach on clinically measured PGI data is planned. Also other classification methods could be evaluated.

## OC-0567 Reconstructing the 3-D proton dose distribution from the modelled iono-acoustic wave field

E. Lens<sup>1</sup>, A. De Blécourt<sup>2</sup>, D. Schaart<sup>1</sup>, F. Vos<sup>2</sup>, K. Van Dongen<sup>2</sup>

<sup>1</sup>Delft University of Technology, Radiation Science and Technology, Delft, The Netherlands ; <sup>2</sup>Delft University of Technology, Imaging physics, Delft, The Netherlands

### Purpose or Objective

Real-time range verification during proton therapy is paramount to ensure patient safety as well as treatment effectiveness, but remains a major challenge. Here, we investigate if the iono-acoustic wave field generated by the protons can be used to reconstruct the 3-D dose distribution during treatment.

### Material and Methods

We developed a new numerical method to model the pressure field generated by a clinical proton pencil beam. To compute the field, we convolved a 3-D Green's function, representing the impulse response of the medium, with a volume density of injection rate source. This source describes the expansion of the medium due to a local temperature increase caused by the energy deposited by the protons. An analytical model is used to describe the spatial and temporal shape of the proton dose distribution. Next, we used this method to compute the

pressure field as would be measured by a 2-D transducer array consisting of 900 point-receivers. During a measurement the pressure field resulting from a number of proton spills is detected, this set of proton spills is defined as a proton pulse (Table).

For the model-based reconstruction of the proton dose distribution, we assumed prior knowledge of the temporal behaviour of the proton beam. To solve the resulting linear inverse problem, we used a conjugate gradient minimization scheme.

### Results

To validate our method, we modelled the acoustic wave field generated by a 100 MeV clinical proton therapy beam in water. All selected beam parameters such as beam width, beam current and proton pulse duration were selected such as to reflect clinical values based on an isochronous cyclotron (Table). A cross section of the original proton dose distribution used to model the pressure field is shown in the figure (top row). Next, the figure illustrates a snapshot of the resulting pressure field (middle row). The bottom row shows the reconstructed dose distribution using the proposed method.

The simulated measured wave-field had a centre frequency around 30 kHz and an amplitude of approximately 55 mPa. It also showed all the characteristics typical for the iono-acoustic wave field with a clear pulsed behaviour, corresponding to the field generated by the protons at the Bragg-peak location. The resulting reconstructed dose is similar to the original dose distribution and the error in the location of the Bragg peak is 3.9 mm.

### Conclusion

The iono-acoustic wave field resulting from a proton beam with clinically relevant parameters has been modelled using Green's functions. Imaging the proton dose distribution is feasible by solving the linear inverse problem, while taking the temporal profile of the proton dose distribution as prior knowledge. It is expected that the error can be reduced significantly, e.g. by optimizing the positions of the receivers or by taking more prior knowledge about the beam properties into account.

Table: Parameters used for the simulation

Parameter	Value	Parameter	Value
$\sigma_t$	1 ns	$R$	63 mm
$\tau$	13 ns	$\sigma_r$	4.5 mm
$\tau_{pulse}$	6.4 $\mu$ s	$c_0$	1520 m/s
$N_{spill}$	492	$\rho_0$	996 kg/m <sup>3</sup>
$N_{proton}$	$1.2 \times 10^6$	$\Gamma_0$	0.8
$I_{proton}$	30 nA		

$\sigma_t$  = Gaussian temporal width of a proton spill

$\tau$  = Temporal spacing between proton pulses

$\tau_{pulse}$  = Duration of a proton pulse

$N_{spill}$  = Number of proton spills in a proton pulse

$N_{proton}$  = Total number of protons

$I_{proton}$  = Proton beam current

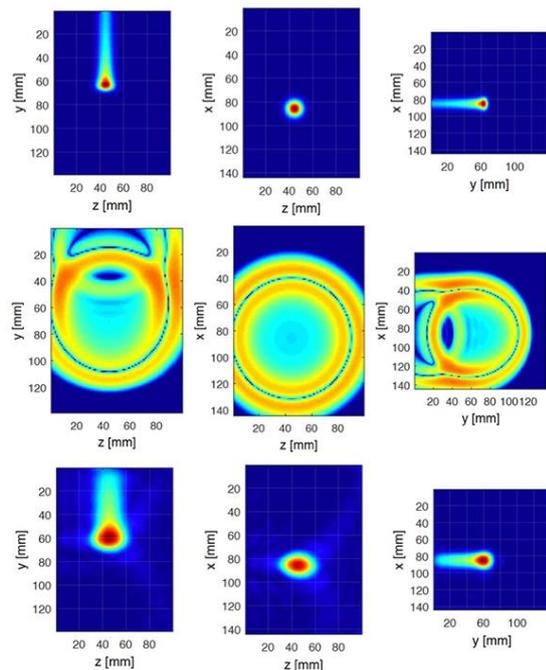

$R$  = Proton range

$\sigma_r$  = Initial proton beam Gaussian spatial width

$c_0$  = Speed of sound in the medium

$\rho_0$  = Mass density of the medium

$\Gamma_0$  = Grüneiser parameter of the medium

#### OC-0568 Experimental dosimetric characterization of a proton beam in the presence of a magnetic field

F. Padilla Cabal<sup>1</sup>, L. Fetty<sup>1</sup>, P. Kuess<sup>1</sup>, D. Georg<sup>1</sup>, H. Fuchs<sup>1</sup>

<sup>1</sup>Medizinische Universität Wien, Department of Radiotherapy, Vienna, Austria

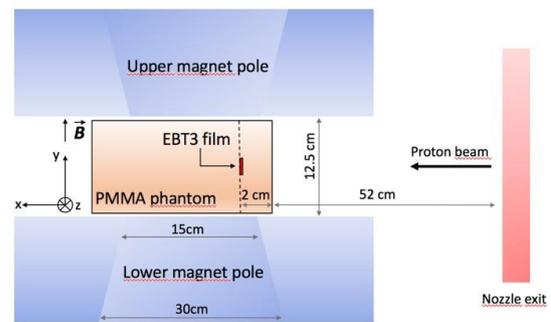

#### Purpose or Objective

Advancements in Magnetic Resonance Image guided photon therapy have recently stimulated research towards MR guided proton therapy. From a physics point of view, magnetic fields induce dose distortions due to proton beam deflections and thus challenge dose measurements and dose calculations. This work aims to study the response of conventional detectors used for absolute dose verification in proton therapy in the presence of external magnetic fields up to 1T.

#### Material and Methods

Measurements were performed using a proton research beam line in the clinical energy range of 62.4 - 252.7 MeV. A resistive dipole magnet was positioned in the isocenter, thus allowing to apply magnetic fields between 0 - 1T perpendicular to the beam incidence plane. An in-house built PMMA phantom ( $200 \times 120 \times 300 \text{ mm}^3$ ) was carefully placed in the center of the magnet, assuring homogeneous irradiations within the entire phantom volume.

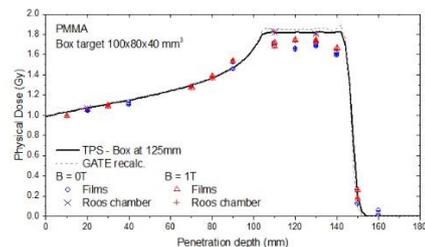

To evaluate the effect of the magnetic fields on different dosimetric methods, calibration curves were determined for EBT3 films and measurements using a Roos chamber were performed. Film calibration was conducted using 148.2 MeV protons at 20 mm depth in PMMA, for dose levels between 0.2-10 Gy, see Fig. 1. Afterwards, dose verification measurements were performed for different targets sizes using the same batch of calibrated films and the Roos chamber. Detectors were placed transverse to the beam, at depths between 20-150 mm covering the plateau and Bragg peak region. Results were compared for B=0T and B=1T. Monte Carlo simulations using the GATE/Geant4 toolkit were used to predict the effect of magnetic fields on dose distributions.

**Fig. 1** Sketch view of the experimental setup used for the EBT3 films calibration.

#### Results

Net optical density calibration curves for EBT3 films up to 10 Gy showed no significant differences ( $p\text{-value}=0.05$ ) between the different applied magnetic fields ( $B = 0, 0.5, 1\text{T}$ ). Relative differences in the Roos ionization chamber response at 20 mm depth in PMMA with/without magnetic fields were below 0.3%. Figure 2 summarizes measured and calculated proton depth dose distributions reaching a box target placed in the center of the magnet, for field strengths of  $B=0\text{T}$ ,  $B=1\text{T}$ . Absolute dose measurements with films showed an under-response up to -8% in the Bragg peak region, exhibiting a similar quenching effect as already observed without magnetic field.

**Fig. 2** Spread out Bragg peak measured without/within a magnetic field region. The continue and dash lines correspond to the planned and MC-recalculated dose distributions respectively.

#### Conclusion

For the first time the effect of magnetic fields on the dose response function was investigated for different detectors in the context of protons dosimetry. The proposed calibration and experimental method offer a viable solution for dose measurements within magnetic fields, considering the neglectable field influence observed. Further investigations using different detectors and irradiation geometries are foreseen.

#### OC-0569 A framework for variance-based sensitivity analysis of uncertainties in proton therapy

J. Hofmaier<sup>1</sup>, G. Dedes<sup>2</sup>, D.J. Carlson<sup>3</sup>, K. Parodi<sup>2</sup>, C. Belka<sup>1,4</sup>, F. Kamp<sup>1</sup>

<sup>1</sup>University Hospital LMU Munich, Department of Radiation Oncology, Munich, Germany; <sup>2</sup>Faculty of Physics LMU Munich, Department of Medical Physics, Munich, Germany; <sup>3</sup>Yale University School of Medicine, Department of Therapeutic Radiology, New Haven, USA; <sup>4</sup>German Cancer Consortium DKTK, partner site Munich, Munich, Germany

#### Purpose or Objective

Due to the physical properties of proton beams, treatment outcomes in particle therapy are more sensitive to uncertainties than conventional X-ray therapy. Sources of

uncertainty include motion, range and prediction of relative biological effectiveness (RBE). We present a platform to assess the combined impact of these uncertainties on dose distributions and DVHs in a variance-based sensitivity analysis (SA).

#### Material and Methods

Since the statistical approach of the variance-based SA requires a large number of RBE-weighted dose (RWD) calculations ( $10^5$ - $10^6$ ), a fast, GPU-accelerated modeling of patient and range shifts was implemented, based on the pencil beam algorithm in an ion therapy extension of the research treatment planning system CERR. It was combined with the repair-misrepair-fixation (RMF) model for fast RBE calculation. In each calculation the input parameters (motion, range shifts, the biological reference parameter  $\alpha/\beta$  for X-rays and RMF model parameters) are sampled independently within their assumed normal distributions (range: 3%+1mm, biological parameters: 10%, motion: 1mm in all 3 dimensions). The parameters are ranked by statistical formalisms according to their impact on the uncertainty of the RWD in every voxel, resulting in relative, normalized sensitivity indices ("S=0: no impact, S=1: only influential input"). Results are visualized in sensitivity maps and DVHs.

#### Results

The complete SA calculation including  $5 \cdot 10^5$  RWD calculations was performed in <2 hours for a meningioma proton plan (dose/fx: 1.8 Gy (RBE)). The largest local uncertainty (0.6 Gy (RBE)) was discovered towards and after the distal fall-off of the spread out Bragg peak (SOBP) (fig. 1), where it is dominated by range uncertainties. In the lateral direction the overall uncertainty is governed by motion, while biological modeling is the most relevant contribution to the smaller uncertainty (0.15 Gy (RBE)) in the center of the SOBP. Consequently, OARs downstream of the target are affected primarily by range uncertainties and OARs lateral to the beam are affected more by motion. The uncertainty of the CTV D95% is affected by mostly by range and biology (fig. 2).

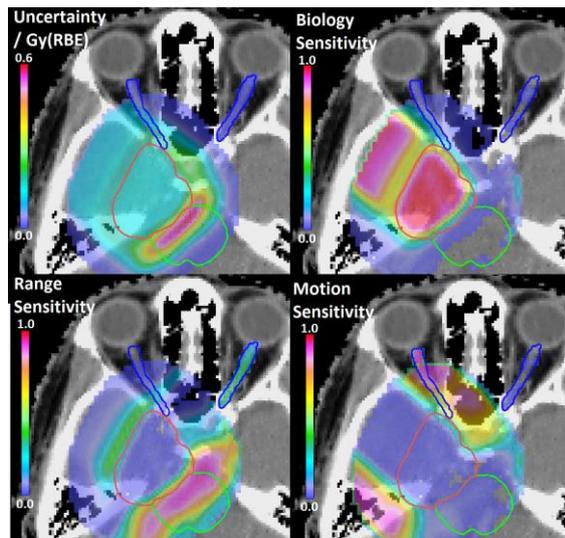

Fig.1: Impact of uncertainties in motion, biological modeling and range on the overall uncertainty (local empirical standard deviation) on a meningioma treatment plan consisting of one IMPT field. The structures shown are the CTV (red), brain stem (green) and optic nerves (blue).

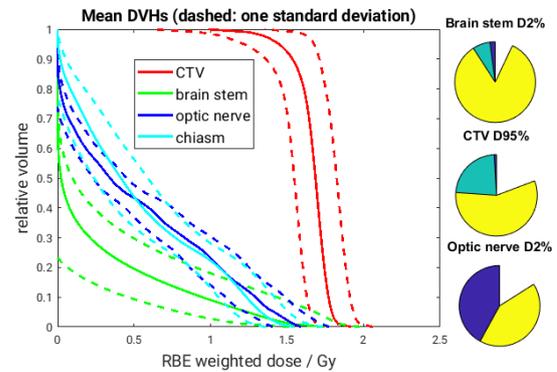

Fig.2: DVHs and sensitivities of selected quantiles. In the pie charts, the sensitivities of the input parameters are combined to three groups: motion (blue), range (yellow) and biology (turquoise).

#### Conclusion

A comprehensive sensitivity analysis framework for uncertainties in particle therapy was implemented. It is a powerful and flexible tool to assess the combined impact and interplay of motion, range and biological uncertainties, with possible implications for PTV definition and robust planning.

#### OC-0570 Dosimetric study to guide preclinical trials in proton minibeam radiotherapy

G. Consuelo<sup>1</sup>, L. De Marzi<sup>2</sup>, Y. Prezado<sup>3</sup>

<sup>1</sup>Centre national de la recherche scientifique, Imagerie et Modélisation en Neurobiologie et Cancérologie, Orsay Ville, France; <sup>2</sup>Institut Curie, Centre de Protonthérapie d'Orsay, Orsay Ville, France; <sup>3</sup>Imagerie et Modélisation en Neurobiologie et Cancérologie, Imagerie et Modélisation en Neurobiologie et Cancérologie, Orsay Ville, France

#### Purpose or Objective

Proton minibeam radiation therapy (pMBRT) is a novel concept that combines the benefits of protons for therapy with the remarkable normal tissue preservation observed when irradiated with submillimetric spatially fractionated beams [1]. Thanks to multiple Coulomb scattering, the tumor may receive a homogeneous dose distribution, while normal tissues in the beam path benefit from the spatial fractionation of the dose. This promising technique [2] has already been implemented at a clinical center (Institut Curie-Proton therapy center of Orsay, ICPO) by means of a first prototype of a multislit collimator [3]. The goal of this work was to develop a set of dosimetric tools to be able to guide reliably preclinical studies.

#### Material and Methods

The complete ICPO beamline and pMBRT irradiations setup were modelled using GATEv7.0 simulations. A clinically relevant energy (100 MeV) was used. For minibeam generation the brass multi-slits collimator used in the experiments was modelled [3]. Dose distributions were recorded in a water phantom and voxelized rat CT images (7 week male Fischer rats), whose whole brains were irradiated at ICPO. One part of the animals was implanted RG2 glioma tumors intracranially. This study includes a control group (tumor-bearing rats, non-irradiated) and a group of tumor-bearing rats that received pMBRT (70 Gy peak dose in one fraction) with very heterogeneous dose distributions.

#### Results

The agreement between the MC and experimental data provided us with a benchmark. We generate a virtual source in the nozzle exit in good agreement with the measurements. Starting from our modelling, we are able to perform preclinical simulations with a significant reduction of the computational time. Hence, we have

performed simulations with voxelized rat CT images of those animals used in experimental trials. Fig.1 shows representative dosimetry maps in three irradiation scenarios. Simulated results provide us a powerful quantitative understanding of the dose distributions within the animal brain. pMBRT leads to a significant increase of glioma tumor control, with 22 % of tumor sterilization. No substantial brain damage was observed neither in the long-term survival tumor-bearing rats nor in the irradiated normal rats, which confirms the widening of the therapeutic window for gliomas offered by pMBRT.

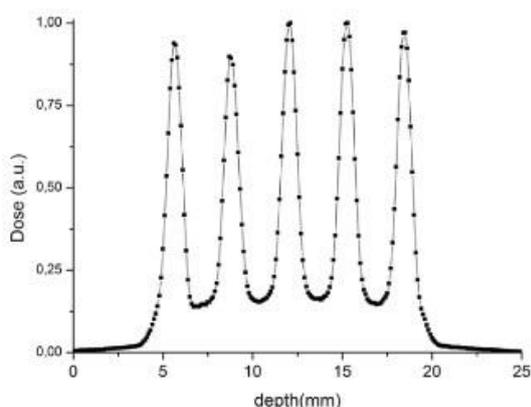

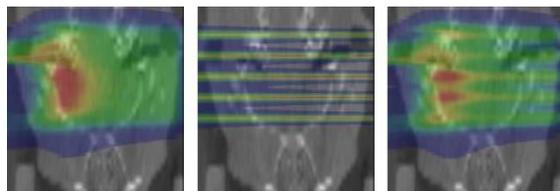

Figure 1: Left: Dose distribution inside the CT rat head in three main irradiation scenarios: broad beam (left), pMBRT (center), and pMBRT (plus solid-water) targeting the tumor position. Right: Corresponding lateral dose profile for the pMBRT case at the tumor position (ML: 5 mm, AP: -3 mm, DV: 5.5 mm).

#### Conclusion

A dose calculation engine for pMBRT has been developed. This tool allows us to reliable guide and interpret the results of our biological experiments.

#### SP-0571 Defining advanced practice roles specifically in radiotherapy

A. Duffton<sup>1</sup>

<sup>1</sup>*Inst. of Cancer Sciences-Univ. Glasgow, Research and Development Radiographer, Glasgow, United Kingdom*

#### Abstract text

The demand for radiotherapy services in the management of cancer has continued to increase over recent years. This has been due to a number of factors including: an ageing population, the ability to treat previously untreated cancers and the curative benefit of RT being realised within clinical trials. As more patients require RT to be delivered as part of their curative or palliative disease management, it has been necessary for service delivery and the workforce to evolve and meet these demands. To deliver good outcomes, professionals must ensure these

treatments are delivered with a timely and high quality approach. An established change in the oncology team workforce has been the diversifying role of the radiation therapist (RTT). This is evident in advanced practice (AP) roles detailed in the evidence base. The aim of this presentation is to describe the background of AP role development throughout Europe for RTTs, and give an overview of the literature supporting benefits of their implementation. Examples of AP roles within the RTT profession will be given, illustrating how their development has been in response to service/departmental needs. The evaluation of AP roles will be discussed, giving consideration to the benefit and impact they have on patient care. Finally, new roles bring about many opportunities for career development and progression to expert practice. This is advantageous to the RTT profession and the multi-disciplinary team.

#### SP-0572 Education and Advance Practice - Defining level EQF 7 and 8 competencies

M. Coffey<sup>1</sup>

<sup>1</sup>*Trinity College Dublin, Discipline of Radiation Therapy, Dublin, Ireland*

#### Abstract text

From an RTT perspective radiotherapy is the use of rapidly evolving technology in the preparation and treatment of cancer patients. This incorporates consideration of the technology and techniques used, the psychosocial management of a diverse patient population, the organisational structure and departmental relationships and current working practices. As a member of the radiotherapy team the RTT must be in a position to positively influence practice and to support effective and efficient service delivery. Evidence from many countries has shown how the development of diverse roles and responsibilities of RTTs has succeeded in achieving this. Unfortunately, in most instances, these developments are not linked to specialist education, professional development, career progression or associated salary increase. The failure to link these elements together results in lack of professional recognition in the wider context leading ultimately to role erosion and restriction of the potential of RTTs going forward. It is important for the recognition of the profession that education underpins defined advanced practice roles to enable a career structure to be put in place at a national and international level. While non-specific education is directly beneficial to the individual and is therefore worthwhile, it does not progress the overall profession in the same way. In this context we decided to define specific roles and responsibilities in the EQF 7 & 8 although the context and content is sufficiently broad to also enable individual development in other areas as they evolve. The roles associated with each area are sub-divided into level 7 or 8 depending on the level of responsibility expected and the education level achieved. This underpins the development of a career structure which supports professional advancement of RTTs and the provision of more efficient and effective service delivery. The roles defined in the ESTRO EQF level 7 & 8 benchmarking document include: advanced contouring and volume determination, treatment planning, advanced imaging: IGRT and ART, management, patient care and support, brachytherapy, research and education.

#### SP-0573 Incorporation radiation therapist RTT into radiation oncologist RO team

B. Bak<sup>1</sup>, J. Michalewska<sup>1</sup>, A. Machtyl<sup>1</sup>, P. Martenka<sup>2</sup>

<sup>1</sup>*Greater Poland Cancer Centre, Department Of Radiotherapy, Poznan, Poland* ; <sup>2</sup>*Greater Poland Cancer Centre, Radiotherapy Ward 1, Poznan, Poland*

## Abstract text

### Purpose

The study assessed the impact of incorporation radiation therapist (RTT) into radiation oncologist RO team in Radiotherapy Wards. We intended to estimate the efficiency of workflow improvement and to investigate whether this would reduce the time gap between the preparation and the start of treatment.

### Material and Methods

For one year RTT worked as a member of interdisciplinary team in two independent Wards. During the first six months selected RTT had worked strictly with RO at Radiotherapy Ward 1 (WR1) and focused on coordination and treatment preparation of patients with oesophagus, stomach, prostate and H&N cancer. In the second half of the year RTT managed patients with H&N and prostate cancer in the Radiotherapy Ward 2 (WR2). The main responsibilities were as follows: 1. participation in the morning report, 2. making an appointment and educating the patient, 3. coordinating the different phases of preparation for radiotherapy (RT) including: initial simulation, initial computed tomography (iCT) and virtual simulation, contouring of organs at risk (OAR), initial verification of treatment plans.

### Results

Mean reduce of time from iCT to intent order was 1 day comparing to period without RTT. Mean time from intent order to initial simulation was > 4 days and from intent order to beginning of the treatment > 5 days. There was no statistically significant time reduction at that point. Average contouring time of OAR's for RTT was 92 min for stomach 115 min for oesophagus case and 81min for prostate and 129 min for H&N cases. In the period when RTT coordinated and managed the radiotherapy pathway the number of treated patients increased by 23% and 11% in WR1 and WR2, respectively.

### Conclusions

Cooperation with RTT results in reduced time of patient's preparation for radiotherapy and increased number of treated patients.

### PV-0574 Evaluation of a clinical decision support protocol during radiotherapy for H&N cancer patients

F. Rodrigues Sousa<sup>1</sup>, Y. Jourani<sup>2</sup>, M. Somoano<sup>1</sup>, T. Dragan<sup>1</sup>, S. Beauvois<sup>1</sup>, D. Van Gestel<sup>1</sup>

<sup>1</sup>Institut Jules Bordet - Université Libre de Bruxelles, Radiotherapy, Brussels, Belgium ; <sup>2</sup>Institut Jules Bordet - Université Libre de Bruxelles, Medical Physics, Brussels, Belgium

### Purpose or Objective

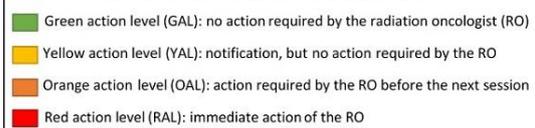

During radiotherapy (RT) treatment, variations such as patient weight loss, tumor regression and diminution of the volume of organs at risk (OARs) are likely to occur. These variations may result in changes in the dose distribution with a risk of overdose to the OARs which cannot be compensated for by a simple rigid repositioning. In order to more easily prioritize these variations according to their potential impact, an action level protocol (ALP) has been put into practice as a clinical decision support system (CDSS). In this study we analyze whether the used ALP criteria are adequate and clinically useful for adaptive planning and whether further optimization of the protocol can reduce the workload.

### Material and Methods

An ALP (Figure 1) based on online provided papers was designed in an in-house developed informatics tool through collaboration between physicians, physicists and RTTs. All CBCT review orders from head and neck patients

treated with VMAT between February and July 2018 were analyzed. These orders were categorized based on the following criteria: change of body contour, gap between skin and bolus (when used), tumor progression or inflammation of healthy tissue, tumor regression, shift of the target, tracheotomy performed after the reference computed tomography (CTref) images, teeth extraction after the CTref, second opinion on matching or other. For these criteria, frequency and follow-up action (i.e. no action required, new CT and plan adaptation) were scored.

Figure 1 - Action levels of the clinical decision support system

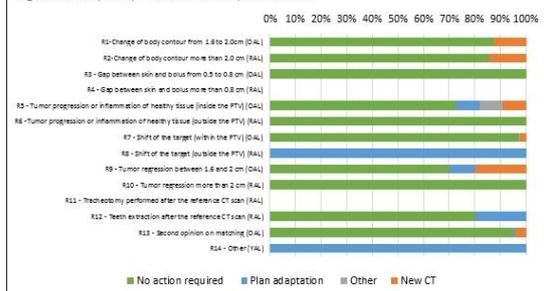

### Results

In the 50 patients, our protocol resulted in 397 review orders: the majority (372; 94%) did not require any further action after investigation; in 17 cases (4%), a new CT scan was made; and in 7 cases (2%), a plan adaptation was done. The latter was seen in categories R5, R8, R9, R12, R13 and R14 (Figure 2). Clinically relevant indicators of potential adaptation were mostly found in time, i.e. in the OAL rather than in the RAL.

CBCT review orders regarding shift of the target (within the PTV; R7) were most often reported, but required hardly any further action. Therefore we could safely decrease the action level of this criterion from an orange action level (OAL) to a yellow action level (YAL; Figure 1), reducing the radiation oncologists (ROs) workload by 57%.

Figure 2: Frequency of action taken per criterion

### Conclusion

Our action level protocol has been proven adequate for identifying patients in need of adaptive re-planning, but it also led to many false alerts. The revised and optimized protocol leads to a reduction of 57% in the workload.

### PV-0575 Is diaphragm dome or bone fusion adequate to IGRT in liver-SBRT compare to fiducial markers?

C. De la Pinta Alonso<sup>1</sup>, D. Sevillano<sup>2</sup>, R. Colmenares<sup>2</sup>, M. Martín<sup>1</sup>, C. Vallejo<sup>1</sup>, E. Fernández-Lizarbe<sup>1</sup>, S. Barrio<sup>3</sup>, V. Pino<sup>3</sup>, J.A. Rojo<sup>3</sup>, S. Sancho<sup>1</sup>

<sup>1</sup>Hospital Ramon y Cajal, Radiation Oncology, Madrid, Spain; <sup>2</sup>Hospital Ramon y Cajal, Medical Physics, Madrid, Spain; <sup>3</sup>Hospital Ramon y Cajal, Radiotherapist, Madrid, Spain

### Purpose or Objective

Stereotactic body radiotherapy (SBRT) in liver tumours is increasingly being used to treat primary and metastatic tumours. The purpose of this study was to compare the liver motion variability between using implanted fiducial markers as surrogates and alternatives methods with diaphragm dome or bone registration. We analyzed in this abstract our preliminary results.

### Material and Methods

Eight patients undergoing SBRT with abdominal compression for primary or metastatic liver cancer were analyzed. We determined the day-to-day correlation between metallic markers compare to diaphragm dome and bone tumour positions in conebeam-CT (CBCT) acquired before each treatment session. A total of 38 CBCT were analyzed. The liver variability observed in metallic markers and bone or diaphragm dome fusion and agreement was assessed using kappa statistic was analyzed. Agreement interpretation was evaluated using Landis and Koch's interpretation of strength of agreement.

#### Results

Fiducial marker-guidance was our gold standard to guiding treatment in this study. Median displacement in anterior-posterior (AP) direction of fiducial, diaphragm dome and bone was 0.06, 0.12, and 0.13cm respectively. Median displacement in lateral direction of fiducial, diaphragm dome and bone was 0.02, 0.05, and 0.06cm respectively. Median displacement in superior-inferior (SI) direction of fiducial, diaphragm dome and bone was 0.05, 0.05, and 0.18cm respectively. In the AP direction displacements of fiducial and diaphragm dome showed substantial agreement ( $\kappa=0,65$ ); and fiducial and bone light agreement ( $\kappa=0,1$ ). In the lateral direction displacements of fiducial and diaphragm dome showed substantial agreement ( $\kappa=0,64$ ); and fiducial and bone light agreement ( $\kappa=0,07$ ). In the SI direction displacements of fiducial and diaphragm dome showed just agreement ( $\kappa=0,36$ ); and fiducial and bone showed light agreement ( $\kappa=0,06$ ). In all group, the largest deviations were observed in the SI direction (variance 0,29).

#### Conclusion

These are preliminary results of our study but we consider image-guided radiotherapy (IGRT) with soft tissue match (diaphragm dome) provides a non-invasive option for daily localization and is accurate within treatment uncertainly for the majority of cases. In this moment we continuing use metallic markers until finish the study.

#### PV-0576 Simulation of EHRT for prostate cancer without monitoring intra-fractional prostate motion

Y. Oguma<sup>1</sup>, H. Shiomi<sup>2</sup>, K. Nagata<sup>3</sup>, K. Okajima<sup>1</sup>, H. Morikawa<sup>3</sup>, Y. Watanabe<sup>3</sup>, K. Mizuno<sup>3</sup>, K. Komatsubara<sup>3</sup>, K. Hata<sup>3</sup>

<sup>1</sup>Nara hospital Kindai University, Radiology, Ikoma, Japan; <sup>2</sup>Miyakojima IGRT clinic, Radiation oncology, Osaka, Japan; <sup>3</sup>Ishikiri Seiki Hospital, Radiation oncology, Higashi Osaka, Japan

#### Purpose or Objective

To examine the effectiveness of extreme hypofractionated radiation therapy (EHRT) for prostate cancer without the monitoring of the intra-fractional prostate motion.

#### Material and Methods

Between January 2015 and December 2016, data from 631 fractions obtained from 43 patients with prostate cancer who underwent more than 10 sessions of intensity-modulated radiation therapy (IMRT) (74 Gy/37 Fr, D50) with image guided radiation therapy (IGRT) before and after irradiation were analyzed. Three-dimensional prostate motions were detected using computed tomography, and the probability distributions (mean and standard deviation for each direction) were calculated. Assuming EHRT (35 Gy/5 Fr), dose distribution changes were simulated 1000 times using the dose shift method with the assumption of the worst outcome, i.e. that the prostate had shifted to the end position immediately. The all-fraction dose distributions were integrated, the equivalent dose was converted into 2 Gy fractions (EqD2) using the Liner-Quadratic model, the equivalent uniform dose (EUD) ( $\alpha = -13$ ) was obtained, and then the TCP ( $\gamma50 = 2.2$ ,  $TD50 = 67.5$ ,  $\alpha/\beta = 1.5$ ) was calculated. Finally, the

decrease in TCP caused by prostate motion was calculated.

#### Results

The maximum prostate motions were  $0.4 \pm 0.9$  mm (L-R),  $1.5 \pm 4.7$  mm (A-P), and  $0.2 \pm 4.5$  mm (S-I). The TCP was estimated to be 71% for conventional IMRT (74 Gy/37 Fr), and 89% for EHRT (35 Gy/5 Fr) without prostate motions. In the worst-case scenario, prostate motion induced the TCP to decrease to 68-70% (90% confidence interval, 74 Gy/37 Fr) and 86-89% (90% confidence interval, 35 Gy/5 Fr).

#### Conclusion

EHRT for the treatment of prostate cancer was observed to be efficient, even when the intra-fractional prostate motion was not monitored and it was divided into 5 or more fractions.

#### PV-0577 Single-institution report of whole breast VMAT radiotherapy implemented with 3D surface imaging

V. Favrel<sup>1</sup>, O. Ruiz Achard<sup>1</sup>, L. Gonzague Casabianca<sup>1</sup>, F. Chabbert<sup>1</sup>, A. Louis<sup>1</sup>, J. Paumont<sup>1</sup>, H. Maillieux<sup>1</sup>, P. Eustache<sup>1</sup>, A. Tallet<sup>1</sup>

<sup>1</sup>Institut Paoli Calmettes, Radiotherapy Oncology, Marseille, France

#### Purpose or Objective

Inter and Intra-fraction motion is a key issue for VMAT breast irradiation. 3D surface imaging allows us to monitor patient movements for all breast VMAT treatment with AlignRT (VisionRT, London, UK). However, we continue to apply CBCT for day 1, 2, 3 and then weekly. We analyzed the rate and causes of definitive stops of AlignRT use during the treatment for all patients (pts), with the aim to elaborate a decision tree to help the team to take the adequate decision for complex cases of discrepancies between CBCT and AlignRT.

#### Material and Methods

From February 2017 to August 2018, 506 patients (pts) were consecutively treated with breast VMAT radiotherapy and AlignRT system. We retrospectively collected data from 11375 sessions to assess the rate and the time of definitive stops of use AlignRT treatment monitoring, with intent to identify causes of the stops.

#### Results

We have identified two groups: G1 (413 pts; 89%) in which all the pts were treated without any stop, and G2 where AlignRT was definitively stopped during the treatment (56 pts; 11%). A subgroup of G1 (G1bis; 37 pts; 7%) represents pts who had to perform a new CT scan +/- new plan during treatment but could continue to be managed with AlignRT.

Data are summarized in the table 1

Sites treated with VMAT	Use of AlignRT during the whole treatment group 1 (G1)			Definitive stop AlignRT group 2 (G2)			
	Without new CT scan	With new CT scan group 1bis (G1bis)		Without new CT scan	With new CT scan		
Breast +/- LN +/- tumor bed	403 (79.64%)	No new planning <sup>2</sup>	New planning	31	No new planning <sup>2</sup>	20	5
496 (98.03%)		14	23				
Tumor bed only	10	0		0			
10 (1.97%)							
Total: 506 patients	413 (82%)	37 (7%)		56			
	450 (89%)			56 (11%)			

Table 1: <sup>1</sup> lymph nodes; <sup>2</sup> after reviewing, the initial plan remained relevant

The median stop occurred at the 9<sup>th</sup> session in G2 vs the 6<sup>th</sup> in G1bis (for G1bis: stop and go with AlignRT). There was no difference due to learning curve between treatments done in 2017 vs 2018 in both groups. The main reasons to perform a new CT scan during the treatment are anatomy changes, patient motion due to pain, and

AlignRT out of tolerances data compared to CBCT. In part because of the lack of homogeneous procedures for complex cases in the Department before July 18, 25/506 pts in G2 couldn't be further managed with AlignRT despite a new scan +/- new plan vs 37/506 in G1; 31/506 pts in G2 did not perform a new CT scan despite persistent discrepancies between AlignRT and CBCT.

#### Conclusion

In our series, AlignRT motion management is robust and efficient for 89% of breast cancer VMAT treatments. For the remaining 11%, AlignRT has been definitely stopped during the treatment for several reasons i.e. anatomy changes, pain, and out-of-tolerance-data compared to CBCT. An inhomogeneous decision-making among the team could be involved in some of these stops. We thus implemented a decision tree since July 18 with the aim to increase the rate of treatments without any stop. We now prospectively collect data to evaluate this implementation

#### PV-0578 Image quality of cone beam CT used as image-guidance for pelvic Stereotactic Ablative Radiotherapy

F. Slevin<sup>1</sup>, M. Beasley<sup>2</sup>, A. Needham<sup>2</sup>, J. Lilley<sup>3</sup>, R. Speight<sup>3</sup>, L.J. Murray<sup>1</sup>, A.M. Henry<sup>1</sup>

<sup>1</sup>Leeds Cancer Centre, Clinical Oncology, Leeds, United Kingdom; <sup>2</sup>Leeds Cancer Centre, Therapeutic radiography, Leeds, United Kingdom; <sup>3</sup>Leeds Cancer Centre, Medical Physics, Leeds, United Kingdom

#### Purpose or Objective

Abdomino-pelvic Stereotactic Ablative Radiotherapy (AP-SABR) is increasingly used to treat oligo-metastatic pelvic nodal disease. Cone beam CT (CBCT) is used for image-guided radiotherapy (IGRT), but image quality is limited by scattered radiation, use of low-dose protocols and streak artefacts from moving bowel gas. These factors could make the process of AP-SABR target-matching more difficult. This retrospective single centre study investigated the extent to which CBCT image quality influenced the ease of AP-SABR target-matching and determined the proportions of images affected by factors limiting image quality.

#### Material and Methods

11 consecutive patients treated with AP-SABR were investigated. Two experienced therapy radiographers retrospectively independently reviewed 139 CBCTs acquired before and after each SABR fraction from these patients in the XVI (Elekta) IGRT system. Target-matching was performed between the planning CT and each CBCT image. Image quality was assessed using a four-point Likert scale (image quality for target-matching excellent, satisfactory, poor or impossible to use). Factors used to determine chosen score were presence of streak artefacts close to the target, lack of soft tissue contrast, small size of target and lack of surrogate structure to aid target matching. Descriptive statistics are presented.

#### Results

CBCT image quality scores were judged by assessors 1 and 2 as excellent in 6 (4.3%) and 8 (5.8%) of 139 images respectively; satisfactory in 63 (45.3%) and 89 (64%) respectively; poor in 66 (47.5%) and 40 (28.8%) respectively; and impossible to match in 4 (2.9%) and 2 (1.4%) images respectively (Figure 1). Streak artefact close to the target was observed in 89 (64%) and 62 (44.6%) images respectively. Source of artefacts was small bowel or combination of small and large bowel in a quarter and three-quarters of images respectively. Lack of soft tissue contrast was observed in 86 (61.9%) and 70 (50.4%) images respectively. Small size of target was found in 70 (50.4%) and 10 (7.2%) images respectively. Lack of surrogate was observed in 13 (9.4%) and 0 images respectively (Figure 2). Agreement between assessors for Likert scores, presence of streak artefacts, lack of soft tissue contrast, small target size and lack of surrogate was seen in 54 (38.8%),

56 (40.3%), 83 (59.7%), 73 (52.5%) and 126 (90.6%) of images respectively.

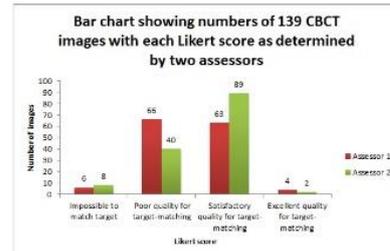

Figure 1 Bar chart showing numbers of CBCT images with each Likert score as determined by two assessors. Large proportion of images judged poor quality for target-matching.

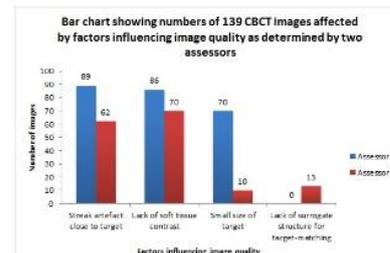

Figure 2 Bar chart showing numbers of CBCT images affected by factors influencing image quality as determined by two assessors. Note large proportion of images affected by streak artefact close to target and lack of soft tissue contrast.

#### Conclusion

Streak artefacts from moving bowel gas close to the target, especially from small bowel or combination of small and large bowel, affected over half of CBCT images. Images were also affected by lack of soft tissue contrast in over half of images. In over a third of cases image quality was felt to be poor or impossible to use because of factors negatively affecting image quality. Use of anti-peristaltic agents to reduce streak artefacts and modification of CBCT dose to improve soft tissue contrast should be investigated. Considerable variation between assessor scores reflects the subjectivity of this assessment process.

#### PV-0579 The impact of intra-thoracic anatomical changes on the delivery of lung SABR

M. Beasley<sup>1</sup>, S. Brown<sup>2</sup>, R. Chuter<sup>2</sup>, C. Favier-Finn<sup>3</sup>, K. Franks<sup>1</sup>, L. Murray<sup>4</sup>, M. Van-Herk<sup>2</sup>, A. Henry<sup>4</sup>

<sup>1</sup>Leeds Cancer Centre- Leeds Teaching Hospitals NHS Trust, Radiotherapy Research Group, Leeds, United Kingdom; <sup>2</sup>The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom; <sup>3</sup>University of Manchester and The Christie NHS Foundation Trust, Radiotherapy Related Research, Manchester, United Kingdom; <sup>4</sup>University of Leeds- Leeds Institute of Cancer and Pathology and Leeds Cancer Centre- Leeds Teaching Hospitals NHS Trust, Radiotherapy Research Group, Leeds, United Kingdom

#### Purpose or Objective

Although evidence is limited, it has been suggested that approximately 70% of locally advanced non-small cell lung cancer (NSCLC) patients undergoing curative radiotherapy develop intra-thoracic anatomical changes (ITACs), with fewer than 10% requiring a completely new treatment plan.<sup>1</sup> The impact of ITACs on patients receiving SABR for early stage NSCLC, however, is unknown.

The aim of this study is to describe the occurrence of ITACs on CBCT imaging and the impact in lung cancer patients treated with SABR. This study was conducted on behalf of the UK Advanced Radiotherapy Technologies Network (ART-NET).

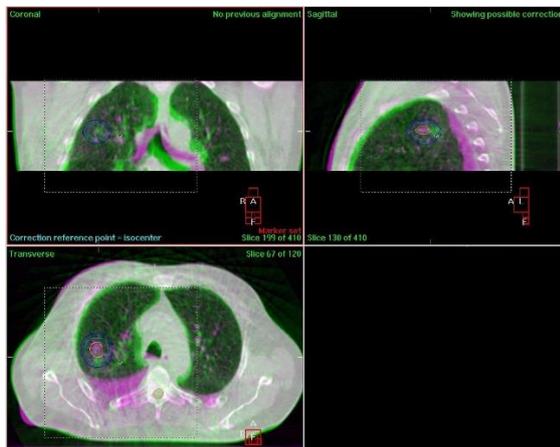

### Material and Methods

100 patients treated with SABR for early non-small cell lung cancer at two large UK NHS radiotherapy centres were identified. CBCTs acquired from 546 treatment fractions were reviewed for the presence of the following ITACs: atelectasis, infiltrative change, pleural effusion, baseline shift, gross tumour volume (GTV) increase and GTV decrease. These were graded using a traffic light protocol, similar to Kwint *et al.*, 2014<sup>1</sup>, in order to assess potential target under-coverage. The frequency of requests for physicists or clinicians to review the impact of ITACs was also recorded.

### Results

ITACs were observed in 23% of patients undergoing SABR for lung cancer at two UK radiotherapy centres. An example of a 'red' ITAC is depicted in Figure 1. The majority of CBCTs demonstrated no ITACs (85%, in 77% of patients). However, 18% of ITACs were graded as 'red', indicating a potential risk of target under-coverage. The highest proportion of ITACs observed (49%) were graded as 'yellow', indicating minimal impact upon PTV coverage. Physicist or clinician review was required for 9% of treatment fractions. Three patients needed to have their treatment re-planned.

**Figure 1:** From clockwise: coronal, sagittal and axial slices of the CBCT acquired at a 1<sup>st</sup> fraction of SABR. This shows the resolution of pleural effusion and a consequential tumour baseline shift. This was scored as red. The GTV, ITV and PTV are represented by the pink, light blue and dark blue isodose lines, respectively.

### Conclusion

The majority of ITACs were minor; however, they are associated with unplanned physicist or clinician review representing a potentially significant resource burden. There is a need to incorporate detailed guidance on the management of ITACs into IGRT workflows. This would provide an evidence-based approach to support Therapeutic Radiographer decision making when treating lung SABR, potentially reducing the impact of ITACs on workflow and the wider radiotherapy service.

### PV-0580 CBCT-based analysis of target coverage-volume changes after prostate SABR with triggered kV-imaging

K. Kisiván<sup>1</sup>, A. Farkas<sup>1</sup>, D. Gugyerás<sup>1</sup>, C. Glavák<sup>1</sup>, Z. László<sup>1</sup>, M. Petóné Csima<sup>2</sup>, Z. Cselik<sup>3</sup>, J. Hadjiev<sup>1</sup>, A. Gulyban<sup>4</sup>, F. Lakosi<sup>1</sup>

<sup>1</sup>Somogy County Kaposi Mor Hospital- Dr. Baka József Diagnostic- Radiation Oncology- Research and Teaching Center, Radiation Oncology, Kaposvar, Hungary;

<sup>2</sup>Kaposvar University, Faculty of Pedagogy, Kaposvar, Hungary; <sup>3</sup>Cholnoky Ferenc Hospital, Department of Radiation Oncology, Veszprem, Hungary; <sup>4</sup>Europe Hospitals, Department of Radiation Oncology, Brussels, Belgium

### Purpose or Objective

To evaluate target coverage and normal volume changes after gold marker-based prostate stereotactic ablative radiotherapy (SABR) with triggered kV imaging using multiple CBCTs.

### Material and Methods

A total of 11 patients (8 monotherapy: 5x7.25 Gy, 3 boost:50.4+3x6.5 Gy) were treated with VMAT based SABR. All patients were prepared according to an institutional bladder and rectal filling protocol. Treatment verification consisted of pre-and post RT CBCTs, while during treatment online triggered kV imaging at an interval of 3 seconds was acquired. In case of  $\geq 3$ mm (deviation limit, DL) displacement, treatment was interrupted and corrected with additional imaging (2D/3D match, kV pair and/or CBCT). Beam interruptions, intrafractional shifts, treatment time were also recorded. Prostate, rectum, bladder were delineated on each CBCT. Target coverage was evaluated by comparing the individual prostate delineations with 95% isodose contour volumes using Supplementary Volume Contoured (% of the evaluated volumes exceeding the reference, SVC) metrics. Furthermore, volumetric changes of the delineated organs were assessed to evaluate bladder and rectal filling compared to baseline, and their intrafractional variations using paired t-test at  $p < 0.05$  significance level.

### Results

The average ( $\pm$  SD) treatment time was: 16 $\pm$ 12 min. On average, beams had to be interrupted twice (range: 0-10) per treatment sessions with a mean of 2.5 mm 3D shifts exceeding the DL in 30% (15/51) of the fractions. Patients were re-positioned 15 times due to inadequate rectal (14) or bladder (1) filling status. Only 4/98 evaluation (2 pre-, 2 post-CBCT) showed deviation from the ideal SVC (=0%) of the target (vs. 95% isodose line) with a maximum of 3%. In contrast, in the 15 re-positioned sessions the SVC analysis showed relevant (>5%) deviation in one third of the cases with up to 34%. The bladder volume on pre-CBCT was significantly larger compared to baseline (271 $\pm$ 161 cm<sup>3</sup> vs. 321 $\pm$ 199 cm<sup>3</sup>,  $p=0.02$ ), and further increased during treatment by an average of 17% ( $p < 0.001$ ). There were no significant inter- and intrafractional changes of the rectal volume.

### Conclusion

Gold marker-based prostate SABR with triggered kV imaging and pre/post-treatment CBCT was successfully implemented in our clinic. The 3D evaluation confirmed sufficient target coverage beside significant bladder volume changes.

### PV-0581 Image Gently for pediatric IGRT on Varian Halcyon and Edge systems: dose and positioning accuracy

Y. Zhang<sup>1</sup>, M. Wang<sup>1</sup>, Y. Huang<sup>1</sup>, H. Wu<sup>1</sup>, W. Wang<sup>1</sup>

<sup>1</sup>Key Laboratory of Carcinogenesis and Translational Research Ministry of Education/Beijing- Department of Radiation Oncology- Peking University Cancer Hospital and Institute, Department of Radiotherapy, Beijing, China

### Purpose or Objective

Reduced-dose protocols have been made available on Varian Edge kV cone beam CT (CBCT) and Halcyon MV CBCT. To assist clinicians in choosing optimal imaging modality for specific patient anatomy, this work compared the imaging dose and positioning accuracy of kV and MV CBCT using various scanning protocols and phantoms.

## Material and Methods

The settings of standard and image gently protocols of kV CBCT was listed in table 1 (OBI V.2.5). The kV imaging dose to the CT dose index (CTDI) phantom was measured using a calibrated PTW CT chamber. After measurement-based validation, the Halcyon MV CBCT imaging dose (V.1.0) to the corresponding volumes were calculated on Eclipse Treatment Planning System (V.15.1), since Halcyon uses identical 6 MV flattening-filter-free photons for both imaging and treatment, enabling the automated incorporation of the two doses. The 'High Quality' and 'Low Dose' modes uses dose rates of 45 MU/min and 27 MU/min, delivering 10 MU and 5 MU per scan respectively. The weighted CTDI (CTDI<sub>w</sub>) were computed for both systems. Using various modalities and protocols, the accuracy of correcting a known couch shift (5 mm on three directions) for the head, thorax and pelvis regions of CIRS 1-year, 5-year and RANDO adult anthropomorphic phantoms were compared.

**Table 1** Comparisons between the Image Gently parameters and the standard scanning protocols

	Image Gently	Head	Thorax	Pelvis
<b>Fan*</b>	Full	Full	Half	Half
<b>Trajectory</b>	200°	200°	360°	360°
<b>kVp</b>	80	100	125	125
<b>mAs</b>	100	150	270	1080

\*The Full Fan and Half Fan modes utilize full and half bow-tie filters, providing maximum field-of-view (FOV) diameters of 26.2 cm and 46.5 cm respectively.

## Results

The CTDI<sub>w</sub> for the standard 'Head', 'Thorax', 'Pelvis' and 'Image Gently' (measured on both CTDI head and CTDI body phantoms respectively) protocols of kV CBCT were 0.45 cGy, 0.54 cGy, 1.93 cGy, 0.11 cGy, and 0.05 cGy respectively. The computed CTDI<sub>w</sub> for MV CBCT in the CTDI head and body phantoms were 8.45 cGy and 6.38 cGy (imaging length=28 cm, the maximum field of Halcyon), 6.88 cGy and 5.55 cGy (imaging length=16 cm, equivalent to that of Edge kV CBCT) respectively, using the 'High Quality' protocol. The exposure of 'Low Dose' MV CBCT was approximately halved. Figure 1 displays the deviations of image registrations from the actual couch shifts [mm] on the vertical, longitudinal, lateral directions and the root-mean-square (RMS), as guided by Edge kV CBCT and Halcyon MV CBCT. Only the positioning error of adult pelvis guided by 'Image Gently' kV CBCT (1.57 mm) exceeded our clinical tolerance of 1.00 mm. All other registrations were satisfactory: the maximum deviations for the 1-year, 5-year and adult phantoms were 0.22 mm, 0.25 mm, 0.58 mm (standard kVCBCT); 0.27 mm, 0.42 mm, 0.54 mm ('Image Gently' kV CBCT excluding adult pelvis); 0.39 mm, 0.37 mm, 0.42 mm ('High Quality' MV CBCT); and 0.44 mm, 0.36 mm, 0.52 mm ('Low Dose' MV CBCT)

respectively.

## Conclusion

'Image Gently' kV CBCT is inadequate for adult pelvis, but is applicable to other anatomies achieving comparable positioning accuracy as standard kV CBCT. Similar registration results were achievable using MV CBCT, but the 'Low Dose' mode is most cost-effective for all phantoms than the 'High Quality' protocol.

## Symposium: Recent insights into adverse cardiac effects from multimodal radiation therapy

### SP-0582 Prediction models for adverse cardiac effects to target optimal cardiac radiation dose distributions in breast cancer patients

A. Crijs<sup>1</sup>

<sup>1</sup>UMC Groningen, Radiotherapy, Groningen, The Netherlands

#### Abstract text

Incidental cardiac radiation in breast cancer radiotherapy results in an increased risk of major cardiac events. Darby et al. found that the lifetime excess risk of an acute coronary event [ACE] increases linearly by 7.4% per Gray of the mean heart dose. However, we have validated that the first 9 years following radiotherapy the excess risk of an ACE even increases by 16% per Gray of the MHD. In the Netherlands, the model-based approach is applied to select breast cancer patients for proton therapy. To qualify for proton therapy, breast cancer patients should have a  $\geq 2\%$  decrease in the absolute lifetime risk of an ACE after planning comparison between photon and proton therapy. To calculate the absolute lifetime risk of an ACE, the validated Darby model is used, with the difference that the observed baseline risk of an ACE is based on the numbers of ACEs in females and males in the Dutch population. However, for optimization of cardiac photon dose distributions and better selection of patients for proton therapy validated prediction models are essential, describing the relationship between radiation dose to cardiac substructures and MCEs. Furthermore, knowledge about early subclinical cardiovascular effects (ESCEs) induced by radiotherapy that eventually develop into MCEs is also needed for development of primary and secondary preventive strategies. Currently these issues are addressed in the European MEDIRAD-BRACE and -EARLY

HEART Projects. An overview of these studies will be presented.

**SP-0583 Practical aspects of estimating and measuring of CIED dose in radiotherapy procedures**

E. Konstanty<sup>1</sup>, B. Bak<sup>2</sup>, W. Szyszka<sup>2</sup>

<sup>1</sup>Greater Poland Cancer Centre, Department Of Medical Physics, Poznan, Poland ; <sup>2</sup>Greater Poland Cancer Centre, Radiotherapy Department II, Poznan, Poland

**Abstract text**

According to AAPM Report No. 45 “Management of radiation oncology patients with implanted cardiac pacemakers” cardiac pacemakers can fail from radiation damage and can exhibit functional changes. Total dose to each type of cardiovascular implantable electronic device (CIED) should be estimated for each patient who undergoes radiotherapy. One of the recommendations of the task group is to estimate the absorbed dose to be received by the device before treatment. Another important document that contains practical recommendations for specialists treating patients with CIEDs with radiation therapy is a clinical guideline of the Heart Rhythm Society: “2017 HRS expert consensus statement on magnetic resonance imaging and radiation exposure in patients with cardiovascular implantable electronic devices”. Maximum expected cumulative incident dose  $\int_{SEP} dD$  should be estimated and minimize (threshold of 5 Gy).

In some cases national guidelines introduce the obligation to perform not only the estimation but also the measurement of CIED dose during radiotherapy session. In this presentation possible methods and technical difficulties of the CIED dose estimation and in-vivo dosimetry will be discussed. Finally, the results of in-vivo dosimetry of CIEDs treated in Greater Poland Cancer Centre will be presented.

**SP-0584 From biological basis of RI cardiac toxicity to the new application of SBRT in the cardiovascular field**  
M. Vozenin<sup>1</sup>

<sup>1</sup>Centre Hospitalier Universitaire Vaudois, Department of Radiation Oncology, Lausanne Vaud, Switzerland

**Abstract text**

Cardiac toxicity induced by anti-cancer treatments including radiotherapy is today an issue for long-term cancer survivors<sup>1, 2</sup> without therapeutic management. The first part of this talk will be dedicated to summarize biology-driven efforts made to develop translatable therapeutic approaches to prevent, mitigate or reverse radiation injury to the heart. Then, recent results will be shown including a yet never described gender difference in both radiation-induced sensitivity and sensitivity to combined treatment based upon RT, paclitaxel and herceptine. Female mice are protected from cardiac defect and this protection is mediated by small GTPase RhoB via its interaction with ERa. In the second part, possible new application SBRT (Stereotactic body radiotherapy) in cardiology will be discussed such as the non-invasive management of ventricular tachycardia (VT) refractory to standard treatments<sup>3,4</sup>. In addition, the first preclinical data will be shown that investigates the physiopathological impact of such large but localized dose of irradiation on the heart using experimental mouse model and Image guided radiotherapy device (XRad225CX-PXi) that enable to mimic clinical SBRT configuration.

**SP-0585 Managing cardiotoxicity in oncology follow up and primary care services**

S. Faithfull<sup>1</sup>

<sup>1</sup>University of Surrey, Faculty of Health and Medical Sciences, Guildford, United Kingdom

**Abstract text**

The purpose of this paper is to explore how primary care and oncology can work together to identify those at risk of cancer related cardiovascular disease (CVD) to provide primary and secondary prevention. Cancer therapeutic agents impact directly on the coronary endothelium, myocardium, heart valves and other structures and the increase in multi-modality treatment with radiotherapy means more patients are likely to be affected in the future. Many of the factors associated with increased prevalence of cancer are also associated with cardiovascular disease for example, ageing, low physical activity, smoking and obesity. Cancer treatment cardiac damage is more responsive to therapy if treated early, so this paper focuses on how as clinical oncologists, nurses and therapy radiographers we can work more closely with primary care to promote earlier diagnosis of cardiac toxicity and instigate protocols for monitoring heart health in those at higher risk during radiotherapy follow-up. Improving cardio-toxicity management requires primary prevention before treatment starts, to reduce the likelihood of a cardiac events after cancer treatment, by active risk reduction [1]. Evaluation of coronary risk primarily by means of screening for elevated cholesterol, diabetes, hypertension, diabetes, smoking and family history can identify patient’s CVD risk profiles. CVD risk reduction should be considered prior to cancer therapy, promoting lifestyle advice and cardio protective measures. Secondary prevention is also important in treating cardiac dysfunction especially in patients at higher risk. Heart failure treatment within 3 months of symptom development is reversible >90% over 2 years whilst after 6 months’ post symptom development management is less effective [2]. Furthermore, in cancer surveillance and follow up, unexpected changes in patients existing CVD should be investigated and that these symptoms may be early signs of cardio toxicity. Primary care services are involved in managing the long-term health of people with cancer as well as holistically their long-term conditions (LTC). More than 40% of cancer patients have one and 15% two LTC. However primary care physicians have limited knowledge of cancer therapies and how these may destabilise previously well controlled cardiovascular disease and diabetes [3]. In recent surveys, primary care physicians, oncology nurses and allied health professionals undertaking follow up of cancer patients were unaware of cardiac toxicity or how best to identify or manage symptoms [4]. Clear reporting and assessment communication between cancer centres and primary care services with potential side-effects listed, risk of occurrence, cumulative dose and referral guidance if symptoms occur should be provided.

#### Purpose or Objective

While in recent years radiomics has been increasingly studied and often associated with clinical endpoints, the relationships of radiomics and tumor biology are largely unknown. In this study, we sought to explore the immunological contexture basis of a previously developed prognostic radiomic signature in head and neck cancers.

#### Material and Methods

Ninety-five patients were included in the analysis. Evaluation for density of CD8+ T cells, FoxP3+ T cells, CD68+ cells, PD-L1 expression and p16 expression was performed on pretreatment biopsy tissue samples with immunohistochemistry methods. A total of 544 radiomics features of the primary tumor were extracted from radiotherapy planning computed tomography scans. We categorized patients into four phenotypes based on p16 expression and a previously developed 24-feature based prognostic radiomic signature [1]: p16+/radio<sup>low</sup>(PL), p16+/radio<sup>high</sup>(PH), p16-/radio<sup>low</sup>(NL), p16-/radio<sup>high</sup>(NH). The correlations between the four phenotypes and biomarker expressions in the tumor micro-environment were analyzed using Spearman's rank correlation test. Survival rates were calculated with the Kaplan-Meier method and compared using the log-rank test.

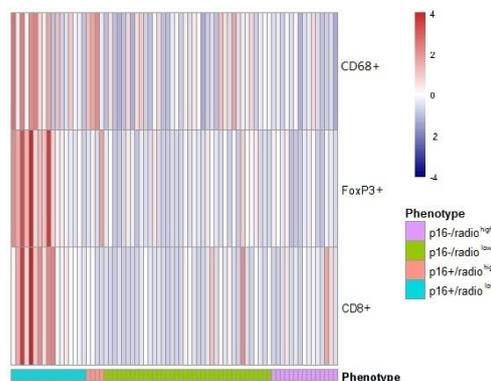

#### Results

The median follow-up was 50 months (range: 4-104). IHC results of CD68 were evaluable for all the 95 patients, CD8 and FoxP3 were evaluable for 74 patients, and PD-L1 was

evaluable for 31 patients. Overall survival (OS) and progression-free survival (PFS) of the four phenotypes were significantly different (5-year OS: PL 95.2%, PH 80%, NL 53.7%, NH 20.8%,  $p < 0.001$ ; 5-year PFS: PL 79.6%, PH 50%, NL 48.7%, NH 7.4%,  $p < 0.001$ ). We found a significant correlation of the p16-radiomic phenotype with density of CD8+ T cells ( $r = 0.39$ ,  $p = 0.001$ ), FoxP3+ T cells ( $r = 0.45$ ,  $p < 0.001$ ) and CD68+ cells ( $r = 0.40$ ,  $p < 0.001$ ), but not with PD-L1 expression. Specifically, all patients with high density of CD8+ T cell, high FoxP3 and high CD68+ macrophages simultaneously, which suggests a favorable immune activated state, exhibit as p16+/radio<sup>low</sup> phenotype (Figure 1).

#### Legend:

Figure 1. Heatmap of distribution of density of CD8+ T cells, FoxP3+ T cells and CD68+ cells according to the four p16-radiomic phenotype (N=74). The columns represent patients and the rows indicate the 3 immune biomarkers. In the bottom color bars each color represents a p16-radiomic phenotype.

#### Conclusion

We demonstrate that radiomic approaches permit noninvasive assessment of immunological characteristic of tumors in head and neck cancers. Further validation in external cohort is required.

#### OC-0587 Preclinical studies of MRI guided BNCT at Torino and Pavia Universities

N. Protti<sup>1</sup>, D. Alberti<sup>2</sup>, A. Toppino<sup>3</sup>, S. Bortolussi<sup>4</sup>, S. Altieri<sup>4</sup>, A. Deagostino<sup>3</sup>, S. Aime<sup>5</sup>, S. Geninatti-Crich<sup>2</sup>  
<sup>1</sup>National Institute of Nuclear Physics INFN, Pavia Unit, Pavia, Italy ; <sup>2</sup>University of Torino, Department of Molecular Biotechnology and Health Sciences, Torino, Italy ; <sup>3</sup>University of Torino, Department of Chemistry, Torino, Italy ; <sup>4</sup>National Institute of Nuclear Physics INFN / University of Pavia, Pavia Unit / Department of Physics, Pavia, Italy ; <sup>5</sup>University of Torino / IBB-CNR, Department of Molecular Biotechnology and Health Sciences / MBC, Torino, Italy

#### Purpose or Objective

Boron Neutron Capture Therapy (BNCT) is a binary hadrontherapy performed on head and neck recurrent and primary cancers, skin melanomas and highly malignant brain tumours. BNCT is based on the capture reaction induced by low energy neutrons on <sup>10</sup>B selectively delivered by tumour-targeting drugs. A couple of high LET hadrons triggers cell death through the local energy deposition along densely ionizing tracks with ranges of 5-9  $\mu$ m, which destroy tumour cells without affecting adjacent healthy tissues. This makes BNCT a promising treatment for disseminated and infiltrating tumours that cannot be handled by surgery, conventional radiotherapy or heavy ion therapy, which require a precise localisation of the pathology.

The real time knowledge of  $^{10}\text{B}$  concentration in tumour is crucial to exploit BNCT selectivity. Aim of the present work is the efficiency evaluation of a theranostic agent for MRI guided BNCT.

#### Material and Methods

The theranostic agent, developed at Torino University, consists of a carborane cage (10 atoms of boron) bound on one side to a Low Density Lipoprotein (LDL) used to target tumour cells, and a  $\text{Gd}^{3+}$  complex on the other for the detection of the agent through Magnetic Resonance Imaging (MRI). The expression of LDLs transporters is upregulated in many tumours and here is exploited to reach the  $^{10}\text{B}$  selective uptake.

The theranostic agent was tested in different murine tumour models including: B16 skin melanoma, Her2+ breast tumour, ZL34 and AE17 malignant pleural mesothelioma. EML4-ALK transgenic mouse model was used as primary lung tumour.

The *in vitro* and *in vivo* studies of selective accumulation and  $^{10}\text{B}$  quantification were carried out at Torino University, while the thermal neutron irradiation was designed and performed at the TRIGA Mark II research nuclear reactor of Pavia University.

#### Results

The *in vitro* studies showed the tumour selective uptake of the theranostic agent and led to the identification of the optimum post injection time to realise BNCT. Three groups of animals for each models were considered: the cold control group, the neutron irradiated group (without  $^{10}\text{B}$  administration) and the BNCT treated group. The animals were followed up for 20 up to 40 days after irradiation and in all the experiments the BNCT treated groups showed a significant reduction in tumour growth with respect to the control groups.

#### Conclusion

A theranostic agent for MRI guided BNCT was developed and positively applied in preclinical treatment of small animal tumour models. The possible use of this kind of boronated agents in clinical BNCT will improve BNCT outcomes making possible the personalisation of the treatment on the  $^{10}\text{B}$  accumulation response of each single patient.

#### OC-0588 Combing hyperthermia and/or OXi4503 with low LET radiation is equivalent to high LET radiation alone

P.B. Elming<sup>1</sup>, B.S. Sørensen<sup>1</sup>, H. Spejlborg<sup>2</sup>, J. Overgaard<sup>1</sup>, M.R. Horsman<sup>1</sup>

<sup>1</sup>Aarhus University Hospital, Dept. of Experimental Clinical Oncology, Aarhus, Denmark ; <sup>2</sup>Aarhus University Hospital, Dept. Oncology, Aarhus, Denmark

#### Purpose or Objective

Tumor hypoxia is a major factor causing resistance to low linear energy transfer (LET) radiation (i.e., photons). One solution to this problem is to use high LET radiation (i.e., carbon ions), but such an approach is not so readily accessible. However, additional therapies increase the efficacy of low LET radiation and may make tumor response equivalent to that seen with high LET radiation. We investigated this by combining low LET radiation with hyperthermia and/or the vascular disrupting agent (VDA) OXi4503.

#### Material and Methods

A C3H mammary carcinoma, implanted in the right rear foot of CDF1 mice, was used for all experiments when at 200 mm<sup>3</sup> in size. Treatments were performed on restrained, non-anaesthetised, animals with the tumor bearing leg exposed and immersed in a water bath maintained at 25°C for radiation (240 kV X-rays) alone or with heating at 41-43°C for 60 minutes. Radiation was applied either in the middle of the heating period (simultaneous treatment), or 1-hour (early sequential treatment) or 4-hours (late sequential treatment) prior to heating. OXi4503 (50 mg/kg) was intraperitoneally

injected 1.5 hours prior to irradiating. Tumor response was the percentage of mice showing local tumor control 90 days after treatment with graded radiation doses, and following logit analysis of the radiation dose-response curve, the TCD50 value (radiation dose causing tumor control in 50% of mice) was estimated.

#### Results

The TCD50 value for low LET photon irradiation alone was 54 Gy. Our previous studies with carbon ions in the same tumor model reported a TCD50 value that was 1.5 times lower than that seen with photons (Sørensen et al., Acta Oncol., 2015;54:1623-30). A similar enhancement ratio (ER; ratio of TCD50 values for radiation alone and radiation + modifier) of 1.5 was obtained with a temperature of 41.5°C when administered simultaneously with the low LET radiation. For a late sequential radiation and heat treatment, temperatures of 42.5°C and above were necessary, although an ER of 1.5 was observed at 41.5°C if this sequential treatment was combined with OXi4503; the VDA alone gave an ER of around 1.3. The effect of using an early sequential approach is under investigation.

#### Conclusion

The local tumor control obtained with high LET carbon ions is also possible with low LET photons if combined with hyperthermia. However, the temperature at which this equivalent response is observed is dependent on the radiation and heat sequence, and whether a VDA is included in the treatment schedule.

#### OC-0589 RBE-weighted dose in carbon ion therapy: impact of the RBE model translation on clinical outcomes

Hasegawa<sup>6</sup>, L. Preda<sup>7</sup>, P. Fossati<sup>8</sup>, F. Valvo<sup>2</sup>, M. Ciocca<sup>1</sup>  
<sup>1</sup>National Center for Oncological Hadrontherapy, Medical Physics, Pavia, Italy; <sup>2</sup>National Center for Oncological Hadrontherapy, Clinical Department, Pavia, Italy; <sup>3</sup>Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway; <sup>4</sup>Institute of Radiology IRCCS San Matteo University Hospital, Department of Diagnostic Medicine, Pavia, Italy; <sup>5</sup>University of Milano Bicocca, Faculty of Medicine, Milano, Italy; <sup>6</sup>Osaka Heavy Ion Therapy Center, Clinical Department, Osaka, Japan; <sup>7</sup>National Center for Oncological Hadrontherapy, Radiology Department, Pavia, Italy; <sup>8</sup>MedAustron, Clinical Department, Wiener Neustadt, Austria

#### Purpose or Objective

With the aim of taking advantage of the long term experience in carbon ion radiotherapy (CIRT) of the National Institute of Radiological Sciences (NIRS), we implemented at the National Center for Oncological Hadrontherapy (CNAO) a conversion scheme for relative biological effectiveness (RBE)-weighted prescription doses ( $D_{\text{RBE}}$ ) to account for the use of a different carbon ion RBE model (1). No correction was applied for NIRS defined constraints to optic pathways, brainstem and rectum, thus following a conservative approach. The purpose of this study is to assess the clinical implications of the described method on tumor control.

#### Material and Methods

Plans of 60 Adenoid Cystic Carcinoma (ACC) and 25 sacral chordoma (SC) patients, previously treated at CNAO with a Local Effect Model I (LEM1)- $D_{\text{RBE}}$  optimization, were exported for recalculation with a Microdosimetric Kinetic Model (MKM)- $D_{\text{RBE}}$  calculation system. The latter model is currently in use at NIRS. In addition, 10 patients treated at NIRS for a pancreatic lesion were used for RBE evaluation in this tumor site. LEM1 prescription doses were 68.8 Gy(RBE) and 70.4 Gy(RBE) in 16 fractions and 57.6 Gy(RBE) in 12 fractions for the ACC, SC and pancreas cases, respectively.  $D_{\text{RBE}}$  to 95%, 50% and 2% of the clinical

target volume (CTV), for LEMI- and MKM-RBE computations, were criteria to assess target dose. Selected ACC and SC included patients presenting a tumor relapse at follow-up. Recurrences were retrospectively contoured on the follow-up MR scan corresponding to first diagnosis. The relapse location, with respect to CTV and spared OARs, and relative dose distributions in the two RBE systems were analyzed.

### Results

The MKM- $D_{RBE}$  analysis showed that prescription dose conversion factors correctly acted on median CTV  $D_{RBE}$ , but allowed the generation of low and high MKM- $D_{RBE}$  regions (figure 1a-b) linked to the steeper MKM-RBE variation along the beam path. Location of inhomogeneities was related to tumor volume, beam number and configuration. The average MKM- $D_{RBE}$  reduction at 95% of CTV ranged from 8% to 2% of the expected value, for the lower and higher fraction doses, respectively. ACC and SC relapses were mainly (38% ACC and 25% SC) related to poor CTV coverage due to OARs sparing to a MKM- $D_{RBE}$  significantly lower than expected (figure 1c). No clear evidence was found of a cause-effect relation between low MKM- $D_{RBE}$  to 95% of CTV and loss of tumor control.

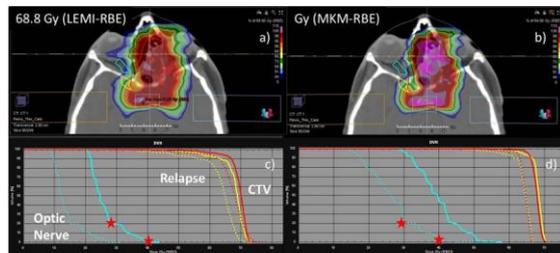

Figure 1: a) Transversal  $D_{RBE}$  distribution of a LEMI-optimized ACC plan to 68.8 Gy (RBE). The CTV contour is plotted in red, the optic nerve in light blue and the relapse in yellow. b) Transversal  $D_{RBE}$  distribution of the corresponding MKM-re-calculated plan, showing the appearance of CTV hot and cold spots. c) DVHs corresponding to LEMI (solid lines) and MKM (dotted lines) computations. The red stars point to the MKM-defined NIRS constraint to the optic nerve. d) DVHs corresponding to a MKM-optimized plan to 64 Gy (RBE) (dotted lines) and corresponding LEMI-re-calculated plan (solid lines).

### Conclusion

The use of a MKM system, as a starting point for LEMI optimization, could reduce CTV dose inhomogeneities and their potential impact on tumor local control and patient toxicity (figure 1d).  $D_{RBE}$  deviations between LEMI and MKM plans were significantly higher in regions where steep dose gradients were applied to spare OARs, than in the target region. New constraints are currently being defined for optic pathways, brainstem and rectum at CNAO to improve target coverage with no expected increase in tissue complications.

Radiotherapy, Center of Oncology- University Medical Center Hamburg-Eppendorf UKE, Hamburg, Germany

### Purpose or Objective

Breast cancer comprises a heterogeneous group of tumors of whom 20% are categorized as triple-negative (TNBC). A specific tumor therapy for this subgroup is still lacking. Important biological characteristics and potential therapeutic targets of TNBC include a basal-like and mesenchymal so called stem-cell phenotype and a defect in the DNA repair pathway Homologous Recombination (HR), which feeds the observed elevated chromosomal instability (CIN) in these tumors. This project aims to develop treatment intensification strategies based on the simultaneous exploitation of the HR-deficiency and the stem-like phenotype, using specific inhibitors such as ATR, CHK1, RAD51, and PARP1 in combination with irradiation.

### Material and Methods

The investigations were performed in three TNBC cell lines MDA-MB-231 which metastasize systemically (WT), into the brain (BR) or into the bone marrow (SA) and their respective radiation resistant subclones selected by repeated irradiation (10x4Gy). Luminal MCF7 cells served as controls. Expression of HR-related and stem-like factors was determined and DNA repair in general (53BP1) as well as HR functionality (RAD51 foci formation, MMC-sensitivity and plasmid reporter assay) was analyzed. Replication processes were examined by using the DNA fiber assay and migration assays were also performed. Radiosensitizing effect of several HR and S-phase specific inhibitors were analyzed by colony assay and correlated with expression profiles of stem cell markers and DNA repair proteins in the METABRIC database.

### Results

A significantly increased expression of the stem cell markers ALDH1, ZEB1 and Vimentin was observed in all four radioresistant sublines, both on single cell basis and in Western blots. This led to an increased activation of ALDH1 in the Aldefluor assay in all investigated clonal subpopulations. After irradiation, survival in the clonal subpopulation was significantly increased compared to the original cell line. In accordance with this, the radioresistant subclones showed a lower number of 53-BP1 foci, indicating improved DNA repair. Also HR capacity seem to be improved. This is confirmed by a significantly stronger activation of the Intra-S phase control point, with an increased activation of CHK1. This results in a distinct radiosensitization after CHK1i; the most radioresistant cell line was most strongly sensitized (EF=3) and also showed up in DNA replication processes: the higher the EF the stronger the inhibitory effect on DNA replication. The effect of other inhibitors on radiosensitivity is currently being investigated. A second promising target is RAD51, because a METABRIC analysis (952 TNBCs) showed that both, RAD51 and CHK1 are differentially expressed according to their degree of chromosomal instability.

### Conclusion

In conclusion the results presented here show that DNA repair and a stem-like phenotype are closely intertwined in determining resistance to tumor therapy of TNBCs with high CIN.

### Purpose or Objective

This single arm interventional multi-center cohort study was designed to evaluate the pathologic and radiologic response after MR-guided single dose ablative preoperative partial breast irradiation (PBI) in early-stage breast cancer patients with low risk on local recurrence.

### Material and Methods

In the ABLATIVE study (ClinicalTrials.gov: NCT02316561), we included women with unifocal, estrogen-receptor positive and HER2-negative tumors with a maximum diameter of 20mm (age 50-70 years), or 30mm (age  $\geq$ 70 years) as assessed on MRI. Furthermore, patients were required to have a tumornegative sentinel lymph node biopsy, no history of breast cancer and no indication for chemotherapy. Patients were treated with MR-guided single dose ablative preoperative PBI: 20Gy to the gross tumor volume (GTV) and 15Gy to the clinical target volume (CTV=GTV+2cm margin). GTV and CTV were expanded by 3mm to create the planning target volume. Breast-conserving surgery (BCS) was originally performed 6 months after PBI. After the first 15 patients this interval was prolonged to 8 months to evaluate whether this would increase the rate of pathologic complete response (pCR). Primary outcome was the rate of pCR, which was defined as no residual tumor cells. Secondary outcomes were radiologic response and treatment-induced toxicity. Radiologic response was evaluated by dedicated breast radiologists on tumor morphology, diffusion restriction and contrast enhancement kinetics using DCE- and DW-MRI every 2 months until BCS was performed. Toxicity was assessed according to CTCAE v4.03.

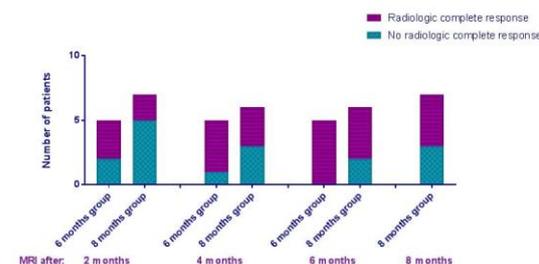

### Results

From May 2015 until November 2017, 32 patients were recruited. Median follow-up was 18 months (range 9-36). The median tumor size was 13mm (range 5-20) and median age 64 years (range 51-78). pCR was reported in 5 and 7 patients (33% and 41%), and near pCR in 5 and 6 patients (33% and 35%), after 6 and 8 months respectively (table 1). Radiologic response assessment showed an increase in complete response during follow-up. Radiologic complete response was only observed in patients with pCR or near pCR, however, 11 of the 23 patients with pCR or near pCR did not show a radiologic complete response (figure 1). Five patients received preoperative endocrine treatment which was initiated after PBI; 2 of these patients had pCR. Only mild treatment-induced toxicity (i.e. grade 1-2) was observed and all grade 2 toxicity was transient. Observed toxicity was grade 1 fibrosis (91%), grade 1 breast pain (59%) and transient grade 2 breast pain (3%).

Table 1: Pathologic response according to interval between single dose ablative preoperative PBI and BCS.

	6 month interval (N=15)	8 month interval (N=17)
pCR (no residual tumor cells)	5 (33%)	7 (41%)
Near pCR ( $<$ 10% residual tumor cells)	5 (33%)	6 (35%)
Partial response (10-50% residual tumor cells)	4 (27%)	2 (12%)
Stable disease ( $>$ 50% residual tumor cells)	1 (7%)	2 (12%)

Figure 1. Radiologic response in patients with pCR at 6 and 8 months following PBI.

### Conclusion

MR-guided single dose ablative preoperative PBI resulted in pCR in one third of the patients. Radiologic complete response on MRI was not recognized in all patients with pCR. Further assessment of MRI and other response monitoring techniques should be considered in single-dose ablative preoperative PBI.

### OC-0592 5 year results of the Preoperative Accelerated Partial Breast Irradiation (PAPBI) trial

S. Bosma<sup>1</sup>, F. Leij van der<sup>1</sup>, S. Vreeswijk<sup>1</sup>, M. Vijver van der<sup>2</sup>, S. Rivera<sup>3</sup>, T. Foukakis<sup>4</sup>, D. Bongard van den<sup>5</sup>, E. Rutgers<sup>6</sup>, A. Scholten<sup>1</sup>, H. Bartelink<sup>1</sup>, P. Elkhuisen<sup>1</sup>  
<sup>1</sup>The Netherlands Cancer Institute, Radiation oncology, Amsterdam, The Netherlands; <sup>2</sup>Amsterdam UMC, Pathology, Amsterdam, The Netherlands; <sup>3</sup>Institute Gustave Roussy, Radiation Oncology, Paris, France; <sup>4</sup>Karolinska institutet, Radiation Oncology, Stockholm, Sweden ; <sup>5</sup>UMCU, Radiation Oncology, Utrecht, The Netherlands ; <sup>6</sup>The Netherlands Cancer Institute, Surgery, Amsterdam, The Netherlands

### Purpose or Objective

Accelerated Partial Breast Irradiation (APBI) is a treatment option for low-risk early stage breast cancer. Preoperative APBI (PAPBI) provides several advantages compared to conventional postoperative radiotherapy (RT), including improved target localization, accurate tumor delineation, the possibility for response evaluation and excision of the high dose irradiated volume. Here, we present the 5-year results of the PAPBI trial providing novel data from a large set of preoperatively irradiated patients.

### Material and Methods

In the multicentre PAPBI trial, 138 patients were included between 2010-2017. Women aged  $\geq$  60 years with an invasive, unifocal  $\leq$  3 cm on MRI, (non-lobular) adenocarcinoma of the breast and a negative SN received PAPBI (40 Gy in 10 fractions in 2 weeks or 30 Gy in 5 fractions in 1 week). 6 weeks after RT a wide local excision was performed. The primary endpoints were breast fibrosis and cosmetic outcome. Local recurrences (LR) should not exceed 4% at 5 years. Toxicity was scored 3-monthly in the first year, then every 6 months for the first 5 years and yearly thereafter. Cosmetic outcome was evaluated by the treating physician and the (Dutch) patients before start of treatment, 6 months after treatment and then yearly.

### Results

133 patients were analyzed with a median follow-up of 4.6 yrs (0.9-8.3 yrs). Baseline characteristics are displayed in table 1. 78 (59%) patients were treated with 10x4 Gy and 55 (41%) with 5x6 Gy. A postoperative complication occurred in 14% of patients, of which 4 patients required re-surgery. 11% had a postoperative infection requiring treatment. Acute skin toxicity was absent in 65% of patients and 34% of patients had grade 1 skin toxicity. At 1 year of follow-up, induration/fibrosis at the tumor area was absent in 30(26%) and mild in 69(60%) of 115 patients. At 3 (n=94) and 5 years (n=55) of follow-up, respectively

37% and 65% of patients had no fibrosis and 50% and 29% mild fibrosis at the tumor area. The global cosmetic outcome was good-excellent in 70% after 6 months, 88% after 2 years and 93% after 5 years (figure 1). Patients were very satisfied/satisfied with the cosmetic outcome in 78% after 6 months, 84% after 2 years and 93% after 5 years. An LR was detected in 4 patients: 3 were located along the biopsy trajectory. Subsequently, we adjusted the protocol by surgical removal of the biopsy route.

#### Characteristics

Median age (yrs) 68 (60-87)

Tumour size (mm) 12 (5-27)

#### Grade

1 35 (27%)

2 89 (68%)

3 7 (5%)

#### Subtype

ER+/PR+/HER2- 86 (65%)

ER+/PR-/HER2- 36 (27%)

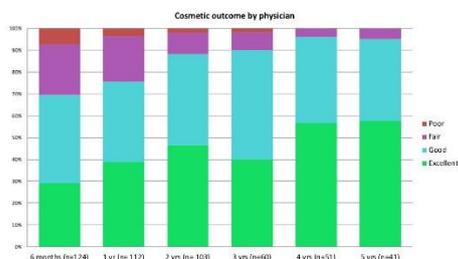

ER-/PR-/HER2- 8 (6%)

HER2+ 2 (2%)

#### Systemic therapy

Hormonal 89/129 (64%)

Chemotherapy 5/129 (4%)

#### Conclusion

PAPBI is a feasible and promising treatment for low-risk breast cancer patients resulting in excellent cosmetic outcome and limited fibrosis, presumably due to removal of the high dose area. Postoperative complications are comparable to surgical complications before PBI. Cosmetic outcome improved over time. A few recurrences in the biopsy tract occurred before adjustment of the protocol.

#### Purpose or Objective

To determine if treating large breasted women with adjuvant breast radiotherapy (RT) in the prone position reduces acute skin toxicity when compared to the supine position.

#### Material and Methods

From 2013 to 2018 a total of 357 large breasted women (bra size 40in and/or D cup or greater) from 5 centres in Canada receiving adjuvant RT to the breast alone were randomized to the supine or prone position. Patients were initially treated to 50Gy/25 fractions (conventional fractionation), though the protocol was amended at 3 years to allow 42.5Gy/16 fractions (hypofractionation) which was almost exclusively used from that time onwards. Randomization was blocked on postoperative RT boost. Acute toxicity including moist desquamation (MD), erythema, and pain as per CTCAE 4.03, was assessed by an observer blinded to treatment position at baseline, weekly during RT and up to 6 wks post treatment. Comparison of the frequency of grade 2-3 MD between treatment arms was performed using a two sample two-sided test of proportions providing an OR and its associated 95% CI. Multivariable logistic regression analysis evaluated the relative risk of acute skin toxicity as the dependent variable. The various independent variables tested included the treatment position, boost delivery, fractionation, breast size, and chemotherapy.

#### Results

A total of 357 patients were accrued, 182 treated supine and 175 prone. 180 received conventional fractionation (92 supine, 88 prone) and 177 treated with hypofractionation (90 supine, 87 prone). On bivariate analysis there was significantly more acute MD in patients treated supine compared to prone (39.6% vs 26.9%; OR 1.8, CI 1.1-2.8, P=0.01). This association was confirmed on multivariate analysis with increased MD in the supine position (OR 1.9, CI 1.2-3.1, P<0.01). Additional factors independently associated with MD included use of RT boost (OR 2.8, CI 1.6-4.7, P<0.01), conventional fractionation (OR 3.0, CI 1.8-4.9, P<0.01) and larger bra size (OR 2.4, CI 1.4-3.9, P<0.01). There was no association between MD and chemotherapy. Similar analyses showed only boost and conventional fractionation were associated with erythema and pain. In an unplanned subset analysis, there was significantly more acute MD in patients treated with conventional fractionation compared to those treated with hypofractionation (OR 2.5, CI 1.6 - 4.0, P < 0.0001) and this was true for both the supine (OR 2.7, CI 1.5-5.0, P<0.0001) and prone (OR 2.4, CI 1.2-4.8, P<0.0001) positions.

#### Conclusion

This multicentre single blinded RCT confirms that treatment in the prone position leads to significantly less acute MD compared to the supine position in large breasted women receiving adjuvant radiotherapy. It also shows increased toxicity using an RT boost and conventional fractionation.

### Purpose or Objective

To analyze the tolerance in the French randomized phase 3 trial (BONBIS) that investigated the role of the boost to the tumor bed after breast-conserving surgery for ductal carcinoma in situ (DCIS).

### Material and Methods

From November 2008 to July 2014, 2004 DCIS patients were treated by tumorectomy followed by whole-breast irradiation (WBI) to a dose of 50 Gy in 25 fractions for 5 weeks. Patients were randomized after surgery and before WBI between an additional boost to the primary tumor bed (16 Gy in 8 fractions of 2 Gy, n=1002) and no further treatment (n=1002). Stratification factors were centre, age (below or above 40), hormone therapy (yes or no), histological grade (low or intermediate or high), diagnosis mode (clinically or by mammography), surgical margins (1-2 mm vs 3 mm). Acute toxicities were prospectively recorded from baseline to 3 months after radiotherapy completion.

### Results

A total of 1928 DCIS patients were evaluable for acute tolerance. Median age was 57 years. Re-excision was needed in 20% of patients in each treatment arm, mainly due to involved margins or postoperative complications. Median time for radiotherapy initiation was 54 days from surgery [min; max=5; 146]. Mean volumes of breast (CTV1) and of boost (CTV2) were 545 cc [min; max= 6; 2818] and 25 cc [min; max= 0; 754], respectively. A significant higher rate of radiotherapy disruption was observed in boost arm (3.9% vs 1.5%; p=0.015) due to acute toxicities occurrence with a mean time of disruption of 3 days. A significantly higher rate of grade ≥2 overall toxicities (including skin, edema, pain) was observed in the boost arm (54.6% vs 36.4%; p<0.001). Similarly, grade 3 erythema was significantly increased in the boost arm (5.4% vs 2.1%; p<0.001).

### Conclusion

In the boost arm, a higher rate of grade ≥2 acute toxicities was observed compared to the control arm. However, grade 3 erythema was quite low even though its occurrence was significantly higher in the boost arm. A multivariate analysis of acute toxicities will be presented at the congress.

### OC-0595 Does seroma predict patient-reported adverse effects following breast radiotherapy in IMPORT HIGH?
